The dynamic land use-transport connections and the impacts on travel behaviour: evidence from China

Abstract

There seems to be a consensus on the interdependence between the built environment and transport among academics and practitioners: the evolution of transport could lead to changes in urban form, and the changes in land use could also result in transport consequences. However, there is quite little empirical evidence to verify the hypothesis. In this paper, we aim to examine the dynamic relationship between built environment and transport system, using the case study of Nanjing metropolitan area in China where unprecedentedly fast pace of economic, social and spatial transitions have taken place. Through a comparative study based on the cross-section data of Nanjing Residents Travel Survey (NRTS), 2008 and 2011, it is found, on the one hand, fast motorization and huge investment in public transport have caused the urban form of Nanjing transforming toward low densities expansions with spread-out opportunities; on the other hand, the changing built environment has resulted in enlarged daily travel distance and considerably increase in the use of private cars and the ridership of public transport at the expense of non-motorized transport modes. The paper also finds that the impacts of the built environment are even pronounced in determining travel behaviour in 2011 while the 'classic' socio-demographics of individuals show attenuated impacts.

Keyword: Built environment; Travel behaviour; Dynamic relationship; Urban China

1. Introduction

Urban China is now experiencing unprecedentedly fast pace of economic, social and spatial transitions (Logan 2011; Friedmann 2005; Ma and Wu 2005). The fast economic growth with more than 8% rise every year (CSB 2000-2011) has greatly facilitated individual affluence. According to statistics, the average income of urban resident tripled in the last five years (CSB 2000-2011). Alongside the income rises, car ownership also rapidly increases. From 2005 to 2009, the car ownership ratio has raised from 3.4% to 10.9% in China. The increase in income and car ownership might lead to substantial changes in travel behavior as showed by studies conducted in western countries (Giuliano and Narayan 2003; Susilo and Maat 2007).

Economic growth also resulted in some social consequences. The first is the increasing social inequality caused by the widening gap in income. While majorities have improved their economic status a lot, some minorities, especially the urban poors slid further into economic despair, reflecting the nation's great economic polarization (Wang 2004; Ma and Wu 2005). Another change is 'rise of the individual and the consequential individualization of society' (Yan 2010, p.489). Individuals in Chinese society are getting more free form most previous social categories, such as family, kinship, gender, etc., and show more individualistic treats, such as self-reliance and pursuit of personal interests (Inglehart and Baker 2000). These transformations supported by higher income and car ownership will be expressed in more

differentiated and diversified lifestyles of the individuals which will eventually influence people's travel behaviour.

Besides economic and social transitions, some spatial changes are also observed. The most prominent result is the accelerating urbanisation and expansions of cities. Statistics show that yearly about 12 millions people flood into Chinese cities (CSB 2000-2011). In order to accommodate those huge new urban residents, cities expand rapidly. Taking Nanjing for example, from 2005 to 2009, the city expanded with 85 km^2 (NSB 2006-2011). Secondly, the fast motorization of transport has fuelled suburbanisation. Emerging luxury villas and gated communities have been built for a growing class of car-driving homeowners in the suburbs (Feng and Zhou 2005). Thirdly, the affluent society also provides people new options and activity opportunities, such as big shopping malls in the suburbs as well as specialized shopping, eating and entertainment districts (Wang and Jones 2002), for instance, *Xintiandi* in Shanghai.

Urbanization and development of functional specialization have offered urban residents more choices opportunities. However, in the meanwhile, they also induce dramatic increase in travel demands and therefore place intense pressures on the urban transport system (Shen 1997; Ng et al. 2010). To alleviate the tension, Chinese cities have encompassed a broad range of urban and suburban public transport investments including subway, light rail and rapid bus transport. It is reported that from 2009 to 2015, China will construct 87 mass transit rail lines, totalling 2,495 km, in 25 cities at the cost of 98.9 billion EUR (Business Sohu 2010). It is to be expected the fundamental changes in the built environment and transport supply will have large consequences for destinations and modes choice.

All three macro transitions, the economic, social and spatial changes, as mentioned above, will have important implications on travel behaviour. We might expect that travel distance will be considerably enlarged and the share of car and public transport use will increase dramatically at the expense of non-motorized transport modes as a consequence of the macro transitions. To date, most of existing literature about the determinants of travel behaviour draws on analyses of cross-sectional data gathered at a single point in time from Western countries. Quite little is known about the dynamic relationship between the built environment and travel behaviour ***over time***s, especially for the unique context of China where unprecedentedly fast and voluminous changes is occurring, which is never seen in Western countries. The study aims to understand the meaning of the changes of socio-demographics and built environment on travel behaviour, particularly with the expectation it can gain a richer, deeper and perhaps more general understanding of the true nature of the built environment-travel connections.

Drawing on data from the repeated cross-section data of Nanjing Residents Travel Survey (NRTS), 2008 and 2011, this paper will trace the trends of mode choice, daily travel distance and time in Nanjing metropolitan area and examine the impacts of the changing social-demographics and the built environment on above travel behaviour over time. The remainder of the paper starts with a review of relevant literature on the dynamic linkage between built environment and transport in section 2. An overview of the data and methods used is presented in section 3. Then we turn to some descriptive empirical results in section 4, which is followed by a discussion of regression analyses in section 5. The results will be further discussed in the concluding section 6.

2. The dynamic linkage between built environment and transport

There seems to be a consensus on the interdependence between built environment and transport in the transport and geography academia (Giuliano 1986; Badoe and Miller 2000; Wegener and Furst 2009). It is widely believed that the evolution of transport could lead to changes in urban form, and the changes in land use could also result in transport consequences. The most famous case could be Muller's four-stage model of intrametropolitan transport eras and associated urban growth patterns, which demonstrates the persistently strong relationship between the intraurban transport system and the spatial form of the metropolis of the US urban history in the past two centuries: walking-housecar era, the electric streetcar era, the recreational automobile era and the freeway era (Muller 1995). A similar classification could also be found in Newman and Kenworthy's (1996) research, who put forward three types of cities throughout urban history concomitant with the dominant transport modes that is, the walking city, the transit city and the automobile city. This classification again confirmed the closely inter-linked urban form and transport connection.

Actually, the dynamic linkage between transport and land use could be decomposed into two directions: the impacts of urban form on transport and the effects of transport on land use (Wegener and Furst 2009). For the influence of urban form on transport, the land use locations of activities in space, together with the transport resources connecting them, impact people's daily activity (travel) pattern which is expressed as flows on the transport network, therefore affects the transport system. And for the effects of transport on land use, it is the characteristics of the transport systems which configure accessibility-the ease of moving one place to another-through which the locations of activities and the land use pattern are influenced (Giuliano 1986). Jointly, these two directions form the so called 'land-use transport feedback cycle' which is commonplace in the planning literature (Handy 2003; Wegener and Furst 2009).

Both of the two directions have attracted numerous attentions from researchers. With respect to the influence of the built environment on transport, in the last few decades, a spate of studies originating from a diversity of sources and encompassing a variety of geographic scales and locations has contributed to this theme (Ewing et al. 2001; Zhang 2004; Susilo and Maat 2007). Those studies observed that various aspects of built environment have impacts on travel patterns, albeit in some cases only limited effects could be found. Compared with the effects of urban form on transport, the reverse impact from transport to land use is relatively less well known (Wegener and Furst 2009). Research in this domain is mainly concentrated in the influence of two transport means: automobile (highway) and transit on local and regional accessibility, redistribution of employment and population, economic consequences, etc. (Boarnet and Chalermpong 2001; Cevero and Landis 1997; Nelson and Sanchez 1997). They observed both highway and transit operation have been a necessary but not sufficient condition for the scale of suburban growth, low development density, dispersed employment and population and urban sprawl (Handy 2003).The land use-transport connection developments are also related to some social consequences (Preston and Rajé 2007). The famous 'spatial mismatch hypothesis' is the case in point, which addresses the problem that the social vulnerable groups, especially the urban poor, get economically and socially excluded in the urban form developed based on fast transport mode, especially, private car (Kain 1992; Gobillon, et al. 2007).

To data, there is quite limited research focusing on the dynamic relationship between land use and transport ***over times***. Susilo and Maat (2007) examined the influence of the built environment on commuting parameters at three points in time: 1995, 2000 and 2005 in the Netherlands, and found that the contribution of built environment in commute distance and commute mode choice models has increased. Through a comparison of commuting duration in 1977 and 1996 in Quebec city, Vandersmissen, et al. (2003) found that due to decentralization and the scatteration development, accessibilities measuring the degree of mutual co-location of jobs and housing have decreasing effects on commuting time. With respect to the research in China, to the best of our knowledge, there is no literature examining the dynamic linkage between land use and travel. The limited research draws on analysis at single point of time. For example, Pan et al. (2009) examine the impacts of urban form on travel behaviour in four neighbourhoods of Shanghai and find that people of pedestrian/cyclist-friendly neighbourhoods travel shorter distances than those of other types of neighbourhoods. Wang et al. (2011) reported that residents of the newly developed built environments, such as commodity housing community and social welfare housing community tend to travel longer distance and time with more private cars than people living in traditional *danwei* community in Beijing.

Our review of the literature has revealed that few studies have focused on the dynamic relationship between socio-demographics, built environment and travel behaviour ***over times***, especially in China. In the current paper, we have the following hypothesis: due to the expansion of the metropolitan area, the increase in car ownership and huge investment in public transport, especially in transit system, it is expected daily travel distance will be enlarged accompanied by the increase in the use of private cars and the ridership of public transport while travel time remains steady according to 'time budget hypothesis' in Nanjing metropolitan area, just as what have taken place in western counties; the 'classic' socio-demographics are expected to be less influential in determining travel behaviour owing to the more individualized society; as a result of the constructions of new metro lines as well as more diversified group composition in built environment in terms of density and mixed land use compared three years ago, the built environment is expected to get even weight in influencing travel behaviour.

3. Research design

3.1 Data and case study area

Our case study area is Nanjing metropolitan area. It is the capital of Jiangsu Province, and the second largest commercial centre in East China. As a former national capital, the city has a prominent place in Chinese history and culture (Cotterell 2008). Our data on travel behaviour in Nanjing results from the Nanjing Residents Travel Survey (NRTS; in Chinese: Nanjingshi jumin chuxing chouyang diaocha). It is conducted on all Tuesdays, Wednesdays and Thursdays in June every year. Our sample contains 2991 cases in 2008 and 1990 cased in 2011. The big difference in sample size is because that in 2008, Nanjing Transport Planning Committee made so called 'Comprehensive Transport Planning', and thus more samples are conducted. The reason why we choose 2008 as the start point is because since that year, the suburbs of Nanjing city have been included in the survey.

One might argue that the time period is too short to have sufficient changes for comparing. However, urban China is experiencing fast transitions in economic, spatial and social aspects nowadays and the speed for Nanjing, one of the pioneering cities in the east part of China, is even notable. Table 1 shows some of the basic socio-demographic, the built environment and public transport supply information in Nanjing in 2008 and 2010. Because the statistical data for 2011 is not yet released, here we use the data of 2010 by which we can see that huge changes are already observed. As indicated by Table 1, the pace of built-up area increase is much faster than that of population, which results in a large reduction in population density. Household car ownership increases at a speed of more than 2% every year which could be the consequence of the rapid rise of income. With regard to public transport, both bus and transit supply increase considerably in only two years. It is needed to note that in 2008 there is only one metro line while in 2011, there are two more. The built environment changes can also been found in figure 1.

Insert Figure 1 here

3.2 methods

In investigating the changes of daily travel behaviour, what are the appropriate characteristics? Daily travel behaviour can be measured in terms of travel frequency, distance and time spent travelling, and mode choice. Travel frequency captures the total number of activities conducted, but provides limited information because of the small variations between individuals (Giuliano and Narayan 2003) and is thus excluded in our analysis. Existing literature shows that mode choices vary substantially with travel purposes (Zhang, 2004). In our analysis, we split mode choice into two sets: mode choice for commuting and for shopping-leisure trips (including shopping trips, social visits, sports, culture, recreation, waling or cycling around). The daily travel distance can fairly measure the 'everyday competence' or the ability to accomplish maintenance activities and to participate in social and economic activities of a person (Mercado and Paez 2009) and total daily travel time represents an indicator for the ability of people to move through the city for pursuing their daily life. In sum, in this paper we will focus on four travel characteristics: mode choice for commuting, mode choice for shopping-leisure, daily travel distance and time.

The general model for travel behaviour is:

$$Y=f(X, B, \mu)$$

Where, Y=daily travel behaviour; X= attributes of the individual; B= attributes of the built environment; μ= unobserved factors. The X variables capture the main socio-demographic characteristics related to travel. In this paper, we include gender, age, education level, household car ownership, household composition and household income in the regression models. The built environment variables including in the paper are population density, access to transit measured as distance to the nearest metro station and land-use mix (add note here, for methods of the calculation of land-use mix).

The present research intends to examine the changing impacts of socio-demographics and the built environment on travel behaviour between year of 2008 and 2011. To do so, the two sets of observations are pooled into one set. Here, the 2991 observations for 2008 are added to the 1990 observations for 2001, producing a pooled sample of 4981. Dummy variables are then

used to test both independent and first-order interaction effects (Giuliano and Narayan, 2003; Vandersmissen, et al.; 2003) as shown in the following equation:

$$Y=f(X, B, \mu, XR, BR, R)$$

Where, R= yearly dummy, which equals 0 for 2008 observations and 1 for 2011 observations, are used to test the difference between the intercepts. XR and BR are the interaction variables of the original independent variables multiplying by the yearly dummy variable R, which are used to test the difference between the regression coefficients of each variable.

4. Descriptive analysis

Insert Table 2 and Table 3 here

In this section, we show the changes in mode choice, daily travel distance and time by some cross-tables. The discussion here serves as a background of multivariate analysis.

As demonstrated in Table 2, big changes in mode choice have occurred in only three years time. The use of public transport and car both increase by 4 percent at the expense of decline of cycling. These changes are duo to, firstly, the great increases in public transport supplies in both bus and metro systems and fast motorization, as shown in Table 1. Secondly, the fast urban expansion and suburbanisation has enlarged the average trip distance which stimulate use of fast transport modes.

Compared with 2008, travel distance shows a sharp increase of 0.8 km per person per day. Checked for specific travel purposes, it shows the increase mainly stems from commuting trips. This might be caused by urban expansion and residence suburbanisation. As shown in Table 1, Nanjing metropolitan area has been extended with 32 km^2 in only two years, which leads to increase of travel distance. The statistics show that in 2010, the population of the central part of the metropolitan area decreased about 5 000 person while in the suburbs, the population increased with 30 000 person (NSB 2006-2011). Economic reconfiguration, fast motorisation and expansion of infrastructure are the main reasons for this spatial redistribution (Feng and Zhou 2005). Nanjing is still at an early stage of suburbanization so far, only residences of the urban population moved out to the suburbs while employment is still concentrated in the central city. This causes substantial increase in commuting distance from 3.8 km to 5.6 km (Table 3).

Unlike with mode choice and travel distance, total daily travel time shows negligible change in the last three years. This seems to be in line with the so called 'travel time budget' hypothesis (Zahavi and Ryan 1980). Table 3 shows that the stable total travel time is actually a react of a large increase in commuting time and a decrease in travel time for shopping and other travel purposes.

Turning to specific transport modes, all transport modes show increase in travel time. The exception is public transport which could be the consequence of the operation of two new metro lines in Nanjing which greatly improved the speed of the public transport system. Our dataset shows that trip time of public transport decreased from 51.7 to 43.9. The time for commuting by car increased the most, which might be caused by the increasing car ownership

and usage. Less time is spend on shopping, leisure and other purposes by car which might be a reflection of the chaining of these trips.

In sum, in only three year time, large differences are already shown in mode choice and travel distance. In the next section, we will employ regression analyses to reveal what are the reasons for those changes. We have conducted regression models for mode choice and travel distance and time. However, in the travel time model, quite few variables have significant changes, moreover, the information of those significant result could be sufficiently covered by the models of travel distance and mode choice. Also for the reason of limited space, here we only demonstrate models for mode choices and travel distance.

5. Multivariate analysis

5.1 Mode choice for commuting trips

Insert Table 4 here

As indicated in Table 4, the dummy variables of the year of 2011 for both walking, public transport and car are positive and significant, meaning that the possibilities that people choose these transport modes for their work trips increase compared with cycling when independent variables are zero. This is in line with the descriptive result that cycling decreases the most among the four modes. The dummy variables here capture the many differences between the two points in time that are not explicitly controlled for in the model. For example, the road environment is becoming more and more crowded and unsafe for cycling, owing to more cars flooding into the roads which are mixed used by both bicycles and cars (Li et al. 2010). This change will make people hesitate to cycle. In this section we only focus on significant parameter for changes.

There is only one variable having significant change in the column of walking. The effect of distance to the nearest station on choosing walking relative to cycling decreases significantly. In 2008, as there is only one metro line, stations are located at the employment and shopping centres where all kinds of facilities distribute compactly. Consequently, the nearer to the metro stations, the high propensity to walk. But in 2011, more metro lines and more stations were constructed. Some new stations are no longer located at employment and shopping centres. For instance, some of them were located in residential areas which might be far away from employment centres. People living there therefore have to commute by other means rather than walk. For this reason, the impact of access to metro station diminishes.

With respect to public transport, women are less likely to take public transport for commuting than men, but in 2011 the gap was significantly narrowed. This might be interpreted by the diminishing gender difference in commuting distance. Our dataset show that the gap decreases from 0.6 km in 2008 to 0.3 km in 2011. The diminishing gender differences actually is the result of more provision of daily care facilities for children and elderly (Goh 2009), more higher educated women and the emancipation of the society (Leund 2003), which all relieve women from heavy household task and allow them to have the same jobs as men. For the households with cars, the propensity of using public transport for commuting increases significantly. In Nanjing most households have only one car which means other members except the one who use car have to commuting by public transport. The impacts of

household composition do not change so much with only couples having significant increases in the usage of public transport. Since the big increases in public transport supply have encouraged all people to commute with public transport, especially for couples who confront less time pressure and easily make coordination with family members, however, public transport is less attractive to core families, due to the inconvenience to combine other trips such as sending child to school with commuting. Only one measure of built environment has significant changes: population density shows decreasing negative impacts on the choice of public transport. The reason is that recent public transport provisions are located in the suburban communities where the density is not so high, which makes density not so efficient indicator for public transport use as before.

Gender differences also significantly diminish in choosing private car for commuting in 2011. Again, the decreasing gap of commuting distance between men and women might account for this change. The gap between people of more than 50 years and young people in using private car is significantly widened due to the lower rate of car and licence ownership of the employed elderly. With respect to the effect of income, people of low income are less likely to commute by car than they were three years ago relative to high income which is a consequence of relatively low car ownership amongst low income category. Couple is the only household type showing significant increasing in choosing private car in household types. The gap between core families and couples is narrowed, which might be a consequence of the complex travel patterns and tight time budgets of families. As for the built environment, in contrary to the changes in public transport, population density is even more influential in choosing private cars for commuting. The emergence of lower density communities in the fringe of the city in which people mainly use car for commuting to cover the long distance might account for the effect (Zhou and Logan 2008). People who live far away from the metro stations are more likely to use cars for commuting than they were three years ago. This could be the case that the places far away from metro stations are actually the places far away from employment centres. Consequently, when public transport is not an option, people will rather likely commute by cars.

5.2 Mode choice for shopping-leisure trips

Insert Table 5 here

Similar to the model for commuting trips, the dummy variables of 2011 for waling, public transport and car are significantly positive. The same reason could be found. The other significant change appearing in the column of walking is from people of more than 50 years old. Compared to three years ago, people of this category are more inclined to choose to walk instead of cycling. This is not surprising, given that the elderly should be more sensitive to the 'cycling-unfriendly' road environment changes mentioned above (Mercado and Paez 2009).

With regard to public transport, people of more than 50 years old again show increasing propensity to use public transport instead of cycling compared with three years ago. The improved public transport service could have changed their perception of using public transport, and consequently more use of public transport are observed. A short distance to the nearest metro station has a strong positive impact on the use of public transport, and in 2011 the impact is enhanced. The reason might be that more shopping and leisure centres are linked by metro lines compared with three years ago, which induces more people to use it for shopping and leisure trips.

More significant changes appear in car use. Females are more likely to use car for shopping and leisure than three year ago, which partly is the result of a dramatic increase of driving license from 13% to 21% among women. The difference in car use for shopping and leisure trips between people of more than 50 years old and the young people is enlarged in 2011. In the three years, more rural resorts are emerging in the fringe of the metropolitan area to provide opportunities for the urban residence to experience farm life (Gao et al. 2009). Compared with the elderly, young people are more likely to drive car there for recreational activities.

The importance of household income is more pronounced in 2011 on car use. The difference between people of high income and middle income is decreased while the gap between people with high income and low income was deepened. For the middle income people, the relatively lower cost for owning and using private car compared with their income increase, encourage them to own and use more of cars (Ng et al. 2010). But for the low income people, especially for the urban poor, things go the other way around. Due to the increasing inflation, the increase of transport cost is actually relative higher than their income increase. Compared with three years ago, extended families are more likely to use car for shopping and leisure activities relative to cycling. This makes sense since: extended families have more financial resources to afford the ownership and use of car than core families. Cars are more suitable for complex travel patterns in extended families than other modes.

Compared with the commuting trip model, the impact of the built environment is less changed in affecting car use. The only significant change is the enhancement of the positive impacts of distance to the nearest metro station, suggesting that people living far away from metro station are even more likely to choose car for shopping and leisure trips. The reason could be same as that in commuting trip model. Generally, the results here indicate that when public transport is not an option, people will choose the car if they live far away from city centres.

5.3 Daily travel distance

Insert Table 6 here

Table 6 shows the regression result for total daily travel distance. The last two columns indicate the changes of confidents of independent variables, which actually are our main focus. The Yr 2011 dummy has a significant positive coefficient as expected and of reasonable magnitude. Like the dummy variables in the regression models of mode choices, it also captures the many differences between the two years not explicitly controlled for in the model, for example, social changes in values (more intention to have out-home activities due to the tendency toward recreation and consumerist society (Chao and Myers 1998; Stockman 2000)), expansion of the metropolitan area (longer trip distance), relative low transport cost compared with income increase in general (financial support for longer travel), and transport supply differences (more bus lines available), etc, which contribute to the longer distance in 2011.

With regard to socio-demographic attributes, people of more than 50 years old travel significant longer than they were three years ago. Due to the social changes mention above, people tend to have more out-home activities than before, and the elderly confront less time constrains which ensure them travel more (Mercado and Paez 2009). Household car ownership shows no significant impact on distance travelled in 2008 but significant positive

influence in 2011. This might be related to the change in value of use of car from status symbol to instrumental purposes (Li et al. 2010). Similar to model for shopping-leisure trips, the two categories of household income changes in different directions. The same reason could be expected. With respect to household structure, couples travel significant longer distance than they were three years ago relative to core families. This could be an effect of social changes mentioned above that couples who live together are more inclined to make more out-of-home activities, while for the adult member of core families, the presence of a child largely offsets the effect.

All of the three measures of the built environment have expected impacts on total travel distance. The significant coefficient of the interaction term of population density indicates that it has larger impacts compared with three years ago. Two possible reasons might be given. First of all, population density can be considered, to some extent, a surrogate of distance to city centre (Levinson and Kumar 1997). Duo to the concentration of jobs in city centre and residential suburbanization, commuting distances have increased. Secondly, during the three years, more lower density and relatively mono-functional communities are developed in the suburbs (Zhou and Logan 2008). Compared with high density communities, these low density areas are more diversified in that high density places are more similar with each other in levels of accessibility, transit availability, etc. (Giuliano and Narayan 2003). The more diversified group compositions increase the importance of population density. People living near to metro stations seem to be inclined to travel larger distance. Those two new metro lines in Nanjing have created network effects that have greatly promoted the accessibility of more places and induce people travel longer distance.

6. Conclusion and discussion

The present study set out to explore the changes of mode choice, travel distance and time in Nanjing metropolitan area. As expected, impressive changes have occurred in only three years. The ridership of public transport and use of private cars increased sharply at the expense of cycling. Meanwhile, daily travel distance also enlarged considerably. Through analysis, it is found that those changes can be partly explained by two interrelated causes. On the one hand, economic development results in individual affluence, fast motorization and expansions of infrastructure, which provide more opportunities to use the fast transport modes. Motorization and investments of infrastructure, on the other hand, fuel expansions and suburbanization of the metropolitan area, which increases the average travel distance and in turn facilitates the need to use fast transport modes. The results here lend some supports to the hypothesis of Muller (1995) which assumed that urban form and the dominant transport systems are dynamically linked as mentioned above, It is worth noting that the significant yearly dummy variables in the regression models for travel distance and mode choice indicate that the changes in travel behaviour are also partly the result of other period-specific factors that not directly incorporated in the models. For instance, the lower transport cost relative to the income increase provides more financial resources for ownership and use of private car and longer travel.

Our analyses support the hypothesis that the classic socio-demographics of individuals show attenuated impacts on travel behaviour. The economic growth and spatial transformations have provided people more opportunities in terms of more financial resources, more

specialized destinations, and more transport mode choices, etc. which make it possible that majority of the population to choose from various options in their consumer, specifically travel, behaviour and lead to more individualized and contextual behaviour. Many researchers have claimed that some of the objective socio-demographics such as gender, age and education, will lose weight in determining travel behaviour and make way for the subjective elements including personal attitudes, values and preference and wishes (Scheiner 2010). The current empirical study supports the hypothesis. In our model, the travel differences caused by 'classic' socio-demographic such as gender, education and age are diminishing. Our results here suggest that to make precise projections of travel behaviour of metropolitan residents in the future as the base for policy making, it is not insufficient to count only on the conventional factors, other lifestyle-oriented variables including personal attitudes and preferences, etc. are also needed.

In contrast to the increasing influence of socio-demographics on travel behaviour, the built environment are even pronounced in determining travel behaviour in 2011, also as expected. This could be the result of more diversified group compositions in urban configurations of 2011. For instance, communities in 2008 show more similarities with each other in built environment in terms of high population density. While in 2011, more low density commutes are developed and consequently, more diversified communities is emerging. Since land use, which is considered as effective means to achieve desirable transport objectives is premised on that residents' travel behaviour can be influenced by the regulation of land use patterns, our results here have implications for transport policy. The increasing impacts of the built environment on travel behaviour enhanced the premise and therefore provide theoretical base for planning initiatives.

However, the picture of urban China also shows some dissimilar to western countries. Due to the urban form of Nanjing transforming toward development with spread-out opportunities, the number of economic and social opportunities in the same radius decreases and causes social inequalities for social vulnerable groups, especially the urban poor, in that less economic and social opportunities can be accessed within the same distance compared 3 years ago. Unlike western countries, which developed at a much lower speed and have time to relieve the tension of the mobility inequality between different social groups, the massive changes taken places in a very short time in urban China make them confront even severe situation. More attentions should be paid to promotion of the mobility of special social groups and the reduction of the transport-related social exclusion in the future to guide the development towards socially sustainable direction.

Another negative consequence of the current developments is the transformation of land use-transport system of Nanjing metropolitan area towards a direction away from environment sustainability. Fast motorization, more use of private cars and longer travel distance all contribute to the increasing emission of CO2 and noise and energy consumptions. Statistics show that China has already become the world's single largest emitter of greenhouse gases (International Energy Agency 2010), while the country is still in the early stages of motorization, with just 32 vehicles per thousand persons in 2007, compared to 595 per thousand persons in Japan and 820 in the United States (World Bank 2010). How to guide the Chinese cities to develop in a sustainable way will become the biggest challenge for the policy-makers in urban China.

As mentioned in the literature review, Muller has identified four eras of land use pattern in line with dominated transport modes for the US urban development history: the 'Walking-Horsecar Era', the 'electric Streetcar Era', the 'Recreational Automobile Era', and the 'Freeway Era'. The theory is also suitable for the urban development of some European countries. However, when applied into Chinese cities, the four-stage model needs modifications. Due to the fast and massive urbanization, industrialization and motorization coming at the same instant, we might see that urban China seems to be compressing these four eras into a single hybrid. It is possible that the urban form of Chinese cities will be much more fragment in land use configuration than their western counterparts: some parts of the cities is 'walking-cycling' city , some parts 'transit city' and other parts automobile city shaped by the dominated transport modes-walking (cycling), transit and automobile-respectively.

The fast and massive changes in economic, social and spatial dimensions have made China a quite unique and complex case and pose great challenge for the policy-makers. Thanks for the strong capability of controlling land and other resources (Pan et al. 2009), the government can quickly and effectively respond to those changes and resolve the problems, to some extent, through land use planning and other policy instruments. However, as there is always lag between planning and the reality as well as uncertainty of planning outcomes, there still are big risks that the Chinese cities go in an unintended and unsustainable direction.

The research has some obvious limitations. For instance, we only have a three year period, which might be too short for the social changes, especially the changes in people's world view and perception, though economic changes are considerable. It should be more valuable to investigate the dynamic connections between socio-demographics, built environment and travel behaviour in a long term. Another shortcoming is that we only include the conventional 'object' socio-demographics in our models with no subject lifestyle-oriented variables, such as personal values and preferences. Since the society is transforming toward more individualized settings, those variables are expected to explain more of people's behaviour. Therefore, in the future, more research that incorporates those effects is needed. Despite these limitations, however, the results provide a pioneer research for systematic comparative analysis on travel behaviour and its determinants over times.

Seismic Risk Study for the Sustainable Development of Tbilsi City Urban Area

Nino Chachava[1], Malkhaz Lekveishvili[2], Nikoloz lekveishvili[3]

Abstract

The international Experience of Developed countries and the Socio-Economical losses during the recent earthquakes happened in Tbilisi City underlined the importance of seismic factor consideration at all stages of governmental policy

- In governmental will, caused by social needs
- In city development concept at the realization level
- In Tbilisi City Master Plan Development at the legislation level

For integration of seismic aspects into Tbilisi City Master plan the evaluation of all city-forming factors becomes necessary in accordance with seismic hazard of territory.

Recent several years we have been working in this direction, especially on the problem of urban seismic risk reduction [1].

This gave us, the Association “Engineering Idea”, the possibility, by the support of Swiss Agency for development and cooperation, UNDP, Georgian National Committee of Disaster Risk Reduction and Environment Sustainable Development, in collaboration with the M.Nodia Institute of Geophysics, the K.Zavriev Institute of Structural Mechanics and Earthquake Engineering, “Idea Design Group” LTD and Georgian Technical University, to develop the special model of seismic risk study for Tbilisi urban area [2,3].

The urban factors were ranged according to their relation with seismic effect.

According to the limitations and special requirements the urban factors’ data were grouped and defined by the level of seismic vulnerability and fixed as the seismic risk.

The model of seismic risk assessment which was transformed and developed in ARC GIS System gave us possibilities for visual assessment of any urban area according to the factors separately or in complex.

The positive points of this methodology were: the opportunity of scenarios development; visualization of results; simplification of Urban factors seismic risk arrangement; creation of close links between the urban databases and city maps; strong management between city layers.

1. Faculty of Architecture, Urban Planning and Design of Georgian Technical University, Georgia, Tbilisi - nina_chachava@yahoo.com
2. NINCLP "Engineering Idea" , Georgia, Tbilisi - m.lekvei@gmail.com
3. indipendant expert, Georgia, Tbilisi - nikolozle@gmail.com

This gave us possibility for quick testing of all urban decisions and visual analyses of their outcomes.

The seismic risk urban analysis show the diversity of urban factors nature in different environments, influence of seismic micro-zoning data on seismic risk assessment, impact of urban factors to each other during this assessment.

The special recommendations were prepared for Tbilisi Master Plan Development, for private and Institutional organizations involved into the City system and construction management, expertise, insurance and estimation.

The general outcomes were developed for urban seismic risk mitigation

1. Introduction

The increase of population in cities and urbanization in seismic-prone areas causes the growth of infrastructure. The goal of society is to create infrastructure that is protected from destructive earthquakes and to minimize the expected losses. The proper assessment of seismic risk is of crucial importance for sustainable economic development of cities and protection of society.

2. Case Study for Tbilisi Urban Area

This problem is of vital importance for Tbilisi as it is a capital of Georgia and one of the most important cities of Caucasus Region. According to the last seismological

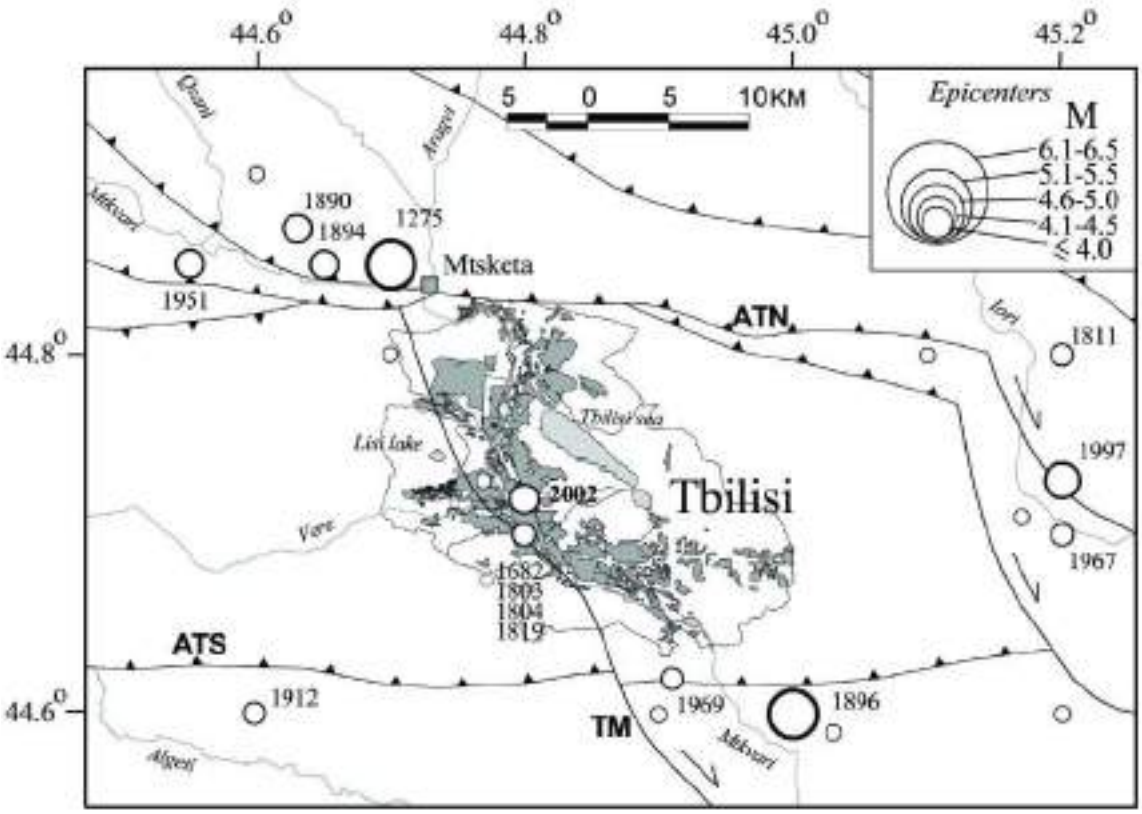

Fig. 1 ATN -The North Achara-Trialeti thrust fault; ATS - The South Achara-Trialeti thrust fault; TM - Tbilisi-Mtkvari dextral strike-slip with reverse fault.

investigations and databases new seismic foalt was developed across the river Mtkvari exactly under the City [3] (Fig.1)
New seismic building codes can't keep up the rapid growth of the city demands. That is why the risk to be injured by the collapses, fires or floods caused by the earthquakes increased significantly.

It must be mentioned that the tourist infrastructure, governmental, nongovernmental activity, private business development concentrate the intensive construction works exactly across the river line as well as in the most densely populated historical built up environment, without the a seismic analyze during the general reconstructions of engineering and transport communications. This was confirmed by Tbilisi earthquake of 2002 years.

The new Master Plan for Tbilisi City future development (Fig.2) was excepted in 2009 (registration N 010.270.000.36.101.013.215, Georgia, 2009). But unfortunately the seismic hazard and risk factors were not included there again . Due to this there was significant gap in the evaluation of main transport, functional and other potential distribution units.

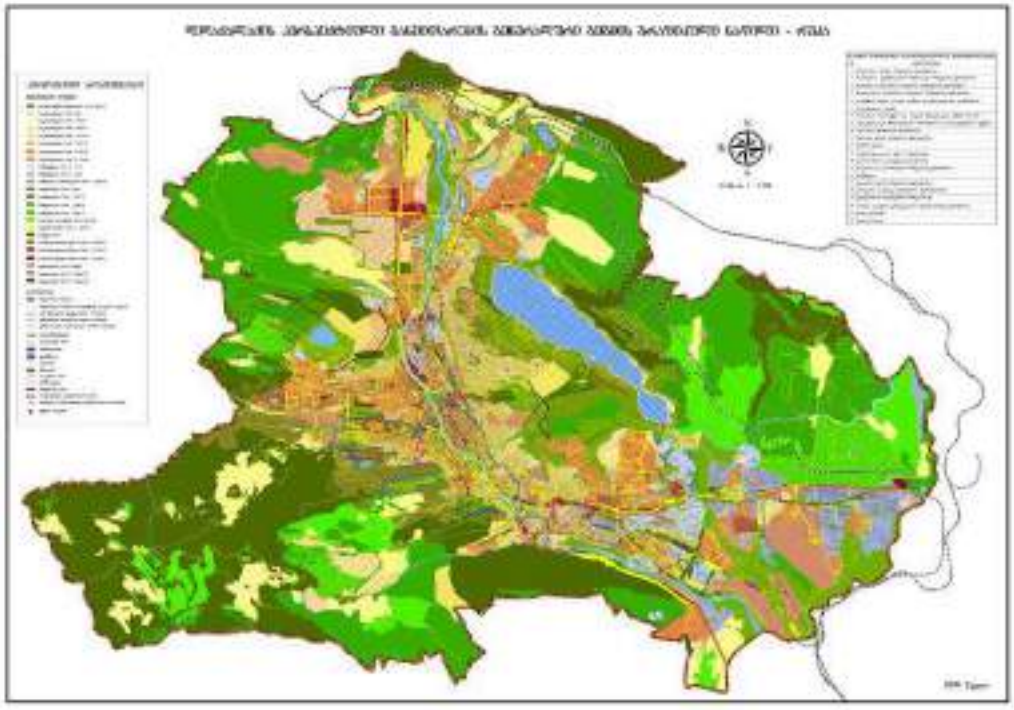

Fig. 1 ATN -The North Achara-Trialeti thrust fault; ATS - The South Achara-Trialeti thrust fault; TM - Tbilisi-Mtkvari dextral strike-slip with reverse fault.

The Municipality of Tbilisi suffered big socio-economical losses in the city after the 2002 earthquake, which provoked intensive damages in the city, especially in its historical part not only during the seismic shakes but after them too.

By the support of Swiss Agency for development and cooperation UNDP, in collaboration with the Georgian National Committee of Disaster Risk Reduction and Environment Sustainable Development, Georgian Technical University, M.Nodia Institute of Geophysics, the K.Zavriev Institute of Structural Mechanics and Earthquake Engineering, Association "Engineering Idea", "Idea Design Group" LTD, the special model of seismic risk study for Tbilisi urban area was developed.

3. Methodological Bases of Urban Seismic Risk Study

The scheme below shows the methodological bases and objectives of urban Seismic risk study (Fig. 3).

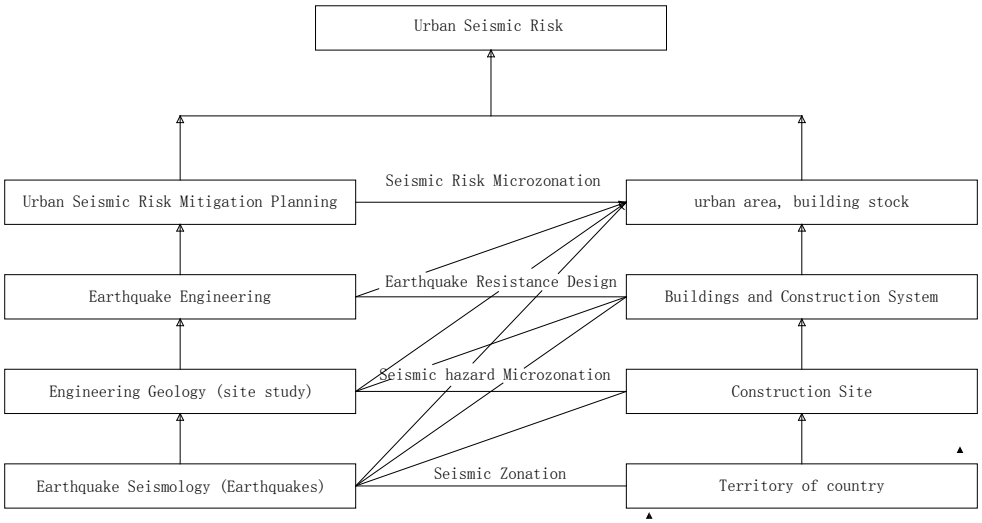

Fig. 3. The methodological bases and objectives of urban seismic risk study

For integration of seismic aspects into the Master Plan of Tbilisi City development we evaluate the seismic vulnerability of deferent city-forming factors.

This enable us to develop the special model of relative seismic risk R, which becomes the indicator of seismic hazard influence on the urban factors' seismic vulnerability [3]. (fig. 4)

$$R_j = \frac{\sum_{i \in S} f_i\left(k_{i,j}\right)}{\sum_{i=1}^{n} f_i\left(k_{ij}^{\max}\right)}$$

Fig.4 The Formula of relative seismic risk R identification

In Fig 4. R_j - value of relative seismic risk of the site; f – value of a function or modifier which define risk; s - number of factors which define risk of one element; n-number of factors which define risk; j – index of a site.

The main regions of Tbilisi City were investigated in this work empowering us to fix the significance of urban factors influence on urban seismic risk reduction across the large territory that gives the possibility of efficient construction and planning management for sustainable development of the city.

According to the limitations and special requirements the urban factors' data were grouped and defined by the level of seismic vulnerability.

According to the limitations and special requirements the urban factors' data were grouped and defined by the level of seismic vulnerability (Table 1).

Table 1. Vulnerability Evaluation for Functional Factor

Code	Usage of Object	Level of seismic Vulnerability
A	Unusable objects (Open Spaces, parks, playgrounds)	1
B	Not very usable objects (2-3 story, 1-4 multifamily apartments)	2
C	Very usable objects (Banks, 4-8 multifamily residential, small commercial and office apartments.)	3
D	Highly usable objects (big banks, hotels, schools, fire and police stations, railway and bus stations, theatres, industries, high-rise residential and commercial buildings)	4

In Table 2 is presented the vulnerability evaluation for city roads

Table 2. Vulnerability evaluation for city roads

	Type of the Roads/ The level of vulnerability	1	2	3	4
A	The Roads of City Significance and main trunk highways	>45	30-45	10-20	10>X
B	The Regional Roads	>30	25-30	25-15	15> X
C	Local Roads	>30	25-30	25-15	15> X
D	The Roads of trunk communication between cities	>65	45-65	30-40	20-30

Table 3. Vulnerability evaluation for historical heritage

Code	Usage of Object	Level of seismic Vulnerability
A	New building Stocks	1
B	All Buildings in Historical Area (Old Quarters)	2
C	The Monuments of Local Importance	3
D	The Monuments of National Importance	4

As a result, it became possible to unite all urban factors in one system and assess the relative seismic risk for any urban area as a whole or separately, for each factor (Table 4).

Table 4. Vulnerability level of Building type and other factors

		Weight Coefficient	Width of the Roads m			
A	The Roads of City Significance and main trunk highways	3	>45	30-45	10-20	10>X
B	The Regional Roads	2	>30	25-30	25-15	15> X
C	Local Roads	2	>30	25-30	25-15	15> X
D	The Roads of trunk communication between cities	1	>65	45-65	30-40	20-30
	The level of vulnerability		1	2	3	4

The model of risk assessment was transformed and further developed in ARC GIS System.

This gave us possibilities for visual assessment of any urban area according to the factors separately or in complex.

The positive point of GIS methodology is its capacity to develop various scenarios, visualize results, simplify urban factors seismic risk arrangement, create close links between the urban databases and city maps, rank the data and strong management between city layers represented various urban factors. This gives us possibility for quick testing of all urban decisions and visual analyses of its outcomes.

4. Impact of Urban Factors to the Evaluation of Seismic Risk across the Territory of Tbilisi

Below is presented relative urban seismic risk according the various factors separately or in complex

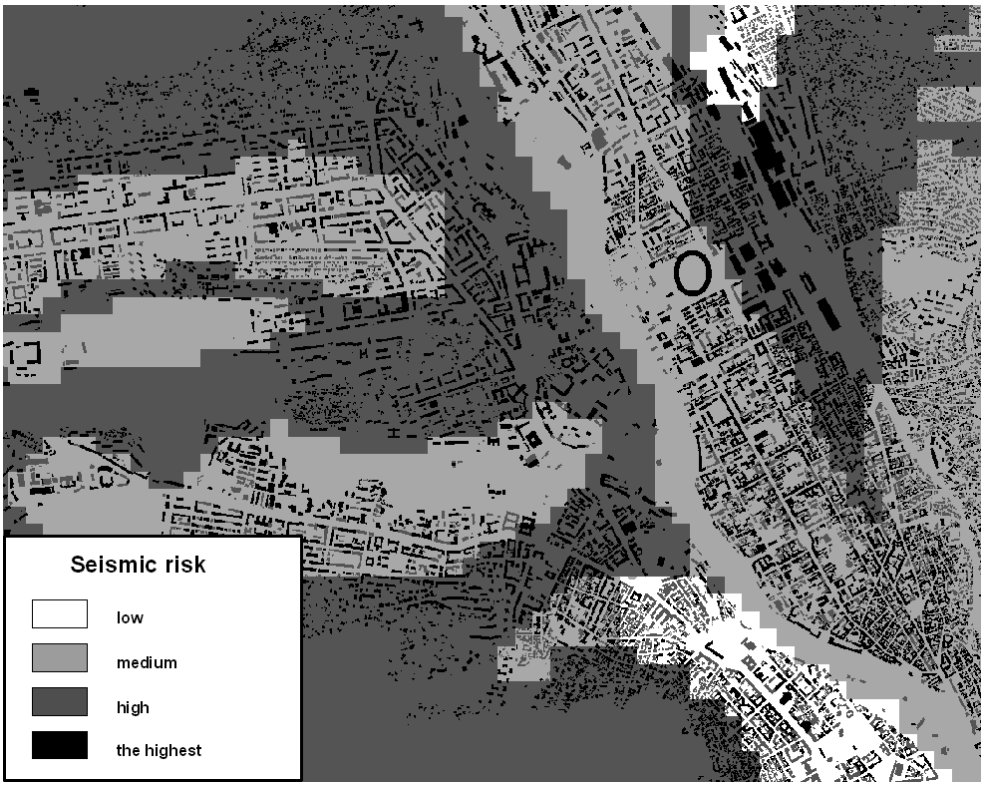

Figure 5. The seismic vulnerability of Building type, functionality, building density and seismic hazard

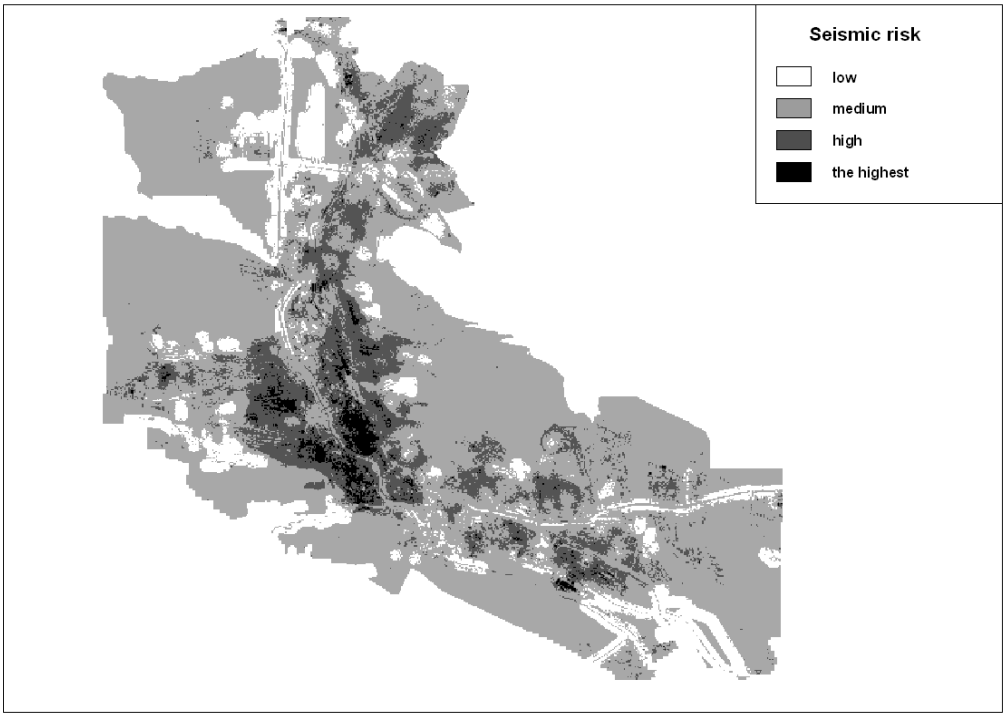

Figure 6. The seismic vulnerability of building type, functionality, building density, population density, roads and seismic hazard

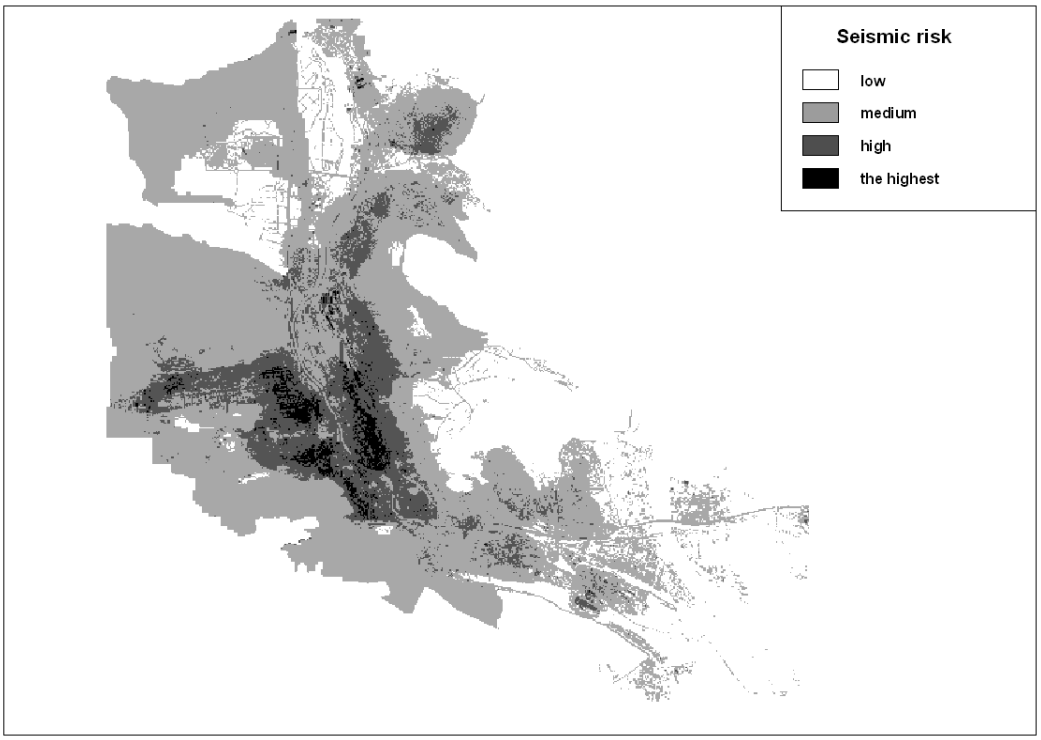

Figure 7. The seismic vulnerability of building type, functionality, building density, population density, road, distance from safe area and seismic hazard

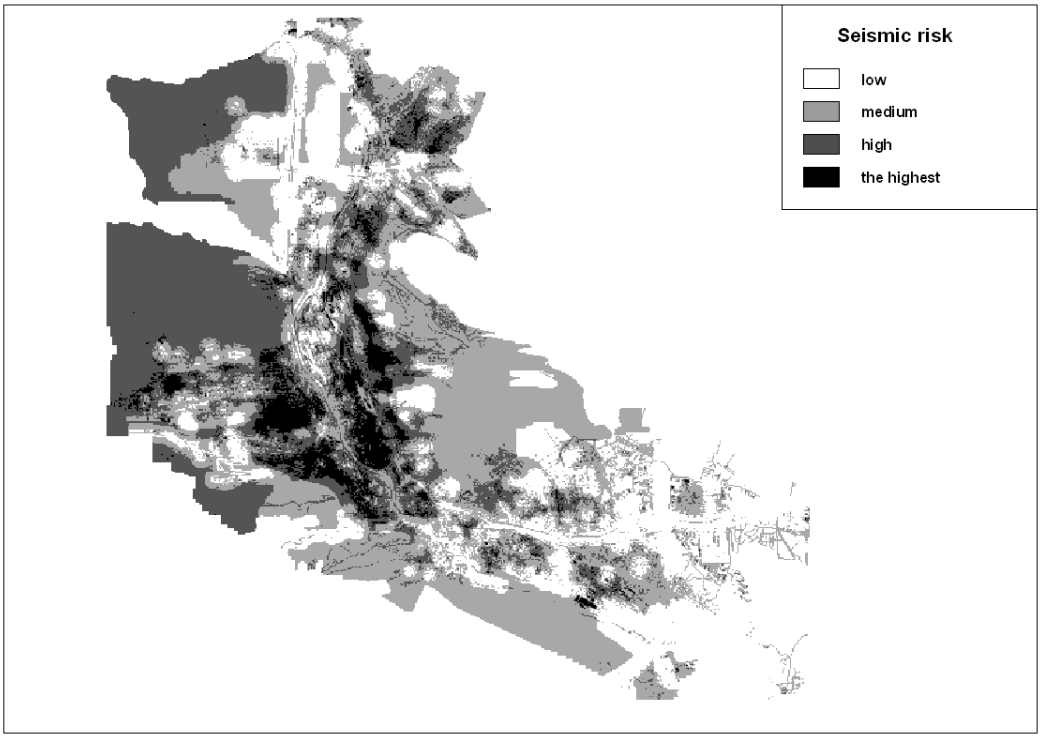

Figure 8. The seismic vulnerability of building type, functionality, building density, population density, road, distance from safe areas, cultural heritage and seismic hazard

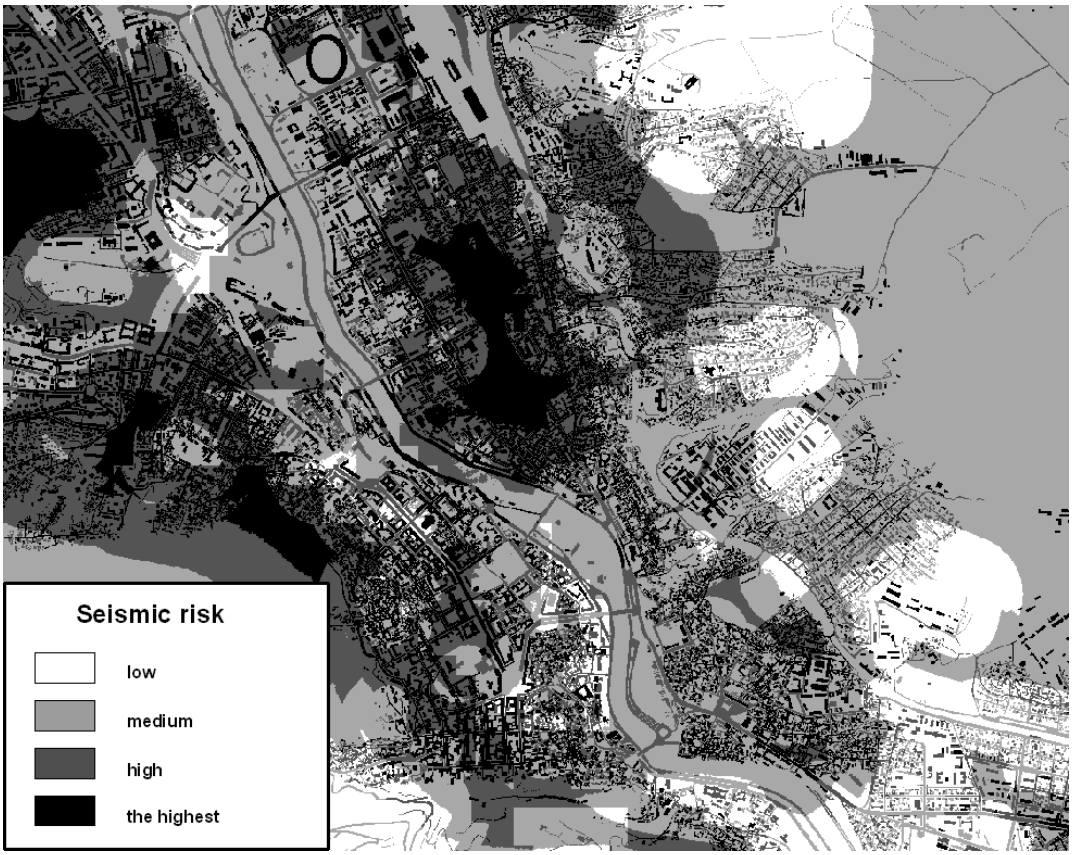

Figure 9. Relative seismic risk without seismic hazard will be added.

5. Results

Seismic risk analysis shows the diversity of urban factors nature in different environments, influence of seismic micro-zoning data on seismic risk assessment, impact of urban factors to each other during this assessment.

Thus, the urban seismic risk study results must become the natural undetached part of Tbilisi City Master Plan Development.

This should give the governmental, private and non-governmental bodies possibility to manage correctly their work and financial activity.

The urban seismic risk assessment creates good basement for bank and insurance system to be involved into sustainable development of City.

The protection and regulation of the social and functional processes in the cities located in seismic prone areas can be realized by urban planning and seismic risk testing.

The concentration and location of urban functions is based on the usual social relations between the inhabitants, their general demands, their work , their ways to relaxation.

6. Conclutions

In order to regulate the seismic risk in the process of the designing and planning it is desirable to follow the recommendations given below:

- To consider the seismic intensity of the site during the general plan development.
- To Organize the main transport distribution areas as potential logistic points during the strong earthquakes
- To Create special life lines for replacement in the case of damages on the main lifeline roads
- To protect the areas of high seismic risk, by the regulation of building stock and population density
- To define the directions of safe City development by the way of functional zoning
- To carry out the demolition of heavy damaged buildings in time.
- The disposition of the buildings of public significance and responsible buildings in convenient territories.
- Making of parks, green recreational areas in seismic hazard areas.
- Building of underground garages and parking-lots in order to unload heavy traffic in the center of the city
- Organization of the movement system in the region – creation of new passages instead of damped buildings by partial opening of ground-floors and deadlocks, which will significantly facilitate the evacuation of population and other salvage operations during the earthquakes, other disasters and their secondary element (fire, flood, landslide etc.).
- The positive influence of basements on the earthquake resistance of the buildings in case of regulation of underground waters, can be used as additional territories, that will safe historical buildings from high rising during the reconstruction process.

UNEASY AND CONTRADICTING COHABITATION OF NEOLIBERALISM AND PLANNING: WHAT IS NEXT?

Tuna Tasan-Kok[1], Guy Baeten

---Draft version, not for circulation!---

Abstract

Neoliberalism may be a widely used term in both scientific and popular writings, but there remains much confusion over what its exact contents are – Brenner et al. (2010a) have called it a 'rascal' concept but confirm elsewhere (Brenner et al. 2010b) that it remains a "keyword for the understanding of regulatory reforms of our time". Infact, neoliberalisation manifests itself as a "prevailing pattern of market-oriented, market-disciplinary regulatory restructuring" (Peck, Theodore, and Brenner 2009a, p. 51). The neoliberalisation of social, economic and political processes pervades urban development, planning and governance discourses and practices, and pushes them in a market-oriented direction; however the terms 'neoliberalisation' and 'planning' are seldom heard together in the same phrase. The concept of neoliberal planning may actually seem to be a contradiction to some planners; while to others it may be a signal to 'give up'. Planning, if anything, may be seen as being in direct contrast to neoliberalism, as something that should be rolled back or even annihilated through neoliberal practice. To combine 'neoliberal' and 'planning' in one phrase then seems awkward at best, and an outright oxymoron at worst. To admit to the very existence or epistemological possibility of 'neoliberal planning' may appear to be a total surrender of state planning to market superiority, or in other words, the simple acceptance that the management of buildings, transport infrastructure, parks, conservation areas etc. beyond the profit principle has reached its limits in the 21st century. Planning in this case would be reduced to a mere facilitator of 'market forces' in the city, be it gentle or authoritarian. Yet in spite of these contradictions and outright impossibilities, planners operate within, contribute to, resist or temper an increasingly neoliberal mode of producing spaces and places, or the revival of profit-driven changes in land use. This paper aims to tackle this uneasy cohabitation of neoliberal planning and show the contradictions created by it while underlining the need for new planning approaches to 'deal with' neoliberalization of urban development.

1. Introduction

Neoliberalisation and market-friendly policies have been affecting the way cities develop and function for more than three decades. While cities have been going through a massive transformation process due to the deindustrialisation during the 20th century, there has also been a transformation from traditionally interventionist land-use planning dynamics towards neoliberal planning dynamics. Slowly but surely, planning institutions began to agree more and more with the changing priorities of local governments who are slowly left on their own

[1] TU Delft, OTB Research Institute for the Built Environment, m.t.tasan-kok@tudelft.nl

by the neoliberalising states to provide necessary services and infrastructure. This required new mechanisms to allow flexible interventions to accommodate multiple actors to the process of urban development and planning. This also meant deregulations to allow involvement of new actors and also to allow the accumulation of capital in cities.

The aim of this paper is not to understand the processes of neoliberal urbanism but to underline the challenges to planning in neoliberalising cities, which need to respond to contradictory processes. Neoliberal planning can best be understood as the embodiment of a set of contradictory urbanities that typify contemporary urban neoliberalism across the Western world (Baeten 2011). This paper will put these contradictions within a framework and will highlight the growing need for new approaches in planning.

The most interesting of these contradictions is in the neoliberal urban development system, which is based on market-oriented dynamics and can only function if land-use decisions are regulated by planning institutions. In other words planning is a prerequisite for neoliberal urban development. In the absence of control, property owners and landlords are at liberty to act as they please in the way they develop their property, and this will have a direct influence on the value of other land and properties. Thus, land-use planning specifically, and planning institutions in general, are needed to regulate the land and property market. Why then, has there been a transformation from traditionally interventionist land-use planning dynamics towards neoliberal planning dynamics that require more flexible intervention mechanisms?

As a result of globalisation and the increasing mobility of capital, large-scale capital investments were mobilised into the cities, especially in the form of large-scale property-development projects. Such investment opportunities became a target for capital investors, who replaced small-scale individual property owners. Looking from the land-use planning point of view, controlling and regulating the intervention of large capital investments in the city is a lot easier than controlling small-scale investments across the city. The city is now divided among major capital holders who are willing to pay the high cost of land development (and redevelopment) and small-scale property investors who invest in the rest of the land market. This division in the urban land and property market allows both small- and large-scale capital investors to exist in the city without interfering in each other's activities. Obviously, when compared to a rigid and regulatory land-use planning process, a more flexible and negotiable strategic planning process will do more to encourage such land and property market dynamics, and it is this trend to which the neoliberalisation of planning refers.

Instruments of neoliberalism have been adopted within different policy contexts in different periods, and naturally they have different meanings and outcomes in different institutional contexts. What these neoliberal agendas, strategies and policies have in common is that they all create contradictions between the principles and practices of planning for urban development. While planning literature is replete with critiques of neoliberal urban development, it ignores the consequences for the planning profession itself. In spite of these contradictions and problems, planners operate within, contribute to, resist or temper an increasingly neoliberal mode of producing spaces and places, or the revival of profit-driven changes in land use. We all agree that new planning perspectives are needed to understand the increasing weakness of cities with respect to economic, social and ecological pressures and

threats; to pay attention to the growing concerns on risks in the globalised economic system; and to bear in mind the processes that misguided development under the hegemony of capitalism (Eraydin, forthcoming). Yet, new planning approaches and concrete studies on credible alternatives are missing.

There is enough literature that points out the evils of neoliberal urban development and planning processes. Already two decades ago Albrechts (1991, p. 126) invited planners to take a new approach, calling for a paradigm shift 'from planning for capital' to 'planning for society'. He advised the planner not to become an entrepreneur and avoid attempts to steer economic forces, but so far that shift has not taken place. The blame lies not with the planners, but with the system in which they necessarily serve as agents of neoliberal urbanism. While planners keep rejecting the idea that neoliberalisation is occurring in urban spatial development and policy processes, neoliberalisation is slowly finding its way into every subfield of planning. Moreover, this 'prevailing pattern,' including its embodied contradictions, is settling into everyday practice. Marketisation initiatives have caused uneven economic stagnation, thereby intensifying inequality, inter-local competition, coordination problems, and social insecurity (Peck, Theodore, and Brenner 2009b, p. 51). While participation and bottom-up approaches are encouraged and regulated in contemporary urban societies, their effectiveness is limited by public decision-makers whose principles may be a result of pressure from market forces.

Private sector intervention has always been an issue for public policy makers but the growing problem is that planning operates more than ever within the one-size-fits-all market solutions, without powerful alternative visions of urban justice trickling down to the planning office. New planning approaches that began to mushroom everywhere, although fragmented and small scale, are not put together below umbrella conceptual frameworks. In a recent publication (Tasan-Kok and Baeten, 2011) we pointed out what is wrong in this planning approach and what contradictions are created by the system for cities and their residents with some case studies from Africa, Asia, North-America and Europe. These studies revealed the uneasy cohabitation of 'planning' – some kind of state intervention for the betterment of our built and natural environment – and 'neoliberalism' – a belief in the superiority of market mechanisms to organise land use and the inferiority of its opposite, state intervention. These contradictions included dynamics that are not alien to the scholarly literature: Displacements due to property-led gentrification processes, global processes intervening local networks of governance, marginalisation, proactive role of the state in the introduction of market principles, self-responsibilization, privatisation of infrastructure provision, opportunism, entrepreneurialism, etc. In this paper we plan to provide an overview of the outcomes of this study, putting the contradictions into a structured framework.

The paper will first give an overview on the historical development of neoliberalization of the planning institution, followed by a section that systematically defines the contradictions that neoliberal planning creates. Finally we will end the paper with a discussion on our ideas for future approaches.

2. A bit of history: Changing approaches of planning

Since the late 1970s the twin processes of deterritorialisation and reterritorialisation of capital are played out at various scales: in the neighbourhood, city and metropolitan region. Public-sector responsibilities are decentralised or privatised, economic sectors are deregulated and welfare services are replaced by workfarist social policies that favour innovative and competitive economic development (Leitner et al. 2007; Jessop 1993). While the state is being hollowed out, 'a dramatic intensification of coercive and disciplinary forms of state interventions' (Peck et al. 2009b) is occurring to cope with the effects of these marketisation initiatives and their consequences. In response, the wealthiest nations had to bail out their financial institutions as they teetered on the brink of bankruptcy during the credit crunch of 2008–2009, yet individuals and homeowners were able to take no benefit from state intervention.

Over the past two decades or so, urban development has become a common activity of a diverse group of stakeholders: public agencies, semi-independent public organisations, private companies and public-private partnerships, who have shared the responsibilities and risks of pursuing decentralised goals through individualism and entrepreneurialism. The stakeholders of neoliberal urban and regional governance (policy-makers, planners, mayors, decision-makers, municipal commission members, NGOs, civil society organisations, neighbourhood committees, urban residents, etc.) all take part in planning, either directly or indirectly, but are increasingly dependent on the neoliberal debt-oriented economy as individuals or organisations that are being held responsible for their own actions. This complex system has accelerated the trends of entrepreneurialism, consumerism and property-led development, and thereby, actors in the urban land and property market have been elevated to the position of key players in urban development. As the expanding role of governance engenders more participatory practices and a further democratisation of urban society, some public responsibilities are decentralised to semi-dependent public bodies, while others are transferred to private organisations or public-private enterprises.

During the 1950s, comprehensive land-use planning became the most prominent approach to planning. Few of the adopted plans had much legal effect, however, policy-makers tended to ignore them (Altshuler 1966). In the 1960s, many planners believed in a future in which social problems could be controlled and humanity liberated from the constraints of scarcity and hunger; while critics of this vision argued that planners were more concerned with formal planning procedures than with their outcome (Albrechts, 1991). From the late 1970s onwards, greater flexibility and the loosening of rigid rules became a common thread in planning discourse (Healey and Williams 1993). In the 1980s the Anglo-American experience suggested that plans should be continually revised to take into account new information and events. As a consequence, flexible, short- or middle-range planning gradually came to replace long-range, end-state planning (Taşan-Kok 2008), and the focus of planning practices shifted to projects (Albrechts 2004; Healey and Williams 1993; Motte 1994) and land-use regulations. Since the beginning of the 1990s planning scholars have increasingly supported strategic spatial planning as a solution to the growing complexity and increasing concern about rapid, random and fragmented development in many West European countries (Albrechts 2004; Healey 2004), where this method was considered more realistic and effective. Traditional planning practices and processes had become ineffective and were too passive to deal with property-led urban development (Fainstein 1994). Entering the 2000s, the planning profession lacked clear boundaries and a recognisable identity (Myers and Banerjee

2005). In the practitioners' eyes, the field was porous and vaguely defined, and the increased flexibility in planning was related to this openness (Taşan-Kok 2008). Besides being more flexible, the role and scope of the planner became more ambiguous during this predominantly neoliberal era, when a blurring of the boundaries became evident not only in the field, but also in planning literature. This change was precipitated by a few developments (Tasan-Kok, 2011):

- *Varieties of capitalism*, fragmented spread of neoliberal economic policies, and diverse reactions of planning institutions due to 'contextual embeddedness and path-dependency of neoliberal restructuring projects' (Peck et al. 2009b);
- *Ambivalent position of planning institution* due to the blurred boundaries between public sector and private markets (Alexander 2008);
- Increasing *opportunity-led approach* of planning institutions.

3. Contradictions of neoliberal planning

The contradictions of neoliberalism and the neoliberal state have been dis-cussed explicitly in previous literature, however their implications for urban planning have been largely ignored. The ambivalent position of planning, as set forth above, has created contingent path-dependencies and specific contradictions in the functioning of planning institutions. In this regard, it may be enlightening to con-sider the analytical framework advanced by Peck, Theodore, and Brenner (2009b, p. 55), which applies the Schumpeterian notion of the creative destruction of cities. When analysing the destructive and creative moments of institutional restructuring there are two assumptions that should be kept in mind. First, the conceptualisation of destructive and creative moments helps to simplify the highly contradictory trajectories of institutional change; and secondly, these moments are interconnected. In this light, the neoliberalisation of planning may be seen as a process of creative destruction that results in a cluttered and contested institutional environment where newly created and highly unstable spatial dynamics contradict inherited regulatory arrangements (Peck, Theodore, and Brenner 2009b, p. 57). In short, the dynamics of property-led urban development prevail in a city where a comprehensive planning system has been well established; but the destructive moment arises when a new large-scale commercial property appears at a crucial spot in the centre of a traditionally social-democratic city where some other service functions were foreseen in the zoning plans. The local government allows a change in the zoning plan, convinced that a large commercial facility in the centre would enhance the city's competitive advantage. The expected outcome of the land transaction includes a new image for the city, besides rent (and tax) revenue for the local government. Thus, despite opposition from surrounding neighbour-hoods seeking to avert high-density development and gentrification, the local government revises the zoning plan. Allowing this new type of large-scale mixed-use project requires not only altering the zoning plans, but also reversing the chain of command. Though contested, a new space of neoliberalisation is thereby created on the basis of property-led dynamics. This is just one of many examples to be gleaned from the institutional responses to the demands of neoliberal actors. That said, creative destruction does not happen systematically, nor does it conform to a standard model due to the path-dependencies mentioned earlier. The contradictions created in each planning system are path-dependent and unique due to the contradictory trajectories of institutional change. Figure 1 depicts this relationship schematically.

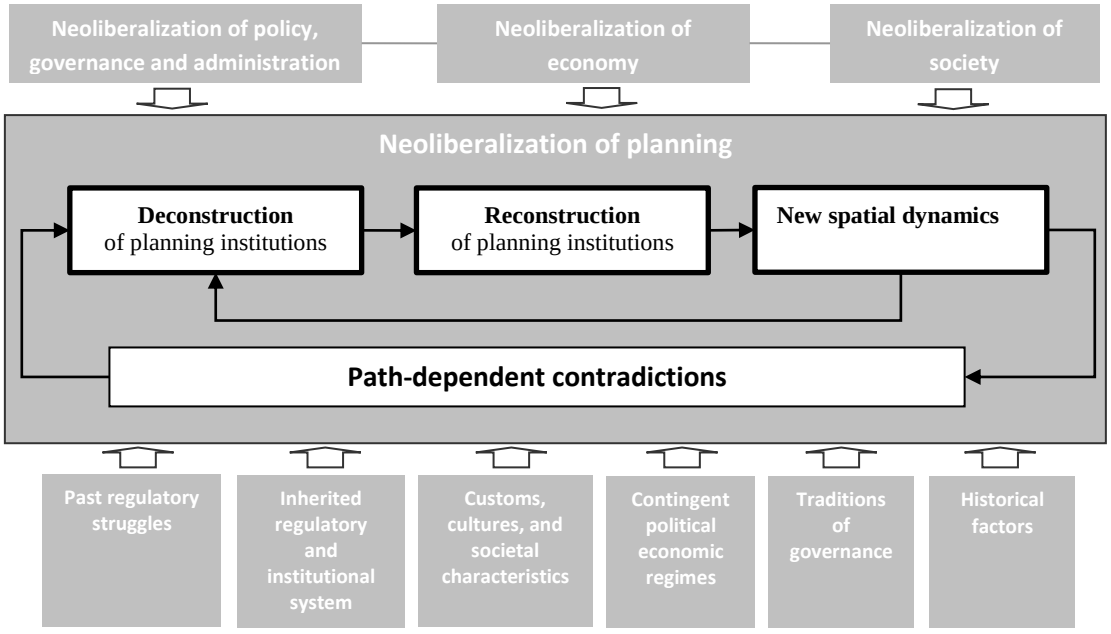

Figure 1. Neoliberalization of planning (Tasan-Kok 2011)

Harvey (2005) explored the shadowy areas and conflicts within the general theory of neoliberalism and came up with a number of general contradictions. Peck, Theodore and Brenner (2009b, p. 51) have pointed out some serious disjunctures between the neoliberal ideology and its everyday political operations. Combining these analyses, we can group the divergent incongruities into a few contradictions that are inherent in the neoliberal state. What is in common in diverse institutional structures is that they all reveal the uneasy coexistence of 'planning' and 'neoliberalism,' and explore the diverse contradictions created as a result of this coexistence.

First of all, *the transfer of responsibilities to the general public or private companies creates contradicting processes*. The general public are expected to become entrepreneurial and responsible, creating their own chances, which on the one hand create opportunities for democratic/bottom-up participation (van Dyck, 2011), but on the other result in exclusive processes (Raco, 2011; Smith and Coombes, 2011). This aspirational political approach sees citizens as entrepreneurs or consumers and this kind of policy framework requires individuals to contribute to the competitiveness of the places, and is aimed at upgrading places, as derelict areas diminish the aspirations of the public (Raco 2011). Raco (2011) argues that neoliberal policy defines a citizen profile on the basis of aspirational citizenship (competitive, entrepreneurial, highly educated, commercialised etc.), where citizens with low aspirations should take people with high aspirations as a model in attempts to become successful and competitive. In this respect, aspirational policies in the UK promoted the idea of social sustainability, while also facilitating increased social polarisation. Moreover, as Smith and Coombes (2011) argue, responsibilisation reframes individuals as agents of their own destinies, although van Dyck (2011) shows that in Canada this type of responsibilisation may also increase chances of participation and social economic progress (even though the practice

of social entrepreneurship is limited). Private companies are expected to take over the tasks that cause fragmentation (or hybridisation), and the meaning of service provision changes a result, becoming more technocratic and delimiting public access to decision-making, thus excluding certain parts of society.

Secondly, the changing role of planners creates contradictions in that *neoliberalisation increasingly frames planners as information providers whose role is merely to recommend the thresholds of safe behaviour to consumer-citizens* (Smith and Coombes 2011). Planners may shift the balance in property rights to promote risk avoidance, but the consequential decision on how to use land is transferred to occupiers, developers or tenants to the benefit of those economic actors with access to scientific and legal expertise. Consequently, responsibility is offloaded from planners, as private matters and their consequences are rightfully contemplated at the level of individual households (Smith and Coombes, 2011). Oranje (2011) also emphasises some contradictions that have been created by neoliberalism for planners and politicians, exploring ways and the extent to which neoliberalism has created a setting of rules and actions that have facilitated the continuation, development and sustenance of the approaches and actions of property developers. Oranje's (2011) case also shows how neoliberalism has increased the appetite for transformation among urban planners in South Africa, turning them into willing agents of neoliberal accumulation.

Thirdly, planning practice has moved away from *democratic and participatory processes* (Beaten, 2011). Despite the frequent 'participative planning' discourse, in planning practice the participation of ordinary citizens goes no further than including some of their reflections in the shaping of the ongoing competitive developments (if the community is participating at all), but not in such fundamental decisions as whether the project should be carried out in the first place. As Taşan-Kok and Korthals Altes suggest (2011), local networks of participation are also affected by the interference of transnational trade agreements (such as European Competition regulations).

Fourthly, the *competitiveness agenda creates contradictions for the social cohesion of cities.* Neoliberal urban policies are confronted with the uneasy task of matching competitiveness goals with the provision of collective goods and ensuring social cohesion, as Loopmans and Dierckx (2011) show in the case of Belgium. They argue that neoliberal urban development projects appear to be too divisive for the local populace to provide a basis for broad-based collective mobilisation. In the same vein, and complementing Baeten's (2011) arguments, Raco (2011) argues that the persistence of deprived or problematic groups are seen by policy makers as a hindrance to national competitiveness and generate additional financial burdens on the welfare state and society. Thus, the distinctions and differences that exist between social groups are beginning to have a negative impact on the overall competitiveness of cities and regions in this policy framework.

Fifthly, in the neoliberal agenda, *urban development strategies of central and local governments can be inconsistent and in conflict*. Eraydin (2011) shows in the case of Turkey that while the central government transferred certain planning rights to local governments, it sought to retain, or even extend, its privileges in major urban areas, especially in metropolitan regions.

Finally, property-led development creates contradictions, as Jou, Lund and Wu (2011) show in the case of Taiwan. Their findings suggest that strategies of 'flexible' accumulation by dispossession centring on land acquisition and property development are key elements in the 'prevailing pattern' of contemporary neoliberal planning, and that cities have become important spaces of neoliberalism and entrepreneurial urban politics (Harvey 1989) that are more accommodating towards investors and developers, as implemented in cities throughout the globe. This, as also emphasised by Baeten (2011), has led to the creation of disconnected patches of elite islands, and thus discontinuity and detachment in the city.

4. Discussion: What is next?

The contradiction of neoliberal planning lies in the epistemological impossibility to tackle obvious urban injustices in the absence of a convincing theoretical and conceptual framework, even if the need for planning intervention that goes beyond paving the institutional way for more market-friendly planning is obvious, acute even. Of late, leading authors in geography and planning have started to tackle this obvious conceptual hiatus that has been steadily growing during decades of neoliberal urbanism. Susan Fainstein (2010) has launched the concept of 'the just city', centered around diversity, democracy and equity, as an alternative for the 'ideological triumph of neoliberalism' which has caused "the allocation of spatial, political, economic, and financial resources to favor economic growth at the expense of wider social benefits". In Seeking Spatial Justice, Soja (2010) insists on the assertive recognition of the social-spatial dialectic (the spatial will be a constitutive part of any form of urban justice). Harvey (2008) and Mitchell (2003), inspired by Lefebvre (1968), have tried to revive the notion of 'right to the city', while both Friedmann (2000) and Amin (2006) have tried to answer the question what constitutes the 'good city'.

Meanwhile, regardless of the increasing momentum in reconceptualising notions of urban justice in academic circles, planning operates more than ever within the one-size-fits-all market solution, without powerful alternative visions of urban justice (so far) trickling down to the planning office. The success of the neoliberal restructuring ethos as an organising principle for urban policy and planning is perhaps less dependent on some form of admirably coherent economic theory than it is on keeping possible alternatives at bay. As Leys (1990, quoted in Peck et al., 2009a) formulates it, "for an ideology to be hegemonic, it is not necessary that it be loved. It is merely necessary that it have no serious rival", and, without trying to suggest the existence of mystically conspiring neoliberal powers, there seem to be tactics at work in different parts of the world that try to exactly keep alternatives out of the limelight. One is to incorporate critical social movements into the mainstream of planning through neoliberal logics such as 'social entrepreneurship' that forces social movements to prioritise the logic of funding and financial survival rather than the attainment of original social goals (van Dijck, 2011). Another tactic is to portray market-led solutions not as an option but as a necessity. In times of 'geo-Darwinism', only cities fit to successfully compete with other cities for scarce resources of capital, be they financial or human, will be or become prosperous places to live and locations where the creative classes will thrive. The 'good city', then, is the neoliberal city that successfully prioritises market so-lutions and attracts its 'fair' share of people and investment – which can be interpreted as 'just' – even if this Darwinian survival logic contradictorily leads to deeply uneven urban development at a larger scale. But cities, within this impeccable market logic, have the right to compete for profitable

investment, and urban dwellers have the right to try their luck in the world of urban opportunities created by market-led development. Further, the portrayal of neoliberal urban development as desirable, necessary, unique, or unavoidable, has a highly divisive effect on urban actors. If neoliberalisation is about the 'restoration of class power' as Harvey (2005) would summarise it, then neoliberalisation can be a strongly desirable project for those who are – or think they are – empowered by it, whether house owners selling their property with a sizeable profit in gentrifying areas, or community groups successfully bidding for financing, planners pushing through (large) development projects, politicians leaving their mark through flagship projects, or developers, estate agents and construction companies making profits from the systematic transformation of urban space under neoliberal conditions.

Neoliberal planning, however paradoxical, is tempting in many ways for many users of urban space, not necessarily including those who gain most from it, and often after the temporal suspension of genuine social concern amongst planners, politicians or community groups to enable 'development' in the first place. The thrill of competing for funding, pushing through plans, seeing spectacular architecture rising from the soil, or contributing to favourable statistics on investment, population, local GDP, etcetera can be far larger than the search for democracy, equity and diversity in the city. Neoliberal planning, then, involves the installation of a new 'planning subjectivity' in town halls and grey administrative buildings where planners do their everyday work. The excitement, pride, respect and recognition that follow from successful neoliberal planning implementations, stand per-haps in sharp contrast with the management of the poor and their poor neighbour-hoods within very limited and ever shrinking social budgets. Contributing to the overall 'gain' for the city, to the 'good' for the city, as defined by neoliberal planning principles, acts as an aphrodisiac for planners and other policy makers, since those principles form the parameters of urban success. At the same time, it be-comes increasingly difficult to stand up for the 'other' city, the city of 'loss', the 'bad' city. Seen through this lens, 'punishing the poor' (Wacquant 2009) may be an undesirable part of the urban neoliberalisation process, but nonetheless necessary and unavoidable in an age of unforgiving interurban competition in which the ghetto has no place. Moving out of sight those who are obviously guilty of failing to grab the opportunities offered by the neoliberal city, has become a constitutive part of neoliberal urbanism.

This leads us to a final contradiction of neoliberal planning. Reducing the city to an 'economy' defines everything and everybody as either economic gain or loss, with nothing outside this dichotomy. Economic reductionism, on the one hand, simplifies the view of what constitutes good planning – planning that triggers economic gain – but, on the other hand, turns planning practice more complex, as all planning issues that fall outside the economic imperative lack an over-all vision to effectively deal with (other than 'removal', as described by Wacquant 2009). The separation of the economic sphere and the social sphere under neoliberal conditions, in other words, turns the planning profession schizophrenic, as it has to pursue goals that only suit part of the urban public. The dichotomy between the social and the economic in the age of neoliberal planning is reflected in the gradual separation of planning frameworks for either 'social' or 'economic' planning. Cities have 'hard' planning-theoretical frameworks for economic policy, with Richard Florida's hypothesis about the mobile 'creative class' (2002) as the undisputed paradigm. It unashamedly suggests to favour the highly qualified, private enterprise and technology, in a chauvinistic attempt to plan for the muscled, 'masculine', assertive city that shows no patience with democratic reflections about

how people may want 'their' city to be. Conversely, cities have 'soft' conceptual tools to plan for social purposes, or plan in poorer neighbourhoods. In sharp contrast with Florida's proposals, the communicative turn in planning theory, headed by Patsy Healy (1997), amongst others, offers democratic, considerate, 'feminine', dialogical, inclusive planning frameworks that sensitively take people's preferences and feelings into account. It goes almost without saying that this planning-theoretical dualism, grown out of and reinforcing the separation of the 'social' and the 'economic' in neoliberal times, disempowers planning that engages with the social, and empowers planning that prioritises economic growth. The contradiction lies in the theoretical and practical impossibility to separate social and economic aspects in urban planning – it belongs to the *raison-d'être* of planning to be integrative in order to come to 'good' land use decisions.

What Explains Urban Poor's Access to Water? Case Study: Kabad Khana, BHOPAL

Tuba Dogu[1]

Abstract

Access to water is one of the critical issues for urban poor in India (12th Plan) and globally. While there are attempts being made to address the issue, still 50.3% of the urban households have no access to piped water within their premises in all Indian cities (BDP, 2005).

Recognizing this continuing urban poverty challenge, this paper analyses whether urban poor can really access the formal water supply system, taking a case study of slum area on Bhopal, India. To do this, effects of different levels of governance and power relations on the ability of the poor to access water from different sources and supply systems are assessed. The paper starts with identifying the actors involved in various processes of water supply management planning and implementation in Bhopal. Three levels of analysis are captured – household, community and city, all of which together determine and shape whether a poor person in slum area has access to water. We provide rich account of how these multiscale processes, governance and facilitation by different actors affect the water access on household level at the location of urban poor. We further advance the analysis by looking at the how poor and disadvantaged groups are represented in the planning processes and to what extent the city level governance actors are accountable to the voice of the poor people as citizens. We locate serious gaps in planning and management approach of the municipality and suggest alternative approaches that involve better understanding of the poor and their livelihoods, better community engagement and accountable governance system.

1. Introduction

1.1. Urban Poverty

There is no universally accepted definition of poverty but in the context of our research we defined poverty in the view of the Asian Development Bank (ADB), as a deprivation of essential assets and opportunities to which every human is entitled (ADB, 1999). This includes the basic services and infrastructure facilities such as access to clean and quality drinking water, sewerage and sanitation facilities.

Urban poverty is quiet different and presents more unique challenges as compared to rural poverty. Thereby, it is very essential to understand and study the scale of urban poverty. The study depicts that urban inequalities are increasing in terms of basic services such as food, water and sanitation.

[1] Izmir University of Economics, Izmir, Turkey – tuba.dogu@izmirekonomi.edu.tr

In the case of Bhopal which is one of the urbanising cities of Madhya Pradesh (India) emerging as one of the busiest commercial centre with an area of 2,772 km², and a population of 1,836,784 (Census, 2001). Population in Bhopal is ever increasing due to the rapid urbanization stressing on the resources of the city which in turn has resulted in the formation of squatter settlements and slums. 35% of the population in Bhopal lives in the slums (ibid.).

Bhopal has only two main water sources which come from the Upper Lake and Kolar Dam. Old city, comprising the majority of the slums, receives water from the Upper Lake. Although this source has the capacity to supply the demand, due to the inadequate water supply network and the limited number of community stand posts, majority of the slums are lack of basic infrastructure as sufficient water supply.

Based on JNNURM (2005), many Government interventions have been implemented to improve the urban poverty especially in the slum area but they lacked of integrated approach.

1.2. Access to Water

According to Adriana Allen, the quality of water, its' affordability, sufficiency, regularity, safety, distance to source and user density are commonly used key determinants affecting the levels of access to water (Allen et. al. 2006). Allen also underlines the meaning of the socio-cultural context, inside which the process of water supply takes place. This means that the parameters affecting water access are embedded in a specific socio-cultural context. There we are focusing on governance, where access being one of the critical components of the water governance from the urban poor's perspective (Figure 1). By governance we refer to the process of decision making, involving actors on multiple scales. Thus interpreting Allen, we can draw a following graph:

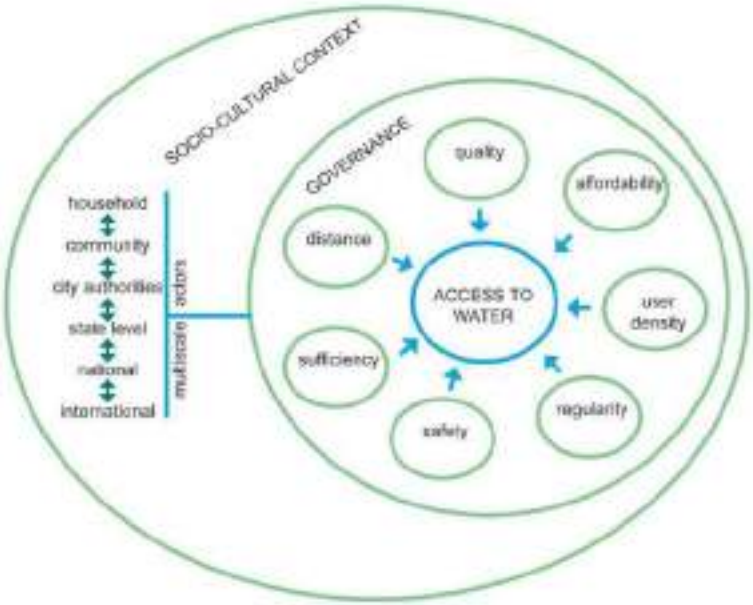

Figure 1: Access to Water

1.3. Climate Change and Water

Strong connection between climate change and urban poor is to help them adapt and resilient to possible change which is initiated, although to date attention has focused on mitigation rather than adaptation (Muller , 2007).

The effects of climate change on available water are more difficult to predict due to overlaping number of effects. To illustrate; if temperatures increase, there will be more evaporation from soil and transpiration from plants, and less water will flow into rivers or seep into the underground aquifers; but if rainfall is more intense, a larger proportion of water will flow off the ground as floods or infiltrate through the soil into the deeper groundwater (ibid.). According to IPCC, it is confirmed that South Asia's water system will be critically affected through decline in water flow and increase in flash floods (Bates et al., 2008). This will bring challenges to the South Asia countries particularly India to organize water management from local communities and government from various levels.

Water conflict is already severe, and would be more complicated with the climate change impact. In India, more than 60 case studies related to water have been done (Joy et al., 2008). Most of these case studies reflect patterns of conflict over water users and among diverse water users in India. But those studies have not really linked the dimensions of climate change into water conflict and governance.

1.4. Methods

By undergoing the existing water issues and look through the water accessibility to the urban poor, we found that access to water is critical issue for urban poor in India. Variety of documents such as the City Development Plan supported this subject. Several key points based on the issues crossed our mind and it guided us to come out with specific research questions. In overall, this paper aims to investigate the main question of what affects urban poor's access to water in the slum community level. To this end, specified under three main sections, each section addresses a specific research question that are:

1. Policy Analysis: How are the current policies including the issue of water access to urban poor?
2. Empirical Research: What are the key issues of water access from the perspective of urban poor? What are the perceptions of different actors in relation to water access to a slum community?
3. Initial Analysis and Interpretation: How do analysis of these different views help us to understand the urban poor's access to water?

To answer the above questions, a case of Bhopal is selected which represents various power relations among different actors. The case study approach was used to explore access to (or lack of) water of urban poor through various levels of actors.
Regarding the research methods, the following steps are taken:

- Actor-oriented approach

- Multiscalar Analysis
- Mixed Methods
  - Qualitative: narratives, short interviews, collected experiences
  - Quantitative: survey, literature and previous studies
- Case Study: Kabad Khana Slum Area
  - Survey of 30 households
  - Deep interviews of 5 households
  - Snowballing amongst inhabitants
- Deep interviews of 10 key actors from BMC, academics, NGO's, private sector

2. Case Study: Kabad Khana

Figure 2: Map of Bhopal city and the focus into Kabad Khana Slum Settlement

Kabad Khana is a slum squatter settlement in the old city area. The voting population of Kabad Khana is 2913 people though the actual population is assumed to be around 5000 people. Referring to Bhopal Municipal Corporation (2011), this is a private (BMC) land having an area of 96 acres (Table 1).

Type of land	Size (acres)
Commercial and Manufacturing	72
Inhabitants squatters (e.g: Patta)	14

Table 1: Existing Land Use in Khaba Khana

Due to increasing population and inadequate resource from the existing clean water, the water supply for the area cannot only depend on the Upper Lake located in the Old City catchment area. This situation leads to the use of other alternatives such as groundwater and tankers, particularly exploiting ground water for daily needs.

However, there are some arguments regarding the quality of the groundwater and particularly its safety. A reason to that is the Kabah Khana area emerging around the scrap-commercial area of old city where recycling and manufacturing activities are actively involved. The scrap activity has resulted with lots of waste dump and improper waste management in Kabad Khana. This indirectly causes contamination and polluted ground water. Yet not directly relevant but still being an important factor, the industrial disaster known as gas tragedy which took place in 1984 has long term effects on the living standards of these people and the ground water resources. This tragedy is said to have contaminated the ground water resources in and around the union carbide site. Many inhabitants of Kabad Khana are said to be gas victims and the second generations affected genetically or by drinking the toxicated ground water which they were unaware of till 2009 (Sambhavana Clinic, 2012). However, the ground water resources in the Kabad Khana area may or may not be toxicated since there has not been any precise study conducted in the area.

Water supply infrastructure covers 66% of Bhopal (Bhopal CDP) and rest is covered by water tankers and common piped connections of bore wells . In Kabad Khana specifically, water is supplied on alternate day basis maintaining a capacity of 160 lpcd (BMC) which is more than the actual parameter entitled to each household that is 135 lpcd. This is to maintain the sufficiency of water for two days. However, based on the site surveys in Kabad Khana, only 40% people have in-house connections whereas the rest have to collect water from piped connections from the bore wells outside. This is one of the reasons why water supply is insufficient in the areas where all the inhabitants of one street collects water from these piped connections.

As this area follows the same living standards of a slum, the inhabitants neither have proper in-house connections nor have any overhead tanks to store water. Since they have to go and collect water from outside, the people use buckets or water drums to carry and store water in their premises. According to the site survey, it is evident that all these households require minimum 3-4 buckets of water for daily use which they manage to divide it for the basic purposes of drinking, cooking , bathing and washing.

3. Findings on the Status of Access to Water

Since urban poverty is multidimensional and complex issue, uniformly designed programs and strategies do not give space for addressing context specific needs nor for available potentials and opportunities (Amis, 2007). With this given information, this section evaluates the determinants of access to water one by one and utilises the diagram defined by Allen et al. as an assessment tool, meanwhile raises a critical view in regards to the sufficiency of the parameters. Consequently, we first look into all the other determinants of access than the socio-cultural practices and governance, allowing the latter determinant formed under another section in order be examined more in detail.

3.1. Quality

According to the conveyed surveys at the site area, 40% of the respondents mentioned that water is not clean (Figure 3). 36% of these respondents futher expressed that there are health issues occurred due to the unhygiene conditions of water (Figure 4). Moreover, based upon the visual observations during the site visits and the interviews with the inhabitants, several cases highlighted the facts of the quality of water such as: drinking water having green color and insects being present in the water. Site surveys revealed out the fact that the unhygiene state of water is due to pipelines not being proper and that wastewater is getting mixed with drinking water through the leakages.

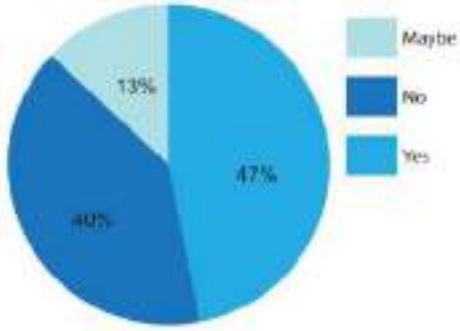

Figure 3: Cleanliness of Water

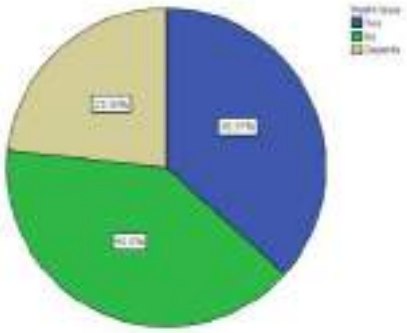

Figure 4: Presence of health issues related to water

3.2 Affordability

Monthly income of Kabad Khana residents generally range between 1000Rp and 9000Rp. According to the family members constituting the average number of seven members per household, it can be claimed that at least 23% of the households remain below poverty line (Tendulkar Committee, 2011) in the area (Figure 6). According to Urban Administration Development Department (UADD) in Bhopal, people below the poverty line (BPL) pay only the half of the water charges. However, despite the presence of the residents falling BPL, water prices seem to be fully charged (Figure 8). Yet, an opponent remains interesting. The majority of people living in the area either are not charged for water due to their illegal occupation of the land or simply do not pay their water charges (Figure 7).

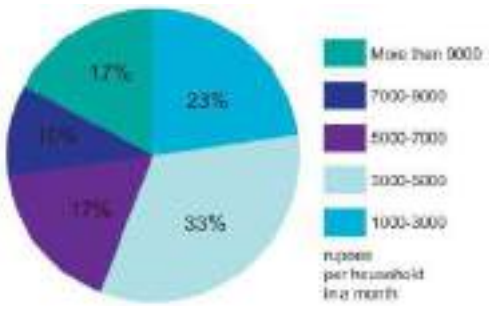

Figure 6: Percentage of Income Levels for Water

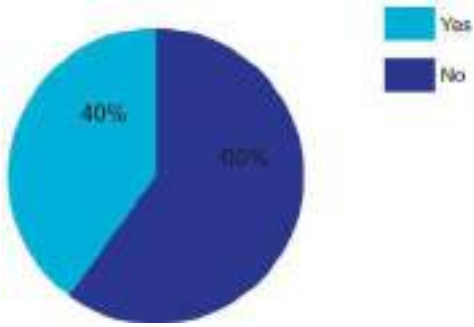

Figure 7: Percentage of People Charged

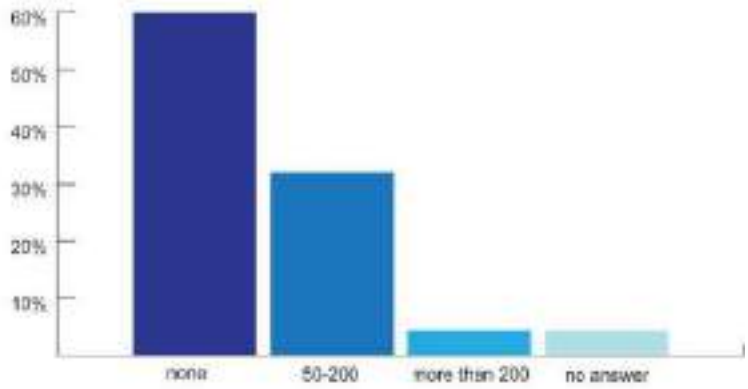

Figure 8: Percentage of Charged Water Prices

3.3 User Density

This parameter of access to water can be defined through the number of users utilising the water sources and facilities in sequence (Allen et. al. 2006). It is evident that the user density has increased as the population of Bhopal has grown with an approximate rate of 35% within the last 10 years (BDP, p.26). Even though the implications of these factors currently remain vague, in the long run they are likely to become primary factors effecting the user intensity in relation to water access.

Yet, there is another scale of user intensity found to be effective. Although it is hard to ascertain the number of people sharing one water connection, during our open questions, seven people mentioned that they queue for water. Additionally, it is known that 60% of the inhabitants of the case area do not have water connection at their homes.

3.4. Regularity

The two main identifying components of regularity are frenquency and timing of service availability (Allen et. al. 2006). Even though it is believed that the city of Bhopal has sufficient quantity of water, there is still challenge in distribution due to the problems of availability with certainty (Academic, 2012). This factor is also supported through the data maintained in the area of Kabad Khana. According to the Figure 10, it can be observed that the practice of collecting water take place usually in early morning time where only 10% of habitants can receive water any time they need. The situation tends to get harder especially during the period when septic tanks need to be emptied as the process can take months to get someone to do the job. Temporary precautions such as storing water are taken to overcome the issue of water being received each day at different hours. As a result, since certainty in receiving or collecting water is highly lack in the area, it would not be too far to state that the issue of receiving water is more likely to be irregular.

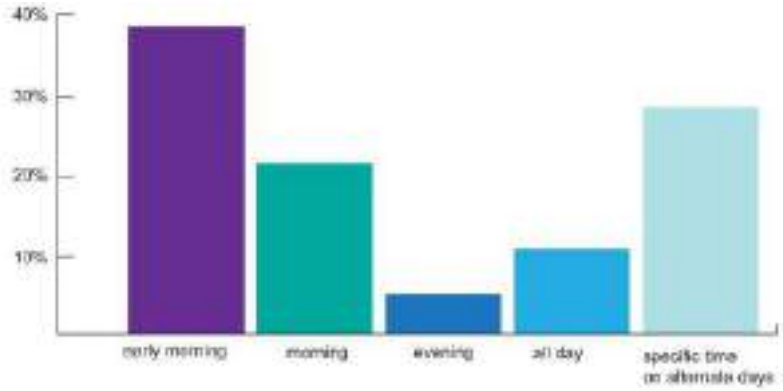

Figure 9: Percentage of Time to Receive Water

3.5. Sufficiency

This determinant is measured by water availability per capita (Allen et. al. 2006). However, since time being a major constraint, the analysis is done per household quantifying the amount of water measured on bucket basis. Almost the 60% of the residents living in the area receive more than 10 buckets, whereas the amount is limited to 6-10 buckets of water in 30% of the inhabitants (Figure 10). Nevertheless, it should be mentioned that the average number of members living in each household is seven and that water is not being collected on a regular basis.

The universal recognition of reasonable access to improved sources has been defined by WHO&UNICEF and stated as the 'availability of at least 20 litres per person per day within one kilometre of the user's dwelling' (WHO & UNICEF 2000, p.77). Based upon this state and referring the data collected, it could be said that the amount of water received is not sufficient. Further prove can be provided through the open questions where seven people out of thirty mentioned that summer time is often difficult since there is just simply not enough water.

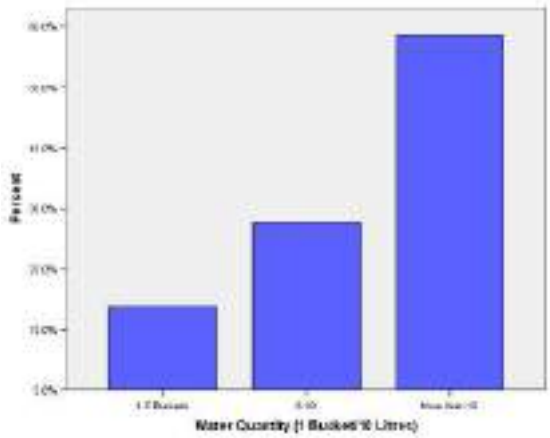

Figure 10: Received Water Quantity

3.6. Safety

This measure has been defined in terms of access to the use of facility (Allen et. al. 2006). Although there is no quantitative data specifically attributed to this parameter, open questions obtained during the site visits certainly stress out that there are evidences regarding the level of safety. An inhabitant stated that there are fights for water and other controversies especially in summer time when demands for water is higher. Another women inhabitant puts the situation into words such that due to the existance of fights regarding the collection of water, women do not let men fetch water anymore. Supposing that this is due being men and naturally having a more violent nature, she continues that men are much more aggressive than the ladies and that they start the fights more easily.

3.7. Distance

This parameter of access can defined as the physical road covered in order to reach the source or the facility. Figure 11 below presents that 40% of the inhabitants reach the water facility in 5 minutes walk whereas 35% states that they have water facilities in their homes. Although this data reflects that a quiet well percentage do not require any personal challenges to receive water, nearly 18% still walks half an hour to reach the water source. On the other hand, 8% claims that distance to water source depends on the various criteria which are mentioned as the seasonal changes, natural occurances such as flood in the open surveys.

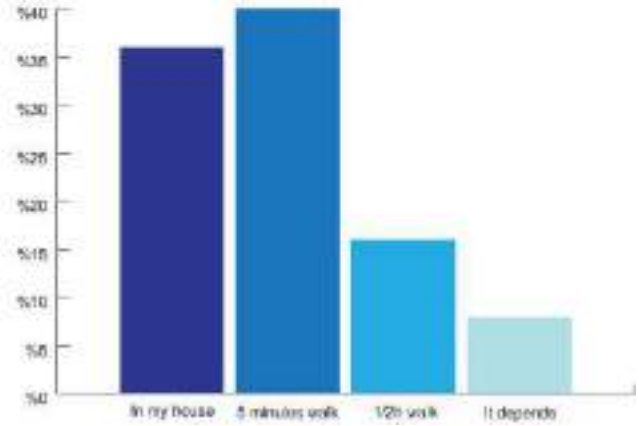

Figure 11: Distance from Water Source

4. Actors in Multiple Scales

4.1. Household Level Actors

Priorities in access to water is highly dependant on the gender factor among urban poor communities (Academic, 2012). This factor is due to the traditional practices that frames out each genders role as well as determined by employment situation and education levels in each family. In most cases, it is common to come across with situations where the one who goes to earn or learn has the priority to utilise water than the one who is neither employed nor assigned in any education institute (ibid.).

According to MPUSP, in various slum areas in Bhopal, it has been seen that women and children has been actively engaged in participatory practices in the context of health and hygiene. However, men remain less engaged and show less interest in access to water as they strongly believe that it is women's duty to collect water (Mittal 2010, p.41).

This very situation is also observed during the site visits conducted in Kabad Khana Slum area. Based upon the site surveys being held, it is seen that the task of collecting water is mostly done by women (Figure 12). Moreover, with reference to the qualitative data, it is observed in Kabad Khana that women use water for cooking whereas men getting ready for work and school.

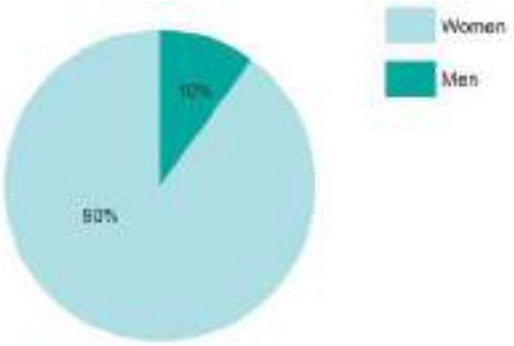

Figure 12: Water Collection by Gender

4.2. Community Level Actors

In localities of urban poor there are communities within communities and inside these a rich variation of actors with different levels of water access. In Kabad Khana neighborhood, there are strong power relations at community level that define access to water. Several conditions such as tenureship patterns and duration of habitance in the area might have implications on these power relations. During the site visits, these power relations were expressed by many inhabitants. As a vivid example, several people mentioned the conditions of exclusion and inclusion when they are forced to queueing system which has no rules, thereby one with more power stands simply first in the line to collect water. Strong community leaders could also be identified. Their power was visible in situations such as the community leader allowing us to communicate when he was present only with the inhabitants he preferred. Moreover, another inhabitant mentioned that due to these power relations strongly existing in the neighborhood, the ones who have no power can even be totally excluded from public water system.

Despite the strong power relations, there are still traces of collective action. Once more, open questions imply that community members gathered together to cover the open drainages in front of their houses, collected money in the community to bore a tube well to get their own pipeline connection.

4.3.The municipal and upper level actors

The assessment of drinking water supply and sanitation in India is the result of a collaborative exercise between the Planning Commission of India, the World Health Organization (WHO), and the United Nations Children's Fund (UNICEF) as part of a joint monitoring programme (JMP) for the sector. This country-level report in India comes in the wake of the four global assessments (JMP reports of 1991, 1993, 1996, and 2000) completed through the JMP process.

Water supply and sanitation is a State responsibility under the Constitution of India and following the 73rd and 74th constitutional Amendments, the States may give the responsibility and powers to the Panchayati Raj institutions (PRIs) and Urban Local Bodies (ULBs). At present, States generally plan, design and execute water supply schemes through their State Public Health Engineering Departments or as in the case of some States, through Panchayati Raj Engineering Departments or Rural Development Engineering Departments and Water Boards. In Bhopal there are 400 people employed to look after the water supply in co-operation both in BMC and PHE.

Of the total wastewater generated in the Bhopal, barely 30 per cent is treated before disposal. Thus, untreated water finds its way into water systems such as lakes and groundwater, causing serious water pollution. In Bhopal, the Lake Conservation Authority and BHOJ Wetland Project look after the discharge of municipal sewerage and solid waste to lake.

There is plenty of overlapping in the development of current policies. There are so many actors and projects going on. We encountered at least twenty different policy projects at national level dealing with water supply and sewerage management. When one of these schemes arrive to municipal level, it usually forms several action plans and thus the amount of projects rise further (India Assesment 2002). However, due to existing rivalries and disagreements in-between two projects acting on similar tasks, leading to outcomes where these two projects cancel each other is likely to happen.

At the municipal level we found problematic understandings on what the slums are and how urban poverty is conceptualized. We came across with situations, where it was claimed that development in one area requires underdevelopment at another part of the city. We were also informed that it would not be possible for a contemporary middle-class family to survive without employees in house to do the shopping, cooking and cleaning and that being the reason of why the poor people are needed. A municipal level planner stated that there is not enough space inside the city, so the poor people from the slums need to be moved outside the city where there are better conditions. We also encountered views such as the poor people just don't care about cleaniness or hygiene, they buy a two-wheeler or a mobile phone rather than invest on sanitation.

Climate awareness has not reached the municipal scale of actions. Currently, there are no policies on climate change. When interviewing planners and higher officers at BMC, the usual response was that there are much more important questions than climate climate change. There were also doubts on whether climate change is even an issue on the city of Bhopal.

There are highly contradictory views on water supply system. The most relevant ones concern whether the groundwater in Kabad Khana after the Union Carbide disaster is drinkable or not. According to State Research Unit, the Environmental Quality Monitoring Group, the groundwater in Kabad Khana is not contaminated. Municipal level planner shares this view. However, independent research units working together with local NGOs such as Sambhavna clinic have diverse views. A central person of the clinic stated that if a 3,5km radius circle around the Union Carbide site is drawn, all the groundwater until the depth of 100m is contaminated. Khabad Khana lies inside that circle. Contradictions rise also in several examples such as whether flooding is considered as a problem. According to municipal level interviews, flooding does not really occur in Kabad Khana. Nevertheless, during the surveys, flooding was often mentioned by the inhabitants and further stated that over a four hour rain, houses are flooded till their rooftops.

5. Analysis of Water Governance Practices

5.1. Equity

Based on our observations, we found out that there is little gender equity among the community members. Women are undertaking the role of collecting water. This can be due to the traditional practices as well as forced situation since in most cases only men work for household's income. Regarding the distributional equity, priority in access to water is for the habitants who are either working or studying. Women living in the case area stated that every night they wake up in order to make sure that there is enough water in the house for the morning. People who go out from the house to school or work need to wash themselves before leaving. If there is not enough water in stock for this, women would get out and look for it, because the water simply is needed to be there.

On the other hand, there are also strong commitments to be equal at community level. The neighbourhood in the case area has a rule of giving every household the right of having four buckets of water daily. No one takes more, because if someone exceed this limit, it would mean that someone else would get only two.

At city level, we cross the question of equity especially when talking of what is identified as a disadvantage in relation to prevalent situation and where these limits are drawn. This applies to whether an area is defined as a slum and at what state, if a person is identified to have a below-poverty-line card allowing cheaper tariffs on services or if someone is recognized as a gas tragedy victim having rights to compensations. Urban project manager at municipal level describes the situation

causing lots of frustration. According to him there is a problem with strict rules. As an illustrative example he asks to imagine that he is asked to provide slums with water. What happens if an area is not identified as a slum and still is not having adequate water services? To him the answer is clear, the area is to be left out.

In terms of physical access to water, we found no priorities given for the more vulnerable ones such as elderly and children in access to water.

5.2. Accountability

In formal decision making mechanisms in urban bodies the actors are often seen strictly accountable to upper lever or to larger scale actors, but not really to citizens. The accountability of urban bodies to slum dwellers is even weaker.

The planner from municipal level explains how this strict accountability to bigger scale actors can also become a burden. According to him, the selling and buying of land is a state level issue. Nevertheless planning remains as a municipal level task. This means that the city needs first to ask from the state to have ownership on the land, only then can city start to makes plans on the plot. Once plans are ready, they still need to get admitted at state level. Process is slow and leads to situations, where only 5-6% of the Master Plan becomes ever built.

Lack of accountability also exists inside the urban bodies themselves. Project manager at state level was critical on the practice of establishing new departments and changing responsibilities from one actor to another. According to him, new staffs are hired seldomly. If the subject of that new department was not familiar to staff before, how could they be competent? A retired higher level officer added to this that he does not see the municipal corporation or any other urban body being able to manage any controlling. According to him the Pollution Control Board has had many failings, as well as the Health Department.

People in the slums feel that they cannot count on services provided by municipal corporations. In situations such as the constant blockage of sewerage lines or water cut downs due to accidents, the inhabitants have difficulties in reaching the authorities. Even though they had made formal complaints which could take whole day meaning that losing a daily wage, there was neither physical action nor reply by the authorities. Taking almost a year to fix the water lines, there has been cases where the inhabitants were totally dependant on the water tankers.

The politicians are seen even less accountable towards the urban poor. Several inhabitants mentioned the policy of votes, that the politicians make promises only to get votes, however those promises are never met after getting the votes. According to a municipal planner, residents of the area are now aware of this issue, thus the voting rates have lately been really low.

In India the problematics of accountability towards the citizen has been identified. Although the consequences have not been observed in the case of Kabadkhana, the Right to Information Act was established in 2005. The importance of the right to information lies in its role in enforcing democratic accountability. This right is important not only for the exercise of political and civil rights but also social and economic rights. Independent information is also important for the people to make informed choices. In order to implement Right to Information to its full extent the support of social groups is needed. Social groups campaign for the enactment and use of a right to information law to be effective and accessible to all, and support people's efforts at developing the ability and motivation to use the right to information for addressing individual and social problems. They work at disseminating the RTI law and encourage and support the development of materials related to transparency and governance, the raising of awareness about the fundamental value of information, the conduct of research, and the setting up of information clearing houses (RTI, 2005).

5.3. Representation

Based on the site survey, figure 13 below clearly indicates that inhabitants are only weakly present in the decision-making processes on their water management. Respondants were asked to consider on whatever decision making, in a community or city level, into which they might have been participated.

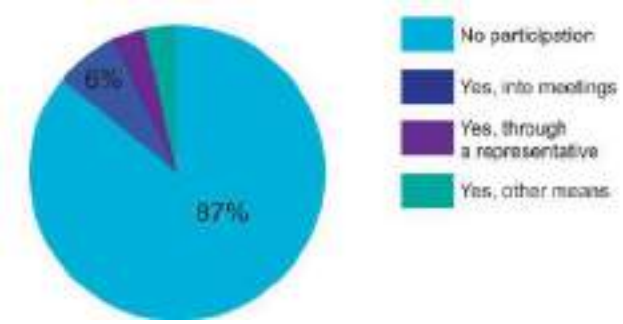

Figure 13: Decision making on water management

Although there are meetings being held among the community, they might be exclusive or they remain at community level without reaching city authorities. With representation people mostly refer to a community leader or other powerful person in their community that acts as a link towards the city authorities. Here participation through other means refers mostly to demonstrations or riots.
The community leader being a representative towards the authorities is both seen as a positive empowering possibility and a problem. According to a man in her thirties, one has to go several times to talk to our community leader. He might send people off and ask back and send off. When he feels like it, he will hear their concerns and then he will make the applications for water connection to work for them. He felt that there is no other means to reach the authorities.

In Kabad Khana a young man pointed a board of politicians and asked us a question: how come could those people represent slum-dwellers? They don't even dare to come to Kabad Khana, their prestige would be threatened if they would be seen here.

6. Conclusions

6.1. Community level governance is critical.

Community level governance is found to be more critical in determining water access than assumed by current policy analysis and scientific discussions. We found that the distribution of water happens in the end at micro-scale, even inside households. Municipality supposes that they are reaching all the rest who have no pipeline connection by covering those communities with tankers. Nevertheless the community level power relations come into play and determine who gets water first, how much, where and at what price. We found also water connections used by groups of people. We can say that there often lies a one more dealer in between the municipal water supply system and the household or individual urban poor and that this dealer is critical in determining how accessible water is.

6.2. There are problematic understandings on what urban poverty is.

At policy and implementation level there are problematic understandings on what urban poverty is. The diversity of different levels of access to water is not recognized. Neither is the variety of actors at community level. The genesis of slums is more usually seen to lie in insufficient housing stock rather than in insufficient income of people and thus in the migration of people in search for livelihood. Housing is often seen more essential than developing basic services. Poor people are regarded to as passive consumers or receivers of services, not so much as active agents to be included in development as sources of skills or labour. We can also find traces of thinking that follow dependency theory, in a way that among authorities there are beliefs that an area cannot develop without another area being underdeveloped. In these few examples it did not come into question, that several parts of the city could thrive and actually mutually gain from that thriving.

6.3. Interaction in-between different actors at different scales is lacking.

There is a lack of poor to be presented in decision making on water supply system. From the perspective of urban poor the possibility of inclusion is seen almost impossible. Trust in government or politicians is lacking. At the level of authorities, there are several urban bodies with overlapping tasks at different scales and the actions are experienced bureaucratic and slow. On the other hand, the division in-between state being responsible for land ownership issues and city of the planning and implementation is experienced challenging.

6.4. There are no precautions on climate change.

There is little or no awareness to external stresses to the water supply system, such as posed by climate change. At municipal level , there are no mitigation or adaptation programs. We found climate change related data being collected at state level only. On international scientific arenas the challenges of climate change and its extra stress on water systems has been identified. In scientific discussions it has also been identified, that climate change will pose stress especially on the water supply of urban poor. Many international cities, such as New York, have seen it important to prepare climate change adaptation programs.

7. Implications

In its newest plans on developing water supply, Bhopal municipality is proposing Private-Public Partnership as a method to implement and maintain the system. Private sector is seen as rather independent actor that would also be responsible on collecting water charges. Collection of revenue, implementation of new systems, as well as maintenance have been experienced as almost impossible tasks for the municipality. Thus by bringing in a new independent actor, it is supposed, that the efficiency and quality of service would rise.

In privatization of basic services, the affordability of water and inclusion of urban poor as customers is nevertheless endangered. If private sector invests in water infrastructure, it covers the costs by the revenue from the charges. There are less risks and more money to make in offering services to people with better income. Urban poor also live in areas to which the implementation of infra can be more difficult and costly. This all biases the water supply system towards the rich.

Instead of relying on private sector as such, here lies an opportunity to bring in an enterprise, that might actually re-establish the connections in-between authorities and urban poor communities, enable more context sensitive implementations, employ local people, share ownership of the enterprise with local communities and help in re-structuring the power relations in community level. We are talking of social enterprises, that can be defined as organisations with an explicit aim to benefit the community, initiated by a group of citizens and in which the material interest of capital investors is subject to limits. They place a high value on their independence and on economic risk-taking related to ongoing socio-economic activity.“The social impact on the community is not only a consequence or a side-effect of economic activity, but its motivation in itself.” (Nyssens, 2006)

8. Acknowledgements

This paper is the product of a collaborative research project involving Elina Alatalo (Research fellow at Tampere University of Technology, Finland) , Nor Hasnida (Master student at The University of Sydney, Australia), Richard Rozerio (Ungraduate at Maulana Azad National Institute of Technology, India) and myself. The data and arguments presented here would not be possible without this

collaborative working relationship. I acknowledge support for this research from the Global Studio which is a place-based action research program. I would like to thank Hemant Ojha and Krishna K. Shrestha for mentoring us through the research. I would like to thank all those who took the time to discuss water supply in Kabad Khana, Bhopal. The names of all respondents kept confidential.

ACTIONS TO IMPROVE SOUNDSCAPE IN THE "PLAZA NUEVA" IN BILBAO.

Gemma García-Blanco [1], García Pérez Igone[1] Aspuru Soloaga, Itziar[1]
García-Borreguero, Ibone[1] Herranz Pascual, Karmele[1]

Abstract

One of the main challenges of the cities is to improve the quality of life of their citizens by means of the urban design. To achieve this goal, urban design should integrate the sensorial dimension of spaces considering not only aesthetic aspects, but also the sound atmosphere or soundscape.

Plaza Nueva is a characteristic Square of Bilbao (municipality in the north of Spain) with the main function of allowing on it meetings with friends in pubs and in public areas, including conversations, food and drinks. The square also offers places where children can play around. These activities are directly connected with the cultural heritage of people from Bilbao, which is interesting to be preserved.

The square is placed in the historical district of Bilbao and the municipality has opened a public participation process to define the strategy for the renewal of this district. One of the objectives defined in this strategy is to maintain the places for leisure activities, balancing their use with a more comfortable environmental experience. Tecnalia proposed to consider sound dimension as an urban design parameter in this renewal strategy. On that sense, one of the public spaces analysed is the Plaza Nueva. As a first step a diagnosis of the current soundscape was developed.

The methodology for the soundscape study combines two approaches: development of acoustic measurements and psychosocial assessment (questionnaires). This study is complemented with an analysis of the architectural elements of the area to identify which of them deals with soundscape and how do they influence in the sound atmosphere.

This approach is useful to identify the urban elements that can improve this sensorial dimension of public places and to propose actions in which possible interventions could be defined once the renewal process would start.

Key words: Soundscape, urban public spaces, sound atmosphere, urban design

[1] Tecnalia Research & Innovation, Bizkaia, Spain – gemma.garcia@tecnalia.com/ igone.garcia@tecnalia.com.

1. Introduction

For the first time in human history there is more people living in cities than in rural areas [1]. It is known that spending time in natural areas contributes to well being and health [2, 3]. But the possibilities of citizens enjoying these benefits depend on the proximity of these natural areas to their residential areas. It is a fact that the citizens of urban areas do not have many opportunities of being in natural areas.

A possible solution to this handicap is creating areas in the cities, as "natural" as possible. Citizens refer to "quietness" as one of the aspects that they associate with the natural dimension of places [4, 5]. This concept involves much more than the acoustical atmosphere of the places, although this is one of the items to be considered.

On the other hand, there are a lot of references that conclude that the acoustical comfort of places not only requires low noise pollution, but it also needs to consider the soundscape concept, that is related with the perception of sounds [6, 7, 8].

Finally, improving the quality of life by means of the urban design involves considering the integration of all the senses, not only the aesthetical and functional dimensions. This approach of considering other senses (such as hearing) is especially interesting in squares and parks (areas to be enjoyed).

All these different points of view derive in the same conclusion: it is necessary to consider the acoustical comfort (soundscape) as a parameter to be integrated in the urban design of places.

The Bilbao municipality, being aware of this fact and with the main objective of improving the quality of life of citizens, is collaborating with Tecnalia to integrate the soundscape approach in urban squares renewal processes. The challenge is that soundscape analysis would give relevant conclusions to be considered when making decision about the renewal interventions to be adopted in public places.

In this approach, soundscape study involves not only the consideration of the acoustical atmosphere analysis (objective and physical dimension of sounds), but also the perception approach (in this case using questionnaires).

2. Description of the study area

The area that was studied is an urban square located in the historic district of Bilbao called "Plaza Nueva".

The area is divided in subareas, applying variables of differentiation of the spaces based on their functionality and use. In the Plaza Nueva two differentiated subareas were identified.

Each subarea is considered as a homogeneous unit for the soundscape approach. Each subarea has common characteristics regarding to soundscape, so, it must have, not only the same sound atmosphere, but its use or functionality must also be similar, since this characteristics influence the expectations of the citizens [(9)].

Subarea 1: Arcade unit. This area is covered by arcades and people meet in the vicinity of bars in the area. It is an area with cultural meaning.

Subarea 2: Square center unit: it is an open area used by children to play, while adults are enjoying their time at Subarea 1.

The municipality has opened a citizen's participation process to define the renewal strategy in the historical district. On that sense, different forums and meetings with stakeholders are in course. This analysis includes Plaza Nueva, since it s one of the most popular places in the district. The results of the soundscape approach presented in this paper will be one of the inputs in the decision making process of selecting renewal actions to be considered.

3. Soundscape approach

The analysis was developed on weekdays (always on Wednesday or Thursday) during the timetable of use of the areas by the citizens (from 17:30 to 19:00). The evaluation was done during a total of an hour and a half, but the data were processed for each half-hour, as this is the average time of use of areas (estimated time that the same person spends at the same place).

The assessment involves two complementary approaches:

A- Physical Acoustic Measurements: ESEI (Environmental Sound Experience Indicator).

In each homogeneous unit, the measurements were developed at two points. The locations of the points were selected avoiding the limits or the centre of the area.

Subarea 1: Arcade unit	Subarea 2: Square center unit

The acoustic setting of the measurements were fixed to a temporary resolution of 1 s, and a spectral analysis of 1/3 octave resolution. The physical acoustic indicators analysed were: L_{Aeq}, L_{AFmax}, L_{AFmin}, L_{10}, L_{50} and L_{90}.

Besides, the sounds present in the area during the measurements were stereo recorded. The aim of this recording is to obtain complementary information to process the information in order to calculate the ESEI (Environmental Sound Experience Indicator).

The ESEI indicator takes into account the following inputs to assess the acoustical atmosphere:

- Sound levels: the amount of acoustic energy that is received in the area.
- Sound sources that are dominant in the generation of the acoustical atmosphere. Identification of those sources present during more time and with more energy.

- Number of acoustical events that are relevant with respect to the background noise level [10].
- Subjective evaluation of sound sources: it relates to whether the sources that characterize the sound atmosphere are perceived by the people as "pleasant" or "unpleasant" and if they are congruent (expected to be listened) or not in the specific place [11].

As it is shown, the ESEI indicator not only considers the results of the acoustic measurements, but it also considers some data from the psychosocial study about user's evaluation of sound sources. The recordings are also useful for a "post in-situ" evaluation.

The ESEI indicator values range from 0 to 12.. A high value of the indicator means a positive soundscape (perception of the sound atmosphere). The sound quality of an urban public space can be divided in 3 classes depending on the ESEI results:

- ESEI values between 0 and 5 mean that the soundscape is not suitable for the area. In the case of urban areas it can be related with the presence of environmental noise (pollution).
- ESEI values between 5 and 10 means that it is possible to include soundscape concepts in the area, going beyond aspects merely related to acoustic pollution. Therefore, in this range of ESEI values, possible actions to improve soundscape will not only include noise abatement measures.
- ESEI values between 10 and 12: (10 is the threshold of excellence). A soundscape with these results of ESEI means a good situation, so it must be preserved or protected.

B- Psychosocial approach: Soundscape questionnaire

The main objective of the psychosocial approach is to collect the users´ evaluation about soundscape. Besides this, the questionnaires also provide information regarding the general perception of the place. There are several previous researches about the analysis of the acoustic comfort by means of the sound perception [12, 13, 14].

The psychosocial evaluation was partially based on conducting questionnaires to people present at the place, simultaneously to the acoustic measurements. A total of 50-60 questionnaires were gathered at each unit of analysis .The questionnaire includes open and closed questions. The content of the questionnaire was defined, trying to optimize the time to fill it, getting a good compromise between maintaining the interest of people answering the questions and obtaining of as much quality information as possible. The questionnaire requires a total of 5-10 min to be answered by citizen

Other interesting information was also collected by the questionnaires. This type of data can be described as it follows:

- Socio demographic information of the person.
- Information about their health and lifestyle.
- Psychosocial factors: satisfaction, noise sensibility …
- Experience at the place and perception of it: frequency of visiting it, activity developed on it, time of presence, descriptors selected for the place, best and worst rated items…
- Emotions: regarding the experience of being in the place.

Information obtained from the acoustic measurements and the questionnaires is very useful for the soundscape approach. The analysis combining information from both approaches allows a good understanding of the reasons of a particular soundscape perception. This understanding will be a solid base to define actions to improve the soundscape.

4. Results of the analysis at Plaza Nueva

4.1 Soundscape Assesment

The following paragraphs show the ESEI results for each subarea. Each resulting value is acoustically explained for a better understanding of its meaning. It is also presented the information obtained on the psychosocial analysis considering, not only the soundscape assessment, but also more information regarding the use and the perception of the place.

These inputs are used to propose some key aspects in which interventions could be focused for the soundscape improvement of the place.

Subarea 1: Arcade unit

ESEI value: 6.6
The sound levels in the area are around 70 dBA LAeq. Sound levels are mainly associated with human activities. There are some sound events and most of them are well perceived by citizens.

Psychosocial analysis:
The main use of the area is social meeting with friends, talking and drinking outside the bars in the area. People are mainly standing up in groups outside the bars.
The place is perceived as pleasant and spacious.
- The most appreciated characteristic of the area is that is pedestrian and covered.
- The less appreciated characteristic of the area is that it is too noisy (due to reverberation at arcades) and it is a bit crowded.

Description of Soundscape: citizens consider that the soundscape is not relaxing. Sound of voices (40%) and some natural sounds (wind) are considered as unpleasant.

Other sound sources that are identified in the area are related with bars activities: ventilation, air conditioning, kitchens, etc.

Subarea 2: Square center unit

ESEI value: 7.5
The sound levels in the area are around 65 dBA LAeq. Sound levels are mainly associated with human activities. There are some sound events and most of them are well perceived by citizens.

Psychosocial analysis:
The main use of the area is relaxing and caring of the children. People are mainly sit down in benches and secondly going through(walking). Children are playing around, running and moving all around the area.
The place is perceived as pleasant and noisy.

- The most appreciated characteristic of the area is its quietness and aesthetic.
- The less appreciated characteristic of the area is the fact that children play with balls. Neither it is well appreciated that the area is windy and crowded.

Description of Soundscape: citizens consider that is a harmonic and natural soundscape. Regarding identification of sound sources, in most cases sound of voices (including children) is considered as pleasant.

4.2 Key aspects for possible interventions

Ideas and key aspects that could lead to possible intervention actions to improve soundscape were defined following a two steps methodology:

- Defining the clue ideas or general requirements that would condition any proposal.
- Developing a "brain-storming" process with acousticians, architects and psychologists to obtain the more proposals as possible, as open ideas.

Some open ideas were obtained through the application of this process. Anyhow, all of them should be discussed with responsible of the municipality to select the most interesting ones and to analyse their possible integration at the moment of addressing the renewal of the square Plaza Nueva.

The results obtained for each subarea of the square are described as follows:

Subarea 1: Arcade unit
General requirements: it is an area highly valued because of its use (connected with the cultural heritage of being a citizen of Bilbao). The main aspect to change regarding the sound atmosphere is the chaotic situation caused by the high acoustical reverberation caused at the arcades. It is considered as a non relaxing soundscape.

Key aspects for possible interventions:

- Reduction of acoustical reverberation in arcade.
- Abatement of noise sources related with bars activities: ventilation, air conditioning, kitchens, etc.

Subarea 2: Square center unit

General requirements: Enhance the natural value and pleasantness that is referred at the place, but avoiding elements that can increment the windy sensation. The presence of children is assessed positively, but not some of the activities they do (play with balls).

Key aspects for possible interventions:

- Increase the option of enjoying the place with relaxing activities. Extend the options to people of being sat.
- Strengthen the perception that the square is natural. It is excluded the option of installing some water elements in the square since the square is perceived as windy and the water could worsen the perception, creating a sensation of cold. The open idea is to include more greenery items (more natural elements).
- Make it difficult for children to play with balls and, instead of this, encourage alternative activities for children to play. It might be interesting to build some installation to facilitate other types of games.

5. Conclusions and expected results

This paper presents an initiative for the consideration of soundscape as an interesting point of view in urban renewal processes.

To develop this task, after analysing different approaches [(15)], a five steps methodology has been defined:

A- Preliminary analysis of the area: delimitation of homogeneous units for the soundscape approach, identification of relevant urban elements and design of the measurement campaigns for the second step.

B- Soundscape assessment: acoustical and psychosocial analyses are combined to obtain conclusions regarding the sound atmosphere quality in the area and the elements that originate it.

C- Identification of aspects of soundscape to be improved and definition of general requirements for the interventions. The actions and the variables that condition the interventions are defined taking into account the results of the previous step, and also the general characteristics of the place, its perception and the interactions between the place and the citizens, derived from the psychosocial evaluation.

D- Definition of open ideas about the interventions: to obtain as much ideas as possible, a brain storming dynamic is proposed. In this process is recommended to involve diverse professional profiles, such as, Acousticians, Architects, Psychologists and Urban designers. This step finishes with the selection of the specific actions that are interesting for the interventions.

E- Final design of the interventions: this step includes the definition of a prototype and a very detailed design of each solution or action that will be implemented to improve soundscape. This step deals with the challenge of adjusting the action to the particular environment of implementation.

In the case of the area studied, the square in Bilbao called “Plaza Nueva”, the process is at this moment in the forth step. All the open ideas found in the process should be discussed with responsible of the municipality to select the most interesting ones and to analyse their possible integration at the moment of addressing the renewal of the square Plaza Nueva. The most challenging aspect will be to be able to provide a prediction of the effects of the actions designed in the fifth step on the soundscape of the studied area. Tecnalia foresees showing the outputs of this prediction in terms of ESEI and soundscape semantic differential scale.

6. Acknowledgements

The content of this paper is an example of the first results of the bet of the City of Bilbao of integrating the environmental comfort and, more specifically, the soundscape in the renewal processes of urban squares. It is gratifying that the City is relying on the technical capabilities of Tecnalia to contribute in their challenge of improving the quality of life of citizens.

We would like to thank to the Public Works Department of Bilbao Municipality for their involvement in the project configuration and to the Regional Bask Government for the funding resources.

USAGE OF THE URBAN GREEN AND OPEN SPACES IN CASE OF EARTHQUAKE- KUCUKCEKMECE-CENNET DISTRICT AS A CASE STUDY

Hilay Atalay[1] , Ayşe Sema Kubat[2]

Abstract

Urban green and open spaces are getting more important day by day and these spaces which have really important functions in urban areas were destructed after 1950 by the urbanization development process of the cities without planning. After the Marmara Earthquake in Turkey in 1999, significance of the earthquake was understood more importantly that we are under risk and it pointed the green and open spaces which are used as a shelter, a evacuation after Marmara earthquake that we haven't got enough capacity. The purpose of this study is to find out a analytical method to determine the urban green and open spaces whether we have got enough or not which will be used in case of any earthquake risk. Initially on this study it was touched on the concept of urban and urbanization, the importance of the urban green and open spaces, the concept of earthquake and the relationship between earthquake and planning. It was advised methods to be able to determine areas which will be used as a shelter and evacuation points after earthquake and to examine their sufficiency according to the sample studies. The urban green and open areas which will be use as evacuation and shelter areas after earthquake in Cennet quarter, Kucukcekmece administrative district which was chosen as an example were determined and these areas were analyzed in terms of their efficiency. Within the context of being prepared for earthquake, determining the green and open spaces which will be used as shelter, evacuation areas and analyzing their sufficiency and giving advises in case of where these places are insufficient.

Keywords: Urban Green and Open spaces, Earthquake, Gathering Area, Sheltering, Evacuation Area,

1. Introduction

During the rapid urbanization in Turkey, urban population growth created by the migration to the towns has conduced to toward the urban deposition area in unplanned developing urbanization area. Due to the fact that the open and green areas in rapid urbanization process have been damaged and due to the increasing the population density, the green area amount per person has been decreasing. And the problem has faced with because of unawareness of the open-green areas in the unhealthy structured towns and the attention has not paid to the existence of the urban reinforcement area. On

the other hand, because of the earthquakes occurred in Turkey, usage of the open and green areas in the cities has become important and the problem has occurred because of the insufficiency of this area in the qualitative and quantitative terms. In this study, in case of any possible earthquake risk in Turkey where is located in the earthquake zone and the aim is to define the functions of the urban open and green spaces after the earthquake occurred, and to determine the urban open and green spaces to be used by the population after the earthquake and as well as to define an analysis method to measure the capabilities of these areas.

2. Disaster And Earthquake

The disasters are very difficult to cope with is natural, technological or man-made event that cause physical, economic and social losses and that interrupts ordinary life, social and economic activities or stops them as well as affects the societies indeed (Kadıoğlu, 2002). Among disasters, the most destroying and destructive one is earthquakes, which cause the loss of life and most. Because of crustal deformation, the earthquake occurs suddenly and it spreads and shakes the land accordingly.

Turkey is located in the most active region of Alpine-Himalayan earthquake belt. Northern Anatolian fault line affects all around Turkey from west to east. 96% of Turkish land and 98% of Turkish population are under the earthquake risk because of various earthquake risk (Palpal, 2000). The possibility of seismic earthquake risk in Istanbul has not finished after the earthquakes occurred in 1999. In accordance with the current researches, depending on the historical earthquake risk of the area, the most destructive earthquake has been expecting in the Marmara Sea that affected Istanbul several times (Kubat et al, 2008).

Due to the uncontrolled and rapid urbanization in Istanbul, the wrong applications of city and region planning and failure construction techniques and applications, lack of infrastructure and services, environmental degradation, the earthquake risks have achieved the highest levels. It is inevitable that the disaster preparation and emergency response methods must be defined and must be put into application before, during and after the earthquake in Istanbul if the disaster happens (İDMP, 2003). Natural disasters and particularly earthquakes induce disasters when occur in the large settlements such as metropolitan areas (Kubat et al, 2008).

3. Usage of Urban Open and Green Spaces After the Earthquake

When the disaster occurs, in parallel to the rescue and first aid activities, in spite of the fact that it takes long term to repair or reconstruct the buildings damaged by the disaster, the accommodation and basic needs of the earthquake victims should be covered within this process (Yılmaz, 2003).

During and after the disaster, people whose homes have damaged or destroyed should seek for sheltering alternatives until the permanent resident solutions will be determined. Temporarily sheltering could be considered as a step of re-sheltering process after the earthquake and a type of physical sheltering stock after the earthquake indeed (Johnson, 2007).

The urban open and green areas have undertaken a leading role in the urban sense by means of their usage and transformation before, during and after the earthquake. Open and green areas have been undertaking different functions before and after earthquake.

The open areas which is the indicator of a prosperity and life standard in daily life has become vital for emergency access, gathering, access by air, storage and distribution of emergency rescue materials, emergency tent using or temporary sheltering area. During emergency conditions, urban open areas have been required by many reasons. Security and temporary sheltering, temporary storing activities that are important for survival are more than important during and after the earthquake. Green areas, sport areas, car parking areas squares and etc. should have sufficient size and should be close to the population in order to serve them efficiently and effectively and these area must be empty. For this reason, these areas must be in proper size and close to the settlements and should be allocated these areas in the master plans. (IDMP, 2003).

After the major earthquake, many people have faced with great difficulties to find a place in a small evacuation center due to the fact that the damaged buildings have blocked the roads. In case of emergency evacuation, the large open and green areas as well as large evacuation roads are required. In the high-density housing areas, it could be more than difficult to find large open and green spaces. In the risk and disaster situation, in spite of the fact that it could not be known when and how the disaster occurs, it is vital to prepare relevant plants and area for emergency evacuation (Shiozaki et al, 2006).

In order to protect population in the earthquake-affected region, a new emergency evacuation system is needed because of the reasons below (JICA, 2002):

- To decrease the loss of lives resulted from second/third aftershocks,
- To decrease the loss of lives resulted from second disasters,
- In order to carry out the distribution of response teams and emergency materials etc. effectively, the relevant information about preliminary damage should be collected from the local community to be evacuated.

In the coming days after the earthquake, during the emergency process, the families whose houses have damaged are evacuated in different places. These areas are composed of empty public buildings, hotels, homes belonged to their families, tents and other arrangements. (Coburn and Spence, 2002).

3.1. Classification Of Urban Open And Green Spaces According To Their Usage Types After The Earthquake

After the earthquake, the urban green and open spaces can be used for different aims such as temporary gathering areas, tent areas and temporary settlement areas in different scales and in different timelines.

Temporary Gathering Areas

Immediately after the earthquake, people inside the buildings want to go out in order to protect themselves against the aftershocks and to protect from the major earthquake as well. In this situation, if there is any open area where the buildings are located, people will prefer these areas and if not, they have to go closest open public space.

The gathering areas and sheltering places which are close to the building and business places and where the information and organization could be found should be defined accordingly. These area should be publicized and should provide gathering area function to act as counter after the earthquake as well as should perform their functions for emergency mobilization. In the most density structure where the high rise buildings are located, it could not be so easy to find gathering areas Many towns do not have sufficient area for 1 m^2 per person to plan gathering places(Coburn and Spence, 2002).

It was suggested that the evacuation areas should be located in each neighborhood unit for the inhabitants of that region and all people (gross minimum area: 1.5 m^2/person).
The gathering areas should be equipped to enable people staying outside for hours. Particularly in the harsh weather condition, it could be difficult to prevent people from going back to their home and business places. For this reason, the relevant equipment should be provided against the extended evacuation process by including rest rooms, shelters, food, tents for sleeping and blankets. After one or several days, if such kind of equipments could not be provided, people would like to go back their homes for their clean clothes, shower needs and other requirements. If the requirements of the people could not be covered, it will be impossible to prevent them from going back to their homes accordingly. (Coburn and Spence, 2002).

Tent Areas

In order to provide emergency sheltering for great number of homeless people, the tent areas are most appropriate sheltering form. Because the tents could be easily stored, pitched-up and could be protected against the weather conditions. The tent areas are safe against the major earthquakes and aftershocks that could be occurred. Generally, people would like to pitch up their tents next to their destroyed homes or around their houses (Coburn and Spence, 2002).

Temporary Settlement Areas

It could take long time to carry out planning and implementation activities regarding the reconstruction and resettlement of the buildings affected by devastating earthquakes. In this process, it is considered that there are emergence sheltering and Temporary Settlement coordination activities as well. For the transitional process to the Temporary Settlement and regarding the reconstruction to be selected, the strategies generally take too much time and the problem could be faced in the next steps (Coburn and Spence, 2002). While organizing the land use plans in the earthquake risky region, the reservation area should be allocated to be used as Temporary Settlement and to be also used for the green area requirements in the existing situation (IDMP, 2003).

3.2. Classification Of Urban Open And Green Spaces According To Their Ownership

The urban areas will be used for the purpose of temporary gathering area after the earthquake, tent area, temporary settlement area and other management areas are made in three types as public, semi-private and public, private areas. Urban open and green areas are the public areas and these spaces that have been used actively and passively in the cities such as park area, children play grounds, sport areas, exhibition and festival areas, private thematic gardens (in small and large size), refuges, squares have been mostly used after the earthquake.

Neighborhood parks have been used as the temporary sheltering area during and after disasters as well as temporary health and other technical requirements. On the other hand, the neighborhood parks must have infrastructure and must be planned to provide service within the storing area for the relief material and food distribution after the earthquake (IDMP, 2003). In these areas, due to the fact that the infrastructures such as toilet, fountain, lights, recreation and sitting areas are available in the existing conditions, it would be more than easy to transform them into the tent towns (Orhon, 2002).

The squares that have been used in different purposes in the towns have become a resource in the establishment of disaster management center during the activities of relevant authorizations during the disasters. In spite of the fact that the squares have been representing the towns and each one, in case of shock and astonishment during the disaster, has very well known these could be a gathering area where everybody could meet easily. For this reason, after the earthquake, these areas have been undertaken very important roles to provide organization after the disaster and to collect relief materials for the victims of the earthquake as well as to distribute the relief materials. Besides, the exhibition and fairground could be used at the same purpose (Orhon, 2002). After the possible earthquake, the public areas could be transformed into the temporary meeting/evacuation, tent town and temporary settlement areas.

Semi-private and public spaces cover the open areas of the public buildings that are not completely open to the public use in the towns. Open areas or gardens of official, education, health and religion facilities among others which have been used after the earthquakes. After the earthquake, in these official buildings and their gardens, in order to continue vital activities of people ,the relevant materials and equipments for the victims of the earthquake should be stored before the earthquake. In order to continue the vital activities in the education buildings, these could be easily transformed to the gathering areas and tent towns for their evacuations. Religion facility areas are mostly important to provide the vital requirements such as toilet and water after the earthquake.

4. Definition of the Method

In the process of generating this method, It has been searched and analyzed different approaches and methods about determination and measurement of sufficiency of urban open and green spaces used gathering areas after earthquake

In the first step of the method, lands uses of the parcels are determined. By defining the current structure parcels, the urban open and green areas to be used as evacuation and gathering areas have been defined. In the process of defining open and green areas, the field trips, have been carried out and by defining physical specifications such as open area position and topographic situation. After the analysis the most suitable areas have been determine that will be used as gathering areas. The urban open and green areas to be used after the earthquake and their intention of purpose are defined as follows:

- Parking Areas
  - Neighborhood Parks: Gathering/Sheltering Places
  - District Parks: Gathering /Sheltering Places
  - City Parks: Temporary Settlement Area
- Open Areas/Gardens Of Education Facilities
  - Primary School: Gathering Area
  - Secondary School: Gathering Area
  - High School: Gathering Area
- Open Area Of Health Facilities: Health Services
- Open Area Of Public Facilities: Disaster Management Centers
- Car Parking Areas: Gathering Area
- Empty Spaces: Gathering Area
- Open Area Of Mass Housing Area: Gathering Area

Only education facilities among the public facilities have been accepted because the open areas of health facilities will be used for the purpose of treatment. On the other hand, the open areas of the official institutions will be used for the disaster management center indeed. During the determination process of urban open and green spaces, each

area has been reviewed on the site and the pictures of those areas have been taken as well as the risky position of the areas have been ascertained. Risky position of the open areas could be assessed in accordance with the building availability on the boarder of parcel by individual observance, the distance to the nearby buildings and height of the buildings as medium and low safety.

The areas where the buildings are not located on the parcel building are classified as high security areas. The areas where at most four layer buildings are located in the parcel border are classified as medium and the areas where more than four layers are located are classified as low security indeed. As a result of the analysis made in the site, the obtained data are associated with ArcGIS program. Data of gathering areas prepared on the basis of parcel, by associating with the gathering area number as Tn, classification information and name of the place, current land use, risk status through the A, B and C symbols as well as risky situation and total parcel area information through ArcGIS program, the tables that show the gathering area information have been established.

- High security areas: A
- Medium security areas: B
- Low security areas: C

In the second stage, the structure parcels that will provide services as the gathering areas have been defined and in accordance with the population. By carrying out the sufficiency analysis of the areas based on the structure parcel, the structure parcels where the gathering areas could not provide service are defined in accordance with the distance to the structure parcel. As the movement distance from the city block to the gathering area, the maximum walking distance has defined as 200 meter. For this study, in the first step, by means of gathering areas associated with the ArcGIS program, the city blocks are defined accordingly. For the measurement of areas, firstly, capacity of open and green areas are calculated. For each gathering area, the structural elements of the area have removed from total parcel area and total open area for each area could be determined. Depending on the area standards per person, it is defined as 1,5 m^2. The number of people to be served that is the capacity of the gathering areas are calculated by dividing the open area to 1,5 m^2. The calculation of each gathering areas capacity is as follows:

- Ct: Capacity (person)
- Et: Total parcel area (m^2)
- Eu: Total built-up area (m^2)
- Ex: Open area (m^2)
- Size of gathering area per person: 1,5 m^2
- $Ct = (Et – Eu) /1,5$

Calculating the capacity of gathering areas and defining city blocks within 200 meter sphere of influence, the city blocks that will serve for the each gathering areas and number of people have been defined accordingly. The process of the method can be seen In Figure 1.

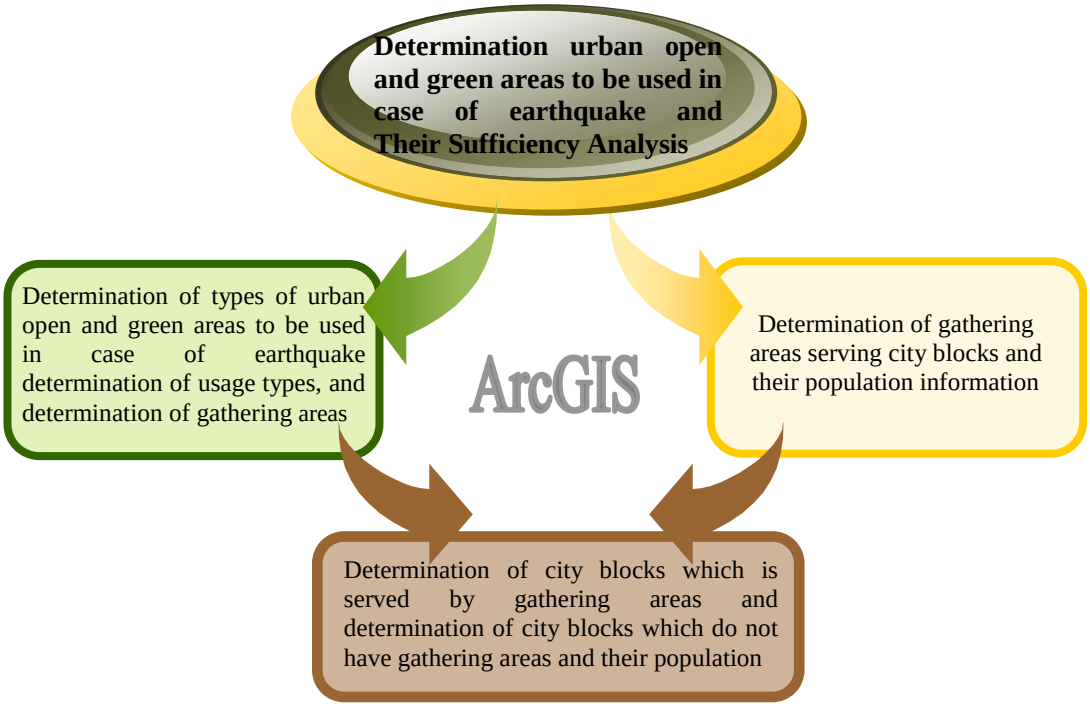

Figure 1. Scheme of the Method

As a result of the study, it has been defined that which person will use which gathering area and the city blocks that the gathering area could not provide service. By means of the calculations associated with ArcGIS program, the analysis could be organized as map and tables. The information could be seen regarding each gathering areas as mentioned in Table 1.

Table 1. Gathering Area Information

Area no	Name of the Area	Function of the Area	Total parcel area	Total Building Area	Open Area Amount	Capacity	Risk Status	Served Population amount	Served city blocks
Tn	-	-	Et	Eu	Ex	Ct	A,B,C	Number of people	City block number

For the definition of gathering areas and analyzing their sufficiency, the data in the Table 2 has been used.

Table 2. Data used in the analysis method

Parameters	Data
Spatial distribution of the population	Numerical value in the table in the city block data
Road routes that help people to access safety areas	The access roads to the open area, the evacuation roads that must be open at all times for the emergency
Risk status of the open areas	Symbol A-B-C that characterized the risk status in the feature table of the open areas
The gathering area size per person	The value of the open area in the feature table ; 1,5 m^2
Capacities of open areas	The numerical values of open areas in the feature table (capacity)
Option right for the safety place	Symbol in the feature table
Maximum distance from their homes	The numerical value defined for every going-200 m

5. Usage Of The Urban Green And Open Spaces In Case Of Earthquake-Kucukcekmece-Cennet District-Case Study

In order to determine the urban open and green areas that will be used after the earthquake and to analyze the sufficiency of these gathering areas, the Cennet Street of Küçükçekmece country is selected as s. The reason of this selection is that Küçükçekmece is one of the ten districts under the earthquake risk in accordance with JICA studies. On the other hand, due to the fact that Cennet Street that is located in the southern part of the district are among the risky neighborhood unit according to the JICA studies and the organized and disorganized structure are combined together, the urban open and green area sizes are not sufficient.

5.1.Cennet Neighborhood in Küçükçekmece District

Cennet neighborhood is neighbor with E-5 highway in the southern part of Küçükçekmece district. In the South of the street, Bakırköy district and in the east, Yeşilova neighborhood, in the West, Fatih neighborhood and in the North, Yenimahalle is located accordingly. The information and datas about Cennet neighborhood was collected in 2008. The location of Cennet neighborhood in Küçükçekmece district is

seen in Figure 2. Cennet Street is at the size of 88 ha and it is composed of 2.35% of the district. The population of the district is 38.460 persons.

Figure 2. Location of Cennet Neighborhood in Küçükçekmece District

Cennet Neighborhood is one of the central commercial area of Küçükçekmece. In the working area, it is considered that urban social infrastructure areas such as education, health, religion facilities are not sufficient according the population of the area. In the area, there is totally 4 park areas with 1.4 ha and only one park area is over 5000 m^2 . The 3 park areas are under 5000 m^2 and the park areas are not sufficient for the population. There is approximately 3.1 empty areas in the working field.

Active green areas, health facilities, primary school- secondary school areas, religion facilities and technical infrastructures have been compared with their normal ground sizes as per the population defined in the planning regulations. As it is seen in Table 3 active green areas, urban social infrastructure areas and urban technical infrastructure areas are not in the proper size as much as they are.

Table 3. The Amount Of Facilities According to Planning Regulation and Comparison with the Current Conditions in Cennet Neighborhood

Land Use	Area (ha)	Standards in Planning Regulation m^2/person	Necessary Area for population in Planning Regulation (ha)	Areas Covered in Existing Situation (%)
Park Areas	1,4	10	39,0	%4
Health Facilities	0,2	1	3,9	%6
Primary School	2,1	4	15,6	%14
Secondary	-	3	11,7	-
Religion Facilities	0,8	0,5	1,9	%42
Technical Infrastructure	0,2	2	7,8	%3

Urban open and green areas that are one of the most important indicators for the urban prosperity and quality of life are not sufficient in terms of urban social infrastructure areas and this case has decreased the life quality of the Neighborhood.

5.2.Defining Urban Open and Green Areas to be used in Cennet Neighborhood after the earthquake and Analyzing its Sufficiency

In case of possible earthquake, the gathering areas that will provide sustainability of vital activities and will cover the sheltering needs of the affected population who could not go back their homes and whose homes were damaged by the earthquake are composed of urban open and green areas. In Cennet Neighborhood that is faced with the earthquake risk within the preparation activities against the possible earthquake, the gathering areas where 38.460 population will use have been defined.

The study of definition of gathering areas are not only for people whose homes have damaged or lost their homes but also assessed for all population. The proposed method has been used to define the urban open and green areas and to analysis, their sufficiency's in Cennet Neighborhood after the earthquake.

5.3. Determination of Urban Open and Green Areas to be used after the Earthquake

In case of possible earthquake, while the gathering areas have been defining to cover the requirement of entire population in Cennet Neighborhood, urban open and green areas have been used. The following current areas in the site have comprised of urban open and green areas:

- Parking areas
- Open sport areas
- Training areas
- Open car parking areas
- Empty areas.

The religion facilities in the site have not been proposed as gathering areas because of structural specifications of the mosques and also public facilities have not been suggested, because these areas could be disaster management center in case of earthquake. In the Cennet Neighborhood, the urban open and green areas which are able to be used as gathering areas have been analyzed according to their physical specifications such as topography, open area status and these areas selected among others having at least 100 m^2 unstructured areas. One empty area available in the field has very much plant area and because of its curved structure could not be proposed as gathering area.

Afterwards, the risk position of the gathering areas have been defined depending on the proximity to the building having risk and height of the buildings by individual observations. The areas that do not have any building on their parcel border are classified as high security, the areas that have at most 4 layer buildings on the parcel border are classified as medium security and the areas that have more than 4 layers are classified as low security.

- High security area: A
- Medium security area: B
- Low security area: C as classified.

In the neighborhood, Total 14 gathering areas have defined. 3 of them are composed of primary school are, 1 is for secondary school field and 4 of them are composed of education facilities, 4 empty areas, 4 parking areas, 1 open sport area, 1 car parking area have been proposed. Gathering areas which belong to private ownership are suggested to be publicized. Name, current position, total parcel areas, security levels and their explanations of the gathering areas are submitted in Table 4.

Table 4. Gathering Area Information

Name of the Gathering Area	Explanation	Function of the Area	Risk Status	Et (Total parcel area) m^2
T1	Marmara High School	Education	B	5439
T2	Remzi Yurtsever Primary School	Education	B	2683
T3	Yeşilyuva Primary School	Education	B	6980
T4	Empty Space	Empty Space	A	6903
T5	Empty Space	Empty Space	A	6685
T6	Antikalar Park	Park Area	A	3890
T7	İ. Gaffar Okkan Park	Park Area	A	5373
T8	Open Sport Area	Sport Area	A	7483
T9	Sevgi Park	Park Area	B	1212
T10	Empty Space	Empty Space	A	6026
T11	Behiye Selim Pars Primary School	Education	B	6269
T12	Open Car Parking Area	Car park	A	4694
T13	Şair Nedim Park	Park Area	A	4018
T14	Empty Space	Empty Space	A	3385

There are not any low security areas in the proposed gathering area in the site. Due to the fact that there are not any buildings in the parcels of park areas and car parking areas. Only Sevgi Park has 1212 m^2 area has been assessed as medium security due to the fact that it is close to the building on the parcel next to the Park. Within the parcels of the education facilities defined as gathering areas, in spite of the fact that there is not any high structures more than 4 layers , they have been defined as medium secured structures.

It is seen that the gathering areas in Cennet neighborhood have not been dispersed homogenously. Gathering areas in field of study locational distribution and land use in the current status and total areas have been seen in Figure 3.

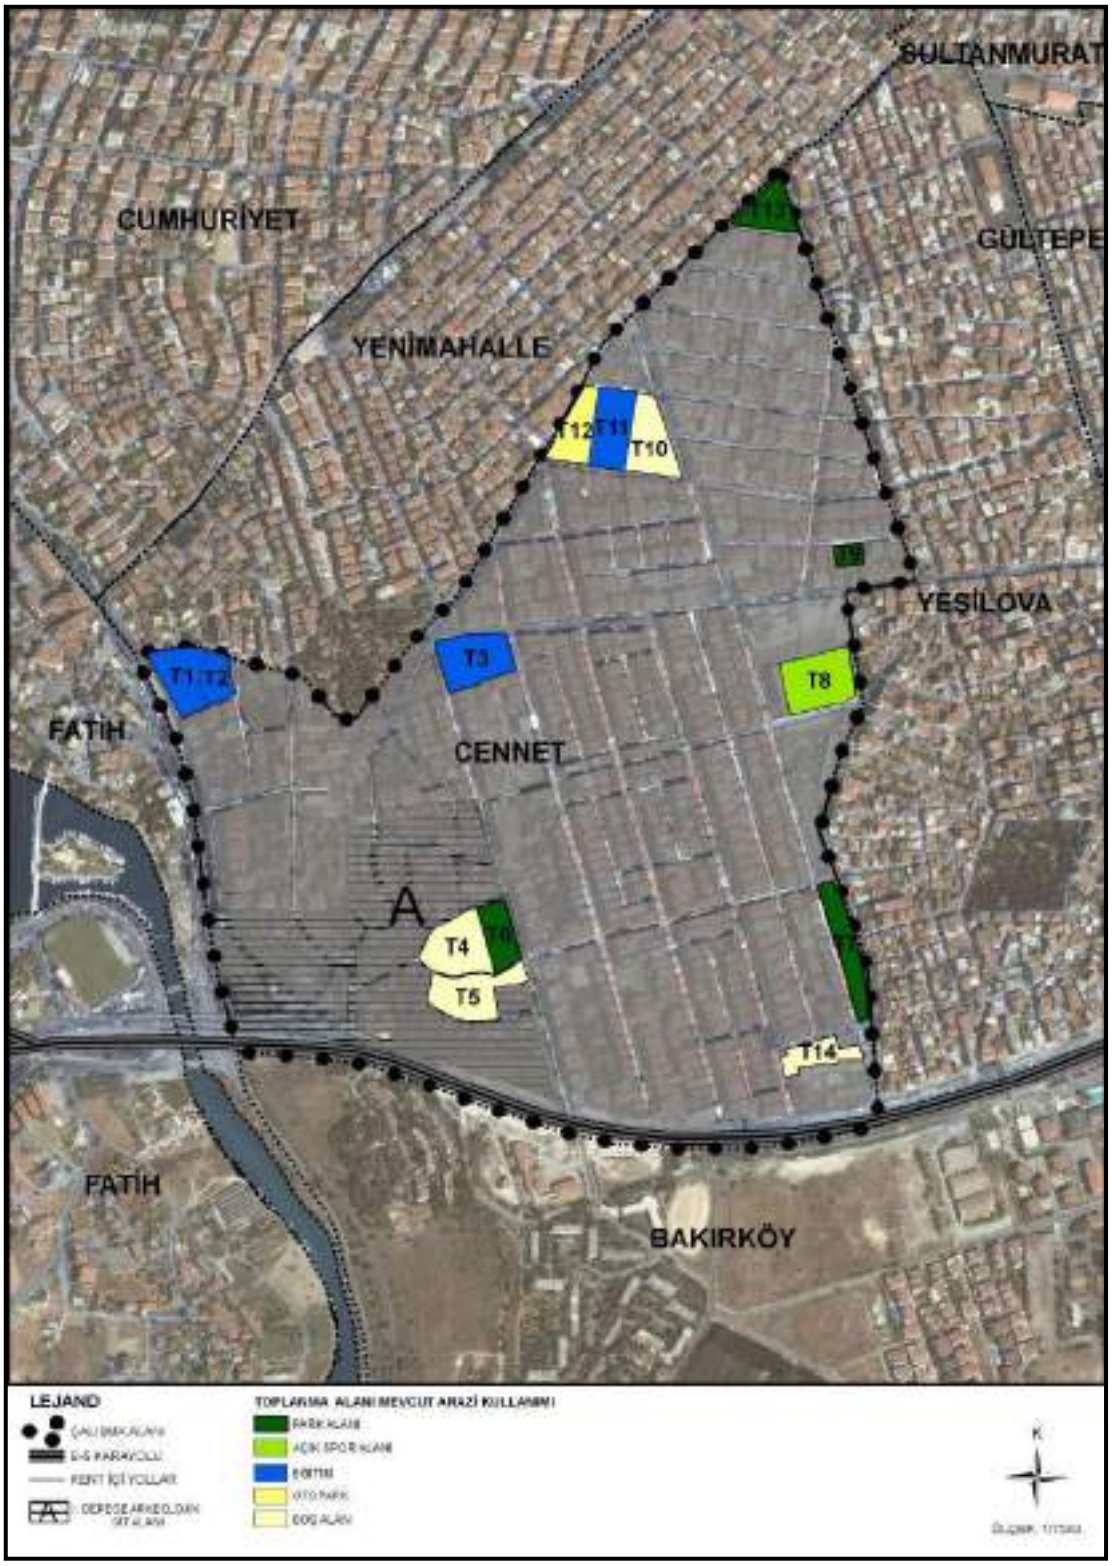

Figure 3. Location of Gathering Areas and Their Functions

.

5.4.Measuring the Sufficiency of The Urban Open and Green Area to be used in case of Earthquake in Cennet Neighborhood

After defining the gathering areas, as the second stage, measuring the sufficiency of these areas have been carried out. Firstly, in order to determine the city block which will be served by gathering areas and population, 200 meters of influence area of every gathering area and city blocks which are in this influence area has been identified. In figure 4, 200 meters of influence area for the gathering areas could be seen. In case of that more than 50% of city blocks areas are in 200 m influence area and when 200 meters maximum distance have not been exceeded, these city blocks have accepted as city blocks in the influence area. The capacity of gathering areas and population amount to be served has been calculated as 1.5 m^2 per person. The capacity of the gathering areas are calculated with follows:

- Ct: Capacity (person)
- Et: Total parcel area (m^2)
- Eu: Total Building area (m^2)
- Ex: Open area (m2)
- Size of gathering areas per person: 1,5 m^2
- Ct = (Et – Eu) /1,5

After calculating the capacity of gathering areas, considering city blocks within 200 meters sphere of influence, city blocks which gathering areas will serve have been determined according to capacity of them.

As a result of analysis, it has been identified that the gathering areas for the population in any case of earthquake and city blocks that do not have any gathering areas. As it is seen in Figure 3, the color of gathering areas and served city blocks are the same. Thus, it could be defined which gathering areas have been served for which city blocks. In case of possible earthquake, the connection between the evacuation corridors and gathering areas that must be open at all times has established accordingly. The total capacity of defined gathering areas are composed of 42.979 people and the total population to be served is 29.444 people. The information about gathering areas is seen in Table 5.

As a result of analyses, the city blocks which do not have gathering area have been determined. In the current situation, it has been also determined that the gathering areas for 9016 persons in 19 city block are not available after the earthquake. It is seen that the city blocks that do not have gathering areas are located in four different locations that are next to each other. In the case study, some city blocks could not benefit from the service from gathering areas, although these city blocks have been located are in the 200 meters influence area of gathering areas, due to the fulfilling the capacity of the gathering areas. On the other hand, although some gathering areas have the capacity to provide service for the more population, they could not provide any service to the city blocks due to fact that they are not located are not in the 200 meters influence area of gathering areas. As a result, in the analyzing the sufficiency

of the gathering areas, there are two important criteria's so that the cross correlation of these two variables could be seen.

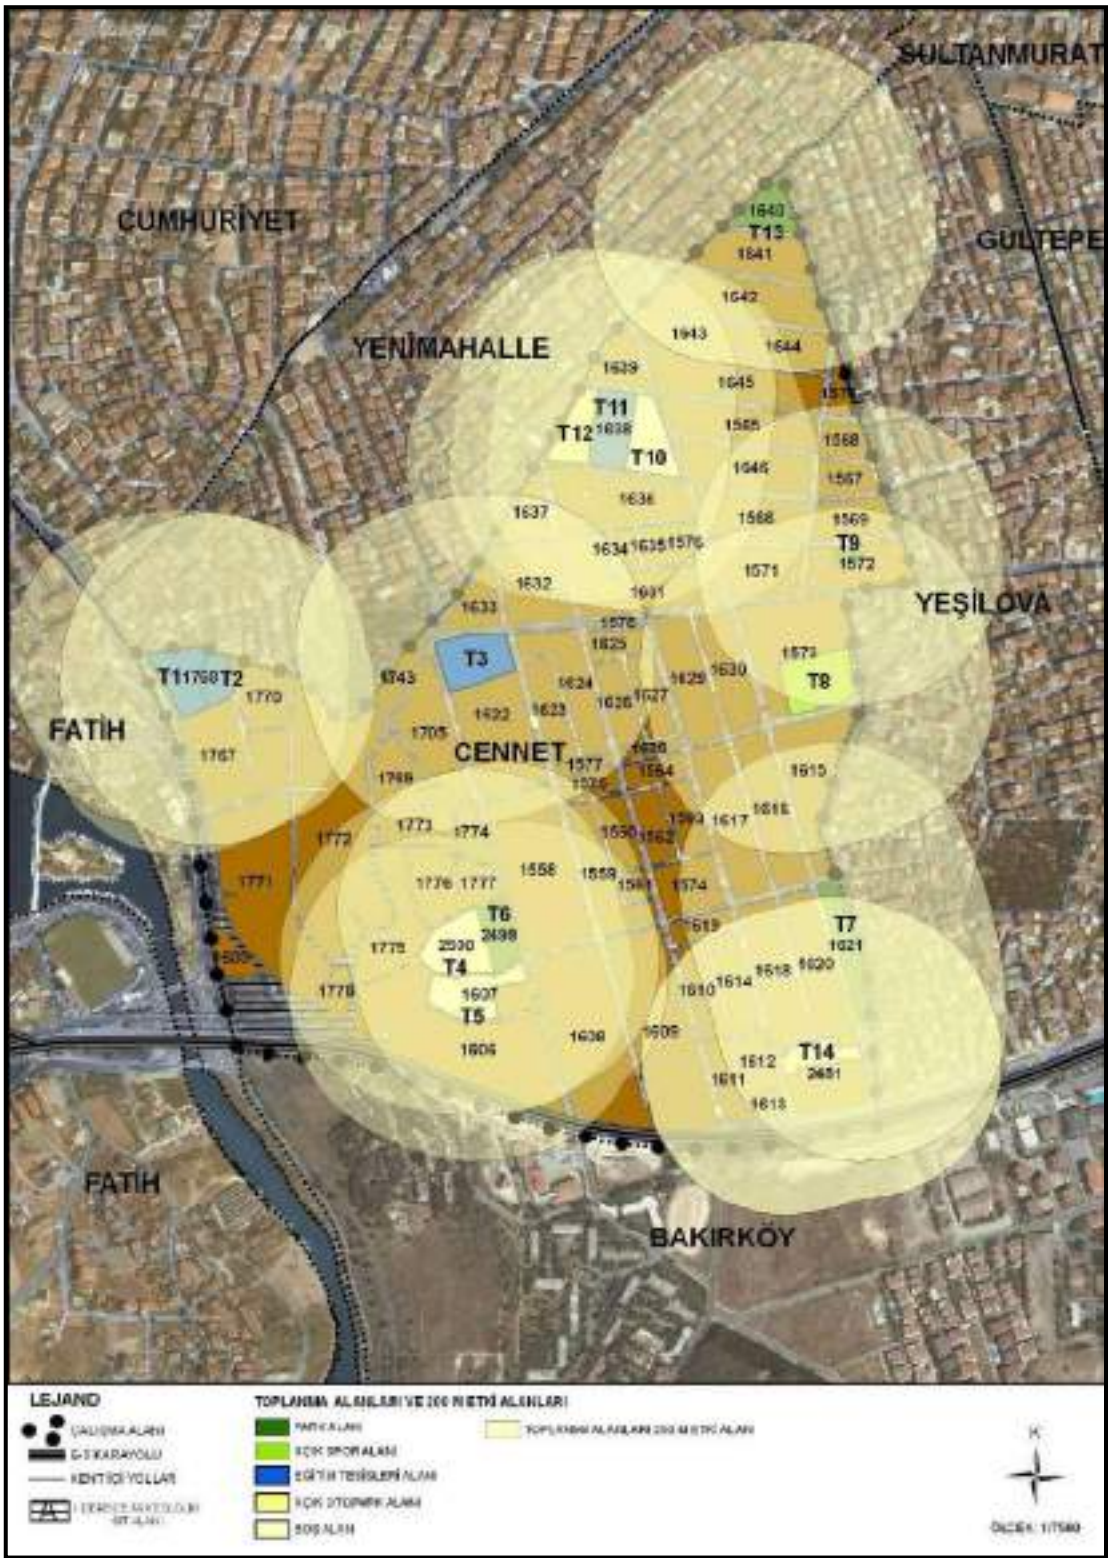

Figure 4. 200 Meter Influence Area Of Gathering Areas

Table 4. Gathering Area Information

Area no	Name of the Area	Function of the Area	Et Total parcel area	Eu Total Building Area	Ex Total Open Area	Ct Capacity	Risk Status	Served Population amount	Served city blocks

T14	Empty Space	Empty Space	3385	51	3334	2222	A	1751	1610-1611-1612-1613 2481

As a result of analysis for entire population in Cennet district, there is not any sufficient urban open and green areas that will be used for gathering/sheltering purpose after the earthquake. The city blocks that do not have any meeting areas and their population could be seen in Table 6 and Figure 5. It can be said that 19 city blocks and 9016 will not be able to use any gathering areas.

1567	220
1569	411
1609	2597

Figure 5. City blocks that do not have any gathering areas

6. Results And General Assessment

Because of sudden occurrence of the earthquakes, the panic could be experienced mostly after the earthquake and immediately after the earthquake, people generally could not decide on what they should do in the short time. It is essential that the towns should be prepared for the earthquakes.

The urban open and green areas that have very important functions such as ecological, recreational, economic and social functions have been acted as key elements to continue for vital activities after the earthquake. In case of possible earthquake, urban open and green areas could be evacuation areas. After the earthquake, people whose homes have been damaged and could not go back their homes because of earthquake risk have been sheltered in such kind of areas until the problem will have been solved. After the earthquake occurred, the several problems occurred in the gathering/sheltering areas and particularly in Turkey where such kind of places are not sufficient, it has been seen that any planning activities has not been carried out before earthquake.

For this reason, urban open and green areas that have been used as gathering points, temporary sheltering and tent areas should be handled to prepare for the earthquakes and to mitigate the earthquake losses and must be planned systematically in case of earthquake. When the earthquake occurs, these areas must be ready in accordance with the number of population. The qualification and numbers of these areas should be analyzed if these are sufficient or not in case of disaster.

As a result of defining the gathering areas to be used after the earthquake in Cennet neighborhood and analyzing its sufficiency, it could be seen that the urban open and green areas that are insufficient to cover the needs of the affected population will be insufficient in case of the earthquake indeed. In order to make urban open and green areas ready after the earthquake, the more reconstruction activities must be allowed accordingly.

The temporary gathering and tent areas have been defined as gathering areas must be reorganized. In order to provide livelihood and to cover the needs of food, water, sheltering etc., the storing areas and infrastructure systems should be established. The park areas should be organized to transform into the earthquake park after the extraordinary situations.

The evacuation corridors must be organized in case of possible earthquake to be used for life supports and open in each time for the access. The Evacuation corridors must provide access to the gathering areas and the access between the gathering areas and city blocks accordingly.

The temporary settlement areas and tent towns have been handled in the city scale and associated with the neighbor regions as well as assessed in the town integrity. In the short term gathering points/areas, in the middle term temporary settlement areas

and tent locations must be defined previously and their sufficiency's must be measured.

In the regions where the gathering places are not sufficient, the urban open and green areas must be produced to be benefited from entire population and to raise the life conditions in the towns. First, by determining the urban open and green areas that have proposed in the master plans, which have not been applied, the relevant actions must be taken for these green areas. In addition, taking into the consideration of possible earthquake risk in the new the plans, and these new plans must be integrated with disaster plans.

Active functions must be added to such kind of areas defined before the earthquake occurred in the daily life and the relevant infrastructure should be provided to be used after the earthquake. On the other hand, these areas must be announced to the local people before the earthquake and the information must be conveyed to the people to find these places easily during the earthquake.

Acknowledgements

I would like to thank to Prof. Ayşe Sema Kubat and Project team of Ordinary / Emergency – UTITU Workshop on Galata (2008) that they share workshop results with me.

The Power that Influence Cirebon's Urban Form and Urban Process
Case Study: Cirebon, West Java, Indonesia

Ira Irawati[1]

Abstract

Urban process through the time indicates the influence of process of city-making by some power through legal and economic history (Kostof, 1991). Cirebon as a coastal area in North Java had unique historical phase that shaped by the power of the legitimate authority for 532 years. Begin from a small vilage, Lemahwungkuk, that built based on Moslem culture, Cirebon became a traditional moslem-based monarchy or *Kesultanan.* Furthermore, the power breakdown of tradional monarchy changed by Colonial government, had reshaped Cirebon as a unique city feature that can be seen in the mix of urban character between traditional (monarchy) and colonial city artefacts.

This paper would explore physical evolution of the city that could be reflected by the history of spatial urban shape and structure from Kasultanan or pra-colonial and early-colonial era, colonial era, and pasca-colonial era. Moreover, using urban physical element clasification from Kevin Lynch (1982) and diachronic historical method (Kuntowijoyo, 2003), identification of the shape and structure of the city was constructed. Through identification of Lynch (1982) elements which are paths, edges, districts, nodes, and landmarks through the three eras, urban process had been formed Cirebon as fan shaped cities, expanded from the grid pattern of the urban path in the pra-colonial and early colonial era to radial pattern in the colonial era. At last, in the pasca-colonial era, the mix of grid and radial pattern has been a combination archetype due to the changing of city transportation infrastructure from river and sea orientation to road and railway orientation.

The Cirebon's urban structure alteration itself has been change from concentric in the pra-colonial era, where Keraton as the palace of monarchy building was the center of the city, to multiple-nuclei in the colonial era that last until today, where Keraton is not the main orientation of the city; but city hall, main mosque, and some retail area also as city's point of references. Although this monarchy city could shape the cosmic city in the beginning, due to existence social hierarchy which refer to Kostof (1991) as a model cosmic city, Cirebon with moslem's culture and economic orientation had shaped the practical city. The reason for this is the monarchy that shape the city only has cosmic city model in limited Kesultanan area; and, the rest of the city had functional construct of interrelated parts to support economic activities.

Key words: *Urban shape, urban structure, planning history.*

[1] Institut Teknologi Nasional, Bandung, West Java, Indonesia

1. Introduction

City is manifest of human activities that change by the time. Some factors that support that development are human itself, activities of human, and network and movement among some centre of activities (Sujarto, 1990). The motive of the people and the authority that lead the city will give a power to shape the city. Political power will always exist through the time. However, people power as part of participation of stakeholder in urban development will justify the political power in the precise portion. This mixture of power will be sharpened the city shape in different way for various places.

Cirebon as one important city in the West Java Province has been passing the transformation of city pattern and city authority. Begin with small village, to Islamic monarchy; and then, the colonial city, all changes had brought significantt footstep in Cirebon's pattern and culture. Finally, how the post-modern city nowadays adapt to those changes with different motive, power, and obstacles will be part of Cirebon's history.

Trough identification of physical elements of the city (Lynch, 1991), urban structure and shape that formed could be traced. Moreover, who and how this transformation done is very important to identify as lesson learn for city planner and other stakeholder to plan and fill the city with activities.

Figure 1. Cirebon Orientation in West Java and Banten Province

2. Analysis and Result

2.1 Urban Growth Periods

Diachronic approach used on this paper has an objective to capture social structure and function of society and activities in the time-frame or time stages (Kuntowijoyo, 2003). Thus, Cirebon's development phases could be analyzed by the time when the power or even political power had formed the city.

Kostof (1991) simply categorized the cities by three kinds which two of them are clasified to time periods. Furthermore, these consideration could identify the land use, activities, and social structure that belong on it which are *pre-industrial* city and *industrial* city. First, *Pre-industrial* city as a city with relative-small size and also small population, whose only two groups of inhabitants which are an elite and a lower class. In the centre of the city is for government, religion facilities, and residences of the elite; with no specific land use classification. Second, on the other hand, industrial city has more segregation uses of land, based on rent of the land property.

Categorization of the city in Indonesia itself, stated by Sujarto (1990) on four genetic time stratification for urban development in Indonesia, which are:

1. Pre-colonial era (before colonial),
   In the early of this era, cities were influenced by Hindu religion; and later on, Islam unified them until 1400. The identity of this era from both cultures was the mixture of monarchy urban structure with mosque's orientation. Furthermore, while early-colonial government had strengthened the commercial area in the harbour and its nearby area; China's trading company had influence especially in the exclusive settlement and commercial centre architect which also commonly placed in the harbour area.
2. Early-colonial era
   In this era, cities had grown in the VOC (Netherland's Commercial Company) who had built wall not only for a fortress in the city as a prevention tool from other colonial countries and Islam's influence; but also to expand the trading area and occupation of the land.
3. Colonial era
   This era begin in the early 19 century when VOC governed Indonesia as "Bataafschen Republiek". As well as industrial revolution was happened in Europe, colonial government applied "Cultuurstelsel" which had shaped Indonesian cities as centre of plantation production such as rubber and tea and centre of collection and distribution for that products.
4. After-industrial revolution era
   Indonesian cities in the late 19 century were called as Indonesian Modern Cities. These cities had grown and developed based on modern cities planning concept which had been fully fledged in West-European countries; and also as reaction of degradation that resulted by industrial revolution.

Cirebon growth age itself in this research devide in three stages that first and second era in the periods above is combined in one stage which are:

1. Pre-colonial until early-colonial era (1479 – 1906)
   In this era traditional city was grown; and in 1479 Cirebon Monarchy (Kesultanan Cirebon) was established. Later on, in 1677, VOC that was existed in Cirebon acted as guardian for this Kesultanan.
2. Colonial modern era (1906-1945)

In 1906 Kesultanan Cirebon had no *de jure* power to the region due Dutch Government as Colonial had taken over the authority; and change Cirebon name to *Gementee Cheirebon*

3. After-colonial era (1945-now)
   This era begin with Indonesia's independence as well as new development of Indonesian modern cities.

2.2 Urban Shape and Urban Structure Elements

Physical elements of the city are the city shaping component, like social and economic, which could be seen as clear as can seen. These constituents had explained by Lynch (1982) as part of city image, Branch (1995) and Shirvani (1985) as aspects that develop the city. In this paper, Lynch's elements are used for identify Cirebon's pattern and shape, due to availability of historical data. However, although Lynch's used as primary aspect; but, others elements from Shirvani and Branch also support the detail as can seen at Table 1.

Urban shape and urban structure itself generally called urban pattern or just urban form. According to Kostof (1991), there are three urban form that modelled by Kevin Lynch in the Good City Form book (1981) called as "normative models". First is *cosmic model*, or holy city, as construal of the universe and gods as expression of power. Monumental axis, gates to protect, major landmark, regular grid, and spatial structure by hierarchy are the characteritics. Second, *the practical model*, or the city as machine, where space are divided on differentiated functional cluster which are small, autonomous; although, every parts are undifferentiated; but there are linked up as a one huge machine. The last, *the organic model*, or the biological city, city is similar to living thing which has a specific border and an optimum size, a unified, indivisible internal structure.

Furthermore, in this paper, the basic urban forms divided in the two type urban forms which are *urban shape* and *urban structure*. *Urban shape* is physical pattern of built environment that take place based on transport network especially street, land carrying capacity, a spread of natural resources, and government policy. Additionally, urban shape has several types which are the square cities, retangular cities, fan shaped cities, rounded cities, ribbon shaped cities, star shaped cities, and grid cities (Yunus, 2000). Moreover, Kostof (1991) defined some shape for the political diagram in linear system where axis alignment exist as urban diagram that link the authority buildings. Next is centralized systems, concentric (relative-circle) and radial organization (combination of concentric and street arrangement connect the centre).

Urban structure is a pattern of activities and land use which are created by like the urban shape; but with one additional aspect which is functional relation between activities and land use. Moreover, types of urban structure (Yunus, 2005) imply by Burgess in 1924 is *concentric model* where CBD in the central, continued in the next-larger circle by commercial and light-manufacturing area, then by low-class

settlement, then by middle-class settlement, and finally in the outer ring is for high-class settlement. Another type is *sectoral model* designed by Hoyt in 1939 where CBD still in the centre, however other functions spread outward the centre in certain axis. The last type is multiple-nuclei model designed by Ulman-Harris in 1945 which could accomodate high growth urban activities, population, and size where severeal city centre and some groups of other functional areas. Later on, this two urban form will be identified by Lynch's elements on the three Cirebon's time phase as follow.

Table 1. Physical Elements For Indentify Cirebon's Form and Shape

Primary Elements (Lynch)	**Supporting Elements**		**Urban Shape**	**Urban Structure**
	Branch	**Sirvani**		
District	Open space, vegetation, density	Landuse, open space, activities		•**
Path	Topography, park, pedestrian, and street furniture	Circulation and parks, pedestrian	•*	•**
Landmark	Building	Building shape and mass	•	
Edges	Edges		•*	•
Nodes	Density			•

Notes: Path* = primary transport network that generate urban built environment
Edges* = linear or curve-linear shape as border beetween built environment and non-built environment
Path** = streets or primary transport network that connected city main activities
District** = domination function or activities of land use

2.3 Cirebon Structure and Shape Evolution

A. Pre-Colonial and Early-Colonial Era (1979-1906)

In the early-city development, the city ancestor would adjusted their settlement to condition of topography such as riverine settlement, natural port, linear rim, hilltop town, and sloped landscape (Kostof, 1991). This condition also came about in

Cirebon, with sloped land on the bay, early dweller started built small village on the harbour area called Muara Jati and subsequently grown as small city called Nagari Singapura (Kusuma, 2010). In this time there were two power that created activities and settlement, first was *religion power*, Hindu and Budha and then Islam as guidance for social and religious activities, and second was *economic power* which had extended the harbor function as a gate for trading to other Nusantara region (Indonesia name before independence). However, due to limited data, this small city had no specific urban settlement structure and shape precisely.

Afterwards, as well as the growth of Islam in this area, the enlargement of population had moved settlement to Lemahwungkuk, 5 km to the south; and then Kesultanan Cirebon, Keraton Kasepuhan, as local monarchy established at 1479 based on Islam philosophy. The combination of traditional and religion culture, as happened in other Javanese monarchies or keraton has resulted specific civic centre design that still last until this post-modern era. In addition, this civic centre has some components park or alun-alun in the middle encircle by keraton building on the south heading the alun-alun, mosque in the west, social or commercial or building on the east and the north (Sunardjo, 1983). Moreover, this arrangement show the hollines concept of Islam or cosmic model that expressed the universe and gods as expression of power (Kostof, 1991). This pattern expressed multiple function of city centre especially civic centre for administrative and civic, economic, social, cultural, and even defence (Poerbo on Kunto, 1986).

Dutch colonial company VOC, in the beginning, in 1677, acted like guardian for the kesultanan due an advance war equipment, later acted as colonial government and attained full power for economic with built *De Bescherming* castle as military defence for Cirebon and also as the centre of the authority (Sunardjo, 1983), kesultanan Cirebon itself acted as symbol for local authority and local community. Along with the growth of trading activities, Chinesse trader came and built settlement, and made successful acculturation which proven by ceramic ornament on the kesultanan dan mosque buildings (Irawati, 1996). In this time, VOC was not change the inner-structure of the city. However, the existence of the VOC bastion in Cirebon was a part of trading stations along north-sea Java in Tegal, Semarang, Jepara, and Surabaya (Margana, 2010).

The urban shape of Cirebon in this era characterized by elements that formed *fan-shape type* (modified from Kusuma (2010)):

a. Landmarks: Keraton Kasepuhan as the centre of the city
b. Paths:
    - Internal: river pathway around the keraton area, street in grid pattern that arranged the city centre (keraton, commercial area, port, and settlements)
    - External: linear street along the sea bay on the east that connect Jakarta (Batavia) and the north part of Cirebon with East Java, curve-linear street from the west to east Java that join in the linear street mention before, and linear street from the city centre to the Bandung on the West of Java
c. Edges: Java Sea on the east, some river on the west, south, and north.

Figure 2. Cirebon's Fan-Shape Model in the Pre-Colonial and Early-Colonial Era

However, the urban structure in this phase created a *concentric type*, although the centre not in the middle of the city but in the right-part near to the sea which characterized by (modified from Kusuma (2010)):

a. Paths and edges: same as above
b. Nodes: Muarajati Port, *De Bescherming* castle, industrial cluster for pottery products, markets in Kanoman and Jagasatru.
c. District: city centre consist of keraton, commercial centre, warehouse and port, outer ring was settlement district for Chinese, Arabic, and European, the outest ring was settlement for local community.

Figure 3. Cirebon's Concentric Structure Model in the Pre-Colonial and Early-Colonial Era

Both Cirebon's shape and structure built up firstly by the power of politics, colonial for the external connection and Kesultanan Cirebon for the internal network, secondly by the power of economic especially for colonial trading activities.

B. Colonial Era (1906-1945)

This colonial era also called modern-colonial era, modern-colonial era in world-war II era, and independence war era which has function and motive or power to develop (Sujarto, 1990). Cirebon, like other colonial area in Nusantara, has function as centre of government authority, centre of military activities, centre of plantation and mining administration, and centre of port and commercial facilities. Obviously, the motive or power of Cirebon spreading out was politic and economic similar to previous era.

After a kesultanan authority's break up on three kesultanans which are Kasepuhan and Kanoman (1677), and Kacirebonan (1803) that had made powerless traditional monarchy, Dutch Colonial Government got more strong dominance on Cirebon. Furthermore, the legal authority of Kesultanan Cirebon was removed with *Gemantee Cheirebon* statement (Cirebon City) which covered 1.100 hectare area and 2,000 populations (Stlb. 1906 No. 122 dan Stlb. 1926 no. 370) (Sunarjo, 1983).

In addition, colonial government constructed several facilities and infrastructure to support the colonial function for centre of mining, plantation, and trading such as warehouse, tobacco processing company, central bank, post office, and church. For the accessibility of the plantation product distribution from its hinterland (Cirebon, Kuningan, and Indramayu) they developed railway (Kusuma, 2010).

The urban shape of Cirebon in this era still formed *fan-shape type* with more large area and especially to the north and east (port extension); and *a change of grid pattern of internal city centre to radial* (modified from Kusuma (2010)) which charaterized by:

a. Landmarks: Keraton Kasepuhan as the centre of the city, and city hall for colonial government administration.
b. Paths:
    - Internal: river pathway around the keraton area, street in grid pattern that arranged the city centre (keraton, commercial area, port, and settlements)
    - External: extended linear street along the sea bay on the east that connect Anyer and Panarukan via Cirebon as part of Daendels post network transportation, linear street from the city centre to the Bandung on the West of Java, and linear street from the city centre to Kuningan.
c. Edges: Java Sea on the east, two rivers on the south and north, and flood canal on the west.

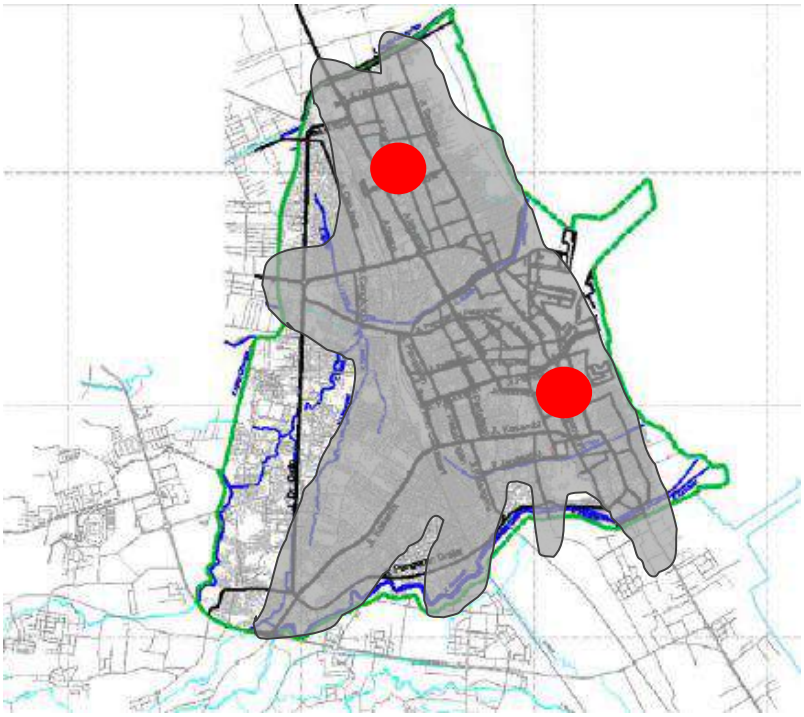

Figure 4. Cirebon's Fan-Shape Model in the Colonial Era

Cirebon's urban structure in this stage was a *multiple-nuclei type*, which characterized by (modified from Kusuma (2010)):

a. Paths and edges: same as above
b. Nodes: Muarajati Port, *De Bescherming* castle, Kanoman and Pasar Pagi market place, two main railway stations.
c. District: i) inner city district where there are several important building such as city hall of colonial government administration, social meeting building, hotel, main park, pendopo for local officer administration, ii) sport and reacreation centre, iii) central bussiness district (consist of tobacco processing company, central bank, post office, and church) and port, iv) settlement districts, v) retail distict, vi) port and warehouse district.

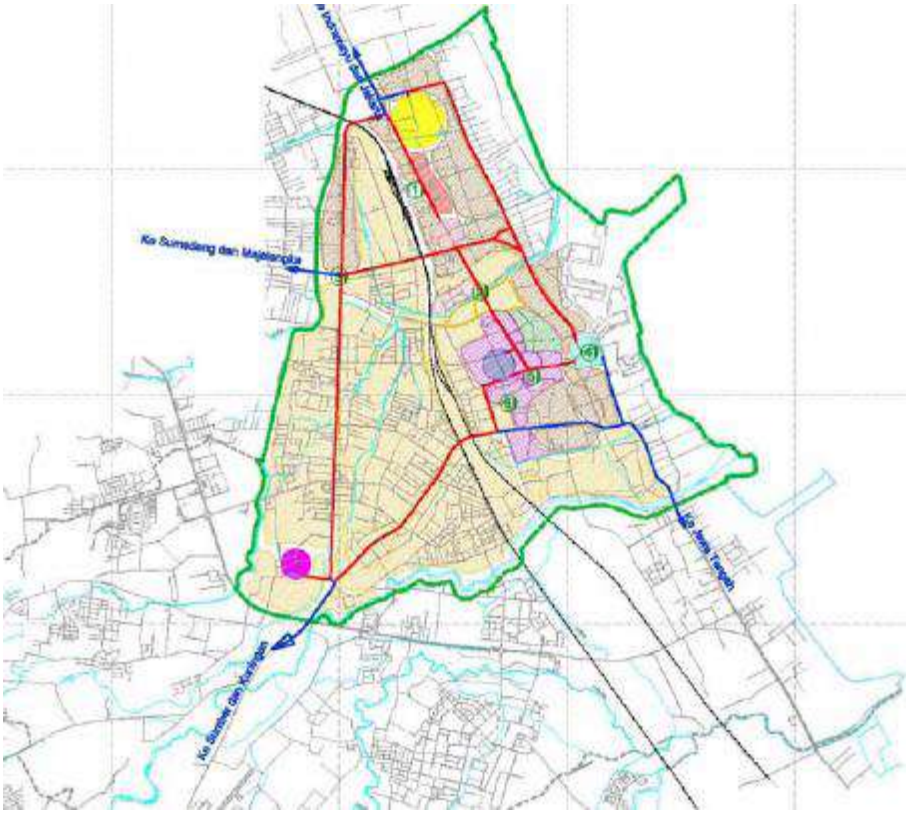

Figure 5. Cirebon's Multiple-Nuclei Structure Model in the Colonial Era

In this era the politic power for economic reason of colonial government had strong influence in both Cirebon's shape and structure, tradional monarchy and religion power has been removed. A change of colonial government to Japan was not change the urban pattern.

C. After-colonial era (1945-now)

Cirebon enter modern and post-modern era which start from independence of Indonesia from colonial government (from Japan). From independence until 1960's Indonesian government faced instability of social, economic, and political condition; and, in the same time urbanisation which is growing population moved in from rural area to the cities (Sujarto, 1990). In addition, cities confronted with a lack of city management, resources, appropriate law and policy, effective city planning, and segregation of urban growth. This also happened to Cirebon. In 1957 Cirebon declared as municipal with 3,300 hectare and more extended to 3,600 hectare.

Nowadays, Cirebon is centre for national activity with leading sectors such as industri, fishery, agriculture, and mining. Furtermore, Cirebon also stated as orientation centre for its hinterland: Indramayu, Palimanan, Jatibarang, Sumber, Majalengka, Kuningan, and Ciledug (Kusuma, 2010). In this post-modern city, not like in the colonial era which the goverment had great power to set up the city and

community had formidable power to do their activities, the transpose condition happened with a broader public control on private property and how government should set regulation to compromise the private property right with the process of urban facilities development (Levy, 2009). Consequenly, with the lack of city planning vision, Cirebon driven by market such as malls development and retail area that spread all over the city as products of post-modern era. However, some memories of colonial planning survived and emergent in modern forms (Ward, 2002) which appear in Cirebon on the preservation of old central business district and some government building style.

Those transformation create rencently *extended fan-shape type*); and a mixture of *grid pattern of internal city centre and radial* (modified from Kusuma (2010))
that characterized by:

a. Landmarks: city hall as city centre, grand mousque, Keraton Kasepuhan, mall
b. Paths:
    - Internal: primary street that connect government buildings area, connect city center with sport and recreation centre, and connect city centre with hospital.
    - External: extended linear street along the sea bay on the east that Jakarta with East Java, west outer ring road to connect Bandung and Indramayu, south outer ring road to connect city to central Java, and linear street from the city centre to Kuningan.
c. Edges: Java Sea on the east, one river on the north, and Cirebon Residence on the south and west.

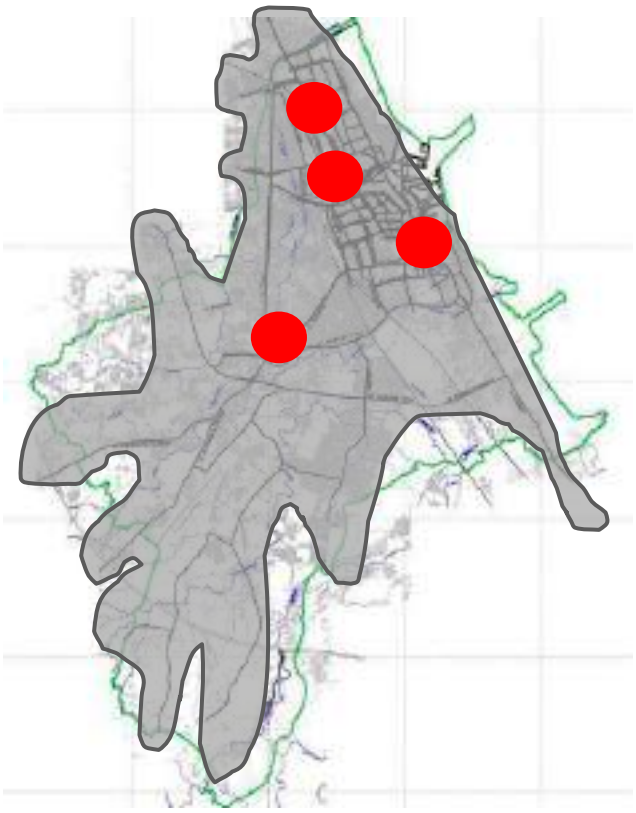

Figure 6. Cirebon's Fan-Shape Model in the After-Colonial Era

Cirebon's urban structure in this stage was a *multiple-nuclei type*, which characterized by (modified from Kusuma (2010)):

a. Paths and edges: same as above
b. Nodes: Muarajati Port, some market places, two main railway stations, bus terminal, local transport terminal.
c. District: government administration district, commercial district, settlement (spread all over the city), centre of education facilities district, industrial district, and health facility district.

However, the port and warehouse in this era are not exist anymore due low of sea level on the bay area.

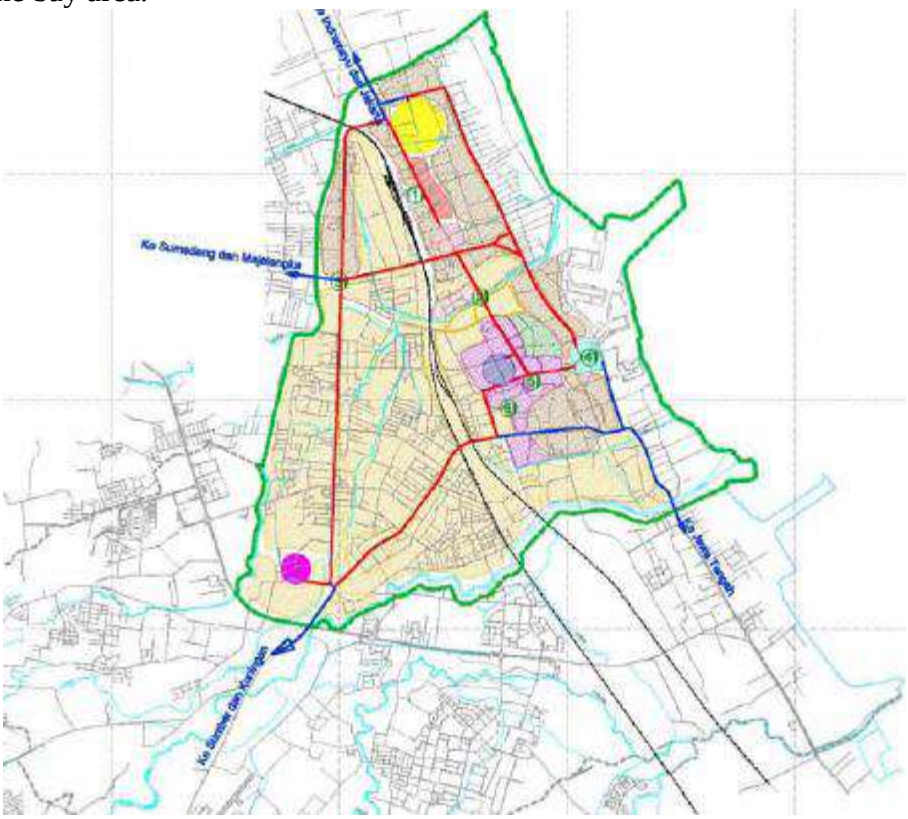

Figure 7. Cirebon's Multiple-Nuclei Structure Model in the After-Colonial Era

Those transformation although still came out from political government power, but market or economic power and community power had been shape Cirebon right now.

3. Conclusion

Cirebon urban evalution has been change in two different city model from the small religion city and tranditional local monarchy as cosmic model to practical model which is commercial and other functional land use composed the city. The reason of

this tranformation is the changing power that govern and influence the city, first Cirebon's pattern shapping by the power of local authority as religious-monarchy power. Second, with the changing of authority to Dutch colonial government political power as well as economic power change the city pattern. Finnaly, in the indepence and postmodern era, again political power of municipal government marks the city shape side by side with market or economic power and community power to private property. Furthermore, nowadays, kesultanan just as symbol of the past without any power to shape the city.

Although the power through three time has been change, howerver, the limitation, geoposition, and natural landscape and disaster of Cirebon could not be avoided. The natural force that has been made the bay steeper make the port function as the most important hub to collected and distributed Cirebon and its hinterlands products denied. Consequently, some industrial centre and warehouse changes to retail and commercial area. However, learn from the history will always beneficial for Cirebon to step forward as sustainable city in its own power.

Socioeconomic Changes and Suburban Housing Forms in the Bangkok Metropolitan Region of Thailand under the Globalizing Economy

Shigeru Fukushima[1]

Abstract

Rapidly expanding metropolitan areas of Bangkok are frontiers of industrialization and housing. This study aims to analyze suburban housing forms and their socio-economic characteristics of the Bangkok Metropolitan Region (BMR), an area that is transforming into a modern society, with integration into the global economic system. I have attempted to understand the housing forms of the BMR from a socio-economic perspective, using the conceptual framework "integration into the global economy — industrialization and changes in employment and household economy—land and house markets / housing policies / urban development — housing forms." The questionnaire survey targeted married families was conducted to clarify the socio-economic attributes of the households and their housing forms in the Eastern Development Corridor (Samutprakarn) and Northern Development Corridor (Pathumthani) of the BMR. A total of 324 sets of valid responses were obtained.

The housing markets of the BMR has been transforming rapidly. Overall housing forms of the BMR has been formalizing and improving in the national economic growth and the modernization of urban society. However, for every generation, there was a large income gap, with a ratio of 1.8 to 3.3 times between different levels of educational groups. This gap in economic strength resulted in a housing disparity in terms of housing ownership, the quality of housing and living environments, and the formality of housing, since in Thailand there is little government intervention in the

housing market. In the BMR, the following four factors worked to inhibit the gap in income from leading directly to a housing disparity: (1) easy access to housing loans by provided by the GHB and private financial institutions, (2) an affordable rental housing market, (3) purchase timing, and (4) the government housing programs such as the BUA program and the BM program.

1. Introduction

[1] Meijo University, Kani GiFu, Japan – fukusima@urban.meijo-u.ac.jp

Based on its outward-oriented economic policy, Thailand has incorporated capital and technology from the outside through direct foreign investments to achieve rapid modernization in industry, a process often referred to as "compressed industrialization." What socio-economic changes did the industrialization and economic development of Thailand produce in different generations and social strata under the global economic system, and what housing opportunities did they provide? Rapidly expanding metropolitan areas in ASEAN countries are frontiers of industrialization and housing. This study aims to analyze suburban housing forms and their socio-economic characteristics in the Bangkok Metropolitan Region (BMR), an area that is transforming into a modern society as a product of the global economic system.

This study is an extension of the ongoing research into global cities, the aim of which has been to analyze changes and the reorganization of spaces in urban societies under the global economic system (Friedmann, 1986; Sassen, 1994; McGee, 1991; Scott, 2001, etc.), but this study focuses on changes in housing forms in an Asian newly industrial society, in particular the BMR, Thailand. I have attempted to understand the housing forms of the BMR from a socio-economic perspective, using the conceptual framework "integration into the global economy — industrialization and changes in employment and household economy—land and house markets / housing policies / urban development — residential forms." Fukushima et al (1996) examined the changes in suburban housing forms in the BMR under rapid industrialization and globalization based on their field survey conducted in 1995, which corresponds to the early stage of the industrialization process. Fukushima (2000, 2001) evaluated the impact of the Asian financial crisis on suburban housing forms, in particular on the fluctuation in housing ownership. This study functions as a kind of follow-up to these past studies.

2. Analytical Framework and Main Surveys

Economic growth, development, and industrialization have had particular influences on different generations and social groups, resulting in varied occupation structures and economic conditions. Different generations and social classes have had varied housing options at the time of settlement and also during successive eras, along with distinct economic conditions. These varied options, together with housing preferences, have created diverse housing demands and conditions. Thus, it is clear that industrialization and rapid economic development have influenced the housing forms of different generations and social groups. (Figure 1)

In this study, I will categorize sample households based on the generations and educational level of the family heads. The heads of the households are classified into three generational groups: those in their forties who entered the labor market in the 1980s when Thai society and its economy were at a turning point, those in their twenties and thirties who entered the labor market during years of drastic change, i.e. during the booming economy, Asian financial crisis and recovery from that crisis, and those in their fifties or older who entered the labor market when the economy was that of a developing country. In Thai society, educational background is a primary factor that determines the social stratum to which one belongs. I will distinguish three educational categories, and regard respondents with a primary-school-level education or lower as the "low education group (LEG)," those who graduated from junior or senior high school or vocational schools as the "medium education group (MEG)," and those with two-year college, technical college, or university level education or higher as the "high education group (HEG)." Sample households are therefore classified into nine groups, since each of three generational groups are each split up into three educational background groups. Based on this nine-group classification, the characteristics and mechanisms of formation of each housing form were analyzed.

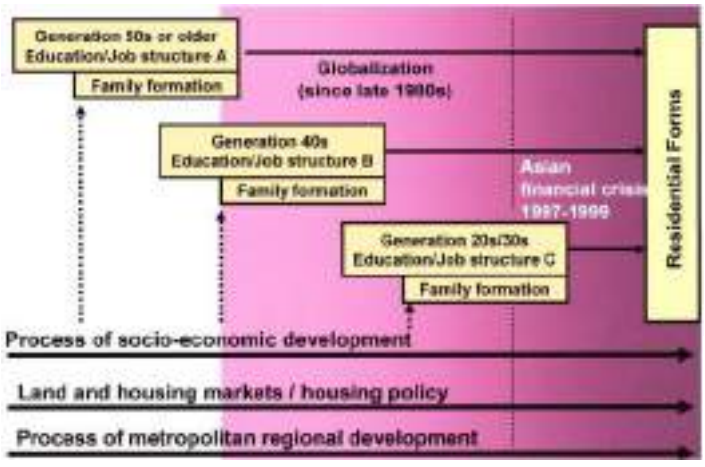

Figure 1.
Analytical framework: Suburban residential forms in development process

The questionnaire survey targeted married families living in the suburban areas of the BMR was conducted to gain the data of socio-economic attributes of the residents and their housing forms, by visiting each household in January 2005. A total of 324 sets of valid responses were obtained. The BMR consists of the Bangkok Metropolitan Administration (BMA) and five surrounding provinces, including Nonthaburi, Pathumthani, Samutprakarn, Samut Sakhon, and Nakhon Pathom. In this study, the Eastern Development Corridor (Samutprakarn) and Northern Development Corridor (Pathumthani) were selected as the areas to be surveyed. The Eastern Development Corridor is expanding from Bangkok to the east coast industrial area, and the Northern Development Corridor is expanding northward from Bangkok to the central development area, such as Ayutthaya and Saraburi. In conducting these questionnaire surveys, sampling was carried out using the point sampling method.

3. Developments and Housing Market Trends of the BMR

3.1 Socio-economic Developments and Changes in the Housing Markets in BMR

Industrialization has accelerated since the late 1980s in the BMR as direct investment increased rapidly, and the economic growth caused the employment structure and labor market to undergo changes. The BMR became a very important node linking the global economy and the national economy. The city center of Bangkok accumulated the functions for financial, business and commercial center, while the development of many manufacturing, housing, and retail facilities took place in the nearby provinces (Tasaka, 1998). Although the Asian financial crisis of 1997-1999 affected the Thai economy and society very seriously, the Thai economy was able to recover by promoting export-oriented industries with the depreciation of Thai bahts and continuous inward foreign direct investments. The GDP per capita which had fallen by 1,827 dollars in 1998 recovered to the same level as just before the crisis in 2006, and reached 4,984 dollars in 2010. The population of the BMR has expanded from 7,537,700 for the BMA and 3 vicinity provinces in 1988 to 10,326,100 for the BMA and 5 vicinity provinces in 2010 due to the economic development of the BMR. Young workers continued to form households, creating a demand for housing.

The housing markets in the BMR have been changing in association with these

economic development circumstances. The housing market trends of the BMR can be described as follows: (1) a dual structure of housing delivery with formal and informal housing before the mid-1980s, (2) the housing boom from 1990 to 1996, (3) the deadlock in the housing supply from 1998 to 2002 after the Asian financial crisis, (4) recovery and stable housing developments since 2003. Since the late 1980s, the commercialization and formalization of housing delivery have progressed. Private

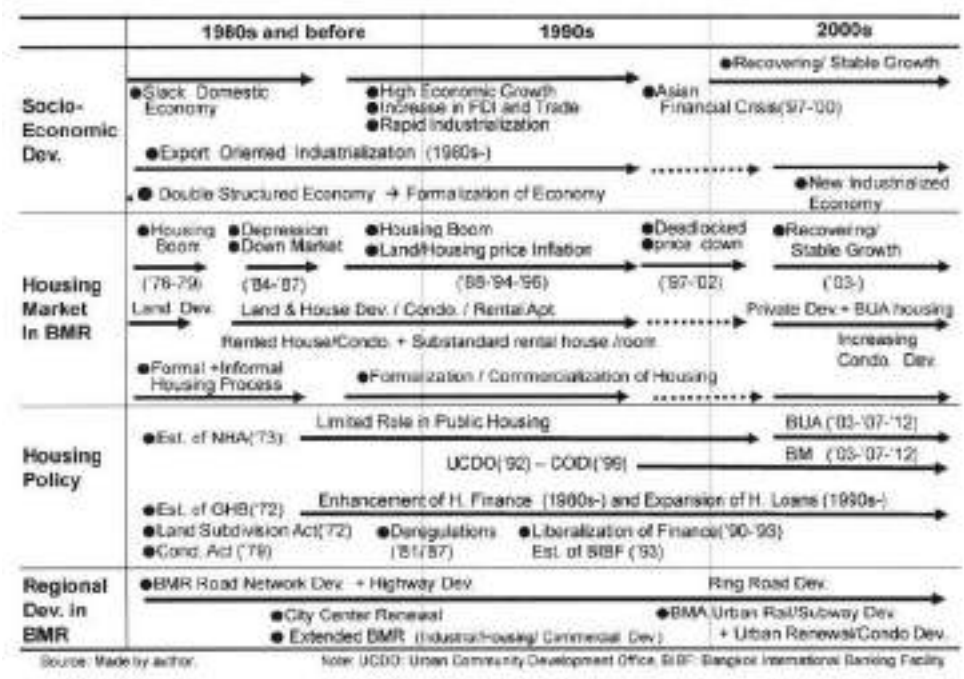

Figure 2. Development Process and Housing Market in BMR

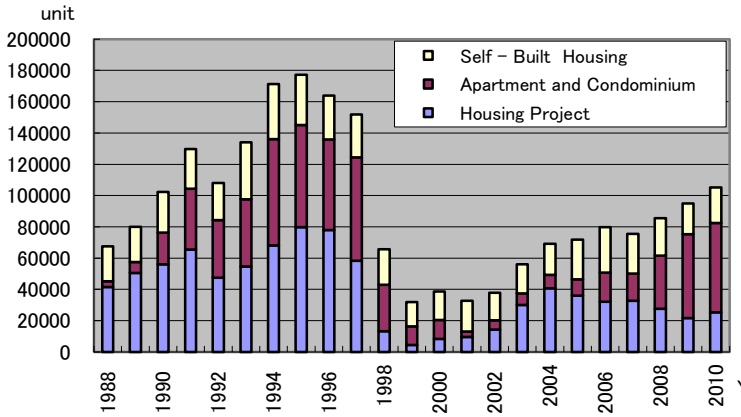

Figure 3.
Housing Supply Trends in BMR

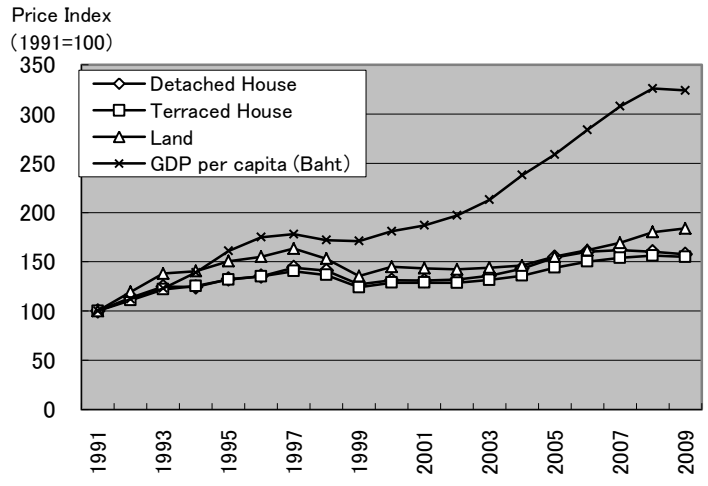

Figure 4.
Housing Price Trends in BMR
Made by author based on data of REIC

housing developers responded to the increased housing demand in the BMR very actively. During the housing boom, 142,279 housing units were supplied annually on average, among which 113,012 units were developed by developers.

This large supply of housing units was made possible by the lenient regulations on land and housing development and an ample supply of funds through domestic and foreign money markets (Yap and Kirinpanu, 1998). However, this huge housing supply did not develop only in response to the real housing demand, but also to the speculative demand. The inflation trends in housing prices after the late 1980s attracted many speculators and lowered housing affordability for workers in lower income groups. The Government Housing Bank (GHB) reported that the price of land and townhouses in the BMR increased 1.63 and 1.41 times, respectively, during the period from 1991 to 1997 (GHB, 1999).

The financial crisis caused the housing market of the BMR to change completely. Many housing development projects reached deadlock as the supply of funds was discontinued. After the crisis, the number of housing developers dropped drastically, from around 2,000 to only 200 companies (Vanichvatana, 2007). The annual housing supply also dropped to 41,350 units on average from 1998-2002, and most of these were completed units started before the crisis or self-built by the owners. Since 2000, as the Thai economy has recovered, the housing markets of the BMR have followed suit, and the housing supply recovered gradually, from 56,040 units in 2003 to 105,152 units in 2010.

3.2 Characteristics of Thai Housing Policy

Thai housing policies are traditionally characterized by little public intervention. Although the government has been promoting public housing developments through the National Housing Authority (NHA) since 1972, the share of public housing, remained only a few percent of all housing supplied. The government’s stance on housing policy seems to be closer to an enabler that promotes private housing

development through the deregulation of development control, the enhancement of housing finance by the GHB, and community development and improvement of the living environment by the Community Organizations Development Institute (CODI) (Yap, 2002; Yap and De Wander, 2010). In particular, the GHB has increasingly helped to supply housing loans and development financing in, response to the expansion of the housing demand during rapid economic development. Both the expansion of housing finance and the deregulation of the Land Subdivision Control Act in 1981 and 1987 led housing developers to supply lower-priced housing units, opening up segments of the market for the lower medium income group (Archer, 1991; Angel and Chuated, 1987).

Under the former Taksin administration, the government started to intervene in the housing market in 2003, although it did so through temporary programs rather than the permanent public housing system. The NHA has conducted the *Baan-Ua-Arthorn* (BUA; "we are concerned with housing" in Thai) program, a home ownership promotion program for low income people. The government provided a subsidy of 80,000 bahts per unit for the BUA program, and the NHA sold the units for 390,000 bahts per unit. The NHA completed construction of 172,107 low-cost housing units in the BMR by 2012 (Kolaka, n.d.), although there are criticisms such as delivering the units to not only low income group (the eligible income level was later relaxed from 15,000 bahts to less than 40,000 bahts). The CODI has conducted the *Baan-Mankong* (BM; "housing security" in Thai) program which supports poor communities in securing land and housing tenures and improving their housing and living environments. The CODI has conducted 282 of the BM projects, which benefitted 35,933 households in BMR by 2010.

4. Housing Options and Housing Forms in the Suburban Areas of the BMR

Based on an analysis of the survey results and the analytical framework mentioned in Section 2, I will examine the housing options and housing forms of the suburban areas in the BMR.

4.1 Housing Options in the Suburban Areas of the BMR[1]

Here I examine the options for housing available in the housing market and public housing delivery to verify how the suburban areas had functioned as a frontier for housing. It should be noted that there were transitional points along the hierarchy of

household income at which one option for housing changed to another. The transitional point between formal and informal housing was in the income range of 5,000 to 10,000 bahts (monthly household income, hereafter referred to as household income). If the household income was less than 5,000 bahts, the available options were squatter housing or a rented room in a slum settlement. There were hardly any households whose household income was less than 5,000 bahts in the BMR, where double incomes were commonplace and even unskilled factory workers could usually earned 5,000 to 7,000 bahts monthly. As income increased to the 5,000 to 10,000 bahts range, formal rental housing became an option. This rental housing, in ascending order of price, included wooden tenements with shared utilities and rented rooms (rent: 1,000 to 1,500 bahts), simple wooden row houses (rent: 1,200 to 1,800 bahts), and apartment houses with utilities (rent: 1,800 to 2,500 bahts). Wooden tenements, rented rooms and wooden row houses were regarded as a kind of substandard rental housing, although these were not like slum and squatter housing. In the 10,000 to 15,000 bahts income range, the percentage of people living in substandard rental housing decreased, with terraced houses, detached houses or condominiums for rental (32%) or apartment houses with utilities or low-cost flats for rental (29%) becoming prominent. As the people in this income range could not afford to purchase a small terraced house that would involve paying the monthly installment of about 5,000 bahts for a housing loan, they opted to rent a terraced house and pay 3,000 to 4,000 bahts for the rent.

There were many terraced houses and condominiums that were bought as investments and then turned over to the rental housing market until their resale time (Pornchokchai and Perera, 2005)[2]. The owner of a rental house made investments in anticipation of a rise in the price, and expected that when it would be sold, the interest payment burden and other investment costs, as well as part of the opportunity cost, would be covered by the rent until a profit could be secured. More importantly, the rent of such an investment property was usually undervalued, as the rent was determined based on its affordability to potential tenants. Thus, this type of rental house helped to improve living conditions for people in the income range of 10,000 to 20,000 bahts.

The income range of 15,000 to 20,000 bahts must be a transitional point between owned and rental housing, as the levels of ownership and rental were comparable. The home ownership rate likewise increased to 67%, 74%, 84% and 91% as household income moved up along the hierarchy of income ranges, i.e. the income

ranges of 20,000 to 30,000 bahts, 30,000 to 50,000 bahts, 50,000 to 70,000 bahts, and more than 70,000 bahts.

There were several options for home ownership for people in the income range 10,000 to 15,000 bahts, such as low-cost flats, BUA housing provided by the NHA, and self-built simple detached houses in spontaneous development sites. Low-cost flats as owner-occupied housing were unpopular due to maintenance problems and to their low quality, while self-built simple detached houses were losing popularity among the younger generations. The number of BUA housing units supplied was still very limited at the time when the survey was conducted. As suggested by the fact that the NHA relaxed the eligible income condition for BUA housing from less than 15,000 bahts to 40,000 bahts, the lower creditability of housing loans for people in this income range made it difficult for them to achieve homeownership.

The owner-occupied low-cost flats were unpopular due to maintenance problems. According to our survey, 92% of low-cost flats were rented, while only 20% of terraced houses were rented.

Table 1 Housing Options of the Suburban BMR (2005)

Household Income [baht]	Ownership		Rental	
	Price range [1000 baht]	Options	Rent range [baht]	Options
50,000 and over	3,000 and over	●Detached house [Upper grade estate]		Prefer to ownership
30,000 - 50,000	1,500 - 3,000	●Terraced house [Upper grade estate] ●Detached house [Ordinary grade estate] ●Shop-house [Local town center]		Prefer to ownership
	800 - 1,200	●Terraced house [Ordinary grade estate]		
20,000 - 30,000	600 - 800	●Small terraced house [Ordinary grade estate] ●Small simple detached H. [Lower grade estate]	5,000-7,000 3,000-4,500	●Shop-house [Local town center] ●Terraced house [Ordinary grade estate]
10,000 - 20,000	200 - 500	●Self-built house [Land subdivision site]		
	300 - 500	●Low cost condo	2,500-3,500	●Rental apartment with better finishing/design
	390	●BUA house (by NHA)		
5,000 - 10,000	-200	●Self-built simple house [Spontaneous dev. Site without infrastructure]	2,000-2,500	●Low Cost Condo
			1,500-2,500	●Factory workers' apartment with utilities
			1,000-2,000	●Wooden row house ●Wooden simple house
			1,000-1500	●Rental room of wooden apt. with shared utilities
Less than 5,000	Less than 50	●Squatter/slum house [Informal settlement]	Less than 1,000	●Rental room [Informal settlement]

4.2 Housing Forms in the Suburban Areas of the BMR by Generation and Level of Education

(1) The Generation in Their Fifties or Older

1) Socioeconomic attributes

In this generation, the majority (76%) belonged to the LEG, while the shares belonging to the MEG and HEG were estimated to be 15% and 8%, respectively, based on the 2000 census. There is a clear tendency for different employment patterns according to the level of education. As of the survey conducted in 2005, 20 to 30% of people in this generation had retired from active life. Therefore, I checked the past occupational status of the heads of households as of 1995. High percentages of the HEG and MEG worked as government employees (33% and 45%, respectively). Other major occupations included managerial/specialist personnel in private companies (33%) for the HEG and self-employed workers (25%) for the MEG. The employment patterns of the LEG in 1995 varied rather widely: other unskilled wage workers (27%), factory workers (18%), self-employed workers (25%), informal workers (14%) and farmers (13%). In 2005, the share of self-employed workers increased to 34% due to people retiring from their original jobs and shifting from agriculture.

Differences in educational background affected household income. The monthly household incomes (median value) of the HEG, MEG and LEG were 27,500 bahts, 23,000 bahts, and 15,000 bahts, respectively. The income disparity of 1.8 times between the HEG and LEG was not very large compared with those of the younger generation. This was because (1) many of the HEG and MEG members were government employees whose salary level was not very high, (2) around 20-30% had already retired, and (3) the LEG included successors to ownership of small-scale businesses.

2) Housing forms

There were considerable differences in housing forms among the different education groups. This housing gap seems to be larger than the level of difference in their incomes due to the accumulation of income over the years, differences in accessibility to housing loans, and differences in the assets and family support available. Ninety-four per cent of the HEG and 71% of the MEG had their own houses, while only 57% of the LEG was able to achieve formal home-ownership (excluding owned houses built on leased lands). With regard to types of housing, 93% of the HEG and 79% of the MEG lived in detached or terraced houses, while 47% of the LEG lived in such housing types and more impressively, 20% of them lived in informal houses such as slum and squatter settlements and 14% lived in simple detached houses or simple wooden row houses in spontaneous development

sites. With respect to public services and local infrastructure, 10 to 15% of the LEG, mainly those living in informal settlements, could not access drainage facilities, garbage collection services, or access roads, although almost 100% had access to water and electricity supply services.

Table 2. Household Attributes and Housing Forms in the Suburban BMR

Age	Level of education	Occupation	Household income (baht/)	Housing ownership rates	Type of housing	Ownership status and housing quality	Room configuration	Purchase price (1,000s of baht)	Average rent (baht/)
Twenties and thirties	LEG	① Self-employment (46%) ② Other types of wage labor (17%) ③ Informal employment (13%)	11,600 12,910 (1.6 persons) Has stable income: 67%	① Rental house (42%) ② Own house (29%) ③ Own informal house (13%) Rented room (13%)	① Terraced house (35%) ② Apartment house, detached house, informal house (13% each)	① Rental - A (30%) ② Ownership- A (26%) ③ Informal (13%) ④ Rental-B (13%)	① 2BR +LR+DK (34%) ② One room (26%) ③ 1BR+LR+DK (13%)	645 581 [1999]	2796

*1: Age, education level, and occupation are those of the head of the household.
*2: The household income at the top is the median value. That at the bottom is the average value. In the household income row, the value shown in parentheses is the average number of income earners per household.
*3: In the type of housing column, * "own house A" includes detached houses, terraced houses and shop-houses; * "own house B" includes simple detached houses and LC-Condos; * "rental house A" includes detached houses, terraced houses, and houses with shops; * "rental house B" includes apartment houses and LC-Condos; and * "rental house C" includes wooden row houses and rented rooms.
*4: In the purchase price row, the value at the top is the median value, the value at the bottom is the average value, and the year shown in brackets is the average year when housing was purchased.
*5: The differences between the categories are significant at 1% level by the analysis of variance.

It could be said that the HEG and MEG were able to enjoy a stable life and better housing conditions. This was not true for the LEG as mentioned above, since the majority of members of this group were self-employed and their economic and housing situations were dependent on whether or not their businesses were successful. As the majority of individuals in this generation were in the LEG, this created an overall polarization between those with satisfactory and unsatisfactory living situations.

(2) The Generation in Their Forties

1) Socioeconomic attributes

The education level of the respondents improved in comparison with the older generation. Although more than a half (56%) still belonged to the LEG, the HEG and MEG made up 17% and 28%, respectively. Amid the rapid expansion of direct investment and the rapid economic growth that occurred from the late 1980s until the mid-1990s, many people in the HEG and MEG were employed as high-level or middle managerial personnel, as there was a scarcity of qualified labor force. However, because the impact of the Asian financial crisis on the labor market was so serious, the share of self-employed workers increased greatly for all of the education groups between 1995 and 2005. In 2005, the major occupations of the HEG included government administrators (26%), managers/specialists in the private sector (26%), sales/service personnel (26%) and self-employed workers (22%), while the MEG and LEG worked as self-employed workers (36% and 32% respectively), sales/service personnel (30% and 23%) or factory workers (12%, and14%). Fourteen per cent of the LEG was engaged as informal workers, although there were no informal workers in1995 before the crisis.

Differences in monthly household income (median value) according to level of education were large. The household incomes of the HEG, MEG and LEG were 50,000 bahts, 21,750 bahts, and 15,000 bahts, respectively. The household income of the HEG was 3.3 times more than that of the LEG. Involvement in the global economy caused the wages of the workforce with higher levels of education to rise

significantly and, as a result, caused the income gap between the HEG and LEG to widen (Fukushima et al. 1996, Funatsu and Kagoya 2002).

2) Housing Forms

Diverse socioeconomic conditions and being in a life stage transitional for home ownership caused diversity in the forms of housing this generation used. The home ownership (formal) rate for people in their forties varied greatly depending on level of education. Although 87% of the HEG and 72% of the MEG had achieved home ownership, only 36% of the LEG had done so. There was also a gap in the level of housing quality. The HEG and MEG generally lived in terraced houses or detached houses (78% and 60%, respectively), while only 14% of the LEG did so, and a considerable number of them lived in low-quality housing. i.e., 19% in simple detached houses and 19% in simple wooden row houses or rented rooms in spontaneous development sites. The percentage of those living in informal housing, however, was 5%, which is much lower than that of people in their fifties or older.

In the BMR, the rental housing market gained attention as a mechanism to reduce the housing disparity. Many members of the MEG and LEG used this sector of rental housing. MEG households living in rental housing paid an average rent of 3,455 bahts; they lived in terraced houses or housing at an equivalent level. A large income gap among the LEG led to a housing disparity in this group, ranging from substandard rental housing to rented terraced houses.

(3) The Generation in Their Twenties and Thirties

1) Socioeconomic attributes

The level of education of people in this young generation was substantially improved compared with the previous generation. The ratio of the LEG dropped to 33%, while those of the MEG and HEG rose to 44% and 23%, respectively (estimated based on the 2000 Census). The MEG became the majority, and one out of four or five people had a high-level educational background.

The improvements in educational background affected the labor market. As the number of new graduates of tertiary education expanded rapidly, the time when university graduates were automatically promoted to be white-collar employees or managerial level personnel was passing. The marginalization of the labor force with a low level education progressed, because a large young labor force with a secondary education entered the labor market. The HEG worked as self-employed workers

(37%), sales and service personnel (20%) or specialist/managerial level personnel (12%), while the MEG worked as factory workers (30%), sales or service personnel (28%) or self-employed workers (22%), and nearly a half of the LEG worked as self-employed workers (46%). There were also people in the LEG who were informally employed (13%) and some who were not employed (4%) at all. This was evidence of the marginalization of the LEG. It is difficult to judge whether this tendency to opt for self-employment among all the education groups was driven by the financial crises, mismatches in the labor market, or was a step that the younger generation took in order to become successful.

Although the gap in employment patterns depending on level of education decreased, there was still a large gap in household income. The monthly incomes (median values) of households in the HEG, MEG and LEG were 37,500 bahts, 18,250 bahts, and 12,000 bahts, respectively. The income for households in the HEG was 3.1 times that for those in the LEG.

2) Housing Forms

For this younger generation, there had already been a gap in the home ownership rate (for formal housing) depending on the level of education due to the income disparity. While 64% of the HEG had their own houses, the corresponding percentage was only 29% for the LEG and 33% for the MEG. Although a gap was also seen with regard to their housing types, it was smaller than that in the ownership rate due to the presence of affordable rental options. For example, even 47% of the MEG and 57% of LEG lived in detached houses, terraced houses or shop houses, while 75% of the HEG did so. In fact, there was not a large difference in the average rent paid by the different education groups, i.e. 2,700 to 2,900 bahts. Even 30% of the LEG rented terraced houses or similar quality of housing, spending more than 30% of their household income for rent. This was not seen for the LEG of the other generations. However, the fact that 22% of the LEG lived in wooden row houses (tenements), rented rooms or informal housing showed the polarization of living conditions for the LEG.

5. Conclusions

In this study, I researched how the industrialization and rapid economic development of Thailand have influenced the suburban housing forms of the BMR for different generations and social groups. For every generation, there was a large household income gap, with a ratio of 1.8 to 3.3 times between different levels of educational

groups. This gap in economic strength resulted in a housing disparity in terms of housing ownership, the quality of housing and living environments, and the formality of housing, since in Thailand there is little government intervention in the housing market.

There were transitional points along the hierarchy of household income at which one option for housing changed to another. The transitional point between formal and informal housing was in the income range of 5,000 to 10,000 bahts. If the household income was less than 5,000 bahts, the available option was informal housing. As income increased to the 5,000 to 10,000 bahts range, formal rental housing became an option. The transitional point between owned and rental housing was in the income range of 15,000 to 20,000 bahts. With regard to household income (median value) categorized by level of education, the LEG earned 11,600 bahts to 15,000 bahts, the MEG earned 18,300 bahts to 23,800 bahts, and the HEG earned 27,500 bahts to 41,700 bahts. Home ownership was, therefore, very affordable for many members of the MEG and most members of the HEG, while it was not so for many in the LEG. As there were hardly any households whose household income was less than 5,000 bahts in the BMR, the forms of housing were becoming more formal, and fewer informal housing options were chosen.

In the BMR, the following four factors worked to inhibit the gap in income from leading directly to a housing disparity: (1) easy access to housing loans by provided by the GHB and private financial institutions, (2) an affordable rental housing market, (3) purchase timing, and (4) the government housing programs such as the BUA program and the BM program. For the lower medium or the above income group, it was easy to gain access to housing loans, and the inflation of wages allowed housing loan debtors to enjoy “subsidies from the past”. Many houses acquired for speculative and investment purposes were then supplied to the rental housing market at reasonable rents. Many of the members of the MEG and LEG in the younger generation who could not afford to purchase a house were thus able to rent adequate housing units. With regard to purchase timing, some of the LEG and MEG members in their fifties or older acquired private low-cost housing in the early 1980s, when a down-market trend prevailed, before land values and housing prices soared in the booming economy. Some members of the younger generations could buy a house during the period when housing prices dropped and during the initial recovery stage in the early 2000s.

Acknowledgement

The author is deeply grateful to Dr. Kundodibiya Panitchpakdi and Ms. Kittima Leeruttanawisut, the Chulalongkorn University, for their support of my field survey in the BMR.

Heritage, neighbourhood communities and planning in the context of change

Identifying conditions to analyze the appreciation and assimilation of neighbourhoods with historical and cultural values within regions of change in Europe and China.

1.1 Introduction

Our paper will present the first results of a 3 years research project called 'Pumah' on 'Planning, Urban Management and Heritage'. The project will identify the varying roles, positions, ideas and functions of sites, surroundings and objects through which time and place are culturally connected, within regions with varying speed of urban development: Europe and China.

The paper presents the outcome of two interrelated studies at the neighbourhood level. One looks at Europe, its economic conditions to heritage and how this affects life of neighbourhood communities. The other looks at China, linking heritage to processes of urban renewal, community participation and gentrification.

These neighbourhoods qualified as heritage (in China these are called 'hutong') connect identities of the past with today's cultural, physical and social manifestations. These neighbourhoods are not relics from the past, just representing a world that 'once was', isolated from its contemporary spatial context, functionally excluded from daily life and related social activities. These neighbourhoods can be and are almost always functional parts of contemporary live, while embedding symbols of the past. Keeping these symbols high could contribute to the appreciation of the neighbourhood by its community and its wider social and cultural environment. However, maintaining these symbols will not be without any costs. It will have constraining effects on the neighbourhood's community, such as gentrification, social exclusion and environmental

nuisance. These neighbourhood communities and their interactions with and their adaptation to the neighbourhood's spatial and cultural qualities is what is at stake in this paper. We are seeking for conditions, causalities and perceptions which relate a neighbourhood's wellbeing with consequences of being qualified as heritage, within regions which are open to change but differ in the pace of change taking place. These conditions, causalities and perceptions are essential in answering questions about how to maintain a robust representation of an appreciated past while being able to make use of its artifacts in a flexible and reasonable way, allowing as well various trajectories in time to progress and to evolve, such as spatial and social transformation and cultural identity.

1.2 The case of the Jewish Quarter in Budapest

Decision making in urban planning in Budapest is officially in the hands of the chief architect, mandated by mayor of Budapest every 4 (or 5?) years. (The local chief architects are mandated by the mayor of the local governments.) Albeit, in the last years, every chief architect resigned from their own free will before their mandate expired. They did it mostly without providing a reason, except István Schneller, who said that "as a leader who wanted to make technical decisions… [I] was opposed with political and financial lobby interests day by day" (Index, 2006).

Mechanism: During the Communist Regime, everything was state-owned. In 1990, the local governments became the owners of buildings in their district and they sold the building, mostly for the people who were already renting them. Many building got empty, because many people moved to suburbs. Also there were a lot of gipsy families moved into the empty building, which is illegal so they could get easily get kicked out, same for those who are renters because they are not protected by law in Hungary.

From 2002 (Sipos-Zolnay, 2009), some houses became very attractive even though the area was empty and remote (in Jewish District, the location is great for offices as well as small flats for those who really want to leave in the heart of Pest). There is great pressure from financial lobby interests on the obviously very corrupt local government who sells the houses for very little price, the houses end up in foreign investors' hands and people are obligated to move out but they get some substitution. If the investor want to demolish or make changes on houses (heritage houses) than the political interests put a great pressure to the National Heritage Office, who will allow it at the end.

"State capture is the phenomenon in which outside interests (often the private sector, mafia networks, etc.) are able to bend state laws, policies and regulations to their (mainly financial) benefit through corrupt transactions with public officers and politicians. The notion of state capture deviates from traditional concepts of corruption, in which a bureaucrat might extort bribes from powerless individuals or companies or politicians themselves steal state assets. State capture is recognized as a most destructive and intractable corruption problem, above all in transition economies with incomplete or distorted processes of democratic consolidation and insecure property rights." (U4 Anti-Corruption Resource Centre, ?)

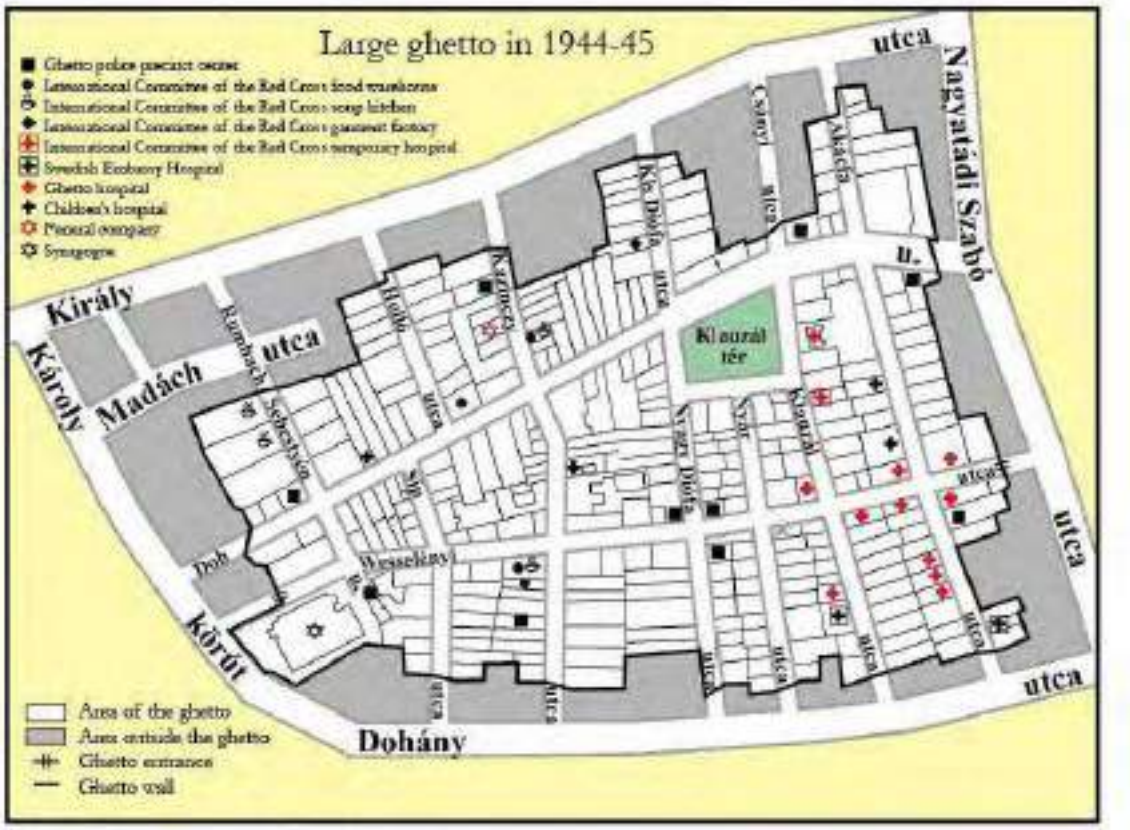
The History of the Jewish Quarter in Budapest

The Jewish, settling down in great numbers in Budapest in the 18th century, were facing a society with mixed signs of condemnation and reception in Austro-Hungarian Empire. In order to subsist and blossom, they had to define their ways of contribution to the modern and bourgeois Hungarian society.

The regulation of Enlightenment monarch Franz II (1741-1790) in 1781 made it possible for the Jewish to move to the cities, although in Budapest, they could only settle down (build a synagogue) in the areas outside the inner-city wall. They were also able to buy land and carry out farming and merchant activities. The law also required them to use German language, the official language of the Austro-Hungarian Empire that time but during religious activities the use of Hebrew language was allowed. In 1833, the Jewish community in Budapest were officially registered. In 1867, Emperor Franz Joseph I (1830-1916) legislated equal rights to the Jewish.

This liberal milieu enhanced the process of disjunction of Hungarian Jewish between those who wanted to assimilate and those who wanted to hang on to the traditional religious-communal forms of lifestyle. During the 19th century, a great proportion of Hungarian Jewish assimilated on their own will, especially the rich living in the cities (Reiche, 2006). The religious Jewish in Budapest belonged mostly to the mild reformed Neologue movement of Judaism, who adopted Hungarian language which became official language as well in the Hungaro-Austrian Empire under Franz Joseph II. Assimilation and retraining tradition were carried out on various levels and diverse ways, of course.

Budapest evolved 1973, has a symmetrical …. This area has been fringed upon three synagogues in Dohány Street (by architect Ludwig Förster in 1859), in Rumbach Sebestyén Street (by architect Otto Wagner in 1872) and in Kazinczy Street (by architect Béla Löffler in 1913). All were occupied by three different Jewish religious movements, forming the "Jewish Triangle in Pest". This part of Budapest's 7th district (Belső-Erzsébetváros) evolved during the turn of the 19th century. The quarter has been a traditional Jewish merchant centre, the main neighbourhood of Jewish people in Budapest. The Jewish Quarter became a ghetto in 1944-1945.



Map 1. The WWII Ghetto in Budapest. Source http://epiteszforum.hu/node/11736, 16 March 2012

During WWII, about 70% of the Jewish population of Budapest was deceased in Holocaust. After 1948 under the communist regime, due to religious restrictions and anti-zionist actions, assimilation was the only way to sustain for the remaining Jewish in Hungary.

After the fall of the Soviet Union in 1989, Hungary became a democratic country. Since then, there has been a renaissance of Jewish religious-communal lifestyle national wide. The area lieing in the East part of Budapest's inner city now has been called Jewish Quarter (Zsidónegyed) since 1990. The reconstruction of the Great Synagogue in Dohány Street (the largest synagogue in Europe) ended in 1998 and it is now available for touristic purposes, it is also a memorial (for example graveyard in the garden) and by the Neologue Community it is used for religious purposes as well. The Rabbinerseminar (the oldest existing Rabbinerseminar of the world, founded in 1877) started to function legally again, Holocaust memorials were set up and some cultural-religious associations were founded. For instance "Negyed6Negyed7 Festival" is a festival of the quarter, organized a few times in the year to keep traditions and represent Jewish culture and heritage for everybody. The synagogue in Kazinczy street is also restored and occupied by the Orthodox Jewish community but the third on in Rumbach Sebestyén street is still in a very bad condition. Close to the synagogue in Kazinczy street, the building of the Mikveh (a bath used in a purpose of ritual immersion in Judaism, it is central to an Orthodox Jewish community) was also party restored and can be used now for religious purposes.

In the Jewish Quarter, kosher shops and restaurants were opened again. Even though the symbols of Jewish traditions and the merchant life of the quarter still remains far less remarkable as it was before 1944 and the Jewish community has been heterogeneous in religion, these initiatives resuscitate the Jewish identity, heritage and religious life.

The heritage of the Jewish Quarter

In the 18th century, the spontaneous urban development generated an organic urban landscape in this area. During the 19th century, the quarter attained its peculiar atmosphere where the majority of the population was Jewish. The quarter, which was entitled as Jewish Quarter later in the 21st century, was located between the city border and the main access road towards the Danube, which is now called Rákóczi Avenue. It became a densely populated, vibrant merchant area. The residential area buildings were influenced by mixed classicists and secessionist architecture and the religious centres were influenced by oriental-style Jewish art. The quarter mostly consisted of narrow, scraggly lined streets with hick town-like houses which had spacious yards for storage and workshops. Businesses were run in the shops on the ground level and in cafes and bazaars of the arcades and passages.

Heritage issues related to Jewish Quarter

The decline of the quarter started before WWII and it is still continuing. After the collapse of Soviet Union in 1989, there has been an emerged demand of saving the heritage of this area. The Jewish Quarter of Budapest was added to UNESCO's World Heritage List in 2002. In 2004 it was entitled as protected area because its role as a puffer zone of Andrássy Avenue, which was recognized as UNESCO World Heritage Site in 2002. As being a protected area of heritage, the buildings and public spaces should be legally saved of destructing and building actions which do not add or decrease the value of the quarter. At the same time, the general regulation plan (which were first established in 1990) are often accused to be biased for holding the quarter for property development purposes rather than for the purpose of preserve its traditional character (Sipos-Zolnay, 2009). The Jewish Quarter has been facing contention of civilians, businesses and local governmental stakes.

Town planning and architecture

Between 2002 and 2006, the local government of the 7th district was trading 47 buildings to private investors, mainly with demolishing admission and with the condition of vacate the habitants of protected residences. According to the urban regulation plan, Madách Avenue was planned to built, during which a great amount of houses would have been demolished, but at the end only the smaller Madách Square was constructed. The local government changed the structure of several streets which destroyed the traditional passages and gave permissions to build new buildings and extensions which did not meet a warm response from the public.

Some architects support demolition but demand a deliberate conception of rehabilitation of the area. Whereas most of the houses are in a danger of complete

demolition, some of houses are changed to hotel- and housing complexes in a way that they keep the original frontage and a passage with its surrounding residential buildings called Godzsu Garden (Gozsdu Udvar) was partly restored and extended to the inherited original state in 2008, after it as empty for more than 10 years due the process of settling out the inhabitants. The building originally consisted of big 39 apartments, which were split into 120 small flats. On the ground floor, there were several small shops, which were gone through just the opposite because they were merged into a few bigger shops. Somehow, many of them go out of business (MTV, 2008)

Keeping the façade is not a good solution:

1. Because they were block buildings, with a big yard in the middle, which gets build-in.
2. Because the new building are higher, than the original was
3. Heritage still gets removed, because it was also represented inside (like handrails with David star motives).
4. Atmosphere is still gone because of the new (glass and steal for example in Gozsdu Garden and cheap material they are using.

Local NGOs

The civil society association 'ÓVÁS!' (PROTECTION!), founded is 2004, actively tries influence the decision making process about the Jewish Quarter and wants to conserve many of the remaining buildings of the quarter. They want the original houses to be restored in the original form.

Entrepreneurship

This system of corrupt businesses dates back from 2004. The mechanism of the system is explained by Sipos and Zolnay (2009). First, a very young limited company with minimal capital stock gets the call option of the chosen real estate. This financial instrument conveys the buyer the right to buy something at a specific, fixed price (strike price), but not the obligation to engage in that transaction, while the seller incurs the corresponding obligation to fulfill the transaction. This company is now appreciated with the option call. In the second phase the majority of the company business share will be owned by a foreign offshore company and it will be sold to the real investor. The original price of the real estate at best just covers the buyout of the owners and the costs of the moving out of the renters, but the limited company with the right of the option call usually do not even pay for that when entering into the contract. Their capital stock is less what would be required for that. The strike price is of course a depressed price and this could be realized because the local governments own trustee itself is estimating the value of the real estate. In the third phase, the difference of the values of the business shares are enormous, usually around twenty times. The company usually pays the amount of the strike price, which is a small change at this point.

Preservation of Jewish culture

It is very true that the Jewish associations make efforts to get conserved the cultural and religious heritage of the place for those who want to identify themselves by these. Some of them attract tourists as well (Great Synagogue). There is synagogue for the Orthodox and Neologue community and a community house for the Reformed (Moishe House of Budapest). There are festivals, cafes, restaurants, shops and other communities (Bálint House, Marom etc.)… But still, the majority of Jewish people live elsewhere and if visit this place than only for religion-related activities (Shabbat, Hanukah etc.).

Jewish people have been very heterogenous in assimilation or retraining to tradition. In an interview, a young, Jewish man who returned to his roots says: "You do not need to be religious to be Jewish… [I] believe in tradition rather than in God." (HVG, 2011). Those who have Jewish roots and aware of that, do not automatically wish to have the traditional lifestyle what is required by most associations and communities. Without a demand, there are not as much shops (only 6), restaurants etc. and there is a much less vibrant Jewish life going on in the quarter, as it used to be before 1944.

The biggest association representing the Hungarian Jewish is Mazsihisz, which is often accused by ÓVÁS! Association to express little resistance towards the demolition of houses or even got related to these issues, like Péter Torday's company, who was a president of the association (Gadó, 2009).

The problem evaluated

Aesthetical:

- Because of the efforts of ÓVÁS! Civil Association, …. buildings have been granted with protection because of their heritage value. Still, they have been or will be potentially demolished.
- The small passages disappear, the street structure changes, which results that it's peculiar atmosphere (oriental, merchant) disappear.
- Because of the many offices, during the day streets are crowded with cars and in the night they are empty.

Ethical:

- heritage and Jewish culture is disregarded (except the Great Synagogue in Dohány steet and its surrounding, but that is at the edge of the quarter).
- Because of a new building, the very last piece of the ghetto wall was removed. According to UNESCO, the ghetto wall should have been preserved as much as possible, as a memorial.

Emotional:

- feeling treated unfair/unjust and not protected by juridical institutions,
- seeing the things getting gone forever,
- unsuccessfulness of civil associations and activist gives the feeling of defencelessness to corruption,
- even those who are not directly affected get upset. Activists continuingly say, that it is a matter for whole Budapest.

1.3 The case of Nanluoguxiang Hutong in Peking

With China's rapid urban development from the 1980s, the urban areas are enduring continuous regeneration. Beijing, as China's capital city and with its substantial cultural heritage in the inner city area, is rather typical in its process of redeveloping the neighborhoods. The preservation of heritage, the relocation of residents, the revitalization of houses and the expropriation of land for development for the needs of different stakeholders are in great tension.

The Hutong representing heritage

The Beijing courtyard house and Hutong is a traditional type of residential neighborhoods built hundreds of years ago which symbolize old Beijing. Since the old courtyard houses are too decayed, from 1990s on, the People's Municipal Government made a plan called Beijing's Old and Dilapidated Housing Renewal program to renew the city center. The housing renewal program quickly became a large-scale speculative form of development involving massive demolition and ruthless displacement, resulting in an enormous loss in social and cultural values of this ancient city (Zhang and Fang, 2003). From 1990s till 2002, as many as 700, 000 residents were relocated (Goldman, 1999) and in the year 2003 to 2006 third of the central old city has been destroyed (Opendemocracy, 2006). Those incredible figures remind us the urgent need for a good mechanism for conservation.

Hutong, as a cultural heritage, symbols the meaning of the past glorious Beijing but remains a living style for the present people residing there. Why we shall preserve the hutong and who are we preserving for are very key questions here. There are many stakeholders in this heritage planning process, such as the affected community, the government, the developers, the academics, and even the tourists. Nevertheless, by analyzing the case of Ju'er hutong's renewal, Zhang et al. think that economic growth became the real motivation for emerging political coalitions between local government and local enterprises and the interests of the residents, the intended beneficiaries who have had little voice in the redevelopment process, were largely sacrificed (Zhang and Fang, 2002).

Heritage is created and produced in, and as a resource for the present thus it is more about meanings and values than material artifacts (signed by Waterton).In the worldwide, the authorized heritage discourse (AHD) is challenged and more attention now is paid on community inclusion, participation and consultation. Amenity and government bodies can engage with heritage conservation and preservation to promote the greater inclusion of a range of often-marginalised stakeholder groups into the management process (Waterton et al., 2006).The conservation is not only for the heritage's physical structure but also for the people and with the people in the affected community. How in this process different stakeholders prioritize their interpreted image of heritage and use their discursive power to practice it, decides the outcome of the heritage conservation, whether it be renovation, gentrification or redevelopment.

Besides, the residents in hutongs have their individual different needs, and they have the right to improve their living standard. The living condition of these Hutong residents is

rather below the average standard living in Beijing. The lack of modern facilities and sanitary equipment and lack of space are major problems facing them. The historical residential houses are their property and the co-management is necessary. It is very important to create discursive space for community participation in the process with the aid of expert knowledge and in the framework of government policy.

The conceptual model can be understood as follows:

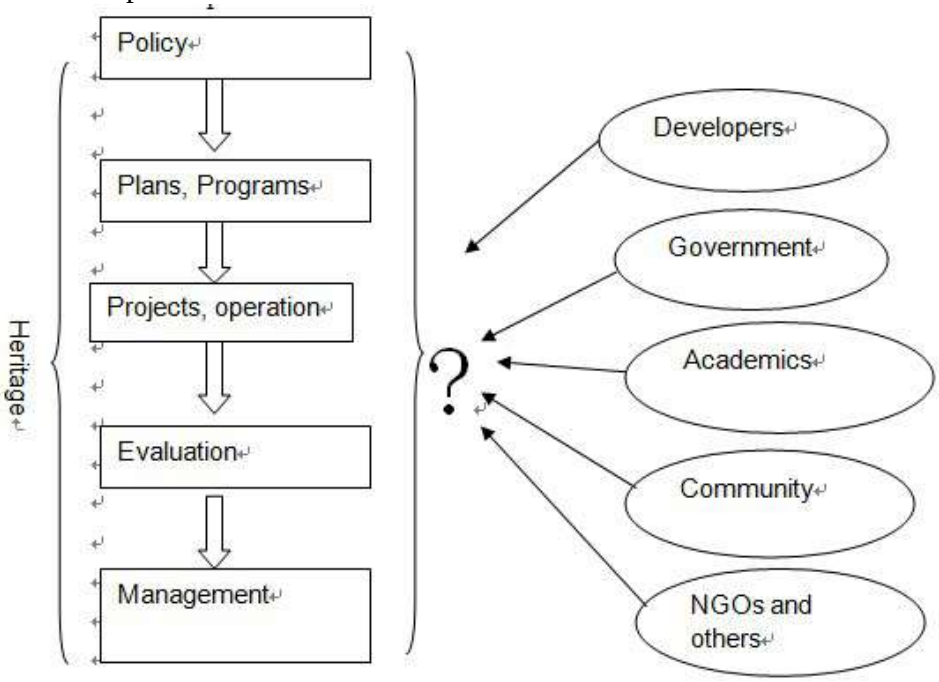


Figure 1 Conceptual model of heritage process (made by author)

Discursive space for community participation

With this case we will investigate the heritage discourse by the case of Beijng hutongs and identify how the different stakeholders interpret, manage and preserve the heritage. By analyzing the dynamic interaction and participation of various actors in the face of heritage changing process, the discursive capability and power relations lying behind would appear up. Finally the mechanism for an inclusive and participative mode of dealing with heritage could be advised generally.

Nanluoguxiang, also named South Luogu Lane, is one of the oldest alleyways (hutongs) in the Beijing city center. It has a history of 800 years and a must-see attraction in Beijing. It is 800 meters long vertically and located on the northeast of the Forbidden City and has a population of more than 50,000. It is one of 25 “Traditional Courtyard Housing Preservation Districts” designated by the 1982 Master Plan of Beijing (Zhang et al., 2003). In the neighborhood, there are more than sixteen hutongs stretching horizontally and a main street called South Luogu Lane vertically right across the middle (see figure 2). However, in the recent 10 years, the houses in the hutongs of the area have been going through many times’ demolitions by various renewal projects. Lots of old-style courtyard houses were redeveloped into high-rise buildings in the historical streets and thousands of people are affected.

Among this, Ju'er Hutong is a typical example of converting decrepit into new hi-rise courtyard houses and won the World Habitat Award in the 1990s. But it also gets some criticism, for example, Zhang and Fang (2002) claim that the case of the Ju'er Hutong project illustrates that neighborhood revitalization is inherently a profoundly value-laden process in which a society redistributes power and resources. And that local governments and local State-Owned-Enterprises (SOEs) built growth coalitions to accumulate wealth (exchange value) at the expense of providing local residents with adequate places to live and work (use value)(Zhang and Fang, 2002).

There are many other interesting stories happened or happening in this neighborhood, which arose my interest to target it as my case study area. For example, by the report of The Telegraph, there was an opposition to the conversion of Drum and Bell Tower and the surrounding hutongs into an underground shopping complex and a themed "Time City" in 2010.

Since 2005, the research team led by Prof. Lü Bin of Peking University has been working on the comprehensive hutong planning programme aided by the local government to foster preservation and cultural creative industry in the hutong complex.

Through in-depth interviews with semi-structured questions members of affected community will be approached. But the sample size is not fixed in case of inadequate information collected and resources limitation. In this way, a simultaneous data review

and analysis can be done in conjunction with data collection. Additional interviews will be done to get more insights to the research question. Snowball sampling is also a useful tool to discover potential respondents. By making use of participants or informants' social networks, the researcher can refer to other participants who could contribute to the study.

Focusing on people having local experience, know about, or have insights into the Hutong heritage revival, the goal will be to discover process of planning and decision-making behind the stories told.

Mobility in the child (and carer) friendly city: SEQ vs. Stockholm

Deanna Grant-Smith[1], Peter Edwards[2] & Laurel Johnson[3]

"I felt humiliated – I had the impression that, as a woman with two inconvenient children and some inconvenient luggage [a pram], I was barely tolerated on that bus system. Obviously two factors influenced my feelings there – the attitude of the driver and the design of the bus, neither of which made allowance for my – not-extraordinary – needs."
(Wright 1994:33)

"...the physical environment both reflects and conditions the wellbeing of children and gives children a very clear message about how they are valued (or not) within their community."
(Woolcock & Steele 2008:5)

Notions of public good and community obligations underpin public transport provision and are based on principles of equal citizenship and people's individual rights.
(Tedmanson 1994:13)

Abstract

The rationale for providing state subsidized public transport has changed over time from a social obligation to provide transport options for those without access to private transport to an environmental and economic imperative to minimize congestion and greenhouse gas emissions. In many jurisdictions this shift has seen a greater focus on the provision of peak hour commuter services and a shift in the demographic profile of the riding public and a significant increase in the number of commuter passengers relative to others. The scheduling of commuter services is not geared to meet the needs of children and their generally female carers who often need to engage in trip chaining and travel outside peak commuting periods and on weekends. In addition to service scheduling difficulties, transport infrastructure, both onboard and supporting infrastructure such as bus stops, train stations and connecting footpaths often do not support children and their carers to use public transport services. Combined with a negative attitude by passengers and service providers, such as bus drivers, which may see children, babies and young people as out of place and unwelcome on commuter services, these issues conspire to hinder the use of public transport by children and their carers. Overlaying feminist geography analysis and insights and child-friendly cities objectives, this paper proposes some basic criteria for the provision of public transport services and supporting infrastructure which meets the needs of children, babies and their carers and juxtaposes the achievement of these in South East Queensland, Australia and Stockholm, Sweden.

Introduction

Our interest in this research project was sparked by a recent controversy in inner city Brisbane, Australia in 2010 (Ironside 2010) involving claims of discrimination on public transport by mothers with prams. The story reported in *The Courier-Mail* shared the experience of Anita Flowers who was turned away from two buses and a train on her way to work at around 7 o'clock one Monday morning. Ms Flowers claimed that the bus drivers told her she could not board unless she folded up the pram carrying her sleeping five-month-old daughter. Ms Flowers says that she "accepted this and walked to the nearest train station where [she] waited for at least 15 minutes, and when the train finally arrived, the guard told [her] that [she] would have to wait for the next one as this one was full." She alleges the he then proceeded to tell her that "all trains are full at this time, you should wait".

Based on her experience, Ms Flowers lodged an online petition to the government calling for a pram friendly carriage on trains. Other parents who signed her petition said they had experienced similar acts of discrimination and some admitted to spending thousands of dollars each year to park in the city rather than catch the train because of the discrimination experienced when travelling with their child. Supporters of Ms Flowers said that "Other passengers are on the whole not tolerant of children in their space".

The comments provided on the Courier-Mail's online comments following the story were vitriolic demonstrating negative attitudes toward the use of public transport by mothers and their children, with or without a pram; both of which were deemed to be 'out of place' on peak hour services, despite the fact that Ms Flowers herself was a commuter on her way to work.

In affluent countries (with relatively high measured female workforce participation rates) like Australia and Sweden, the rationale for providing state subsidized public transport has changed over time from a social obligation to provide transport options for those without access to private transport to an environmental and economic imperative to minimize congestion and greenhouse gas emissions and service the economy through commuter travel. In many jurisdictions this shift has seen a greater focus on the provision of peak hour commuter services and a shift in the demographic profile of the riding public. It has also seen a significant increase in the number of commuter passengers relative to others and a withdrawal of some non-commuter services. The scheduling of these services is generally not geared to meet the needs of children and their carers who might need to engage in trip chaining and travel outside peak commuting periods and on weekends. As Ms Flowers' experience shows, even parents travelling during peak hours with their children experience difficulties.

In addition to service scheduling difficulties, transport infrastructure, both onboard and supporting transit infrastructure such as bus stops, train stations and connecting footpaths do not support parents with children. As the vitriolic comments surrounding Ms Flowers' experience demonstrate, these physical barriers are often combined with a negative attitude by passengers and service providers, such as bus drivers, which may see parents travelling with children and babies as out of place and unwelcome on commuter services. This is not surprising as it has been noted for many decades in the feminist geography and social justice fields that the needs of women are often overlooked in the planning and delivery of public transport services (Hanlon 1996, PLM&GTA 1995, Fritze 2007). What Ms Flowers' story demonstrates most clearly is that there is also a deficiency in transport planning and service delivery with respect to meeting the travelling needs of children and babies and their carers.

The needs and aspirations of children and young people are often overlooked in the planning, design and management of our cities and neighbourhoods (Baker et al 2010). This is also often the case with transport planning and design. The child friendly cities agenda has generated some discussion on the need for effective models for involving children in the governance and development of their communities (UNICEF 2012:55). This approach recognises the right to safe and accessible transport as a prerequisite to delivering just cities for all citizens, but most particularly children.

The delivery of child friendly transport can slow the observed decline in children's independent mobility (Love & Whitzman 2011:1) and can welcome children and young people back into our communities. As well as a children's rights framework, the development of child friendly transport criteria in this paper is also informed by an understanding of the feminist geography literature on women's transport issues which recognise mothers as carrying a disproportionate burden of travel with children and for having to deal with the consequences of child unfriendly design and services.[4]

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: (Varsayılan) Times New Roman

As in Australia, Swedish women are also disproportionately responsible for journeys related to care and purchasing (Vagland 2004:192). This paper proposes some basic criteria for the provision of public transport services and infrastructure which meets the needs of children and their carers and juxtaposes the achievement of these to date in South East Queensland, Australia and Stockholm, Sweden.

Transport and gender

Because of their youth, children often travel with others, however, the burden of transporting children is not equally distributed among parents with young children more than five times as likely to travel with their mothers than their fathers (McDonald 2006:1).

It is generally agreed that women carry a greater transport burden than men (Mashiri et al 2005). For example, women are primarily responsible for domestic work, including shopping and child rearing, regardless of their employment status (Hamilton 2001:3). As a result women's trips are more likely to relate to caring and family responsibilities while men are more likely to travel for business and leisure (Scottish Government 2002). Mothers are more likely to have responsibility for meeting children's travel needs, and children make more go-along trips with mothers and those trips on which mothers take them along are for household-sustaining purposes, such as shopping (McDonald 2006:4). Indeed it has been suggested that much of this travel is "babysitting on the go", particularly for single mothers for whom there may be no other form of child care available or by working mothers attempting to spend some time with their children (McDonald 2006:6).

As a result women make the majority of non-work trips with the exception of social/recreational, return home trips and childcare and education trips which are predominantly undertaken by children or women with children (Abrahams 1998). Women make more trips to and from education (including escorting children) and more shopping trips than men (Scottish Government 2002). Women are more likely than men to work part-time, to be responsible for child care and housework, and to perform tasks that are considered inherently "interruptible". The division of paid and unpaid labour and the assumption that women's work (paid or unpaid) can be interrupted may shape women's travel patterns in ways that men do not experience because women's travel patterns often reflect and reinforce the same message of interruptibility that characterizes their work (Spain 1996:276). As a result, journey to work is of less significance to women because women's travel patterns are more complex in duration, time of day and mode, due mainly to family and domestic responsibilities (Abrahams 1998).

Women are more likely to be accompanied by children and encumbered by baggage when travelling (Abrahams 1998). Women with family responsibilities have particular travel needs and for them the transport task is complex and multi-faceted. Their journeys are more likely to involve a range of different modes of transport (Scottish Government 2002) and to rely on trip chaining (completing multiple tasks within a single journey) to meet the complex demands of their multiple roles.

[4] Certainly not all women are the same or have the same life experiences, however, research suggests that there are sufficiently significant differences between women's transport demands and experience as opposed to those of men in terms of access, patterns of commuting and in childcare responsibilities to justify treating women separately (Hamilton 2011:2).

The result is that women need more travel flexibility than men (Spain 1996:277). Despite this transport planning has tended to focus on peak hour movement, the journey to work and movements into and out of the CBD (Mashiri et al 2005; Dowling & Göllner 1997). This focus is more appropriate to middle class men's employment (industrial areas are generally poorly served, if at all) and travel patterns than to women's and children's. As a result "they are poorly and disadvantageously serviced by current transport arrangements, and in particular public transport" (Dowling & Göllner 1997:8). As Ms Flowers' experience shows even women and children who attempt to mirror male commuter travel patterns and to take advantage of the services provided are not afforded equal access. Based on these constraints women travellers often seek more frequent and reliable services, safety and security, and good physical access (Costain 1995, Wright 1994, Ybarzabal 2010). Transport policy-makers need to understand that women with family responsibilities, particularly those who work outside the home and have children often have negative transport experiences (Austin 1994). These transport difficulties create significant barriers to accessing services, social networks and community participation for parents and their children (Fritze 2007).

Transport in the child-friendly city

While children have been variously described as including anyone from the age of birth to 18 (UN 1989), the transport needs and unmet transport demand of each of these groups is very different (table 1). In recent years a great deal has been written about that unmet transport needs of older children, young people and young adults, particularly in Australian regional and rural Australia (e.g. Currie et al 2005, Currie 2007). As relatively autonomous and independent travellers, in some respects the transport needs of these groups are not too different to those experienced by other able bodied adults, particularly with respect to a demand for frequent, reliable and affordable public transport services that operate outside non-peak periods (Demasi, Grant-Smith, Poulsen & Doring 2007). Significantly less has been written about the transport needs of younger children who are seen more as travel companions than travellers in their own right, perhaps because the majority of trips for infants are escort trips travelling with patents (Currie 2007).

Indeed in many respects these children are considered incidental travellers and their needs subordinate to other travellers. This is despite them having specific needs that are more in line with those of travellers with a disability and other special needs travellers, a point that Ms Flowers also made.

Table 1: categories of children and their transport needs and characteristics

category	indicative age	transport needs/characteristics
infants and toddlers	0-3 years *babies & toddlers*	Do not travel alone. Often undertake companion/care trips. Require carrying or travel in a stroller/pram some or all of the time. Requires high level of public transport accessibility and a good pedestrian environment where walking is required.
pre-school children	4-5 years *pre-school*	Can move more independently (i.e. not confined to stroller) but do not travel alone and often undertake companion/care trips. Require high level of public transport accessibility and a good pedestrian environment where walking is required. A strong emphasis is placed on the safety of transit situations because children of this age may act unpredictably (Gilbert & O'Brien 2005:21).
young children	6-10 years *primary school*	Some journeys are made without supervision (eg. school transport where they may travel with other children but are met at pick-up/drop off points by adults) but most travel tends to be with parents, carers and other family members.
older children	11-14 years *early to middle high school*	Many day-time journeys (walking, cycling and public transport) are made without supervision. Often travel in groups rather than alone.[5]
young people	15-18 years *high school or vocational training*	Start to begin to move independently within the community. May have a licence and access to a car in later years.

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: (Varsayılan) Times New Roman

It has been noted that public transport

> *trips are imagined as being made by independent individuals, each contained in a body that is a distinct, separate and equivalent unit. Although there is some recognition of the physical needs of particularly groups (such as people with impaired mobility), bodies appear in conventional transport planning models as discrete entities with independent trajectories. However, we might query to what extent that model holds true. For example, someone travelling by train with a baby must carry the infant with them to ticket office, toilet stall, boarding platform and train compartment, and must manage the physical demands of embarking and disembarking while carrying baby (not to mention stroller and baggage). In a sense, then the bodily boundaries of the adult escort expand to encompass the small child.* (Law 1999:581)

While such a view recognises the travelling needs of the parents it still views the child as part of the adult and not a traveller in its own right and with its own rights. Certainly a large number of responses to Ms Flowers' story questioned the right of her child to be transported on a commuter bus during peak hour at all either in or out of a pram. This view of children as being subpersons without the full rights of adults is not uncommon and is part of the rationale behind the United Nations Convention on the Rights of the Child (1989) and the child-friendly cities movement it spawned.

Cities aspiring to be child-friendly commit to implementing the principles of the Convention on the Rights of the Child, including through a strong participatory approach and the mainstreaming of children's rights in budgets and policies. The convention is based on four core principles: non-discrimination; the best interests of the child; the right to life, survival and development; and considering the view of the child in decisions which affect them (according to their age and maturity) (UN 1989). UNICEF (2012:55) believe that within the urban context, an inclusive environment can be created with a focus on two major issues: transportation (the focus of this paper) and space.

[5] Hanlon (1996:652) makes the interesting observation that while parents are often happier if their children travel in a group for safety reasons, "this 'group' of children, seen through the eyes of a bus driver, may easily be regarded as a 'gang'".

Internationally, the concept of child and youth friendly cities has been led by the United Nations as a means to improve the lives of children and young people in developed and developing countries. The United Nations Convention on the Rights of the Child (1989) promotes the rights of children and young people to influence their communities, participate in family and community life, access basic non-discriminatory services and green and unpolluted spaces and live safely. This rights framework has been extended by some Australian Governments (State Government of New South Wales and various Local Governments) to include the design of the built environment. Safe public transport and well-regulated traffic are vital components of a city fit for children. For instance, successful initiatives in Colombia, Sweden and the Netherlands have combined car-free areas, dedicated bicycle and pedestrian routes, and public transport to reduce injuries and deaths (UNICEF 2012:71). In Australia, a number of local governments have adopted child friendly cities principles to inform the delivery of their services and their engagement with local communities (e.g. Baker et al 2010).

The Australian Research Alliance for Children and Youth (ARACY 2006) has defined a child friendly community as one in which children are valued, supported, respected, provided for and actively included. Based on this view ARACY developed a range of indicators or criteria for encouraging child-friendliness within communities (Table 2).

Table 2: Themes for encouraging child-friendliness within communities (ARACY 2006)

criteria	description
welcome and connection	learning how to listen, plan and take action with local children
value	recognising that local children and their families are valuable contributors to community life
safety	providing safe places to play close to home and connect communities with the care of children
meaningful action and self-determination	developing a joint community vision and imagining together what a child friendly community will look like locally
space	designing creative spaces for and with children and providing people with a reason to come into those spaces and use them
learning and development	recognising that learning and development happens in everyday places and in many different ways and that it is important to utilise these places, and to document the processes and outcomes for children as they learn and grow in everyday spaces
support	establishing practical and friendly pathways for families to get services they need
time	taking time and making time when working with children to counter the idea that consultation with children is a one-off event

The concept of a child friendly city is not based on an ideal end state or a standard model. It is a framework to assist any city to become more child friendly in all aspects of its environment, governance, and services. Access to appropriate transport is often identified as a factor in the achievement of child friendly cities (Commission for Children & Young People and Child Guardian 2006:7).

This idea has been expanded by researchers at the Centre for Sustainable Transportation in Canada (Gilbert & O'Brien 2005, 2010; O'Brien, Ramanthan, Gilbert & Orsini 2009) through the development of a set of guidelines for child and youth friendly land use and transport planning. These guidelines (Table 3) centre around four principles: putting children and youth first; providing for children and youth as pedestrians; providing for children and youth on bicycles (and other wheels); and providing for children and youth as public transport users.

Table 3: Guidelines for child and youth friendly land use and transport planning[6]

Putting children and youth first
The needs of children and youth should receive as much priority as the needs of people of other ages and the requirements of business in transport and land-use planning decisions
Within each municipality, designate a staff member or council member, or both, as responsible for bringing the perspectives of young people to consideration of transport and land-use planning issues.
As may be appropriate, establish or adapt one or more forums for children and youth to ensure that their perspectives are considered by land-use and transport planners.
Providing for children and youth as pedestrians
Identify where children and youth want to go or need to go and, to the extent possible, provide ways of getting there by foot.[7]
Assess pedestrian routes used or to be used by children, youth and a person wheeling a stroller to ensure that they are as safe and suitable/usable for them as possible.
Separate sidewalks used by children and youth from heavily travelled roads to avoid harm.
Ensure that sidewalks are always cleared of ice and snow and debris.[8]
Providing for children and youth as public transport users
Ensure that every part of a public transport system is safe and welcoming to young people and children, and affordable.
Avoid transfers by routing vehicles where children and youth want to and need to go; make transfers easy where necessary.
Examine every aspect of a public transport system from the perspective of a parent with a child in a stroller, and make adjustments to meet such a traveller's needs.[9]
Keep fares for children low, so as to encourage their use of transit systems.
Help ensure that school policies and practices favour walking, cycling, and other modes of active transport for trips to and from school, and also regular public transport where this is available and appropriate.
For younger children, help arrange walking school buses[10] and other means of supervision.
Where destinations cannot be reached by foot, bicycle or public transport, arrange land uses so that in-car time is reduced.
Post and enforce much lower speed limits, particularly in urban areas (and around schools).
Do what is possible to reduce amounts of motorised traffic generally and reduce its adverse impacts.

[6] It should be noted that guidelines were also provided for children and youth on bicycles and other wheels. Although we recognise their importance in increasing child mobility and travel independence these guidelines have been excluded as they do not related directly to the public transport task.

[7] Similar considerations apply to children and youth who use wheelchairs.

[8] It's hard to push a stroller or wheelchair through uncleared snow, an icy sidewalk or uneven path or to expect a toddler or even a slightly older child to walk there.

[9] Among the most challenged users of transit systems are passengers with young children in strollers. These users have particular difficulties when there are stairs or steps and when vehicles are overcrowded. (Gilbert & O'Brien 2010)

[10] The essential feature of a walking bus is a line of children, even holding a rope if they are under five years, led by and followed by one or more adults.

Preliminary criteria for child and carer friendly public transport

An engagement with feminist approaches to public transport is characterised by a political agenda to effect change and "to challenge the conductions that have led and continue to lead to gender inequalities in transport" (Buiten 2007:23). So too the child friendly cities agenda is trying to affect a similar change for children. Thus combining the two approaches is not incompatible given the overlap in their interests and the disproportionate role mothers have in ensuring their children's travel needs are met.

In the past policy makers and service providers have not always recognised the differential effects of their provision on some groups and the barriers they may impose on people who do not fit within the dominant pattern of need for which the provision has been developed (Scottish Government 2002). The frustrations and safety concerns of trying to use transport systems and a built environment which is not designed for parents with young children make completing daily activities unnecessarily difficult (Fritze 2007: 34).

From Ms Flowers' case we can understand that child-friendly passenger transport is as much about infrastructure and service deficiencies as it is about less tangle issues like the provision of assistance and the attitudes of other passenger transport users. Based on the child-friendly transport criteria and understanding of the challenges facing parents travelling with small children the following tentative criteria for child and carer friendly public transport are proposed (figure 1).

Figure 1: Criteria for child and carer friendly public transport

Biçimlendirilmiş: Yazı tipi: (Varsayılan) Times New Roman

Biçimlendirilmiş: Yazı tipi: (Varsayılan) Times New Roman

Accessibility

Accessibility is one of the most significant barriers to using public transport identified by the parents of small children (Fritze 2007). The use of public transport by people travelling with children is affected by physical and practical considerations relating to the structural design of buses, trains and trams. Inaccessible vehicles not only make travel physically difficult and emotionally stressful but also in some cases prevent carers from travelling at all (Fritze 2007:10-11). Buses are generally considered to be worse than trains because parents can generally move a pram on and off a train relatively easily. Issues with bus accessibility are exacerbated by policies requiring carers to fold up their prams before entering a bus. Many researchers have highlighted the indignity and difficulty associated with this issue (Fritze 2007:10-11, Wright 1994). Because those travelling with small children are often further encumbered by baby strollers and heavy shopping the design of many vehicles and carriages makes getting on and off under such circumstances extremely difficult (Hanlon 1996). The provision of physical access to vehicles, facilities and the surrounding built environment is important. This includes the development and provision of facilities for children to meet the needs of women travelling with

children and the provision of adequate space on vehicles and within facilities (such as waiting areas) to allow for the storage of prams, bags and others items (Scottish Government 2002:9).

Practical constraints that seriously hinder access and ease of movement include: high steps which are difficult to negotiate for the very young; a lack of storage space for shopping, baby strollers, and other paraphernalia; lack of proper provision of seating for children and no seat belts; lack of organized assistance for women getting on and off who are laden with children, strollers/prams and shopping (Hanlon 1996). Accessibility constraints often extend beyond the actual vehicles to include: impractical siting of bus stops and train stations; inadequate provision of seating and shelter at stops and stations; toilets at stations and interchanges which are too small to accommodate an adult with a baby stroller/pram; awkward steps and crossings at railway stations and the quality of the paths to bus stops and train stations. In some instances, these 'constraints' and difficulties' can be dangerous. At the very least, they serve to deter parents and carers from using public transport and hamper them when they do choose to use it (Hanlon 1996).

Assistance

The barriers presented by inaccessible vehicles are exacerbated in many cases by policies in some areas requiring parents to fold prams before entering the bus, and by bus drivers failing to provide assistance. Difficulties in boarding and alighting from inaccessible buses and the need to fold up prams create a corresponding need for assistance using services. Current occupational health and safety 'no-lift' policies, nominally in place to protect bus drivers (but, ultimately, to protect bus operators from workers' compensation risk), have unintentional impacts on the ability of parents and carers to use bus services and can result in parents having to rely on strangers to hold their babies or to put the children down on the nature strip or pavement while they fold their prams or assist their other children on to the bus (Fritze 2007).

The availability of assistance for parents at transport facilities and onboard vehicles by staff who have an awareness of the issues faced by parents travelling with children can also have a positive impact on the travel of children and their carers and should be encouraged (Scottish Government 2002:10). It has been suggested that the development of policies to increase the usability of transport services for carers of young children should include designation and publication of when accessible services are timetabled; removal of operating policies that require prams to be folded; more assistance from drivers and other staff to assist women with prams or small children to board vehicles; and more involvement of drivers in ensuring that those holding young children have access to priority seating (Fritze 2007:13).

Affordability

On the whole women have lower income levels than men and some groups of women (such as single parents) are likely to be disproportionately represented among lower income earners. There is a need to encourage the general provision of public transport at a reasonable cost. The provision of flexible options which can reduce the costs of transport (such as multi-journey and through ticketing) can support affordability (Scottish Government 2002:15). Similarly, discounted or free travel for children can support affordability. An example of this principle is in operation in the Metropolitan Region of Helsinki which offers free use of the public transport system for people travelling with babies to encourage care givers travelling with their children to use public transport (UN Habitat 2008:193).

Availability, frequency & reliability

Public transport travel can be long and arduous, especially with young children in tow, due to lack of connectivity between services and long waiting times as well as a lack of direct services (Fritze 2007:20). It has been suggested that most transportation planning and modelling is based upon assessing the capacity of the system to handle rush hour loads and home-based-work trips, not off-peak, non home-based trips. This single minded attention overemphasizes capacity considerations on major facilities and de-emphasizes the difficulties faced by women forced to trip chain, make suburb to suburb or inner city to suburb trips and generally lavishes funding and

attention on the part of the travel market dominated by men (Dittmar 1996:669). The provision of integrated services without identifiable gaps in services is important (Scottish Government 2002:11) as waiting with children can be difficult especially in uncomfortable or unsafe environments such as those exposed to the weather or traffic.

Amenities & Services

A more carer and child friendly transport system would incorporate design features and service standards that reflect the realities of travelling unassisted with prams, baggage and young children (Fritze 2007:32). The lack of availability of baby change and toilet facilities of an acceptable standard in and around public transport is often a significant issue for parents travelling with children. Parents will often prefer to change their babies in their prams or cars rather than use public toilet and baby change facilities that are considered unsafe or unhygienic, or in some cases simply unusable or unavailable (Fritze 2007:21). This also extends to the provision of appropriate safety features onboard vehicles.

Attitudes

In the past, policy makers and service providers have not always recognised the different effects of their provision on women and the barriers they may unwittingly impose on groups which do not fit the dominant pattern of need for which the provision has been developed (Scottish Government 2002). Traditional transport planning has a tendency to determine and direct transport investments based largely on mainstream (unencumbered and able-bodied) commuter patterns and to tackle transport issues through a top-down approach, concentrating on technical requirements (Buiten 2007:28). Hanlon (1996:649) suggests that a contributing factor to the fact that these issues are not adequately addressed by the transport planning industry is that "women are woefully under-represented as professionals and as service providers". This has resulted in public transport provision and planning is "an industry which is male dominated and little influenced by any awareness of the importance of gender" (Hanlon 199:654).The child friendly cities agenda recognises a similar absence of concern with the needs and voices of children, which their parents can assist in providing (particularly for very young children).

Mainstreaming these issues requires the examination of the policy process to ensure that issues relating to parents travelling with children have been examined and built into public transport policy and delivery. This involves actively seeking the views of parents and children specifically and taking action to address their identified issues (Scottish government 2002:4).

While the needs of carers with young children must be considered as part of accessible transport planning, including the design of public transport vehicles, buildings and facilities (Fritze 2007), a child and carer friendly public transport system also relies on the goodwill and attitudes of drivers, transport staff and other passengers (Wright 1994) in making women and their children feel welcome on public transport.

Child and carer friendly transport in SEQ

Biçimlendirilmiş: Yazı tipi: Times New Roman

South East Queensland is one of the fastest growing regions in Australia with its population expected to grow from 3.1 million in 2009 to 4.4 million in 2031 (TMR 2010). In July 2008, TransLink Transit Authority was established as the statutory authority responsible for leading, planning, specifying and providing mass transit in South East Queensland – an area that stretches from Gympie and the Sunshine Coast to Coolangatta on the Gold Coast, and west to Helidon. TransLink operates across 23 zones and 7 regions in South East Queensland (map 1). By 2016 there will be significant extensions to TransLink services in line with the predicted SEQ (South East Queensland) Regional Plan urban footprint for 2026 (TransLink 2012c). TransLink delivers bus, train and ferry services, information, ticketing and infrastructure across South East Queensland – one of the largest integrated public transport networks in the world with TransLink and its partners providing more than 178.6 million passenger trips in 2010–11 (TransLink 2011). TransLink coordinates nearly five million bus, train and ferry services across the 10 000 square kilometre region of South East Queensland. The TransLink network spans 23 zones in a service area that is six and half times the size of London's Oyster card network

(TransLink 2011:8). Unlike metropolitan based public transport systems, which traditionally service large numbers of customers within a small geographical area, the size of South East Queensland means that TransLink must provide services and infrastructure to customers across a broader, more dispersed area.

Map 1: TransLink area of service
(http://translink.com.au/resources/about-translink/our-service-area/region-map.jpg)

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: Times New Roman

Availability

TransLink works with nineteen different public transport operators to plan and deliver more than 4.9 million services to South East Queensland (TransLink 2012d)[11]. The TransLink network encompasses: **rail** with 201 three-car trains (generally coupled to make six car trains) which operate across 145 train stations and 740km train track; **buses** with 21 busway stations, 25km of busway system, more than 12,000 bus stops and more than 2300 buses; and **ferries** with 17 city cats and 9 city ferries (TransLink 2011:38). Public transport operations are both publicly and privately owned, with services provided under service contract arrangements with the Queensland Government.

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: Times New Roman

The TransLink authority has improved the availability of public transport in the region by enhancing timetable integration across modes. Nevertheless, the frequency of public transport services in South East Queensland favours commuters travelling to the Central Business District of Brisbane at peak times. In peak commuting times, there are generally more scheduled buses and trains and more express public transport services. The cost of travel in peak periods is slightly higher than a comparative trip in an off-peak period. This is designed to discourage non-commuters from travelling on peak hour public transport services. The common "hub and spoke" system of service provision such as the South East Queensland network can make travel between suburbs difficult (Scottish Government 2002:12) and is better suited to meeting the needs of commuters travelling to the CBD. It should be noted that the Queensland Government does provides dedicated school transport services (for high school and primary students) on some routes.

Affordability

The high cost of public transport travel in South East Queensland is a contentious issue for the region's communities. This concern, which has been accompanied by a decline in patronage, has been attributed to ongoing fare increases of 15 per cent per annum (PS News 2012b) since 2009. A single 15 km trip can cost an adult traveller up to $8.00. Pre-paid travel (using a *go-card*) is up to 30% cheaper than *pay as you go* travel. Children aged four years and younger travel for free on TransLink buses, trains and ferries while children aged 5-14 (inclusive) are eligible for a concession fare (TransLink 2012) though they are not entitled to a seat if adults are standing.

The Queensland Government has committed to reintroducing discounted weekly fares for regular users of buses, trains and ferries (LNP 2012a) which will include free travel after nine journeys in a Monday-to-Sunday week for *go* card users (LNP 2012b, PS News 2012b). This is part of a strategy to deliver public transport in South East Queensland that works for commuters by delivering a reliable, frequent and safe network (LNP 2012a) and is unlikely to result in cost savings to those who are not employed in a full-time capacity.

Accessibility

TransLink, like all Australian public transport networks, works under the Australian Government's *Disability Discrimination Act 1992* and *Disability Standards for Accessible Public Transport 2002*. TransLink is continuing its program of upgrading infrastructure and rolling out new buses, trains and ferries to meet the *Disability Standards for Accessible Public Transport 2002*. TransLink is also upgrading its existing 12 000 bus stops in the TransLink network to meet the Commonwealth Government's target of 100 per cent DDA compliance by December 2022. This shift to DDA compliant transport infrastructure will assist service accessibility for parents and carers travelling with children as more lifts, ramps and onboard wheelchair bays combine to support the travelling needs of infants and young children.

Assistance

Due to workplace health and safety concerns TransLink staff are not required to assist in folding and loading prams and other large objects (TransLink 2012a). It is Translink policy that children may travel on buses and trains in a pram or stroller provided it is parked in the designated

[11] This does not include dedicated school transport services which are provided by private providers on behalf of the State Government through Department of Transport and Main Roads.

wheelchair space with its brake on and the child is secured in the pram or stroller harness. However, children need to be removed from prams and strollers and the pram or stroller folded and stored in the luggage rack under the following conditions: if travelling during peak times[12] if the bus driver advises that there is not enough space on-board the bus to safely park the pram, if it is not a wheelchair accessible bus, or if the designated wheelchair space is already occupied or it is required (for a wheelchair) throughout the trip (TransLink 2012a). It is TransLink policy that adults travelling with small children should be given priority seating on all TransLink services (TransLink 2012a). While the allocation of priority seating is a positive recognition of the additional needs of some passenger groups, it relies on the good will of passengers to relinquish their seats or on the confidence of passengers with special needs to request them to do so. Realistically, this does not guarantee access to these seats for those who need them (Fritze 2007).

image 1. getting onto a bus with a toddler and folded stroller

Amenities

Safety handles on buses are connected to the roof and are designed for adult travellers. Stop request buttons are also generally positioned at adult height. There is limited storage on buses and school bags are a particular problem during before and after school travel. You can only travel on a bus with a bike if it is a small fold up bike. Travelling with bikes on trains is also highly restrictive and is not allowed between 7am and 9.30am Monday to Friday (towards the city) and 3pm and 6.30pm (travelling away from the city). Drinking water fountains are provided at train stations in south-east Queensland (PS News 2012a).

Attitudes

TransLink consults with a range of interest groups in planning and providing services including those advocating for the interests of older people, people with a disability, students and people from culturally and linguistically diverse backgrounds. They do not appear to have specific engagement with women or children (with the exception of parents and citizens group). In her PhD research into gender issues in public transport in SEQ Ybarzabal (2010) concluded that there is a lack of effective engagement with women in SEQ and that greater attention to gender consideration in developing public transport policies is required. She notes that while the Queensland Government has made a commitment to improving public transport provision for women it appears that such rhetoric has not yet translated into practice.

Child and carer friendly transport in Stockholm

Stockholm County is the capital region of Sweden, comprising more than 2 million inhabitants and growing at a rate of 30-40 000 inhabitants per year (Länsstyrelsen I Stockholms län, 2011a).

[12] Off-peak times are from 9am to 3.30pm and after 7pm weekdays until 2am the following day and all day weekends and gazetted public holidays (TransLink 2012b).

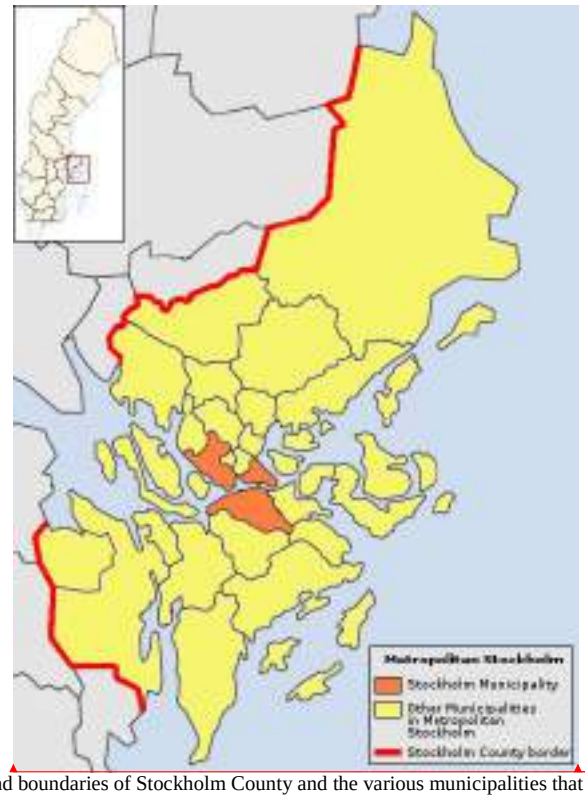
Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: (Varsayılan) Times New Roman

Biçimlendirilmiş: Yazı tipi: (Varsayılan) Times New Roman

The county covers 6488 km2, with approximately half of the county area covered by forests (Länsstyrelsen 2011a). This is approximately 2/3 of the TransLink area in SEQ, with 2/3 the population, making Stockholm County more densely populated. Within the county, there is a further administrative sub-division into 26 municipalities (map 2).The higher administrative structures have different roles, with the County Administrative Board (a central government appointed board) responsible for planning and development in the county, coordinating among other things, transport planning and gender equality (Länsstyrelsen, 2011b). The county also comprises the County Council (landstinget) (2011b), an elected policy-making body, mainly responsible for health and public transport. The County Council controls public transport through a limited-liability company with a politically appointed board, *AB Storstockholms lokaltrafik, SL* (Landstinget, 2011a).



Map 2: Location and boundaries of Stockholm County and the various municipalities that make up the county. Illustration - TimSE.

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: Times New Roman

Availability

There is a similar mix of public transport options in Stockholm and SEQ. In Stockholm, SL oversees the running of buses on 450 routes, commuter trains on 200km of track with 51 stations, local trains on 110km of track and 98 stations, trams and three metro lines with 107km of track and 105 stations (SL, 2011a). Ferries also operate throughout the Stockholm Archipelago, but are run through a separate limited liability company (Waxholms Ångfartygs AB) (Landstinget, 2011a). In many ways, SL operates in a similar way to SEQ's TransLink. Both agencies oversee public transport without actually providing the services themselves. SL contracts out transport services to seven private operators. Focusing on bus services, SL notes that there are over 700 000 passengers using public transport in Stockholm on a normal weekday, with approximately 40% of those passengers taking the bus (Landstinget, 2011b).

Accessibility

From personal observation, there are two 'types' of bus service – there is one type of service that is oriented towards commuters, moving people between outer municipalities and the central city and another type of service that moves people around a municipality. The commuter services seem to generally use high floored buses with steps and no capacity to 'kneel' (image 2a), thus making access difficult or impossible for parents with prams. The 'city' services generally seem to use newer MAN Lion's City buses with low floors and 'kneeling' abilities to allow access for parents with prams (image 2b).

image 2a (left) and 2b (right).

2a shows an older style commuter bus without the capacity to kneel and with narrow entry and exit doors. Additionally, there are 2-3 steps up once inside the bus, making it additionally difficult to load a pram. 2b shows a city bus that is low floored, able to kneel and has double mid-bus exit doors allowing easy access for prams.

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: Times New Roman

Biçimlendirilmiş: Yazı tipi: Times New Roman

SL has introduced a number of enhancements to bus operations and policies to ensure that it is easier for parents with prams to travel on buses within Stockholm County. These include rear or middle door entry, large designated spaces to 'park' prams, ability to secure prams and payment policies. Each of these will be described and discussed in the following paragraphs.

SL provides designated pram 'parking' in the front and mid third of each bus. The pram parking is therefore directly opposite and/or adjacent to the rear or mid exit door (depending on the specific bus model). For ease of entry, the mid or rear exit door has a door opening button on the exterior of the bus (image 3) so parents with prams are able to open the door (if no one is exiting the bus) and directly enter the bus to park their pram in the designated area. An additional feature of allowing parents with prams to enter the bus via the mid or rear exit doors is that there is a much higher chance that space will be available to them, rather than having to take their chances in the queue with other passengers.

image 3. Button on the exterior of the buses by the mid exit door to allow parents with prams and people in wheelchairs to enter the bus easily.

Affordability

When accessing an SL bus with a pram that holds an infant or toddler, the parent is not required to pay where the fare (25 SEK or ~3 Euro) is collected or ticket stamped by the driver. SL explains that this is a safety issue so that the parent does not have to leave the pram and their child unattended while they move forward to pay or have their ticket stamped (SL 2010; M. Ellman personal communication 2012-05-15). This policy however, does not extend to commuter and local trains, trams, the metro or even buses where the driver does not collect the fare of stamp the ticket. An example of this would be at Liljeholmens bus terminal, where fares are checked or collected by a ticket attendant upon entering the bus terminal.

There is one other exception to the no fare for parents with a pram policy – if the pram is empty or is being used to transport other things, the person with the pram must pay the fare. The child does not have to remain in the pram while on the bus – the parents are welcome to hold the child and still ride for free.

While SL appears to note that allowing parents with a child in a pram to travel free on buses is a convenience and safety feature, it is also a step towards the County Administrative Board's goal of ensuring gender equality through improving access to public transport for parents (mothers in particular) and their children. It also allows stay at home parents the ability to get out of their residence and conduct 'normal' daily activities. However, if this were the case, having fare-free access to local trains, metro and trams would be a greater indicator of this goal. Having access for prams via the exits also allows parents an equal chance of 'getting a place' on the bus with other passengers who do not have an additional burden of a pram.

Children under the age of 6 should be accompanied on SL services. As long as the accompanying older person has a valid ticket, the child travels for free. From age 7 to 20, children and adolescents pay a cheaper concession fare when travelling on SL public transport services (SL, 2011b).

Assistance

While bus drivers generally do not provide assistance to parents with prams, there is some 'mechanical' assistance provided – having kneeling buses to reduce the gap between the floor and sidewalk, and allowing parents with prams to enter via the mid-exit doors.

Amenities

Depending on the specific bus model, there may be room for three to five prams (with no wheelchairs present) (figure 6). Once on board the bus, there is the possibility to secure the pram to the bus using provided straps, and there are signs asking that parents ensure that the pram is secured. Pram brakes are expected to be applied. Some bus models have fold-down seating so when there are no prams, more passengers can be seated.

Attitudes

Women need to be involved in planning, implementing and evaluating gender-sensitive transport policies and programs (Mashiri et al 2005). It has been noted that gender equality has a long and successful history in Swedish politics. Indeed the incorporation of gender into the transport sector began in the mid-1990s when the Swedish parliament adopted a national directive requiring all committees and working groups to include an analysis of how their proposals might affect gender equality (Polk 2004:181). By the turn of the century, Swedish transport departments made gender equity the sixth goal of transport policy in response to legislation enacted in 2001. The transport policy equity goal reads: “the transportation system shall be designed so that both women’s and men’s travel needs are satisfied; women and men shall be given the same possibilities to influence the system’s design, formation and administration; and women’s and men’s values shall receive equal consideration” (Proposition 2001/02:20, translated in Polk 2004:180). By 2003 this commitment had been further extended to include an objective to achieve “an equal distribution of power and influence between men and women in every mode of transport” (Vagland 2004:193).

A Network for Women in Transport Policy with around 100 members across Sweden was established in 2002 to make a contribution to attainment of the gender equality objectives (Vagland 2004:193). However, Polk (2004:182) notes that although gender mainstreaming has a prominent role in official transport policy and has encouraged more attention to what gender equity could mean in practice it has not necessarily resulted in any real integration in subsequent works. Indeed, it has been noted that “there is still a dominance of men in the transport sector, and most of the decisions concerning planning, designing, or managing the transport system are taken with out a proper gender analysis” (Vagland 2004:194).

Conclusion

In 1921, Edith Cowan, the first woman to be elected to an Australian Parliament raised the issue of women and children and transport in her maiden speech. She referred to the problems women with children had in getting prams onto trains and demanded that the Minister for Railways "parade the streets...for the whole of one afternoon with a heavy infant in one arm and a bag of groceries in the other!" (Tedmanson 1995 in PLM&GTA 1995:2). More than a century later the fundamental issues relevant to parents travelling with children have not changed significantly. This paper has argued that a just public transport system must take into account the travel needs of its most vulnerable users, children, and their parents.

Our transport systems are failing to meet the needs of parents and children (and other disadvantaged groups). In part this is because their transport needs need to be better understood "and not just defined as deviations from the normal" (Gallagher 1994:49). While this paper is by no means intended as an exhaustive or comprehensive analysis of the issues related to public transport for women and children it does aim to stimulate debate around and engagement with the political and practical issues associated with meeting their transport needs. It also aims to demonstrate the benefits of extending feminist analysis to include the concepts embodied in the child friendly cities agenda to delivery transport benefits to both children and their most often female carers. The idea of the child friendly city may be another way of addressing issues experienced by women, especially mothers because it draws attention to meeting the needs of vulnerable groups. It is hoped that applying the criteria in this paper may go some way toward assisting them to do so and delivering a public transport system in which both parents and children feel valued, welcome and as though they have "a rightful place on the buses" (Wright 1994:33).

THE EFFECT OF LAND USES LEGISLATION IN THE FUNCTIONAL STATUS OF THE GREEK URBAN TISSUE

Dimelli Despina[1], Vakalopoulos Dimitrios[2], Dimelli Maria[3].

Abstract

The paper will focus on the way the land uses legislation has until today shaped the Greek cities functional character. It is divided in two parts. In the first part, the historical frame that shaped the Greek cities functional status is examined in an effort to realize the parameters that have influenced the functional character of the Greek cities. The period that will be examined starts in 1831 when the first decree for the development of the remains of the war gave every Greek citizen the right to own a certain piece of land where he could construct his house, with some restrictions. Through time the effort of the state was to control cities through restrictions, aiming to their development based on hygiene rules as rapid population increase was noticed. The paper will examine the basic legislative rules that have tried to control land uses until today and it will focus on their effect in the Greek urban web.

In the second part the research will evaluate the effectiveness of today's land uses legislative framework, using two case studies. The first area that will be examined is the metropolitan basin of Athens, the area that concentrates the country's population and employment majority. The second case study is Athenians municipality the core that today is the central area of the basin, the initial core that has been constantly functioning since the creation of the Greek state

The methodology that will be used includes three steps. In the initial step it will focus on the kinds and posts of land uses before the application of the plan that defined the desired land uses structure and allocation. That will be realized with the use of Principal Components Analysis on the recorded employment in urban functions and the investigation of its allocation. In the second step it will examine the intentions of planning and the result it aims to induce. Finally in the third step the same procedure with the first step will take place, but with the use of records that were selected ten years later, in order to reveal the kinds and posts of land uses after planning. The evaluation will result from the compare of the aims of planning and the shaped status after the legislative plan's application. This will show if planning was effective and the examined areas have been developed as they were planned or if finally other parameters have

[1] Technical University of Crete, Sarantaporou 6, email:dimelli@arch.tuc.gr

[3] PhD candidate in Urban Planning N.T.U.A. Ploutarhou 17-19 Athens, email:dimellimar@dsa.gr

deteriorated the initial plan and finally city is shaped under the influence of other stronger incentives.

1. Introduction

After the creation of the Greek state, the efforts for the development of Greek cities were taking place with different intensity through the years. The first plans of the proposed cities initially showed the shapes of the building blocks and the posts of public uses. Through time, more kinds of uses that were allowed to be allocated in certain city's posts and progressively more restrictions were legislated. The initial intension for the regulation of public uses was replaced by the creation of rules that tried to manage the mixture of all uses. These continuous changes have led to the functional changes of the areas where they were applied. These changes and the degree of the effect of urban legislation are the subject of the current research. Because of the plethora of the many and different laws that have been legislated and concern all Greek cities the research will focus only in the laws that concern land uses as these constitute the basic factors that shape the city's functional structure.

The case studies that will be examined are the metropolitan basin of Athens, which concentrates the majority of population and employment. The research will focus on its functional structure before and after the application of its regional plan in order to evaluate its effectiveness. The second case study is the Athenians municipality. The research will evaluate if Planning took into consideration the existing functional structure of the capital's center and then it will investigate the degree of effectiveness of the existing legislative framework.

2. The land uses legislation from 1833 until today.

The creation of the New Greek state was a fact since 1831. The ruins of the war were the remains where the Greek cities had to be developed. The first effort for the new cities reconstruction took place with a decree that was signed by the first Greek Governor J. Kapodistrias. According to this decree, every Greek citizen had the right to take a piece of land (from 300-450 square meters) where he could construct his residence. The restrictions that this decree had were that the houses had to be built in one year, this property could not be sold and that the State could primarily choose the areas where the public buildings could be built.

A representative plan of the way land uses were allocated in the cities is the plan of Kleanthis and Shaubert that was designed in 1833. This plan was never applied but it is a strong example of the way Urban Planning defined the positions of public uses. It is also characteristic that planning took into consideration public buildings and high income class. The low-income class and the industries were allocated in areas close to the cities without any restriction. Two years later, a decree that was legislated and was named as "the decree for the healthy construction of cities" defined that public buildings had to be

constructed in the cites, the hospitals and the slaughterhouses out of the cities in areas where the air was clean, the industries could be constructed after they ensured police license and finally the tanneries in a half hour distance away from the cities.

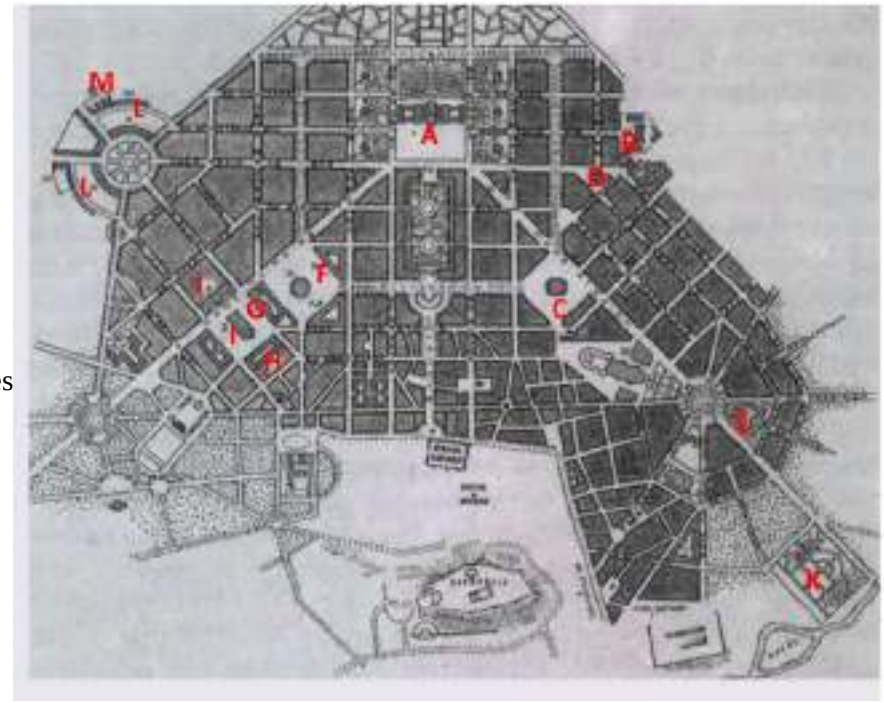

Fig. 1- The Kleanthis and Shaubert plan.

Progressively most of the Greek cities were planned this way, until 1922 when 1,5 million refugees arrived in Greece. This arrival led to the need for the creation of new residence areas that were allocated on the empty fields close to the existing industries. Except from the rich refugees that chose the suburb of Nea Smirni, the rest were directed to the West industrial basin where small houses with cheap materials were constructed and the living conditions were difficult.

All this pressure led one year later to the creation of a decree that has affected decisively the Greek Urban status. As for land uses, in this decree restrictions were mentioned in four articles. The first innovation that was imported was that all areas primarily would be residential and after this condition was satisfied, all other uses would be allocated. The second innovation that was imported was that industries could not be allocated in the city's tissue, as they were until now, but they had to be away from urban areas.

The decree that changed the way land uses were allocated in Greece was legislated 56 years after 1923. In articles 3 and 4 of the 1979 decree, two categories of land uses are

defined, the general uses and the particular uses. The innovation of this decree was that it imported categories of land uses, attempting to create multi-functional areas.

Only one year later (1980) a new decree for land uses was legislated. It was innovate as it tried to connect the land uses with the building restrictions. It defined eleven categories of land uses, it separated the industrial uses from residence and the rest urban functions and it defined for the first time two categories of residence, the Unmixed residence and the General residence. The Unmixed residence aimed to the creation of areas where strictly residence was allowed with some small supplementary uses, as small shops. On the contrary, the General residence was a category that included residence, shops, hotels, restaurants, education and cultural uses and other functions.
Two years later, in 1983 a new decree tried to "manage" the Greek cities. It was the time the "Enterprise of Urban Reconstruction" was founded and it focused in the creation of Greek cities with standards, trying to provide the necessary infrastructures for the Urban tissue.

Although this decree did not have specific rules for land uses, the majority of plans that were created after its legislation were based on categories as urban centers, residence, industry, education, disconnecting land uses from building restrictions.
The fact that no certain decree for land uses existed, led four years later, in the legislation of a decree that until today constitutes the base for urban planning. The decree of 1987 defined nine categories of land uses and its main objective was the mixture of land uses. It is characteristic that land uses participate in many categories. It is also interesting that residence exists in seven of the total nine categories.

Although many laws have since then been legislated regarding urban planning it is remarkable that a new land uses decree has yet not been legislated, but Planning is still based on a decree that was legislated 24 years ago. The explanation that can be formulated is that this decree is successful so it does not have to be changed. But is the existing decree for land uses of Greece successful? For the evaluation of the decree's effectiveness, the current paper will focus on the way land uses are allocated after the application of the existing land uses legislation examining two case studies of its application in the most complicated areas of the Greek urban tissue.

3. Methodology

The main aim of the research is to examine the form and the composition of land uses groupings. The land uses groupings will be revealed with the use of Principal Components Analysis. This statistical technique reveals the structures of the variables that are inserted in the Analysis, which in our case are land uses, measured by their recorded employment (Dixon, 1983). These Analyses reveal the functional structure of the examined area expressed by the extracted Components. These Components are structured by the best linear relationship of the land uses. That is to say, which land uses

are areally related. Finally, the Components are rotated in Varimax rotation, which allows the best thematic and areal correlation of land uses (Brannen,1989).

4. The Athenians basin.

The concentration of the population's majority in Athens the capital of Greece with different intensity that varied according to political, social and economic conditions with the simultaneous lack of Planning led to a laissez-faire in land uses allocation. Although many plans were created, after the second world, it was 1985 when for the first time a regional plan for the Athenians basin was legislated. Its main aim was to encourage a multi-centric development in order to decongest the central overpopulated center. The question that arises is if this aim was achieved or if the freedom that was provided allowed a different status in land uses allocation.

4.1. The Athenians basin in 1978.

In 1978 the Athenians basin was a pole of new residents attraction, with industrial zones developing in its around while the tertiary activities were developing in its central core. The employment that was recorded was 619.664 people. The majority of employees were concentrated in the tertiary sector (57%) while the industrial and manufacture activities gathered the 43% of the recorded employment. This time as told, in the Athens basin existed nor regional neither urban planning, in order to define the detailed allocation of the 37-differnent kinds of land uses. So, the main parameter that influenced land uses allocation was the coverage of the basin's citizen's everyday life needs that ensured the best activity's function, hence it's maximum profit.The extracted functional structure, from the Principal Component Analysis, in 1978 is composed by five components that explain the 24,5% of the total variance of the existing employment situation (Table 2). The first group of land uses (composed by 12 of the 14 tertiary activities) defines Urban Centers while the rest four groupings are formed exclusively by the remaining 23 industrial uses.

The study of the central uses allocation (Fig. 3) shows that they are concentrated on the Athens center and they have also shaped five (5) sub-centers distributed in areas that cover the wider region's needs. The industrial uses are all (and the four components) allocated with common principles. They are concentrated in the central area due to the lack of planning restrictions and also distributed in the total of the basin, with intense condensation in the west traditionally industrial area (Fig.4).

It has revealed that although restrictions regarding land uses did not exist, the activities themselves seeking to take advantage of the profits that can be ensured by certain areas position have shaped cores where activities are concentrated. It has also revealed that industrial uses have shaped groups as they need areas with common characteristics that

means low land prices and adjacency with main axes and in some cases they function on an assembly line.

Table 2. The Land Uses Groupings in 1978

Component	Economic activity
CENTRAL DAILY NEEDS LAND USES	Retail Trade
	Wholesale Trade
	Transactions of Affairs
	Brokers and representatives

4.2. The Regional plan of 1985.

The congestion of the Athenians center and the intense air pollution led in 1985 in the legislation of the first regional plan for the Athenians basin. Its basic aim was the development of sub-centers in order to achieve multi-centric development. The regional plan was followed by local plans for each of the 54 municipalities that were based on sub-centers development. The new legislated centers hierarchy and their allocation in the Athenians basin is shown in Figure 5. In these areas the land uses that were allowed to be allocated were central uses that is to say trade, offices and other tertiary activities as well as residence.

4.3. The Athenians basin in 2001.

Since 1978 the basin's population and employment was continuously increasing and from the middle of the 90's it is stabilising with a very small reduction. Meanwhile, planning has discouraged the manufactures that pollute the environment but it has also allowed land uses mixture. The majority of employment is recorded in tertiary sector while the employees in manufacture are reduced.

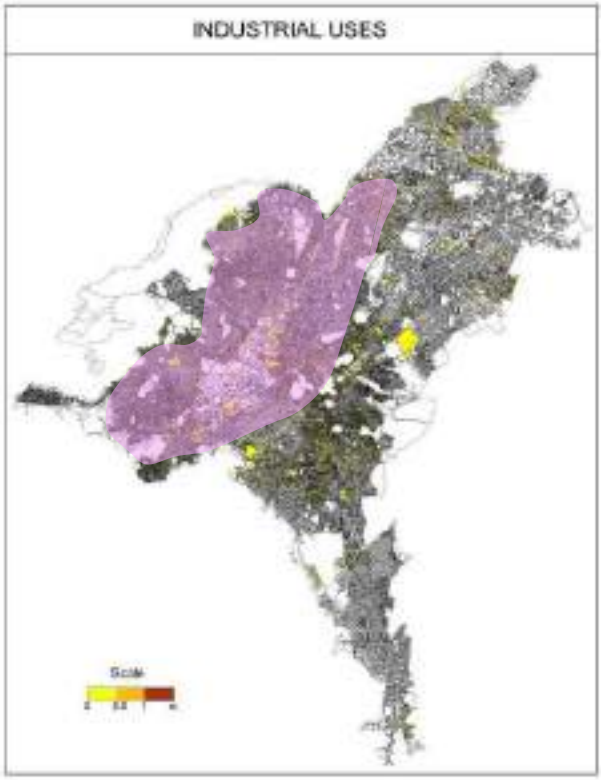

Fig.4 The allocation of industrial uses

Fig.5 The allocation of central activities according to the 1985 regional plan.

The examination of the activities structures that have been created according to the 2001 census, shows that five groupings of land uses are revealed (Table 6). The first grouping concentrates the majority of activities. It is composed by manufacture, constructions, trade, hotels and other incompatible activites. Some of its elements are functionally related while others seem to take advantage of each area's characteristics. The second grouping includes central bussiness district functions as it is composed by supralocal activities that require accessability (Bourne,1972) . The third and the forth groupings are composed by manufacture activities that are functionally related and "prefer" areas with low land prices. Finally it is characteristic that the fifth grouping includes only transport activities, fact that shows that some activities create specialized structures.

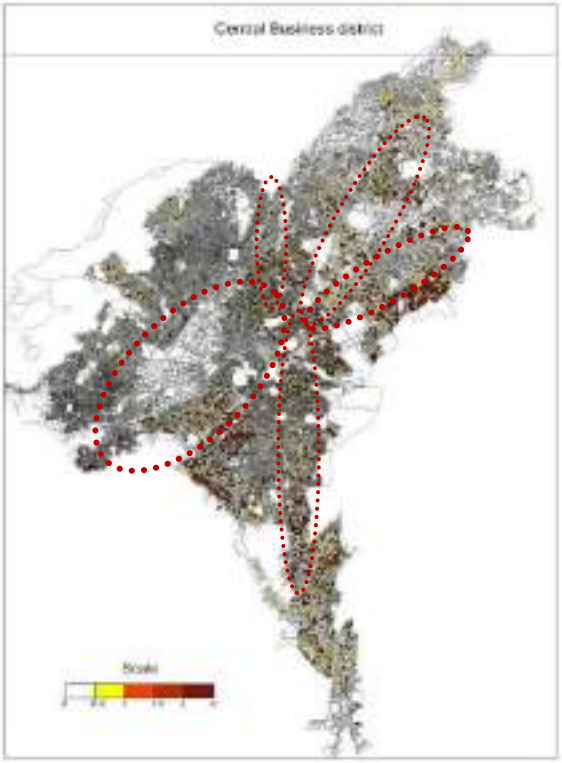
Table 6. The Land Uses Groupings in 2001.

Component	Economic activity
Constructions, trade and services	Constructions
	Clothing manufacture
	Hotels and restaurants
	Retail trade
	Manufacture of metallic products
	Furniture manufacture
	Recreation, cultural and athletic activities
	Travel agencies
	Food manufacture
	Publications
	Transport
	Administration and social seervices
	Other services.
	Textile manufacture
	Trade
	Plastic equipment manufacture
	Timber manufacture
	Paper production
	Basic metals productin
	Leather production
	Organisations
Central bussiness district	Finance organsation
	Education
	Health
	Information technology and relevant activities.
	Post offices and telecommunications
	Insurances
	Air transports.
	Chemical goods production
Rentings and manufactures.	Equipment renting
	Tobacco pruduction
	Oil and fuel Production
	Vehicles trade
	Research
	Computer production
	Real estate
Manufactures of engines	Production of engines
	Medical tools production
	Electrc engines production
	Manufacture of equipment
	Cars production
Transports	Water transport
	Manufacture of of transports equipment.

The areal distribution of the five groupings is shown in Figures 7-11. The first grouping appears with intense condensation in the central area of the basin where intense residence is also recorded in 2001 and it is less intense in more distant from the center areas (Fig. 7). The second, central businesses district grouping is concentrated on main road axes that "begin" from the center of the basin and cross it towards all directions except the east industrial area (Fig. 8). Finally, the three rest groupings are almost uniformly distributed in the basin's area. The fact that the central activities, as trade services and offices, are concentrated in the center shows that the aim of multi-centric development has not been achieved while the fact that the rest groupings are uniformly distributed is a sign of satisfactory service in local level. So the fact that groups of incompatible activities are concentrated in the basin's center is evaluated negatively as functions as manufactures of plastic and timber overload the environmentally congested central area.

Figure 7. The allocation of trade constructions and services.

Figure 8. The allocation of central business district



In 2001, the majority of the recorded cases shows that tertiary and manufacture activities are more intensively mixed. Therefore, the thematic mixture of land uses remains random in the majority of the recorded cases. In the north south and east basin in 2001

the new mixed uses groupings are scattered in all areas where intense central functions groups are also allocated. It seems that the activities of this grouping, that are mixed in a random way, are allocated with the criterion of the maximum coverage of the until then not satisfactory served areas. Therefore, new enterprises of all kinds avoid the congested center and prefer areas that had not until then developed functional centers but had increasing population.

Figure 9. The allocation of Rentings and manufacture

Figure 10. The allocation of Manufactures of engines

Figure 11. The allocation of Transports

So, autonomous areas have started to develop, concentrating all kinds of functions. This auto-regulation that is not exactly following the legislated plans, that tend to sub-centers creation, show that traffic minimization has up to a point been achieved, while autonomously functioning sectors are created with a big degree of randomness. It is concluded that a thematic and areal balance has not yet been achieved. This phenomenon is related to the constant employment and population increase of many areas assisted by the freedom that is provided by the existing legislative framework**.**

5. The Athenians municipality.

The Athenians municipality constitutes the most populated municipality of Greece, as it concentrates 313.177 residents. The first Urban plan for the municipality was created in 1989 and it was modified two times in order to adjust to small local level changes. Its recorded employment has decreased in all sectors more intensively in manufacture and industries.

5.1. The functional structure of the Athenians municipality in 1988.

The execution of Principal Components Analysis in the 1988 recorded employment has revealed 15 kin land uses groupings, that can be grouped in four categories: the Urban centers (4 components), the manufacture uses (5 components), the industrial uses (4 components), and the incompatible uses (2 components). The last group includes uses that should not co-exist (schools and industries) but they are recorded in the same areas taking into advantage the lack of restrictions. The revealed components are shown in Table 12. It is realized that although there was not any legislative restriction to define the kind and the position of land uses, they have created groups that optimize their function The allocation of the four groupings categories is shown in Figure 13.
The industrial and manufacture uses are allocated in the municipality's center and in its west areas while urban centers are allocated not only in the central area but also on main road axes sides. Finally, the incompatible uses groupings are allocated in residential areas.

Table 12 The functional structure of the Athenians municipality of 1988.

Components	Economic activities	Loadings
Manufacture uses	Leather and furs Industries	0,802
	Clothing and footwear Industries	0,769
	Rest Industries	0,618
	Wholesale Trade	0,539
Urban Centers	Banks and rest Economic Institutions	**0,670**
	Brokers and representatives	**0,588**
	Retail Trade	**0,522**
	Transactions of Affairs	**0,460**
Incompatible grouping	Industries of Oil and Mine products	0,595
	Insurances	0,837
Manufacture uses	Industries of products from tyre and plastic material	**0,746**
	Industries of Furniture and goods of furnishing	**0,627**
	Industries of Timber and Cork	**0,583**
Manufacture uses	Tobacco industries	0,824
	Printing, Publications and relevant activities	0,783
Urban Centers	Education	**0,760**
	Services of Recreation and Culture	**0,618**
Industrial uses	Chemical industries	0,804
	Textile Industries	0,794
Industrial uses	Basic Metallurgic Industries	**0,684**
	Manufacture of metallic products	**0,600**
	Manufacture of electric machines, appliances and	**0,425**
Industrial uses	Industries of not metal mining products	0,615
	Manufacture of machines and appliances	0,615
Manufacture uses	Storages	**0,830**
	Wholesale trade of Litter and Clippings	**0,446**
Industrial uses	Paper Industries	0,762
	Manufacture of Carrier means	0,706
Incompatible grouping	Restaurants and Hotels	**0,595**
	Transports	**0,535**
	Personal Services	**0,485**
Urban Centers	Communications	**0,744**
	Social Security	**0,722**
Manufacture uses	Drinks Industries	0,769
	Industry of Food except drinks	0,550
Urban Centers	Mobile Renting	**0,726**

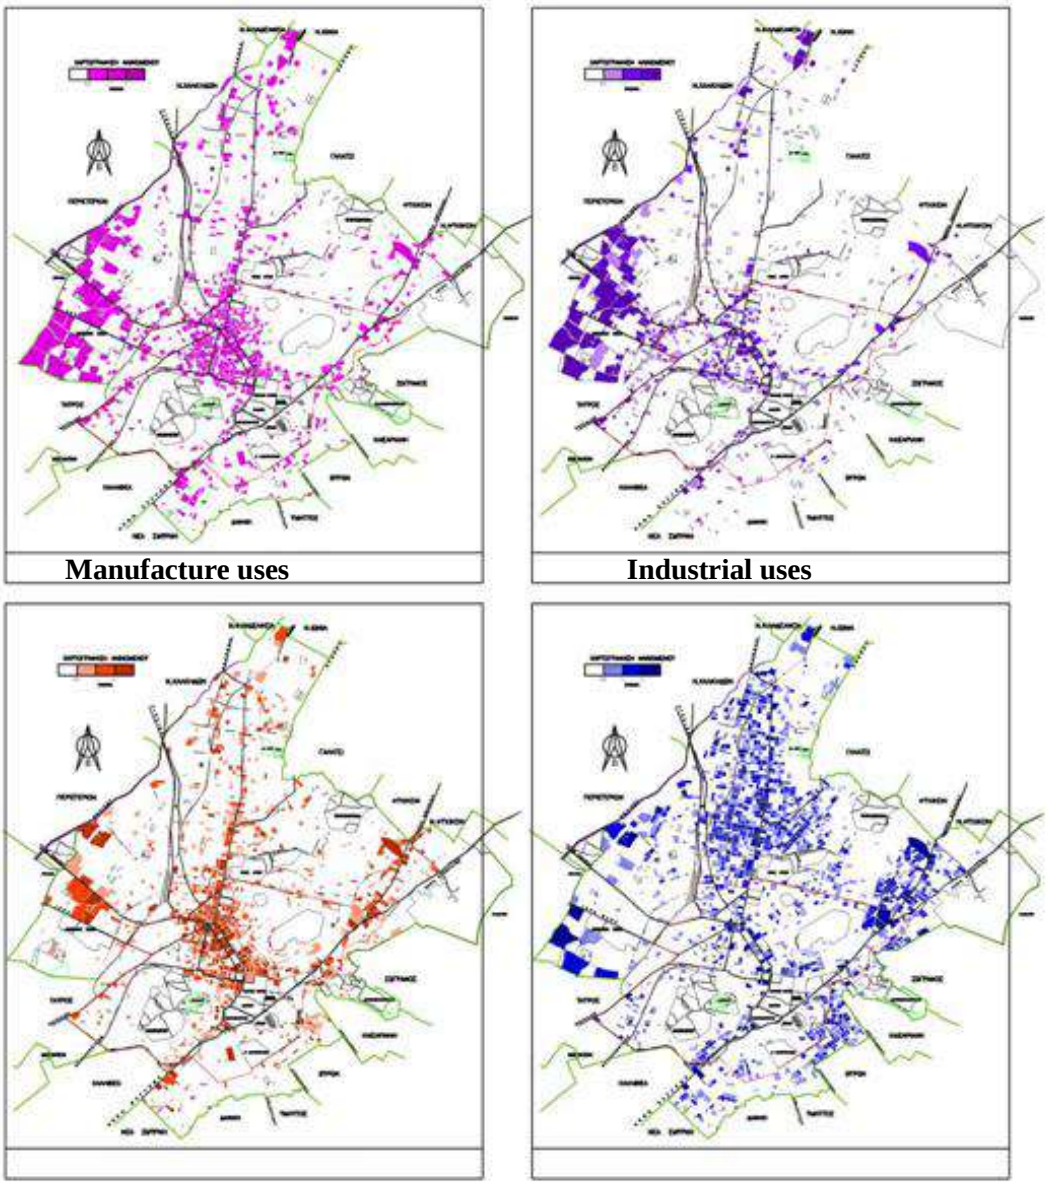


Figure 13. The allocation of the functional structure's components in the Athenians municipality in 1988.

5.2. The Athenians municipality urban plan.

The priority of this plan that was legislated in 1989 was the reveal of the municipality as a metropolitan center with the simultaneous removal of all the uses that degraded the

area. The kinds and posts of the allowed uses are shown in figure 14. It encouraged land uses mixture but it limited the incompatible uses, as the allowed uses were all compatible.

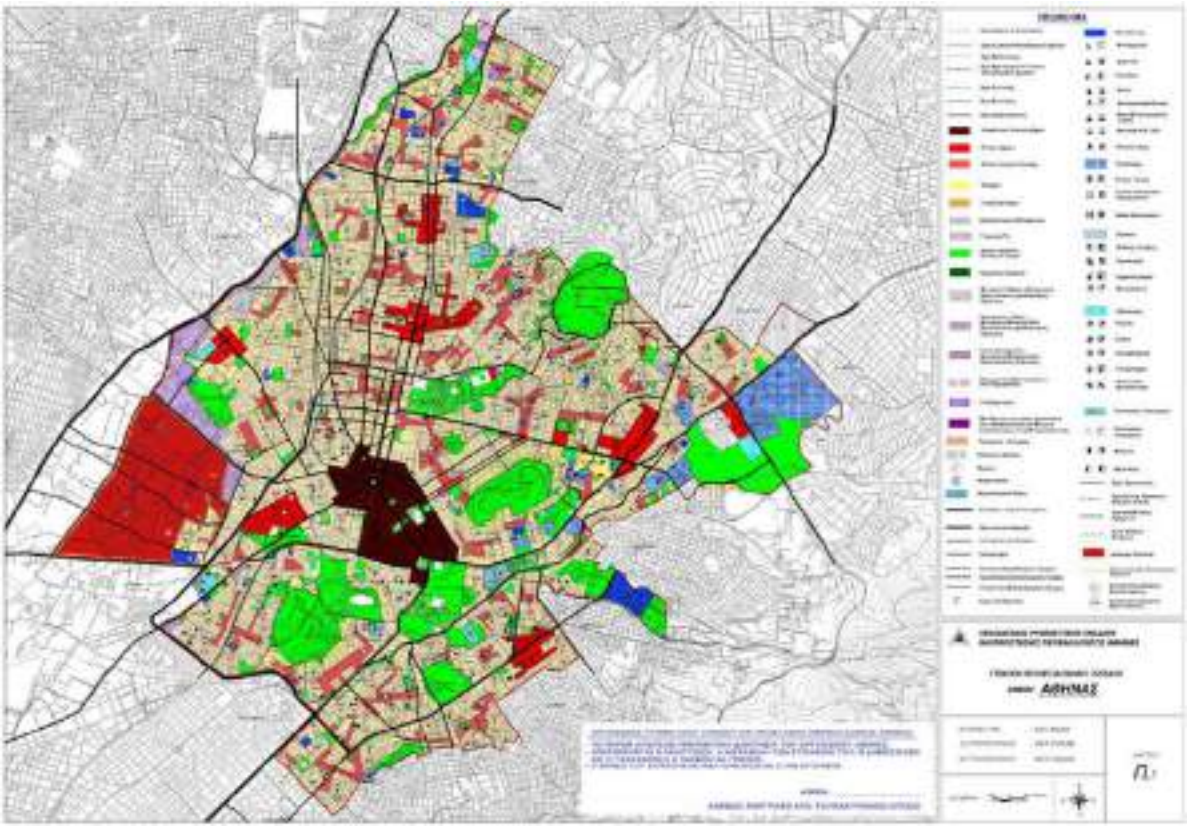

Figure 14. The Urban Plan of the Athenians municipality.

It is obvious that manufacture areas were delimited in specific city's parts while the center concentrated the supra-local central activities. It is also realized that a multi-centric development was proposed as urban sub-centers are legislated in many city's parts.

5.3. The functional structure of the Athenians municipality in 2001.

The execution of Principal Components Analysis in the 2001-recorded employment revealed nine land uses groupings that are grouped only in three categories as incompatible land uses groupings don't exist. It is shown that since 1988 urban centers

have been created and are divided in three different groups, while manufacture and industrial groupings are reduced (Table 15).

Table. 15 The functional structure of the Athenians municipality of 2001.

Components	Economic activities	Loadings
Urban Centers	Education	0,75
	Other services.	0,73
	Health	0,67
	Recreation, cultural and athletic activities	0,64
	Hotels and restaurants	0,57
	Publications	0,56
	Information technology and relevant activities.	0,54
	Retail trade	0,52
	Post offices and telecommunications	0,49
	Insurances	0,44
	Research	0,41
	Air transports.	0,33
	Chemical goods production	0,32
Industrial uses	Water transport	0,71
	Constructions	0,65
	Textile manufacture	0,58
	Manufacture of metallic products	0,56
	Land transports	0,51
	Clothing manufacture	0,44
	Furniture manufacture	0,43
	Food manufacture	0,42
	Manufacture of equipment	0,40
	Electrc engines production	0,39
	Timber manufacture	0,35
	Plastic equipment manufacture	0,34
Industrial uses	Oil and fuel Production	0,48
	Paper production	39,00
Urban Centers	Real estate	0,66
	Finance organsation	0,30
Manufacture uses	Medical tools production	0,60
	Manufacture of of transports equipment.	0,34
Urban Centers	Organisations	0,86
	Administration and social seervices	0,55
Manufacture uses	Tobacco pruduction	0,54
	Leather production	0,36
Industrial uses	Production of engines	0,65
	Vehicles trade	0,51
Industrial uses	Engines production	0,78

The above groupings allocation is shown in Figure 16. It is obvious that the manufacture and industrial activities have moved from the municipality's center, while central activities are allocated there in a nucleus form.

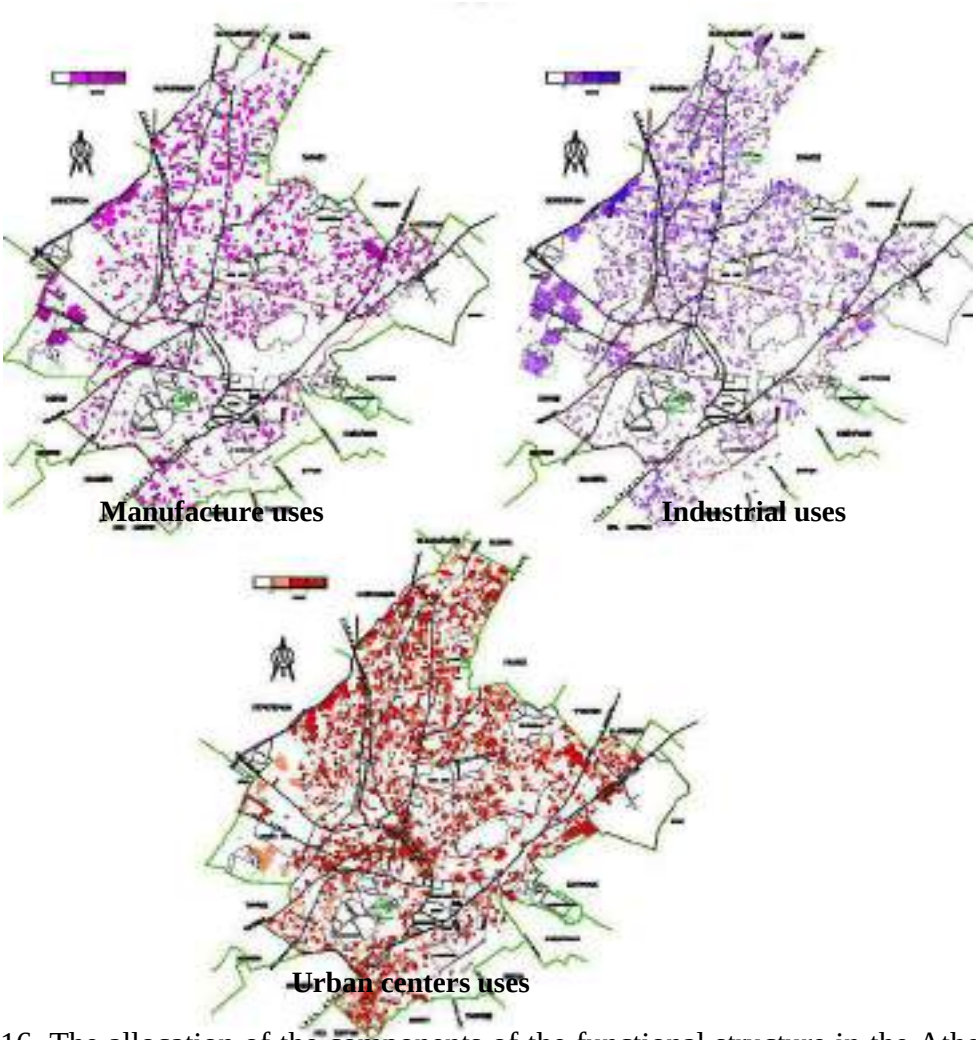

Figure 16. The allocation of the components of the functional structure in the Athenians municipality in 2001.

Therefore, it is concluded that in the case of the Athenians municipality, Planning that took into consideration the existing functional status did not succeed to shape a new functional character in the municipality. The new groupings that have been shaped are composed by functionally relevant activities that are up to a point allocated in the proposed by Planning posts. New sub centers have been created while incompatible functions co-existence does not exist. But is has failed to result its initial aim as still manufacture and industrial uses are recorded in scattered form in areas where residence and its supplementary uses that is to say manufacture with no further specification are allowed The fact that the land uses decree provides a freedom in the allowed categories shows that land values and market forces can shape their own functional status

It results that Urban Planning must focus on the particularities the cities have and the parameters that shape city's development and propose specialized solutions in order to achieve the best urban function that will lead to the city's citizen's best living conditions.

6. Conclusions

The aim of the current research was the investigation of the effectiveness of the existing land uses decree of Greece. The two case studies that have been examined are the most complicated functionally areas of the Greek urban tissue so they constituted the proper areas for the aim of the research.

It is concluded that in the Athenians basin as well as in the Athenians municipality land uses structures and allocation have up to a point been achieved according to the existing corresponding regional and urban plan. It is obvious that urban planning does not seek for zones of certain activities and that land uses have to be mixed in order to create livable cities. However, when this mixture is thoughtless and market forces create structures based on the highest possible profit then it is concluded that restrictions should be imposed. Legislation has up to a point influenced this development as it has some restrictions especially in the allocation of industrial uses but it also provides freedom for the rest land uses to be allocated in the majority of urban web. Therefore, it is obvious that Urban Planning must focus on the particularities the cities have and the parameters that shape their development and propose specialized solutions in order to achieve the best urban function that will lead to the city's citizens best living conditions.

Resilience in the transition town movement - 3.1 The idea of transition - 3.2 Origins and quantitative consistency – 3.3 Purpose and principles - 3.4 Common characteristics – 4. Conclusions. Towards new territorial governance in urban development and spatial planning? - References.

Abstract

The concept of resilience, typical of natural sciences, is some years joined in the glossary of spatial planning. In particular, in the urban scale, it is usually associated with initiatives of the transition town movement (Hopkins, 2008 and 2011). This movement is one of the recent and bottom-up initiatives led by civil society. The transition towns, better called “urban initiatives for the transition”, are a set of bottom-up practices of urban organization, inspired by the concept of resilience, aimed at achieving a self-sufficient, sustainable and “zero impact” model of urban development. In this perspective, the research question is: are the transition towns model the only possibity to apply the cultural concept of resilience in spatial planning?

The paper will explore the ethical dimension of the concept of resilience in spatial planning. The purpose is to understand the real innovation extent in planning practices and territorial governance. The paper will also investigate common elements and characteristics of resilient communities with particular reference to the role of institutions and to territorial governance (North,

1 Politecnico di Torino - Interuniversity Department of Regional and Urban Studies and Planning (DIST), viale Mattioli 39, 10125, Torino, e-mail: grazia.brunetta@polito.it.

2 Politecnico di Torino - Interuniversity Department of Regional and Urban Studies and Planning (DIST), viale Mattioli 39, 10125, Torino, e-mail: valeria.baglione@polito.it.

1990). As initial hypothesis, the concept of resilience is unexplored in spatial planning. As Walker B. says, resilience is « […] *the capacity of a system to absorb disturbance and reorganise while undergoing change, so as to still retain essentially the same function, structure, identity and feedback*» (Walker et al., 2004, p. 5). The resilience is therefore a bottom-up process that could deeply change the role of institutions and the community in the territorial governance. Could this new paradigm of development and spatial organization really be – in what mean and by what tools - a new approach in the local governance?

The paper will provide first a reflection on the ethical value of the concept of resilience applied to spatial planning. Secondly, the paper will identify a list of elements, common to all resilient communities. The survey will look how the concept of resilience is declined in the main and most significant experiences of the transition town movement. More specifically, it will be referred to a collection of virtuous examples of transition town, belonging to the European and global context. Some elements investigated in empirical analysis are: spatial extent, the role of actors, fields of action, tools and policies.

The main outcome aims to reflect on the epistemological dimension of the concept of resilience. In particular, the reflection is about the implications of the concept in spatial planning. The related outcomes aim to reflect the perspective of the istitutional innovation. In other words, the paper will demonstrate, starting from the empirical analysis and the comparison between similar experiences of transition town, if could be promoted institutional learning. Finally the paper will attempt a prospect of a new territorial governance.

1. Introduction

The concept of resilience, widely studied in ecology, has recently become part of the glossary of spatial planning.
According to an theoretical initial hypothesis, it means «*the capacity of a system to absorb disturbance and reorganise while undergoing change, so as to still retain essentially the same function, structure, identity and feedback*» (Walker et al., 2004, p. 5). This definition has been randed in the spatial metaphor of “resilient city”.
A more thorough inquiry (Folke, 2006) into the adaptive capacity of social-ecological systems instead underlined the real innovation of the concept of resilience. This second definition allows the study of a recent phenomenon in which the resilience concept has been implemented in the spatial metaphor of “transition town” (Hopkins, 2008 e 2011). This movement has already spread

into several contexts. Yet despite this phenomenal growth and the wave of positive publicity the movement has received, there has to date been very little empirical research into the development and character of these initiatives, or the impact they have achieved and the barriers to be overcome (Seyfang, 2009).

The paper will discuss the following three issues concerning to the concept of resilience in spatial planning: (i) the first relates to its origin and evolution in theoretical debate, (ii) the second identifies its innovational meaning in spatial planning and (iii) the third considers an approach linked to the ongoing territorial governance processes.
In particular, the paper proposes:

- a review of the main theories of resilience;
- a list of criteria for empirical analysis (spatial extent, role of actors, fields of action, planning tools, local policies) of the transition town experiences;
- a perspective on the true extent of the innovative concept of resilience and possible implications in terms of territorial governance.

The aim is to formulate the first answers to some fundamental research questions: is the transition town the only model to apply the concept of resilience in spatial planning? Could this new paradigm of urban development really be a new approach in local governance?

2. Resilience. Definition, origin and evolution

The concept of resilience has been widely studied in many disciplines (Seyfang, Haxeltine, 2009). First formulated in ecological sciences (in the 1960s-1970s), and particularly in a special branch of ecology, this concept has influenced many other research fields including anthropology, human geography and other social sciences (Folke, 2006).
Today it is the heart of the research and debate in the sustainable development field. Recently, the concept of resilience has also been discussed in the urban and regional planning sector.

2.1 The origin of the concept in ecology

Early studies in the Sixties and Seventies[3], essentially based on empirical

3 See: Holling, C.S., 1961. Principles of insect predation. Annual Review of Entomology, 6, pp. 163–182; Lewontin, R.C., 1969. The meaning of stability. In: Diversity and Stability of Ecological Systems. Brookhaven Symposia in Biology, 22. Brookhaven: New York;

analysis of ecosystem dynamics through mathematical models, focused on resilience as the capacity to absorb shocks and still maintain its functions. Holling (1973) proposed that «resilience determines the persistence of relationships within a system and is a measure of the ability of these systems to absorb changes of state variables, driving variables, and parameters, and still persist» (p. 17).
In this theoretical perspective, the consequent policies relating to natural resource management were “linear approach” type (Folke, 2006).

Since the Nineties[4], when ecosystems analysis on a large-scale included the social sphere (institutions and people), the necessity for policies to manage by change rather than simply to react to external shocks emerged. These policies should imply uncertainty and surprise[5], or - as we say today - a dynamic ability to adapt to the evolving external disturbances through time and space. This vision has led to the study of socio-ecological systems (Folke 2006; Gallopin 2006), which are conceptualization models of linkage between the human and ecological spheres, useful to identify practices of adaptive management[6]. In this approach, the concept of resilience shifts from a system capacity which maintains its original status towards a system capacity able to adapt, innovate and transform, under certain conditions, into new more desirable configurations. It also «*concerns the capacity for renewal, re-organization and development, which has been less in focus but is essential for the sustainability discourse.* […] *In a resilient social-ecological system, disturbance has the potential to create opportunity for doing new things, for innovation and for development*» (Folke, 2006, p.259).

Pickett et al. (2004) therefore recognize two distinct research phases in the evolution of the concept of resilience, one based on balance and the other based on imbalance. In the first phase, the resilience is the system's ability to

Rosenzweig, M.L., 1971. Paradox of enrichment: destabilization of exploitation ecosystems in ecological time. Science, 171, pp. 385–387 and May, R.M., 1972. Will a large complex ecosystem be stable? Nature, 238, pp. 413–414.

4 Especially after the publication of the volume *Barrier and Bridges to the Renewal of Ecosystems and Institutions* by Gunderson et al. (1995).

5 For a further, see: Carpenter, S.R., Gunderson, L.H., 2001. Coping with collapse: ecological and social dynamics in ecosystem management. BioScience, 51, 451–457 and Berkes, F., Colding, J., Folke, C., eds., 2003. Navigating Social–Ecological Systems: Building Resilience for Complexity and Change. Cambridge (UK): Cambridge University Press.

6 Recent advances include understanding of social processes like, social learning and social memory, mental models and knowledge–system integration, visioning and scenario building, leadership, agents and actor groups, social networks, institutional and organizational inertia and change, adaptive capacity, transformability and systems of adaptive governance that allow for management of essential ecosystem services (Folke, 2006).

return to the starting point by overcoming a crisis period; in the second more inclusive one, it is the system's ability to adapt to internal and external disturbance (Gunderson, Holling, 2002; Gunderson et al., 2010).
So Folke (2006) defines resilience as the characteristic which «*emphasizes non-linear dynamics, thresholds, uncertainty and surprise, how periods of gradual change interplay with periods of rapid change and how such dynamics interact across temporal and spatial scales*» (p. 258).
Following Carpenter et al. (2001), social-ecological resilience is interpreted as (Folke 2006):

- the amount of disturbance a system can absorb and still remain within the same state or domain of attraction.
- the degree to which the system is capable of self-organization (versus lack of organization, or organization forced by external factors).
- the degree to which the system can build and increase its capacity for learning and adaptation.

Even today, resilience is defined in the literature as the ability of a system to absorb external disturbance and reorganize itself on the basis thereof to return to the same function, structure and original identity (Walker et al., 2004). According to social system analysis, resilience is defined as the ability of human communities to withstand external shocks such as social, environmental, economic or political ones (Adger, 2000). In the opinion of Folke (2006) «[…] *resilience is not only about being persistent or robust to disturbance. It is also about the opportunities that disturbance opens up in terms of recombination of evolved structures and processes, renewal of the system and emergence of new trajectories*» (p. 259). From this perspective, he proposes (2006) the theory of the adaptive renewal cycle, a heuristic model based on dynamic ecosystems observation, divided into four phases of development driven by discontinuous events and processes: «*there are periods of exponential change (the exploitation or r-phase), periods of growing stasis and rigidity (the conservation or K-phase), periods of readjustments and collapse (the release or omega-phase) and periods of re-organization and renewal (the alpha-phase). The sequence of gradual change is followed by a sequence of rapid change, triggered by disturbance*» (p. 258). The cycle rapidly repeats itself over time retaining the experiential memory of the previous phases (Panarchy model): «*the panarchy is therefore both creative and conservative through the dynamic balance between rapid change and memory, and between disturbance and diversity and their cross-scale interplay*» (Folke, 2006, p. 259).
The latter definition adapts to peculiarities of the complex systems «*because it is more dynamic and evolutionary*» (Pickett et al., 2004, p. 373). It enables the use of the concept of resilience in spatial planning. Cities, by their nature, are

evolving complex systems and, thereby, they are subjected to constant external disturbances. At the same time, they are able to respond to disturbance with a spontaneous and self-organised behavior (Jacobs, 1961).

2.2 Evolution of the concept in spatial planning

What led spatial planning to tap into the ecology glossary and toolbox?
According to Pickett et al. (2004), ecology and spatial planning share both the use of metaphor and the relationship between structure and function.
In spatial planning metaphor has traditionally had a particular appeal; the most famous is Howard's Garden City but there are also the first hypotheses of bioregionalism formulated by Geddes and Mumford at the beginning of the Twentieth century.
Today the new metaphor of “resilient city” (Musacchio, Wu, 2002; Newman et al., 2009; Otto-Zimmermann, 2011) could be the synthesis between ecology and spatial planning. It suggests the vision of the city as a complex system able to withstand external disturbance and, at the same time, to react flexibly, to adapt gradually and to learn from the past. In this synthesis the metaphor, based on resilience, seems to outstrip the traditional and well-established paradigm of sustainable development. This traditional paradigm foresees growth (also in an urban context) which safeguards the wellbeing of future generations. The resilience paradigm ensures the development of urban systems through the ability to react to external disturbances by storing past experiences. In other words, it means ensuring the future, absorbing present disturbances and looking back.
In these terms, spatial planning has the aim of putting metaphor into action in a territorial dimension.

Taking the concept of resilience from the theory of the adaptive renewal cycle and panarchy model (Folke, 2006), the reaction of systems to external disturbances depends on a certain degree of their self-organization and creativity. Accordingly, in order to propose a comprehensive definition of the resilience concept in spatial planning, it is useful to study empirical experiences which also take these aspects into account. Examples are the recent experiences of transition towns (Hopkins, 2008 and 2011; Hopkins, Lipman, 2009). Rob Hopkins, author of the first transition town in the UK, proposed the original use of the concept of resilience as reaction to the external disturbance of peak-oil.

3. Resilience in the transition town movement

The concept of resilience is the central principle of the experiences of the

transition town movement. We will understand how it is used in recent international experiences.
According to the main resilience definition in ecology, we can list four principal elements of application to the urban scale, as indicated below:

Socio-ecological systems. The first element concerns the linkage between the ecological and social dimensions of systems. Urban systems are based on the close relationship between environmental resources and human capital, they are socio-ecological systems. This is particularly clear in the transition town movement, the new paradigm of urban development indeed refers to primary resources (eg. energy and food supply).

Complex systems. The second element concerns systems as a whole and not only part of them (Folke et al., 2010). Cities are indeed complex systems wherein several subsystems interact. The transition town model proposes a new paradigm of urban development which is a comprehensive strategic vision of the city and does not just consider a single subsystem (Brangwyn, Hopkins, 2008).

Adaptive renewal cycles. The third element concerns the adaptive renewal cycle theory. It is composed of the sequence of several status phases. Each status phase involves the loss of resilience and the consequent vulnerability of the system. In the transition town model the sequence is clear and closely linked to the widespread use of oil; peak oil – or at least its shortage - is the external disturbance which involves the loss of resilience and the consequent vulnerability of the system (Hopkins, 2008). Following this approach, the urban system has passed the period of growing stasis - K-phase - and is now going through the readjustment and collapse period – Omega-phase. The transition town model proposes over coming the current phase of crisis and reaching the last phase of renewal and re-organizing – a-phase[7]. The adaptive renewal process also has memory ability. The memory of the urban system is a key feature of the transition town model (eg. Key role of the elders knowhow and wisdom in terms of lifestyle not yet dependent on oil) (Brangwyn, Hopkins, 2008).

Self-organizing capacity. The fourth and final element is the self-organizing capacity of complex systems. Folke's theory (2006) proves that complex systems are in a continuous adaptive renewal cycle, which never stops but is

7 Each transition initiative takes into account that «[...] *life with dramatically lower energy consumption is inevitable and it's better to plan for it than to be taken by surprise and our settlements and communities presently lack the resilience to enable them to weather the severe energy shocks that will accompany peak oil*» (Hopkins, 2008, p. 134).

able to react creatively to external disturbances. The transition town movement is a practical example. It is a bottom-up movement, it is part - even without knowing it - of the a-phase of the cycle and so it is an example of the reaction of the urban system to external disturbance. It proposes a new paradigm of urban development and a consequent social organization model.

3.1 The idea of transition

Another key assumption of the transition town movement is transitioning.
The usage of most relevance to discussions on sustainability is the body of research on transition in socio-technical niches[8], «[...] *protected spaces where new social and technical practices can develop*» (Seyfang, Haxeltine, 2009, p. 3). This concept has been the subject of numerous scientific projects and debates with reference to its innovative solutions and alternatives to the sustainable development topic (Foxon et al., 2008; Smith, Stirling, 2010).
Extending this concept into the social economy, Seyfang and Smith (2007) propose a model of grassroots innovations to describe «*community-led, value-driven initiatives for sustainability, which respond to local problems and develop innovative socio-economic arrangements as much as (or in preference to) new technologies*» (p. 3). The benefits of grassroots innovations for sustainable development derive principally from their creation of a space for the development of new ideas and practices, for experimenting with new systems of provision, and for enabling people to express their alternative green and socially progressive values, and from the tangible achievement of environmental and social sustainability improvements, albeit on a small scale (Seyfang, Smith, 2007; Seyfang et al., 2010).
Assuming the socio-technical niches theory, the transition town movement proposes a bottom-up paradigm of urban development which comes from the creativity of the urban community. In other words, «*the transitions movement represents an example of a new type of civil society movement, with a focus on bringing together diverse parts of a community to act and produce change and innovation at the whole systems level*» (Seyfang, Haxeltine, 2009, p. 21). Creativity becomes new ideas, practices and policies for urban management.

8 On Strategic Niche Management (SNM) and, especially, Netherlands case studies, see for example researches by Rip, A., Kemp, R., 1998. Technological change. In Rayner, S., Malone, E., eds. Human Choices and Climate Change II. Battelle: Columbus: 327-399. Also Rotmans, J., Kemp, R., van Asselt, M., 2001. More evolution than revolution: transition management in public policy. Foresight, 3 (1): 15-31. Also Smith, A., Stirling, A., Berkhout F., 2005. The governance of sustainable sociotechnical transitions. Research Policy, 34: 1491-1510. Also Geels, F. W., 2005. Technological transitions and system innovations: a co-evolutionary and sociotechnical analysis. Elgar: Camberley. Also Loorbach, D., 2007. Transition management: new mode of governance for sustainable development. International Books: Utrecht.

3.2 Origins and quantitative consistency

The transition town movement was founded in 2005 in Kinsale, Northern Ireland, by Rob Hopkins, a permaculture teacher[9].
The first transition town initiative involved the small town of Totnes (2006), in south-west Britain. Starting from this initial experience, which actively began in 2009, the transition town movement quickly spread, first in the UK and then in other European and non-European countries (Seyfang, Haxeltine, 2009).
To date, we could list hundreds of initiatives[10] worldwide. According to recent researche, the transition towns are located in Europe (about 50% in the UK and the remainder in Ireland, Germany, the Netherlands and Italy), but also in Oceania (Australia, New Zealand) and North and South America (the USA, Canada, Brazil and Chile) (Hopkins, Lipman, 2009; Smith, 2011).

Tab. 1_Geographical distribution of Transition Town initiatives

Region	**Formal initiatives (July 2009)**	**Mullers (Sept 2008)**
UK and Ireland	119 (83)	496
Continental Europe	4 (1)	48
North America (of which)	37 (5)	143
USA	33 (5)	113
Canada	4 (–)	30
Latin America	1 (1)	7
Asia	1 (1)	4
Africa	– (–)	4
Australasia (of which)	24 (15)	100
Australia	17 (9)	54
New Zealand	7 (6)	46
Total	186 (106)	802

Source: Bayley et al., 2010

As with other current organizational movements (eg. cohousing), the

9 Permaculture, another key assumption of the transition initiatives, is not discussed here. For more information see Holmgren, D. (2002). Permaculture: Principles and Pathways Beyond Sustainability. Hepburn Springs: Victoria.

10 It seems difficult to determine a list of the initiatives currently active in the world. The literature shows a lack of data: according to Bailey et al. (2010) to July 2009, the phenomenon involved more than 186 cities, according Seyfang and Haxeltine (2010) to January 2010 it involved only 156 even in the UK and 109 in the rest of the world.

transition town movement is a social-niche phenomenon that also involves a small part of society. A recent survey on Uk transition initiatives (Smith, 2011), shows that 86% of respondents are well-educated to post-graduate level. It is not possible to determine whether this trend is valid for all initiatives, but we can stress that - at least according to recent researche - the phenomenon is progressively spreading. This trend also depends on the different kinds of initiatives in terms of location (urban, rural and island) and extent (local transition initiatives, regional transition networks, regional hubs, national transition support organisations/networks, temporary groupings of local initiatives to carry out particular projects, as well as other manifestations) (Hopkins, Lipman, 2009).

3.3 Purpose and principles

Hopkins and Lipman (2009) define the transition initiatives as «[...] *an emerging and evolving approach to community-level sustainability*» (Hopkins, 2008, p. 134). Bailey et al. (2010) complete this definition by considering the transition town movement as «*an environmental movement that has both drawn extensively on the perspectives and techniques of its predecessor and peer environmental movements, and adapted these to the specifics of peak oil, climate change and relocalisation*» (p. 601).

The formation process of each transition initiative follows seven principles[11], twelve steps[12](Connors, McDonald, 2011) and three stages[13]. Although this set of guidelines, listed by the Uk Transition Town Network, should only provide directions for the process (Hopkins, Lipman, 2009), in some cases it is considered quite binding and prescriptive (Connors, McDonald, 2011).

Following the concept of resilience, the purpose of transition initiatives is «*to support community-led responses to peak oil and climate change, building resilience and happiness*» (Hopkins, Lipman, 2009, p. 7). According to socio-

11 The seven principles are (Hopkins, Lipman, 2009): positive visioning, help people access good information and trust them to make good decisions, inclusion and openness, enable sharing and networking, build resilience, inner and outer transition, subsidiarity.

12 According to Brangwyn and Hopkins (2008), the 12 steps of transition initiative are: set up a steering group and design its demise from the outset; awareness raising; lay the foundations; organise a great unleashing; form working groups; use open space; develop visible practical manifestations of the project; facilitate the great reskilling; build a bridge to local government; honour the elders; let it go where it wants to go; create an energy descent plan (EDAP).

13 According to Hopkins and Lipman (2009), each transition initiative should follow a succession of stages: the initial stage (meeting and gathering around the principles of the transition), the mulling stage (contacting and joining the Transition Network Ltd) and the formal transition initiative (declaration of intention).

technical niches theory, these initiatives are virtuous examples of interplay between system supply/use of resources and new models of social institutions and regulation especially in terms of their influence on sustainable lifestyle (Seyfang, Haxeltine, 2009).
In particular, at local level[14], transition initiatives concern crosswise all urban management fields with particular reference to oil-led ones (such as food and energy supply). For each field there is an organization subgroup that deals with strategic and propositive activities. The final goal is to outline the Energy Descent Action Plan[15] (EDAP).

Tab.2_Main activities of Transition Town Totnes.

Working group	**Main activities**
Building and housing	Eco-construction Co-housing
Economics and livelihoods	Local currency: the Totnes pound ATMOS: sustainable business park Oil vulnerability audits with local companies
Education	Transition tales with local schools Public future scenario workshops
Energy	Totnes renewable energy supply company Solar water heater challenge Partnership with good energy
Food	Garden share project Sustainable fisheries Seed and plant swaps Allotments association
Health and well-being	Directory of complementary health practitioners Collections of illness-to-wellness stories Discussion group on national health service and sustainability
Heart and soul	Meetings to discuss events and experiences Meditation meetings
Local government	Building of links with town, district and county councils to support and encourage inclusion of climate change and peak oil in decision-making

14 At regional level, the best practices in the transition initiatives are shared in order to support those that are newly active and those in the process of formation and to manage partnership with private or public corporations. At national level, these collect and monitor all the initiatives (eg. Uk and USA)(Hopkins, Lipman, 2009).

15 Two other assumptions of the transition town movement are: *«we have to act collectively, and we have to act now and by unleashing the collective genius of those around us to creatively and proactively plan our energy descent, we can build ways of living that are more connected, more enriching and that recognise the biological limits of our planet»* (Hopkins, 2008, p. 134).

The EDAP anticipates three phases of aims (Brangwyn, Hopkins, 2008): a local resources framework, a transition timeline and a set of resilience indicators (such as the percentage of food grown locally, the amount of local currency in circulation, the number of businesses owned locally, the percentage of energy produced locally, the quantity of renewable building materials, and so on).

The Energy Descent Action Plan constitutes a strategic urban plan of a future vision to be carried out through specific practical activities. It differs from traditional strategic planning for a voluntary and shared community-led vision. The public sector role, especially of local government, is still central but it has to support - not to drive - transition initiatives, as happened in the Totnes, Lewes, Stroud, Penwith transition towns (Brangwyn, Hopkins, 2008).

3.4 Common characteristics

The comparison of the main international transition towns enables the common characteristics, both in terms of promoter organizations and initiative typologies[16], to be listed as follows.

According to the first term, the main characteristics are:

- *voluntary*[17]. Unlike traditional strategic planning for urban sustainable development, the transition initiatives focus on community-level action, essential to the success of the initiative (Seyfang, Haxeltine, 2009). Common action implies the voluntary of community members toward a shared goal.

16 In literature there are no surveys, the only exception is the work of Seyfang and Haxeltine (2009) on the British case studies.

17 The survey of Seyfang and Haxeltine (2009) underlines that «[...] *the vast majority (89.0%) are set up by individual citizens (76.7% are set up by several individuals coming together to instigate the group, and another 12.3% are set up by just one person at the outset). At the same time, 19.2% have one or more pre-existing groups involved in setting up the group. Only one of the respondent groups (1.4%) had a business involved in setting up the group, and none of them were started by local councils*» (p. 6).

- *common mission.* The common mission is building local self-reliance[18], shared by all community members at the time of agreement.
- *legal form*. This ensures greater legal credit is given the organizations' actions and facilitates external partnerships. Different contexts affect the legal form of the transition organizations.
- *internal network*. The internal network is made up of working groups and subgroups. There is no leadership but network organization. Interplay between members is inclusive and participative (Hopkins, 2008).
- *external network*. The transition movement is not isolated but it interacts with other local and pre-existing social organizations[19] (Seyfang, Haxeltine, 2009). The goal is to focus the actions of civil society on a common aim, without losing the identity and specificity of each initiative. Network organization also avoids the risk of excessive localism. At the same time, there is a network between all the transition initiatives (eg. sharing best practices).

According to the second term, the transition initiatives are characterized by:

- *same strategic actions*. The strategic actions concern fields of energy (renewable resources), transport (sustainable mobility), open space (community gardens) and building planning (eco-compatibility), urban economy (food supply, local currency) and community (learning, sense of community, human capital)(Hopkins, 2008; Bailey et al., 2010). Local currency is not a necessary criteria.
- *relationship with the public sector*. The relationship with the public sector is usually promoted by transition organizations but it may be the case that local governments are interested in the transition initiatives in terms of forms of cooperation (Bailey et al., 2010).
- *EDAP as final goal*. Although sharing strategic actions fields, each plan concerns a set of initiatives that originated from the local contexts. Therefore, each plan is different because it is flexible within local contexts.

4. Conclusions. Towards new territorial governance in urban development and spatial planning?

Folke's theory (2006), especially related to the adaptive renewal cycle and the

18 Data confirm that 55.2% of the respondents share this mission (Seyfang, 2009).

19 Seyfang and Haxeltine's survey (2009) emphasizes that 82,4% of the initiatives are linked to other initiatives promoted by pre-existing social organizations (in particular 86,5% are environmentalist ones).

panarchy model, enables the transition town movement as a practical example of the use of the resilience concept in a spatial dimension to be analyzed.

In particular, the resilience concept in the transition town movement emerges as a *new paradigm of urban growth and development* (Connors, McDonald, 2011) based on oil-free ideas, practices and policies for urban management.
In this movement, resilience is the capacity of systems to react to the external disturbance of peak-oil. Regarding this disturbance, the transition initiatives propose new ways of using environmental resources that focus on energy conservation and closing energy cycles (eg. food supply based on local production).
However, peak-oil is not the only external disturbance (Trapese, 2008). There are indeed several external disturbances that could spark off system shocks (eg. the current economic crisis). Consequently, resilience is not only the capacity of systems to react to peak-oil disturbance but is closely linked to the adaptive and progressive capacity to react to all evolving external disturbances (Folke, 2006). It is a progressive, adaptive (also to context) and learning process, that could take a long time and may not involve all urban systems in the same way, at the same time. In this sense, the transition towns movement is only one model in terms of the use of the resilience concept in spatial planning.
As a first conclusion, we can affirm that resilience has a broad extent. It concerns the rethinking of the traditional idea of urban growth and development that outstrips the traditional paradigm of sustainability and concerns the use of resources in general (Latouche, 2005).

On the other hand, resilience concept in the transition town movement also emerges as *innate capacity of systems* to propose *bottom-up ideas, practices and policies for urban management*.
In fact, extending our gaze to the nature of the phenomenon itself, the transition town movement is a social movement – like several others - that provides solutions in order to manage urban complex systems, especially on a local scale.
As Jane Jacobs said (1961), the renewal of cities – as complex systems – is innate in the capacity and interest of citizens. The transition town movement was indeed born in and spread through the urban context and it is a practical reaction promoted by the urban community. The movement never refuses the idea of the city. Bottom-up strategic actions aim at new common and shared solutions in terms of urban management.
In this sense, the concept of resilience underlines how some events could be chances to improve the current system status, trigger social mobilization,

recombine sources of experience and knowledge for learning, and spark novelty and innovation. It may lead to new kinds of adaptability or possibly to transformational change (Folke et al., 2010).
As a second conclusion, we can affirm that resilience is the innate adaptive capacity and creativity of urban systems to react to various external disturbances and propose new paradigms of growth and development. In other words, system reactions to external disturbances (not only peak-oil) are not related to top-down solutions but to solutions innate in the systems, especially in their characteristics and memory.

According to both meanings of resilience in spatial planning – as a *new paradigm of urban growth and development* and *innate capacity of system to propose bottom-up ideas, practices and policies for urban management* – we can stress that it is an approach, a way of thinking, able to propose a *new territorial governance perspective* (Folke et al., 2002).
This new territorial governance, based on the concept of resilience, concerns urban systems management relating to bottom-up learning capacity and the adaptive ability to propose new paradigms and practices. In other words, it means rethinking urban management through a new rules framework that concerns the three features of *stakeholders*, their *roles* and consequent *tools*, as follows:

- *Stakeholders*. Community-led movements – and those of transition towns – could be stakeholders able to propose new paradigms of urban development and planning practices, like the public sector (Friedmann, 2011).
- *Roles*. Citizens may have a more central role in public choice and, on the other hand, the public sector could innovate itself, learning from bottom-up experiences. In other words, the new territorial governance perspective concerns restoring the balance of the stakeholders' role. It means understanding the relevance of inclusive decision-making and (horizontal) subsidiarity (Hirst, 1994; Hirst and Bader, 2001; Brunetta, Moroni, 2012).
- *Tools*. Finally, both features - regarding all stakeholders and their new balanced roles - may have repercussions on urban management tools (policies and practices). In particular, it means promoting more inclusive policies and practices, which also learn from bottom-up experiences (eg. EDAP).

To sum up, the resilience concept and its use in the transition towns movement suggests a new territorial governance perspective that takes into account evolving social, economic and territorial organization and consequent

systems complexity. It may be based on a new balance between institutional and social stakeholders in both decision-making (policies) and subsidiarity (tools achievement).

The inadequacy and problematic functionality of public open space in the modern Greek city and the need to overcome its deficiencies

Aris Sapounakis,
Assistant Professor, University of Thessaly, Volos, Greece
Evanthia Athanasopoulou,
Civil Engineer – Regional Planner, PhD, Technological Educational Institution of Patras, Greece
Ioanna Katapidi,
Urban Planner, MSc (UCL), researcher at Cardiff University, UK

Abstract

Public amenities and public space in particular in Greek cities constitute a major aspect of concern, as their inadequacy impacts upon the environmental degradation of urban spaces with direct negative consequences on the quality of urban life. The inadequacy of public spaces has been accentuated by the escalation of urbanization and the increase of urban population in the recent past as throughout the postwar period and especially during its early decades, Greek cities experienced acute pressure for urban expansion. Legislation has played a significant role towards this direction as it has been particularly late in establishing the means to secure the open spaces and public amenities required by a comprehensive and balanced urban development program. Still it is made clear that the inadequacies in public open space are also due to objective and subjective difficulties such as financial restrictions, and tedious legal and administrative procedures. Furthermore and despite the pressing character of the need for efficient planning, local plans conducted in the ‘80s and ‘90s encompassing a holistic approach to the provision of public amenities, were only partially implemented. It lies beyond doubt that the development of cities in Greece however, presents an example in which the organization of public open space has not been properly approached, the main reason being that urban development has tended to follow the needs of individual stakeholders, whether small scale or large scale. Thus, as the urbanization trends escalated, planning legislation in Greece has been particularly late in establishing the means to secure the open spaces and public amenities required by a comprehensive and balanced urban development program, even at times when the dimension of sustainability and the requirements it has set on environmental performance were not overtly expressed. The present paper examines the adequacy and contribution of public open spaces in the large urban centers in Greece. More specifically it attempts to provide a critical overview of past and current legal instruments and policies pertinent to the issue, paying particular attention to their functionality. The above will be tested against the present situation in medium sized cities like Patras and Volos where haphazard development has been less acute than the main urban centers of the country.

1. Introduction

As modern cities are continually aware of the need to maintain an adequate standard of environmental performance, a major issue concerning their capacity to develop resisting mechanisms to the degradation of their environmental parameters relates to the distribution, shape and above all availability of open spaces in the urban fabric. Taking into consideration the requirements of the compact city as the means to sustain development within the urban milieu, space and especially public open space may be considered as a luxury that needs to be well organized and managed so as to support the requirements of urban land uses while also maintaining its symbolic function needed.

More specifically, cities require open spaces, whether public or private, because they cater for the needs of urban communities in a manifold manner, not only covering their social and recreational needs but also, at a psychological level, relating to the

needs for symbolism and identification (Norberg-Schulz,1980; see also Gehl, 2011). Thus, apart from purely functional, the benefits of public open spaces may be classified as environmental, social and economic ones. Still research has shown that Greek cities tend to follow an even more deprived pattern of public open space coverage than cities in other Mediterranean countries, which still are trailing behind the ample northwestern European archetype (Fuller & Gaston, 2009). Even though there is evidence to suggest that public space and especially parks in Greece may be used differently (as examined in Tsopouridou, 2008), the question is to examine the extent to which the ancient Greek Agora (as in Madanipour, 2010: p. 7) and other forms of public open space still manage to secure the needed coverage so as function in medium sized Greek cities as it did in the past.

2. The Legal Framework

The traditional method to secure open space in a city on Greece has been land expropriation as based on the legal framework of the 1920's. This method that has often taken the form of compulsory purchase, apart from being costly, was not readily accepted by the general public and especially those who lost their property. Apart from the most evident reasons for the negative notions associated with this, one must take into consideration that in earlier years compensation for the purchase of property tended to be very low, a fact further accentuated by the strong attachment of Greeks to private property as a result of many decades of political uncertainly and turmoil. The security feeling provided by having a house of one's own is depicted characteristically on the high percentage of home ownership in Greece that has always tended to exceed 80%.

Much later, it was during the 1980's that new legal instruments provided more flexible means to urban planning. This shift in the country's legal framework with reference to the development of cities was based on the notion that the land needed for open space and public amenities in general was drawn from land contributions by individual property owners prior to their property's incorporation within the official city plan. Thus there was no need to employ land expropriation, a measure which apart from its unpopular character relied on financial resources that had usually been hard to secure (Lalenis, 2004). In addition to that, contemporary legal framework not only requires ample coverage for public open space but also specifies a standard of 8 square meters per person for green spaces. Yet even then, in reality local plans still had to face the difficulty of having to conform with neighborhoods of usually unauthorized building activity that had already developed in the periphery of the existing official city plan. As a result and although well conducted in as much as their interest in public open space is concerned, local plans seldom manage to be fully implemented

The difficulty in securing open space in Greek cities is elucidated when one focuses on specific paradigmatic cases and approaches the manner in which their urban fabric has developed. Thus in the present context, two medium sized cities in Greece, Volos and Patras, are addressed, focusing on the legislative frameworks as it has

been shaped during the years and aiming to examine the reasons behind the inadequacies of public amenities. The reason of selecting the particular case studies lie on the facts that (a) they are both medium sized cities that are representative of the Greek paradigm, (b) their urban fabric presents notable similarities as they are both coastal and (c) they both present a record of sizeable urban sprawl. Furthermore both cases represent typical examples of the implementation of urban development policies that have been applied so far in Greece, unpacking the critical policy's issues that led to the present situation with reference to public space.

3. The case of Volos

Volos is a medium sized city with a population of around 150.000 people located in Thessaly in central Greece. Volos has a long history, traced back in the prehistoric period, indicating that the specific area has been continually inhabited since then. However the present form of the city is fairly new and has little geographic relation with the original settlements. It is a city that has basically emerged a few decades before the year 1900 based on a mid-19th century plan that covered a fairly extensive coastal zone between the already inhabited stronghold of Palia and the uphill village of Ano Volos (Haritos, 2004). Since then a extensive number of annexes gave the city its present form. In as much as the central quarters are concerned, the original city plan did not specify land use and hence has been unable to secure open spaces, the provision and organization of public amenities being a matter of negotiation. As a result, the city center is characteristically poor in public open spaces as the few squares created were in fact nothing more than the necessary breathing space provided for the few centrally located churches built before 1881 (Hastaoglou, 2007).

To become more precise, it is worthwhile explaining the current situation with specific reference to the provision and adequacy of public amenities through the examination of the city's urban development during the last two centuries in the city. From 1840 onwards and especially after its independence from the Turkish 15th-19th century occupation in 1881, the city started to expand to the southeast, an area formerly used for storage. Indeed, within a period of 25 years the particular area has grown in size from 80 warehouses to more than 1200 dwellings. The road network consisted of four main streets parallel to the waterfront and forty roads vertical, thus creating a settlement of nearly 200 blocks. At that period urban development did not follow other official plans apart from the original overall grid merely adjusted to individual needs (Hastaoglou, 2007).

This problematic situation was further intensified due to the population increase. The transformation of the city's profile in one of the most important industrial cities in Greece generated the need to accommodate new land uses and increased the demand for public amenities and open space in general. By the turn of the century, the inadequacies of public space in the city center obliged the municipality to expand the width of the waterfront. The Volos waterfront is until today very popular, both due to its image and its functionality, operating as the principal zone of entertainment based on the leisure activities it has attracted.

In as much as both the creation and distribution of public space in Volos is concerned, it is important to note that middle income districts tend to be better equipped compared to those of lower incomes. In particular, areas that attracted population of higher incomes, such as Agios Nikolaos in the southeast, have been benefited by more open space, whereas lower income areas, such Analipsi at the western part of the city was not given particular attention in terms of public spaces until very recently.

The issue of public amenities and public space in particular has attracted increasing attention after the 1920's leading to the establishment of the relevant legislation for the first time in Greece. At that period the Volos city plan was adjusted so as to meet the new legislative requirements. However, the updated plan which still covered only the central zone of the contemporary city, envisaged only one more public square with no concern for other forms of public space. In addition to this, even this only square provided by the plan did not actually function as a purely open space since it was occupied by the municipal gym. What underlines further the lack of concern for public space is the fact that the new urban blocks as indicated by the plan, reached the edge of both streams that surround the city center, leaving no room for the development of a sizeable green belt between the urban fabric and the stream. Furthermore, these two streams which might potentially offer the public space and greenery needed, are not only in a state of dereliction, but also threatened by new urban development in the very recent past.

The plan adopted in 1930, despite its inefficiencies, was not transformed or updated before 1957. Hence, for a period of almost 30 years the development of the city was based on a plan with little concern for public amenities. The plan was amended only two years after 1955 following two massive earthquakes that devastated the city providing an opportunity to reconsider its condition and expansion. Still it was as late as 1968 that a more substantial amendment was conducted following the residents' demand. In as much as public amenities are concerned, the new plan suggested the allocation of 17% of total space for open spaces. However this venture was particularly complicated and was never implemented, due to the difficulty of intervening in an environment that already existed and for this reason involved excessive funding to acquire the space required.

The most decisive changes with regards to public spaces in Volos have taken place after 1980. In particular, the aim was to decentralize land uses in order (a) to enhance the quality of peripheral districts in the urban fabric and (b) to allow public space to develop in the packed city center. However, it should be noted that these changes usually tended to remain in paper, not reaching the stage of implementation both because of the financial shortages mentioned above and because of subjective public and private sector inadequacies (see also Lalenis, 2004). Thus despite some changes that are already evident in new peripheral quarters of the city, the percentage of public space in Volos still remained low.

It was as late as 1982 when the first contemporary local plan was adopted. The plan was based on the grid that already existed and attempted to allow the areas of expansion to blend with the already established layout of the city so as to become a homogeneous entity. Although the plan is characterized by a number of innovative elements, the concern for public amenities has still remained low and the six new public squares provided were not only failed to meet the per capita coverage criteria, but were also randomly distributed in the urban fabric. It is noted however that this inadequacy was more due to the objective difficulty in employing the instrument of compulsory purchase in the expropriation of property in view of the lack of economic resources, rather than a purely subjective one.

Furthermore, public amenities have attracted major attention by the Master plan adopted in 1986. This envisaged the creation of public squares at neighborhood level, the organization of pedestrian and cycling networks and the unification of private back yards in a manner that may allow them to be used as public space. The Master Plan also suggested the upgrading of the area around the stream of Krafsidonas and the need to regenerate the area of Palia. What must be noted at this stage is that although the plan introduced a number of changes that could improve the condition of public space in Volos, these changes were either not implemented at all or have not been operating as planned. More specifically, the plan's provisions relevant to open space were concerned with the following:

- Proliferation of public squares: The plan envisaged the creation of 11 public squares which were intended to be distributed in different neighborhoods of the city. However these interventions required substantial economic resources causing severe implementation problems.
- Organization of pedestrian and cycling networks: an extended network for cyclists has been established, still being characteristically problematic as (a) the cyclist network is not functional as a whole, (b) cyclist routes do not blend with the geometry of the existing road network and (c) the separation between the road and the cyclist surface is made by barriers that are dangerous for cyclists.
- Upgrading the area around the stream of Krausidonas: Although the stream is acknowledged that it may function as an important element that could enhance public open space and the presence of the natural environment along the edge of the urban fabric, nothing has been done towards this direction so far.
- The regeneration of Palia area: Although the plan indicates the need to upgrade the specific district and certain actions and measures have already been implemented two decades ago, little has been done by the public sector to sustain the initiatives already taken and support the private sector towards this direction.

4. The case of Patras

Patras is a medium sized city with a population of around 210,000 people located in the south of Greece at the north-western corner of the Peloponnese. In as much as urban development is concerned, the city of Patras bears a number of similarities compared to Volos, i.e. Patras' inhabitancy has a long history traced back to the 3rd millennium BC, while the form of the contemporary city is a product of continual expansions and transformations. Furthermore, public space tends to be integrated in the rectangular grid plan principle followed by a sizeable portion of the city's layout.

During the 19th Century, the development of the city of Patras boosted following the country's independency. Still, unlike Volos, from the very early stages of the evolution of modern Patras, planning had to deal with the existing built environment which restricted the adoption of decisive interventions. In view of the above, public spaces were formed accordingly, their quantity and quality usually being confined by the existing situation and by the insufficiency of economic means to implement planning intentions.

These intentions have been expressed through a series of plans, the first of which was prepared by St. Voulgaris immediately after the independence of the Greek State from the Turkish occupation in 1829. One of the most important elements in the plan's rationale lied basically on its attempt to follow the principles of contemporary urban design according to which the main roads axes were directly linked to major reference points. Another important concern directly linked to the provision of public space, has been the creation of green zones around the archaeological sites (Tsonakas, 1997).

In addition to interventions relating to the already developed built environment, the plan suggested the expansion of the city across the western side of the waterfront. The layout of the expansion zone followed the rectangular rationale and approached the need for public amenities and pubic space in particular by providing a green walkway along the coast and five public squares distributed evenly in the urban grid. A major innovative suggestion with regard to public space was the attempt to unify patches of un-built private space, which when made accessible to the general public, would increase the total coverage of open spaces in the city. It is important to note that this idea had been coined in the case of Patras much earlier than in Volos. Still this suggestion as well as the ones mentioned earlier, were not finally implemented as they were rejected in several occasions for a number of reasons. More specifically, the final plan, approved in 1858 included both areas mentioned above but ended up having adopted very few of the initial concerns for public space:

- Public squares and green zones around archaeological sites have finally been reduced dramatically compared to the initial plan. In particular, only two out of five squares proposed were approved and implemented, while the green zone around the city's castle has never been established, new building development literally touching its walls.
- The green walkway, suggested by the plan, was never implemented although the area was built.

- The idea of the unification of un-built private space was abandoned as the compulsory purchase procedure of properties from the municipality was considered exceptionally costly and time-consuming, being further hindered by legal complexities.

Furthermore it is interesting to follow the approach to the provision of public space as the city later gradually expanded, starting from the years between 1877 and 1929. It is evident that the issue of public spaces was neither on the focal point of planning nor of implementing the interventions. In fact, as the city's size reached 384.5 Ha, its public space consisted of only the 2.2% of its total coverage, thus merely allowing a measure of only 1.41 square meters per resident (Tsiatoura, 2011). More specifically:

- Two expansions of the city were suggested and took place in 1877 and 1882 respectively. However, in both cases the issue of public space was neglected. The zone around the Roman amphitheater was finally conceded to private development as in the case of the green belt protecting the south side of the castle that had been abandoned earlier.
- Similarly the expansions adopted in 1886, 1900 and 1903, which were almost symmetrical to the city center, did not entail a comprehensive approach to the need for public space.
- Likewise, public space was not considered important in the case of the unavoidable expansions of the city from 1903 to 1929 a measure of which catered for the housing needs of the refugees from Asia Minor.

In contrast to the years between 1877 and 1929, the period between 1929 and 1971 is characterized by planning inactivity. The absence of organized urban development paired with the dramatic demands for urban sprawl gave rise to the phenomenon of unauthorized building activity, threatening the image of the city and setting the concerns for public space aside. It is interesting to note that central government authorities at the time conducted a fairly extensive Patras Development Plan in which both living conditions in the residential areas but also the need for public space attracted minimal attention (Ministry of Coordination, 1967).

It is further important to note that after 1971, both the coverage and the population of the Patras conurbation developed differentially as the coverage of 1996 was six times the size of 1971 with only a 0.6% population increase for the same period (Pappas et al, 2000). This dramatic change in the city's institutional character in fact rested on the fact that the city plan expanded so as to gradually incorporate extensive neighborhoods of unauthorized building, devoid of public amenities, that had already been developed in the form of clusters along the outskirts of the existing official city plan. Thus areas that chiefly consisted of low-cost haphazard unauthorized development became officially parts of the city in 1971 and 1972. Although these areas are characteristically poor in public amenities, their low densities produce a misleading picture of exceptionally favorable densities for Patras (Papadatou-Giannopoulou, 1991).

The amendment of the Master plan during the aforementioned period and the expansions that have taken place respectively have increased the proportions of

public spaces both within individual neighborhoods and the entire city. However it must be noted that some neighborhoods, particularly new ones, have been benefited more in terms of public space as they are not susceptible to comply with earlier restrictions. Hence, the expansions and amendments of the Master plan between the years 1971 and 1979 led gradually to the allotment of 5.73% of the city's total coverage to public space, which corresponds to 10.49 square meters of public space per resident (including roads). The above proportions vary among the different neighborhoods ranging from 3 to 7% of the total public space coverage and from 5 to 36 square meters of public space per resident respectively.

Similarly, in the case of expansions of the city plan that have taken place after 1980, the proportion of public space is 4.79% of the total area. The allotment of public space coverage per resident for the whole city is respectively 12 square meters, reaching in specific neighborhoods the figure of 190 square meters. The discrepancies in public space coverage among the various neighborhoods indicate not only the imbalances among the different parts of the city, thus questioning its functionality, but also the failure of the plan to approach the issue of public space holistically (Polydoridis, 1986).

In total, the proportion of envisaged public space for the whole city comes up to 37% of the total area, 32% of which concerns roads while only 5% is allotted to public squares, open spaces and public greenery in general. It is important to note that from the above envisaged percentages less than the 2/3 have been acquired by the municipality in order to implement the plan. More specifically, out of 32% public space (including roads) proposed by the plan, only 69% has been already acquired, while the remaining 31% is still to be obtained. At this point it should be noted again that economic restrictions do not allow the purchase of the land required. Indeed what normally happens is that as delays in acquiring the land allocated for public space are usually too long, private owners generally manage to claim their property back.

This indicates that although current legislation allows local plans to arrive at comprehensive suggestions towards the right direction in as much as public amenities and especially public open space are concerned, their implementation tends to be particularly tedious. Planners and policy makers are already aware of this situation and they are very careful in arriving at too radical proposals concerning public space, the result being that plans tend not to envisage adequate land coverage for public space.

5. Conclusions

The preceding brief overview of the history of the development of the urban fabric for the cases of the two cities with reference to their open spaces has attempted to show the difficulties involved in securing them, while it also elucidated a number of key issues explaining their inadequacy. It is clear that the shortages in open space observed in the central quarters of both cities are not only due to earlier legal

framework which did not emphasize the need to provide public amenities bit also a matter of economic and practical reasons. In many cases private ownership has not been against land expropriation due to unfavorable compensation. Thus compulsory purchase becomes tedious. Furthermore, as owners are faced with their prime property being unable to be exploited, the procedure is often legally invalidated. Thus even when local plans are particularly favorable in terms of the public open space they provide, as in the case of the early Voulgaris plan for Patras, the interests of individual owners and the private sector in general may annihilate the plan's intentions.

It is interesting to note the case of multiple expansions of city plans to incorporate unauthorized urban sprawl of the post war period. In most cases as in the case of Patras, the approach of new local plans could do nothing more than to grant official status to extended neighborhoods built without any provisions for open space and public amenities. It is evident that such approaches are fragmented and do not contribute to the improvement of the living standards in the urban milieu.

On the other hand, local plans conducted after the 1980's were more efficient in providing open space as not only they had to conform to better standards concerning their land coverage but they also could rely on land contribution of individual property owners as the main instrument for securing it.

Apparently for the cases of both cities, the delay in the formulation of the required legal framework, paired with specific objective and subjective deficiencies of the public as well as private sector, have been responsible for the sizeable inadequacies in the provision of open space in the urban milieu. Some of these difficulties, like those concerning the legal aspect, do not pose the same problems as they did in the past. Taking into account the European standards of cities in terms of the proportion of green spaces per resident (such as London and Paris with 9 square meters per resident, Berlin with 13sq meters, Amsterdam with 27 sq m., Vienna with 20sq.m.) and the fact that in Greek cities in general public space (including roads) does not exceed 10 square meters per resident, it is evident that a lot of work is needed to be done towards the direction of achieving cities with adequate and more functional public space

Introduction

Transport planning is known as a traditional field of planning in which technical and quantitative knowledge and information is of prior importance (Willson, 2001). This appears more and more problematic for several reasons. First, transport planning is no isolated profession. It is mingled with other fields of planning and non-planning. Integrated approaches of urban issues are very relevant to coop with complex planning assignments (Bertolini et al., 2005, Banister, 2008, Straatemeier and Bertolini, 2008). Seeing transport and infrastructure developments separately from housing, recreation and other developments is hardly possible any more. An integrated approach, though, asks for a different approach for assessing transport plans, namely an integrated one (Curtis, 2008, Hull et al., 2011) that takes local and context specifics into account. Second, society has changed in a way that it demands different assessment assets. Issues like quality of life and sustainability have become core subjects of public debates and not solely accessibility or decreasing traffic jams. Not that these later more traditional issues are not important anymore, but intangible effects like increasing the quality of life are added and the public desires both to be addressed. This, again, changes the demand for planning and assessing transport plans (Handy, 2008, Willson, 2001).

In the Netherlands the cost benefit analysis (CBA) is an important tool for assessing integrated spatial transport plans as it is mandatory for national government funding (Ministry of transport and water management and Ministry of housing spatial planning and the environment, 2009). However, it has been questioned how a traditional assessment tool like CBA with a welfare economic foundation can assess complex integrated spatial transport plans (Annema et al., 2007, Jong and Geerlings, 2003, Beukers et al., 2012, Mackie, 2010, Naess, 2006, Mackie and Preston, 1998). Assessing complex plans in CBA comes along with several process bottlenecks (Sager and Ravlum, 2005, Martinsen et al., 2010, Eliasson and Lundberg, 2010).

Practitioner's experiences with applying CBA in Dutch planning practice gave more background for some of these doubts (Beukers et al., 2012). From a (local) planners perspective the CBA appeared to be experienced mainly as a final assessment; a final examination which judges if the plan fits the CBA criteria and experienced by some planners as hurdle which needs to be taken (Page et al., 2009, Beukers et al., 2012). This, though, leaves out the desired opportunity to use the CBA output to improve the analyzed plan (ECMT, 2004, Beukers et al., 2012). Furthermore, Dutch CBA processes have been characterized by two opposing groups of practitioners: the planners as well as the plan owners (the ones who feel responsible for the assessed plan) on the one side and the economist as well as the evaluators (the ones who conduct the CBA) on the other side. These two groups appeared to have trouble in their mutual communication and expressed a low level of mutual trust (Beukers et al., 2012).

This article presents a theoretical search for improving the CBA process when assessing complex integrated spatial transportation plans. The overall question is: How to improve the bottlenecks in CBA processes theoretically? These bottlenecks are articulated in section 1. In section 2 a theoretical framework is made on how these bottlenecks are interrelated, which forms the fundaments for a hypothesis. This is the starting point for a thorough literature research in section 3 on how to improve communication and build trust between different kinds of experts to support a learning use of assessment tools in planning. This search is focused on the research fields of deliberative planning and organizational learning. In section 4 the lessons from these two research fields are synthesized and analyzed with the CIMO-framework (context, intervention, mechanism and output) (Denyer et al., 2008). This gives the necessary input for a theoretical design on how to improve the bottlenecks in the CBA process and increase the fitness of this traditional evaluation instrument to the contemporary demands of transport planning.

Section 1: CBA process bottlenecks

Research on CBA process bottleneck gave three main findings: the CBA was experienced as a final assessment, whereas its use as a learning tool was desired (1); the two main participant groups in the CBA process, the planners and evaluators, expressed mutual distrust (2) and deficient communication (3) (Beukers et al., 2012). These bottlenecks are discussed further in this section.

1.1 Perception of CBA as final assessment

The overall experience on the use of CBA in Dutch planning processes was that the CBA was mainly carried-out when the assessed plan was already finalized and the process of designing, discussing and forming compromises to gain public support was closed. This timing of CBA at the end of the planning process downgraded its function to only examining whether a plan is good or bad in CBA terms, which is expressed in the summary table of the CBA in a number. This practice was perceived as undesirable for two reasons. First,

the planners, felt the CBA didn't do justice to the total benevolence of the plan. Hence, many intangible planning objectives are often not or poorly assessed in CBAs and not or poorly integrated in the overall balance (Naess, 2006, Mackie and Preston, 1998, Mackie, 2010). Therefore, a fully informed decision about a plan based on CBA is not possible as a CBA will give a limited overview of the plan's expected impacts. Hereby it should be noticed that the formal role of CBA in Dutch planning is not to make decisions, but to support decision-making (Eijgenraam et al., 2000). Nevertheless, the Dutch planning participants experienced a judgmental use of the CBA. This perception was increased by the obligatory character of CBA in Dutch planning. Every large spatial transportation plan funded by national government needs a CBA assessment. This obligatory character was experienced especially frustrating if the CBA method does not or partly fit the characteristics of the assessed plan. Secondly, the described late and perceived judgmental use of CBA was expressed as undesirable, because participants felt frustrated that they could not use the output of CBA to improve the assessed plan anymore. Even though the planning process was more or less closed at the time of assessment, it was perceived as a lost chance not to use the CBA output for improving the plan and possible improving the CBA balance.

1.2 Distrust between planner and evaluator

Another experienced bottleneck was a low level of trust in the CBA process among the planners and evaluators as well as towards the plan and the CBA itself. This experience was expressed for example in the fear of the planners that using CBA to support decision making could result in a dominancy of 'hard' effects over 'soft' effects. The CBA is better equipped to assess the so called hard effects; tangible effects which have a market value and can be translated in monetary terms quit easily (Meyer and Miller, 2000). Soft or intangible effects have, on the contrary, no market value and are more difficult to be monetized (Meyer and Miller, 2000). These soft effects, like effects on the air quality, loss of nature or sustainability, are sometimes monetized by the use of shadow prized and sometimes appear in the CBA balance as PM (pro memory) items. In either way, monetized or not, the integration of these effects in the total of the CBA balance is disputable (Wee, 2011, Mackie and Preston, 1998, Naess, 2006, Page et al., 2009). Planners feared that soft effects might be overlooked in decision making and were therefore suspicious towards the assessment tool. Especially because these soft effect often represent very important planning objectives like, improving the quality of life, sustainability or regional competitiveness.

Furthermore, the planners experienced that the evaluators tent to pay less attention to the soft effects in comparison to the hard effects. This behavior of the evaluators was characterized by the planers as rigid and fuelled the planners perception that the soft effects were not or poorly included in the CBA balance. By this the CBA was giving an incomplete assessment of the plan, which discouraged the planners to take the CBA and its output seriously. So, the planners not only distrusted the CBA as not equipped to fully assess their plan, they also were suspicious towards the evaluators because of their indifferent behavior towards integrating soft effects in the assessment.

The evaluators, however, also expressed a sense of distrust towards as well the planners as to the assessed plan itself. The evaluators, namely, experienced that planners tented to use the CBA strategically. They felt that planners were often too optimistic and would embellish the expected plan effects. Furthermore, the CBA experts experienced that the CBA output was used selectively by the planners following the political preferences. They perceived that if the CBA showed a positive balance, the analysis was not under debate. If the CBA showed a negative balance, though, the evaluators experienced that the methodology and calculation assumptions were attacked intensively, which would position the CBA as being useless and not worthy to support decision making.

1.3 Deficient communication

The third discussed CBA process bottleneck is a perceived communication deficit. Communication in the CBA process was characterized as being done too late, too little, too limited and too little structured. The experiences were for example that not enough time was planned for a necessary discussion on the used assumptions and fixed numbers in a CBA. These discussions, which could not be overlooked anyway, caused therefore delays and put pressure on the process. Also the process of testing the CBAs in second opinions (which is an obligatory step in Dutch planning) was described as unstructured and therefore less effective.

Furthermore, the planners criticized the CBA as not transparent: as a black box of which it was not clear what was actually calculated and how. They perceived a limited communicative value of the CBA report and of the evaluators, who did not manage to explain sufficiently what the CBA actually does and calculates. The urge of the planners, however, to know exactly what and how the CBA calculates is strongly related to the second bottleneck. Because of the sense of distrusting the CBA and the evaluators, the planners wanted to control what happened in the assessment of their plan and demanded to open up the black box.

Another example of limited communication was the perception of the evaluators that the CBA and decision-making process had too little room for uncertainties. Considering a CBA balance without its limitations does not support well informed decisions, so the uncertainties needed to be described too. However, the evaluators expressed that decision-makers and planners expected clear cut information and tended to overlook mentioned uncertainties in the CBA report.

1.4 Dichotomy between planner and evaluator

These CBA process bottlenecks made clear that the planner as well as the plan and the evaluator as well as the CBA form a dichotomy of two different and clashing rationalities in the CBA process in relation to the lack of trust and deficient communication. Conflicting rationalities as between the planner and evaluator in the CBA process resonated too in other studies. Similar conflicts between rationalities are noticed for example between transport planning and urban planning (May et al., 2008, Willson, 2001) and between technical rational

approaches and communicative rational approaches for plan evaluations (Owens et al., 2004). In this latest stereotype the technical rational approach represents a positivist belief that rational knowledge exists and can be provided by technical instruments (such as CBA) operated by experts. The communicative rational approach, on the contrary, is fundamentally a reaction to this positivist thinking. Its basic premise is that knowledge is a construction whereby the role of the planning expert is to create a space or place for different actors to communicate and to let inter-subjective knowledge come into existence (see for example Huxley and Yiftachel, 2000). Within this dichotomy, the CBA and its prescribed use seems to be an exponent of the technical rational approach, whereas the transport planning domain, especially when considering integrated plans, seems to increasingly tend towards communicative rational approaches (Durning, 1999, Te Brömmelstroet and Bertolini, 2011, Willson, 2001). Thereby, planners and evaluators represent different values and thinking which, apparently, does not fit easily together.

The description by Rayner (2003) of what he calls the (contemporary) age of assessment is illustrative for the setting of conflicting rationalities in the CBA process. In the assessment age governmental decision making is strongly dominated by scientific-based or evidence-based approaches. Technical experts and professionals tent to dominate, whereas at the same time electoral participation is declining. As Rayner noted, social scientist try to counter this movement by designing participation processes to involve the non-expert public. Although planners are often typified as being experts themselves, in the age of assessment they may represent the urge to open-up the assessment process and involve values and perspectives from non-experts through participation. This, however, is not incorporated in the natural behavior of the evaluators who are used to deliver the information required for scientific-based and evidence-based decision making. Moreover, although participatory techniques may be implemented in political culture of scientific and evidence based expertise, the technical assessment rationality may still dominate the assessment context. Rayner (2003: 168) substantiated this by the example that British citizens were consulted about the technical term ‘genetically modified crops’ instead of in every-day language; about ‘food and the country-side’.

Essential in the theme of conflicting rationalities is that two types of professionals, with their own set of concepts and values, have to cooperate to make a useful assessment of a plan. The appeared dichotomy between the planner and evaluator in the CBA process will form the focus of the remaining of this article, starting with theoretically framing the use of assessment tools, trust and communication in section 2.

Section 2: Relating communication, trust and conceptual use of CBA: A hypothesis

The emerging variables that form important bottlenecks in CBA processes, namely trust, communication and the use of the CBA (as a final assessment or as a learning tool), brought forth the questions if and how these three variables are interrelated. What is the importance of mutual communication and mutual trust for the use of an assessment tool in a learning way? And how are communication and trust interrelated? These questions are answered is this section through a literature review.

2.1 Communicative and trust conditions for a learning use of assessments

A desired shift from a judgmental and instrumental use to a learning use of CBA was described as well by Khakee (2003). With the rejection of a positivistic perspective and the development of post-positivistic approaches like communicative planning, central issues of evaluation were evolved too. Instead of expecting to measure all performances of a plan or program in an objective way the aim of evaluation has moved into facilitating an integrative and learning approach.

> *"[…] the central issues of evaluation are how best to organize an inclusive discourse, to promote a learning process which is emancipatory and expedites progress, and to emulate political, social and intellectual capital. […] Evaluation is thus a question not only of effectiveness and legitimacy but also of integrity and mutual understanding. Evaluation itself becomes a form of interactive discourse where all those involved can explain their values, problems and concerns."* (Khakee, 2003: 346).

Evaluation then may be a cognitive process in which social realities are constructed and actors develop self-reflective learning abilities, find unexpected meanings in their actions and build up networks of people actions and thoughts (Selicato and Maggio, 2011). Thereby it appeared crucial that actors actually meet the other actors, appreciate them, recognize their commitments and struggles, and their strong and weak points. Instead of using evaluation for problem solving by comparing alternatives, evaluation could be used for problem setting whereby the definition of the problem will not be a starting point, but is one goal of the evaluation process. Selicato and Maggio (2011: 173) made a strong plea for an increased learning perspective in evaluation processes instead of a judgmental perspective.

> *"Research […] shows more and more the need to consider evaluation not as the final outcome of administrative actions, with the aim of approving or rejecting the contents of a given planning tool, but as a work methodology, a "process of gradual learning" that it is useful to undertake even small steps at a time and by partial experiments (Brunetta and Spaziante, 2000). In fact, the aims of evaluation are not so much to formulate a judgment of the admissibility of the choices in terms of characteristics and the availability of resources, but to increase the awareness of the choices taken, within the context of the decision-making process."*

Kidd and Fisher (2007) recognized as well that both within integrated appraisal methodologies as well as within sustainability literature a strong plea is made to intensify a participatory dimension in assessment processes. This relates to the concerns for stakeholder engagement and openness in decision making. Likewise, Saarikosi (2000: 5) explored the integration of participation into environmental impact assessments (EIA): not just as a supplement, but as *"a collective process where different actors—affected citizens, interest groups, authorities, and experts—can deliberate and exchange their views of the goals and their knowledge on the impacts of the proposed developments*". This requires citizens to acknowledge and respect each other's perspectives and moral positions and disapprove the use of stereotypes. Parties need to learn about each other's identities to

understand where everybody stands and what is really important to them. Moreover, in order for EIA to serve as a learning process, participants should discuss conclusions and search for mutual solutions collectively. Furthermore Saarikosi (2000) emphasized the need for a safe environment as a condition for effective communication: an environment where each participant can speak, where non-expert knowledge and speech is acknowledged, where active listening is encouraged and where people can explore ideas freely.

Communication and trust as conditions for a learning assessment process

The articulation of a learning use of assessment tools made clear that the setting for such a use differs from the setting for an instrumental or judgmental use. When considering a learning use of assessment tools the focus has to be on organizing an inclusive discourse and promoting a process which is emancipatory so that all those involved can explain their values, problems and concerns. It relates to stakeholder engagement and an open decision-making process. A process in which different actors can exchange views and knowledge without the dominance of expert knowledge in an environment which feels safe to share and explore ideas together.

When the generation of (new) knowledge and ideas are considered or the acquiring of a profound and shared understanding in assessment processes, it relates to how actors communicate and how individual knowledge, tacit and explicit, can be combined and integrated. This relates as well to how communication between involved participants in the assessment process should be organized. Also the importance of mutual trust and a trustworthy environment is present. When acknowledging and respecting each other's perspectives and identity without using stereotypes it shows interest in each other which may encourage sincerity, sharing of personal knowledge and mutual trust. This is encouraged by a trustworthy environment in which participants feel safe to communicate and share ideas freely.

We therefore conclude that a high level of communication and trust between assessment participants form important conditions for a learning use of assessment tools. It appears that these conditions determine if a process of gradual learning is possible and if an interactive discourse can be formed where all those involved can explain their values, problems and concerns. How participants communicate with each other is of influence on a learning use of assessment tools as well as the level of trust among participants and a trustworthy environment..

2.2 Interrelatedness of communication and trust

Due to the relevance of trust and communication for a learning use of assessment tools a deeper understanding of these variables and their relatedness are necessary. A definition of communication may be of help in this, although communication is a muddy and dynamic concept. Communication could be describes as, for example, the transmission of information or as a system for communicating information (Littlejohn and Foss, 2008). A more detailed description is given by Lievrouw and Finn (1990: 49).

> *"Communication is human behavior that facilitates the sharing of meaning and takes place in a particular social context. Any interacting set of social and technical structures which facilitates the sharing of meaning among people is a communication system."*

Within the CBA process communication takes place especially between planners and evaluators. The communication then is a form of dialogue or face-to-face communication between people. Such a dialogue is a process in which concepts are built in cooperation with others and which provides the opportunity for one's hypothesis or assumptions to be tested (Nonaka, 1994). Or, as Healey (1999: 117) wrote,

> *"Conversations imply the exchange of knowledge and understanding and of claims for attention. Their 'performance' requires some degree of trust and a preparedness for some degree of mutual understanding."*

So communication in the CBA process is a form of interpersonal communication or small group communication which takes place in a dialogue or conversation. Interpersonal communication relates to interpersonal behavior and interpersonal relationships (Miller, 1978). It is a form of communication in which minimal two actors are involved, the degree of physical proximity is relatively high, the availability of channels (communication modes) are high and the opportunity for immediate feedback is optimal. According to Miller (1978) the development of communication to move from impersonal to interpersonal depends on the growth of qualitative characteristics of the relationship over time. Through getting to know each other, the uncertainties about possible reactions and feedback on communication diminishes. Furthermore, this feedback estimation can be based more and more on explanatory information about someone's behavior and believes and less on social cultural information (to which social group the other person belongs). So the communication is more and more becoming personal and between persons as more personal details are shared.

Moreover, a shift from impersonal to interpersonal means a shift in the communication rules.

> *"With impersonal relationships these* [communication] *rules are based on social norms and exist before the communication takes place. With interpersonal communication these rules are negotiated and defined by the communicators when their relationship is getting shape. So the conditions move from being extrinsic to intrinsic. These changes imply that the communication takes place more and more between individuals, instead of between undifferentiated role occupants." (Miller, 1978: 170).*

As with communication, the literature on trust is divers and entails very different perspectives, which makes is hard to form one definition.

> *"Economists tend to view trust either as calculative or institutional. Psychologists commonly frame their assessments of trust in terms of attributes of trustors and trustees and focus upon a host of internal cognitions that personal attributes yield. Sociologists often find trust in socially embedded properties among relationships among people and institutions." (Rousseau et al., 1998: 393).*

Nevertheless, literature agrees that trust is very important in several ways. It enables cooperative behavior; promotes adaptive organizational forms, like network relations; reduces harmful conflicts; decreases transaction costs (in for example a business transaction); facilitates rapid formation of working groups; and promotes effective responses to crisis (Rousseau et al., 1998). Furthermore, literature agrees that trust is a complex and multi-dimensional concept that is in its essence relational. There is a strong and reciprocal relationship with risk, which means that risk creates an opportunity for trust that leads to risk taking. Besides risky, trust is interdependent: the interests of one party cannot be achieved without reliance upon another (Rousseau et al., 1998). This is clarified if the following quotation.

> *"A (the trustor) trusts B (the trustee) with regard to X. Trust is A's subjective assessment of the probability that B will act as agreed when B's actions significantly affect A, independently of A's capacity to monitor B's actions." (Gambetta, 1988 in: Laurian, 2009: 371).*

Where the communication literature emphasizes the importance of forming relationships, the trust literature describes how trust is a necessary component to from such relationships. Moreover, the trust literature describes that communication between actors is necessary to build trust: by getting to know each other through communicating with each other relationships can take shape and can become more personal which increases the degree of interpersonal communication and trust. Interpersonal communication and interpersonal trust are thus interrelated concepts. These insight are, if not literally, recognized by several planning scholars. For Stein and Harper (2003) for example, trust is essential for community, social, political, familial, and even linguistic relations. For them trust forms a basic concept for understanding human relationships and institutions. It forms a necessary condition for any kind of communication, cooperation, understanding, knowledge, or learning. Or, as they stated it, trust is essential to the work of planners, because without it everything will collapse. Also in the work of communicative planners, trust forms an essential element for a communicative performance and a degree of mutual understanding (Healey, 1999). As Laurian (2009: 384) described:

> *"While trust is necessary for open communication and collaboration, open communication and collaboration are also preconditions of trust. […] When participants trust each other (even if they hold different values or goals) and trust the fairness of the process, they are more likely to communicate actively, listen empathically, and work toward consensual solutions*" (Laurian, 2009: 382)

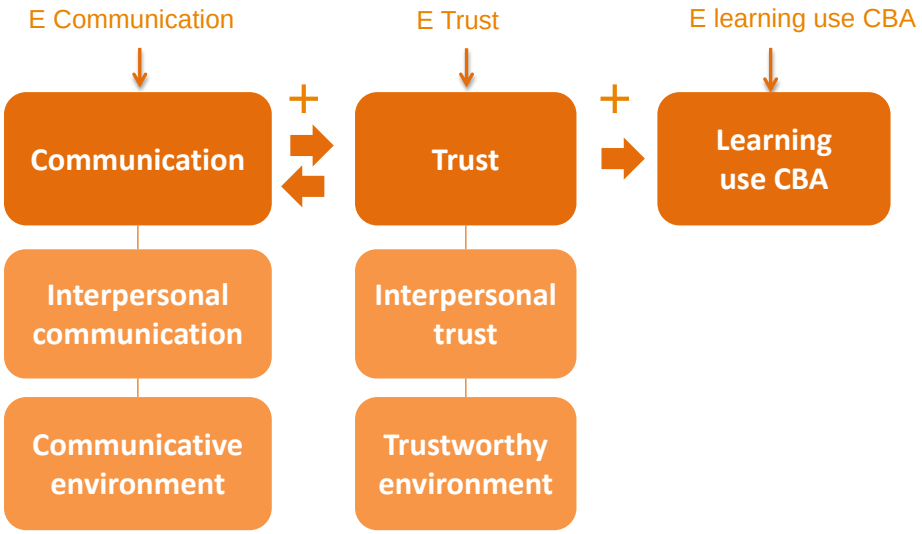
2.3 A hypothesis: High levels of communication and trust lead to learning use of CBA

The experiences of CBA participants (Beukers, et.al., 2012) of both a low level of communication between planners and evaluators as well as a low level of mutual trust are not surprising anymore considering the concepts of communication and trust and their interrelatedness. Even more, the finding that the learning use of CBA is experienced as low, and instead an instrumental and judgmental use is experienced, seems to be a logical result considering that a learning use of assessment tools requires high levels of communication and

trust. It seems evident that the levels of interpersonal communication and trust need to be increased in the an equal way to materialize the expressed desire by the CBA process participants to use the CBA as a learning tool. This forms the basis for a hypothesis: ***High levels of communication and trust between planners and evaluators are conditions for a high learning use of CBA.*** This hypothesis is illustrated in the conceptual model in figure 1. It focusses on interpersonal communication and trust between planners and evaluators, the interrelatedness of these variables and their relation to a learning use of CBA. Other influences on the possible use (or not) of the CBA as a learning tool are plausible too. For instance, the timing of the CBA in the planning process, as set in planning legislation or policy rules, determines if the plan is still open for changes through learning or not. Also power imbalances between the planner and evaluator in the CBA process may be of influence on its use as a learning tool. These explanations, though, are not within the scope of this article.

It seems necessary to increase the levels of communication and trust between the planners and evaluators to improve the CBA process and the use of CBA as a learning tool. The aim in section 3 is therefor to clarify how to increase the levels of communication and trust between experts, the planner and evaluator, engaged in a learning process.

Figure 1. Conceptual model on communicational and trust conditions for increasing the conceptual use of CBA



Section 3: Communicative and trust mechanisms and interventions

Two questions form the leitmotiv of section 3:

- How to improve communication between planners and evaluators in a CBA process?
- How to build trust between planners and evaluators in a CBA process?

These questions are answered through a literature review of research on cooperation between experts in learning assessment processes with a focus on communication and trust. The literature review concentrates on the research fields of deliberative planning and organizational learning. These fields contain many studies on communication and trust between different kind of actors and thus form a core source for potential directions on how to improve these aspects.

Firstly, the research field of deliberative planning elaborated extensively how planners should and could act in communicative interaction with various kinds of stakeholders. Although deliberative planning theorists mainly focus on improving communicative processes between planners and the community (see for example Innes and Booher (2010); Bickerstaff and Walker (2005); Huxley and Yiftachel (2000); MacCallum (2008); McAlister (2010)), their work is insightful as well for improvement of communication and trust between experts from different rationalities. Secondly, the research field of organizational learning gives helpful insights on improving communication and building trust between different experts as it has focused on for example understanding how innovation takes place within organizations or how to create interactive and shared knowledge. The focus of many organizational learning researches is on how firms can improve their innovative capacity through the creation of innovative knowledge (Nonaka, 1994, Argyris, 1991). Hence, organizational learning is about the learning capacity of an organization as whole to create innovative knowledge and use that knowledge in its development of adjusted and new products and strategies. Similarly, planning, evaluation and CBA practices or processes may be seen as (temporarily) organizations. Insights from organizational learning have therefore inspired several planning studies (Te Brömmelstroet and Bertolini, 2008, Suárez-Herrera et al., 2009).

The search within these two fields on how to improve communication and build trust concentrated on those articles which represent the main lines of thinking on communication and trust. The publications were selected on the basis of how often they have been cited in the field and can be considered as leading articles. Furthermore, publications were selected on the basis of their richness of communication and trust directions. In processing these publications all directions on how to improve communication and trust between different kinds of experts were selected and grouped based on the similarities in their reasoning. This gave a comprehensive overview of how-to-directions from both research fields. In prevention of a loss of the richness of the selected items the groups of directions on communication and trust are presented in appendix 1. Furthermore the grouped directions from the two research fields were compared and synthesized in section 4.

3.1 Deliberative planning

Open conversation

Much effort has been put by deliberative planning researchers in understanding and effectuating Habermas' ideas on open conversation among diverse people through which truth and values can be established. Healey (1999) for example argued to use Habermas' social theories to shape places and form policy.

> "*Through the work of discussion itself, new knowledges, ways of organizing, and networks may be established. […]Through such processes of exchange of conceptions and interpretations, learning is likely to take place that could change understandings and provide new bases for constructing place identities"* (Healey, 1999: 118).

According to Healey, a condition for conversation to take place is the acceptance of a degree of collaboration and reciprocity. This means that one must have an open perspective towards comments of another and accept the state of being that a scientific truth does not exists as absolute truth and values are the outcome of social interaction within specific contexts. Innes (1998) too showed that it is not the end product, i.c. an impact analysis or country report, that has the biggest effect on its developers. Instead, it is the process of collectively making and shaping information.

> *"The process of producing information shapes perceptions that become part of the assumptions and given knowledge - and those frame the choices"* (Innes, 1998: 56)

Although quantitative analysis and expert knowledge are to her not considered as unnecessary, a process of collectively creating meaning is desired for information to become embedded in the understanding of participants. The conventional instrumental model, with its presumed objective expertise, fails to do so, because it is not integrated in political and bureaucratic processes. Only if there is "plenty of talk" about the meaning of information, its accuracy and implications, it will become shared knowledge (Innes, 1998: 56). However, to let a communicative process take place, Innes states that it is necessary that not only formal knowledge is accepted and addressed. Other kinds of knowledge needs to be allowed too, like participants' own experiences, personal stories and intuition.

Habermas' structure in three steps of when what kind of knowledge needs to be addressed is helpful in this. It explained that if we want to produce predictions and choose strategies, scientifically grounded information is needed. Secondly, if we want to interpreted the meaning and consequences of these predictions and want know its practical implications, we are served by knowledge grounded in experience, in stories and metaphors that help participants make collectively sense of a complex and uncertain array of facts and contentions. And finally, if we want to break out of assumptions, rules, and expectations to stimulate innovation, intuitive knowledge is crucial (Innes, 1998).

To create the right kind of talk for deliberation and learning in a collective and communicative way an effort is required.

> *"[…] we need appropriate rules, parallel to those of the scientific method, to ensure that the products of these discussions are acceptable and socially worthwhile, as well as properly informed"* (Innes, 1998: 60).

Rules which should be aimed for in a communicative process are for example that the individuals representing all the important interests must be at the table; that all must be equally empowered in the discussion; power differences from other contexts must not influence who can speak or who is listened to, or not; that the discussion must allow all claims and assumptions to be questioned, all constraints to be tested; and finally that the group should seek consensus (Innes, 1998).

Planner's communicative experiences

Another seminal description of communicative directions between planners and stakeholders can be found in the work of Forester (1987). In this research he focused on what communicative strategies worked in planning processes and what not, based on the experiences of planners in practice. It elaborated for example that planners have to deal with a lot of distrust in the planning process from all sides; from stakeholders towards each other and towards the planner. Building up trust appeared an important element of the planner's tasks. To do that, the planner needed to listen carefully and, even more, assure that the thoughts and feelings of all stakeholders were acknowledged and respected. Doing so, the attention had to be first on the person and then on the words. Furthermore, special attention should be given to anger. This particular emotion should get the right attention, but not too much as it can predominate throughout the process. The planner's experience was that stakeholders should get the opportunity to 'let off steam' in order to move on and let the anger go.

According to Forester (1987) the planner had a role in finding a balance in building up trust and streamlining the appropriate communicative action to achieve that. Thereby, it seemed crucial for the planner not to behave arrogantly as the one who knows best as it will offend people. Furthermore, the planner had a role in preparing the stakeholders to face each other by mentioning the objectives from both sides at forehand and letting the stakeholders formulate their arguments in preparation of the discussion. This may prevent discussions from becoming too emotional if stakeholders felt confronted with (unpleasant) surprises. In this, the planner has a role of a mediator to negotiate between the stakeholders and their several interests.

Within this mediation process, however, Forester (1987) underlined that the planner is not an objective and neutral party, since he or she often has their own interests. If a planner acted neutrally and detached this attitude may even be experienced by the stakeholders as not really being interested in the case. If stakeholders had for example financial or emotional interests in a certain spatial development, they wanted their interests to be heard and a planner who is concerned and not neutral. This, again, asks for finding

balance and giving enough room for feelings and emotions, besides the facts and figures. Moreover, it requires the planner to act as a diplomat. Thereby, a strong overall condition is needed that "*no single party is so dominant that is does not need to negotiate at all*" (Forester, 1987: 444). Hence, planners cannot solve problems of radical power imbalances and need to be clear about that.

In a later work Forester (1999) stressed that even though negotiation is important, the intention of deliberative planning is not just to build consensus. Instead it is about acting and learning together, building relationships and finding win-win situations in which everybody gains. This entails several behavioral challenges in a deliberative process: to be close and keep a distant at the same time; to show empathy and critical judgment; to recognize and respect, rather than to dismiss human emotions of anger, fear, impatience and suspicion.

> *"The quest for understanding requires asking and listening, correctly interpreting the others language and putting oneself in the other's place. It requires making suggestions that the other may not have thought of, and learning from both acceptance and refusal."* (Forester, 1999: 63)

Doing so, deliberative action requires a dialogue space, which could be in meetings, negotiations, discussions, project reviews and hearings that bring affected citizens, regulators, developers and public officials face-to-face. Moreover, Forester (1999) noted that also informal meetings are important in deliberative processes, because then participants can develop more familiar relationships by learning more about each other. This happens typically during coffee breaks, small workshops or informal gatherings.

Communication modes and attributes can also function as a dialogue space. Forester (1999) gave an insightful example of a deliberative process where a sketch of a plan played an important role. It regulated and facilitated the deliberative process, because the plan was presented as a sketch still open for discussion. Every participant could take the initiative to pick up a pencil and draw some ideas on the sketch to illustrate them for the other participants. The sketch helped the participants to make clear what they meant and to share and sharpen their arguments. Nonetheless, because the sketch already gave some rough outlines of the plan, it focused the discussion as well by giving some borders and a clear topic. This regulated the discussion and prevented it from becoming too broad. So, the sketch was a means to encourage asking questions as well as a way to steer the questions. Thereby, the essential condition for a sketch, plan, evaluation or other mode to foster a deliberative process is not to present it as *the* ultimate sketch or plan, but as work in progress.

Collaborative dialogue

Innes and Booher (2003) shared insights for a collaborative dialogue as a deliberative process with many communication and (to some extent) trust building lessons. As a basic condition they explain the heuristic of a collaborative dialogue, which is listening to others, treating them respectfully and looking for common interests rather than differences and challenging assumptions. They used these basics to formulate some

principles for negotiation as an element of collaborative dialogue. In such negotiations parties must begin with sharing their interests rather than their positions; learn about each other; seek mutual gain solutions as far as possible; and accept that there is a tension between cooperation and competition and advocacy and inquiry in public policy cooperation (Innes and Booher, 2003: 37).The experience is that when stakeholders explain their own situation and needs they begin to learn about their interdependence and the need to negotiate.

However, Innes and Booher (2003) stated that participants not only need to listen and ask questions, they also need to interact with one another in, for example, brainstorming or scenario building.

> *"A truly collaborative discussion has the typical form of cooperative scenario building and role playing by participants who tell the stories of what is wrong and develop alternative stories until they find the narrative of the future that is plausible and appealing to all of them." (Innes and Booher, 2003: 42)* .

Thereby, scientists and agency staff need to be engaged with lay people who challenge assumptions and analyses, using their local knowledge. Through interacting in a collaborative dialogue relationships are build which help people to build trust among them. Moreover, the dialogue in itself helps participants to articulate their identity and develop shared meanings.

To achieve this collaborative dialogue a professional facilitator has a critical role in ensuring that the group makes a shared analysis of interests and conflicts, does joint-fact-finding, addresses issues deeply and feels comfortable and safe to say what is on their minds. Moreover, participant have to be stimulated to think outside of the box as well as to be willing to put forward half-baked ideas (Innes and Booher, 2003: 46). A facilitator can stimulate this by asking for clarifications or examples when needed and challenge assumptions and question status quo. Furthermore, it is essential that only recognized representatives of an interest group participate and that they check regularly back with their constituencies.

Spatial strategy making

As with collaborative dialogue, presented as a deliberative process, spatial strategy making can be interpreted as such (Healey, 2007) and contains several thoughts on communication and trust building. When considering spatial strategy making, Healey emphasized that this is created in a process of filtering and focusing attention, highlighting some issues and pushing others aside. Moreover, spatial strategy making happens in social construction sides or arenas in which multiple ways of knowing about what is significant, and about what could happen, are explored, conceptualized and symbolized and tested (Healey, 2007: 236). Thereby, the challenge is to translate feeling and potentials of an ambiance, such as accessibility and urbanity, into particular qualities that could be deliberatively cultivated by public intervention. Spatial strategy making requires therefore a specific approach to the production of knowledge and the development of understanding through the creation of meaning shaped by situations, trajectories, activities and values of particular social groupings (Healey, 2007: 243). This is especially relevant when different stakeholders are involved with multiple frames of references,

logics and value, which preferably happens as urban development dynamics are too complex to be grasped through the work of a single discipline.

So, spatial strategic ideas need to be validated and legitimated in an interactive way through talk, social encounters, discussion, debate and exchange of thoughts. More specifically, spatial strategy-making requires (Healey, 2009: 452):

- A capacity to know a place and all its complexities, its collective expressions and relations, and in the fine grain of its social, environmental, political and physical fabric
- The imaginative capacity to see opportunities
- The necessity to engage in systemic thinking, drawing together understanding and insights to imagine future trajectories and select specific pathways

This puts a lot of attention on how to produce knowledge in order to be useful in spatial strategy making. Besides recognizing the value of multiple sources of knowledge about places and their development, it is important to maintain an open-minded stance towards what is going on and what is at stake. Open-mindedness means actively stretching out to access multiple perspectives, challenging established assumptions and cultivating debate and arguments among different viewpoints (Healey, 2009: 448).

Healey (2009: 453) formulated four dimensions which characterize the process steps in (transformative) spatial strategy making which may function as a guideline to steer and stimulate this process. Namely through mobilize attention, scope the situation, enlarge intelligence, create frames and select actions. In the dimension of mobilizing attention the aim is to re-orientate attention to issues which lie behind immediate agendas, where this would highlight neglected opportunities and challenges. When scoping the situation the aim is to identify where the energy for change may lie and build coalitions for change which expand this energy. In the dimension of enlarging intelligence the focus is to explore and recast agendas of problems, issues and potential actions and stakes, through accessing multiple sources of knowledge. The dimension to select actions means to articulate strategic ideas within which specific issues and actions can be prioritized and given some justification and coherence.

Planning and trust

The review on deliberative (and collaborative) planning showed many communicative lessons and some references towards the importance of trust. However, the issue of trust has a slightly underrepresented position in deliberative and collaborative planning literature although the interest of planning scholars in this theme is growing. Stein and Harper (2003) explained this underexposed status by an overexposed interest on the issue of power based on the critical work by Foucault and Foucauldians. Even though Stein and Harper did not undermine the Foucault argumentation that all social relations are affected by power (or repression), they did argue that this approach may function like a doctrine and leaves too little hope for democratic and

deliberative processes to function and contribute to planning. Instead of describing the world in power relations and using mainly this vocabulary, Stein and Harper suggested that another vocabulary would be more productive; namely the vocabulary of trust which they present as its opposite.

> *"Whereas unequal power relations can undermine and thwart a community, trust can underwrite it"* (Stein and Harper, 2003: 135).

Even though trust is often identified as a missing element in ineffective processes, the planner profession's theoretical and empirical understanding of the interactions between trust and planning is still limited (Laurian, 2009). However, with the communicative and collaborative turn in planning, the importance of trust is only increased, since trust facilitates cooperation and in turn trust can be increased through successful cooperation. As noted by Ehrman and Stinson (1999), while consensus does not require common values, it does requires the existence of trust among stakeholders, agencies and mediators.

As elaborated in section 2, trust is a prerequisite for deliberation processes, communication, cooperation, the resolution of collective action problems and effective democratic governance (Laurian, 2009). Laurian (2009) gave several directions for building trust; for example through face-to-face interactions and sharing decision-making power. When sharing decision making power an agency, like a planner, shows trustworthy behavior and displays trust in the public. It can narrow the distance between, for example, the expert and non-expert. Information sharing, deliberation and democratic governance to enable shared decision-making are thus important to support the emergence of trust, and planners can play an integral role in this process (Laurian, 2009: 375, Switzer et al., Forthcoming). Another way to facilitate trust (or to mitigate distrust) is the use of mediators in support of open and effective communication. Moreover, Laurian emphasized that the ideal speech conditions for undistorted communication by Habermas are as well conditions that support trust: namely through comprehensibility, truthfulness, sincerity, legitimacy, equal standing and respect for all forms of knowledge, inclusiveness, openness and transparency mutual disclosure and information sharing. This again underlines the reciprocity of trust and communication.

The importance of open communication to build trust was supported in a study by Switzer et al. (Forthcoming) as well as a timely and sincerely sharing of information between parties. Not sharing information or learning about it through other (media) circuits could lead to suspicion and distrust especially when it confirms prejudices. Furthermore, the trust relations were benefited by getting to know the counterparts and by fulfilling promises.

How to improve communication and build trust according to deliberative planning literature?

The communicative and trust building lessons from deliberative planning have underlined that the planner has to take a different role when acting in complex and uncertain contexts. The planner should not act as the one who knows best and can provide politics and civil society with the answers needed. Although many

deliberative planning literature has a problem orientation which often only indicates mal communication and distrust, the cited literature shows that there are plenty ideas on how to overcome these communication and trust related problems. However, the main focus in deliberative planning is still on the planners who have to choose a different and deliberative role. Within the CBA-process the roles of involved actors cannot be characterized as a planner versus lay person. In contrary, in the CBA-process the planner has an experts role as well as the evaluator or the planner even is the lay person when considering specific CBA-knowledge. Therefore, when engaged in a more deliberative and learning CBA-process, both planner and evaluator have to choose a different role. The communicative and trust lessons from deliberative planning are grouped in appendix 1 and summarized in table 3.1 and 3.2.

Table 3.1 Directions on improving communication in deliberative planning

1) Have an open approach to all knowledge: a) Exchange different kinds of knowledge, feelings and interpretations b) Allow all knowledge in the discussion and allow to question it c) Give attention to issues behind immediate agendas
2) Behave appropriately: a) Have an open perspective towards each other b) Have an open attitude to change one's own assumptions and understandings c) Behave actively by asking questions and listen carefully
3) Have interaction: a) Create shared and embedded knowledge and understanding b) Have all stakeholders involved, empowered and interacting c) Act and learn together to develop familiar relationships d) Focus on (shared) interests and win-win solutions
4) Have a supportive communicative context: a) Create a safe environment to say what is on one's mind b) Prepare stakeholders for a constructive discussion and formulate arguments at forehand c) Create a dialogue space d) Use familiar dialogue modes e) Use a mediator

Table 3.2 Directions on building trust in deliberative planning

1) Show trustworthy behavior: a) Don't behave arrogantly b) Fulfill promises c) Listen carefully and focus on the person first, then on the words d) Timely and sincerely sharing of information and decision-making power e) Communicate comprehensively, truthfully, sincerely, supportively and legitimately
2) Have interaction: a) Acknowledge and respects all knowledge, thoughts and feelings

	b) Build relationships c) Use a dialogue space d) Use a mediator
3)	Prepare participants to participate in the discussion: a) Prevent confrontation with unpleasant surprises b) Formulate arguments at forehand c) Mention objectives from both sides

3.3 Organizational learning

A critical point in organizational learning is the argument that knowledge is more than an universal justified true belief, as many (western) scholars used to think. This notion of knowledge is too limited as it leaves out for example physical skills, tacit aspects, language, experiences and perceptions (Nonaka 1991: Nonaka et al., 2006: 1181). It has been emphasized that knowledge is never free from human values and ideas, history dependent, context specific and sensitive. In this notion, the core of organizational learning is how to overcome the fragile transmission of knowledge between individuals in the organization. Akgün et al.(2003) explained that the success of an internal learning processes of an organization can be depicted by the organization's interactive cycle of individuals' behaviors and actions. These cycles are affected by the knowledge structures of an organization, which are shaped by social interactions, culture and reflexivity. In this sense, knowledge develops from, and is manifested by, a complex web of relationships and social activities among people. This view thus emphasized the importance of culture, communication and group activities in organizations (Akgün et al., 2003).

Several cultural aspects can facilitate learning, like openness, transformational leadership, a participative decision-making culture, learning orientation, positive supervisory behavior and organizational support (Bapuji and Crossan, 2004). Furthermore, factors that influence the organizational learning capacity are for example formal procedures for learning, cross-functional communication and stability of team membership. While the type of organization structure and procedures affect learning within an organization, similarity between systems and structures facilitates learning between organizations (Bapuji and Crossan, 2004).

Knowledge creation

Nonaka and Takeuchi (1995, in: Nonaka et al., 2006) formulated four-stages for knowledge creation or for knowledge to transform from being to becoming in an interactive process. In such knowledge conversion, personal subjected knowledge is validated, connected to and synthesized with others' knowledge (Nonaka et

al., 2006, Nonaka et al., 2000). This process evolves in the four stages of socialization; externalization; combination; and internalization (SECI).

- Socialization aims at sharing tacit knowledge among individuals
- Externalization aims at articulating tacit knowledge into explicit concepts
- Combination aims at combining different entities of explicit knowledge
- Internalization aims at embodying explicit knowledge into tacit knowledge

In this process innovative knowledge evolves from being individual and internal to become shared, explicit, external and collective to become internal again in the last stage of internalization. In the process of such knowledge conversion, the individuals externalize their experiences and due to social justification it can be shared with others. Then, for newly created knowledge from combining externalized and shared tacit knowledge to become useful in the organization, it needs to be integrated in the organization's knowledge system. Or, from an individual's perspective, newly created knowledge needs to be made of one's own.

The process of SECI was related to the concept of *ba*: a shared space for emerging relationships as the context for knowledge creation, in which individual experiences are required, as well as reflections of the experiences of others (Nonaka and Konno, 1998, Nonaka et al., 2006).

> *"To participate in ba means to become engaged in knowledge creation, dialogue, adapt to and shape practices, and simultaneously transcend one's own limited perspective or boundaries." (Nonaka et al., 2006: 1185)*

The concept of ba knows different stages when the different steps in the SECI process are relevant. The originating ba is about meeting face-to-face, sharing emotions, feelings, experiences and mental models. This represents the socialization of the individuals. The interacting *ba*, supports externalization and combination. Through dialogue the mental models and skills are probed, analyzed and converted into common terms and concepts. Then in the exercising *ba* the individual's internalization of explicit knowledge are supported, for example through training with instructors or colleagues or repetitive exercises to stress behavior (Nonaka et al., 2006, Nonaka et al., 2000).

Central in organizational learning are insights on double-loop learning, which explain why it is so difficult for organizations to change internal structures and really solve problems instead of covering them up, as happens in the more common single loop learning. To detect and correct errors in an organization, double loop learning asks for publicly questioning underlying policies and goals, assumptions, norms and objectives, instead of enabling the organization to carry on its present policies (Argyris, 1977, Argyris, 1991). The underlying aim of a double loop learning process is to produce valid information, make informed choices and develop internal commitment to those choices. Moreover, this approach emphasizes the building of trust.

A critical factor of for double loop learning is an awareness of prepositions. To change private assumptions people need to become aware of their internal maps and see that some assumptions are

counterproductive for learning. Moreover, it is necessary to produce new assumptions by combining articulated views with questions by others. Furthermore, all must acknowledge their own mistakes, recognize defensive behavior and have an open dialogue. Workshops and seminars are useful in stimulating this change and learning process to move from old to new and shared assumptions (Argyris, 1977). As Argyris (1977) ideally saw, in such learning process people would advocate their views in a way that it would invite confrontation, challenge positions and stimulate testing them publicly.

Reflection-in-action

The work by Schön (1983) on the reflective practitioner relates to the change and learning process in double loop learning as elaborated by Argyris. It seems essential to reflect on how one thinks and acts and how it may influence a learning process. A basic notion thereby is that professionals think while acting, conscious or not, which influences the acting and vice versa. Therefore, not only the trained knowledge is used while acting, but also past experiences with acting in different and similar situations (see also Flyvbjerg (2001) on how professionals reflect in action). This is phrased by Schön as 'tacit knowing' or 'reflecting-in-action' (1983: 54). However, reflecting in action happens somewhat unaware and is sometimes even ignored or not considered as real knowledge.

Professionals were often taught to solve problems with an agreed set of solutions, but when situations are uncertain, disordered and indeterminate the fixed solutions may not work. Besides the problematic starting point of this approach that all problems need to be known at forehand to find a fit solution, the focus on solving problems in itself seems problematic. Hence, finding the problem is many times part of finding the solution. Moreover, the challenge is to keep the means and ends unseparated and to define them interactively to frame a problematic situation (Schön, 1983: 68). In the process of collective problem-setting, the problem is to be named and framed, which is in itself not a technical but rather a non-technical process (Christensen, 1985).

> *"Technical rationality depends on agreement about eds. When ends are fixed and clear, then the decision to act can present itself as an instrumental problem. But when ends are confused and conflicting, there is as yet no 'problem' to solve."* (Schön, 1983: 41)

Schön gave several directions to achieve this in a reflective manner (1983: 231 - 232). He stated that it is necessary for reflection to give and get valid information and speak in direct observable categories. Doing so, this information, data, reports and speech are open to disconfirmation. Furthermore, Schön underlined the urge to create awareness in the reflective process: awareness of the values at stake in decisions and of the limits of one's capacities. Moreover, there is the need to make designing and managing a bilateral task so that the several parties involved can work towards freedom of choice and internal commitment. Also a protected environment is needed to ensure that no one withholds negative information from the others or withholds testing this information and assumptions publicly. When following such directions, professionals may see the

other as minimally defensive, open to learning, committed to their position but equally committed to testing and confirming them, open to the reciprocal exploration of risky ideas, open to test assumptions publically and open to set a learning-cycle in motion.

Practitioners use various modes to reflect in their action, such as media, languages, and repertoires to describe reality (theories, role-playing, story-telling) and to conduct experiments. Independent of the modes used in reflection-in-action, it is important that the practitioners are familiar with the same modes they use when working together. Furthermore, reflection-in-action requires a reflective surrounding: a social context which supports reflective actions as well as cooperation with other reflective practitioners or clients. A classical professional-client relationship, for example, whereby the professional has all authority and the client submits to it is not possible. In reflecting-in-action the client has to participate in a reflective conversation with the professional and has to give valuable input of its own. This asks for an expert that does not act arrogantly and encourages the client to share thoughts and feelings. It asks for a different attitude of the client too whereas the experts cannot be approached just to solve the client's problems. The client therefor has to ask questions and questioning the experts knowledge, without hostility (Schön 1983: 300).

Organizational learning and trust

Many studies in organizational learning focused specifically on trust: how it relates to innovations, contracts, competitiveness, institutions (Bachmann and Inkpen, 2011), team work, group performances or cooperation (Peters and Karren, 2009, Jones and George, 1998, Bachmann and Inkpen, 2011, Erhardt, 2011) and how to build trust in an organizational context (Six and Sorge, 2008, Mayer et al., 1995, Abrams et al., 2003, Lander et al., 2004, Edelenbos and Klijn, 2007).

Edelenbos and Klijn (2007) for example, explain that trust is generated in social interaction and is influenced by existing codes and institutional rules and vice versa. Trust, then, develops especially in embedded relationships, through stable, frequent and tight interactions as '*trust does not appear as at the snap of a finger, but must be built up in the interaction among actors."* (Edelenbos and Klijn, 2007: 33). Furthermore, Edelenbos and Klijn (2007) emphasized that trust is fragile and needs to be nurtured and cherished. They give three guidelines for trust management to build and maintain trust:

- Intensify interactions: Create reciprocity in the relationships and repeated interaction
- Process management: Stabilize and manage interactions. For example through mediators and facilitators
- Institutional design: Design process rules to frame risk and opportunistic behavior. Decide on what to do when in conflict, how benefits are distributed and what to do if one of the involved actors wants to change the relationship.

Abrams et al. (2003) have a more abstract view on building trust. When engaged in a network for information sharing and knowledge creating two dimension of trust are to them of main importance: benevolence and

competence. Benevolence relates to the experiences of caring and being interested in the well-being of another and one's goals. Competences relates to the notion that one has relevant expertise. This brings them to the following factors which may develop one's trustworthiness (Abrams et al., 2003: 68):

- Act with discretion so that people need to feel safe to share confidential information
- Be consistent between word and deed
- Ensure frequent and rich communication on a personal as well as on a professional level
- Engage in collaborative communication in which both sides feel free to share and really listen to each other's thoughts and ideas
- Ensure that decisions are fair and transparent
- Establish and ensure a shared vision and language
- Disclose your expertise and limitations by being open about strengths and weaknesses

Another variation of trust building factors are given by Lander et al. (2004: 512). They asserted that trust building was influenced by repeated and positive interactions, integrity (being forthright and truthful in interactions and fulfilling promises) and perceived reputation. Moreover, communication turned-out the most relevant factor in trust building; communication which enabled sharing of relevant information and knowledge, provision of timely feedback, creation of a common language, creation of a shared vision and offering of explanations for decisions. Besides communication, Lander et al. (2004) noticed that when control and responsibility was shared this was perceived as an act of showing trust.

According to Six and Sorge (2008), the challenge is to be more precise in how organizations may build trust and what policies might be of influence. Their research focused on how to stimulate an interactive process in which individuals learn to establish and maintain trustworthiness, under given organizational (contextual and structural) settings and subject to policies directly or indirectly, positively or negatively sanctioning the building of interpersonal trust. They outlined several concrete policies which may be relevant to reach this stage of trust:

- Promote a relationship-oriented culture: Enable informal meetings; give (public) compliments
- Discuss at forehand how to deal with conflicts: Address troublemakers directly and *"in a way that you say 'yes' to the person, send a clear positive relational signal, and then allow the individual to be direct about the troubling behavior ('no' to the behavior)."* (Six and Sorge, 2008: 871)
- Explicit socialization to make newcomers understand the values and principles of the organization and how things are done

How to improve communication and build trust according to organizational learning literature?

The cited literature from organizational learning showed a wide range of views and approaches to communication and trust. Even though all are convinced of the relevance and importance of communication

and trust when considering the functioning of organizations (it's innovative capacity, competitiveness, learning capacity, knowledge and information sharing capacity, et cetera) the literature shows that the studies have their specific focal points as well as many overlap. Table 3.3 and 3.4 summarize these different (and similar) views on how to improve communication and how to build trust within an organizational context. A more detailed overview can be found in Appendix 1.

Table 3.3 Directions on improving communication in organizational learning

1) Interpersonal behavior to support communication a) Open attitude to test assumptions b) Open attitude towards learning, including from risky ideas c) Be explicit and accurate
2) Interaction a) Sharing and combining tacit and explicit knowledge b) Define means and ends unseparated and interactively c) All actors meet, discuss and become engaged in a knowledge creation process d) Use various modes to reflect which are familiar to all practitioners involved
3) Organizational context to support communication a) Leadership open to transformation and sharing of decision-making b) Supportive structure: stability of team members, learning procedures, training c) Safe environment and emerging relationships

Table 3.4 Directions on building trust in organizational learning

1) Personal awareness of others and trustworthy behavior a) Awareness of (underlying) (pre)positions and openness to discuss them b) Trustworthy behavior: act integer, discrete, really listen, be honest about expertise and limitations, give compliments, address troublemakers directly c) Fulfill promises
2) Interaction and forming relationships a) Create knowledge together through communication b) Have stable, frequent and informal interactions to form relationships c) Form a shared language or vision
3) Trustworthy environment a) Share control b) Make fair and transparent decisions c) Make rules to frame risks, opportunistic behavior, how to deal with conflicts

Section 4: Synthesis and conclusion

The research fields of deliberative planning and organizational learning are rich on directions, experiences, perceptions and lessons on how to improve communication and build trust between different kinds of experts. These insights were grouped as summarized in the tables 3.1, 3.2, 3.3 and 3.4. A closer look to these tables reveals the resemblance between the two fields. In this section, we are going to synthesize the lessons on improving communication and building trust in order to develop an overall answer on the question how to improve the bottlenecks in CBA processes theoretically that forms the leitmotiv of this article.

Communication and trust: Two sides of the same coin

Both research fields show that communication and trust are interrelated. This is widely acknowledged in communication and trust literature as described in section 2. However, the literature research on deliberative planning and organizational learning shows that this notion is not common knowledge; not yet at least. The importance of trust to improve, increase and intensify communication is often somewhat hidden under the surface of many other insights. Nevertheless, both concepts ask for the same elements. Building trust and improving communication requires, in short, appropriate interpersonal behavior (open, sincere, non-defensive, et cetera), interaction (to get to know each other, to build a relationship, to share knowledge and ultimately to create shared visions and knowledge), a proper preparation (to avoid unpleasant surprises and defensive behavior) and a supportive environment or context (a safe place to meet, management that stimulates interactions, et cetera).

The communication lessons from both research fields, though, have in comparison to the trust lessons a stronger focus on what to communicate and how: that all knowledge needs to be integrated and therefor all stakeholders need to take part in the interaction; and that it should be encouraged to discuss or question all knowledge and assumptions openly. Stakeholders need therefor to open up in order to communicate in this way. They need to be explicit what their concerns and insecurities are about, where they stand for, be honest and let the other 'take a look into their kitchen'. This means that one have to accept to be vulnerable, which requires a lot of interpersonal trust to do so. On the other hand, taking a look in one's kitchen will increase the level of personal information. One gets to know each other better and knows better what the other is capable of, which in turn will increase the interpersonal trust.

The resemblance as well as the differences between deliberative planning and organizational learning insights on communication and trust can be linked to their overall effort to be innovative. Within deliberative planning the concern is to develop innovative (strategic) plans to improve a location's competitiveness. Whereas with organizational learning the objective is to create innovative products to improve the organization's competitiveness. Both fields agree that in order to do so and to be innovative different kinds of

knowledge need to be integrated. However, the kinds of knowledge to integrate are slightly different in the two fields. In deliberative planning concerns are mostly about local and context specific knowledge that is embedded in history, location, politics and people (Allmendinger, 2002). Whereas organizational learning focuses more on the integration of inter- and intra-organizational knowledge; formal and informal knowledge; implicit (tacit) and explicit knowledge.

These subtle differences are welcome additions to each other, but do not change the overall view on how to improve communication and build trust between different kind of experts.

- One needs to behave appropriately: open, critical, non-defensive, sincere.
- Interact to create shared knowledge and form relationships
- Have the interaction guided by rules, a facilitator and discussion modes.
- Be prepared to interact, share and create knowledge collectively
- Have a supportive environment: safe, stable and supported by the management/ politics.

Conclusion: Context, intervention, mechanism and outcome

The overall aim of this article was to make a theoretical design on how to improve the bottlenecks in the CBA process articulated as low levels of communication and trust between planners and evaluators and the use of the CBA as a final assessment instead of as a learning tool. The final challenge in this article is to relate the described lessons from the literature review to the CBA process and the participating planners and evaluators. The CIMO-framework (context, intervention, mechanism and outcome), introduced by Denyer et al. (2008) is helpful for this. The overall question of CIMO is: Within a specific context, what interventions can be used to trigger the necessary mechanisms in order to get a desired outcome. Thereby, the mechanisms reveal how something works and how the different elements function in relation to each other, whereas the interventions inform what concrete action is needed to trigger these mechanisms.

In the scope of this article this CIMO-question would be translated as: In the context of a CBA process, what interventions can be used to trigger the necessary mechanisms in order to have high levels of communication and trust between planners and evaluators? The context of the CIMO-framework is a CBA process (and more precisely when assessing integrated spatial infrastructure plans) and the desired outcome is increased, enriched and improved communication as well as build trust between planners and evaluators. This outcome was hypothesized in section 2 as a condition to use the CBA as a learning tool which is the desired outcome one abstraction level higher. So, the interventions must trigger mechanisms for improving communication and building trust. The lessons from the literature review are ordered in line with this reasoning in communication and trust building interventions and the related mechanisms as articulated in table 3.5.

Table 3.5 Interventions and related mechanisms to improve communication and build trust in a CBA process

Context = CBA process that supports communication and trust building between participating planners and evaluators	**Intervention = A dialogue space where planners and evaluators meet face-to-face** **Triggered mechanisms =** Planners and evaluators have the opportunity to get to know each other and build a relationship, so that they can judge better how the other will react in possible interaction and build interpersonal trust. Doing so, they may feel more safe and can be more open, share more and more detailed information and listen more carefully. Then they may pay more attention to issues behind the immediate agendas, ask and receive critical questions and collectively change and build assumptions.	**Outcome =** A learning use of the CBA: reciprocity between the development of the plan and its assessment in CBA
	Intervention = Share and discuss knowledge together **Triggered mechanisms =** Planners and evaluators understand better each other's standpoints and may see shared interest which may increase the opportunity for finding win-win solutions. They get more information about each other (the plan and the CBA) which increases the predictability of how they might respond and therefor increases the interpersonal trust. This might support to be even more open, critical, share even more knowledge and possibly change one's own perceptions based on the perspectives of others.	
	Intervention = Be prepared to share and discuss knowledge together **Triggered mechanisms =** Planners and evaluators do not feel unpleasantly surprised or attacked by new arguments, know better how to make their own standpoints and reasoning explicit, know how to incorporate or internalize outside critique without acting defensively. Furthermore, Planners and evaluators may feel support by the management to act communicatively and trustworthy if they receive training on these matters and are more likely to act that way.	
	Intervention = Have the interaction guided by a moderator **Triggered mechanisms =** The moderator makes sure that all can speak freely, feel safe, all kinds of knowledge are taken seriously and get a worthy place in the discussion and the attention of the discussion is on finding shared interest, win-win solutions and issues behind immediate agendas. When Planners and evaluators feel guided and protected by the moderator, they may be encouraged to share more, more detailed and divers knowledge; be more open towards each other; give and receive criticism without attacking the person and without responding defensively.	
	Intervention 5 = Use dialogue modes (sketches, simulation, story board, role play): presented as 'work in progress' **Triggered mechanisms =** Planners and evaluators may feel encouraged to give their standpoints, to illustrate their arguments, make them context specific and explicit. This gives the others the opportunity to respond in their turn and illustrate, contextualize and explicate their points of views.	

It is our expectation that applying these interventions early in a CBA process will stimulate the involved planners and evaluators to improve their interpersonal communication and to build interpersonal trust so that they can use the CBA as a learning tool. Moreover, we expect that this will increase the fitness of the CBA when assessing integrated spatial transportation plans. These expectations, though, need to be tested in, for example, simulated CBA processes or ex-post analyses of CBA processes in which the CBA was used as a learning tool.

Appendix 1: Grouping of directions on communication and trust improvements from deliberative planning and organizational learning

Directions on improving communication between experts in deliberative planning
1. Have an open approach to all knowledge: **A. Exchange of different kinds of knowledge, feelings, interpretations** Exchange conceptions and interpretations Give room to feelings and thoughts **B. Allow all knowledge in the discussion and allow to question it** All kinds of knowledge allowed, like experiences, personal stories, and intuition All claims, assumptions and constraints are allowed to be questioned and tested Recognize and respect human emotions of anger, fear, impatience and suspicion Stretch out to access multiple perspectives Challenge established assumptions and cultivate debate and argument among different viewpoints Challenge assumptions and analyses by using local knowledge Ask for clarifications or examples when needed and challenge assumptions and question status quo. Encourage to ask questions **C. Give attention to issues behind immediate agendas** Re-orientate attention to issues which lie behind immediate agendas Address issues deeply **2. Behave appropriately:** **A. Have an open perspective towards each other** Have an open perspective towards comments of another Have an open-minded stance towards what is going on and what is at stake Prevent discussions from becoming too emotional Treat each other respectfully **B. Have an open attitude to change one's own assumptions and understandings** Stimulate a change of understandings Explore and recast agendas of problems, issues and potential actions and stakes, through accessing multiple sources of knowledge Learn from both acceptance and refusal **C. Behave actively by asking questions and listening carefully** Be close and keep a distant at the same time Show empathy and critical judgment Ask and listen Interpret the others language correctly Put yourself in the other's place Make suggestions that the other may not have thought of Think 'outside of the box' and put forward 'half-baked' ideas

3. Have interaction:

A. Create shared and embedded knowledge and understanding

Stimulate information to become embedded in the understanding of participants
Shared knowledge
Share and sharpen arguments and meanings
Ensure that the group makes a shared analysis of interests and conflicts
Stimulate the creation of meaning shaped by situations, trajectories, activities and values of particular social groupings

B. Have all stakeholders involved, empowered and interacting

All relevant individuals at the table and equally empowered
Scientists and agency staff need to be engaged with lay people

C. Act and learn together to develop familiar relationships

Accept a degree of collaboration and reciprocity
Act and learn together
Learn about each other
Build relationships
Have a process of collectively creating meaning and shaping information
Have conversations or "plenty of talk" about the meaning of information, its accuracy and implications
Have a dialogue
Organize brainstorming; scenario building; role playing; telling stories; and joint-fact-finding
Be validated and legitimated in an interactive way through talk, social encounters, discussion, debate and exchange of thoughts

D. Focus on shared interests and win-win solutions

Look for common interests rather than differences and challenging assumptions
Focus on the shared interests rather than the positions
Seek mutual gain solutions as far as possible;
Develop alternative stories that are plausible and appealing to all
Find win-win situations in which everybody gains
Negotiate between the stakeholders and their several interests
Identify where the energy for change may lie and build coalitions for change which expand this energy.

4. Have a supportive communicative context:

A. Create a safe environment to say what is on one's mind

Feel comfortable and safe to say what is on one's minds

B. Prepare stakeholders for a constructive discussion and formulate arguments at forehand

Prepare stakeholders to face each other by mentioning the objectives from both sides at forehand and
Help the stakeholders prepare for a constructive discussion
Let the stakeholders formulate their arguments in preparation of the discussion
Help participants to articulate their identity

C. Create a dialogue space, use familiar dialogue modes and use a mediator

Dialogue space
A sketch still open for discussion
Use a mediator or facilitator

Directions on building trust in deliberative planning

1. Show trustworthy behavior:

Do not behave arrogantly
Fulfill promises
Listen carefully and focus attention first on the person, then on the words
Timely and sincerely sharing of information and decision-making power
Communicate comprehensively, truthfully, sincerely, supportively and legitimately

2. Have interaction:

A. Acknowledge and respects all knowledge, thoughts and feelings

Assure that thoughts and feelings of all stakeholders were acknowledged and respected
Equal standing and respect for all forms of knowledge,
Openness and transparency mutual disclosure
Assure inclusiveness

B. Build relationships

Develop familiar relationships by learning more about each other
Build relationships to build trust
Getting to know the counterparts

C. Use a dialogue space

Create a dialogue space: meetings, negotiations, discussions, project reviews and hearings that bring affected citizens, regulators, developers, and public officials face-to-face, informal meetings
Have face-to-face interactions

D. Use a mediator

Use a mediator
negotiate between the stakeholders and their several interests

3. Prepare participants to participate in the discussion:

Prevent discussions from becoming too emotional if stakeholders felt confronted with (unpleasant) surprises
Formulate arguments at forehand
Prepare stakeholders to face each other by mentioning the objectives from both sides at forehand
Give attention to anger

Directions on improving communication in organizational learning

1. Interpersonal behavior to support communication

A. Open attitude to test assumptions

Transcend one's own limited perspective or boundaries.
Be open to test assumptions publically
No one withholds negative information from the others or withholds testing this information

B. Open attitude towards learning, including from risky ideas

Open to set a learning-cycle in motion
Open to the reciprocal exploration of risky ideas

See the other as minimally defensive, open to learning and committed
Have a learning orientation

C. Be explicit and accurate
Give and get valid information
Speak in direct observable categories (opening them to disconfirmation)
Create awareness of the values at stake and the limits of one's capacities

2. Organizational context to support communication

A. Leadership open to transformation and sharing of decision-making
Transformational leadership
Make designing and managing a bilateral task
Participative decision-making culture

B. Supportive structure: stability of team members, learning procedures, training
Stability of team membership
Positive supervisory behavior
Formal procedures for learning
Training with instructors or colleagues or repetitive exercises to stress behavior

C. Safe environment and emerging relationships
Work towards freedom of choice and internal commitment
A shared space for emerging relationships
Create a protected environment

3. Have interactions

A. Sharing and combining tacit and explicit knowledge
Sharing tacit knowledge among individuals
Articulating tacit knowledge into explicit concepts
Combining different entities of explicit knowledge
Embodying explicit knowledge into tacit knowledge
Individuals externalize their experiences
Personal subjected knowledge is validated, connected to and synthesized with others' knowledge
Produce new assumptions by combining articulated views with questioning by others of these views

B. Define means and ends unseparated and interactively
Keep the means and ends unseparated
Define the means and ends interactively to frame a problematic situation

C. All actors meet, discuss and become engaged in a knowledge creation process
Clients participate with the professional and give valuable input of their own
Become engaged in knowledge creation, dialogue, adapt to and shape practices
Have cross-functional communication
Meet face-to-face, sharing emotions, feelings, experiences, and mental models
Through dialogue mental models and skills are probed, analyzed and converted in common terms and concepts

D. Use various modes to reflect which are familiar to all practitioners involved

Directions on trust building in organizational learning

1. Personal awareness of others and trustworthy behavior

A. Awareness of (underlying) (pre)positions and openness to discuss them

Be aware of prepositions

Be aware of internal maps and see when present assumptions are counterproductive for learning

Advocate their views in a way that it would invite confrontation,

Challenge positions

Stimulate testing them publicly

Question publicly underlying policies and goals, assumptions, norms and objectives

B. Trustworthy behavior: act integer, discrete, really listen, be honest about expertise and limitations, give compliments, address troublemakers directly

Acknowledge mistakes

Recognize defensive behavior

Act discrete; people need to feel safe to share confidential information

Really listen to each other's thoughts and ideas

Disclose one's expertise and limitations (being open about ones strengths and weaknesses)

Being forthright and truthful in interactions

Give (public) compliments

Address troublemakers directly saying 'yes' to the person and 'no' to the behavior

C. Fulfill promises

Be consistent between word and deed

2. Interaction and forming relationships

A. Create knowledge together through communication

Move from old to new and shared assumptions

Have workshops and seminars

Have both sides feel free to share

Reflect on how one thinks

Have an open dialogue

Open communication to build trust

Use mediators and facilitators

B. Have stable, frequent and informal interactions to form relationships

Form embedded relationships

Through stable, frequent and tight interactions

Create reciprocity in the relationships and repeated interaction

Stabilize and manage interactions

Ensure frequent and rich communication on a personal as well as on a professional level

Engage in collaborative communication

Repeated and positive interactions

Enable informal meetings

C. Form a shared language or vision

Establish and ensure a shared vision and language

Make newcomers understand the values and principles of the organization and how things are done

3. Trustworthy environment

A. Share control, fair and transparent decisions

Trust emerged when control and responsibility was shared

Ensure that decisions are fair and transparent

B. Make rules to frame risks, opportunistic behavior, how to deal with conflicts

Discuss at forehand how to deal with conflicts

Design process rules to frame risk and opportunistic behavior

Inter-sector cooperation in emergency preparedness: The Israeli case.

Alex Altshuler

Abstract

Emergency preparedness process involves a wide range of stakeholders. Clearly, efficient coordination is necessary between them (Peek & Sutton, 2003), and the quality and extent of inter-organizational and inter-sector partnerships highly influence the level of emergency preparedness (Drabek, 2007). Enhancement of the inter-sector and inter-organizational cooperation throughout the emergency preparedness process on the local level was one of the main conclusions drawn after hurricanes Rita and Katrina (Simo & Bies, 2007). Importance of the cooperation between local authorities' emergency managers and various governmental and non-governmental stakeholders in the framework of preparedness for a war-caused disaster was highlighted also in the nationwide study in Israel (Altshuler, 2008).

In Israel, periodic warfare is, unfortunately, a common source of disaster, which injures the civilian population, Jewish and Arab alike (Laor, Wiener, Spirman & Wolmer, 2005). A fairly recent reminder of this type of disaster is the Israel-Lebanon war in summer 2006 (Ben-Harush, 2007; Sharkansky, 2007); in addition are the successive flare-ups since 2000 in the southern regions of Israel on the Gaza border, indicating the possibility of full-scale warfare between Israel and Gaza, as indeed happened in the winter of 2008-2009 (Altshuler, 2011b). In such situations emergency preparedness for becomes extremely important.
The current article will present a coherent, up-to-date and integrated picture regarding the inter-organizational and inter-sector cooperation in emergency preparedness for a war-caused disaster in Israel. It will be based on the recent scientific empirical findings that are first-of-its-kind in the country and a thorough analysis of the public policy trends.

Introduction

Emergency preparedness involves multiple organizations and groups (Peek & Sutton, 2003). These stakeholders include representatives of governmental sector and the two non-governmental sectors (the private sector and the third sector, which includes non-profit organizations). There is a fundamental difference between the governmental sector and the two non-governmental sectors. While the relevant public agencies and authorities (such as, emergency management authority, fire department, relevant military representatives and more) have formal and legal obligations to deal with emergency preparedness, the non-governmental sectors deal with that issue usually on a voluntary basis. This principle difference creates a substantial challenge of finding the ways to encourage the non-governmental sectors' involvement in emergency preparedness and create effective inter-sector cooperation. Additional differences between the governmental and non-governmental sectors in organizational culture, values, regulation and more may also affect the establishment of partnerships between them. In order to achieve a continuous interaction and mutually benefitting cooperation between the sectors all the above differences should be discussed between the interacting parties and mechanisms to overcome barriers should be established (Altshuler, 2011a).

The quality and extent of cooperation and coordination between the various stakeholders are highly influential factors among those concerned with the level of emergency preparedness (Drabek, 2007). Systematic improvement and expansion of inter-sector and inter-organizational cooperation in emergency preparedness on the local level was one of the main conclusions drawn after hurricanes Rita and Katrina in USA (Simo & Bies, 2007). Similar lessons regarding the local and the national level, in both the Jewish and the Arab sector, were learned in Israel following the war between Israel and Lebanon in 2006 (Katz, Raviv, Yogev, Yaacobi, Levinson, Alon & Gidron, 2006). The positive statistical relationship between the extent of inter-sector cooperation and the level of emergency preparedness of local authorities was also found in scientific empirical study in Israel (Altshuler, 2008).

In Israel, periodic warfare is one of the most frequent sources of disaster in the country's history, which injures civilian population, Jewish and Arab alike (Laor et al., 2005; Sharkansky, 2007). The two recent major reminders of this type of disaster were the Israel-Lebanon war in summer 2006 (Ben-Harush, 2007; Sharkansky, 2007) and full-scare warfare between Israel and Gaza in the winter of 2008-2009 (Altshuler, 2011b). In addition, it should be mentioned that there are successive flare-ups since 2000 in the southern regions of Israel on the Gaza border, while the last escalation occurred in August 2011. In such unstable reality emergency preparedness for war-caused disaster and its increase through inter-sector cooperation becomes extremely important issue.

Recent empirical research findings regarding inter-sector cooperation in emergency preparedness on the local level in Israel.

Until recently, there was no scientific empirical research regarding the various aspects of emergency preparedness of local authorities in Israel and the factors that influence them. This lacuna was filled by the first-of-its-kind nationwide research on emergency preparedness for war-caused disaster of local authorities in Israel that was conducted by the author in 2008 (Altshuler, 2008). This examination is currently the only empirical scientific source for thorough analysis of emergency preparedness issues in Israel. Among the central issues that were examined in this study was inter-sector cooperation in emergency preparedness. This cooperation was measured through the level of joint activities of local emergency managers with various non-governmental stakeholders. Regarding each of the private stakeholders, the chief local emergency managers related to the extent of the joint activities with them according to the five- point Likert scale (1- not at all, 5 – very high extent). The level of cooperation was examined in most of the local authorities in Israel (141) in the Jewish and the Arab sector. This research found empirically that the extent of joint activities of local emergency managers with non-governmental stakeholders was among the most significant predictors of the level of preparedness of local authorities for a war-caused disaster. This fact highlights the theoretical foundations and practical implications regarding the importance of inter-sector cooperation as one of the important measures to promote the actual level of emergency preparedness.
On the basis of the above study (Altshuler, 2008), it is possible to present the data regarding the specific levels of cooperation between the local emergency managers and the 12 non-governmental stakeholders. These findings appear in the following table:

Table 1: Means of joint activities of local emergency managers with non-governmental stakeholders according to the five- point Likert scale (1- not at all, 5 – very high extent).

Description of the non-governmental stakeholders	*Mean*
Community centers	3.28
Local assistance and volunteer organizations	3.27
Health funds	2.79
Lay residents in the local authority	2.70
Neighborhood committees	2.38
External professional experts	2.14
National assistance and volunteer organizations	2.05
Local businesses	1.92
Professional unions	1.76
Local philanthropies	1.63
National philanthropies	1.54
National businesses	1.36

The data in the above table is presented in descending order. In general, it may be said that with most of the stakeholders the partnerships are not so strong. Only with two of them – community centers and local assistance and volunteer organizations – the appraisal of partnership was higher than 3. These two stakeholders are central "players" on the local social arena and the cooperation with them is very important, but additional partnerships should also be strengthened. Given the significant relationship, found in the research, between inter-sector cooperation and the actual level of emergency preparedness, the current not high levels of cooperation reveal the fact that the level of preparedness could be substantially increased through greater public-private cooperation. In the above research (Altshuler, 2008) the average level of preparedness for a war-caused disaster was found as medium-high (3.52), but could be even higher if inter-sector cooperation were more widespread.
It is interesting to mention that the cooperation with lay residents (2.70) was found to be higher than with most of the formal stakeholders. It may reflect a non-trivial desire of a substantial portion of citizens to be involved in emergency preparedness. Another prominent finding is that businesses and philanthropies are less involved in cooperation with local emergency managers than other non-governmental stakeholders. Since the war between Israel and Lebanon in 2006, the involvement of businesses and philanthropies in emergency management was increased, although it is more "natural" for them to be involved in disaster relief (when the consequences of the disaster are already evident) than in emergency preparedness (when disaster cannot be actually "seen"). There is no doubt that if philanthropies and businesses will be interested and able to provide additional financial and other resources, it will substantially increase the preparedness and will enable to save more human lives in the case of emergency.

Analysis of the public policy trends regarding inter-sector cooperation

The war between Israel and Lebanon in 2006 was kind of a turning point in development of inter-sector cooperation and coordination in the field of emergency preparedness in Israel. In this war, the civilian population of a country – Jewish and Arab alike – was exposed to massive missile attacks that lasted 33 days and affected most of the northern region in Israel. The public structures aimed to deal with civic aspects of emergencies were unable to address the whole

range of multiple needs of the population in that situation (Elran, 2011). However, various private stakeholders, that do not have any formal responsibilities in that field, were highly involved in assistance to the civilians in northern Israel during the war. Their activities started spontaneously in most of the cases and the cooperation between them and the relevant governmental bodies was not substantial. However, some of those stakeholders continued their assistance to the population during the recovery phase and usually coordination with the governmental authorities at this period was much higher than throughout the war.

The expansion of activities of non-governmental stakeholders in emergency-related issues was related also to major socio-economic long-term processes that characterize the Israeli society: 1) continuous expansion of the third sector (Gidron & Alon, 2007; Gidron, Bar & Katz, 2003; Yishai, 1998), which increases the involvement of non-governmental associations in multiple social spheres, 2) privatization and outsourcing (Azriel, 2007; Dekel, 2006), which transfer the actual operative responsibility from the governmental organizations to private businesses or social organizations. The above policy trends served as additional catalysts for change of the governmental "monopoly" in emergency management.

Emergency preparedness became a much more prominent issue on the public agenda in Israel as a result of the war consequences, in both the Jewish and the Arab sector. The change in the Arab sector was even more substantial since prior to the war, most the local leaders in this sector preferred not to deal with emergency preparedness, since they believed that other Arab countries surrounding Israel will not attack Arab towns and villages inside Israel. In this war, for the first time, it was not the case and Arab civilian population also suffered from massive missile attacks. The functioning of the governmental bodies was revealed as insufficient and the need for the involvement of private stakeholders in emergency preparedness became more and more evident. There are two main categories of private stakeholders: 1) business corporations and philanthropies which donate money for specific activities in the field of emergency management, 2) non-governmental social organizations that are involved in practical activities aimed to increase the level of emergency preparedness. In most of the cases, the main financial resources of these social organizations come from donations of philanthropies and business corporations. Since 2006 private money was invested in the fields such as renovation and building of public shelters in the neighborhoods with severe socio-economic problems, education programs for volunteers in the field of emergency management, enhancement of inter-organizational cooperation on a local and regional level, and more. Following the war of 2006, the involvement of social organizations in emergency management in the Jewish and the Arab sector was substantially increased. Some of those organizations deal mainly with emergency management, while others are active in parallel in additional social and educational fields. Among the organizations, there are different scopes of activities in geographical terms: local, regional and national. Most of the organizations deal either in the Arab or in the Jewish sector, although there are some important exceptions to that general tendency: 1) The Israel Trauma Coalition for Preparedness and Response operates regional resilience center in both the Jewish and the Arab sector, 2) The Association for Children at Risk and its Resilience Center actively deal with educational programs in emergency management for the local municipalities' employees in both the Jewish and the Arab sector. In parallel to the substantial increase of activities of the non-governmental stakeholders in the field of emergency preparedness since 2006, fundamental changes took place also in the public sector. In organizational terms, there were created two new structures that were mainly aimed to improve cooperation and coordination among the public and the private stakeholders. In 2007 the National Emergency Authority (NEA) was established and in 2011 the Ministry for Home Front Protection was created. NEA was established in the framework of the Ministry of

Defense, to coordinate the activities of all agencies dealing with emergency preparedness, on the national as well as the regional and the local level. Gradually, this organization increased cooperation with both public and private stakeholders. One of the central tools it used to facilitate collaborative processes and increase inter-sector cooperation was active participation of multiple stakeholders from the private and public sector in annual National Home Front Drills, which examined various aspects of civilian emergency preparedness. The learning process prior, during and after those annual drills increased partnerships and working connections between public and private stakeholders on the local, regional and national levels. In continuation to the process of higher prioritization of emergency management in public policy in the recent years, the Ministry for Home Front Protection was created in 2011. Its exact structure was not finalized yet, but what is already clear is that NEA will be its main operational body. The new ministry is aimed cooperate with both the relevant public structures (such as, the Home Front Command of the Israeli Defense Forces, emergency departments of the governmental ministries and local authorities) and the private stakeholders, that are involved in emergency management. The establishment of this new ministry embodies the potential of further improvement and expansion of inter-sector cooperation, although at this stage it is not possible to determine to what extent this potential for a substantial positive change will be actually exploited.

Conclusion and summary

This chapter presented the important potential that inter-sector cooperation have to increase the level of emergency preparedness for a war-caused disaster. However, it also showed that in the Israeli case of preparedness on a local level, the exploitation of this potential is still rather limited. The combination of the above two facts poses challenge for emergency managers and for all the relevant public and private stakeholders to find more effective and efficient ways to expand and improve the inter-sector cooperation.

The analysis of public policy trends regarding the emergency preparedness in Israel in the recent years reveals that the system gradually becomes more integrated, new important national bodies are established and more efforts are taken to increase inter-sector cooperation. The direction seems positive in terms of greater cooperation between the sectors, although the current stage is still initial and the potential for cooperation is still exploited only in part. In the Arab sector in Israel emergency preparedness activities were very limited prior to 2006 and in the recent years were substantially expanded. It is hoped that this direction will continue in the future.

In conclusion, I would like to relate to a more general point. It is clear that emergency preparedness is not limited to war-caused disaster. Another major source of risk in that region is an earthquake. A strong earthquake in that region, at least in the last few centuries, occurred approximately every 80-100 years (Avni, 1999; Begin, 2005; Salamon, 2005). The last such earthquake happened in 1927. A future earthquake will affect both Israelis and the Palestinians, and this fact should urge the two sides to promote the cooperation between them. However, because of the political disagreements this did not happen until now. The scientists may serve as a bridge for cooperation and the author of the chapter participated in one such a meeting with Palestinian colleagues in 2006. It is hoped that future efforts will be more successful and will result with achievement of the ultimate goal for which we all make research, act and hope – to save more human lives when disaster strikes.

‘STRATEGIC PLAN’ AND ‘ENVIRONMENT PLAN’ IN TURKEY IN THE CONTEXT OF A QUESTION: “CAN ‘ENVIRONMENT PLAN’ BE COMBINED TO ‘STRATEGIC PLAN’ TO GET A NEW PLANNING TYPE NAMED ‘STRATEGIC SPATIAL PLANNING’ IN TURKEY?”

Cihan Erçetin [1]

Abstract

In recent decades, new planning approaches have been applied to spatial planning field in the world. Rapid transformation of the world’s new socio-economic organization particularly in urban areas and traditional planning methods were criticized because they remain insufficient in front of the new obstacles and facts. In this case, Strategic Spatial Planning approach appeared in planning field. Besides this, Turkey does not have proper planning system in terms of the integrity of spatial planning; therefore, there are many problems with regard to determination of the metropolitan regional development strategies. In Turkey, Strategic Plans include existing situation analysis, future strategies, vision, policies as in the Regional Plans and this helps to make criticism for Turkish experiences: Strategic Plans are lacking of spatial proposals and remain only as written documents. On the other hand, ‘Environment Plan’ exists in the hierarchy of Turkish planning system as an upper scale blueprint plan including strict spatial proposals similar to the ones in each scale of Master Plans and with its policies. Thus, a critique stands as ‘Environment Plan’ has many problems in terms of its overlapping scale and boundary with municipal Master Plans; and this plan has been still discussed about which actors take part in planning, how to establish planning-implementation relationship and what the content of the plans will be. Consequently, in this study, the hypothesis will be the unification of two perceptions of above mentioned planning types in Turkish planning practices: combination of the concept of ‘Strategic Plan’ with ‘Environment Plan’ to get ‘Strategic Spatial Plan’ concept. In other words, in Turkish planning practice, both Strategic Planning’ and ‘Environment Plans’ have problems and the discussion will be carried out in the context of the question of why there is a need for such unification.

Keywords: Strategic Spatial Plan, Environment Plan, upper scale planning, spatiality.

1. Introduction

In recent decades, the planning authorities in many countries have argued the irrelevancy of mainstream planning perspectives because of the rise of globalization processes. This resulted in emergence of new concepts, dynamics and problems in urban areas and affected the urban space (Gedikli, 2010). Until the emergence of these changes, the spatial patterns and regional development were determined according to strict, physical plans that were prepared according to vertical hierarchy as in Turkish current planning system.

New facts and new obstacles in recent years have experienced because of influential transformation of the world’s new socioeconomic organization particularly in urban areas. In addition, traditional planning methods were judged for the inadequacy of them in front of

these new obstacles and facts in large cities. As a result of this new era, Strategic Spatial Planning approach has become prominent in current agenda (Gedikli, 2007).

[1] Middle East Technical University, Ankara, Turkey- ercetin@metu.edu.tr

Turkey is one of the countries that considered these developments inevitable to adopt in its planning legislation as 'Strategic Plan' in order to meet the newly constituted demands in a most effective manner. When Turkish planning system is investigated depending on the 6th title of 3194 Zoning Law, plan types were categorized into two main groups: the first one is upper scale plans (Regional Plan) and lower scale plans (Master Plan, and Development Plan). Nevertheless, in the 5th title of the law introduces a new scale and new type of plan named 'Environment Plan' ('*Çevre Düzeni Planı'* in Turkish) as a physical land use one (Ersoy, 2006). It may be considered as an upper scale plan; however, it is still a problematic question whether it is a type of Regional Plan or not with its strict spatial and physical decisions and uncertain scale proposals. In other words, the administrative and structural problems of Environment Plan make it controversial for the current upper scale planning discussions.

Another type of newly introduced plan named Strategic Plan in Turkey is differentiated from the ones practiced in other parts of the world in terms of its spatial content which was preferred to be named as 'Strategic Plan' not 'Strategic Spatial Plan'. The question of 'to what extend it is spatial' is crucial for its implementation priorities of responsible institutions. Besides, it is still not included in Zoning Law of Turkish planning legislation which means the borders, responsible institutions, its content and scale are not designated exactly.

When these two types of plans –Environment Plan and Strategic Plan- are discussed with their problems, a solution proposal will stand exactly in themselves: combination of two types of plans in terms of their different aspects to constitute a new upper scale, spatial and participatory plan named 'Strategic Spatial Plan' for Turkey.

2. Strategic Spatial Planning in General and its Reflection on Turkish Planning System

Planning can be considered as a legal tool to make the potentials visible. Sub-scale development plans are only interested in the borders of a small piece of land aimed to create land use plans, therefore there is a need for a regional perspective for these potentials.

The concept of Strategic Spatial Planning has become prominent in agenda in recent decades and two-channel development can be mentioned to examine its revival period. First channel is represented by the processes of globalization including their effects on space in general. The "competitiveness agenda" stands as the distinctive characteristic in this process; in addition the reflection of this agenda on space can be exemplified as investments in transportation infrastructure, tourism, etc. The "environmental agenda" has also emerged in this period which means preservation of environmental/urban assets and development of life quality in living spaces (Albrechts, 2005). Accordingly, the aims of spatial planning interested in two important aspects –environmental and economic policy agendas- as multi-dimensional concept in the first channel development. (Gedikli, 2010)

After the late 1980s, in the second-channel development, spatial planning has started to be affected from post-modern philosophy which characterized the new understanding as decision making after consensus and expression of opinions of each stakeholder without considering positivist methods in planning (Blotevogel, 1999). Gedikli (2007) summarizes this process as "this new approach has led to the involvement of social networks in urban decision-making processes… A 'Communicative Rationality' paradigm comes into effect here, contrasting the 'instrumental rationality' paradigm of modernist era".
The emergence of multi-dimensional approach and new interactive processes enabled the revival of Strategic Spatial Planning that can be defined as "a public sector-led, socio-spatial process through which a vision, actions and means for implementation are produced that shape and frame what a place is and may become" (Albrechts, 2004). It consists of wide range of different participators to achieve multi-level governance in planning process such as national governments, sectoral units, agencies, banks, universities, chamber of commerce, non-governmental organizations, etc. (Albrechts, 2008). Another viewpoint developed by Sartorio (2005) describes the general characteristics of Strategic Spatial Planning as:

- Necessity to planning for a long term period
- Interaction
- Process oriented
- Comprehensiveness with a multi-actor process
- High participation
- Mutual connectedness

The process of Strategic Spatial Planning has become significant in realization of the plan after effective decision-making and determination of objectives in its process (Figure 1). The vision, objectives and guiding principles should be reflected into urban space through the help of spatial proposals within plan about development macroform, economic development or the ways of increasing life quality. According to Cavenago (2004), there are several components that always need to be parts of the process.

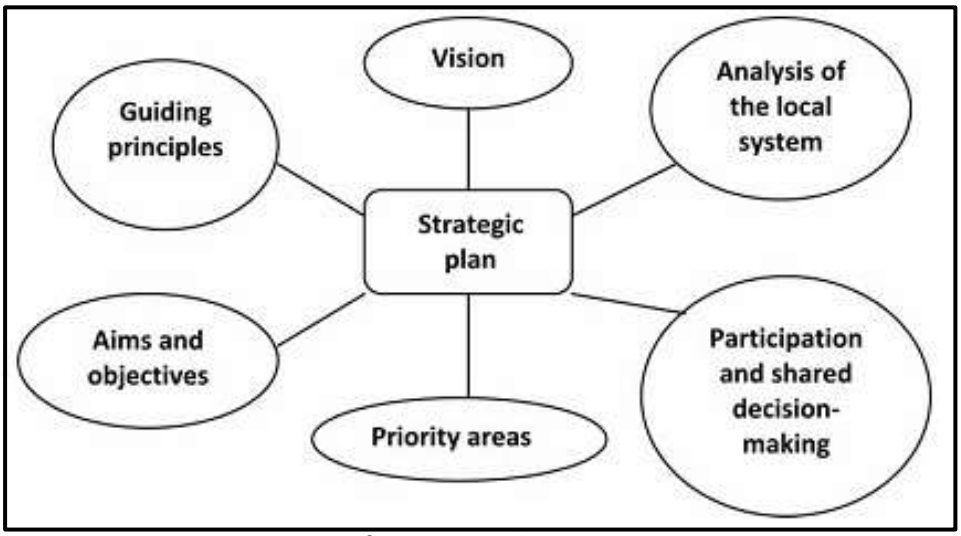

Figure 1. Components of Strategic Planning Process

2.1. Strategic Spatial Planning in Turkey

A common consensus on the definition of Strategic Spatial Planning does not exist despite its increasing popularity. Its perspective has widely accepted common characteristics and it is

practiced in different manners in different countries, because each country has its own planning technique, method and tradition. The perception and the use of this concept can be affected from different perspectives and personal experiences in different spatial units (Gedikli, 2007; Sartorio, 2005). Turkey is one of the countries which adopted Strategic Spatial Planning depending on its own planning traditions and methods.

Turkish planning system has adopted an increasing concern for participatory processes in its methods and practices. Since the beginning of 1970s, social democrat municipalities in metropolitan administrations embraced the significance of public participation in local processes in municipalities (Özcan, 2000). New perspectives of development and region comprehension, new world economy and also adaptation process to EU have created an increasing interest in 'Strategic Planning' in Turkey (Polat, 2011). By 1980s and 1990s -the years of increasing authorities of local governments- adaptation of participatory methods has become prominent. In addition, after the acceptance of the principle of local actor participation in local decision making process in United Nation Rio Conference on 1992 which Turkey is the participant country, participatory local decision making practices have started to become widespread. Particularly, after Local Agenda 21, local strategic plans were practiced in several cities in Turkey through Local Agenda 21. At the beginning of 2000s, in the 8th Five Year Plan (2001-2005-prepared by State Planning Organization) strategic approach in regional and sub-regional planning scales was stated and finally, Strategic Plan have found its legislative base in 2004 in a series of laws related to public administrations such as Municipalities, Special Provincial Administrations and Ministries (Gedikli, 2010).

2.2. Strategic Planning in Turkish Legislation System

After 2004, Strategic Planning emerged in Turkish Legislation System. After the change in 'Municipal Law' and 'Special Provincial Administration Law', those interested institutions have become responsible to prepare and control Strategic Plans as Corporate Strategic Plans (Hazanay, 2006). In this study, only the existence of Strategic Plans in municipal Law will be mentioned including its recent changes because of its similarity in titles of 'Special Provincial Administration Law about Strategic Planning.

- **5393 Municipal Law (2005)**

  - **"Functions and powers of the Municipal Council"**

"To discuss and approve the strategic plan, investment and work programs, activities of the municipality and performance scale of the personnel".

  - **"Duties and powers of the Mayor"**

"To manage the municipality according to the strategic plan, to develop corporate strategies of the municipal administration, to prepare the budget, to direct municipal activities and to determine scale of performance on the basis of these strategies; and to undertake implementation, follow-up and assessment of the same; to submit report to the Municipal Council related to these activities".

  - **"Strategic Plan and Performance Plan"**

"… the Mayor shall prepare a development plan and program, as well as a strategic plan in compliance with the regional plan (if any) … to be submitted to the municipal council. The strategic plan shall be prepared by obtaining the opinion of the universities and chambers, and

non-governmental organizations and shall be put into force upon approval of the municipal council. It is not necessary to prepare a strategic plan in the municipalities with population less than 50.000."

2.3.Concluding Remarks

After all, the definition of Strategic Spatial Planning in literature can be summarized as "a participatory approach through which people from different institutions come together and produce visions, strategies and projects for the development of their locality" (Gedikli, 2010). Turkish planning system has adopted main characteristics of Strategic Spatial Planning; but, a significant component of it is failed to be noticed: its relationship with space as mentioned in its title which is 'Strategic Plan', not 'Strategic Spatial Plan'. In the following sections of the study, the problems, a new model to overcome them and the roles of spatial planners in the process by mentioning another planning title named 'Environment Plan' in Turkey will be discussed in detail.

3. The Concept of 'Environment Plan' in Turkey

In Turkish planning legislation there are plans that represent upper scale regional policies in hierarchy (Table 1). By 1990s, Environment Plan has emerged between Regional Plans and Urban Development Plans hierarchically depending on 3194 Zoning Law. (Gedikli, 2009)

Table 1. Planning Hierarchy in Turkey

PLAN TYPE	RESPONSIBLE AUTHORITY
Five-year Development Plan	Ministry of Development
Regional Plan	Regional Development Agencies
Provincial Environment Plan	Greater City Municipalities in metropolitan cities Special Provincial Administrations and central municipalities in other cities
Environment Plan	Ministry of Environment and Urban Planning
Provincial Strategic Plan	Special Provincial Administrations
Municipal Strategic Plan	Municipalities
Urban Development Plan	Municipalities

According to the 5th title of Zoning Law, Environment Plan is defined as 'a plan which determines the land use decisions of housing, industry, tourism and transportation compatible with national and regional decisions". In addition, 'Regulation about Principles of Plan Making' introduces the legal definition of Environment Plan as:

'Environment Plan,

- provides the balance of protection-use between urban-rural structure and development, natural and cultural resources, and housing, industry, agriculture, tourism and transportation sectors;
- determines the land use decisions within the borders that displays spatial and functional integrity;
- prepared compatible with Regional Plan decisions (if any) and on the scales of 1/25000, 1/50000, 1/100000 or 1/200000;
- consists of physical plan, plan notes and plan report;
- can contain one or more provincial boundaries;
- is made or have it made by the Ministry of Environment and Urban Planning;
- includes collecting opinions of institutions about disaster areas, infrastructures, conservation areas, etc. in its preparation process;

- includes field studies, threshold studies, and economic, social, cultural, political, historical, sectoral and technologic analysis; also, macro scale population distribution and density decisions;
- provides the policies which represent data to sub-scale planning'.

Afterwards, it is reasonable to define Environment Plan which exists on hierarchically second stage and is prepared on region, basin and provincial level in accordance with Regional Plans. Thus, Ministry of Environment and Urban Planning is responsible to prepare 1/50000, 1/100000 or 1/200000 scale Environment Plan on region and basin level; Special Provincial Administrations, Greater City Municipalities or other municipalities are responsible to prepare Provincial Environment Plan which contains just provincial borders and on inexplicit scales (Ersoy, 2006).

3.1. Historical Background of Environment Plan

In Turkish planning history, it is believed that the concept of Environment Plan emerged as a result of the need to plan adjacent areas of cities. According to Duyguluer (2005), "1/25000 scale and the name of 'Adjacent Area Plan' were called Environment Plan over time". The concept of Environment Plan was included in 1985 dated Zoning Law as a planning type; however there was no information about its content, scope, scale, and preparation and approval process in the law. Afterwards, the failure of Regional Plans increased the significance of sub-scale development plans and preparation of Environment Plan explicitly which was undertaken by Ministry of Public Works –today's Ministry of Environment and Urban Planning-. By 1985, a detailed regulation is prepared named 'Regulation about Principles of Plan Making' which determined the definition, scales, content and preparation and approval processes. The change in this regulation in 2001 made Ministry of Public Works the only authority for Environment Plan, but Ministry of Environment and Forestry started a new discussion and disagreement for the preparation of the plan and finally, in 2003, a new law determined the new responsibilities and authorities of Ministry of Environment and Forestry. In this law, there was a title which designated the ministry as only Environment Plan making authority (Ersoy, 2006).

Besides, in 2005, Special Provincial Administration had also been an authority to prepare another type of Environment Plan named Provincial Environment Plan which extended the scale of the discussion. Finally, in 2011, there has been an important shift for the structures of Ministries in Turkey: Ministry of Public Works is transformed to 'Ministry of Environment and Urban Planning', and Ministry of Environment and Forestry to 'Ministry of Forestry and Water Works which means Environment Plan authority has been designated to Ministry of Environment and Urban Planning exactly and some of the planning authorities for ministry level have been given to it.

Environment Plan is defined as a strict land use plan in terms of its content and it is located under the scale of Regional Plan and above the Development Plan. Thus, an important question rises here that to what extend it has to be spatial and regional when it is considered together with Turkish version of Strategic Spatial Planning named 'Strategic Plan'.

3.2.The 'Puzzle' of Environment Plan

In Turkey, the complexity of planning legislation by means of too much additions and authority transfers, the reflection of unrelated upper scale plans on urban space in implementation process, and even failure of some of upper scale plans affected the existing planning system in a negative manner. Particularly after 2000s, despite the abundance of plans, it was experienced that their implementations revealed different results than expected before (Eraydın, 2008).

Environment Plan puzzle has made an important contribution to the complexity of upper scale planning in Turkey. The reason to entitle it as puzzle is about its problems of authority ownership, scale complexity, implementation problems, administrative dilemmas, practicing difficulties and the language of the plan. In other words, although the complexity of upper scale planning has been tried to be organized by the improvements in the concept of Environment Plan, the plan could not respond the purpose of planning on that scale and even damaged it. Consequently, it can be stated that the concept of Environment Plan has to be restructured or recreated or even removed by using some other planning channels. In order to construct evidences for a proposal of such a radical change in upper scale planning, the problems of Environment Plan is classified in two groups as administrative and structural problems.

3.2.1. Administrative Problems

The condition of centralization rather than localization stands as the first significant question at the top of the upper scale administrative planning problems in Turkey. Centralization of policy making power in developing countries can be analyzed as an important obstacle for the rise of governance in any practices of administration. Therefore, some of the authorities of central governments have been shifted to local governments (Yüksel et al., 2005). This kind of localization and strengthening local governments are essential in terms of democratization; in this way, transfer of power to local governments is assumed to provide easy delivery of the needs and expectations of local people, increase participation in decision making and strengthen the perception of decentralization (Şengül, 2009). After 1990s Turkey has also experienced the concept of participation on a more concrete manner especially in planning community by defending two causes of participation. Firstly, participation has become a worldwide trend after 1990s with a milestone of United Nations Rio Conference (1992). Another cause that is past planning experiences of Turkey stated that city plans without local participation were not able to regulate urban development as expected (Tekeli, 1993). In this case, bottom-to-top relation rather than top-to-bottom hierarchy is more acceptable in policy making areas including upper scale plan making.

Turkey has also shown some efforts to adopt these kinds of global changes and transformations in its planning practices; however Environment Plan is still a plan which contains a strict top-down hierarchy and almost non-participatory planning process. Central government decides what the borders of Environment Plan regions will be, what kinds of land uses will exist in urban space, where to macroformal urban pattern will be oriented in future and also who to ask about opinions and ideas. For instance, Ministry of Environment and Urban Planning designates the planning region -generally one or more provincial boundaries-, then the ministry initiates a tender for plan making, after that mostly a special firm gets the tender and starts collecting necessary data like maps, photos, infrastructural information etc. In the next period, institutional opinions are collected and Environment Plan documents are

prepared. As a result, here it can be easily mentioned that such a process is not absolutely compatible with any current transitions in the world like transition from government to governance, from top-to-bottom to bottom-to-top relations, and in general, from hierarchy to participatory democracy (Figure 2).

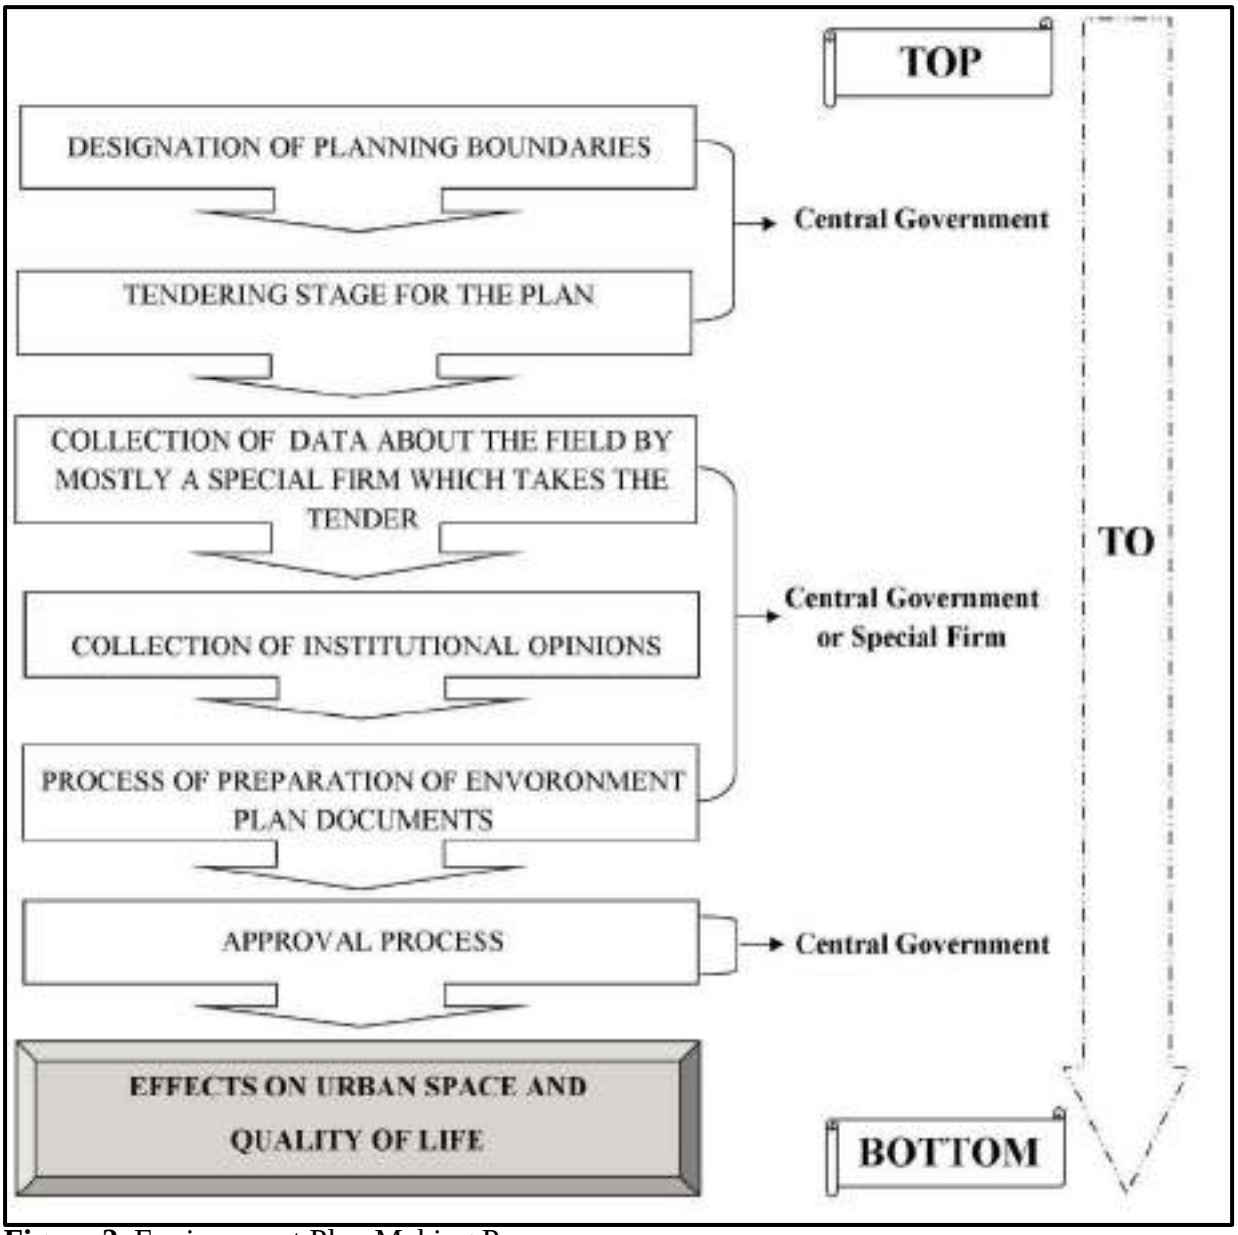

Figure 2. Environment Plan Making Process

In addition, in most of the European Union (EU) countries, planning perspective is differentiated from Turkey, and an implementation and concept named as Environment Plan does not exist in any other part of the world. In EU countries, while planning system can be summarized as 'Regional Plan, Urban Plans and detailed plans' (Ercoşkun, 2005); in Turkey, there is also an Environment Plan concept after Regional Plan in this arrangement within a strict top-to-bottom vertical hierarchy.

Another administrative problem contributing to Environment Plan puzzle is the scale problem. It can be stated that there are contradictions about 1/25000 scale plans depending on new definitions that were introduced to planning. In 2004, it was stated in the Greater City

Municipal Law in its 7th title that providing compatibility with the existing Environment Plan, Greater City Municipalities are authorized for preparing Master Plans inner and outer parts of Greater City Municipality boundaries with a 1/5000 to 1/25000 scale. In fact, by this new regulation in law, the scale of Master Plan has increased from 1/5000 to 1/25000. This caused two main problems: the first is the mystery of the content and the scope of 1/25000 Master Plan compared to 1/5000; and the second is the overlapping boundaries of this kind of Master Plans in 1/25000 scale and Environment Plans in 1/25000 scale that prepared before (Ersoy, 2006). Afterwards, by the emergence of renewed 'Environment Law' in 2006, although Ersoy (2006) stated that "the scale complexity in Environment Plan making finished up by the new title which designated the scale of Environment plan as 1/50000 and 1/100000", two problems still exist and have to be taken into account in the solving the scale complexity. The first one is overlapping boundaries and policies of 1/25000 scale Master Plans and Environment Plan with the same scale that had been made before. Particularly, the other one is dilemma between new 'Environment Law' and 'Regulation about Principles of Plan Making' in this context. As mentioned before, according to 'Environment Law', the scales of Environment Plan are 1/5000 and 1/100000; besides, 'Regulation about Principles of Plan Making' mentions 'Environment Plan…is prepared compatible with Regional Plan decisions (if any) and on the scales of 1/25000, 1/50000, 1/100000 or 1/200000…'. According the hierarchy between laws and regulations, it is obvious that regulations have to be compatible with laws and in the condition of complexity between them, the law would be valid. However, institutional authorities are the process planner and the implementer of 'Environment Plan' and there will always be confusion about scale against them to decide the boundaries of the plan. To sum up, only legislative solutions cannot remove scale challenge of Environment Plan.

This kind of puzzle of Environment Plan also involves the problem of authority conflict. Before the establishment of Ministry of Environment and Urban Planning in 2011, a seriously chaotic circumstance has existed and as mentioned before, removed Ministries of 'Environment and Forestry' and ''Public Works' could not share the authority to Environment Plan making. Finally in 2011, establishment of Ministry of Environment and Urban Planning has partially removed the authority problem by giving all responsibility to this ministry in this case, but the conflict between Special Provincial Administration and Ministry of Environment and Urban Planning still exists. In 2005, 5302 'Special Provincial Administration Law' introduced a new type of Environment Plan named Provincial Environment Plan prepared by the leadership of governor. However, this plan creates many concerns about overlapping boundaries and scales, different proposals due to lack of cooperation between institutions, and implementation troubles since competition between institutions.

Later, some legal changes have limited the boundaries of Provincial Environment Plan to provincial borders, therefore if the district or region is smaller or larger than provincial boundaries, then Ministry of Environment and Forestry was authorized in these areas –then transferred to Ministry of Environment and Urban Planning in 2011-. However, this cannot change the fact that there may be two different and disjoined upper scale plans for one common space or region within a strict hierarchical order in inter-institutional relationships of authorized administrations.

The difference between Regional Planning boundaries depending on NUTs classification (Nomenclature of Territorial Units for Statistics) and Environment Plan regions constitutes the last part of administrative problems of Environment Plan puzzle. The problem here is that two upper scale plans involve different provinces in their regional zoning.

Source: http://www.cedgm.gov.tr/CED/AnaSayfa/CevreDuzeniPlani.aspx?sflang=tr

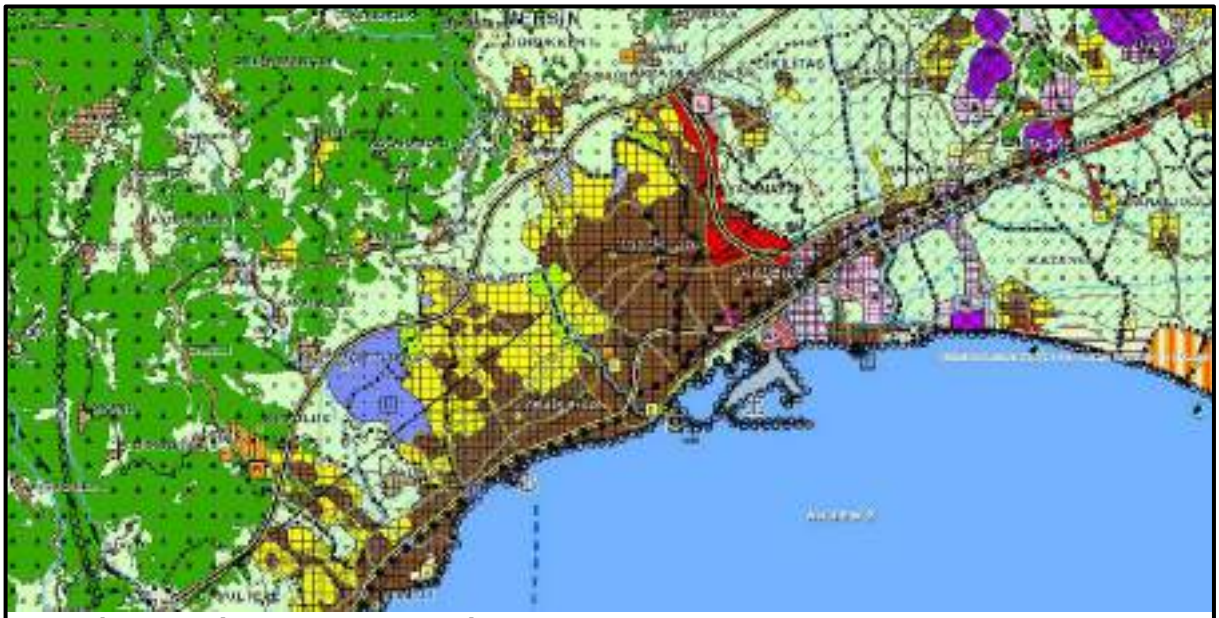
Figure 4. Environment Plan regions authorized to Ministry of Environment and Urban Planning

When the Regional Plan and Environment Plan including Mersin province in their territories is taken as an example, it can be seen that Mersin is combined with Adana province in the territory of TR62 of NUTs 2 level classification for Regional Plan; besides, regarding Environment Plan, Mersin was combined with Karaman province as a region and Adana was introduced as a single territory (Figure 3 and Figure 4). These zonings are both for upper scale planning in Turkey and different kinds of association in terms of regional zoning here may create incompatible regional strategies and disjoined policies which emerge in between the hierarchy of Turkish planning system.

3.2.2. Structural Problems

At the beginning of these problems, strict and inflexible structure of land use decisions comes first. Environment Plan does not provide any flexibility to sub scale plans and it makes other sub scales limited to the boundaries that is designated by Environment Plan practice as seen in some part of 1/100000 scale Mersin-Karaman 2009 Environment Plan which constitutes a

clear example of mentioning strict land use decisions (Figure 5). In addition, some parts of these plans contain 1/1000 and 1/5000 scale detailed policies and decisions which means Environment Plan is sometimes a candidate to be a substitute for sub scale plans; thus this cannot be acceptable for any upper scale plan.



Source: http://gisapl1.cevreorman.gov.tr/cdp/

Figure 5. Central part of Mersin province in 1/100000 scale Mersin-Karaman 2009 Environment Plan

Demonstration in an upper scale plan (1/200000, 1/100000 or 1/50000) have to contain a more conceptual and schematic representations to be differentiated from physical land use decisions of a Master Plan, moreover this also supports the firstly introduced problem item of Environment Plan about lack of flexibility. Therefore, the more legible Environment Plan will be by using conceptual and schematic demonstration techniques, the more flexible and understandable upper scale planning will emerge. When a small part of 1/100000 scale Mersin-Karaman 2009 Environment Plan and 1/25000 scale Mersin Master Plan -contain a part of Mersin Organized Industrial Zone district- are discussed, it can be easily seen that there is almost no difference between them in terms of their demonstration although one of them is an upper scale, another one is a subscale Master plan (Figure 6 and Figure 7).

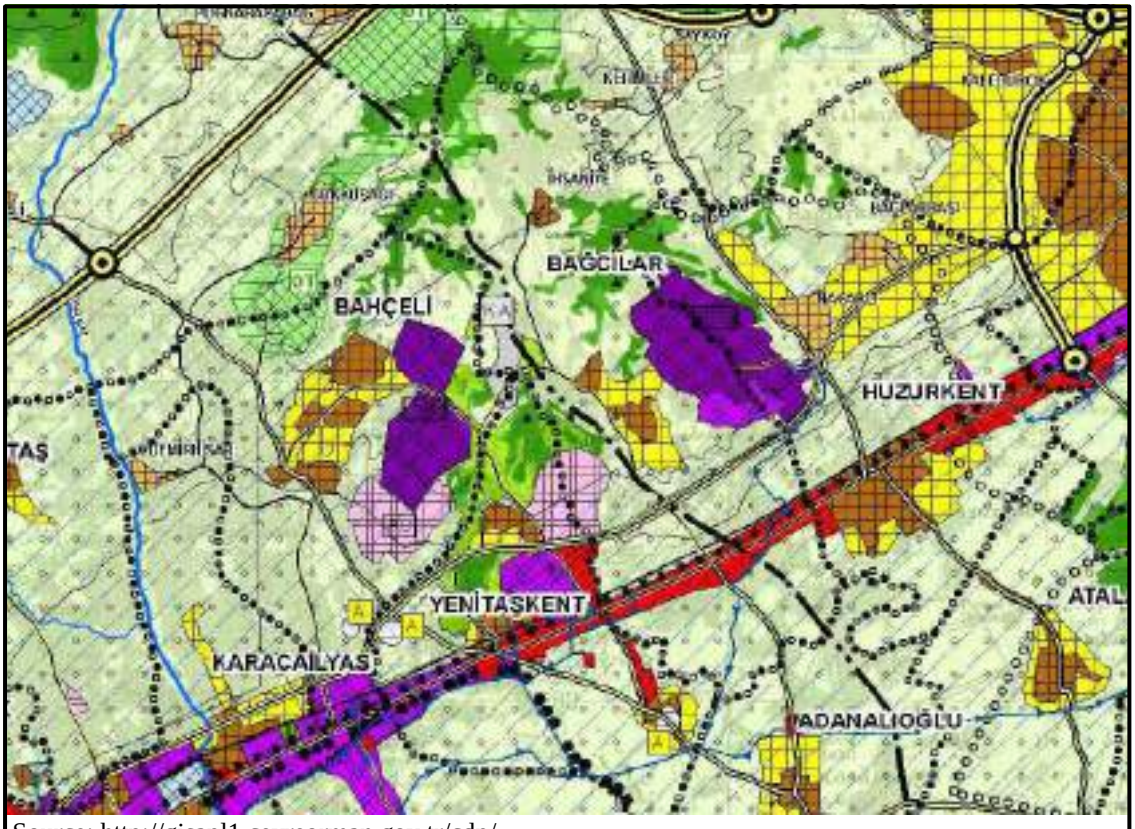
Figure 6. A part of Mersin Organized Industrial Zone District in 1/25000 scale Master Plan



Source: http://gisapl1.cevreorman.gov.tr/cdp/

Figure 7. A part of Mersin Organized Industrial Zone District in 1/100000 scale Environment Plan

Finally, the last structural problem that contributes Environment Plan puzzle is about its lack of strategic decisions and consideration of it as a data bank. Nowadays, the practice of Environment Plan is just oriented to collection of data like infrastructure, existing properties, photographs etc. from the field and it is seen as a tool to reach many kinds of information about the interested region instead of producing strategic decisions, determining priority areas and development axes.

After all, these administrative and structural problems constitute satisfactory evidences for having such a puzzle, thus it can be concluded that this kind of an upper scale plan is not indispensable for Turkish planning system. The main question here is about how this puzzle can be solved by using what kinds of tools. Before the answer, problems of Strategic Planning in Turkey will be mentioned, since the solution for this puzzle contains mainly the method of Strategic Spatial Plan making.

4. The Problems of Strategic ('Spatial') Planning in Turkey

In Turkey, local governments have the authority to prepare Strategic Plans for urban spaces to provide the public interest basically. Local governments try to meet different expectations for urban services and also, overcome increasing and diversifying service demand with limited resources (Emrealp and Yıldırım, 1993). Therefore, the newly world trend of Strategic Spatial Planning can be an effective tool for local governments in Turkey to tackle;

- Rapid urbanization
- Technological and social changes
- Increasing urban problems
- Migration
- Need for a sustainable development
- Lack of urban infrastructure
- Expectation of high quality services
- Need for a strategic, long term decisions for local governments. (Akın and Güleç, 2003)

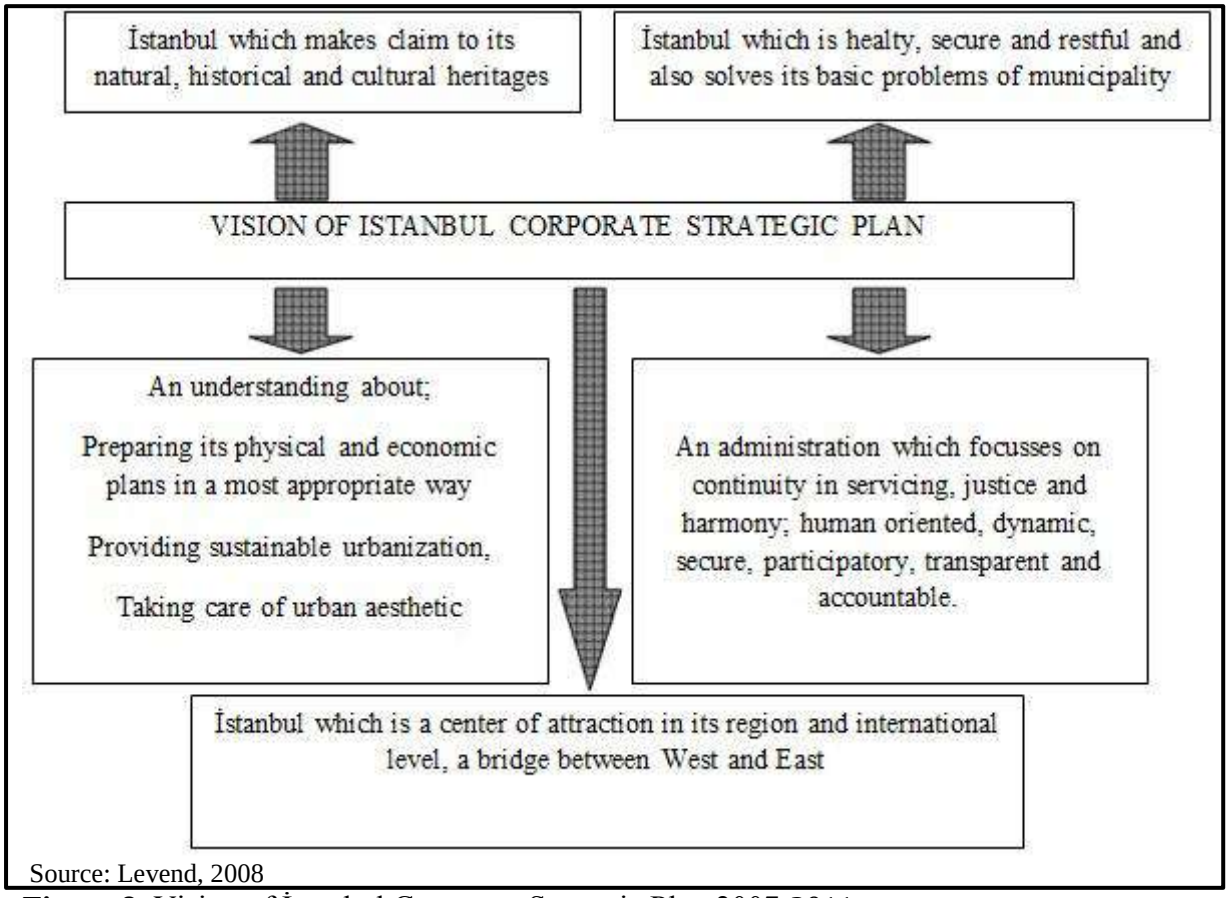
By the emergence of Strategic Spatial Planning practice, most of the characteristics of it have tried to be adopted in Turkey. Nevertheless, two main problems still exist which constitute the most fundamental components of the plan: firstly, the spatiality problem comes depending on the name of 'Strategic Plan', not 'Strategic Spatial Plan', and then lack of efficient cooperation in process stands as a second problem.

4.1. Lack of Spatiality

The name of the plan -called as Strategic Plan- in Turkey constitutes the first problem. This means the term 'spatial' is missing; if it is put differently, the relationship of vision, policies and strategies with urban space has remained missing. Instead of dealing with spatial demonstrations like schemes, strategic policy areas, development corridors and the effects of sectoral proposals on space; the Strategic Plan deals with vision, policies, strategies and usually projects that make the plan be realized. However, any kinds of suggestions about how the space takes what kind of form are not brought forward within the plan.

Strategic Plans have also started to resemble each other in Turkey. They have to contain strong spatial base, proposals and development patterns, thus these kinds of spatiality

concerns will make Strategic Plans differentiated, diversified and most importantly, practicable. Nevertheless, how this kind of Strategic Spatial Plan is prepared and what the general rules of it will be have to be exactly determined at first (Beyhan, 2008). In addition, the increased role of urban planner in Strategic Planning process is directly proportional with spatiality of the plan. Only the public administrators, politicians or representatives of non-governmental organizations cannot challenge spatial proposals, therefore the roles of urban planners have to be carefully considered within the process.



Source: Levend, 2008

Figure 8. Vision of İstanbul Corporate Strategic Plan 2007-2011

In İstanbul Corporate Strategic Plan 2007-2011 prepared by the Greater City Municipality of İstanbul, any spatial proposal cannot be seen to increase the practicability of the vision for İstanbul. There are only written policies and strategies in document (Figure 8). It has already the name of 'corporate Strategic Plan' –not spatial- which consists of "10 strategic service areas, 64 strategic aims, 190 strategic targets and 415 actions" in its policy document (İBB, 2006), but it most probably will remain as a written document without referring the urban space of İstanbul. Thus, what the kind of spatiality of Strategic Plans will be in Turkey remains still as a question in current practices.

4.2. Lack of Efficient Cooperation in the Process

Collaboration between stakeholders has a vital role in Strategic Spatial Planning, since main strategies and policies are constructed onto the efficiency of a participatory process. Efficient participation to the process for both the citizens and the institutions prevents the Strategic Plan to be an institutionally owned one in Turkey, because the ultimate target of Strategic Plan is providing public interest and efficient urban and sectoral development. Therefore, this

target can become realized in case of agreement on common ideas for the future of interested region.

In Turkey, the practice of Strategic Plan exists in both local government units of Municipalities and Special Provincial Administrations. Disconnectedness between both institutions results in two different Strategic Plans for the same territory rather than keeping together in one single Strategic Spatial Plan with an active participatory process. This results in difficulties in implementing the policies of the plan and damaging the targets of the plan. Consequently, cooperation rather than competition between stakeholders stands as a significant point for the efficiency of the plan.

5. New Model in Upper Scale Planning in Turkey: STRATEGIC 'SPATIAL' PLANNING

In recent decades, the significance of upper scale planning has increased in globalizing world, therefore increasing needs and expectations should be managed effectively and the impacts on urban space should be controlled by planning with upper scale visions, policies, strategies and spatial demonstrations in this new era. In this context, Turkey has experienced a dramatic articulation process to this new trend by emergence of two different upper scale planning called Strategic Plan without referring to urban space and Environment Plan with its inflexible planning approach by using classic land use planning logic. In this case, it can be mentioned that significant problems exist in these kinds of upper scale planning concepts and they are not practiced compatible with their ultimate aims (Table 2).

Table 2. Problems of Environment Plan and Strategic Plan in Turkey

Environment Plan	Strategic Plan
• Nonexistence in any other part of the world	• Lack of spatiality
• Vertical rather than horizontal hierarchy	• Ineffective participation
• Scale problem	
• Authority conflict for plan making	
• Confusion between NUTs 2 regions and Environment Plan regions	
• Traditional land use planning	
• Not schematic and flexible demonstration enough	
• Lack of strategic decision and existence as data bank	

In addition, existing planning perspective in Turkey can be criticized for the reasons of:

- being exceedingly technical,
- concentrating on physical dimension of development rather than social,
- remaining plans as only a written document and difficulties in implementation,
- not responding the needs emerging from the changes in the world.

Thus, the significance of Strategic Spatial Plans has increased that constitutes a flexible, short term, project oriented and easily adaptable to political and market pressures approach (Genç, 2008). In this context, upper scale planning in Turkey necessitates either strategic or spatial approaches instead of Environment Plan in order to be adapted to the changes in global world.

5.1. Results and Discussion: Creation of Strategic Spatial Planning Model and its Characteristics

This circumstance of complexity in upper scale planning reminds a question: can Environment Plan be combined to Strategic Plan to get a new planning type named Strategic Spatial Planning in Turkey? Initially, only the spatiality context of Environment Plan can be handled for the new model by formation of a more flexible content of it. Apart from that, other characteristics –mostly the problems- of Environment Plan are not compatible with the current understanding of upper scale planning, which means there is no reason to exist such type of a plan as if it represents upper scale. Then, another question may rise here: in that case, to what extend and how can both plans be combined? Strategic Planning in Turkey necessitates spatial context as mentioned before, therefore the spatiality context of Environment Plan is articulated to Strategic but non-spatial Plan, because the most contemporary and effective planning tool in current agenda can be seen as Strategic Spatial Planning and Turkey has to follow such changes in order not to stay stable rather than dynamic in terms of adaptation to the current developments (Figure 9).

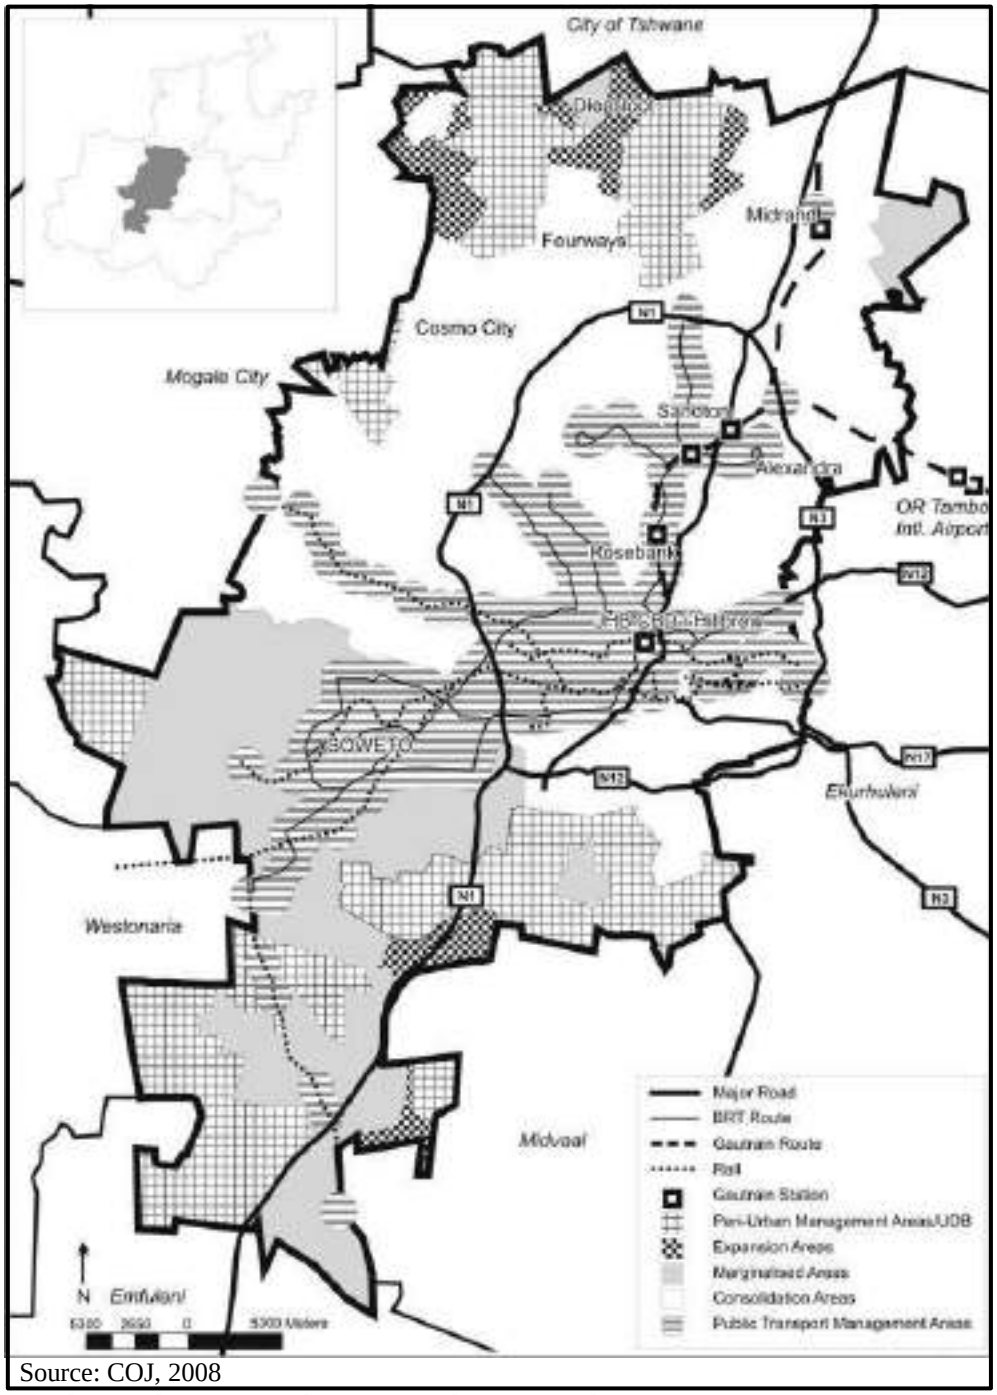
Figure 9. Creation of a New Strategic Spatial Planning Model in Turkey

At the top of its characteristics, bottom-to-top horizontal hierarchy in planning process is adopted. In Environment Plan, lack of participation and central dominance in plan making constitute an important part of its puzzle (Figure 2); instead of it, Strategic Spatial Plan will be prepared by the leadership of local governments' partnership with the participation of representatives from civil society including citizens and non-governmental organizations, central administration and private sector as stated in the concept of government to governance shift.

In this case, institutional cooperation will highly contribute to new model. Both Environment Plan and Strategic Plan processes in Turkey deprive of such kind of cooperation, and institutions are in competition between each other in plan making. Instead of preparing separate Strategic Plans by different administrative institutions, one unique Strategic Spatial Plan will be experienced for a definite region or province by coming together in the process participation of different institutional levels. In addition, the borders of the plan will also be flexible and the decisions of Regional Plans will have to be taken into account within the process of this collaborative environment.

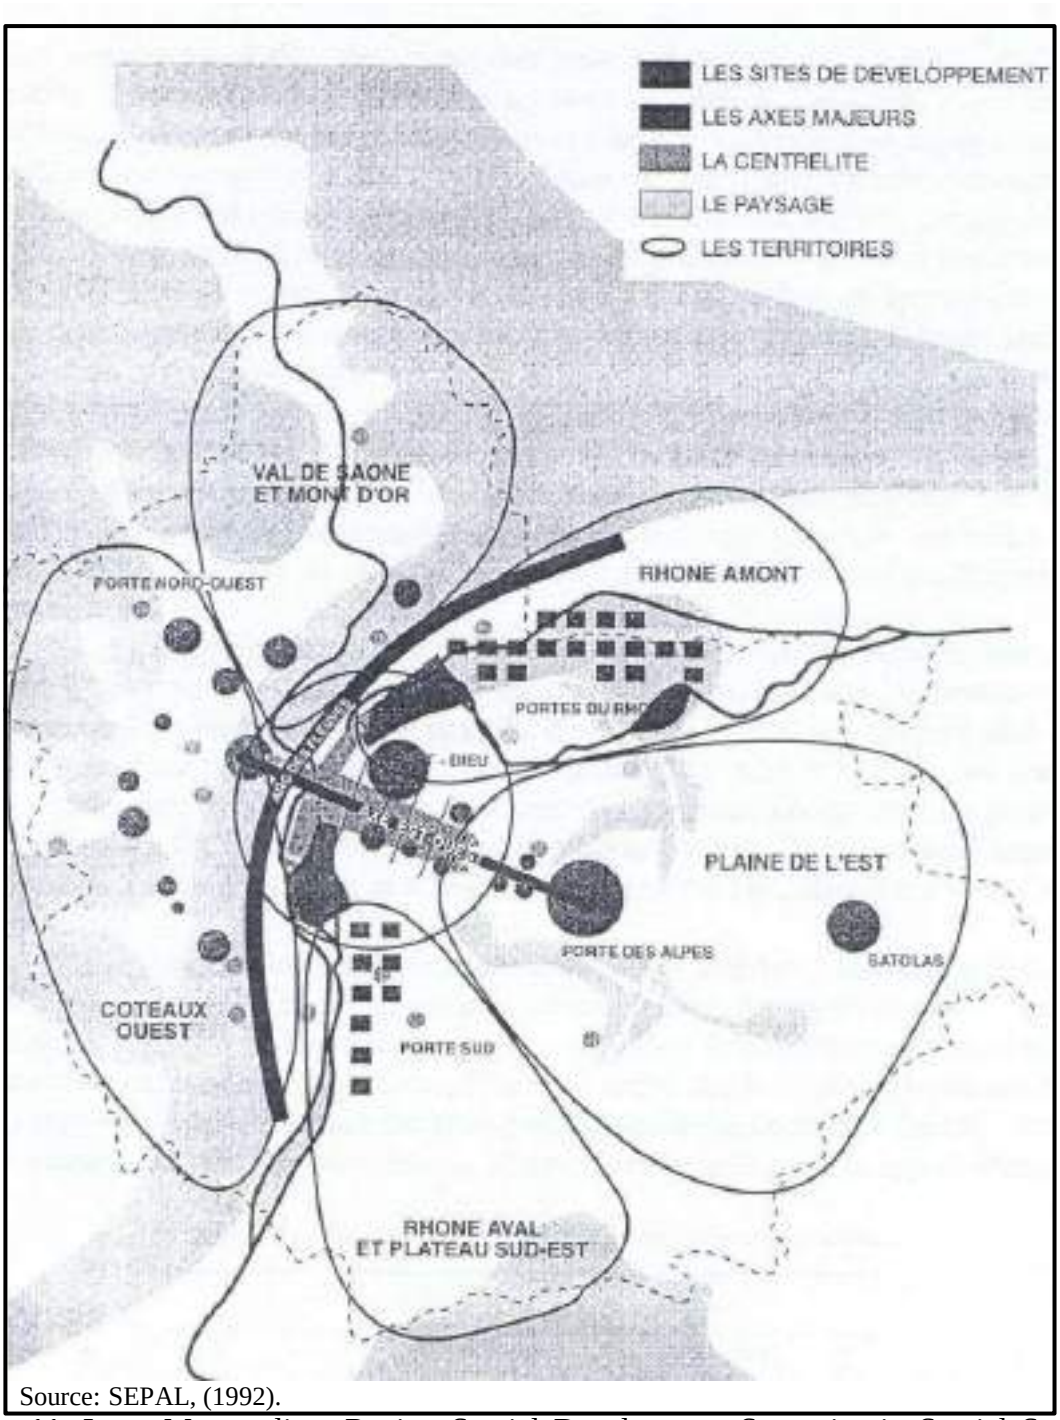
In Turkey, urban plans exist as having either highly a strict spatial structure or a non-spatial written policy document. This Strategic Spatial Plan model will be located in the middle of these patterns. For instance, Environment Plan decides even in sub-scale level and restricts other plans that have to be compatible with it. In this case, an abstract spatial content will exist in the new model of Strategic Spatial Planning which focuses on development corridors, strategic development areas, conservation of necessary fields, sectoral developments,

relationship with other provinces or countries in global scale etc. by using abstract demonstration techniques in a more general and flexible manner as seen in some examples from other countries (Figure 10 and Figure 11).



Source: COJ, 2008

Figure 10. Johannesburg Spatial Framework in Growth Management Strategy



Source: SEPAL, (1992).

Figure 11. Lyon Metropolitan Region Spatial Development Strategies in Spatial Strategic Plan

This kind of spatiality highly depends on the increased role of qualified urban planners by using their perception of space as a whole in Strategic Planning process to achieve efficient spatiality of the plan. In this case, the reason why spatiality is so important rises as a question. In fact, planning would be meaningless without implementation, and relationship of policies and strategies with space facilitates and enables realization of plans.

6. Conclusion

Turkish planning system has tried to be adapted to the changes in current upper scale planning developments in the world. Some parts of the reflection of this adaptation appeared as Environment Plan and Strategic Plan which represent upper scale strategies and policies. However, the problems highly affect the efficiency of plans and realization on urban space. In order to regulate urban development through the aims of public interest and providing increasing and diversifying service demand with limited resources, a new perspective in upper scale planning is needed as an advanced manner of Strategic Planning including spatial context.

Spatiality in Strategic Plan enables the realization of policies on urban space. Through this kind of relation with space, active participation of different kinds of stakeholders in decision making process of the plan can be practiced. As a result, a collaborative environment can be constituted and sub-scale Master and Development Plans can easily be referred to the Strategic Spatial Plans that make them more reasonable and most importantly applicable for urban space.

DETERMINATION OF SEISMIC VULNERABILITIES AND RISKS FOR URBAN MITIGATION PLANNING IN TURKEY

Tuğçe SÖNMEZ[1]

Abstract

As the number of events and the losses from disasters are increasing worldwide, disaster reduction has become an increasingly important issue on the international agenda and the reduction of risks that are particularly concentrated in cities become the major objective and challenge of international disasters policy. As a result of this policy United Nations has established the International Strategy for Disaster Reduction in 2000, organized World Conferences on "Risk Reduction" in Yokohoma-1994, Toronto-2004, Kobe-2005 and announced 2010-2011 as the campaign years for 'Resilient Cities'. These conferences have extended and sharpened awareness about natural hazard risks and efforts of risk reduction on global agenda.

Chronic seismic hazards and resulting secondary impacts are due to the geological conditions of Turkey and the nature of current response mechanisms. Local know-how of building and settlement that evolved over centuries eroded with the growth in population, and the introduction of reinforced concrete building economics. This makes cities the most vulnerable geographical and social entities in Turkey. On the contrary, Turkish disaster policy has mainly focused on the post-disaster period and remains limited due to development of regulations that can not be fully implemented. No incentives or legislation existed to encourage risk analysis, risk mitigation or risk spreading approaches.

With this point of view, the aim of this research is to examine the factors that determine seismic vulnerabilities and risks of settlements and establish if analysis of seismic risks in cities and living environments could be determined on the basis of a set of attributes of the building stock. The scope is to exhibit and analytically compare such factors in settlements of Turkey. Quantitative information about a set of attributes of settlements is investigated statistically to determine which of the factors contribute most to risk levels described locally. Correlation and Regression analyses are employed to determine what combinations of the independent variables might best denote city-level risks. The seismic hazard maps of the Kandilli Observatory and Earthquake Research Institute and statistics published by the Turkish Statistical Institute, like census and housing data have a leading contribution to make. These secondary sources of information help to compose the database for a series of comparisons in the seismic vulnerabilities and risk levels of cities.

[1] Middle East Technical University, Ankara, Turkey - tugcesonmez@gmail.com

This study is expected to provide information about the critically vulnerable assets in cities, whether this could be considered as a function of hazard-proneness. Otherwise, interpretations of the most effective attributes that could describe vulnerabilities best and be related to risk information in cities could be explored. Findings of such analysis could provide guiding criteria for mitigation policies in Turkey and the research may thus generate information for a more effective disaster policy.

1. Introduction

Over the past decade, countries across the world have witnessed thousands of major natural disasters that threaten the sustainability of cities, disrupting their resources and affecting millions of people through losses of life, serious injury and loss of assets and livelihoods. The number of reported natural disasters and their impact on human and economic development worldwide has been increasing yearly and shows a relentless upward movement. Considering that half of the world's population is expected to live in urban areas by 2020 and over three-quarters of the 100 largest cities are exposed to serious natural hazards, it is time to adopt a new approach and invest in pro-active disaster reduction strategies.

In recent years, there has been a major shift in peoples' attitudes and behaviors towards coping with natural disasters. In the past more emphasis was placed on humanitarian response and relief activities, with little attention being paid to disaster reduction that have the potential to save thousands of lives. Today, there is increasing recognition that while humanitarian efforts are important and need continued attention, risk and vulnerability are crucial elements in reducing the negative impacts of hazards and thus essential to the achievement of sustainable development.

The idea for conducting a global review of disaster reduction initiatives was born in the millennium, following the United Nations International Decade for Natural Disaster Reduction (IDNDR) 1990-1999. In 1999, UN decided to continue the activities on disaster prevention and vulnerability reduction carried out during the IDNDR. It thus established the International Strategy for Disaster Reduction (ISDR), which is supported by the scientific and technical expertise and knowledge accumulated during the IDNDR.

Following this idea, a series of declarations of interest and determination to reduce risks have taken place at the international context (Balamir, 2005). These are; World Conferences on "Risk Reduction" in Yokohoma-1994, Toronto-2004 and Kobe-2005 have extended and sharpened this awareness about natural hazard risks and efforts of risk reduction on global agenda.

The reduction of growing rates of risks that are particularly concentrated in cities today is the major objective and challenge of the national and international disasters policy. As recent international policy emphasis has focused on risks and mitigation, the issue of seismic vulnerabilities and risk assessment are the primary objectives of the study.

On the other hand, Report on Disaster Reduction prepared by the Republic of Turkey for the World Conference on Disaster Reduction in Kobe reveals that the approach in Turkey to risk assessment, risk reduction and risk mapping are deficient and remains limited due to development of regulations that can not be fully implemented.

With this point of view, the examination and prioritization of the risk and seismic risk concepts in Turkey with an overview of current understanding and the evolution of the subject from its academic and scientific beginnings to its political implications in the realm of sustainable development of today constitutes the starting point of the study.

1.1. The Aim, Objectives and Scope of the Study

The World Conference on Disaster Reduction in Kobe provided a unique opportunity to promote a strategic and systematic approach to determination and reducing seismic vulnerabilities and risks of settlements. It is a guiding framework on disaster reduction for the twenty-first century.

The Hyogo Framework for Action 2005-2015: Building the Resilience of Nations and Communities to Disasters determined five priorities for action:

1. Ensure that disaster risk reduction is a national and a local priority,
2. Identify, assess and monitor disaster risks and enhance early warning,
3. Reduce the underlying risk factors,
4. Use knowledge, innovation and education to build a culture of safety and resilience,
5. Strengthen disaster preparedness for effective response at all levels.

The overall objective of this research is to evaluate how these priorities are served in Turkey especially; in the identification, assessment and monitoring of disaster risks, the reduction of the risk factors and the use of knowledge to build a culture of safety and resilience.

The major purpose of this research is to develop a method for the identification of vulnerabilities and prioritization of most vulnerable settlements in anticipation of earthquake related hazards.

With this purpose, the aim of this research is to examine the factors that determine seismic vulnerabilities and risks of settlements and establish if analysis of seismic risks in cities and living environments could be determined on the basis of a set of attributes of the building stock. The scope is to exhibit and analytically compare such factors in settlements of Turkey.

1.2. The Approach and Method of the Study

Quantitative information about a set of attributes of settlements is investigated statistically to determine which of the factors contribute most to risk levels described locally.

The seismic hazard maps of the Kandilli Observatory and Earthquake Research Institute (KOERI) and statistics published by the Turkish Statistical Institute (TurkStat), like census and housing data have a leading contribution to make. These secondary sources of information help to compose the database for a series of comparisons in the seismic vulnerabilities and risk levels of cities.

In the determination of seismic vulnerabilities and risks of settlements, “loss levels” in the building stock in each settlement will evaluate based on seismic hazard intensity via seismic hazard maps produced by KOERI and building stock vulnerability curves derived by Demircioglu (2010). Settlement level loss in the building stock is the basic indicator of assumed risk and provides the dependent variables of the research.

The independent variables of the research are composed of building inventory data and related attributes of building stock on each settlement obtained from TurkStat. ‘Building Construction Statistics’ and ‘Building Census’ prepared by Turkish Statistical Institute is used within this research. Independent variables of the research are; Settlement Population, Population Growth Rate, Rates of Agglomeration, Population/Total Number of Buildings and Development Index.

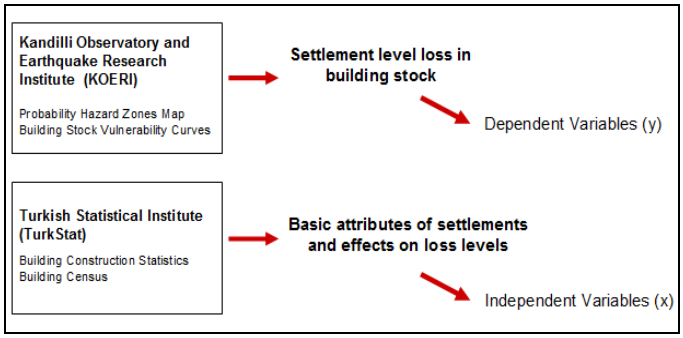

Figure 1. Dependent and Independent Variables of the Research

The study is expected to provide information about the critically vulnerable assets in cities, whether this could be considered as a function of hazard-proneness. Otherwise, interpretations of the most effective attributes that could describe vulnerabilities best and be related to risk information in cities could be explored.

Findings of such analysis could provide guiding criteria for mitigation policies in Turkey.

2. Loss Estimations and Determinants of Vulnerabilities in Settlements of Turkey

In order to determine and compare seismic vulnerabilities and risks in settlements of Turkey, statistical surveys and statistical analyses are used. Quantitative information about a set of attributes of settlements is investigated statistically to determine which of the factors contribute most to risk levels described locally.

Settlement level loss in the building stock is the basic indicator of assumed risk and provides the dependent variables of the research. The independent variables of the research are composed of building inventory data and related attributes of building stock on each settlement obtained from TurkStat.

The basic question of the research is: "How do loss levels in building stock correlate to independent variables?" and regression analyses are used to examine this question.

2.1. Loss Levels in Building Stock as Dependent Variables of the Research

Risk in settlement units is defined as a function of material loss in the building stock with respect to the expected seismic event. It is assumed that loss in the building stock in each settlement can be used as a proxy to express the comparative loss of human life, economic loss, damages in infrastructural systems, as well as secondary and indirect levels of losses in the settlement.

Therefore, settlement level loss in the building stock is the basic indicator of assumed risk and provides the dependent variables of the research.

Y1 = Loss Levels in Building Stock

Determination of Settlement level loss in the building stock has been realized by the following steps:

1. Assessment of the probabilistic seismic hazard, and production of Settlements in Hazard Zones Map (72-years; 50% probability),
2. Determination of Settlement Categories According to Size,
3. Identification of Categories of Building Types in Each Settlement,
4. Determination of Loss Levels of Each Building Category with Reference to Vulnerability Curves,
5. Identification of Loss Levels (Risks) Aggregated at Settlement Level

Following above described procedure, identification of most vulnerable settlements in each size-category and 'provinces with high-risk' are accomplished.

1. Assessment of the probabilistic seismic hazard and production of Settlements in Hazard Zones Map

The intensity distribution for 72 years period and %50 probability map produced by Erdik (2002) used in the assessment of the probability seismic hazard and production of Settlements in Hazard Zones Map.

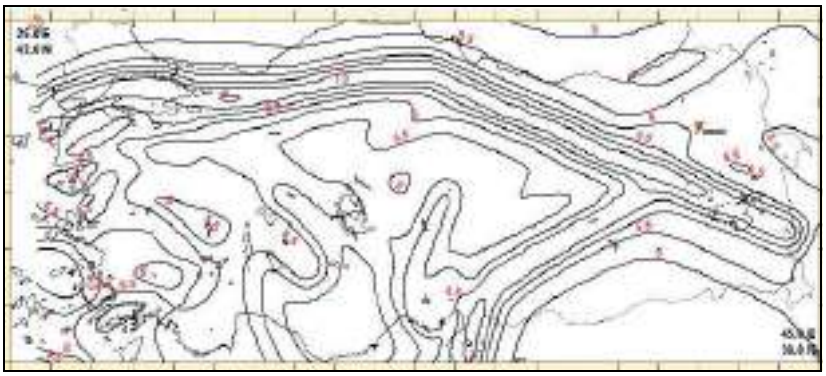

Figure 2. Intensity distribution for 72 years and %50 probability (Erdik, 2002)

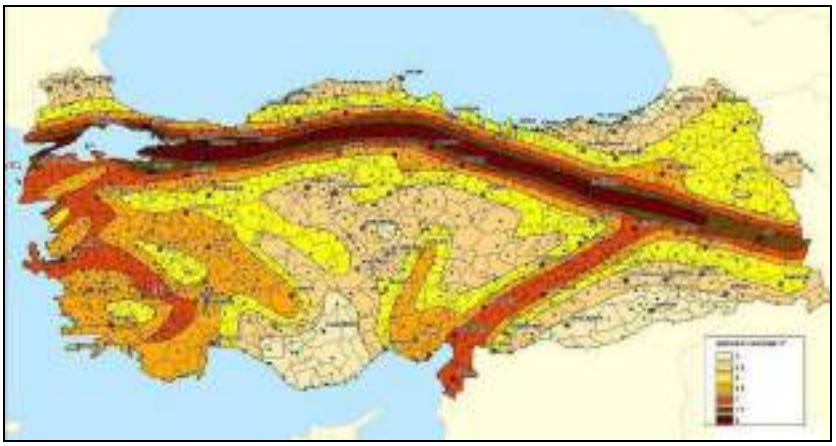

Figure 3. Spatial distribution of 72-year return period intensity and 50% probability

When we examine the distribution of settlements with reference to all seismic intensity levels, we saw that 45% of settlements are subject to intensities lower than 6.0 and 55% of settlements in the country is subject to intensities 6.5 and upper.

Table 1. The distribution of province and sub-province centers with reference to all seismic intensity levels according to number of settlements

Settlement Size Categories	Settlements Subject to Intensity of **5.0**	Settlements Subject to Intensity of **5.5**	Settlements Subject to Intensity of **6**	Settlements Subject to Intensity of **6.5**	Settlements Subject to Intensity of **7**	Settlements Subject to Intensity of **7.5**	Settlements Subject to Intensity of **8**
0- 50.000	43	142	160	154	108	32	38
50.000-490.000	13	21	24	35	22	4	5
Metropolitan p.	0	2	5	22	19	43	16
Total	56	165	189	211	149	79	59
Total %	6	18	21	23	17	9	6

All settlements with an expected hazard intensity level of 6.0 and less are excluded from the analyses assuming that insignificant damage is likely to take place in these settlements.

2. Determination of Settlement Categories According to Size

If absolute vulnerabilities are measured in terms of likely loss levels, a bias for larger settlements and developed regions is inevitable. In order to avoid bias in favour of larger settlements and developed regions, a method of sub-grouping is to be employed. Therefore, it may be appropriate to categorize the hazard-exposed settlements in terms of population size and a categorization of settlements with reference to population is considered as an initial step of the research.

Three groups of settlements are considered according to categorization of settlements with reference to population.

i- Metropolitan cities are identified as a separate category at the upper end. Irrespective of size and location, such province and sub-province centers are considered as a single settlement unit.

The remaining smaller cities are distinguished in two parts, almost identical in terms of total population. This marks the threshold size of 50.000.

ii- Sub-provincial and provincial centers of 50’000-500’000 are identified as a second category of settlements. These are often well-established settlements with higher rates of growth and expanding economies.

iii- Smaller sub-provincial and provincial centers with a population less than 50’000 make the third group of urban centers. These are relatively stagnant settlements.

The frequency distributions of province and sub-province centers subject to seismic disturbance of 6.5+ within 72 years with a probability of 50% are given below in terms of total population. The break-point of 50’000 is indicated in red.

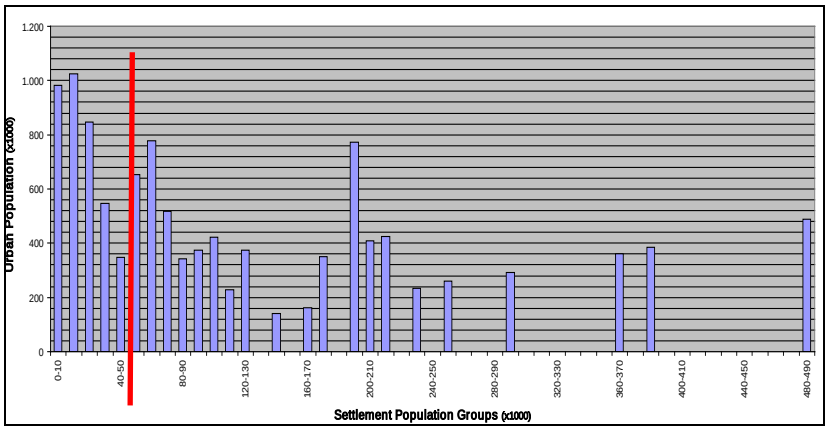

Figure 4. The frequency distributions according to population

The distributions of settlements within each size-category are given below.

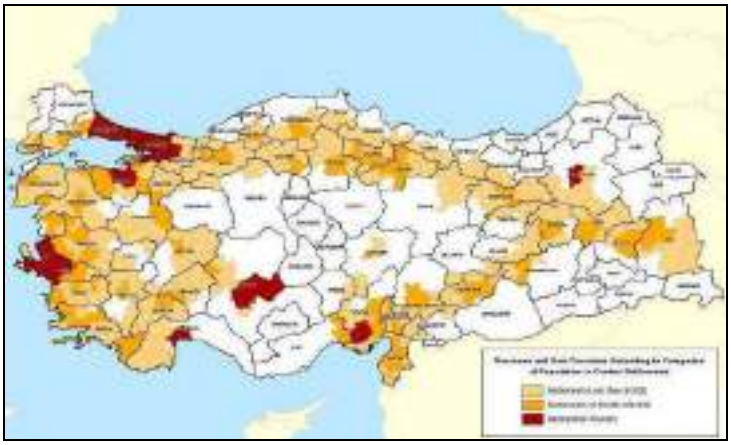

Figure 5. Spatial Distribution of Settlement Categories

When we examine the population distribution of settlements with reference to all seismic intensity levels, we saw that 35 % of all urban population live in settlements subject to intensities lower than 6.0. 65% of urban population lives in settlements subject to intensities 6.5 and upper. As 6.5+ intensities can be classified as the high hazard impact zone, we can easily say that approximately two third of all population lives under serious threat.

Table 2. The distribution of province and sub-province centers with reference to all seismic intensity levels according to total population

Settlement Size Categories	Settlements Subject to Intensity of **5.0**	Settlements Subject to Intensity of **5.5**	Settlements Subject to Intensity of **6**	Settlements Subject to Intensity of **6.5**	Settlements Subject to Intensity of **7**	Settlements Subject to Intensity of **7.5**	Settlements Subject to Intensity of **8**
0- 50.000	578.088	1.256.877	1.520.341	1.780.609	1.213.371	302.697	451.537
50.000-490.000	1.671.998	2.360.181	2.818.789	4.339.446	2.538.841	678.810	415.451
Metropolitan p.	0	5.140.959	4.067.916	4.216.666	3.137.913	14.466.195	1.841.525
Total	2.250.086	8.758.017	8.406.916	10.336.721	6.890.125	15.447.702	2.708.513
Total %	4	16	15	19	13	28	5

Distribution of settlement categories indicates significant variation with reference to intensity of seismic hazard. Almost half of the smaller settlements prove take place at the lowest end of the seismic scale under consideration. This is reversed in the case of metropolitan centers. This trend is observed to repeat itself with even greater shares in terms of population.

3. Identification of Categories of Building Types in Each Settlement

Information concerning building stock properties in each settlement is obtained from Building Census-2000 produced by TurkStat. The publication however of this source of information was not aggregated at the settlement level. A special disaggregated version of the building census 2000 at the level of settlements was accessed for this research.

Following the categorization of the building stock provided in Demircioğlu (2010), four distinct groups of buildings have been identified. Load-bearing buildings, reinforced concrete structures of low-rise, medium-rise, and high-rise building categories are available in terms of number of buildings in each settlement. Apart from 'construction type', the Census of year 2000 contains information on 'number of storeys', 'construction date', and 'use' for every settlement.

Table 3. Building stock categories of settlements according to construction type and number of storeys

Settlement Size Categories	**Wall Bearing Construction (1-3 storeys)**	**Frame Construction Low- Rise (1-3)**	**Frame Construction Mid–Rise (4-9)**	**Frame Construction High–Rise (10+)**
0-50.000	440.905	341.875	54.309	80
50.000 – 500.000	482.844	357.630	128.564	619
Metropolitan provinces	655.200	899.892	541.888	10.862
Total	1.578.949	1.599.397	724.761	11.561

4. Determination of Loss Levels of Each Building Category with Reference to Vulnerability Curves

Fragility (vulnerability) curves for each category of the building stock in Turkey, as empirically derived in Demircioğlu (2010) are employed here to determine the likely loss levels/risks in settlements. According to this procedure, each of the four categories of the building stock in every settlement is separately evaluated in their likely response to the estimated intensity of shake. As a statistical distribution, specific levels of loss from each category of the building stock can be determined by means of the fragility curves.

These curves are devoted for low-rise reinforced concrete buildings, as well as mid-rise and high-rise reinforced concrete buildings. The vulnerability curve of the 'load-bearing' category is assumed to approximate with the low-rise RC type of buildings.

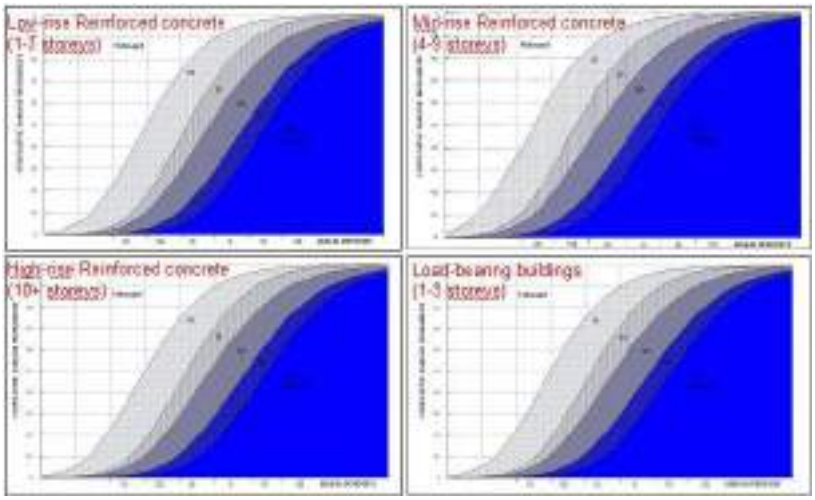

Figure 6. Intensity based vulnerability curves (Demircioğlu, 2010)

Using definitions from MSK-81 Scale, Coburn and Spence (1992) associates damage grades as D1-Slight, D2-Moderate, D3-Heavy, D4-Partial Destruction and D5-Collapse. Damage levels encompassing damages D3, D4 and D5 is an important descriptor of the earthquake damage since D3 represents an approximate borderline between repair and replacement of the building stock exposed to an earthquake.

With reference to the seismic hazard intensity that any settlement is likely to experience, total loss in building stock with its various types and categories are estimated in each group of settlements relying on the vulnerability curves of each building type. The approximate ratios of loss according to seismic intensity and level of damage in each category are observed as given in Table 4 below.

Table 4. Coefficients of likely forms of loss in the building stock of settlements subject to varying levels of seismic intensity

Seismic Intensity	D1 Slight Damage	D2 Medium Damage	D3 Heavy Damage	D4 Partial Collapse	5 Collapse
Low – Rise & Load-Bearing:					
6.5	0.12	0.02	0.01	0	0
7	0.22	0.04	0.03	0	0
7.5	0.37	0.10	0.05	0.01	0
8	0.50	0.18	0.11	0.0.3	0.01
Mid – Rise:					
6.5	0.26	0.05	0.03	0	0
7	0.40	0.12	0.05	0.01	0
7.5	0.52	0.20	0.11	0.03	0.01
8	0.65	0.32	0.19	0.05	0.03
High – Rise:					
6.5	0.12	0.01	0	0	0
7	0.22	0.03	0.02	0	0
7.5	0.36	0.09	0.05	0.01	0
8	0.50	0.18	0.11	0.02	0.01

Number of buildings lost is determined by the combined levels of loss, which means adding up the three categories of the most severe forms of damage in buildings. These are “heavy damage” (D3), “partial collapse” (D4), and “total collapse” (D5) as identified in the building vulnerability curves for each ‘type’ of building.

This level of loss can be expressed in absolute terms (total number of buildings lost), or in relative terms as a ratio of loss from the total building stock. It is then possible to have priority lists in each category of settlement-size in absolute and relative terms.

5. Identification of Loss Levels/Risks Aggregated at Settlement Level

Following above described procedure, identification of most vulnerable settlements in each size-category and ‘provinces with high-risk’ are accomplished. A list of the provinces from the one with the highest risk to the one with the lowest is completed.

The top-10 settlements of the complete list in each size category according to absolute loss levels (Table 5, Table 6, Table 7) and the spatial distribution figures of settlements according to absolute loss and rates of loss is given below (Figure 7, Figure 8).

Table 5. The Top-10 Settlements for Category I According to Absolute Loss Levels

CATEGORY I 0-50.000	Sub-Province	Intensity	Absolute Loss	Total Building	Loss Rate	Sub-Province Population (2009)
TOKAT	NIKSAR	8	1400	8343	0,17	64.930
KASTAMONU	TOSYA	8	1364	8575	0,16	40.894
SAKARYA	HENDEK	8	869	4969	0,17	74.084
CORUM	OSMANCIK	8	786	5037	0,16	45.080
SAMSUN	HAVZA	8	735	4620	0,16	45.933
TEKIRDAG	SARKOY	8	712	4059	0,18	30.248
SAKARYA	AKYAZI	8	681	3668	0,19	83.220
AMASYA	SULUOVA	7,5	633	9653	0,07	47.448
ERZINCAN	UZUMLU	8	631	4187	0,15	15.960
BOLU	GEREDE	8	583	3439	0,17	34.665
Group Average			**96**	**2540**	**0.04**	**27.276**

In the small-sized group of settlements, greatest loss is observed as in the table above, exhibiting the number of building loss. The top 10 of the settlements listed here are significantly above the category averages in terms of total loss, total number of buildings, rates of loss and settlement population.

Table 6. The top-10 Settlements for Category II According to Absolute Loss Levels

CATEGORY II 50.000-490.000	Sub-Province	Intensity	Absolute Loss	Total Building	Loss Rate	Sub-Province Population (2009)
VAN	CENTRAL	7,5	2285	36235	0,06	360.810

In contrast to the previous category of settlements, many cases here prove high levels of absolute loss determined less dependently on strength of seismic shake.

There are variations in seismic intensity levels and rates of loss. Apart from a very few of the cases here, rates of loss seem to be lower than observed in the previous category.

Ordering seems to follow seismic intensities rather than absolute size of the building stock in metropolitan provinces.

Table 7. Metropolitan Provinces According to Absolute Loss Levels

CATEGORY III Metropolitan Provinces	Sub-Province	Intensity	Absolute Loss	Total Building	Loss Rate	Sub-Province Population (2009)
ISTANBUL	ISTANBUL (M)	7,5	83824	864540	0,10	10.149.637
KOCAELI	KOCAELI (M)	8	24077	139423	0,17	970.642

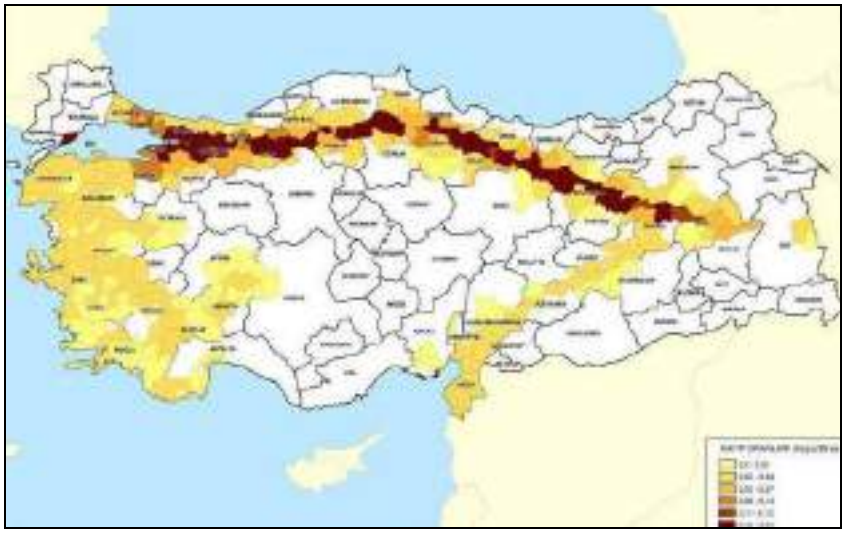

Figure 8. Loss Rate Distributions

2.2 Population-Building Stock Attributes as Independent Variables of the Research

The independent variables of the research are composed of building inventory data and related attributes of building stock on each settlement obtained from Turkish Statistical Institute. 'Building Construction Statistics' and 'Building Census' prepared by TurkStat is used within this research.

Independent variables of the research are;

X1 = Settlement Population
X2 = Population Growth Rate (‰)
X3 = Rates of Agglomeration
X4 = Population/Total Number of Buildings
X5 = Development Index

X1=Settlement Population

We can consider that as the settlement population increases, building densities will increase also and this will increase the potential loss. Besides larger settlements in general have higher index of development implying greater likelihood of direct and indirect economic loss. So, we can say that larger the settlement population, greater is the risk.

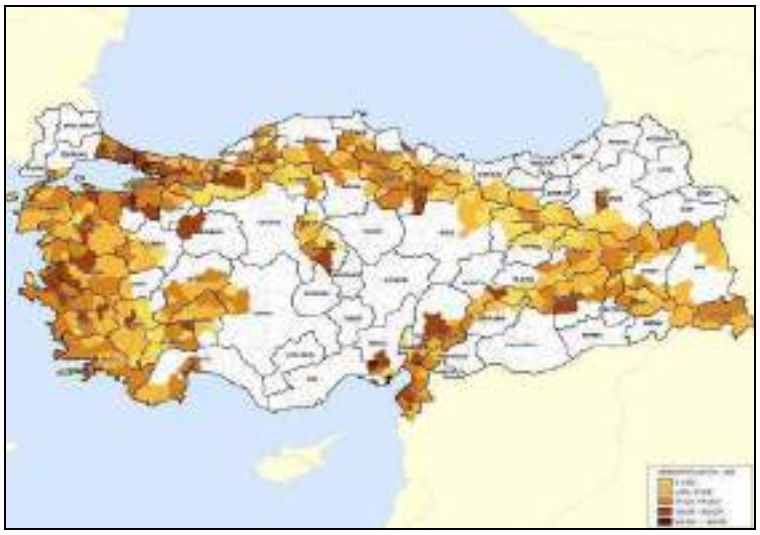

Figure 9. Urban Population Distributions

X2=Population Growth Rate

We can consider that as the rate of growth increases, control deficiencies will increase and this will increase the potential loss.

According to the Table 8; The smaller settlements in the average are either losing population or are stagnant. On the contrary larger cities and metropolitan cities are significantly growing and at the same pace.

Table 8.Average Values of Population Growth Rates in Settlements Categories

AVERAGE VALUES	Total Number of Buildings	Settlement Population (2000)	Total Population (2000)	Settlement Population (2009)	Total Population (2009)	Population Growth Rate (Log-%)
0-50.000	2540	12.292	32.033	11.290	27.276	-0,945
50.000-490.000	14.743	96.999	152.395	120.796	169.592	2,438
Metropolitan P.	235.144	2.086.170	187.9779	2.629.144	2.697.045	2,570

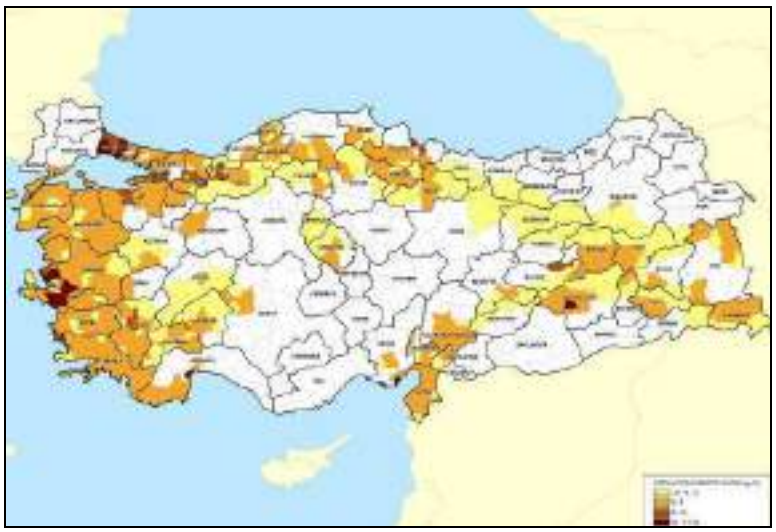

Figure 10. Population Growth Rates

X3=Rates of Agglomeration

Distinct rates of agglomeration are also a good indicator of how rural/urban natures of the sub-province or province differ. We can consider that as the rate of agglomeration increases, required urban services will increase and this will increase the potential loss.

According to the Table 9; Metropolitan settlements seem to have absorbed almost all of the population. However in provinces with smaller central settlements, greater parts of population live in the rural area.

Table 9. Average Values of Agglomeration Rates in Settlements Categories

AVERAGE VALUES	Total Number of Buildings	Settlement Population (2000)	Total Population (2000)	Settlement Population (2009)	Total Population (2009)	Rate of Agglomeration
0-50.000	2540	12.292	32.033	11.290	27.276	0,41
50.000-490.000	14.743	96.999	152.395	120.796	169.592	0,71
Metropolitan P.	235.144	2.086.170	187.9779	2.629.144	2.697.045	0,97

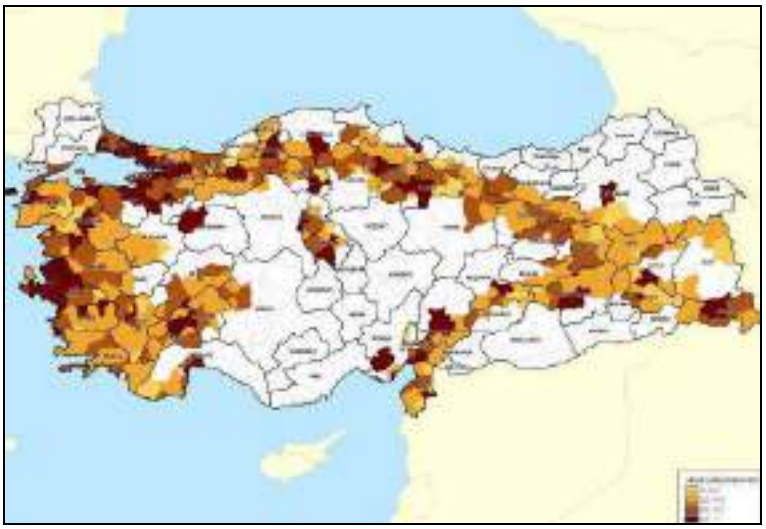

Figure 11. Urban Agglomeration

X4=Population/Total Number of Buildings

Average population density per building is significantly different in the categories identified. This is also a measure or indication of the increasing rate of human life losses in larger cities, another factor to reinforce the probable bias favoring larger settlements.

Table 10. Population Density in Settlement Categories

Settlement Size Categories	Population (2000)	Total Number of Buildings	Population / Building
0-50.000	4.080.822	843.188	4,84
50.000-490.000	6.401.962	973.014	6,58
Metropolitan provinces	18.775.534	2.116.296	8,87
Total	29.258.318	3.932.498	7.44

X5=Development Index

Socio-economic Development Index prepared by State Planning Organization covers demography, employment, education, infrastructure, construction and other welfare indicators.

The group of settlements with lower levels of population than 50.000 has a negative average development index of (-0.171). The average development index of category of 50.000-490.000 is 1.096. The average development index available for the third group representing metropolitan settlements is distinctly higher 5.73946 (Adana, Bursa and Konya only). This index is obviously higher for Istanbul, Ankara, and Izmir to increase the average further.

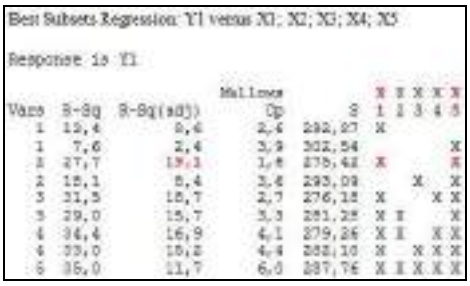
3. Evaluation of Risk Prioritization Variables of the Research

Dependent and independent variables of the research are determined as shown above. Best subsets regression analyses are employed to determine what combinations of the independent variables might best denote city-level risks. The results of the best subsets analyses should give us the "most appropriate combination" for the regression analyses.

3.1. Best Subsets Regression Analyses

Best Subsets Regression Analyses – Category I (0-50.000)

The first best subsets regression analyses is employed between the first dependent variable Y1 (absolute loss) and independent variables (X1, X2, X3, X4, X5) in order to see which independent variable is more related with Y1. In best subsets regression analyses the more related variable is the one that have the biggest number of R-Sq (adj.). According to the Figure 12 the biggest R-Sq (adj.) is 19, 1% in the third line and this means that the most related variables with Y1 is X1 and X5.



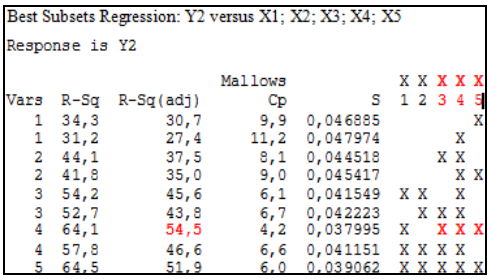
Best Subsets Regression: Y1 versus X1; X2; X3; X4; X5

Response is Y1

Vars	R-Sq	R-Sq(adj)	Mallows Cp	S	X1	X2	X3	X4	X5
1	15,4	8,6	2,6	282,87	X				
1	7,6	2,4	5,9	302,54					X
2	27,7	19,1	1,8	275,42	X				X
2	15,1	8,4	3,6	293,09			X		X
3	31,5	18,7	2,7	276,18	X			X	X
3	29,0	15,7	3,3	281,29	X	X			X
4	34,4	16,9	4,1	279,26	X	X		X	X
4	33,0	15,2	4,4	282,10	X		X	X	X
5	35,0	11,7	6,0	287,76	X	X	X	X	X

Figure 12. Best Subsets Regression: Y1 versus x1; x2; x3; x4; x5

The second best subsets regression analysis is employed between the second dependent variable Y2 (rate of loss) and independent variables, Figure 13 shows us that the biggest R-Sq (adj.) is 54,5% and this means that the most related variables with Y2 is X3, X4 and X5.



Best Subsets Regression: Y2 versus X1; X2; X3; X4; X5

Response is Y2

Vars	R-Sq	R-Sq(adj)	Mallows Cp	S	X1	X2	X3	X4	X5
1	34,3	30,7	9,9	0,046885					X
1	31,2	27,4	11,2	0,047974			X		
2	44,1	37,5	8,1	0,044518			X	X	
2	41,8	35,0	9,0	0,045417				X	X

4	64,1	54,5	4,2	0,037995	X		X	X	X
4	57,8	46,6	6,6	0,041151	X	X	X	X	
5	64,5	51,9	6,0	0,039062	X	X	X	X	X

Figure 13. Best Subsets Regression: Y2 versus x1; x2; x3; x4; x5

Five regression analyses are performed according to the results of best subsets regression analyses for the Category I (0-50.000). These are;
Regression Analysis: Y1 versus X1, Y1 versus X5, Y2 versus X3, Y2 versus X4 and Y2 versus X5.

Best Subsets Regression Analyses – Category II (50.000-490.000)

Best subsets regression analyses is employed between the Y1 (absolute loss) and other independent variables. According to the Figure 14 the biggest R-Sq (adj.) is 19,3 % and this means that the most related variables with Y1 is X2 and X4.

Best Subsets Regression: Y1 versus X1; X2; X3; X4; X5

Response is Y1

			Mallows		X	X	X	X	X
Vars	R-Sq	R-Sq(adj)	Cp	S	1	2	3	4	5

Figure 15. Best Subsets Regression: Y2 versus x1; x2; x3; x4; x5

Four regression analyses are performed according to the results of best subsets regression analyses for the Category II (50.000-490.000). These are;
Regression Analysis: Y1 versus X2, Y1 versus X4, Y2 versus X1 and Y2 versus X4.

Best Subsets Regression Analyses – Category III (Metropolitan provinces)

Best subsets regression analyses is employed between Y1 (absolute loss) and other independent variables. According to the Figure 16 the biggest R-Sq (adj.) is 95, 5% and this means that the most related variables with Y1 is X1, X3 and X4.

Best Subsets Regression: Y1 versus X1; X2; X3; X4; X5

Response is Y1

			Mallows		X	X	X	X	X
Vars	R-Sq	R-Sq(adj)	Cp	S	1	2	3	4	5

Figure 17. Best Subsets Regression: Y2 versus x1; x2; x3; x4; x5

Five regression analyses are performed according to the results of best subsets regression analyses for the Category III (Metropolitan Provinces). These are;
Regression Analysis: Y1 versus X1, Y1 versus X3, Y1 versus X4, Y2 versus X3 and Y2 versus X4.

3.2. Analyses by Means of Regression Methods

Analyses by Means of Regression Methods – Category I (0-50.000)

Five regression analyses are performed according to the results of best subsets regression analyses for the I. Category (0-50.000). These are;
Regression Analysis: Y1 versus X1, Y1 versus X5, Y2 versus X3, Y2 versus X4 and Y2 versus X5.

Regression Analysis 1:

Regression Analysis 1 is performed with Y1 (absolute loss) and X1(settlement population). In regression analyses in order to say that there is a relation between variables, the R-Sq (adj.) must be minimum 64%. As shown in the Figure 18, the R-Sq (adj.) is 8, 6%. This ratio is insufficient to verify the relationship between Y1 and X1, so we can say that there is a **no relation** between the regression equations of Y1 versus X1.

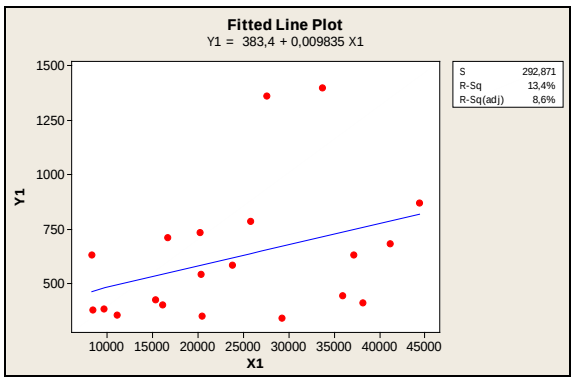

Figure 18. Regression Analysis 1: Y1 versus X1

Regression Analysis 2:

Regression Analysis 2 is performed with Y1 (absolute loss) and X5 (development index). As shown in the Figure 19, the R-Sq (adj.) is 2, 4%. This ratio is insufficient to verify the relationship between Y1 and X5, so we can say that there is a **no relation** between the regression equations of Y1 versus X5.

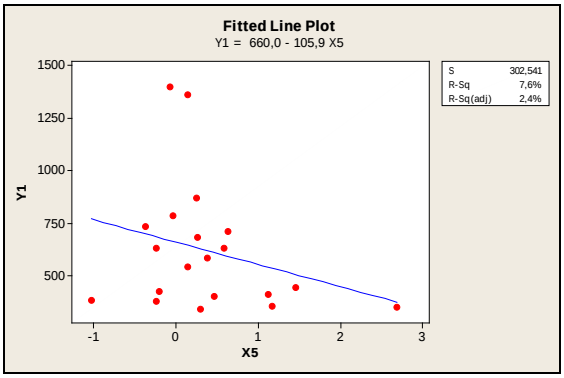

Figure 19. Regression Analysis 2: Y1 versus X5

Regression Analysis 3:

Regression Analysis 3 is performed with Y2 (rate of loss) and X3 (rates of agglomeration). As shown in the Figure 20, the R-Sq (adj.) is 21, 9%. Although this ratio isn't sufficient enough to verify the relationship between Y2 and X3, we can say that there is a **weak relation** between the rate of loss and the rate of agglomeration.

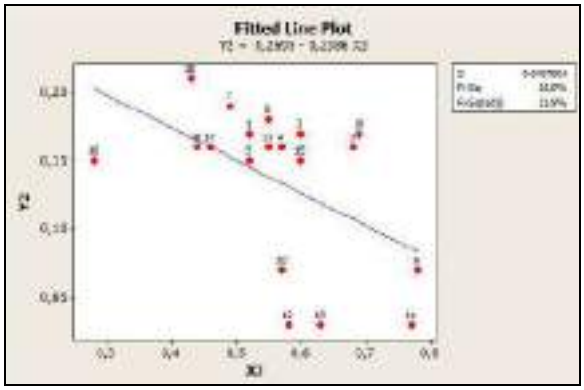

Figure 20. Regression Analysis 3: Y2 versus X3

Regression Analysis 4:

Regression Analysis 4 is performed with Y2 (rate of loss) and X4 (pop. /total number of buildings). As shown in the Figure 21, the R-Sq (adj.) is 27, 4%. Although this ratio isn't sufficient enough to verify the relationship between Y2 and X4, we can say that there is a **weak relation** between the rate of loss and the ratio of population to the number of buildings.

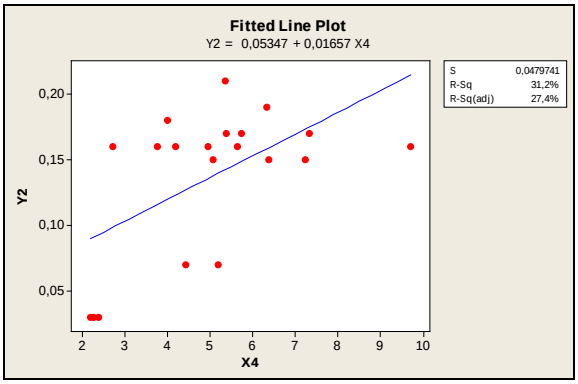

Figure 21. Regression Analysis 4: Y2 versus X4

Regression Analysis 5:

Regression Analysis 5 is performed with Y2 (rate of loss) and X5 (development index). As shown in the Figure 22, the R-Sq (adj.) is 30, 7%. Although this ratio isn't sufficient enough to verify the relationship between Y2 and X5, we can say that there is a **weak relation** between the rate of loss and the ratio of population to the number of buildings.

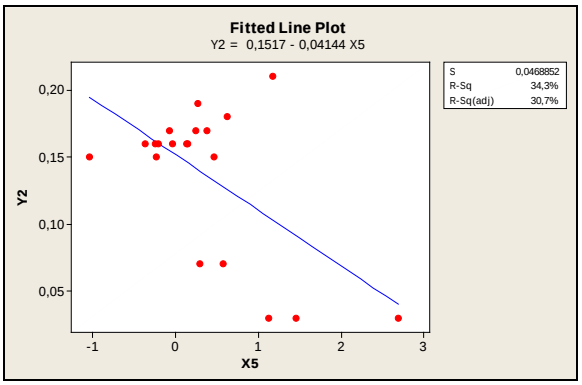

Figure 22. Regression Analysis 5: Y2 versus X5

Five regression analyses are performed for top-20 settlements in Category I. The Results of these analyses show that;

Y1 (absolute loss) has no relation with independent variables and,
Y2 (rate of loss) has weak relations with X3 (Rates of Agglomeration)
X4 (Pop. /Total Number of Buildings)
X5 (Development Index)

Analyses by Means of Regression Methods – Category II (50.000-490.000)

Four regression analyses are performed according to the results of best subsets regression analyses for the Category II (50.000-490.000). These are;
Regression Analysis: Y1 versus X2, Y1 versus X4, Y2 versus X1 and Y2 versus X4.

Regression Analysis 6:

Regression Analysis 6 is performed with Y1 (absolute loss) and X2 (population growth rate). As shown in the Figure 23, the R-Sq (adj.) is 2, 2%. This ratio is insufficient to verify the relationship between Y1 and X2, so we can say that there is a **no relation** between the regression equations of Y1 versus X2.

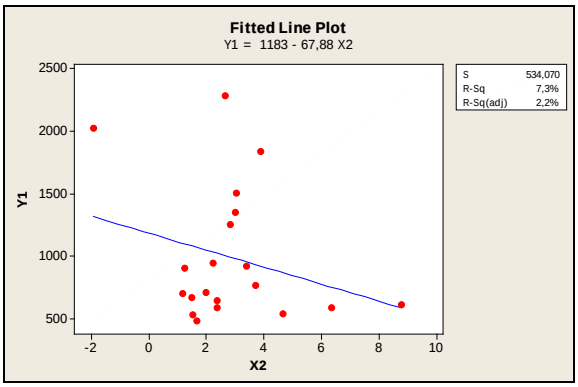

Figure 23. Regression Analysis 6: Y1 versus X2

Regression Analysis 7:

Regression Analysis 7 is performed with Y1 (absolute loss) and X4 (pop./total number of buildings). As shown in the Figure 24, the R-Sq (adj.) is 18, 0%. Although this ratio isn't sufficient enough to verify the relationship between Y1 and X4, we can say that there is a **weak relation** between absolute loss and the ratio of population to the number of buildings.

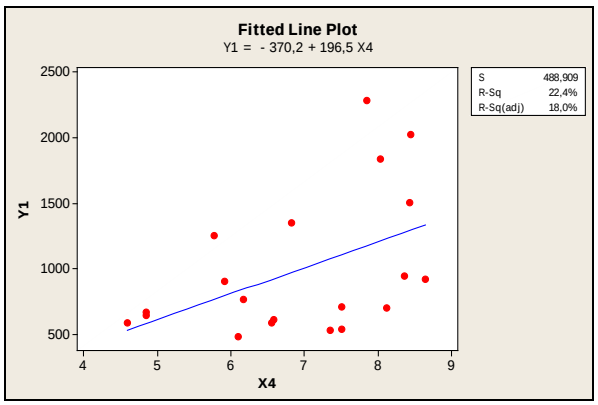

Figure 24. Regression Analysis 7: Y1 versus X4

Regression Analysis 8:

Regression Analysis 8 is performed with Y2 (rate of loss) and X1 (settlement population). As shown in the Figure 25, the R-Sq (adj.) is 21, 5%. Although this ratio isn't sufficient enough to verify the relationship between Y2 and X1, we can say that there is a **weak relation** between the rate of loss and settlement population.

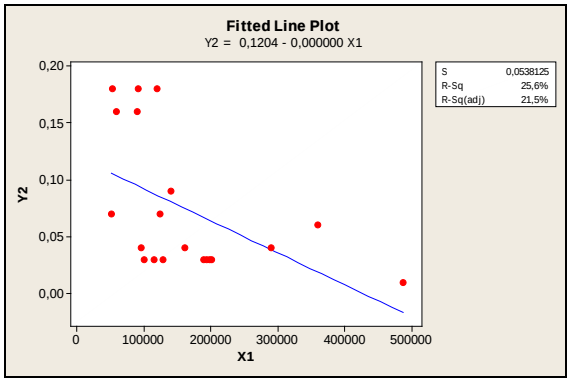

Figure 25. Regression Analysis 8: Y2 versus X1

Regression Analysis 9:

Regression Analysis 9 is performed with Y2 (rate of loss) and X4 (pop./total number of buildings). As shown in the Figure 26, the R-Sq (adj.) is 11, 7%. This ratio is insufficient to verify the relationship between Y2 and X4, so we can say that there is a **no relation** between the regression equations of Y2 versus X4.

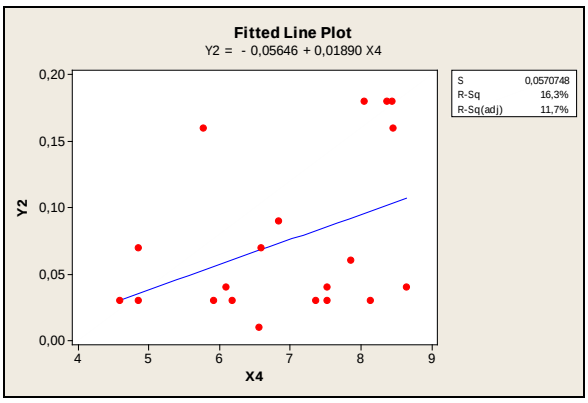

Figure 26. Regression Analysis 9: Y2 versus X4

Four regression analyses are performed for top-20 settlements in Category II. The Results of these analyses show that;

Y1 (absolute loss) has no relation with X2 (population growth rate) and weak relations with X4 (Pop./Total Number of Buildings).

Y2 (rate of loss) has weak relations with X1(settlement population) and no relation with X4 (Pop./Total Number of Buildings).

Analyses by Means of Regression Methods – Category III (Metropolitan pro.)

Five regression analyses are performed according to the results of best subsets regression analyses for the Category III (Metropolitan Provinces). These are;
Regression Analysis: Y1 versus X1, Y1 versus X3, Y1 versus X4, Y2 versus X3 and Y2 versus X4.

Regression Analysis 10:

Regression Analysis 10 is performed with Y1 (absolute loss) and X1(settlement population). As shown in the Figure 27, the R-Sq (adj.) is 91, 1%. This ratio is sufficient to verify the relationship between Y1 and X1, so we can say that there is a **strong relation** between the regression equations of Y1 versus X1.

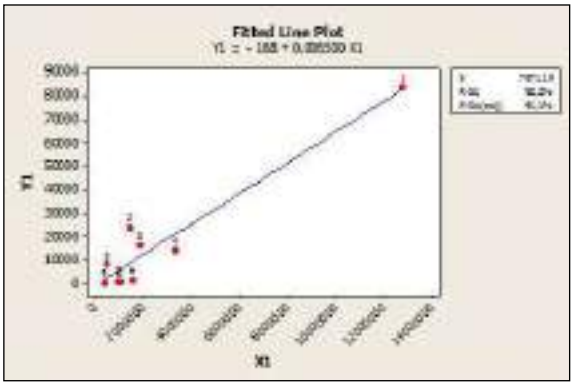

Figure 27. Regression Analysis 10: Y1 versus X1

Regression Analysis 11:

Regression Analysis 11 is performed with Y1 (absolute loss) and X3 (rates of agglomeration). As shown in the Figure 28, the R-Sq (adj.) is 5, 0%. This ratio is insufficient to verify the relationship between Y1 and X3, so we can say that there is a **no relation** between the regression equations of Y1 versus X3.

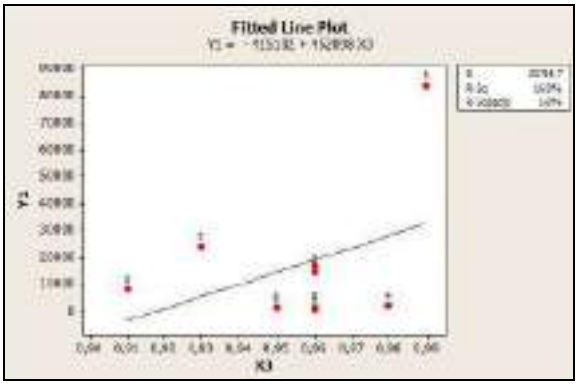

Figure 28. Regression Analysis 11: Y1 versus X3

Regression Analysis 12:

Regression Analysis 12 is performed with Y1 (absolute loss) and X4 (pop./total number of buildings). As shown in the Figure 29, the R-Sq (adj.) is 49, 0%. Although this ratio isn't sufficient enough to verify the relationship between Y1 and X4, we can say that there is a **weak relation** between the rate of loss and settlement population.

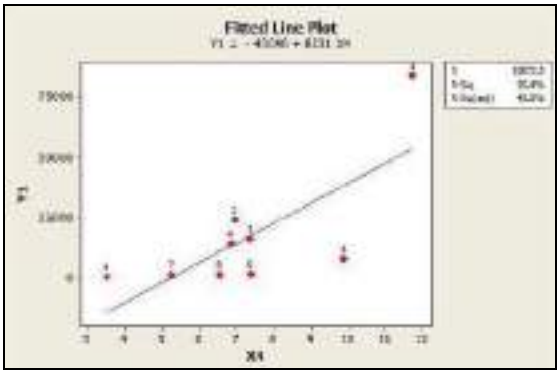

Figure 29. Regression Analysis 12: Y1 versus X4

Regression Analysis 13:

Regression Analysis 13 is performed with Y2 (rate of loss) and X3 (rates of agglomeration). As shown in the Figure 30, the R-Sq (adj.) is 24, 8%. Although this ratio isn't sufficient enough to verify the relationship between Y2 and X3, we can say that there is a **weak relation** between the rate of loss and settlement population.

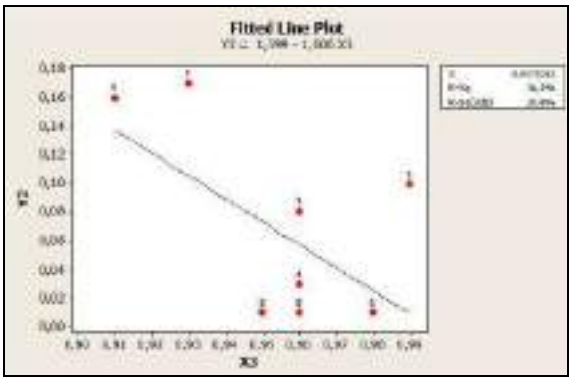

Figure 30. Regression Analysis 13: Y2 versus X3

Regression Analysis 14:

Regression Analysis 14 is performed with Y2 (rate of loss) and X4 (pop./total number of buildings). As shown in the Figure 31, the R-Sq (adj.) is 24, 7%. Although this ratio isn't sufficient enough to verify the relationship between Y2 and X4, we can say that there is a **weak relation** between the rate of loss and settlement population.

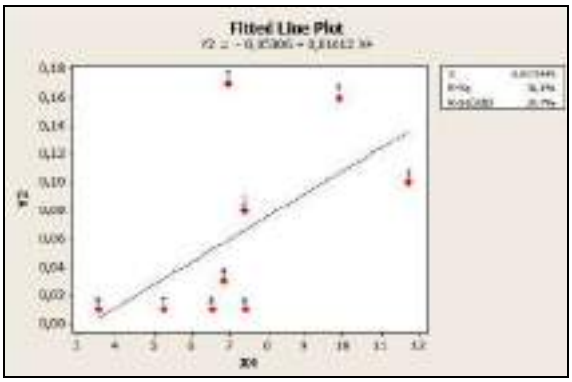

Figure 31. Regression Analysis 14: Y2 versus X4

Five regression analyses are performed for the top-20 settlements in Category III. The Results of these analyses show that;

Y1 (absolute loss) has strong relations with X1 (settlement population), no relation with X3 (Rates of Agglomeration) and weak relations with X4 (pop./ total number of buildings).

Y2 (rate of loss) has weak relations with X3 (rates of agglomeration) and X4 (pop./total number of buildings).

4. Conclusions

This study is set out with the aim to examine the factors that determine seismic vulnerabilities and risks of settlements and establish if analysis of seismic risks in cities and living environments could be determined on the basis of a set of attributes of the building stock. The scope is to exhibit and analytically compare such factors in settlements of Turkey. The basic question of the research is: “How do loss levels in building stock correlate to independent variables?” and regression analyses are used to examine this question.

Five regression analyses are performed for top-20 settlements in Category I. The results of these analyses show that; Y1 (absolute loss) has no relations with independent variables, Y2 (rate of loss) has weak relations with X3 (rates of agglomeration), X4 (pop. /total number of buildings) and X5 (development index).

Four regression analyses are performed for top-20 settlements in Category II. The results of these analyses show that; Y1 (absolute loss) has no relations with X2 (population growth rate) and weak relations with X4 (pop./total number of buildings). Y2 (rate of loss) has weak relations with X1(settlement population) and no relations with X4 (pop./total number of buildings).

Five regression analyses are performed for the top-20 settlements in Category III. The results of these analyses show that; Y1 (absolute loss) has strong relations with X1 (settlement population), no relation with X3 (rates of agglomeration) and weak relations with X4 (pop./ total number of buildings). Y2 (rate of loss) has weak relations with X3 (rates of agglomeration) and X4 (pop./total number of buildings).

Planning for degrowth in big Chinese cities

Jin Xue[1]

Abstract

Discourses on sustainability have led to the development of two distinct ideal societal paradigms: ecological modernization and ecosocialism. Urban planning is on one hand defined by the features of a certain paradigm and on the other hand a vehicle inspiring changes towards that paradigm. China's recent shift in development path as a response to social and environmental issues has a strong salience of ecological modernization. This is evident from the newly enacted national territory development plan. However, the emphasis on promoting competitiveness in wealthy city regions along the eastern coast line and extending economic growth to inland China is argued to be environmentally and socially unsustainable in a long run. For a long-term sustainability, economic non-growth/degrowth is necessary in the affluent cities, while growth opportunities should be channeled to poor regions. This requires a degrowth planning agenda in China and changes in planning rationality and spatial logics over the country. Such an alternative development path can be seen as in line with the ecosocialism paradigm. China's present economic-political conditions and traditional philosophies provide potentials and advantages for such a transition.

Keywords: China, ecological modernization, ecosocialism, urban planning, degrowth

1. Introduction

The emergence of global environmental problems and discourses on sustainability have led to the development of various ideological responses in relation to the societal paradigm and development path. Despite variations, two distinctive camps can be identified: ecological modernization and ecosocialism. The former one pursues green growth within the capitalist society, while the latter advocates overthrowing capitalism and argues for an ecologically friendly socialism. The two strands of societal paradigms for sustainable development confront fundamentally with each other in that they disagree on the possibility of obtaining sustainability within the capitalist mode of production. It is not difficult to imagine an interactive relation between socio-economic-political conditions and urban planning. In particular, a societal paradigm exerts great influences on planning ideologies, and planning practices are able to play a significant role in achieving some of the objectives of that societal ideology.

China has since the late 1970s attempted to build up a socialist market economy. After 30 years of unprecedented economic growth and urbanization, despite rising

[1] Aalborg University, Aalborg, Denmark – jin@plan.aau.dk

average affluence level, China is now in the predicament of resource scarcity, a wide range of environmental pollution, and social inequality. The fruits of growth have not been distributed equally across the country, but been concentrated in some cities especially along the eastern coastline where average affluence level is much higher than that in the inland and western China. In this context, it is therefore interesting to investigate the contemporary dominant discourse on the development path as an approach to those ecological and social problems and how planning is related to it. A lately enacted national territory development plan represents such a shift in development path.

The paper aims to discuss the potentials of this development path and its planning ideologies in relation to the aspiration for environmental and social sustainability in China, and proposes an alternative planning pathway informed by Chinese ancient philosophy and modern socialist traditions. This alternative points out that the prospect for sustainable development rests on a transition to ecosocialism, for which China has advantages and potentials. This implies economic non-growth/degrowth in affluent and big Chinese cities. With its focus on degrowth and urban planning in a Chinese context, the paper aims to enrich the sustainability discourse and to stimulate research that can link the degrowth paradigm with the urban planning profession. The line of the argument is organized as follows.

The paper starts with a discussion about the varied roles and values of planning in two ideal societal paradigms in the light of concerns over environmental and social sustainability. This part will be limited to a theoretical level. Then, the paper will offer a brief overview of Chinese national developmental strategies since the economic reform, with particular attention given to the recent plan for change in the development path in order to deal with sustainability issues. This will be followed by an analysis of the opportunities and limitations of this planned development path in terms of achieving sustainability. Economic non-growth/degrowth in big Chinese cities is argued to be a precondition for both local and global environmental sustainability. Finally, an alternative planning pathway corresponding to the degrowth paradigm and ecosocialism in the Chinese context will be explored.

2. Urban planning under different societal paradigms

If planning is seen as a vehicle to proactively realize a certain societal paradigm, the role, values, and rationality of urban planning must fit the objectives and characteristics of that paradigm. In the other way around, a certain political economy of a society defines the necessity of urban planning and its features, and a changing socio-economic paradigm corresponds to a changing planning paradigm. The discussion will limit itself to two types of socio-economic-political paradigms, i.e. ecological modernization and ecosocialism. The increasing environmental concerns give rise to the concept of ecological modernization which requires transformations within capitalist society. Ecosocialism is an ideology incorporating a strong sustainability vision and advocating the dismantling of capitalism for this vision. As illustrated in Figure 1, the elements and structures of each paradigmatic society delineates the planning ideology (role, values, rationality), which in turn determines planning strategies, policies, system, contents, procedures, etc. at a more concrete

level. These concrete aspects of planning are also associated with specific contextual conditions at a given time and place. The discussion in this section is limited to a theoretical and abstract level without taking into account concrete contexts. Therefore, the focus is on planning ideology. This will be linked to the next section in an attempt to develop a degrowth planning agenda for big Chinese cities with an emphasis on the third level of the diagram.

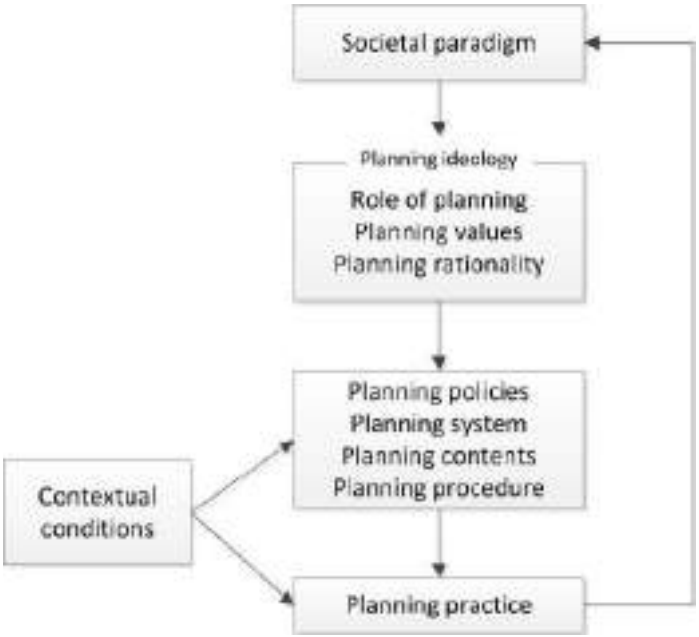

Figure 1. How societal paradigm defines planning paradigm

2.1 Ecological modernization

Ecological modernization theory portrays a paradigm reconciling economic, environmental and social sustainability within the capitalist organization of production and consumption. The adherents of ecological modernization believe that 'there is no principle or theoretical argument making a 'modern' organization of production and consumption and its technology antithetical to sustainability' (Spaargaren, 2000). Reconciliation between economic growth and environmental sustainability mainly relies on the use of market dynamics to resolve environmental problems. The features of an ecological modernization society can be depicted as follows:

1. It is necessary to institutionalize ecologically rational actions into the central social institutions of modernity (such as the economic sphere, the political sphere, the cultural sphere, etc.), i.e. the phrase of 'ecologizing of economy'.
2. Modern science and technology are central institutions for the environmentally induced rationalization of production and consumption (Fisher & Freudenburg, 2001; Jänicke, 2008). Environmentally friendly technologies are the solutions to environmental problems.

3. The innovation and diffusion of eco-efficiency technologies should be carried on by economic agents through market forces, while the state takes the role of 'enabler', providing incentives, standards, and regulations.
4. Ecologizing of economy through market mechanisms requires economizing environmental goods by placing economic values on the environment, characterized as 'economizing of ecology'.
5. The above points suggest cooperation between business, government and social movements in the decision-making process.

The modernization of the existing institutions of society toward environmental sustainability will also influence the practices of urban planning. Constrained by this social and political context, the purpose of planning is to facilitate market processes in order to stimulate economic growth and meanwhile mitigate negative environmental consequences of the market-led economic activities. As an area of public policy which conveys the state's will, the role of planners is to set rules and incentives in relation to land use for capital accumulation in both economically and environmentally efficient ways. It thus draws on a role of growth management. In addition, a cooperative relationship between business, government and social movements implies that planners will have to play the mediator role to balance the interests of various stakeholders in project-led development. Because of the market-oriented planning characterizing the ecological modernization paradigm, planning tends to be issue-based, sectoralized and fragmented, and lacks integration and long-term strategic perspective (Davoudi, 2010). As Blower (2000) put it: 'planning has a necessary but limited role which does not challenge the market/state relationship which is the defining principle of political and ecological modernization'.

The primacy of market mechanisms within ecological modernization theory suggests utilitarianism in urban planning, which pursues maximizing individual pleasure rather than collective well-being. With utilitarianism's emphasis on the summation of individual self-interests, planning based on such philosophical thinking may tend to ignore the distributive aspects of burdens and benefits. Since market mechanisms usually benefit the already better off considerably more than the worst off, planning is likely to contribute to unequal distribution between social groups. In neo-liberal market economy, individual pleasure is usually measured by monetary values. As such, cost-benefit analysis becomes the most popular method to evaluate the goodness of consequences and the basis for decision-making in, e.g. infrastructure planning (Campbell & Marshall, 1999). Nature in this case is economized, seen as a capital stock useful for human beings. This instrumentalism with respect to nature ignores the inherent value of nature.

The typical planning strategy under ecological modernization takes the name of 'smart growth' or 'compact city'. This strategy is considered to be able to both enhance a city's diversity, economic viability which fulfills the vision of growth and counters urban sprawl (Qiu, 2006; Bunce, 2007). However, ecological modernization's emphasis on technologies to secure environmental sustainability encounters limits in the case of the smart growth (Xue, 2012). While it is possible to economize on land use and adopt a densification strategy for a short term, undeveloped land will have to be taken up when the opportunities for densification

are exhausted. Planning under the ecological modernization paradigm is weak in coping with long-term environmental sustainability. Furthermore, as argued by Davoudi (2010), ecological modernization's belief in a technology-based approach to environmental policy is likely to lead to a technocratic and elitist planning process.

2.2 Ecosocialism

Ecosocialism also attempts to build up an ecologically benign society. In contrast to ecological modernization theory, ecosocialism is an ideological and theoretical field associated with Marxism and thus fundamentally challenges capitalist productivism. As ecosocialists believe that ecodestruction is inherent to capitalism due to its relentless capital accumulation which drags nature wantonly regardless of ecosystem's inherent regulation, an ecologically viable alternative – socialism - should replace the capitalist mode of production, its institutions and worldview, if ecological breakdown and even the demise of our species is to be avoided (Kovel, 2008). Socialism undoes the separation of the producers from the means of production, the absence of which is argued to be the essential condition for the ecodestructive dynamics of capitalism. By attaining a freely associated labor and thus ending the alienation form nature, people will have a strong ecological consciousness. Key characteristics of an ecosocialist society are:

1. Fundamentally, ecosocialism requires the public ownership of means of production. This change in property relations will liberate labor from being a commodity for sale on the market. Released from the chains of capital, humans would become freed from the false addictive needs of consumerism (Kovel, 2008).
2. In relation to the first point, the overcoming of separation of producers from means of production leads to the predominance of use values over exchange values which is for profit-making and maximizing surplus in capitalism. Production is to satisfy social needs rather than driven by profit motives.
3. The realization of use values implies that nature is not treated as a commodity. Instead, the intrinsic value of nature is respected. All elements including human beings are integral parts of the ecosystem.
4. As a society embedded with ecological values, ecosocialism acknowledges ecological limits to growth and insists that production should stay within these limits. Therefore, human needs ought to be altered towards authentic needs and sustainability. This will lead to a new ecosocialism civilization beyond capitalist consumerism (Löwy, 2007).
5. Technological development in ecosocialism does not aim to accelerate capital accumulation and pursue exchange value, but is directed to the enhancement of use value and restructuring of needs.
6. Democracy is emphasized at all levels of production and decision-making in order to rule out hierarchical and exploitative relations of labor and avoid totalitarianism.

Within an ecosocialist society, planning will play a more significant role than that in the ecological modernization society, because communal ownership of means of production and discarding market mechanism make planning a public decision in

relation to the goals of development, production, investment, and allocation of resources. As a result, planning becomes a central institution of ecosocialism, in stark contrast to its role as serving the purpose of market in the ecological modernization paradigm. To realize the goal of ecosocialism which is 'a new society based on ecological rationality, democratic control, social equity, and the predominance of use value over exchange value' (Löwy, 2007), planning must place great emphasis on *social purposes* and *ecological sustainability*. Thus, under ecosocialism, focus on economic growth as well as competitiveness as overarching goals would soon be in violation with the primary concerns for social and ecological sustainability. As other public policy areas in ecosocialist society, planning is liberated from the imperatives of capital and profit-making. In the transition to ecosocialism, planning should in some cases counter and supplant market mechanisms in terms of converting the growth-oriented role of planning at the strategic level and containing the amount of land allocated for industries, houses, highways, airports, etc. at the spatial level.

For concerns of ecological integrity, urban planning would need to replace anthropocentric thinking with ecocentrism ethics showing human obligations for non-human nature. This requires planning to show fundamental concern and respect to the inherent values of non-human life and to preserve the richness and diversity of life forms. It also means abandoning the dominant economic rationality as a determinant of decision-making in the planning process (such as cost-benefit analysis in transport planning) which tends to value things according to their instrumental use for humans in a monetary form. The dominance of ecological rationality necessitates a long-term strategic and holistic horizon in planning, as environmental issues have transboundary and transgenerational effects and refer to many sectors and population groups.

The issue of 'limits to growth' is addressed by transformation of needs from a quantitative to a qualitative dimension (Kovel & Löwy, 2002). The implication of this is that planning should aim to combine 'selective degrowth' and 'selective improvement'. The former could include degrowth in the size of the population, urban sprawl, high-speed transport infrastructure, consumption of cars, per capita consumption of dwellings and other material items, export and import, etc. However, the selective degrowth should arguably accompany selective improvement of social services and welfare for the deprived within the city, including affordable housing, medical care, education opportunities and mass transit.

This last point is also associated with the social purposes of urban planning, which concerns social equity and distributive justice. An ecosocialist society does not mean there are no conflicts, e.g. between different population groups in relation to social needs or environmental protection. As a society aiming at no domination and exploitation at all levels, it will be partly the task of planning to solve the conflicts through land use for different activities and purposes based on the principle of social justice. Since the potential for devastating conflicts over distribution of resources is much higher when human activities are to be kept within the ecological limits, the interests of the marginalized and vulnerable population should be fully represented by urban planners, who would to some extent need to work as advocates. In addition, social justice should also be promoted in a deontological approach, which, for

planning, suggests participant diversity, democratic discussion and transparency in the planning process. The role of planners, according to Löwy (2007), will be to present their expert views rather than make decisions. The promotion of democratic process is to avoid top-down and authoritarian decision-making.

3. A recent shift in China's development path: from trickle-down strategy to balanced development

China's development strategy since the economic reform in 1978 can be characterized as a 'trickle-down' policy, which encourages a proportion of population and regions to become rich in the first place and then let other regions catch up later on. With preferential treatment for the eastern coastal areas, most of the country's limited resources and growth-stimulating measures are devoted to a few selected cities (Yao & Zhang, 2001). During the late 1970s, the entire 1980s and the beginning of 1990s, five cities were selected as special economic zones, and 14 cities were designated as coastal cities of open economy, the majority of which are located along the eastern coast line.[2] They are cities open to international investment with preferential development policies. Some of these cities have gradually grown into metropolitan areas and evolved into national or regional growth centers making a vast contribution to the growth of the national economy. However, an overall repercussion of this strategy has been imbalanced development across the country in terms of income, material living standards and social welfare (Kanbur & Zhang, 2005). After 30 years of reform with formidable growth rates, the trickle-down policy is not as effective as what has been expected by the Chinese government. The beneficiaries are those living in mega-cities where wealth is concentrated and polarized, accompanying on average higher per capita consumption levels and a widening gap with populations in impoverished regions.

This period is characterized as a period giving priority to economic growth as its ultimate development goal. Since growth-oriented policies of promoting housing market, attracting foreign investment and constructing large infrastructures are closely related to land use and urban development, physical planning has taken on a local pro-growth role by providing land and proposing large infrastructure projects. Planning decisions are justified based on economic efficiency and technical feasibility (Yeh & Fu, 1999). As a result of decentralization of decision-making to localities, deregulation of market and local government's priority on urban growth, urban planning has difficulties in intervening and controlling development but always has to change to meet the policies of governments on different levels (*ibid.*). In environmental terms, the aftermath has been loss of valuable land resources due to rampant economic development zones and building construction boom, and local environmental degradation.

Environmental problems have to some extent been addressed in the process of economic growth. In the recent couple of years, the inequality issue has become a

[2] The five special economic zones are: Shenzheng, Zhuhai, Shantou, Xiamen, and Hainan (province). The 14 coastal cities of open economy are: Dalian, Qinhuangdao, Tianjin, Yantai, Qingdao, Lianyungang, Nantong, Shanghai, Ningbo, Wenzhou, Fuzhou, Guangzhou, Zhanjiang, and Beihai.

political concern. At the national level, a new development strategy addressing balanced and harmonized development substitutes the single-minded pursuit of high economic growth rates in certain regions. Evident from the twelfth five-year plan for economic and social development (2011-2015), as well as several recent government policy documents, China's state government has been trying to limit the speed of economic growth and set more comprehensive goals focusing on changing the economic structure, building an equitable society, and reducing environmental impacts. Such a shift stems from the rising inequality which threatens political and social stability and from a realization of environmental limits to growth. This shift is clearly illustrated in the authoritative and legally binding national territory development plan issued in 2011, the first of its kind in China's modern history (National Development and Reform Commission of China, 2011).

This national plan sets out the idea of pursuing efficient, balanced and sustainable regional development upon the basis of designation of four types of development priority zones on the country scale. Within this frame, the spatial economic, population and land development strategies are made for each zone. The four types of priority development zones, their key functions and development strategies are listed in Table 1.

Table 1. Types of priority development zones, functions and development strategies

	Cover areas	Functions	Development principles
Development zone to be optimized	Three city regions along the coastal line, which are economically well developed[a]	• Key regions of lifting the country's international competitiveness • Locomotive of national social and economic development • Regions of national innovation • Influential regions capable of participating in global division of labor • Economic and population concentration area	• Upgrade economic structure and develop green economy • Optimize spatial structure, contain urban sprawl and industrial areas • Contain population scale • Optimize infrastructure distribution • Optimize ecological pattern
Key development zone	Cities in middle and western part of China with potentials of developing economy and concentrating population	• National economic growth center • Pivot enhancing balanced regional development • Economic and population concentration area	• Enlarge city scale • Speed up population concentration • Develop modern industries • Improve infrastructure • Protect environment
Limited development zone	Main production areas of agricultural products, and	• Provide agricultural products • Important areas	• Limit extensive and intensive industrialization and

	key ecological function areas	guaranteeing national ecological safety	urbanization
Prohibited development zone	Representative ecological systems, areas of endangered species and valuable natural and cultural heritage	• Key protection areas of national natural and cultural resources • Gene pool of endangered species	• Prohibit extensive and intensive industrialization and urbanization

a The three city regions are: Bohai Economic Rim (economic hinterland surrounding Beijing and Tianjin), Yangzi River Delta region, and Pearl River Delta region.

The areas designated as the zone to be optimized are in line with the definition of big and rich cities in this article. For these city regions, even though economic growth is not explicitly stressed, the pursuit of enhanced competiveness and sociotechnical innovation clearly indicates the influence of globalization and a neo-liberal climate on the selection of development strategy. The assumption behind this strategy is that growth will automatically continue, therefore government interference will change its role from growth stimulation to growth management addressing the quality of growth. For the key development zone, policy concentration on growth stimulation continues to be the first priority, allowing for urban spatial and population growth and subordinating the social and environmental concerns. As stated in the plan, the overall purpose of a balanced regional development is to *extend* economic growth from the east to west and from south to north, in order to form an economically polycentric and network spatial structure. It can be seen from the above that the state attempts to shift its development path from a single-minded pursuit of economic growth to the ecological modernization model. It clearly stated in the plan that 'the building-up of the development zone to be optimized and key development role relies on the market mechanisms, while the government will channel the means of production to concentrate in those areas through making plans and policies' (National Development and Reform Commission of China, 2011).

Emphasis on GDP is superseded by *competitiveness* as an overarching goal for the wealthy regions. According to the plan, to realize the goals in the development zone to be optimized, concrete urban planning strategies include containing urban sprawl, industrial areas and scattered development of economic development zones, enlarging space for service sectors, transport, residences and public infrastructures, promoting compact city development, specifying the functional specialization of cities surrounding the central city in order to advance economic connection and regional competitiveness, controlling inner-city population scale of mega-cities and increasing the capability of peripheral cities in attracting inhabitants, protecting farmland, other types of undeveloped land areas and green open land between cities. However, the question is raised: are the ecological modernization policies capable of obtaining an ecologically and socially sustainable society across the whole country?

4. The necessity of economic non-growth/degrowth in big cities

Recently, a report based on an evaluation of Chinese cities' sustainability index positively concludes that 'some of Chinese cities (rich ones) have been able to *couple* economic growth with gains in sustainability' (Urban China Initiative, 2012). Through an investigation of 112 cities, the report reveals a positive correlation between income and environmental sustainability score, in line with the environmental Kuznets curve hypothesis (*ibid.*). Nevertheless, some caveats need to be addressed. Given the environmental indicators chosen in the report which takes the form of environmental impacts per unit of GDP, an increase of the environmental sustainable score merely means an increase of eco-efficiency, hardly suggesting a decline in aggregate environmental impacts, i.e. absolute decoupling. Thus, a higher environment sustainability score can only indicate that environmental impacts do not increase as fast as economic growth, which is *relative* decoupling. Economic growth in the already rich cities is still at the cost of environmental quality and resources, however with lower environmental costs than before due to efficiency improvement. This general conclusion is supported by an in-depth study on the housing sector in Hangzhou. Residential energy consumption in Hangzhou in the past 20 years has increased but at a slower rate than GDP growth in that building energy efficiency has been increased considerably (Xue, 2012).

One point worth attention in the report is that the correlation between eco-efficiency and economic growth is not as strong in high-income cities as in low-income cities. It indicates that growth in wealth in already rich cities may no longer predict further gains in sustainability (Urban China Initiative, 2012). This can be attributed to the fact that the room for eco-efficiency to improve is decreasing when it is high at the outset. Therefore, continual growth in rich cities or regions cannot be obtained without further degrading the natural environment. The idea that continual growth in those big cities would not undermine the future growth in the impoverished regions is hardly plausible, especially if the national-scale environmental load is to be kept within acceptable limits. To achieve the goal of poverty elimination, environmental protection and satisfaction of long-term needs requires economic *degrowth* in the rich regions. Priority for growth should be channeled to poor regions in inland China and low-income population groups. Giving priority to the worst off regions would be an appropriate response to the fact that resources are limited.

Development in the rich regions has already exceeded the capacity of their bioregion. Such a realization constitutes one of the reasons for avoiding further population immigration and location of resource-intensive industries in those cities as pointed out in the national territory development plan. No doubt, the national territory development plan represents a departure from the previous strong commitment to economic growth in the decades since the 1980s. But it is no more than a strategy framed by the growth paradigm, seeking a combination of competitiveness and social and environmental sustainability. Altogether, this shift in national development strategy does not indicate an escape from the growth paradigm. I am sympathetic to the idea of transferring factors of production to the lagging behind regions and the designation of key development zone as well as its development strategies to

eradicate poverty. However, a strategy oriented towards promoting competiveness of the rich city regions actually aims to convert the growth sectors from being the second industries to the service sectors, a substitution which is usually claimed to be less environmentally harmful. However, the environmental consequences of the service sectors are argued to be not as low as expected (Næss & Høyer, 2009).

In addition to the above argument for economic degrowth in big cities, as far as the local environment of the big cities per se are concerned, degrowth is also relevant. Big cities in China usually suffer from overcrowding, high population density, traffic congestion, noise, water and air pollution, lack of open space, slums and social segregation more than the medium- and small-sized cities (Chan & Yao, 1999). These environmental and social problems have been in part attributed to the agglomeration effects of these city regions, which attract continuous in-migration of floating population and concentration of economic activities, which exceeds the local ecological carrying capacity. Local environmental quality has been moving along a downward curve, adversely affecting citizen's health and eroding the significant economic gains (*ibid.*). To alleviate these pressures on big cities, coordinated development strategies which pursue economic degrowth in the wealthy regions and fuel the growth potential in the middle and western China are needed.

5. Planning pathway to degrowth in the Chinese context

The current climate of the Chinese government's public policy is dominated by the discourse of ecological modernization and its interpretation of the planner's role, which is evident from the national territory development plan. The approaches to the environmental and social problems in the urban context as identified in the ecological modernization paradigm have a very limited potential for obtaining sustainability in a long run. Furthermore, taking a global perspective, the limited natural resources may not support a global affluence level where China is on a par with the present wealthy countries, since technological improvements cannot develop fast enough (Xue et al., 2012). The gaps in affluence level across the country require differentiated regional development strategies. As agued, economic non-growth/degrowth in the affluent regions is necessary for long-term environmental sustainability, while for social equity growth opportunities should be given to the poor regions.

A departure from the growth paradigm to degrowth requires reframing planning rationality and spatial logics. Coordinated and synergetic regional planning which aims at weakening the status of big cities and providing development opportunities for other regions are required. For those wealthy cities and regions, the traditional role of planning in attracting capital and industries under the domination of economic rationality should be shifted to containing growth and promoting social development. Planning should pursue a just and environmentally friendly city rather than focusing on competitiveness.

Degrowth in big cities in the Chinese context refers to decline in the size of population and per capita material consumption level which can include car ownership, dwellings, high-speed transport infrastructure and other material

commodities. Current policies trying to curb population influx into big cities are regarded as socially unsustainable because local authorities of big cities tend to employ the household registration system to protect the interests of the locals at the cost of the interests of the immigrants. Greater emphasis should be given to social injustice between population groups at the city level in terms of unequal education and medical services, and housing affordability. What matters in the degrowth paradigm is not local GDP which has been a single-minded pursuit of Chinese cities in the past three decades, but development with the concern over environmental sustainability and social equity inside and outside the big cities.

On the other hand, planning strategies should aim to upgrade peripheral cities and rural regions to stimulate growth in a socially sustainable manner, as growth will really make a difference in those regions. Note that planning efforts should also be made to decouple the environmental impacts from such growth as much as possible. This requires certain planning solutions in place to obtain high eco-efficiency in land use and energy consumption.

The requirements for revision in planning for degrowth is distinct from current planning practices in big cities that are still endeavoring in competition with other cities in local economic growth. A body of literature has supported Marx' (1858) conclusion that a capitalist market economy is subject to a growth imperative (Gordon & Rosenthal, 2003; Fotopoulos, 2010; Harvey, 2010). The market-oriented economic reforms in the late 1970s have given the neo-liberal thinking a dominant position in China over the last three decades. As such, it is difficult to accept a degrowth paradigm both at the ideological and practical levels. Nevertheless, China's economic system is different from its Western counterpart's capitalist market economy. Some socialist features can still be identified, like public ownership of land resources and the state-owned enterprises. This implies that compared to traditional capitalist societies, China can to a larger extent choose to grow or not. As claimed by ecosocialists, a socialist society does not exist for profit-making and environmental degradation is not inherent to such a society. China as a country claiming to be a socialist country has more potentials and advantages to transit towards ecosocialism (Pan, 2006). The proposed alternative development path for economic non-growth/degrowth fits well with the themes of the ecosocialist paradigm. Moreover, the principles of ecosocialism are compatible with traditional Chinese philosophy (Pan, 2006; Xue et al., 2012). The degrowth planning agenda can be seen as a vehicle inspiring the transformations to ecosocialism.

6. Conclusion

The paper has discussed the limitations of urban planning defined by the development path shaped by the ecological modernization paradigm as a response to ecological deterioration and social inequality in China. Instead, ecosocialism, which is in accordance with China's socialist features and traditional philosophy, provides an alternative development path for long-term sustainability. This entails urban planning to discard a neoclassical/capitalist economic rationality and takes on the role of promoting social justice, articulating the intrinsic value of nature and restructuring human needs. The practical implication is planning for differentiated

and coordinated regional development across the country, with a degrowth planning agenda in the wealthy city regions. Planning should assume the responsibility to facilitate the transition toward an ecosocialist society.

As argued by Kovel (2008), ecosocialism should be universal in order to be successful. This means that if sustainability is to be achieved on a global scale, apart from China, the advanced industrial societies may also need an ecosocialist revolution. Their higher affluence and consumption levels make this transition more urgent than in the developing countries.

CONTRACTING SUSTAINABLE SOCIAL HOUSING? A DEVELOPMENT TOOL FOR NEW URBAN AREAS

Betül Bretschneider

Abstract

The contribution deals with a planning and coordinating method for the new urban development areas within the existing urban fabric of Vienna. Social housing is the main use of these new urban development areas. The emerging housing projects affect the whole urban transformation process in Vienna, the city of 'social housing' since almost 100 years.
This special planning method - 'the housing contractor competition' model - of the City of Vienna has been developed in 1995 to improve the quality of (subsidized) social housing with regard to architectural design, cost efficiency and ecological impact. It is a competition model for the development and planning of new housing buildings and areas: the architects, construction engineers and housing contractors develop together building concepts for an affordable and high-quality housing production. This housing development method requires guaranteed maximum construction and user costs based on the architectural planning of the competition project. By co-operating from an early stage onward, the stakeholders (planners, housing subsidy department and housing contractors) are involved in the planning process to optimize the project under technical, economical and ecological aspects. The competition aims at a better performance and stronger competition between the teams, involving the architect teams and the housing contractors in financial optimization of housing projects.
During the last years architects and contractors appeal for changes in the competition process showing controversial positions and planning traditions. All players of the process are recently seeking new solutions. Involving all players of the urban planning process creates new perspectives in planning practices, which can help to improve and optimize the current planning methods.
The main question of my contribution is: How could Vienna's planning tool for housing production be modified to guarantee the sustainable quality of urban transformation and urban development of the city dominated by historic urban fabric?
What are the controversial positions and conflicting targets of the urban development process? How has the built environment been affected in the last decades by the housing contractor competition? The study investigates the social and ecological character of current practice of urban development regarding building typologies and structures, common and public spaces,

traffic organization and ground-floor-zone. In this context comparable depth-in interviews, hearings, discussion series with the involved architects, planners, contractors, users and planning authorities, as well as newspapers and online publications of city of Vienna deliver new findings.

1. Which city? Eco city, knowledge city or finance centre?

Since the 1990s, in the period of deindustrialization and liberalization of economies, as city has become the major address of capital accumulation and economic growth, the local governments have been forced to install new redevelopment strategies to transform the cities to attractive places for consumption, tourism and headquarters of trans-national companies, which require a fundamental restructuring in urban policy. Various terms have been used to describe this process such as urban regeneration, revitalization, revival, redevelopment, reconstruction and improvement. The 'competition of cities' has changed the urban planning tradition in the European cities. Also in Vienna the city government has transformed the planning strategies by opening up to private developers to build high raise office buildings on the waterfronts, on former brown fields and even in the recreational green areas.
The first head quarter towers have begun to rise in unexpected new development areas. One oft them is Danube City, on the huge concrete platform 'Donau Platte' by the riverside. This huge concrete slab has been originally planned and prepared as Expo-ground, but was not realized after putting Expo to a referendum in 1991 with a negative feedback of the population. A series of new urban development areas, all named as City (Wienerberg City, Siemens City, Bahnhof City, etc.) is already developed or going to be developed.

Parallel to this development, several international institutions (OECD, UN[i], Territorial Agenda for EU[ii], EC[iii], CEC[iv], EEA) issued position papers and declared a cohesion policy towards a sustainable urban development and urban regeneration. Within a very short time the sustainable development has become the most important discourse based on economical growth. (Jenks, Burton, Williams, 2000).[v] Various position papers giving the agenda of sustainability challenge the city governments and local authorities by the implementation of major targets such as strengthening cities, social and physical regeneration in urban areas, protecting and improving the urban environment to achieve the local and global sustainability targets.[vi] One of the recent position papers of the European Commission defines the following economy based objectives as a collective target, besides the revitalization of historic centres: economic development in areas with social problems, exploitation of the technological assets of cities and environmental action linked to economic goals. While compensating the loss of production industries and replacing them with service and knowledge industries, the ecologicalisation of urban policy promoted also energy-efficiency activities in the building sector. However the conflicting interests of the real estate market constrain the rapid implementation of really sustainable development measures.

1.1 High demand on housing as impact of increased migration

Besides the major issue of competitiveness and attractiveness of the cities, social housing, migration and ageing population have been the key issues of the urban policy since 1990s also in Vienna.
Vienna's population has grown slowly but constantly due to the immigration from the neighbouring countries caused by the deindustrialization of the post-socialist territories i.e. in the cities in Germany, Poland and Slovakia and in the cities of Ex-Yugoslavia as well as due to the ongoing immigration from the rural areas and small towns to Vienna within the country. In the last 10 years, the population of the city has grown around 200.000, to 1.8 Mio.[vii] However there are some estimations referring i.e. to the water consumption data of the city population as indicator, that the population has grown already over 2 Mio, due to the unregistered migrants from the neighbouring countries.

1.2 The increasing demand for affordable housing and urban policy

As increased immigration has caused a high demand on (affordable) housing, Vienna's city government began to pay more attention to the subsidized housing and began to reorganize the housing production, to regulate the housing market and to keep increasing rents and property prices under control.

Figure 1. Population growth 1997-2007, City of Vienna,
Municipal Department 23 - Economic Affairs, Labour and Statistics

1.3 Urban renewal versus urban development?

The city government in Vienna has the two main activity fields of urban planning and policy:

- urban renewal authorities managing and promoting the renewal of existing housing stock and regeneration of urban fabric,

- urban development managing and promoting the production of new housing and steering urban (re)development.

The urban renewal program has been established for the renovation and modernization of Vienna's historic housing stock built between the end of 19th century and at the beginning of 20th century, in the period of mass immigration and mass industrialization. 2001 about 1/5 of the building stock and 34% of the total housing units in Vienna have been built before 1919, the First World War (Fassmann, 2009).[viii] These historic buildings are giving the character of the central city areas. Towards the end of the 19th century the older smaller sized building blocks were demolished in only 20 years to make place for the regular block raster system. So the structure of the city was changed fundamentally. The intensive urban renewal program of City of Vienna started in 1984 with the foundation of urban renewal authorities (wohnfonds_wien). After the big city expansion projects of the 1970's (e.g. Schöpfwerk, Alterlaa) and 1980's (e.g. Brünnerstraße), the city of Vienna attached importance to urban renovation and to improvement of urban fabric in the central city areas. Until today a big amount of the housing units in the historical buildings has been modernized by providing bathroom, modern technical equipment and central heating system. Since the mid 1980's the historic building stock has been renovated successfully. Only a small rate of them is still not modernized. Today only a very limited amount of low cost housing units, which are affordable for new citizens, young people and elderly people and for lower income groups, are left in the historic buildings (in low standard). (Bretschneider, 2008)[ix]

The problems such as 'segregation' and 'decline' have been challenging the city government more or less. The ongoing 'gentrification' is going to be also a problem of the well fare city Vienna. During increasing imigration from the de-industrialized cities of neighbouring countries, the City of Vienna has been concentrated on the following goals: to stabilize the economy by attracting transnational companies and by promoting the local real-estate market and the construction industry as well as by producing new housing stock for the increasing demand.

Figure 2. Transformation of the Central Railway Station into a new district Bahnhof City (Sonnwendtviertel) S: www.hauptbahnhof-wien.at (Access. 2012)

Vienna's **urban development program** sets strategies for the development of new social housing and mixed-use urban areas in the central city areas. Vienna's strategic urban development plan (STEP 2000 and 2005)[x] embraces 13 target areas as future development areas. (Fig. 3)
The new development areas are in most cases brown fields of local production companies or the vacant or only partly used rail transport areas (i.e. Bahnhof City, Nordbahnhof, See Stadt Aspern).
The inward development of the city brought more density, new uses and high rise building complexes structured in new urban typologies, which are significantly different than the existing homogeneous block raster structures. (Figure 3)

Figure 3. Vienna's current 13 urban redevelopment target areas
Source: STEP 2005, City of Vienna

Vienna's historic urban fabric consisting of perimeter block structures with internal courtyards and street spaces between the blocks is traditionally the place of functional and cultural diversity, mix in small-scale. The social and functional mix of new development areas is not small scaled like the traditional urban fabric. The high-rise and more density building complexes have been built in urban typologies, which are different than existing homogenous urban structure. The new urban development areas remain as pheripheric areas to the central city without showing the traditional 'urban' character of the rest of the city.

2. The tenure of households in social housing

Both the urban renewal program and urban development program are based on the 'social'housing. Social housing as term here means 'housing run by not-for-profit

or public landlords for rent, normally at below-market rents' (Hills, 2007).[xi] Social housing consists of two main forms of housing tenure in Vienna:

- council housing let by the city of Vienna and
- housing let by the non-profit or limited-profit housing associations using housing subsidies following the housing act (Wiener Wohnbauförderungs- und Wohnhaussanierungsgesetz – WWFSG 1989)

The city of Vienna is the biggest Landlord in Europe owning 220.000 council housing units, all built after the First World War up to the 1970`s. Highly standardized construction and building components produced for the council housing (Blau, E., 1998)[xii] have been the beginning of 'housing as mass-product' with strong working class identity. In Vienna there are 77 % tenants and only 13% owners.[xiii]
Since the 1970's, the city government stopped to build council housing. After the intensive urban regeneration program of the 1980's to modernize the existing housing stock built before the First World War, in the 1990's the housing initiative of the city government had the target of 10.000 new subsidized housing units per year.

2.1 New housing development toolkit: Housing contractor competition

The city government has been regulating and supporting the development of housing in Vienna more than 80 years long. As mentioned before, the main component of the emerging development areas also in Vienna is housing. The new housing projects are mainly developed and built by 'Austrian Limited-Profit Housing Associations' (Gemeinnützige Wohnbaugesellschaften) dealing with the development of subsidized housing.
In 1995 the housing fund of the city of Vienna (wohnfonds_wien) implemented a development model - so-called 'housing contractor competition - for subsidized housing projects to achieve the following aims:

- to increase the spatial and architectural quality of the (subsidized) social housing,
- to reduce the construction costs and the (rental) housing costs for the tenants,
- as well as to improve ecological efficiency and architectural quality.

The housing property development competitions affect directly the urban development in Vienna. Since the implementation of housing contractor competitions in 1995, 44 competitions were carried out on 163 plots by using 752 million Euro housing subsidies for about 18.000 housing units (Vice-major of Vienna M. Ludwig, 2010).[xiv]

The so called 'housing contractor competition' requires a collaborative teamwork of architects, construction engineers, landscape architects and the (limited-profit) housing associations for the development of large-scale multi-storey housing (between 200 and 300 Housing units).[xv] The competition entries contain a

architectural concept for one or more housing blocks including construction costs, time schedule as well as landscape design.
In the recent years the housing competitions have been issued with various emphases such as passive (energy) housing standard, timber and timber containing construction technology, intercultural housing and government assisted housing for the low income groups.

2.2 High-tech standards versus affordability: Assessment Proceeding

An advisory commission consisting of architects, planning experts and housing authorities assesses the competition entries according to the following selection criteria to select the winner project:

- innovation in architectural concept including landscape design,
- social sustainability (mix of different income groups),
- ecology (energy saving standards and material choice),
- economy (construction costs and logistic costs),
- financial conditions for tenants and property owners.

Producing more housing reduces the high demand in the housing real estate market and as a consequence decreases rents and property costs. Since 1970s the majority of the target tenant groups of subsidized housing projects have been middle-income groups.
The new legislations leading to higher security measures (i.e. fire protection, earthquake resistance) and to higher energy efficiency increased the rents and property prices significantly. However the current building regulations require low-energy standards in Austria. Even passive house standards for housing are no rarity anymore.

2.3 The aims and consequences of housing policy:

Generally a new urban development area is planned in two steps: the first step is the preparation of master plans by an architect's office. The second step is the housing contractor competition for the subsidized housing block/s on the current urban development area.
The master plans regulate the parcelling, building structures and building functions. The commercial concerns of 'housing associations' define the way and size of parcelling: They determine (in correlation with the cost limits for construction and building plots) the decision process as well as the physical and social structure of future urban development. The development area is divided into building lots in proper dimensions taking into account the capacities of housing associations. The feasibility of housing blocks (planned for at least 60 housing units) affects the dimensions of the building plots and so the urban character in the master plans. Moreover the building legislations as well as the parcelling system make overlapping small-scale and mixed-use building structures that would be similar to the existing urban fabric very difficult.

2.4 Architectural urban quality versus cost-effective building?

In the past years architects and housing associations having contradictory interests appealed for an optimization of the contractor competition model to guarantee more architectural urban qualities while reducing construction costs and rental costs. The architects, housing developers and planning authorities discussed several times the city making process during the last years. The social and ecological aspects of urban and building planning have gained more importance due to a recent revision of the existing collaborative competition. The subsidized housing sector shows recently the following challenges:

- decreasing amount of subsidies for social housing,
- growing competition between two programs due to the budget cuts

between urban development by producing new subsidized housing and urban renewal by renovation of existing housing stock,

- hardly any available building lots/vacant areas in the central city areas
- increasing final costs of housing for tenants and owners due to the increasing building lot costs and due to the higher technical requirements and strict energy saving standards (the construction costs and as a result rental or property costs are not allowed to exceed the maximal price level given by the housing subsidy authorities).

On the other side for the other stakeholders of the process such as architects and urban planners the problems to realize housing projects have following obstacles:

- over-regulation in planning and design; by the legislative restrictions and regulations (high-tech construction standards and enforcing safety and comfort regulations), by the housing act, by the 'conservative' housing real estate market,
- peripheric character of emerging neighbourhood culture without having vital open spaces and street life (partly accompanied by shortage of children play grounds and places for young people),.[xvi] Difficulties by improving an 'attractive and interactive' ground floor zone and adjacent open spaces between the blocks and within the blocks (the ground floors of the 'new' housing blocks generally belong to garages, garage accesses, storages and waste containers).
- 'conservative' housing real estate market and housing associations forcing a anti-innovative discourse by controlling the architectural design, size and typology of the housing units with classical spatial organization for families with children (although almost the half of Vienna's population like in other European cities are living in single households)[xvii]

Figure 6. A competition site for 650 Housing units on the brown field of former Mautner Markhof ground Source: City of Vienna, wohnfonds_wien, 2010

Recently the interdisciplinary jury of housing contractor competitions consisting of architects, engineers and housing authorities (wohnfond_wien) have focused on the functionality and vitality of ground floor zone and the quality of common

spaces, play grounds, local supply, social facilities, traffic calming measures as important criteria for the selection of the winner project.[xviii]

Another problem is the decreasing quality of the architectural concept of the competition project during the realization process. Especially the quality and usability of open spaces and ground floors are not ensured, due to the obligatory cost savings measures of the contractors or disinterest for the urban quality.[xix]

3. Conclusions: Are affordability and sustainability compatible?

Currently the housing associations and housing contractors finance their housing projects increasingly without using housing subsidies, because in that case the additional regulations and restrictions of the housing act are not valid and therefore the housing construction costs are lower. Furthermore the rental income (yield) is not limited as in the case of the subsidized housing. Although the housing associations are only allowed to be limited profit-oriented, they have to invest furthermore for a guaranteed circulation of capital. As mentioned before, the pressure on the real estate market and the shortage of buildable land in the central areas of the city with easy public transport accessibility are the further reasons for this trend.
Although the city government plans to build additional social housing units, and declares a paradigm shift by the contracting structures (e.g. property owner cooperations, participative housing developing) there are still no convenient measures that are already implemented. The commitments to optimization and promotion of social housing are not concrete. The governance of social housing and urban planning is rather complex, conservative and inflexible.
To ensure the quality of the open spaces and ground floors in new development areas,

- on the one hand a deregulation (less restriction for new users and other or unconventional uses)
- - on the other hand new legislative regulations are necessary to enable the ‘urban’ quality particularly focused on the ground floors and open spaces (restrictions by garage and storages in the street level or the guaranteed realisation of open space improvement measures).

At the end the following questions are still omnipresent: Are the current high buildings standards of building practice the only way to guarantee the ecological qualities and living comfort? How can the transformability of built environment for the future generations relating to demographic changes be ensured?

THE ABANDONED VILLAGES AS A REGIONAL RESOURCE

Luca Di Figlia[1],

Abstract

In recent years, we have witnessed the rediscovery of urban rural realities. Even if these realities may be of small dimensions, they are characterized by a deep-rooted local identity. In many regions, these realities have been exploited to promote actions and policies of local development. Within the same territory, urban, environmental and landscape resources have been identified that could preserve the uniqueness of these places and could counteract the pervasive effects of supra-local development. In this framework, the presence of abandoned villages can gain significant importance.

The uninhabited villages, given their general state of deterioration and abandonment, can be considered both as a discarded element of modern consumer society, which erroneously fails to recognize in them any practical use, as well as a regional asset, reinterpreted from a qualifying perspective which does not stop at observing the current state of decay but instead comes to recognize the value of the identity of such places. The abandoned village is a place of interest for its architecture, built in accordance with ancient tradition, for the dialectical relationship with nature that the construction has established over time, and for the rarefied context of the urban landscape that becomes an evocation of the past. The uninhabited villages reflect the essence of the bond that was dissolved between man and territory.
While the ghost villages have lost their "life function", they are abandoned but not forgotten: their present is located in the past and they do not remember the future, thus they become places in the memory.
However, by attributing new meaning, these villages can acquire a new function, a new use *in* and *for* the territory. Recognizing in the abandoned village a resource identity foreshadows the possibility of tangible and intangible trigger actions for its recovery- actions which can nourish a local economic development in tourism with benefits for the entire territory in which they are located.

The proposal aims to investigate the phenomenon and the reality of ghost villages in order to understand the meaning and role to be given to each abandoned village, to define the areas of comparison between cases identified, and to identify possible models of revitalization.

[1] Department of Urban and regional planning, Florence, Italy - ldifiglia@unifi.it

Finally, the work hopes to stand as a simple witness, because it is in the transmission of knowledge and the evocation of memory that abandoned villages can be brought back to life.

1 Introduction

The land, in its current configuration, manifests itself as a definitive design, a fait accompli, composed of villages and open fields, cities and forests, roads and rivers, man-made and natural elements. Its true reality, however, is revealed only through an awareness that it is the end result of an extensive and diverse web of processes and occurrences, of natural events and historical dynamics, of an intricacy in continuous and progressive change. The complex history of a territory largely coincides with that of the whereabouts of man, or human settlements. Its population depends on a multifaceted interaction of causes of geographical and historical nature and, especially, a subtle and inseparable relationship between man and place. The formal and existential reason for the fabric of the settlement is inserted in an environmental and natural context; its shape is, therefore, a product in and of the earth. The synthesis of ongoing changes in the land can only be evinced as the city itself, a formal and concrete symbol of processes of urbanization perpetrated over time. The settlement, be it a city or village, represents the best opportunity to humanize the natural environment and in to insert the human heritage in a specific place; it delivers to the environment a cultural and externalized form of permanent, collective dynamics.

The city in its form, then, is inseparable from its content: its aesthetic value rests in his appearance, but it is the presence of the man which fills the form. There is an inseparability between the social and the aesthetic issue; physical space constitutes an experienced and historical reality, for this gives validity, value and affective quality to the construct and to architecture[2]. Cities are born from the social necessity to integrate across occupations and human experiences, which being multiple and complex, are organized on the basis of various processes and dynamics. These intertwine and compensate for one other, generating systems which are not absolute, but are imperfect and are therefore subject to change. The true wealth and power of a system , however, lies precisely in this inherent weakness and imperfection, since it is starting from such deficiencies that it is able to evolve. The city system is not rigid but is organically malleable and adaptable to continuously changing human needs[3]. If the city system is strong and well-structured, it confidently confronts various issues and develops in turn, but if the organization of an urban environment is weak and based on rigid dynamics of life, the moment it is subjected to new difficulties, it will fail to preserve its state of being: the equilibrium reached until that point will become

[2] "It is evident and clear that a space acquires the majority, if not all of its meanings through the life that is carried out within it, that also shapes it " (Romano, 2001, p.15).

[3] This concept is explained by the thought of Lewis Mumford: "(...) many elements necessarily rejected by the individual systems are essential to developing the highest creative potential of life (...) from time to time, it is necessary to utilize different systems in order to do justice to the infinite needs and circumstances of life "(Mazzoleni, 2001, p.30).

unbalanced and will give way. This is the case for abandoned cities or villages, in which sudden and violent changes have led the inhabitants to move away permanently and to seek new places to live. The city without the human presence is rendered inevitably empty, stripped of its content, its existential reason; what remains is only a shell, a form without an idea, volume without substance; it is reduced to a pure and simple space, that is, ultimately, to only a sign / design in the territory.

The research proposal intends to present the reality of abandoned villages in their relationship to the land and in the context of the current times. If it is true that the uninhabited village has lost its raison d'être by being deprived of the human element, it may present itself with a new role. The uninhabited village transforms its role within the territory, just before, during, and after being abandoned, acquiring a new identity.
Might the reality of abandoned villages in Italy constitute a phenomenon in itself? What value is attributed to abandoned villages? Is it possible to imagine new scenarios or roles for abandoned villages?

2 The phenonmenon of abandonment in Italy

According to the most recent Italian census conducted in 2001[4] more than 72 percent of the 8,100 Italian municipalities have less than 5,000 inhabitants[5] . There are a total of 3,644 municipalities with fewer than 2,000 inhabitants. These municipalities, composed of small villages and hamlets, carry out a fundamental activity in presiding over the territory. Even if these municipalities are regarded as places of cultural value, they are found to have an uncertain future and can be included in that category defined as "difficult settlements"[6]. These small inland villages and hamlets, concentrated mostly in upland areas in what were once considered mostly strategic locations, are now completely overtaken by the new territorial assets along the coast and in the valleys. Today, they are characterized by a weak economy, low population density and devalued real estate, and are subject to the dynamics of economic impoverishment and a lack of services[7].

In this historical and geographic context, we must analyze the modest reality of the abandoned villages from the beginning of the 1900's until modern times. The phenomenon of depopulation, or more generally of emigration, is a continuing reality. In proceeding forward, it can bring about a demographic increase or decrease of a localized territorial area, until the point in which the territory is completely

[4] The census is conducted every ten years, and the most recent data was actually collected in 2011. However, these data have not yet been disclosed.
[5] With a 7% increase from the census of 1991
[6] *Italy and the difficult settlement*: a survey conducted by Legambiente in collaboration with Confcommercio in 2005.
[7] Data, statistics and percentages cited on this page were taken from surveys sponsored by the following associations: Piccola Grande Italy, Legambiente and snapiccolicomuni Confcommercio. They can be found at the following sites: www.piccolagrandeitalia.it, www.piccolicentrieuropei.com, www.legambientepadova.it, www.confcommercio.it.

abandoned. It is worth highlighting, in fact, that the historical content of the recent past in Italy was profoundly marked by large migratory fluxes, both internal and external: both the internal migratory fluxes, limited to the regional or national territory and the external fluxes, bound towards foreign nations, impacted the density of inhabitants on the Italian territory.

Figure 1. Map of uninhabited villages in Italy

After a thorough investigation carried out with surveys, bibliographical research[8], internet research, and the aid of information furnished by local experts in mail correspondence, 110 urban centers were identified which were evaluated as being in a state of abandonment. This means that these are urbanized places in which, at the current moment, neither the presence of current residents nor the conditions that constitute the customary form of living in a settlement in a permanent or continuous manner may be found[9]. The research was limited to places which were abandoned in the 20th and 21th century. The deepening of the issue has led, first and foremost, to the realization that the presence of abandoned villages in Italy can be considered a real phenomenon. Furthermore, it has led to an awareness of the issue's complexity and its characterization by both common elements and the peculiarities of individual cases .

Through the comparison of data collected, it was possible to obtain an overview of the phenomenon, which has been interpreted on the basis of the following items:

- geographic location, with reference to the region of origin (Figure2);
- period of abandonment (Figure 3);
- reason for abandonment, categorized under natural causes (earthquake, landslide, flood) and unnatural causes (migration, construction of public works, war, declarations of unfitness) (Figure 3).

[8] There are very few bibliographical sources available which are related to the topic.

[9] According to this definition, excluded from the survey were places which are occupied by even a single person and those in which even the subject of recovery work related to temporary events (such as festivals, cultural and commercial activities, etc.) are not found to be situations of a purely residential nature. Also, note that the 110 abandoned villages which are the subject of comparison and evaluation are the result of a selection from a larger series: the exclusion of some cases was decided, not based on the observation of the presence of permanent residents, but because of the difficulty in obtaining of verifiable information and research limits due to the vastness of the area under analysis. In light of this, it may be stated for justification that we note the presence of a greater number of uninhabited villages compared to that which is reported; the work presented, in fact, is part of a research path which is being updated and is evolving over time.

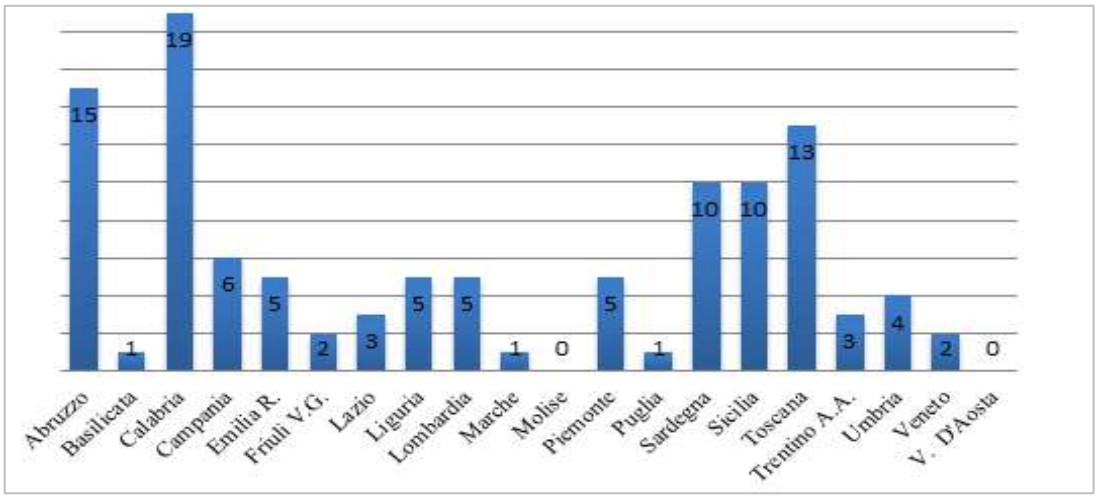

Figure 2. The graphic reports the number of abandoned villages in each region of Italy

From the data that emerges it is evident that, on the National territory, there are areas and regions which are most affected by the phenomenon of depopulation:
• *the Calabrian Aspromonte* area;
• mountain areas have been subject to intense emigration, which led to the abandonment of entire towns, among them, even geographically distinct and distant ones, including areas of *the Tuscan-Emilian Appenines* as well as *the upland areas of Liguria and Abruzzo*;
• the villages in the *Belice Valley*;
• *the agricultural villages of Sicily*;
• *the mining villages of Sardinia*.

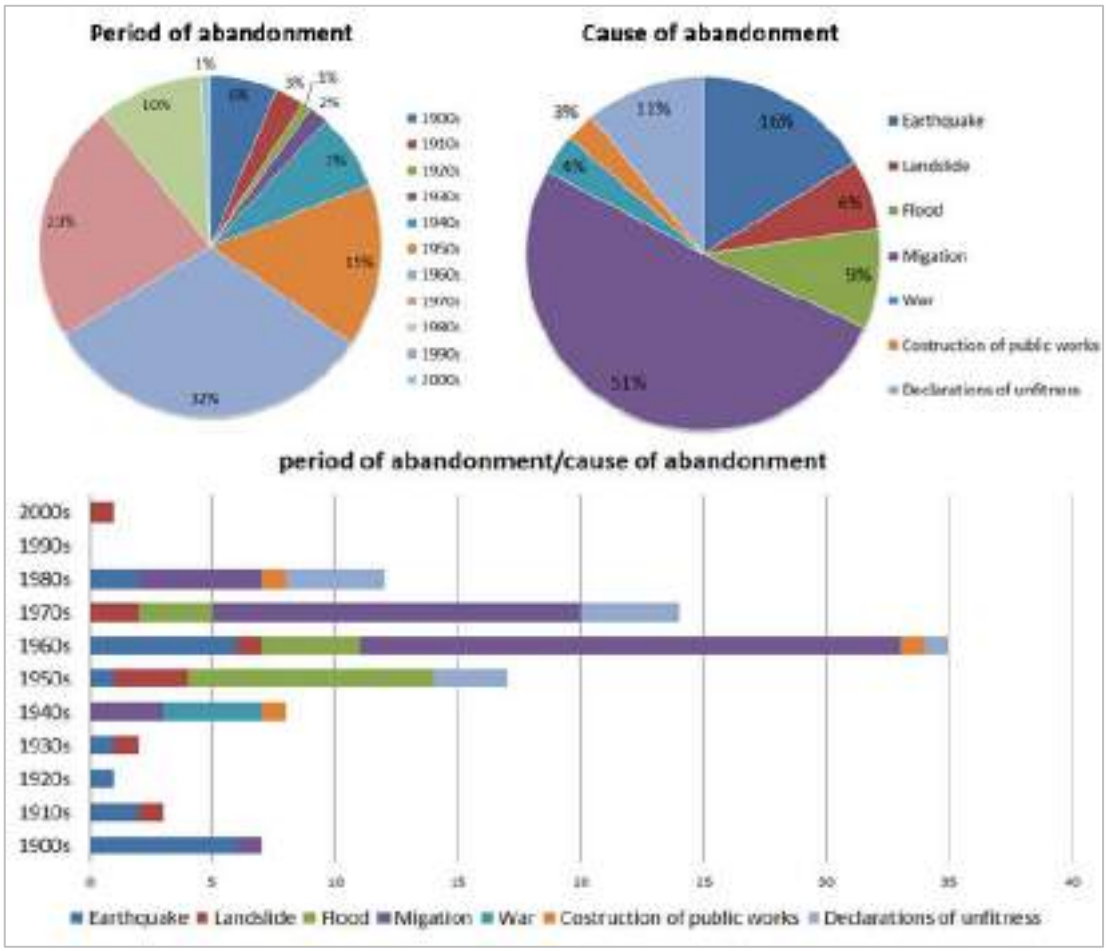

Figure 3. The diagrams show the rapport between period and cause of abandonment

The comparison of the period and the cause of abandonment reveals that the phenomenon peaked in the 1960s and the cause that has most conditioned abandonment in the majority of cases is related to the dynamics of migration. The supported hypothesis is that even in cases where abandonment is related to natural disaster events, significant importance must be attributed to social, economic and cultural factors that influenced the choice.

To understand the dynamics of this choice and the value attributed to the uninhabited village, we will examine two regions which were significantly affected by the phenomenon: the Aspromonte and the Belice Valley.

2.1 The abandoned villages in Aspromonte

Aspromonte is a mountainous area, located in the southern Calabria region. It is bordered on the east by the Ionian Sea, on the west by the Tyrrhenian Sea and the north by the river Petrace. At various points in history, the land of Aspromonte was considered an impenetrable one. However, it was also considered a land rich in

history and popular culture, being part of the Ionic area of Hellenic origin, a recognized area *grecanica* [10] . In Aspromonte, eight uninhabited towns were identified, whose abandonment is concentrated in the early and mid- 20th century. As reported in the table below (Table 1), the causes that led to the abandonment are directly related to natural disasters or catastrophic geological instability. In most cases, the evacuation of the town was followed by a phase of regional planning which, for governmental decisions and with the support of local authorities, led to the reconstruction of the village in a completely different location: the mountain village was rebuilt in the valley, or even along the coast, a great distance from the old village (in the case of Africo, the distance between the new and old village is 33 kilometers). It is clear that these choices were conceived by the inhabitants as an opportunity to radically change the status of living with the prospect of changing from one system linked to agriculture and away from the areas developed a system based on practices of more modern urban life. The link between population and the old town is still alive and is evinced during the feasts of the patron saint: during the religious procession, the statue of the patron saint is placed back in the church of the old village, which has become a pilgrimage destination.
As we report the case of Roghudi as an illustrating example, in which some of the social dynamics related to abandonment emerge more clearly, it should, indeed, be remembered that this action was planned by its citizens as an extreme and unavoidable choice, and that it was taken with conflicting feelings and conflicting inclinations.

Town	**Year ab.**	**Cause ab.**	**New Town**	**old/new town**
Africo Vecchio	1951	flood	Africo Nuovo	33,5 Km
Amendolea Vecchia	1953	flood	Amendolea	0,5 Km
Bianco Vecchio	1908	earthquake	Bianco	3 Km
Brancaleone Superiore	1950	declaratio unsafe	Brancaleone	5 Km
Casalinuovo d'Africo	1951	flood	Africo Nuovo	22 Km
Precacore	1908	earthquake	Ø	Ø
Roghudi Vecchio	1973	flood	Roghudi	38,5 Km
Zoparto	1908	earthquake	Ø	Ø

Table 1. Uninhabited villages in Aspromonte

[10] A clear sign of this cultural tradition is the so-called *"grecanico"* or *"griko"* language, which is still being passed down as an oral tradition from one generation to another.

2.1.1 Roghudi

The name Roghudi is derived from either the word *rochùdi*, meaning cliff, or *rechodes/rexodes*, meaning spiny and rough[11]. Both toponomastic sources emphasize the inhospitality of the place. The village, in fact, is located on a steep spur of rock overlooking the *Fiumara Amendolea*[12]. Roghudi is an uninhabited village, and currently has crumbling houses, rough roads and tracks from the period before depopulation. The depopulation of the country, which occurred in the early 1970s, was caused by a disastrous flood, the latest in a long series of natural catastrophes. The community, by then exhausted, did not react to this additional hardship and somehow accepted an inevitable fate.

The territorial implications have greatly influenced the vicissitudes of the population which found itself confined in a narrow space; this condition led to an inevitable isolation, limited adequate urban sprawl and, consequently, a limited potential population growth. The layout of the area determined an organization of the urban fabric that developed organically, adapting to the mountain ridge[13]. In the eyes of its neighbors, the village appeared to be dogged by bad luck, so it earned the nickname "the unhappiest village in Italy, perhaps the world" (Teti, 2004, pg. 65). The life of the small community of roghudesi (according to the Census of 1911, they numbered 1488) depended on farming and livestock farm. It was in the 1940s that a process of migration began- to the coast of Calabria, or to distant lands- a process which was spurred by a feeling of aversion to a place where nature is revealed to be a step-mother.

The story of Roghudi ends in the early 1970s, when the waters of one of the innumerable floods dragged away with it the gardens, crops, the houses and more importantly, the community's sense of hope and attachment to the place. Roghudi was evacuated due to the flooding and landslides of October 1971 and December 1972- January 1973. Soon after, it was declared unfit for habitation by engineers, but by that time, the village was already empty. The issue of abandonment of Roghudi and villages like it which have met a similar fate is rooted in the history of these places: the flood was just the triggering cause, not the true or sole motivation. From various evidence shows that the decision to evacuate the village was not made without hesitation, and in an instant. Most of the inhabitants had no intention of leaving their homes, but a small minority, most unrelated to the territory, was inclined to leave. In this group, there was also the only dealer who provided the village with a weekly supply of goods and products of basic necessity. The removal

[11] Rochùdi is a word from the Gracanica language while rechodes is a Latin word.
[12] The *fiumara* is a watercourse characteristic of southern regions like Calabria and Sicily. It is characterized as having a very large bed made of pebbles and by the fact that while over the winter, it is full and its waters run swiftly, in other periods of the year it is partially or totally dry. Fiumara Amendolea has a very wide river bed, with a width in some areas up to 5 kilometers.
[13] The difficulty of links and movement is documented by the nails fixed on the outer walls of many homes: some witnesses report in fact, that the children were tied at the waist with a rope, anchored to the nails so to avoid having them fall and roll down.

of this figure, so essential to the survival of the community, caused a domino effect: the other residents were convinced that the abandonment could not be the only choice to make. Within days, the village was depopulated. The catastrophic event in itself must therefore be included in a wider, local, long-term historical context: the "escape" was probably an hypothesis that lived the public imagination for some time and the flood was the pretext that gave a moral justification for taking such an action.

After the depopulation, a new village that was given the name Roghudi Nuovo was constructed near Melito Porto Salvo, nearly forty kilometers from the old village. Its construction was completed in 1988, but only a few roghudesi moved there; most emigrated to other cities. Even though it was much more comfortable, the new village lacked a true identity of its own. Perhaps the re-established village is the real ghost town, as it fails to transmit the residents the strong sense of attachment to place that was inherent in the old village[14].

2.2 The abandoned villages in the Belice Valley

The Belice Valley, located in the upland of western Sicily, is comprised of the district's portion of the river Belice, 76.5 km long. The area of the Belice Valley, inhabited since prehistoric times, is rich in archaeological sites, a testimony to the settlements of the Phoenicians and Greeks. The main economic resource of the plain has always been the agri-food sector and in particular the cultivation of olives. During the night, between 14 and 15 January 1968, an earthquake caused a real emergency in the valley, deeply upsetting the lives of thousands of people. It generated a radical change in the development and organization of many local communities and, as an inevitable consequence, the earthquake was followed by abandonment.
In the 20th century, the economic development of the valley was not comparable to that of the industrialized areas of Italy in the same period. The lack of growth can be attributed to various factors, such as long periods of cyclic drought, frequent floods of the river Belice, the scarcity of fertile soil, an inefficient road network, and lack of dams and infrastructure. Belice, therefore, was an area that was quite backward by comparison. The situation of distress and crisis was not so much due to issues related to the cultivation of the soil, but one of delays resulting from disorganization and the lack of industrial activity. The lack of job opportunities in the '50s and '60s led to an intense migration which drove the residents to move to other Italian regions. Shortly before the earthquake, however, due to the agrarian reform of the ‘50s, the territory of Belice was undergoing a phase of renewal and promising development. Plans included an intensive cultivation of the fields in which rows of vineyards were planted, along with other productive activities linked to the establishment of new roads. As the State’s presence was fading, the fields were increasingly vulnerable to

[14] “(…) it is basically a dormitory, a village with no identity, with nothing. On second thought, lately has actually improved a little: there is a little bit of greenery, some flower beds, but they made houses without balconies, all alike, without a reference point. There is no village square (...) "(Teti, 2004, pg.73).

illegal activities. The community, however, maintained close cultural and religious ties with the territory.

The earthquake of 1968 certainly laid bare in a dramatic way the state of underdevelopment in this part of Sicily: the dilapidated dwellings built on tufa, a population mostly made up by the so-called vulnerable groups (the elderly, women and children) etc.. The morning after the earthquake, there were two types of reactions among the residents: those who found their homes destroyed did not hesitate to leave the village, while those whose homes were only damaged wanted to stay on so that they could guard their property. Tent cities were set up to house some residents, while others were temporarily moved to private homes and in public buildings. To make matters worse, on January 20, Belice Valley was hit by torrential rains which resulted in a veritable exodus: twenty thousand people migrated to the continent, motivated by government incentives.

During the initial emergency, residents gathered in tents, but in the weeks that followed, they were housed in villages-slums, consisting of forty-six prefabricated structures[15]. After the first phase of emergency relief, a multifaceted process of reconstruction began which targeted not only the destroyed and damaged villages, but the entire territory and its economy. Now that more than forty years have passed, the flaws of this restoration attempt now seem obvious, from deficiencies in terms of the design, to problematic timelines for implementation, to the imbalance between the work that was actually completed and the funding allocated. 270 billion lire were allocated for the reconstruction and 57 billion for initial urgent necessities. In 1979, after eleven years had passed and about 900 billion lira had been spent on the project, 8,600 families were still living in shacks. In 2007, it was estimated that the total expenditure for the earthquake amounts to about 7 billion euro. The political management of this event has inevitably attracted many criticisms. However, there is no doubt that the reconstruction of Belice, with the building of homes, entire villages, urban infrastructure on a large and small scale, access to roads, has profoundly changed the characteristics and shape of the entire territory. The earthquake was interpreted by many as a positive opportunity for the development of a land that until then had remained anchored in the past. After the earthquake came proposals to industrialize the area in order to close the persistent gap of cultural, social and economic order which had persisted between those places and others who had instead taken the road of modernization. As a result, the community that had historically inhabited the territory of Belice for generations was traumatically catapulted into a new urban context, deprived of its fundamentally rural identity and assigned a new, artificial, modern one. The population thus moved from the old center to the slums and shantytowns in the new city, which was built in a different

[15] Over the years, these centers, usually located between the damaged village and the new village under the construction, turned into real villages themselves, with lighting, underground cables, water and telephone.

location with urban connotations which differed significantly from those in the original center.
Over the course of the interventions which followed the earthquake in Belice Valley, urban centers were partially and sometimes entirely reconstructed: the villages of Gibellina Salaparuta and Poggioreale were completely abandoned and rebuilt from scratch. The process of abandonment and complete reconstruction of whole settlements reveals dynamic similarities in terms of implementation, in terms of the final result and in terms of the comparisions between the new and old settlements. In the case of reconstruction of the Belice Valley, given the extent and the severity of the case, all of the evidence presents a hyperbolic demonstration of this process.

The new settlements were located in flat areas, according to a criterion based on vicinity to the main network of regional connections or industrial centers, facilitating the construction work. In addition to location, the radical differences between the new and old models of the settlement resulted in a veritable collapse of the local historical narrative. The new urban contexts have redrawn suburban blueprints which were organized according to planners zoning criteria, i.e., the distinction of specific functional areas; clear separation between the constructed element and the countryside, the urban fabric characterized by a marked privilege of open spaces rather than closed ones, so the road becomes the primary element that draws the block, use of serially repeated housing units, formal and perceptual breakdown of the city into two opposing sides: the standard reproduction of the housing unit and the uniqueness of the structure and volume of public buildings. The old villages, in contrast, were characterized as having an organic urban fabric made of clusters situated on the disconnected terrain, low houses built with traditional methods and open spaces conducive to a convivial rapport among neighbors. Two totally different models, particularly indicative is the difference of the index of population density: an of average 3,000 inhabitants per hectare decreased to 350 in the new establishment.

Town	**Year ab.**	**Cause ab.**	**New Town**	**old/new town**
Gibellina Vecchia	1968	earthquake	Gibellina	18,5 Km
Poggioreale Vecchio	1968	earthquake	Poggioreale	0,5 Km
Salaparuta Vecchia	1968	earthquake	Salaparuta	5 Km

Table 2. Uninhabited villages in Belice Valley

3 The sense of abandoned places[16]

At the heart of the phenomenon of the abandonment of a village, even if the decision originated from multiple motives and contingencies, one can note a situation of difficulty and profound discomfort in daily living. In the processes of depopulation,

[16] The title of the paragraph intentionally recalls the name of Teti Vito's book "Il senso dei luoghi" (The sense of places).

is it significant to analyze, along with the specific natural disaster, what happened immediately before, and if a latent process of abandonment was already in place or not. It is also interesting to consider the period immediately after the event, i.e., the reaction the population of the village following the severe damage that was suffered.

With this, we can say that the exodus is largely endemic and it is not exclusively related to catastrophic events, but it is determined by the territory's weak economic, political, and cultural infrastructure. Sometimes the traumatic occurrence becomes a sort of moral justification for making the choice to leave their native land. Most often, a destructive occurrence does not determine the abandonment and relocation of a settlement, but dramatically accelerates a process which has already begun, even when this process has not yet been clearly manifested. Furthermore, with the construction of a new village come materialized plans for change, development and modernization whose elements would otherwise be difficult to construct. Prospettive su cui al momento della scelta sono state riposte molte aspettative e che ad oggi, però, non si sono rivelate tali e hanno evidenziato varie criticità soprattutto in considerazione della perdita d'identità. Outlooks were based on the many positive expectations that were placed at the moment of the choice. To date, however, they have not materialized and various problems have been highlighted, especially the loss of identity. The natural conflict between old and new village is intrinsic to their evolutionary dynamics: if the first is the result of a slow and constant human presence in the territory, the second is due to the frenzy generated by the immediate emergency situation. The image of a place is related to the time factor and the spatial and social processes of evolution. In these contexts, the most crucial aspect is not so much the inevitable dislocation of identity which occurred as a result of the disaster and abandonment, as much as the creation of a new identity, which must be tied to the paths of the memory in order to give the new village a sense of belonging. But this is not an easy journey as seen in the case of Gibellina: The new urban center, based on the model of the garden city, has been enriched by architecture and works of art created by people with great fame and international recognition in order to give the village a new identity[17]. However, even if many people consider this to be an attempt of significant interest, it not inspire within the citizens any real bond to the place [18].

[17] In the 1970s Gibellina became a center of architectural experimentation. We can thus see a series of works: Ludovico Quaroni's Chiesa Madre; the Palazzo Di Lorenzo by Francesco Venezia; Pietro Consagra's Il Mettine, a materialization of the concept of the città frontale; the Municipio by Alberto Samonà, Giuseppe Samonà and Vittorio Gregotti; the Casa del Farmacista and the Casa Pirrello by Franco Purini; the Sistema delle Piazze by Franco Purini and Laura Thermes. Additionally, Gibellina is currently the city with the world's highest ratio between number of works of art and number of inhabitants. In the center of town are: the Città di Thebes, Tris, and the Stella (which acts as a portal of entry to the city) by Pietro Consagra; La freccia indica l'ombra di una freccia by Emilio Isgrò; *Senza Titolo* by Mirko; *Omaggio a Tommaso Campanella* by Mimmo Rotella; *Contrappunto e Sequenze* by Fausto Melotti; the *Torre civica* by Alessandro Mendini; and the *Montagna di sale* by Mimmo Paladino. In addition, there is Burri's renowned *Cretto*, a work that covers much of the old town.

[18] For a deeper analysis of the case of Gibellina, see CRISTALLINI E., FABBRI M., GRECO A., *Gibellina. Per una società estetica*, Gangemi, Roma 2004; NICOLIN P., a cura di, *Dopo il terremoto. Belice 1980:*

The urban construct, no longer a place for residing and living, is deprived of its original meaning by the act of abandonment. However, it is through this occurrence that it earns in the same instant, through what Marc Augé defines as a *form of oblivion*, a new sense. The reality of an abandoned town is configured in a domain of knowledge pertaining to remembrance and the memory. The uninhabited village becomes both the material memory and the concrete impression of one's own past, a past that will deteriorate with the passage of time. In fact, if every place has its unique identity, and if the identity of a living space is represented by consciousness, common values, and behaviors resulting in a feeling of belonging to the given context, what identity can an abandoned village have, if it is not one inherent in the memory of those who lived there? This process corresponds to the creation of what in anthropology is defined as a *re-invention of tradition and identity*. The village, once abandoned, loses its fundamental raison d'être, namely, a place which documents human activities. Emptied of its primary meaning, it becomes a shell with no content and is deprived of the value function for which it was conceived. However, according to testimony and documents gathered, we can say with certainty that at the time a settlement loses its former meaning, it acquires a new one: the uninhabited village changes - just before, during and after abandonment – the image and the value that had been attributed to it until then, by undertaking a process of renewal and a shift in meaning. The deserted villages can be reinterpreted through new lenses, in which they earn:

a sense of identity tied to the memory of the place: every village is the result of a formal stratification of human processes, and the resulting urban transformation of historical events that have followed it over time. As an experienced space, emotional and affective meanings are projected on it. The result is a process that roots a community to its own place. This relationship persists even in abandoned villages, even if there is no longer a direct physical relationship between man and place. Indeed, membership of mind to the abandoned site becomes even more intense and stronger, as it takes on symbolic and nostalgic feelings that project toward the figurative interpretation, subject to myth-creation and emphases, of a past that now cannot return. The uninhabited village, firm and immutable over time, becomes the transposition of a material remembrance of its own history[19];

significance attached to a model of the life of the past: ghost towns tell of a time not far away, still present in the collective memory. These places have not undergone

---

Laboratorio di progettazione, Electa, Milano 1983; TRAINA M., *Valle del Belice: introduzione alla storia di dieci anni di terremoto*, Fiamma serafica, Palermo 1978.

[19] This is evident in re-established villages, in which the community perceives the new urban center as anonymous and not representative, but it feels linked to the old village, rich in history, tradition and memory.

any urban change or urban development since their abandonment, and so they remain motionless and unchanged over time. The settlements were not involved in the process of modernization, industrialization, massive urbanization, to which most Italian cities in the Twentieth century have been subject. These are places that reflect, in the residents' collective imagination, the life of the past, tied to a respect for nature and a less hectic pace of life. Symbolically, this model can be placed in contrast to the model of the modern city;

the charm of the ruins: the buildings and the road network of the abandoned village - left in neglect, to the passage of time and to oblivion- presents itself in an evident state of ruin and decay. The unusual atmosphere that is created in these places holds a kind of sacredness connected to time that stands still, to the typical evocative reminder of the ruins, to incompleteness, and to the transience of human activity.

Ultimately, uninhabited villages have lost their purpose for living. They are abandoned, but are not forgotten. Their present is found in the past and it does not remember the future. Therefore, they become places in the memory.

3.1 Scenarios of revitalization

Aside from being a place of emotional and cultural interest, the abandoned village is also a practical resource in the area. The deserted towns have a traditional urban fabric which is typical of medieval centers- typical of the historical and "multilayered" city. In these urban complexes, organic building development is easily recognizable as is space is free of congestion induced by the urban expansion of the 1960s. The buildings themselves may be considered of historical and architectural interest, in that they remain unchanged from the original condition, according to local construction traditions. Another peculiar element that characterizes many of the deserted villages is their location in natural surroundings within a largely unspoiled landscape. The presence of a natural component becomes an added value for considering these places a territorial resource.

It is interesting to consider that most of the features which were once among the factors that led to the abandonment of these locations (e.g., isolation and remoteness from industrial centers, etc.) can now be assessed as qualifying elements for their recovery. This fact shows that, within a few years, there has been a change of mentality, a cultural evolution that has led to greater attention to environmental issues and the rediscovery of cultural traditions. It is precisely on this evolutionary process one that must base a cultural, and later, material plan for the revitalization of *ghost towns*. The revaluation may be undertaken through two pathways:

cultural development: establishing an objective interest in the individual abandoned village and organizing cultural initiatives at the site of the village, so as to involve - through a network of contacts and relationships - the possible actors in the local context who may be interested in this process . These may include local authorities,

associations and groups those members are directly or indirectly related to the abandoned village. Based on the available human resources in the area, a series of activities might be planned and carried out in uninhabited village. The village could be used as a backdrop and venue for theater, conferences, workshops, festivals, exhibitions, tours and tourist routes. All of this may be done to encourage more people to relate to and to rediscover the individual center that was abandoned, then triggering a series of social and cultural processes suitable for dissemination and awareness;

administrative value: defining, in administrative terms, the concept of "abandoned town" in the legislative municipal, provincial and regional level, particularly in those areas where the presence of uninhabited locations is greater, and then giving that entity a specific legal identity; by collecting the guidelines of interventions that enable protection and recovery plans of territorial and landscape planning; stimulating the attention of the Superintendent of Historic, Artistic and Landscape Heritage, so that the specific abandoned village can be subjected to its constraints, in order to grant it the status of a "*resource of public interest*."

It is only by recognizing an abandoned village's intrinsic value that revaluation projects may be planned or implemented. The possible recovery scenarios are briefly presented here, based on a survey of proposed or finished projects and of models consistent with the context of analysis. The types identified are divided into two categories:
• Recovery for tourism
• New anthropization

The recovery for tourism forsees the recovery of the abandoned site to enhance it as a tourist attraction by one the following means:
• Route tourism: the village is inserted in a network of trails for hiking, biking, trekking,etc;
• Park-museum: the newly accessible village is enhanced and preserved as a outdoor museum.
• Vacation homes and apartments, farmhouses, country-hotels: the village, restructured mainly by private initiatives, is used solely for accommodation / tourism;
• Popular hotels: the village, restructured through public / private sector initiatives has reclaimed following a hospitality project which foresees a widespread partnership among tourist/reception activities, craft activities, commercial activities and residential activities, where the tourist component is of paramount importance.
The first two of these practices enhance the urban characteristics of the urban artifact and its decaying appearance, making no significant changes or renovations to buildings that comprise the village. The image of the ruin and the atmosphere of decay are interpreted and highlighted as part of the tourist attraction, to be included

in broader convergence of regional tourism[20].
The process of converting the abandoned village in a system of cottages, farmhouses, country-hotels and popular hotels provides, instead, a program of restructuring and reconsolidation of the entire residential complex, with the renovation of buildings, access roads and the surrounding landscape. The appearance of the place is then totally changed; and it loses both its aesthetic of decay and its previous designated use as housing. From a place for living and then, a place in ruins, the village then becomes a holiday resort. The recovery for tourism is a well- planned process, providing for the establishment of an architectural and commercial project, often involving both the public and private structures.

Finally, the revival of the abandoned village through means of new human activity is to be considered more rare, also because it involves it complex dynamics and difficult planning. In this case, the revitalization of the abandoned town involves a process of new human settlement by individuals or small groups of people, carried out independently, through self-management or through sharing with one another. The village does not undergo a conversion function, but it is re-used for its original intention, namely, as a place for living.

4 Conclusions

The uninhabited village, given its general condition of decay and neglect, may be regarded either as a reject of modern society, which - framed in a predominantly utilitarian and functionalist logic geared at instant profit - does not recognize it in any practical utility and forgets about it, or, as a territorial asset, reinterpreted in a qualifying perspective that does not stop to consider only the current state of decay, but takes awareness of the existential quality and identity value of that place. By assigning a new meaning, it can acquire a new function- a new use within the territory and for the territory.

URBAN GROWTH - UNDERSTANDING THE DOMINANT DRIVERS AND SPATIAL DYNAMICS OF RISK

Harry Storch[1], Nigel Downes [2]

Abstract

Asian cities located in deltaic settings such as Ho Chi Minh City (HCMC), exhibit higher exposure levels to flood risk primary as a result of their location, their low elevation and if located in tropical regions, the significant annual variations of climatic and weather extremes they incur. In these regions, adaptation to climate change and disaster risk reduction and management needs to focus on minimising exposure and reducing vulnerability via strengthening urban resilience. Scientifically predicted are the direct impacts of climate change on populations (i.e. by urban flooding) and the indirect effects through impacts on the climate-sensitive urban sectors (i.e. housing, energy system). Geographic context gives rise to the biophysical exposure, which includes factors such as topography, connectivity and urban structures which can be mediated by spatial planning or construction technology. Further the urban fabric of a society underlies the patterns of social vulnerability, including issues such as population density, levels of income, education and risk awareness and institutional capacity. Spatial planning measures to enhance the adaptive capacity should be directed towards decreasing biophysical exposures and the social vulnerability from the viewpoint of place-based risk assessments. Key urban impact and vulnerability indicators in megacities and metropolises vary considerably from settlement to settlement and even within settlements. The location, the urban structure types present, dominant building types, social-economic characteristics and existing institutional capacities are all key factors that affect the ultimate exposure, vulnerability and overall environmental performance of a settlement within a mega urban context. Exposure and vulnerability are highly dynamic factors with an important spatio-temporal dimension. Rapid urbanisation and settlement patterns driven by fast changes in socioeconomic development conditions are the key factors influencing the future levels and in exposure and vulnerability to climate extremes. Traditionally only snapshots of the current urban situations have been partially integrated into risk assessments, resulting often for highly dynamic urban regions in an overestimation of climate extremes as a stressor of risk. Our impact assessment study for HCMC highlights, that the influence of non-climatic stressors – like urbanisation as the spatial manifestation of socio-economic processes is still widely under acknowledged. An urgent need has arisen to readdress and improve the scientific methods and datasets to examine these

non-climatic key drivers of future urban risk and to assess their relative importance for risk propagation compared to primary changes in climate. The most significant issue here is the integration of the future dynamics of urban development.

1. Introduction – The mega-urban region of Ho Chi Minh City, Vietnam

Coastal Asia is facing an urban century in which not only the population growth of cities will ultimately determine their resilience and sustainability, but also their patterns of development. The empirical interrelationship between rapid urbanisation processes in coastal Asia and the associated increases of risk to weather and climate-related disaster risks cannot fully be explained solely in terms of changes in population. Much more important however, is the consideration of the spatial distribution of people and economic assets in risk-prone areas, primarily as a result of rapid urbanisation. Here the sensitivity of the exposed population and assets can be used as an indicator for the ability to cope with and reduce risk. There can be little doubt, that a dominant factor contributing to increased vulnerability is urbanisation itself. How this dynamic pattern of urban development assists or hinders risk adapted planning and management is the critical issue that will be highlighted in our indicator-based assessment.

Figure 1. Skyline of Ho Chi Minh City's Central Business District and low-lying areas on the riverbank of Saigon River (Photo courtesy of Joep Janssen).

The southern Vietnamese city of HCMC represents one of the most dynamic examples of urban development and a megacity in the making (see Figure 1). The

city is precariously located on the banks of the Saigon River, 60 kilometres from the South China Sea and northeast of the Mekong Delta, in an estuarine area of Dong Nai River system. In a short space of time, the city has grown into Vietnam's largest and most populous settlement, becoming an important port city for Southeast Asia and beyond and contributing a dominant share to the national economy. The official population of the city as of 2009 was 7.2 million, spread over a total administrative area of 2095 km^2 (Storch & Downes 2011a).

2. Analysing urban development trends in HCMC

The official population forecast estimates that HCMC will become a megacity and reach a population of 10 million by 2020. According to official urban development strategy, HCMC will be developed in the future based on a multi-center pattern along the northeast, south/southeast, north/northwest, southwest direction. Therefore HCMC's planning administration has recently established so-called new urban areas as focal point for this new satellite development, which will integrate fringe areas in the currently more rural outer city districts. The city's current radial development structure is still impractical, resulting in insufficient land available for public services and for open space.

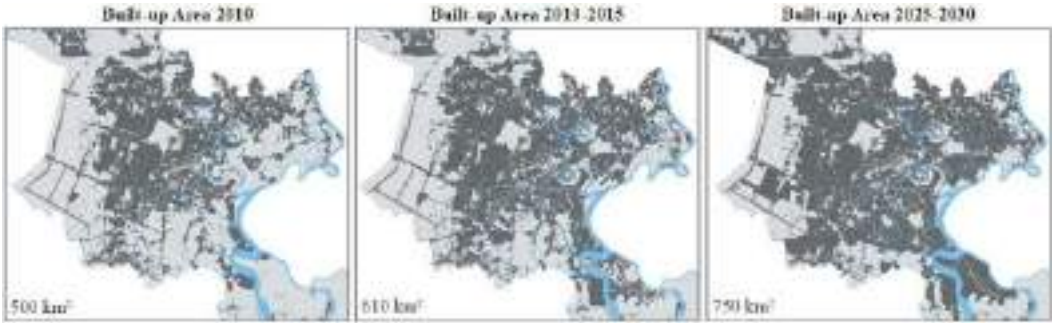

Figure 2. Ho Chi Minh City's official Urban Development Scenario up to 2025/30

Figure 2 illustrates the future urban growth process of HCMC based on the official land-use plans for the next planning period. The implementation of the land-use plans for the years 2010 up to 2025 will increase the total built-up area to 750 square kilometres (an increase of 50 percent) (Storch & Downes 2011a). In order to accurately define the precise spatial extent of the current built-up area, the digitalised version of the official land-use map 2010 at a scale 1:25,000 provided the common spatial geometry based on which a 'current land-use' map for the year 2010 was compiled. Current land-use was determined from visual interpretation of high resolution panchromatic satellite imagery; the classification was based on our urban structure type classification for the entire HCMC urban area (Storch & Downes 2011b; Downes et al 2011). A limitation of simple urban growth scenarios is that the simplified mapping of built-up areas over time does not show real land-use densities and often ignores the structural changes and alterations of the current and future urban settlement typologies.

2.1 Urban structural indicators to analyse development patterns

Urbanization is an extreme form of land use change. Rapid and dense urban expansion and inner-city redevelopment in HCMC in particular have had direct impacts at the local scale by changing the visible urban structure and form, thus triggering indirect effects like changing the urban climate and modifying the urban water-cycle and increasing energy demands for indoor cooling (Storch 2007; Storch et al 2007). The following questions will be explored for climate-related impacts in the urban environment of HCMC:

- Where and how does urban development change the land use pattern of the metropolitan area of HCMC, and to what extent does this affect the climate change related impacts on of the urban environment?

- Which urban structure typologies can be distinguished, and what is the relation between their characteristics and the assessed level of resilience against climate-related impacts?

- How adequate are the existing land use planning and urban-environmental management approaches to the relevant governance structures; to what extent do they contribute to an urban development that takes climate-related urban-structural indicators into account?

- Which hotspot areas can be identified in the context of the predominant climate-related impacts in HCMC, like inner-urban flooding caused by high-degrees of imperviousness, and urban climate caused by high-dense building structures?

An important first step to estimate these hotspot areas is to describe the observable indicators related to urban form and structure. The most dominant feature of the urbanisation process in HCMC is the rapid growth of the city itself and the surrounding urban agglomerations. Urban population growth due to birth surplus and in-migration causes heightened land demands. In HCMC, urban growth and land consumption indicators are just about to be recognized in planning decisions, while a more regulating use of core urban indicators is still limited. Until recently the available information is often inadequate or spatially not explicit enough for assisting urban policies like indicator-based planning regulations.

In general, the ratio between built-up and unbuilt land gives a first overall impression of the spatial character of the city (Gill et al 2008). Built-up areas typically include residential areas, industrial, and commercial areas. In emerging Asian megacities – like HCMC – the monitoring of the building footprint will not be sufficient. In order to analyse urban land use and urban density and spatial development trends over time typically a stepwise indicator approach is used. An initial indicator framework is composed of core sets of indicators measuring different aspects of urban land use and building density. The first step in assessing

the existing urban structure and land-use efficiency is to evaluate changes of the urban form and housing structure and their relation to building density and land utilisation efficiency. The indicator framework leads from basic land use indicators to building density measurements and finally to a combined analysis of population densities and land use intensity. The most important efficiency indicator here is the ratio between built-up and unbuilt areas.

2.2 Dense Urban Development as Adaptation to Natural Flood Conditions

HCMC administrative area is divided into 24 districts, hosting in 2004 an official population of 6.2 million, 5.2 million of which lives in the 17 urban districts occupying an area of 494 km^2 have an average population density of around 11,000 inh/km^2. The inner-city urban areas are concentrating on an area of 140 km^2 more than half of the population resulting in an average density of 26.000 inh/ km^2, with peak values in inner-city informal settlements with up to 80.000 inh/ km^2 (GSO HCMC 2006).

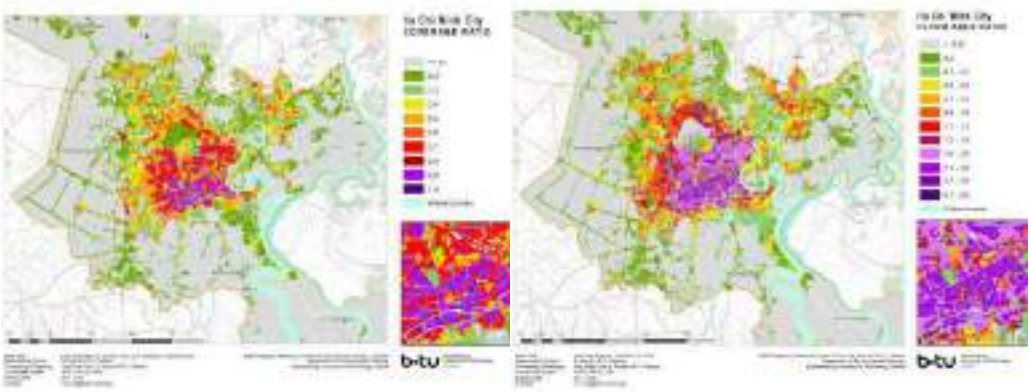

Figure 3. Coverage Ratio and Floor Area Ratio in HCMC's Urban Core in 2005

This extremely high-dense development of the inner city, with built-up (coverage) ratios of more than 0.6 (60% ground coverage) and floor area ratios of 1.5 and more (Figure 3), is mainly a manifestation of the necessary to adapt to the dominant flood risk situation of the city. Originally founded on relatively higher grounds, the city has densified through the infilling of open spaces or the redevelopment of existing buildings. However recently, great concern has bene raised at the city's rapid expansion into the lower-lying and former wetland surroundings, primarily at the expense of urban greenscape and valuable multifunctional natural areas. The city is currently incised by a dense network of rivers and canals of around 8,000 kilometres in length, which account for 16% of the total area. These waterways are affected by a semi-diurnal tide, subjected a high-tide level as high as 1.5 m AMSL. Often coincident with annual rainfall peaks a significant percentage of the city's neighbourhoods regularly experiences floods, due to a combination of tides, heavy monsoon rains and storm surge floods. The dimensions of this flooding are however constantly changing due to the ongoing rapid urbanisation.

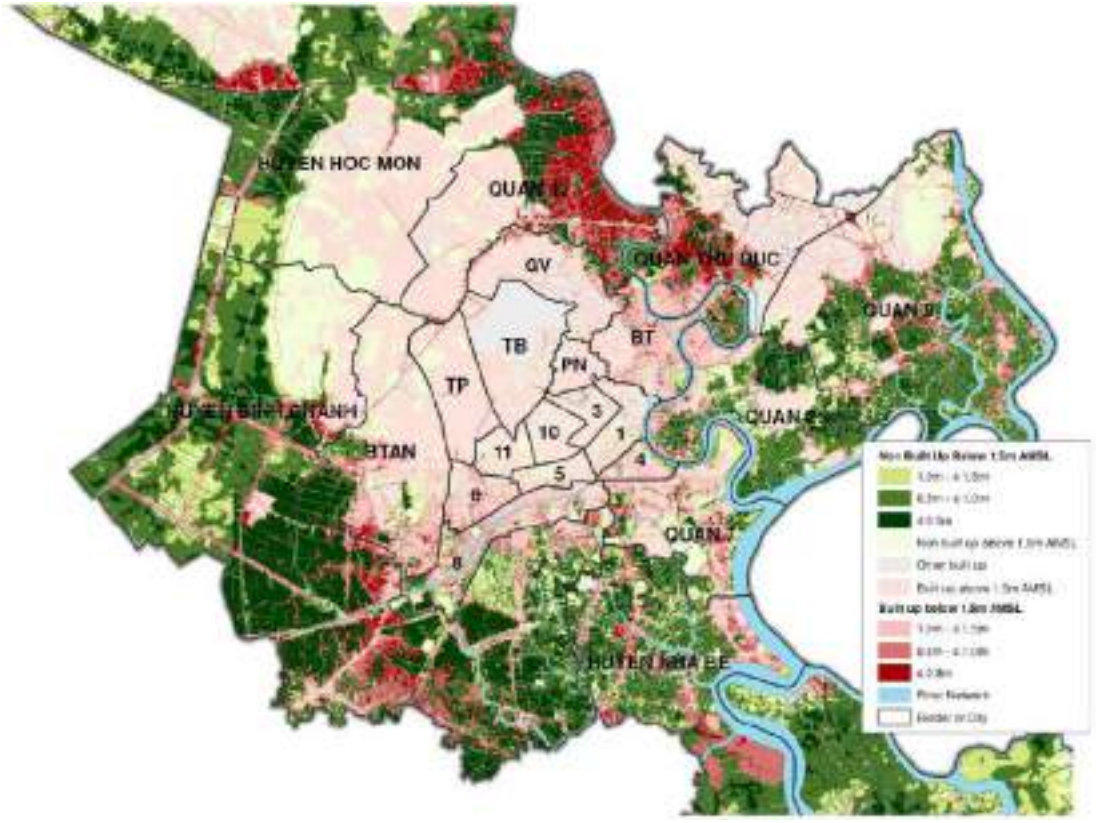

Figure 4. Ho Chi Minh City's Built-up Areas in Flood-risk Areas (areas below high-tide-level 1.5 m AMSL)

Figure 4 highlights well that the current urban form and structure of HCMC is strongly influenced and to some extent constrained by its surrounding natural conditions. The few remaining open spaces surrounding the extremely dense core – mainly agricultural land –have an elevation of below the current high-tide level of 1.5 m AMSL. These spaces act as a natural blue and green belt – akin to flood risk zoning by nature – and strongly influences the ongoing inner-city re-densification. Hence an understanding the interrelationship between urban densification and adaptation processes to current flood risk can guide the spatial adaptation processes of HCMC in the uncertain times of rapid urban growth and climate change.

The dominant building typology in HCMC is currently the so-called shophouse typology, seen often as a flat-roofed row house on a parcel with a plot size of approximately 4 x 20 m. The shophouse typologies are dominant in HCMC, accounting for 95% of the residential Urban Structure Types (Table 1). With building heights between two and five floors, very high levels of density are achieved. It is important to understand the future urbanisation challenges and the requirements for the provision of basic urban services and technical urban infrastructure preparation. Besides sprawling new urban developments, the ongoing continuous compacting and densification, horizontally as well as

vertically, of existing settlement structures are a visible trend for HCMC's development pattern.

Table 1. Density-Indicators of HCMC's Shophouse-based Urban Structure Types

Code /Urban Structure Type Name	Building Footprint	Plan View	3D View	Built-up Ratio (%)	Floor-Area Ratio (%)	Avg. no. of floors
111 / Shophouse Reg. New				45	123	2.7
112 / Shophouse Reg. New Community				26	88	3.4
113 / Shophouse Reg. Alleyways				37	133	2.7
114 / Shophouse Reg. w/ Yards				28	64	2.2
121 / Shophouse Irreg. High-dense				38	134	2.7
122 / Shophouse Irreg. w/ Yards				38	88	2.3
123 / Shophouse Irreg. Scatt. (Peri-urban)				14	30	2.2
124 / Shophouse Irreg. Clust./Line (Peri-urban)				15	29	2.0
125 / Shophouse Irreg. w/ Irr. Fields (Peri-urban)				5	9	1.9
131 / Shophouse w/ Indust.				38	81	2.1

2.3 Urban Indicators describing the change of Built-up Structures

The core indicator set measures the issues linked to the extent and growth of built-up areas and the efficiency of the land utilisation (floorspace) in relation to the common spatial unit of the official land-use blocks. The following urban growth and (re-)development oriented aspects are measured by a comparison of core-indicators over time, describing more specifically the growth rate at which built-up areas and floorspace have expanded and evolved over time, between 2005 to 2010.

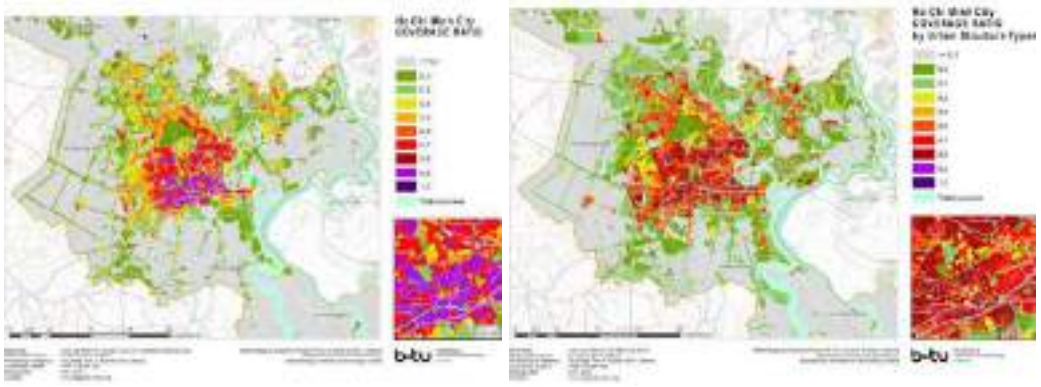

Figure 5. Comparison of the Indicator "Coverage Ratio" between 2005 and 2010 (Map for 2005 (left) is based on building footprint data. Map for 2010 (right) is based on urban structure type mapping).

Figure 5 illustrates the urban development for the period 2005 to 2010 for built-up areas based on the indicator ground coverage ratio. Ongoing sprawl development has taken place along main transportation routes on agricultural land, counteracting the official development according to the satellite urban model. Additionally recent and current residential areas are dispersing towards eastern (District 2, 9 & Thu Duc), southern (District 7, Nha Be) and western directions (District Tan Phu, Binh Tan, Binh Chanh).

Even in the existing urban core (District 6, Binh Thanh) (re-)development activities are high. Overdevelopment in the existing urban core will result in an overload of the limited urban basic services and infrastructure.

Figure 6 (overleaf) illustrates the individual new developments and redevelopment activities – mapped on the level of building types (Table 2) – between 2005 and 2010 lie within the current urban core area. Even if the concentrated developments are focused in new urban areas in the outer districts are more 'visible', the huge number of individual construction activities on multiple single construction sites on building level is surprisingly – while counteracting the official development strategy – dominate in the inner city core areas.

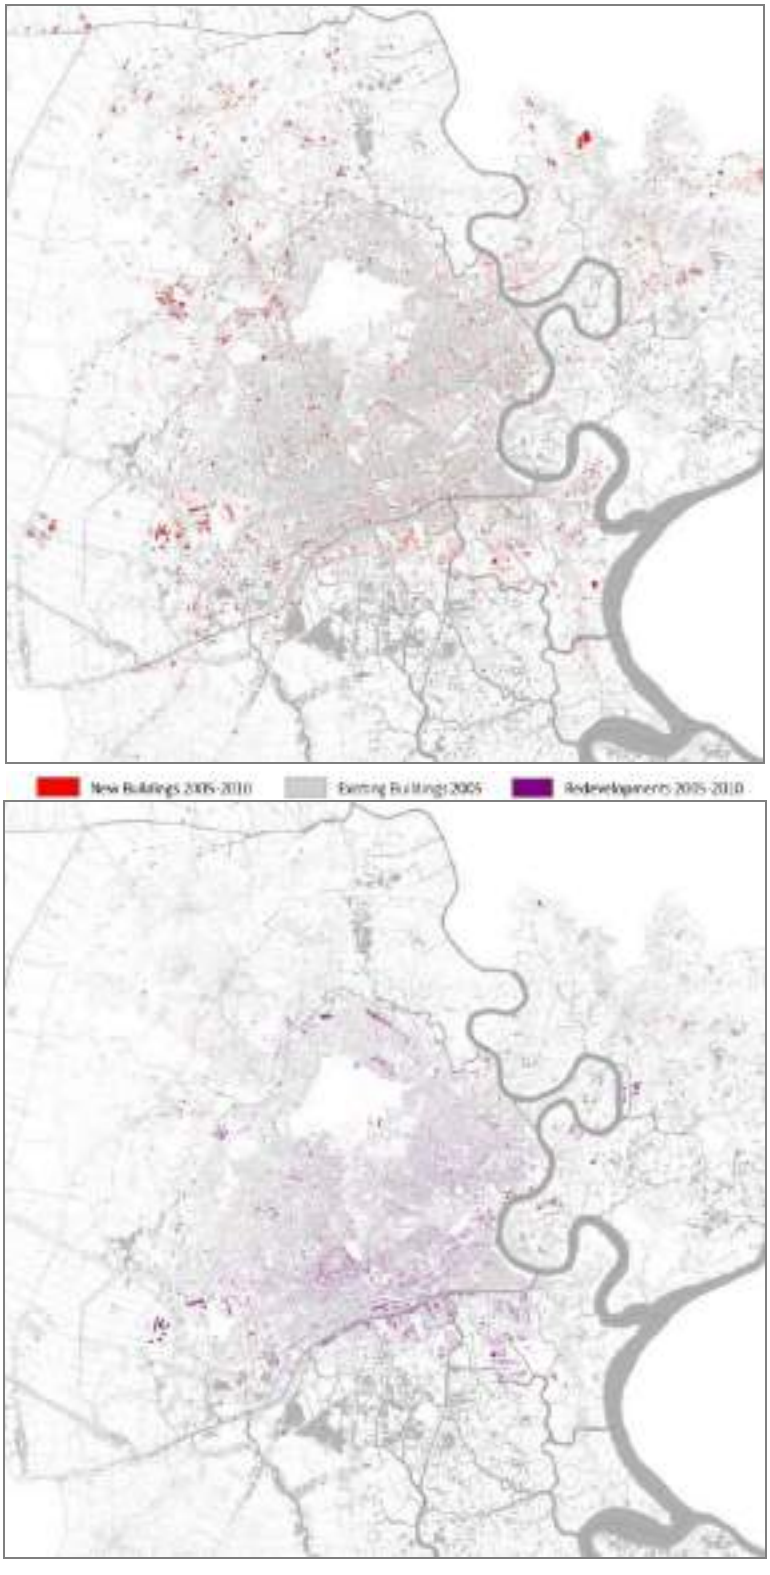

Figure 6. New Developments (Top) and Redevelopment Activities (bottom) between the years 2005 and 2010. (The Analyse is based on a detailed Mapping of Building Typologies, shown in Table 2, on a scale 1:5000 in 2005 and 2010)

Table 2 additionally underlines with the comparison of urban structural indicators (ground coverage and floorspace) and the ongoing densification pattern trend between 2005 and 2010. Except the more informal building types, all building types are significantly increasing in built-up (coverage) and additionally in floorspace density. Especially the dominant shophouse-related building type show a doubling of the total ground coverage and – due to an increase in average height – the floorspace for this type has increased more than 150% in only 5 years.

Table 2. Urban Structural Changes in HCMC from 2005-2010 - Core Indicators for dominant Building Types.

Building Type		Coverage (ha)	Floorspace (ha)	Height (fl)	Coverage (ha)	Floorspace (ha)	Height (fl)	Coverage (%)	Floorspace (%)	Height (%)
		2005			2010			Change 2005- 2010		
Apartment		113	569	5.0	166	890	5.3	48	57	6
High-rise		19	120	6.4	28	223	7.9	51	86	23
Detached		2189	2824	1.3	2872	5893	2.1	34	109	56
Semi detached		317	334	1.1	458	724	1.6	45	117	50
Temporarily-built and others		37	41	1.1	17	21	1.2	-54	-50	8
Terraced		3496	7001	2.0	7154	18001	2.5	105	157	26
Villas		893	1504	1.7	897	1777	2.0	0	18	18
Wood-framed, thatch-roofed		54	56	1.0	52	53	1.0	-5	-6	-1
Markets		8	29	3.5	17	66	3.8	108	126	9
Hotels		39	160	4.1	45	226	5.0	16	41	22
Office building		113	593	5.3	131	777	5.9	16	31	13

3. Administrative Integration and Implementation

Figure 7. Discussion of Planning Recommendations for Adapting HCMC's Land-use Plan to Climate Change, Department of Natural Resources and Environment 2011).

This study highlights the importance of effective land-use planning as a strategy and a key tool for sustainable adaptation, as well as the importance of a better understanding of the relationship between future urbanisation and climate change impacts. Land use planning is seen as having a key role to play in developing strategies to climate-proof HCMC. As such, our research has not been carried out in isolation but from the outset was foremost intended to assist the Department of Natural Resources and Environment (DONRE) with administrative policy making—in making informed decisions underpinned by the latest assessment techniques. Our approach assessing climate change and urban development scenarios aid the development of long-term adaptation strategies. The results presented in this paper show the gravity of the grave challenges faced by DONRE with respect to climate proofing future urban development. Ultimately, DONRE has the task to determine the overall land use, spatial zoning and environmental quality of HCMC. As such, DONRE possesses executive powers over one of the most important instruments for the adaptation of HCMC to climate change, the steering and management of land-use. To their credit, DONRE has become very conscious of its responsibility in relation to climate change responses and the management of associated impacts. Externally, these matters have gained increasing acceptance and importance within the wider administrative structure of

HCMC, while, internally they have reinforced the essential need to adapt their own planning (Storch & Downes, 2011b; Storch et al., 2011). However integrating climate change considerations into land use planning in HCMC is inherently a complex decision-making problem, which requires the careful assessment of the current decision situation, related to space.

4. Summary and Conclusion

In the face the complexity and uncertainty of urban environmental planning for adaptation and mitigation in rapidly growing urban risk areas, spatial urban form matters. It is however often overlooked. Denser and compacter urban environments generally have lower per capita greenhouse gas emissions because they enable public transit. At the same time, a larger blue and green infrastructure is in general beneficial to adaptation, as it provides room for urban open spaces and urban agriculture, the natural spaces for retention of storm and flood water management, and areas to generate and transit cool and fresh air lowering and offsetting the energy demands for cooling in tropical climates. Urban development strategies need to reconcile both goals – mitigation and adaptation - to be really climate resilient.

Planning for risk and uncertainty for future urban growth will not just be a challenge for high flood prone areas; it will be a broader challenge impacting on the nature and location of future urban development, particularly in planning for climate change. There is a strong correlation between the urban vulnerability and physical exposure. Here land use planning that takes into account disaster risks is the single most important adaptation measure for minimising future disaster losses. The spatial planning framework and subsequent urban planning decisions, as currently applied, do not attach sufficient importance to physical exposure and the rate of urban growth being associated with the risk of disaster losses. Urban growth does not increase exposure of population to risks per se. In general, urban governments are responsible for regulating either building or development in a way that reduces risks. For high-dense Asian megacities, the complexity of risk and vulnerability requires high resolution spatial information systems in order to identify hazard patterns, vulnerability and risk at a scale that can provide information for urban land-use and development planning. Urbanisation does not necessarily have to lead to an increasing hazard portfolio and can, if managed properly, contribute to reduce risk. However, there are a number of key characteristics of the urbanisation process that do directly contribute to the configuration of risk. Spatial and physical exposure alone does not explain nor directly lead to increased urban risk. If urban growth in risk-prone locations is directed by adapted land-use zoning and guided by adequate building standards, resulting risk patterns can be effectively managed and reduced. It is the ‘spatial dimension’ the form and structure of urban settlement that concerns urban and regional planning.

5. Acknowledgments

The contribution is based on results of the research project ‘‘Integrative Urban and Environmental Planning for Adaptation of Ho Chi Minh City to Climate Change’’ which is funded as part of the research programme ‘‘Sustainable Development of the Megacities of Tomorrow’’ by the German Federal Ministry of Education and Research (BMBF). The authors would like to express their gratitude to Le Thanh Hoa, Thong Nhat Tran and Hendrik Rujner who partly supported the geoprocessing and Kiduk Moon who assisted the illustration of the urban typologies.

Participatory Democracy and the Governance of Smart Cities

David Ludlow, Zaheer Khan

Faculty of Environment and Technology,

University of the West of England, Bristol, UK.

Email: {David.Ludlow, Zaheer2.Khan}@uwe.ac.uk

Abstract

Citizens' participation in urban planning and policy-making develops the traditional top-down governance model via promotion of bottom-up approaches to policy development and decision-making. This evolution drives social innovation in support of planning initiatives and results in more public-oriented policy specification for better governance and sustainable urban environment. Innovative ICT solutions offer significant opportunity to ameliorate the substantial challenges arising from these developments. Smart city defined initiatives promote the use of ICT solutions for better governance in terms of improved communication and information services, as well as offering the potential to provide policy-makers and urban planners with the tools and intelligence needed to actively manage the urban environment. In this paper, we present and discuss smart planning and urban governance in a smart city perspective. Also, we present a case study based on the UrbanAPI project which aims to develop and deploy different ICT solutions for public participation in planning initiatives and policy making at various scales of urban governance.

Keywords: urban democracy, urban governance, smart cities, stakeholder engagement and public participation.

1. Introduction

The effective governance of the cities and city regions of Europe today fundamentally must address urban complexity, whereby the high degree of interconnectedness and multiple interactions between socio-economic and environmental factors in a territorial context create major barriers to the effective specification and implementation of sustainable urban development.

In this context there is a major opportunity for the application of enhanced ICT driven intelligence in urban management to secure the proactive governance of

cities and the delivery of more sustainable compact cities. In particular ICT enabled urban governance can support the production of an effective basis for the assessment of urban complexity, and decision-making support. In a broader perspective ICT enabled urban governance offers a significant new potential to simultaneously achieve effective management of the complexity of the city, as well as engaging citizens in defining their urban futures.

ICT enabled innovations can enhance public engagement and allow a wider audience to simultaneously contribute to the political debate. This is particularly evident as the convergence of broadband with ICT-enabled innovations (e.g. especially user driven applications based on social computing and mobile technologies) is transforming the way people use the Internet to communicate and interact. Most European citizens embrace the "collaborative Internet" and expect to be able to interact with city governments using ICTs (EXPGOV 2009) . ICTs thereby are seen as enablers of more and better participation (e-Participation), and democracy (e-Democracy) and more inclusive societies (inclusive e-Governance and e-Inclusion), extending beyond enhanced service delivery, to facilitate interactions between actors. Overall technological opportunity is prompting a transformation of the relations between citizens and government agencies, and at the same time the driving forces of ICT enabled governance are also responding to the dynamic of transformational governance and changes in regulatory and governance processes.

Despite all of the above, at the city level there is as yet only limited evidence of the direct effects of ICT-enabled innovations on city governance systems, and in many respects the smart cities revolution is still in infancy and clearly more research, particularly the pan-European level, is required to define the most effective tools and methodologies to support ICT enabled governance.

Research directed by the Interactive Analysis, Simulation and Visualisation Tools for Urban Agile Policy Implementation (UrbanAPI) project (2011 - FP7 DG Information Society[1]) aims to fill this gap in understanding and application. UrbanAPI provides ICT enabled innovations for city governance and adapted governance models to support new stakeholder engagement and citizen participation, in order to enhance sustainable urban policy development and delivery.

The enhanced ICT tools developed by UrbanAPI offer new opportunities for the development of both intelligence sources as well as tools for decision-making support at three levels of urban governance from neighbourhood to city region level, thereby addressing the key dimensions of the management of urban complexity. At the same time by providing a simplified language of communication between different stakeholder groups (virtual reality, visualisation and simulation-

[1] The UrbanAPI project is partly funded from the 7th Framework Programme (FP7) of the European Commission, call identifier: FP7-ICT-2011-7, under the grant agreement no: 288577, started in October 2011.

based communication) developed on a common platform of communication between the different levels of governance including local (virtual reality), citywide (GSM) and city region (simulation). UrbanAPI also advances the state of the art in relation to the necessary collectivity of city governance.

The conceptual frame for the project is based upon the understanding that urban managers throughout Europe face common challenges in responding to the desire for a more participatory democracy, in order to define the basis for urban economic vitality, social inclusion and environmental sustainability. The commonality of the drivers of urban change including global economic instability, demographic and migratory change, as well as climate change offers a major opportunity for the development of common solutions grounded in effective citizen and wider stakeholder engagement in the planning process.

UrbanAPI directly addresses these potentials for the development of common models of policy formulation and implementation in respect of both information generation and management, as well as stakeholder engagement, thereby supporting the potential for widespread application in the cities and regions of Europe.

The structure of this paper as follows: in section 2, we discuss in detail smart governance and urban planning using ICT tools. We also briefly indicate need for information integration at local scale across various administrative units for better intelligence and flow of information between different levels of governance. Then in section 3 we briefly present a smart city perspective followed by the UrbanAPI project example in section 4. Finally, we conclude in section 5.

2. Smart Governance and Urban Planning

Cities sustain 80% of the population of Europe (EEA 2006) and naturally form the focus of political initiatives to secure a more sustainable development plan in response to multiple global and local environmental, social and economic challenges. The core principles of sustainable urban management highlight the need for effective stakeholder engagement and public consultation in relation to the complex of the tensions at play within a multiple system of interactions and often conflicting views between the three pillars of sustainable development (economic, social and environmental) (Jacquier, 2008).

Urban management aims to address the key political concerns of European cities in responding to the challenges of climate change, arising as a consequence of excess greenhouse gas emissions, frequently driven by uncontrolled urban sprawl, and impacting adversely on urban health and biodiversity loss etc. However, urban management is far from straightforward, as cities are extremely complex systems, and the various drivers of change, environmental impacts and political responses

are strongly interrelated, support, alter or compete with each other.

The political priority to ensure that climate change adaptation and mitigation is consistent with, and promotes healthy and economically viable urban communities, is in turn a prime driver of initiatives to secure integrated urban management, reflecting the view that effective solutions must be based on better land use policies as part of an integrated policy response.

Failure to integrate policy can be attributed to a variety of factors including notably organizational and procedural barriers between sectoral planning agencies responsible, for example, for land-use, transport and environment, primarily at the local level, on the one hand, and on the other poor communication between agencies responsible for policy development at local, regional, national and EU levels. A further casualty of the lack of connectivity in the policy model, is the fragmentation of the information and intelligence essential to support integrated policy definitions and policy implementation.

These failures of communication and coordination between government agencies that underpin the concerns of the policy-making community for integrated urban management frameworks, are in turn reflected in the demand for new assessment methodologies and decision-making tools to support urban and regional governance. It is clear that ICT enabled urban governance offers major potential to deliver these assessment methodologies and decision-making supports. However, in accordance with Shared Environmental Information System (SEIS 2008) and other related principles, ICT investment in governance tools and methods must be based on new governance models and not the existing failing model. Accordingly, beyond new assessment methodologies an entirely new paradigm of integrated monitoring (policy model) is required in order to provide a consistent framework and context to systematise the information flows from data collection to assessment and policy support.

Furthermore this new policy paradigm and model of urban governance must be fully user defined, and fully cognisant of the opportunities created by the emergence of transformational governance models.

Classical models of urban governance emphasise expert, centralised, hierarchical, top-down perspectives, supported by departmental defined implementation, delivering one-dimensional solutions. Transformational governance critical to the realisation of sustainable development, demands a new synthesis of expert governance fully articulated with bottom-up stakeholder and citizen engagement to inform decision-making. These new models of governance and management in support of sustainable development require greater stakeholder engagement, partnership between stakeholders, and integration of information and analysis

(cross departmental/multiscalar), with a focus on management of urban complexity, including management of the peri-urban (interface urban and rural), where key challenges for urban planning include issues concerning the containment of urban sprawl and the creation of the compact city.

In this framework of transformational governance new assessment methodologies and decision-making tools must be defined and developed by the ICT community in collaboration with end-user communities according to the requirements of the new models of urban governance. In particular requirements arising from integrated urban management, the defining concept of the new governance model, demands transformation towards enhanced connectivity/communication in two respects. First, in relation to both vertical and horizontal dimensions of government agency engagement and communication in urban governance, and second in support of enhanced communication with stakeholder groups according to the principles of sustainable urban development.

From a technology perspective the development of new methodologies for information acquisition and increase of computing capacities to unprecedented levels opens new fields for monitoring and assessment with high information flow and capacity to manipulate it. The end user defined policy paradigm of integrated urban monitoring and management offers the opportunity for the development of a data model to which improved integrated intelligence can be applied and thereby overcome deficiencies in sustainable urban policy formulation and implementation addressing the key urban challenges including urban sprawl.

2.1 Urban sprawl in Europe – exemplar of challenge and opportunity

The specifications of the end user defined policy paradigms for integrated urban monitoring and management are usefully explored in relation to a more detailed assessments of the challenges arising in the management of cities focused on urban sprawl and its associated environmental, economic, and social impacts.

Apart from wealth, health and happiness, the ideals of the good life and quality of life are often equated with maximum person mobility and car ownership facilitating life in the green suburban environments surrounding Europe's cities. These aspirations provide important drivers for the sprawling urban area, which is arguably the antithesis of sustainable urban development.

Indeed the evidence for the unsustainable nature of Europe's sprawling cities abounds. Car based transport growth associated with the sprawling cities of Europe is a key driver of the growth of transport related greenhouse gas emissions. In 2005 transport emissions accounted for almost 20% of greenhouse gas emissions in

EU25. Road transport is responsible for 93% of all transport emissions and urban transport accounts for half of these emissions. The correlation between the expansion of urban land use and the growth of transport related greenhouse gas emissions is very strong, much stronger than for other factors including population growth and GDP.

Furthermore, it is not just the issue of urban sprawl as a driver of greenhouse gas emissions that raises cause for concern, but also the connection between sprawl and a variety of other environmental impacts in the urban area. For example, car based urban transport growth associated with the sprawling cities of Europe is a prime driver of not only greenhouse gas emissions, but also associated pollutants (Green Paper on Urban Mobility (2007)). Urban transport accounts for 70% of pollutants and 40% of GHG emissions, driving climate change and impacting adversely on human health in the urban area. Emphasis in the analysis of urban challenges and their causality, from a sustainable development perspective is therefore given to the interconnected nature of the challenges in the city, which reflects the ecosystems perspective on the city.

Political concerns with climate change, greenhouse gas emissions, poor air quality and biodiversity loss etc are all fundamentally related in the land-use - transport - environment nexus, in which the complex interrelationship between land-use planning, transportation planning and associated environmental impacts are critically related to the nature of urban form, and in particular the extent to which the urban area is more sprawling or more compact.

These complex interactions between the drivers of change in the urban environment, including land-use and transport planning, the resulting sprawling urban form, and the environmental impacts resulting from these interactions are illustrated in Figure 1: Policy Model - Urban Change Drivers and Impacts.

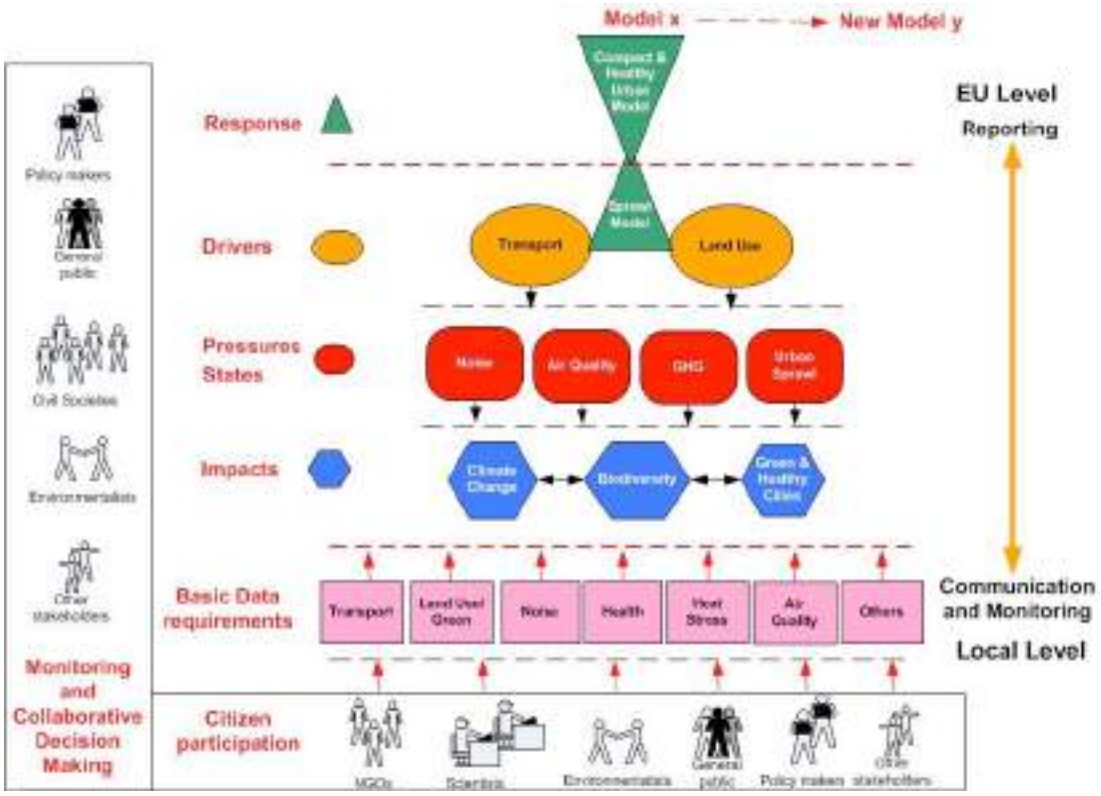

Figure1: Policy Model - Urban Change Drivers and Impacts

2.2 Policy integration – win-win opportunities

Clearly the challenges of urban management are substantial, however set against these challenges the opportunities for sustainable urban development in prising open this complexity are great. Appropriate policies to address the growth of transport related emissions in the context of the land-use - transport - environment nexus can secure the “win-win” possibilities of positive management of climate change, and also effectively address other environmental and social priorities without limiting the economic growth of the city.

This political opportunity to ensure that climate change adaptation and mitigation is consistent with, and promotes healthy and economically viable urban communities, underpins numerous initiatives over the past decade to secure integrated urban management, recognising that more effective solutions must be based on better land use policies according to principles of integrated and holistic policy making.

These principles are well illustrated by the example of urban sprawl impacts. Critical to the formulation of appropriate policies for the management of urban sprawl is the understanding provided by the Green Paper on Urban Transport (Com (2007) 551 final) that the low density environments created by urban sprawl including

dispersed home, work and leisure facilities result in increased transport demand that cannot be effectively satisfied by collective transport solutions. In other words sprawl cannot be fixed by investment in public transport alone, and effective solutions must be based on better land use policies as part of an integrated policy response. Such integrated policy responses inevitably demand collaboration between numerous sectoral agencies at the local level.

Equally, collaboration is required between the levels of government from local to EU levels. This is evident from examination of the widespread failure of local governments to prevent ever greater sprawling of cities. Evidence from the European Environment Agency urban sprawl report indicates that EU infrastructure investments conflict with and thereby undermine local policy initiatives to contain sprawl. Consequently coordination and collaboration is required, and urban planning can no longer be considered just a local or national issue, but that its impact on climate change make it also a matter where EU has clear responsibility to act in cooperation with the local and regional levels of governance. Neglect of this reality furthermore threatens to undermine the achievements of other climate change policies.

Indeed, a principal concern undermining the integrated approach to policy formulation and implementation is the lack of connectivity between levels of governance in both vertical and horizontal policy dimensions, with an accompanying fragmentation of information and intelligence essential to support integrated policy definitions and policy implementation. In For example, at the local level agencies addressing the management of urban regions to contain urban sprawl have a critical need to integrate data across the sectoral domains of land-use and transport. However, given their distinctive departmental identities, the prime sources of information and data, information management and decision support tools developed for land-use and transport policy analysis are typically not interoperable.

Active communication and data integration not only between sectoral agencies at the local level, but also between the levels of governance from local to EU, is clearly critical to the attainment of all policy objectives for urban areas.

These horizontal and vertical dimensions, not surprisingly, also define the prime lines of communication and connectivity between sectoral agencies at the local level, as well as between levels of governance in a vertical perspective, all essential to the development of an integrated policy response. These dimensions for the engagement of agencies in the planning process, thereby provide the structuring principles for policy integration and for the policy implementation model, as identified in Figure 2: Implementation Model - Structuring Principles, below.

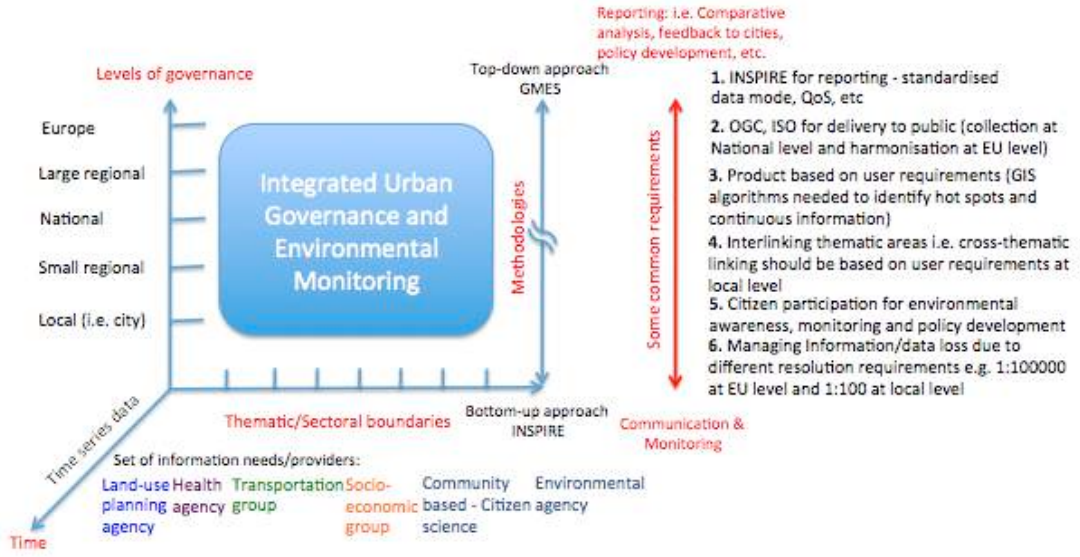

Figure 2: Implementation Model - Structuring Principles (Khan Z, et al. 2011)

2.3 Integrated urban management – new smart governance

Looking forward the structuring principles for the policy and implementation models identified above (Figure 2), offer the basis, according to the necessary interactions between planning agencies, to provide the essential user-defined building blocks for full deployment of ICT applications to secure more effective and transformed integrated urban governance.

This model aims to provide a consistent framework and context to systematise the information flow from data collection to assessment and policy support. The end user defined policy model of integrated urban monitoring and management thereby offers the opportunity for the development of a data model to which enhanced integrated intelligence can be applied and thereby address deficiencies in policy responses. From a technology perspective the development of new methodologies for information acquisition and increase of computing capacities to unprecedented levels opens new fields for monitoring and assessment with high information flow and capacity to manipulate it.

These principles of enhanced communication and technology in support of urban governance are developed primarily in response to classical models of centralised, hierarchical, top-down perspectives mobilising departmental defined solutions and implementation. As we have seen transformational governance critical to the realisation of sustainable development, stimulated by the demands arising from the management of urban sustainability, advocates a new synthesis of expert

governance fully articulated with bottom-up stakeholder as well as citizen engagement to inform decision-making. The emphasis here is upon the need for bottom-up process and effective stakeholder engagement in relation to the conflicting views at the community level (as depicted in Figure 1).

This new governance approach provides additional emphasis on networks of enabling, influencing, mobilisation, coalition and relationship building, between multiple stakeholders at multiple levels, characterised by the following components:

- Linking territories to networks which cross multiple boundaries, with sometimes highly mobile and globalised social-economic groups;
- Multifunctional policy agendas for urban planning relating to energy and carbon, food, leisure, ecology, business park, retail park etc.;
- Multilevel decision making where strategic and local objectives need to be coordinated;
- Multi-sector working, which aims to realise the potential and added value from a wide range of stakeholders and 'communities of interest'.

Accordingly the demands of new governance have challenged existing governance systems, different sectoral agencies speaking different "languages" with different incentives, to respond to agendas which are multi-functional, multi-level, multi-agency, and intergenerational. As a consequence sectoral agencies are able to not only generate more information, but also new intelligence applied through the whole policy cycle from capacity building, to analysis, strategy, implementation and evaluation.

The necessary translation of new governance principles to urban planning processes and structures lies at the heart of the concept of 'strategic policy intelligence' (Plurel 2011). Strategic policy intelligence provides a conceptual framework in response to the new governance model requirements which translates governance priority into urban planning principles and their associated information demands including:

- Exchange of technical information from different sectors;
- Application to the policy cycle, with stages including survey, analysis, strategy, implementation and evaluation;
- Anticipatory governance through foresight and future studies, systems thinking and strategic planning.

Building on these foundations the ICT enabled innovations offer planners, new information and intelligence, new decision-making tools to meet these challenges, and new means of fully engaging stakeholders in the development process. ICT enabled innovations thereby facilitate this process of transformation, and

simultaneously drive further the transformation process, supporting interactions actions between actors, enabling changes in policy-making, and thereby driving change in regulatory and governance processes.

3. Towards Smart cities

The dynamics of ICT enabled urban management identified above in which ICT innovation facilitates the transformation of urban governance, and at the same time is stimulated independently by the dynamics of urban governance, forms one component of wider drives towards Smart cities, in respect of thematic and sectoral responsibilities at the local level. Such an ICT driven urban management can therefore be considered as one step towards smart cities which can be defined as:

"A smart city is a city which invests in ICT enhanced governance and participatory processes to define appropriate public service and transportation investments, that can ensure sustainable socio-economic development, enhanced quality-of-life and intelligent management of natural resources."

ICT innovation brings a significant change in cities' governance, particularly in terms of improved communication and information services, as well as offering the potential to provide urban planners with the tools and intelligence needed to actively manage the urban environment. In addition, it facilitates data acquisition from various sources by using different mechanisms such as remote sensing, sensors, smart phones, census, satellite imagery, etc and performs integration of cross-disciplinary information to obtain knowledge and intelligence for the sustainable governance of cities. The more information intelligence cities possess, the greater the opportunity to realise smarter decision making and governance, and to justify claims for smart city status.

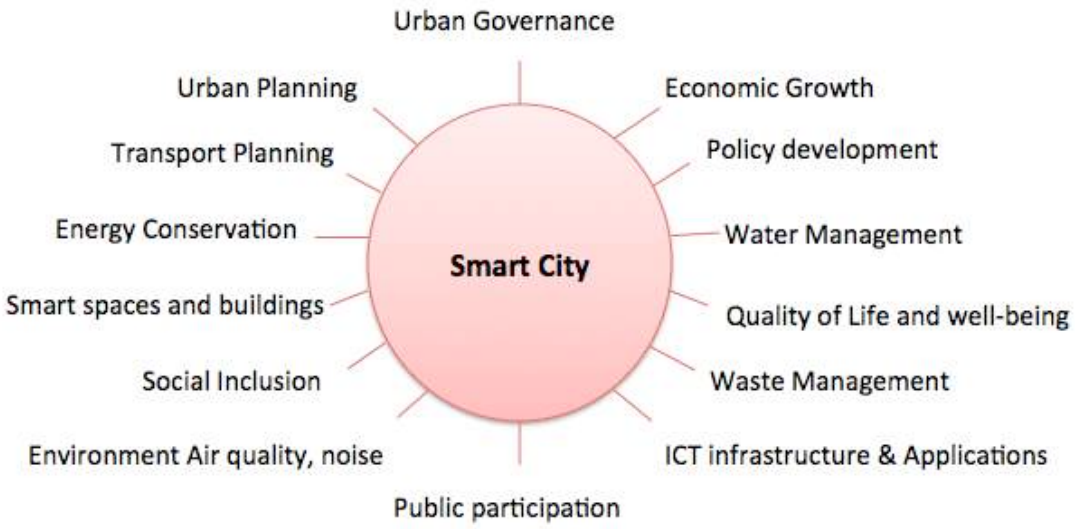

Figure 3: Smart City: Thematic Conceptual Framework

A conceptual framework for the definition of smart cities developed according to a thematic specification is identified in Figure 3, above. These thematic components include: governance, policy development and decision making; efficient use of natural/environmental resources such as water, electricity etc; reduced carbon footprint; efficient energy utilisation; citizens well-being, informed citizens and empowerment; and availability and advancement in ICT such as smart phones with ubiquitous connectivity with internet for context-aware information etc.

ICT as prime enabler for smart cities mainly utilises digital data and transforms it into a useful information, knowledge and intelligence. Cities typical already possess land use, transport, census, environmental monitoring data which is derived from various local sources but rarely is used as integrated source of information for urban governance and planning decisions. The main challenge here is to acquire integrated information from disintegrated data sources at various scales and use this information intelligently to enhance the sustainability of the city. This information can then be effectively utilised to support urban planning and management, citizens engagement, policy development and collaborative decision making.

In the above context, a smart city is primarily defined in relation to the development of ICT solutions for two interrelated issues: i) better governance and management and ii) informed citizens. Former is to get integrated information intelligence about city entities including socio-economic, road networks, structural health of buildings, demographics, environment, transport, utility services, energy consumption, water management, noise, waste management, public health etc for urban planners, policy and decision makers for better governance and sustainable

development of the city. The later is to facilitate general public with access to context aware information such as services, environment, etc. This later perspective can also be used as citizen science i.e. citizens participate in information collection such as environmental sensing data collection, biodiversity and green infrastructures, public/citizen participation for policy development and collaborative decision making. These initiatives empower general public and raise awareness about their environment and health which can result in behavioural changes for green and sustainable healthy city-wide initiatives.

4. UrbanAPI: An example

Evidence from recent surveys of European cities engagement in ICT enabled urban governance, and wider smart city related initiatives demonstrates that with notable exceptions of innovatory progress, there is as yet only limited evidence of the positive impacts of ICT-enabled innovations on city governance systems. It is reasonable to conclude that the smart cities revolution remains in its infancy and that progression towards a more mature status, and wider acceptance by European cities, will benefit from further research to identify a more comprehensive vision of its effective application, particularly where a clear user defined requirement is established. It is precisely this sort of ambition that it is addressed by the UrbanAPI project (2011).

UrbanAPI provides ICT enabled innovations for city governance and adapted governance models to support new stakeholder engagement and citizen participation, in order to enhance sustainable urban policy development and delivery. In this context, the ICT solutions proposed by UrbanAPI offer the potential to provide urban planners with the tools and intelligence needed to actively manage the urban environment. These tools aim to provide planners with precisely the information they need to fully expose the socio-economic and environmental impacts associated with alternative options for territorial development and thereby create conditions in which the political mandate and the basis for more effective management is secured.

UrbanAPI adopts an agile development methodology: cyclic and multiple tasks running in parallel. Furthermore, the UrbanAPI toolset aims to provide advanced ICT-based intelligence in relation to three urban planning contexts as depicted in Figure 4. First, UrbanAPI will directly address the issue of stakeholder engagement and citizen participation in the planning process by the development of enhanced 3D virtual reality (3DVR) visualisation of neighbourhood development proposals. Second, at the city-wide scale, UrbanAPI will develop mobile (GSM) based applications that permit the analysis and visual representation of public movement patterns across the city. Finally, UrbanAPI will develop an ICT simulation application in the city-region context addressing multiple challenges in responding to the

simultaneous demands of both expanding city populations and attractiveness of regions based on settlement and business opportunities.

The key added value offered by UrbanAPI is the extent to which these applications support the development of transformational governance - the shift from a purely top-down planning approach to one which is fully engaged with bottom-up initiatives supported by public intervention. Such applications collectively provide vital decision-making aids for urban planners in the management of the territory, as well as for the associated responsibilities in political negotiation, and wider stakeholder engagement regarding the future development of the territory.

The UrbanAPI ICT toolset and applications are being developed by the case study cities of Vienna, Sofia, Vitoria-Gasteiz, and Bologna. Local initiatives in the four urban regions working in this project are encouraged to participate within the planning process, to contribute to the final solutions and understand and finally accept the expected impacts on environment and habitants. Based on the toolset, adapted urban planning applications will be created, deployed, evaluated and used to support policy makers, planners and stakeholders at different governance and spatial levels (urban quarter level, municipal level, urban region level).

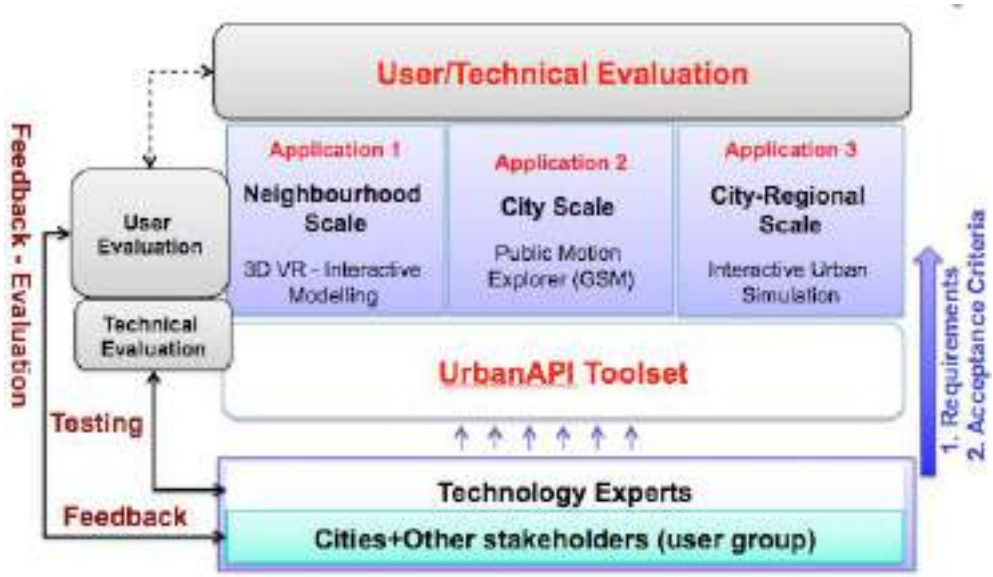

Figure 4: UrbanAPI: requirements, applications and evaluation

Each application developed in one city context is paired with another similar application in another and different city and national context, where context specific socio-economic, environmental and territorial characteristics, as well is governance structures and practices will be evident.

At the same time it is evident that the drivers of change influencing the

development of European cities, including the governance and management of urban areas, have common global and pan-European origin. Therefore lessons will be sought from the comparative assessment of the applications developed in the differing city contexts that will form the basis for the future development of generic ICT tools that can be utilised in the majority of the 500 cities of Europe with populations over 100,000, as well as other smaller cities and towns throughout Europe.

Preliminary analysis derived from the stakeholder engagement and requirement engineering process of UrbanAPI indicates that nearly 50% commonalities exist between two or more city requirements for the 3D VR application. Furthermore, usability aspects including visual aid; data synchronisation and integrity; public participation and ease of interaction with the application; accessibility of the application using different platforms e.g. web, smart phones; change impact assessment; importing new data and exporting results in common formats; and conformance to city administration IT policies form the most common functionalities required by all cities.

In addition, individually specified requirements from cities indicate new potentials which can be developed to improve the overall functionality of the 3D VR application. This suggests that based on commonalities in city requirements, that generic tools and services can be developed which can be adopted and further extended to fulfill the specific needs of new city administrations.

In a similar fashion to 3D VR, there exist about 60% commonalities between two or more city requirements for the public motion explorer (GSM) application. Furthermore, usability aspects including intuitive user interface; visualisation of aggregated population; indicating places attracted by public; extrapolation to reflect the results for overall city population; identifying social biasing; visualising motion traces between city districts/zones; intra-city and extra-city origin-destination matrices and travelling mode; accessibility using different platforms; importing new GSM data and exporting results in common formats; integration of GSM data with data from other sources e.g. GPS, polls; city administration IT standards compliance; and workflow documentation are the most commonly required capabilities for the GSM application. This again suggests that generic tools can be developed to facilitate wider adoptability of the GSM application where more specific requirements from cities add value to these common capabilities.

5. Conclusions

A smart city driven ICT enabled urban governance offers huge potential to secure effective management of the complexity of the city, incorporating new potentials for engaging citizens in defining their urban futures. ICT enabled innovations are

driving the opening up of governance models enhancing public engagement and allowing a wider audience to simultaneously contribute to the political debate and improve the quality of public service delivery. A smart city managed by contemporary ICT solutions not only facilitates enhanced intra and inter-city communication and information exchange but also enables flow of information between various levels of governance at city, regional, national and EU scale.

UrbanAPI project provides a huge potential for participatory planning and policy development by using interactive ICT applications at different urban governance scales. Furthermore, preliminary analysis of the requirements specification of four different European cities indicate that there are commonalities in policy development and decision making processes and hence demand for generic capabilities in the participatory applications can be useful and applicable in other European cities.

Transformation of informal housing settlements into legal housing by urban redevelopment has become one of the major tasks of Turkish urban policy in the last decades. However, in some cases, urban redevelopment could not be facilitated at all, despite prepared plans. Moreover in most of the transformed settlements, added difficulties brought out by urban transformation itself such as lower levels of physical quality, gentrification or dislocation could not be avoided. The study has got use of an empirical research with a case study in Şentepe Neighbourhood of Ankara hypothesizing that there would be available fiscal and non-fiscal policy options for local and central authorities and planning institutions relying on their political and regulative power and resources to overcome most of these bottlenecks. The findings of the empirical study revealed that first and foremost, the problem of disinvestment and very low levels of transformation in the area have been solved dramatically by a new 'project' prepared by the local authority in 2005, after almost twenty years passed since the first redevelopment plans were prepared. Moreover, the results indicate that the Şentepe Transformation Project could also be managed to avoid the common and well-known unintended or undesirable social outcomes of redevelopment like dislocation of residents or lack of social integration of initial and new residents.

Keywords: Urban transformation, urban renewal, urban redevelopment, informal housing

Context, Rationale and Models of Redevelopment Practices in Turkey:

The squatters in Turkey mainly emerged since 1950s and have been perceived as a problem by policy makers and urban dwellers since then. While the responses to this problem have been as diversified as ignoring, banning, granting amnesties or upgrading in the first years, redevelopment have been the major urban policy after 1980s. Despite various efforts, today's Turkish cities still have a considerable amount of untransformed squatter settlements. Moreover, the transformed settlements also still lack what was intended to be achieved by redevelopment; having physical, social and economic problems. This study aims to understand and discuss the underlying

mechanisms of bottlenecks in urban redevelopment processes and availability of certain options to overcome these blockages.

Until now, two major models of urban redevelopment has been implemented to transform the squatter settlements into regular and legal housing environs in Turkey; 'transformation through improvement and development plans' and 'transformation through urban transformation projects' (Dündar, 2001). The first one, dates back to 1984, the enactment of a law numbered 2981 and known as Improvement and Redevelopment Law[1]. The law enclosed those structures built before 1985 and made it possible to make redevelopment plans for the squatter settlements, suggesting a plot-by-plot demolish and reconstruction of housing dwellings by the private sector to create a new subdivision each allowing construction of four-storey apartment buildings reformulating the land ownership structure. Provision of secure tenure and public services to the settlement according to an improvement plan was expected to increase the demand for the settlement where the developers would find it profitable to convert squatter housing paying for land through an exchange of a number of flats to be produced. These plans enabled the squatter dwellings, which are at favourable locations to be converted into apartment buildings in building-selling mechanisms together with an upgrade also in terms of infrastructure such as road network and facilities. However, this mechanism could not work in places, where ownership problems created a bottleneck for redevelopment or in places which do not have locational advantages where construction investment may not be profitable for the house-builders due to low rents.

The second model, "transformation projects" emerged as an alternative model for those areas, which couldn't be transformed by improvement and redevelopment plans at the end of 1980s. Dikmen Valley Transformation Project in 1989, Portakal Çiçeği Valley Project in 1992 and Geçak Project in 1995 were the pioneers of this model. While the 'improvement plan' model have used private resources, which generate extra values to be shared by squatter owners, and speculative house builders; the model of transformation through "transformation projects" uses private resources generated through the project itself, where the extra value generated is shared by more diversified groups of stakeholders, such as local government, project company, squatter owners, landowners and city inhabitants (Türker-Devecigil, 2005). Like improvement plan model, transformation projects too, used extra development rights as the driving factor. Large- construction firms not only introduced more advanced construction technologies, but also manage to cope with ownership problems and bureaucratic difficulties since they have political influence and financial power. On the other hand these firms tried to answer the demands of middle and high-income groups, composed of luxury dwellings of multi-storey apartments.

1 the original name of the legislation is; "Procedures to be applied to Buildings not Conforming to Reconstruction and Squatter Housing Legislation and Modification of an Article of Law No.6785".

Currently urban transformation model is used very prevalently in cities in the form of a number of sub-models of 'transformation projects' differing in terms of organisational schemes, funding and participation levels. Very recently, a central government authority; Housing Development Administration (HDA) has taken over the responsibilities of Ministry of Public Works and of city and greater city municipalities defined by related municipality laws. By 2000s the central government has been directly involved in urban transformation and production of housing through large-scale projects undertaken by HDA. New draft legislations are also being prepared directly related with urban transformation tasks.

By the 1980s, in Turkey informal settlements covered almost almost half of the urban land, some of which were in central locations surrounded by the expanding city. Therefore, the most significant task of redevelopment activities in Turkey are related to these informal settlements which lack sufficient standards, but at the same time being sources of potential location rent. Due to the volume of informal housing stock which is intended to be transformed and lack of conformable financial and technical instruments as well as integral know-how due to the relatively new agenda of urban transformation, the interventions in Turkey to the informal housing stock have not yet to achieve a comprehensive approach such as in urban regeneration practices employed by 1990s in the European cities integrating social, economic and environmental aspects. For instance, in the rationale of the law 2981, the aim of the law is defined as; "providing housing for people who migrated to cities which have become attraction nodes due to economic and social reasons and to legalize the informal housing stock as long as they fulfill certain conditions of urban development legislations and plans". As can be seen from this phrase, the law did not aim or consider any economic, social and environmental aspects of redevelopment; but approaches the problem limited to an ownership and construction requirements level. Nevertheless, the common approach of governments and society has been to expect that the physical transformation would solve the socio- cultural and economic problems as well.

Implications of Redevelopment or Lessons learned; what to achieve, what to avoid:

Almost thirty years of urban redevelopment experience have legalised and transformed a considerable amount of housing stock. However, the implications of urban redevelopment reveals that these interventions have also downsides. A set of four problems of urban transformation in Turkey can be cited;

1. Many informal settlements remain untransformed since they are unattractive for developers and thus disinvested or underinvested although they are envisioned to be transformed by development plans.

Location and locational factors have determining affects in urban redevelopment. Şenyapılı (1996) distinguishes three channels in the process of transformation according to the Improvement and Redevelopment Law since 1984. First, the most advantagely located areas mostly close to city centres have been transformed into large scale, high-rise prestigious residential neighbourhoods by large development firms. Secondly, although not located in or close to city centres, but still advantageously located, like near access roads, near prestigious residential neighbourhoods or urban recreation areas transformations take place into small-scale, four- to five-storey family houses within "build-and-sell" model by small-scale developers. And lastly, in *squatter* areas that are not so advantageously located, the owners attempted to transform their *squatters* into small-scale family apartment houses with their own savings or preferred to wait for the land rent to increase to the levels that would attract small-scale build-and-sellers (Şenyapılı, 1996: 16,19). The last category, are those which mostly remain disinvested or underinvested areas. These areas, which are usually the most inaccessible, having low rent levels, excluded and depredated parts of the cities, remain untransformed and problematic areas. The redistributed income could not reach most of the squatter owners since the regularized development would also follow the locational preferences of the population (Türel, 1985).

In order to facilitate urban redevelopment under any circumstances, some social, economical and physical goals and consequences were not taken into consideration which further created three more problems in the transformed areas.

2. In most transformed neighbourhoods, the built environment still lacks sufficient physical quality and standards.
3. In most transformed neighbourhoods, unintended changes might be observed in social composition; such as gentrification.
4. The socio-economic implications of transformation give rise to ethical debates and social discontent within various sections/ classes of the society.

The second problem of low physical quality and standards in the new built environment produced is associated with the lower standards in Improvement Plans compared to Development Plans. Improvement and Redevelopment Law 2981 gives the flexibility to improvement plans not to fulfil all the service standards of development plans regulated by the Development Law Numbered 3194. In order to obtain additional shares from the increasing rent, potential social infrastructure such as green areas and socio-cultural services occupy minimum shares in the land use, which cause increases in construction and population density and low quality living environs. Considering that the transformation of these newly created and legalized neighbourhoods would be more difficult than transforming the squatter settlements, this would create future challenges for our cities and for the planning profession.

The third group of problems are associated with the social dimensions of urban transformation practices. Various research on redevelopment practices especially those which are carried out by 'transformation projects' model, have shown us that,

they might result in changes in the entire social composition of the transformed neighbourhoods (Dündar, 2001, 2005; Uzun, 2002, 2006; Görk, 2002; Türker-Devecigil, 2003; Kuyucu and Ünsal, 2010). Rather than producing affordable housing for the disadvantaged groups most of these projects targeted middle and upper-middle classes and advertised as 'Prestigious Projects' including those undertaken by central government. These projects are criticised for mainly aiming at demographic as well as physical upgrading rather than to improve the living conditions of the existing inhabitants of the area, thus the process results in property transfer and displacement and damages the social fabric of the settlement since neighbourhood relations and mutual support mechanisms are lost. (Akpınar, 2008; Kuyucu and Ünsal (2010). Mostly some vulnerable groups such as those living in poverty and tenants may suffer from the lack of complementary policies for relocation or dislocation.

The fourth and last group of concerns is ethical problems and take primarily two different forms, although which might seem to be contradictory to each other;

- the argument which claims that housing right of the poor are being grasped by evictions and relocations.
- the argument which claims informal and illegal ways of behaviour are rewarded by rent transfers from those who cannot own a house, instead of punishment for invading land.

The first one emphasises immoral implications of seeking rental income for some sections of the society (i.e. developers, middle class) at the expense of the housing rights of vulnerable or underrepresented groups (i.e. poor, ethnic minorities, less educated). While the transformation projects are introduced as tools for increasing the quality of life of the residents, the process may end up by decreasing the quality of life of reaching to a point of being disposed for some residents.

The latter ethical debate on the other hand, is related with the construction privileges given to squatter owners and emphasises that the squatter residents who become better off by transformation especially by redevelopment plans are able to enjoy high selling price and rental incomes for their properties. In various cases, the squatter residents may end up with owning more than one dwelling after transformation; which creates them an extra rental income as well as creating a convenient housing to live. In her study, Taşan (1996) shows the impossibility of 'homeownership' for a family in rented accommodation in the formal housing stock compared to squatter residents in the same period. This brings out a discontent in the sections of the society other than the advantageous squatter housing residents, criticizing that illegal behaviour is rewarded, but legal behaviour is not.

A number of factors make it crucial to develop better practices in urban redevelopment. First, the pressure of rising land prices makes it irrational to keep those kind of settlements at low levels of capital investment, secondly the pressure of global economy leads that slum and squatter areas could not be a feature of competitive cities and thirdly, the idea to transform these once-poorly-built

structures into more qualified settlements compatible with the new capacity of the society make urban transformation of squatter neighbourhoods the first activity on the agenda of Turkey's urban policy and practice. Therefore, currently, lots of urban transformation projects are being implemented employing various organisational, financial and participation models. The case study will examine one of those projects in terms of whether or not the project could facilitate urban redevelopment while avoiding unintended outcomes such as the problems outlined.

Case study; Şentepe Squatter Neighbourhood

The case study Şentepe is a squatter neighbourhood approximately 12 km away from the city centre located within the District of Yenimahalle in the northern parts of the city of Ankara. The first comers who were mostly from villages of the nearby cities of Ankara coming to find employment and new opportunities, moved to the neighbourhood in the second half of 1950s building squatter housing for themselves. While the neighbourhood was neglected to a large extent during the first decades, in 1984, a 1/5000 scale Master Plan named "Master Plan for Şentepe Squatter Zone" was prepared and consequent improvement and redevelopment plans of 11 phases have been put into practice according to the Law numbered 2981 between 1984-1989. However, only 10-15% of the building stock has been transformed according to these plans and the rest remained as squatter housing according to the established figures of the Municipality of Yenimahalle. Then in 2004, by considering the reasons of the inefficacy of the former improvement plans and also considering the recent changes in the spatial and economic structures and the property market in both local and national levels, the municipality proposed a new project. The municipality announced the project as "Şentepe Urban Transformation and Rehabilitation Project" and put into practice by 2005 to be completed in six phases.

The first strategy of the municipality was to announce the plan as a 'Transformation Project' which for the house-builders has a connotation with higher profits relative to 'transformation by redevelopment plans' model. The municipality has also made some institutional changes in order to ease the procedures for house-builders. The municipality not only increased the amount of social and technical infrastructure in Şentepe Transformation Project compared to the previous plans, but also announced that the project will involve some flagship investments which will be all financed and carried out by the municipality such as a large urban park which might create a positive externality effect for house-builders investing in the area by upgrading the image of the neighbourhood. Since the too small plot sizes were an obstacle for redevelopment in the previous plans; ŞTP rearranged the road network and building block pattern so as to provide larger plots enabling larger size of dwelling units to be produced. Increased development rights enabling more than four storey construction which was not possible in redevelopment plans further increased the profitability of the area and enabled the house-builders and squatter housing owners to agree on contracts more easily since the owners could be offered more units. The plan brought up an incentive for constructions to be carried out on the building block level, by

giving additional development rights in case all owners could agree with the same house-builder on a single project. This has created a more willingness among owners for reaching consensus. Moreover, although not adopting a fully participative model, the municipality carried out meetings with residents to inform as well as to ask opinions or easing or mediating issues of households with house-builders.

Şentepe Transformation Project is chosen as a case for a number of reasons, mainly;

- In the history of Şentepe, the municipality has attempted to transform neighbourhood by two different models of transformation (by redevelopment plans in 1980s and by transformation projects in 2000s) which enable to discuss both of these models.
- While the first of these attempts was not successful to trigger transformation, the second attempt has been more effective, and studying the reasons of this could be useful to develop tools for other underinvested areas of unauthorized housing
- urban transformation according to the project has started by 2005 and still ongoing, thus it is possible to study different household categories altogether; the squatter households whose dwellings are about to be transformed, households who do not like to transform as well as households in the transformed stock and later- purchasers in the area.

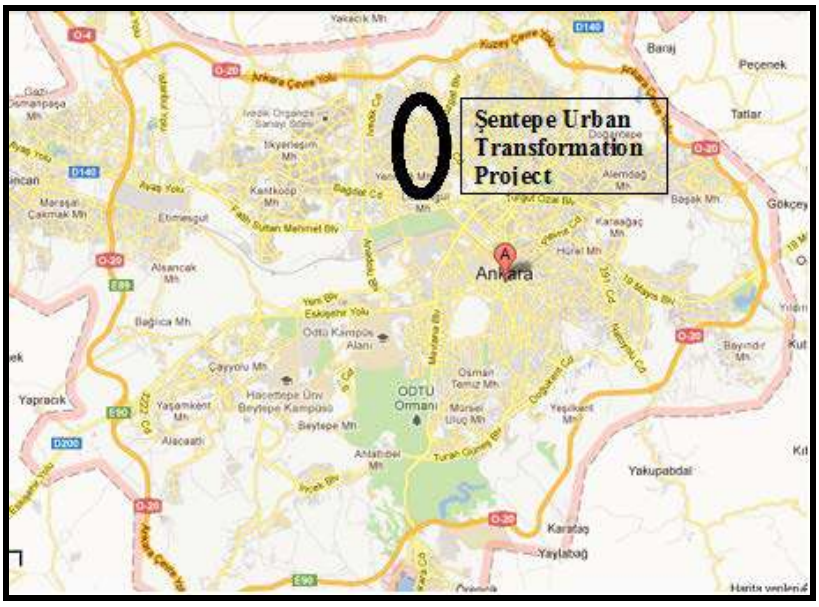

Figure 1. Location of Case Study Şentepe in Ankara

The project area consists of 11 quarters of Şentepe Neighbourhood (Figure 24) and has approximately 425 ha of land with a planned population of 160.000 (current population is 87.000 according to SIS, 2000). According to the plan, 14.000 squatter dwellings are supposed to be demolished and 35.000 new dwellings are supposed to be constructed. Although it is called as a transformation project, it is in fact a development plan in terms of its legal basis and relies on the same principals as transformation by improvement and redevelopment plan model. In Şentepe, transformation has been started and currently in practice. Therefore currently both squatters and transformed apartment blocks coexist even on the same street or on the same building blocks.

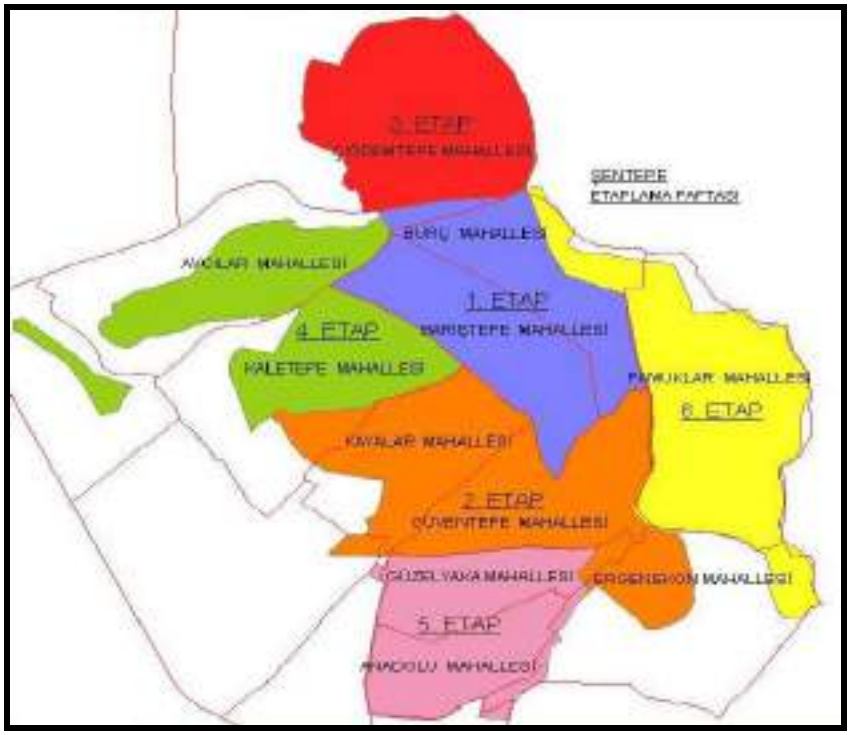

Figure 2. Boundaries and Stages of Şentepe Transformation Project

Methodology of Case Study:

The main pivots of the case study rely on household surveys in Şentepe. The surveys were carried out between 25th and 30th December 2007. The number of households which housing questionnaires have been applied is 160. Based on a sample plan (Table 14), the questionnaire surveys have been undertaken both in unauthorized stock and transformed authorized apartment blocks. Moreover, as seen from the table, households living in apartments fall into two categories, first, the households who obtained their dwellings through transformation (who were formerly squatter owners in the site) which will be referred as 'initial homeowners of flats' in the rest of the analysis; and secondly, the households who have purchased their dwellings in the site after transformation, which will be referred as 'later-purchasers'. Both tenant and owner-occupier households in squatter as well as apartment stock have been

interviewed. By 2007, in Şentepe there were approximately 25 apartment buildings and 800 flats, that households have moved. A total of 80 questionnaires were undertaken in the apartment stock corresponding to a 1/100 sample size. Considering the total population of Şentepe (pop= 87.093, Household size= 4.1, number of Households= 21.242) 160 questionnaires in total represent 7/1000 sample size). Additionally, semi-structured interviews with house-builders and non-structured interviews with municipality officials, mukhtars, real estate agents and housing estate managers were also been carried out.

Table 1. Sample Plan of the Questionnaire Survey in Şentepe

Household Categories	**Freq.**	**%**
Home-owners in squatter housing	30	18,8
Tenants in squatter housing	10	6,3
Home owners in flats constructed before 2005 gaining the flat from being a right-holder	40	25,0
Home owners in flats constructed before 2005 by purchasing the flat after transformation	10	6,3
Tenants in flats constructed before 2005	10	6,3
Home owners in flats constructed after 2005 gaining the flat from being a right-holder	40	25,0
Home owners in flats constructed after 2005 by purchasing the flat after transformation	10	6,3
Tenants in flats constructed after 2005	10	6,3
Total	**160**	**100,0**

Results of Empirical Study; What has been achieved, what has been avoided

The results of the empirical study will be demonstrated according to the set of four problems outlined previously. Therefore, it would be possible to evaluate whether or not the Şentepe Transformation Project (ŞTP) was able to overcome these problems.

> Problem 1: Many informal settlements remain untransformed since they are unattractive for developers and thus disinvested or underinvested although they are envisioned to be transformed by development plans.

Since 2005 when the new project was put into practice, the area seems to be transformed in a high pace which is even recognizable with a first glance. Therefore the implementation of the project seems to solve at least one of the four problems explained. Thus, studying this case would give us clues for other areas and other projects suffering from the disinvestment problem. A total of 403 building licenses (construction permits) (8659 dwellings) have been given between 2006- 2010 according to the figures of Municipality of Yenimahalle.

In the survey different questions were asked to different household categories. For instance, households living in squatter housing were asked whether or not they want their dwellings to be transformed into legal apartment blocks or not. Households living in squatter housing in Şentepe; 86.67% of the squatter owner Households have declared that they would prefer their dwellings would have been transformed into authorized flats.

The squatter owner households were asked why they did not transform their dwellings yet. According to the results of the survey, among the first three reasons households for not transforming the dwellings according to the improvement plans or the transformation projects, first comes "we couldn't afford costs" by 58,7%, then "we couldn't agree with the developer in appropriate conditions" by 13% and "the developers were not interested since our land was small" by 10.9% (the interviewees could chose more than one option in that question).

Table 2. Reasons for Not Transforming Their Squatters by ŞTP (squatter housing owners survey)

Reasons for Not Transforming (squatter housing owners survey)	**Count**	**Pct of Responses**	**Pct of Cases**
Would not afford the costs	27	58,7	90,0
Would be in financial lost if their squatter housing were demolished	3	6,5	10,0
Multiple families in one plot would not get enough number of dwellings after transf.	1	2,2	3,3
we couldn't agree with the developer in appropriate conditions	6	13,0	20,0
the developers were not interested since our land was small	5	10,9	16,7
Disputes with other right holders in the same plot	1	2,2	3,3
Would prefer to live in a detached house within gardens	2	4,3	6,7
The municipality expropriated to make green area	1	2,2	3,3
Total responses	46	100,0	153,3
130 missing cases; 30 valid cases			

The initial homeowners of flats (which were previously squatter homeowners and gained a flat after transformation by ŞTP) were asked for why did they prefer to transform their squatters. The most common reason of initial homeowners of flats for preferring to transform their squatter dwellings is 'higher building quality of flats' (78,8%). Then comes 'more regular housing environs' (51,3%) and then 'opportunity to gain more than one dwelling'(28,8).

Table 3. Reasons for Transforming Their Squatter Housing (Initial Flat homeowners survey)

Why did you prefer to live in an auth. flat by transforming your dwelling (More than one answer is possible) (Initial Flat homeowners Survey)	Freq.	%
For higher building quality of flats	63	78,8
For a more regular housing environs	41	51,3
For the chance to own more than one dwelling	23	28,8
Neighbours in the same/ adjacent plot convinced me to do so	13	16,3
Afraid of loosing their dwellings with an obligatory demolition in the future	10	12,5
Total	**80**	**100,0**
Average Number of Responses: 150 / 80 = 1.9		

Initial homeowners who gained their dwellings by ŞTP were asked why they did not transform their dwellings (according to the improvement plans) before this project. Again in the first place "we couldn't afford costs" by 25,3%, "we would be in financial lost" by 22,7% and 21,3% "we couldn't agree with the developer in appropriate conditions" were mentioned (Table 58). Among all responses of squatter owners, for reasons for not getting their dwellings transformed; the share of disputes with other right-holders in neighbouring plots is only 2,2 % which is one of the least common answer. However, among initial flat owners, among the reasons for not transforming according to improvement plans before Şentepe Transformation Project, disputes with other right-holders constitutes 9,3%. The fall in disputes might be read as Şentepe Transformation is more accredited and trusted by the Şentepe population or some of the planning decisions such as more development rights or larger dwelling sizes in the project decreased the possibility of objections to and thus disagreements in transformation.

Table 4. Reasons for Not Transforming Their Squatter Housing Before ŞTP

Reasons for Not Transforming Their dwelling before (initial homeowners survey)	Code	Count	Pct of Responses	Pct of Cases
Would not afford the costs	1	19	25,3	32,2
Would be in financial lost if their dwellings were demolished	2	17	22,7	28,8
we couldn't agree with the developer in appropriate conditions	3	16	21,3	27,1
Developers were not interested	4	3	4,0	5,1
Disputes with other right holders in the same plot	5	7	9,3	11,9
The plot was not suitable to make an apartment building	6	1	1,3	1,7
Did not know we had such a right/ opportunity	7	5	6,7	8,5
Would prefer to live in a detached house within gardens	8	7	9,3	11,9

Total responses		75	100,0	127,1
Şentepe, 101 missing cases; 59 valid cases				

The need for making an additional payment to the developers might discourage squatter owners from transformation. On the other hand, 92.5% of ex- squatter dwellers in Şentepe indicated that they did not need to pay any additional money to the developer (Table 65). The amount of additional payment varies between 5000 to 200000TL (Average= 49000TL). The time span for demolishing and construction would bring additional monetary and emotional costs for a household. Demolishing of squatter housing and rebuilding of apartment buildings lasted for 9 to 36 months (mean=19.16) and 98,75% did not take any rental assistance. 61.3% of Households in squatter housing lived in rental housing during demolishing and rebuilding of their dwellings, 30% of them lived in a relative's house without paying rent.

Figure 3: Untransformed squatter housing in Şentepe

Figure 4: A Street composed of transformed buildings in Şentepe

Figure 5. Large scale construction facilities of transformation in Şentepe (Çiğdemtepe Quarter)

Problem 2: In most transformed neighbourhoods, the built environment still lacks sufficient physical quality and standards.

Compared to the figures of improvement plans, ŞTP increases the quantity of green and socio-cultural facilities according to the intended amounts of infrastructure to be realized by the municipality according to the plan. According to the household survey, after transformation in Şentepe, the most appreciated factors in housing and neighbourhood condition appear to be the 'inner arrangement of the dwelling' (91,3%) 'Size of the dwelling' (90% answered as it gets better), and the regularization of buildings (73,8%). The answer as getting worse off only appears in neighbour relations with a ratio of 41.3%. (Table 80).

Currently, a number of factors decreases the physical quality of the neighbourhood related with redevelopment efforts. One of them is the coexistence of transformed and untransformed dwelling which creates noise and pollution and the neighbourhood still looks like a squatter settlement or a construction site even if the residents of transformed units are living within a new upgraded dwelling. Another problem in Şentepe is that parks, sports areas and recreational facilities are not completed either by the municipalities or the house-builders (some of the small parks within the gated housing estates are supposed to be provided by the house-builders). That's why it is possible to see children in the transformed stock to be playing on streets just like the squatter neighbourhoods. Absence of some services also decreases the aesthetic quality of housing environs. Although most of the rehabilitation and widening of roads have been completed increasing the quality, the neighbourhood's main connection is only by the roads at its southern part, which causes traffic congestion problem, the transportation system of the neighbourhood is not compatible with the new load of proposed 160.000 population. Moreover 17,6% of households do not pay any monthly fees for management and maintenance of their building blocks. therefore in these buildings, maintenance of the buildings depend on solely voluntary efforts and sensibilities and in the long run this might lead to a decrease in the physical quality of housing environs as well.

Problem 3: In most transformed neighbourhoods, unintended changes might be observed in social composition; such as dislocation and gentrification.

The results of the survey exhibit differences to a certain extent between existing population and new comers in terms of education and income. Table 5 represents the education level (last school graduated) of the household heads (HhH) according to the type of housing and housing tenure status categories in Şentepe. As seen from Table 5, in Şentepe, only 3.25 per cent of the household heads are graduates of a university and all of the university graduates live in apartments. Highest average year of education is 9,2 years in later-purchasers.

Table 5. Level of Education of Household Heads According to Household Categories in Şentepe

Level of Education of HhHs of Şentepe	Squatter homeowner		Squatter tenant		Initial flat owner		Later purchaser flat		Flat tenant		Total	
	freq.	%	freq.	%	freq.	%	freq.	%	freq.	%	freq.	%
No school and no literacy	1	3,57									1	0,65
No school but literate					1	1,32					1	0,65
Primary School	8	28,57	3	30,00	23	30,26	4	20,00	6	30,00	44	28,57
Secondary School	13	46,43	4	40,00	25	32,89	8	40,00	7	35,00	57	37,01
High school	6	21,43	3	30,00	26	34,21	5	25,00	6	30,00	46	29,87
University					1	1,32	3	15,00	1	5,00	5	3,25
Total	28	100	10	100	76	100	20	100	20	100	154	100

Table 6. Average Year of Education of Household Heads according to Household Categories in Şentepe

Hh Categories	Average year of education		
	Mean	N	Std. Deviation
squatter homeowner	7,5	28	2,603417
squatter tenant	8	10	2,44949
Initial flat owner	8,105263	76	2,715776
later purchaser flat owner	9,2	20	3,237933
apt tenant	8,35	20	2,852054
Total	8,162338	154	2,775878

In terms of differences in income between the initial population and the newcomers, there is a 10% increase in favour of the latter. The minimum figure of monthly total income in Şentepe is of squatter housing tenants category (Table 7). In terms of education and income the new comers and initial households are not very sharply differentiated in Şentepe although new comers represent a relatively higher profile.

Table 7. Average Monthly Total Household Income in Şentepe

Hh Categories	Monthly Total Hh Income in Şentepe		
	Mean	N	Std. Dev.
Squatter housing homeowner	868,33	30,00	442,66
Squatter housing tenant	720,00	10,00	193,22
Initial homeowner of a flat	1112,03	79,00	738,29
Later purchaser of a flat	1222,50	20,00	464,10
Tenant of flat	862,50	20,00	480,37
Total	1023,90	159,00	619,23

Households who have purchased their flats after the transformation were asked why they choose to live there. In Şentepe, 35.3% of the responses are for its affordable purchasing prices, and then comes closeness to relatives and friends by 29.4%; 23.5% have answered as they were living in the same neighbourhood before and they got used to living there. Since the availability of relatives and friends is the second most chosen answer in Şentepe, it is possible to conclude that new comers are not only from a similar socio-economic group, but also they are bounded with family and friendship ties to the initial owners.

In Şentepe, 50% of these 'later-purchasers' have stated that the dwelling they lived before coming to their current dwelling was an authorized apartment flat, the rest 50% is some form of squatter or other unauthorized housing types. These figures also indicate a similarity between the new and initial population in Şentepe. These later purchasers are observed to live in Şentepe by 55% before coming to their current dwellings; and 45% lived in other districts or neighbourhoods of Ankara. None of them were living in another city or in rural areas.

Another category of newcomers is the tenants of apartment stock. In Şentepe, 50% of the tenant Households indicated that the reason to choose to live there was the appropriate rents; 45% of them indicated closeness to relatives and friends as another reason, and 45% of the Households stated that they were used to live there before. In Şentepe, 80% of the tenant Households were again tenants in their previous habitation. 85% of tenants were living in Şentepe before moving to current dwelling, and 15% were living in other neighbourhoods/ districts of Ankara. None of them were living in other cities or rural areas. The previous dwellings of flat tenants of

Şentepe live were 25% authorized apartment flats, and the rest 75% were squatters or other unauthorised housing.

Another dimension of social problems is the problems between newcomers and initial owners due to different socio-cultural status, habits and practices. This problem has been highlighted by both types of residents in the area on casual visits to the neighbourhood. The complaints of newcomers are usually depicted through the habits and lifestyles of initial owners described as uncoordinated to the urban life. One of them is explained as shoes and slippers placed and stored just at the corridor before the entrance doors of the dwellings which are common areas of the apartment blocks. This is mentioned as a common practice among initial homeowners. This habit creates an unpleasant smell and unaesthetic image in the building. Another complaint is about hanged out laundry in balconies which again creates a bad image of the streets. On the other hand, it is observed that these initial owners put effort on cleaning of the stairs of their apartment blocks or watering the plants in the garden voluntarily.

> Problem 4. The socio-economic implications of transformation give rise to ethical debates and social discontent within various sections/ classes of the society.

The fourth problem category is the most difficult category to be tested since ethical debates can be more subjective and are not easy to be tested. However, since they are grounded mostly by the social problems themselves; it can be argued that creating less social problems means creating less ethical problems. For instance initial observations during the survey exhibited hardly any sign of gentrification since original residents and newcomers do not present a sharply differentiated profile. This means less social and economical adaptation problems for the original residents while enjoying an improvement in their quality of urban life. Therefore, the original residents do not face with involuntary moves to other parts of the city, which might create social, psychological and economical costs for them.

On the other hand, the survey results indicated that many households gained more than one apartments (of all the initial flat owners; 59,49% gained one dwelling and 40.51% of the Households have gained more than 1 dwelling as compensation of their squatter lands) in the transformation process. These additional dwellings provide an additional rental gain for the households.). Among the Households who gained more than 1 dwelling 39% of them give these dwellings for rental, 31.7% have sold these dwellings, 19,5% of these additional flats are given to the ownership of their married children for residing, 9,8% are given to friends and relatives without rent. Since these households started their housing career with an illegal occupation and end up with a relatively good position compared to those who manage to get a homeownership through legal channels, Şentepe Transformation Project can be criticized in terms of this ethical dimension. In other words, transformation does not only serve to meet housing needs of households, but instead provided lucrative gains for some of them.

Conclusion and Evaluation:

Urban redevelopment by improvement and redevelopment plan model introduced in mid-1980s aimed at simultaneous upgrading of all squatter settlements in the country, rather than of particular project areas. As the model proposed a single template of transformation; (i.e. 4 storey apartment-blocks, with no urban design schemes and with no consideration of the unique locational characteristics of particular squatter housing areas varying in different cultural, social and environmental contexts), only some of the squatter housing areas were managed to be redeveloped. The low investment attractivity in locationally disadvantaged areas and ownership problems (multiple owners, multiple inheritors, hesitant owners) blocked the ways for redevelopment in many areas. On the other hand redevelopment through 'transformation projects' model managed to overcome some of these blockages and enabled redevelopment albeit for the expense of social goals creating consequences of dislocated residents directly or indirectly forced to live elsewhere or bring two groups differing in lifestyles, income and preferences together who would not prefer to live together. Şentepe Urban Transformation Project, attempted to gather the strengths of both models, trying to develop a model in between two models.

The following strategies of the municipality increased the attractiveness of investment of the neighbourhood for house-builders and attractiveness for transforming their dwellings for squatter housing owners;

- announcing the plan as a 'Transformation Project'
- institutional changes in order to ease the procedures for house-builders
- flagship investments which will be all financed and carried out by the municipality such as a large urban park which might create a positive externality effect
- increased the amount of social and technical infrastructure
- rearranged the road network and building block pattern so as to provide larger plots enabling larger size of dwelling units
- increased development rights enabling more than four storey construction
- additional development rights in case all owners could agree with the same house-builder on a single project.
- meetings with residents to inform as well as to ask opinions or easing or mediating issues of households with house-builders

Moreover, it was observed that the project could avoid most of the unintended outcomes of redevelopment to a large extent. Since the project relies on plot by plot renewal by private sector although it is called a ‘transformation project’, there is a gradual transformation where all the squatter housing are not demolished once at a time. Thus the households can adapt themselves to the process more easily and they would be relatively more flexible in their decisions on when to transform and move from their dwellings. Thus, there are no involuntary evictions or time limits for transformation. the project resulted in less ‘radically changed’ housing environs than

those transformed by other transformation projects. So, Şentepe Transformation Project might be evaluated as successful in terms of overcoming the ethical problem of creating dislocated or getting worse-off households. On the other hand, the project could not provide enough satisfaction on households, such as transportation network and delays in the completition of parks and recreational areas. The most referred disinterest in redeveloping their dwellings among squatter housing owners stresses financial issues. Policy Implications of this result designate for the need of further analysis of availability of special groups in terms of financial need and assistance and need for developing appropriate policies for these groups. Developers disinterest in very small and difficult to manage plots also appears as a problem to be solved by institutions such as planning and other regulations to be developed by authorities.

The squares of Athens: The past and the new planning challenges

Theoklis Kanarelis and Pantoleon Skayannis
University of Thesaly. Greece

Abstract

The squares of Athens have gone through a very special trajectory, in parallel with the equally special trajectory of the city's history.

From the initial concept of symbolic building I order to express the new role of the city, passed to the utility design coupled with a certain perplexity, and then to the mature modern era of architectural competitions and optimism. The pursuance of green followed as a reflection of the early sustainability challenges. Today we are in a peculiar post-modern phase of diverse legitimation and frequently pointless interventions. In an era where the city beautiful concept is challenged, such interventions of debatable architectural and urban design quality forms are the last elements required at the moment when a wave of contemporary urban outcasts has appeared and is conquering public space.

This paper attempts to examine the design of the Greek capital, through time, and take a stance in today's challenges facing the problems of the planning of the city per se part of which are the squares with whatever these might mean today.

1. The Greek Independence and the founding of the State - 19th century

After the founding of the Greek state in 1833 and the arrival of King Otto and Queen Amalia from Germany, Athens became the capital of the Nation (a village of 4,000 inhabitants), mainly for historical reasons, since other cities as Nafplio, Patra, Tripoli, Ermoupoli Aegina, etc., were socially and economically much more significant and developed.

This choice signaled the beginning of efforts for the development of Athens into a European capital. The most important of these efforts was the construction of one city under a new plan.

This new plan apparently comprised buildings and public places, and aspired to obey a certain style of urban design.

To achieve this, the first plan was conducted by St. Kleanthes and E. Schaubert whose main idea was the triangular structure of the central part of the new city composed of the three squares, Omonia Sq. (then king Otto Sq. –center) Klafthmonos Sq. (the same as today's Klafthmonos Sq.) and Kerameikos Sq. (near the Conservatory-Kerameikos), while plans were made for a fourth round square in the area of today's Syntagma Square (Biris K., 1966, published 1999: 26-39, Travlos, 1993). Due to reactions raised by land owners, and to economic hardship it was not possible to implement this plan and an

amendment of it elaborated by Leo von Klenze was realized (Biris K., 1966, ed 1999: 34).

In these urban plans German Romanticism and Neoclassicism urban morphological structures that generally characterized urban planning in Europe in the 19th century were evident.

According to Philippidis, "various projects developed in the 19th century by Greek or foreign engineers would rely more on the tradition of classicism having the city avenues planted as boulevards, showing calculated positions and uniform buildings, like the first draft of Athens (1833) of Kleanthis-Schaubert" (Philippidis, 1984:24), while the logic of design is that of G.Haussmann in Paris who according to Philippidis is a representative of the prescribed intervention in the city fabric aiming its very survival"(Philippidis, 1984:23).

Concerning the squares and parks-groves, the form of the proposed and realized squares follow the standard of their European likes showing plans based on the type of a royal park. The smaller parks and squares follow a "romantic" morphology of the English garden style. According to Travlos, "the tree planting of main streets and squares under Queen Amalia's auspices and the creation of Athens National Garden softened the bad impression of the capital during the early years after Liberation" (Travlos, 1993: 250).

European Romanticism - Neoclassicism (and later eclecticism) finds its natural place in Athens functionally and morphologically. The public space and square design regardless of its enthusiasm and magnitude was a combination of the new state power symbolism with the encountered significant obstacles in the realization process such as their acceptance by the local people.For example, there were controversies about the extension of the Constitution Square, prohibited for the fourth time in 1849 by residents while the residents themselves demanded a private land division of other city areas (Kapnikarea area).

The Liberty Square underwent the very first alteration after the public Nursery was built on it (Biris M., 1987, published 2003: 20), while the third square, never materialized as such. The People's Garden of Kleanthis and Schaubert was built after repeated interventions took place and finally became replaced by the building of the Municipal Theatre (Biris M., 1987, published 2003: 26). Other green areas were lost in order to create space for new constructions such as the Municipal Theatre (Biris K., 1966, published 1999: 85-86).

The 1860 plan, by the committee of Vouros, Petmezas, Kalkos, Scoufos, Boulanger, etc. included a proposed unification of archaeological sites (Roman & Ancient Greek Market), and of the Canning, Kolonaki, Monastiraki and Abyssinia Squares, while public buildings on squares were planned to be built. (Biris K., 1966, published 1999: 108-110).This idea was doomed to never be realized as a nonviable plan. The needs of the city led to continuous revisions of plans "for consolidation" which sometimes envisioned the opening of streets, but rarely created squares and green spaces as components of the urban fabric. Until 1900, "no serious care was taken by town planners to ensure spaces for public use. In the municipality of Kallithea only one square was planned in early seventies. Very few squares were designed and built. Green areas were almost totally ignored" (Biris K., 1966, ed 1999: 275).

According to Philippidis, "Haussmann's intervention became widespread in Europe in the last third of the [19th] century. The famous opening of Korais Street in Athens, for which lots of ink was spilled in the past, belongs to this consolidation plans by foreign and local planners" (Philippidis, 1984: 23).

The symbolic value of the design goals was self-evident in the naming and changing of names of squares. In 1862 (year of 'eviction' of King Otto), the "Square Otto" became Omonia Square, Ludwig Square became Liberty Square, and after a while Koumoundourou Square (Biris K., 1966, published 1999: 111). Omonia Square took the form of a 'neoclassical ensemble during the last two decades of the 19th century. Until then it was simply a dump square (Biris M., 1987, published 2003: 24 and note 32: 220).

Similarly, only during the last two decades of the 19th century the three sides of the Constitution square received an architectural finish including few hotels and homes of wealthy citizens (Biris M., 1987, published 2003: 29).

2. The period of the first half of the 20th century (early modernism)

The first half of the twentieth century was marked by wars that resulted in the expansion of the country, as well as in the 'Minor Asia disaster' of 1922. Attempts were made to solve problems of public space and some practical solutions were found, though not in a very inspired way. Nevertheless, especially the inter-war period was a particularly productive period in terms of ideas and projects. Simultaneously, this period was marked by a large expansion of all kinds of infrastructure networks which had already started in financially developed countries in the last third of the 19th century.

As for town planning, dozens of plans and proposals are recorded e.g. the basic literature (mainly K.Biris and D.Philippidis) mentions several projects by P.Bakas (1896), A.Georgiadis (1904 & 1908), L.Hoffmann (1908), Th.Mawson (1914-18) A.Balanos (1917) and E.Hebrard P.Kalligas (1919), St.Leloudas (1918) influenced by Geddes [1915] and Garnier [1917]. Philippidis regards most of the examples as an expression of aesthetic landscaping and Hausmann-like pragmatism in search of normality as a perfect solution for a European city (Philippidis, 1984: 121).

After the 'Asia Minor disaster' (1922) the housing need for more than a million refugees changed the priority setting, but the basic rationale of the proposals remained intact. The Kalligas plan (1922) proposed public buildings, squares, openings and new centers, but was cancelled by the dictatorship of Pangalos in 1926 (Biris K., 1966, published 1999: 284-286). During the same period the first drafts for garden cities were prepared, the conception of which however was closer to English suburbs than to garden cities.

Thus, plans by Sp.Agapitos for Ekali (1922), by A.Nikoloudis for Pschiko (1923), by A.Valvis for Heliopolis (~1925), and by I.Isigonis and Kremezis for Filothei (1931) were delivered. An exception to the endless street proposals were the interventions of the Mayor Spyros Patsis City Design Committee (1925-1929) which proposed the creation of highways (e.g. Acharnon) and the creation or the enlargement of neighborhood squares.

Leloudas in 1929 criticized the timidity of the state, despite the widespread claims of the public authorities for a real reform plan of Athens. His proposals ended up in the final plan in 1938 for the Athens Highway & Skaramangas Highway. An extension plan of the City of Athens (1934) was already at hand when City major was Sp Trikoupis. This plan was confirmed by a series of royal decrees during 1934-1939, in 1934-35 manifesting the "Technical Program of the City of Athens" (Biris K., 1966, published 1999: 297-324 and Philippidis, 1984: 202). According to Philippidis, however, the lack of funding for major interventions, finally limited the program to the embellishment of squares and open spaces (green areas in front of the Evangelismos Hospital, the Dexameni Square, the Cathedral Square and the Fokionos Negri Square).

During this period, the city plan and design did not follow a conscious choice as in the 19th century (when the new state embraced symbolic means of architectural expression), but extended the chaos and the arbitrariness in design as had started immediately after the proclamation of Athens as capital. There was a little and late efficacy of interventions, while some sort of competition between the Ministry of Communications (the Town Planning Office being subject to it) and the Municipality of Athens.

The latter managed to rescue two parks in the Alexandras Avenue from interventions of the Ministry (to convert to building space), while other parks and squares were lost due to Law interventions (Biris K., 1966, published 1999: 298 & 322). One may regard as relatively positive interventions the construction of the underground subway station in Omonia (which functioned as a bus terminal) from 1925 to 1930, the 1929-1930 construction of the monument of the Unknown Soldier and of the square in front of the Old Palace (which changed its use), the creation of the Pedion Areos as a park of Athens, in 1934, as well as the 1939 creation of the Field Infantry barracks park (on the foot of the Petraki Monastery) (Biris K., 1966, 1999 Edition: 302 - 21).

Such developments were certainly not irrelevant to the great social upheavals brought by refugee populations who flocked to Athens and established a territorial mobility. According to M.Biris, during the decade 1910-1920 Amerikis Square was a new venue for wealthy bourgeois who built their mansions around it.

“Neighborhoods - such as around the National Archaeological Museum, Vathis, or the axis of Piraeus Street (Omonia Square – Koumoundourou square) - which during the period 1880-1920 hosted upper and middle class layers, degenerated after years of dramatic changes in the central and western sector (trade, manufacturing heavy traffic, etc.) into a functional mixture that ultimately led to their final degradation. The same happened with private mansions of Patision Street, or cottages in the area of the Angelopoulos area and the Amerikis Square, etc. when new population masses flooded the entire area north of the capital during the inter-war period and after"(Biris M., 1987, published 2003: 26-31).

According to K.Biris after the ‘Minor Asia disaster’, "areas next to the Municipal Theatre and the Town Hall, the Varvakeion Demorateriou and Monastiraki Squares, of the crossing Aiolou and Plouton Streets were filled by wooden shops and stalls - in which everything was sold as food, utensils and clothing house tools, etc.,- small restaurants, cafes and bars". To address the need, the Athens City council created special shelters at the Varvakeion and Demopraterion Squares (Biris K., 1966, published 1999: 291-292).

The prewar period and the period of the war ended during the last years of the '30s, with the extensive debates about the Europeanisation or the Originality of Style (K.Laskaris, K.Biris, etc) (Philippidis, 1984: 202-3), under which the unfortunate demolition of the Municipal Theatre happened (in its present position Kotzia Square Post Office) in 1940-41, and while mainly squares and public spaces were demolished by the Ministry of Transport without any reaction from the Athens City Council (Biris K., 1966, ed . 1999: 291-292: 355). The modern movement became slowly accepted in public architecture and therefore in the public space and squares.

3. The post-war period (1950-90)

The period immediately after WW2 was a period rehabilitation and of reconstruction of the heavily damaged building stock. Yet, it was also a lost opportunity for the planning and redesign of Athens.

According to Philippidis, the Team X in the late '50s, [Smithson, van Eyck, Josic, Woods, de Carlo, Kandylis] worked largely in the urban scale, emphasizing the identity of architecture and urbanism, on an attempt to address the problems of urban space. "The philosophy of this new kind of urban interventions was to respect the existing, to carefully intervene to a limited extent, to revive the fabric of the city, to abandon the earlier technocratic town planning, and to promote advocacy planning that tended to avoid arbitrary interventions" (Philippidis, 1984: 42).

On Greek State level, the design of the capital initially was expressed by the (regulatory) "Reconstruction of the Plan of the capital [Athens]" (City Plan City of Athens [Kostas Biris]) (1945-1946) which foresaw, among others, a new satellite city of Athens named Megarida, and the Ancient Athens Grove (as a wider version of the later project "Unification of Archaeological Sites").

There was care for urban improvement but green areas and squares were not included in the plans made by Biris (see pp. 345-9). The project explicitly included the proposal of Panagiotis Aristofron for the Ancient Academy of Plato and the Ancient Public Cemetery. (Biris K., 1966, ed 1999: 345-9). The only thing that materialized were galleries (Philippidis, 1984: 265), while the plans for the Academy of Plato and thoughts for the Public Cemetery are still ongoing (2012).

A timid town planning practice and the choice of cheap and quick solutions immediately after the war did not enable any important interventions in public space or the creation of new spaces such as squares. The main concern was the opening and widening of roads.

K.Biris mentions that the plan envisioned a capital center free of vehicles not serving its own needs, thus not allowing the passage of cars connecting the Northern parts of town with the South. This kind of connection would be enabled by a ring surrounding the city in areas not yet developed" (Biris K., 1966, ed 1999: 406-8 & 407).

In the above, we can see large-scale design efforts using always as a tool axial connections. The design, of public space was realized by the creation of entertainment

centers in parks and squares (at Pedion Areos and at the National Garden), and by the redevelopment of squares such as the Omonia square (symbol of postwar Athens), the Syntagma Square, the Klafthmonos Square (Philippidis, 1984: 268), and finally of New Smyrni Square.

In the 80's, paved areas of squares served the political parties meetings. The underground surfaces started getting used as large parking lots (K Biris, 1966, published 1999: 410-13).

Adverse developments of the urbanization of the capital demanded new planning efforts. Thus, the Doxiadis Office in 1972 was entrusted with the Town Planning of Athens which resulted in the Athens 2000 Master Plan by the Ministry for Urbanism Housing and Environment, a final agreement plan, reconciling 5 different proposals (Philippidis, 1984: 330). While in the rest of the world the transformation of architecture through the application of the principles of modernism influenced urban design, the Athens Chart became inactive in the case of Athens and Greece as a whole region remained unaware of the very development of the relevant modern trends of thought. Architectural and planning thought stagnated between a generalized sociological criticism in the 70s and a certain list of non-realizable project (Philippidis, 1984: 44).
In fact, throughout 1960-80 there was still no comprehensive planning. Showcase projects in public spaces made their appearance instead, such as pedestrian zones and public playgrounds (Philippidis, 1984: 330).

4. The post-1990 period: Europe and the Olympic Games. The quest of sustainability

The 80s were marked by the recommendations of the Athens Master Plan (minister Tritsis Plan) in 1985 and by the interventions to save the Plaka area (minister S.Manos). Many problems were identified during that period but were not sufficiently faced because of lack of resources. The "reconstruction planning business" was considered more important at national than at local level. Resources from the European Union towards the end of the decade and the beginning of the 90s enabled new attempts (e.g. unification of archaeological sites) and delivered very interesting results.

At the same time, a combination of resources from the Community Support Framework and the Programme for the Olympic Games (both of the proposals for 1996 and later in 2004) especially after the Greek Olympics assignment, triggered a series of projects in the wider Athens transportation network (metro, tramways, railway renovation, Attiki Odos urban motorway, New airport). These works, necessary for the operation of the city, came late and were overriding previous plans (1985 Master Plan).

Some smaller projects were realized, since new Metro stations gave the opportunity to create some free public spaces and places on their surface, such as Kerameikos Square / Metro Station built in 2000, as Kleanthis imagined it as a third pole/square of the city. Instead of making large and substantial interventions (e.g. new public spaces - squares) the remaking of existing squares with unclear architectural - urban planning objectives

(e.g. New Psychico), was considered as an easy way to "absorb EU resources". Another initiative, as a result of the rapidly growing eco-environmental consciousness, sought to find and exploit new free public spaces for green. In this direction, small local initiatives were initiated to save space (and buildings) (the Fix plant at Patission str. and premises of the park at Drakopoulou str. in Ano Patissia, the old municipal market of Kypseli, etc).

The latest intervention set in the city had to do with a series of architectural competitions directly related to the Kerameikos Square (1990) and the Acropolis Museum in 1989 which were related to the award of the 1996 Olympics, and some smaller contests such as those for the squares of Koumoundourou, Omonia, Monastiraki, and Syntagma 1998-99. These competitions allowed individual architects to surface, since the corporate architecture took care of the big assignments. These competitions resulted into ambiguity and weak implementation of the winners design, a fact that reveals significant of the country in terms of administrational culture

In the case at Monastiraki Square, the solution was practically "non- architectural" because that square with the Ancient, Byzantine, Ottoman and Modern surrounding buildings functions like a courtyard and a summary of the history of these buildings. The case of the Omonia square is a typical case of a jury misled by trendy 3D graphic solutions as shown by the images of the international architectural journals. Naive symbolisms and fake semantics copying American or other European examples try to convince the modern Greek citizen how the new European urban landscape looks like. The overall results show that these interventions were undoubtedly useful but were once more insufficient attempts to solve the problem of public space in Athens.

5. Today: The post-Olympics era

The inability to use the accumulated organizational experience during the Olympics, the dissolution of intervention and creativity mechanisms with expertise, as well as the ongoing financial crisis after 2009 paralyzed any practical moves for the implementation of planning and design interventions in public space, which became occupied by social outcasts, the "marginal elements".

In order to ‘re-plan’ Athens two major attempts were made:

a) the Master Plan of minister Souflias (2009) and

b) the Master Plan "ORSA-2021" (ORSA, 2012),

Some other proposals come from the Ministry of Environment, Planning and Climate Change, such as Athens 4x4 and the reshaping of Squares St.Nicholas, St.Panteleimon, Attiki and connecting walkways, the creation of a green axis from the Pedion Areos park to Plato's Academy, and the Panepistimiou ave. pedestrianization project. The City Council of Athens in 2010 appeared being more active in initiatives where European Community founding was highly possible, such as the redesign of squares to become bioclimatic, as well as to the recall of interventions at Plato's Academy and at the 1st Cemetery.
Of course, there are still pending interventions such as the public spaces in the greater Athens area (the Panathinaikos Stadium, the Elaionas urban region, the metropolitan park

of Goudi, and other small-scale housing interventions at Alexandras Ave and Panormou Street.

The new Master Plan of Athens (ORSA, 2012) correctly stays at the level of general guidelines and principles and does not foresee any specific free spaces within the urban fabric, but still its guidelines do not mandate planning for the creation of new public space.

The inability of planning, the lack of resources, political timidity, and financial speculations did not lead to genuinely free spaces for public use (and creation of new squares), but attempted the exploitation of existing sites through conversion. Nowadays, the economy crisis as expressed in Athens, has led to the decline of economic activity, while the flight of large portions of the population and professionals from the city center has led to massive degradation of the city and to its 'occupation' by legal and illegal immigrants and marginal groups. During the years 2010-2012 numerous projects by government agencies and private consultants have been presented with zero results though, while the Ministry of Environment, Planning and Climate Change has long insisted on design type approaches, culminating in the "pedestrianization of the Panepistimiou avenue". In contrast to the above, the City Council of Athens has already made a first and important attempt to develop a more comprehensive plan for addressing the crisis of the city which will however require a significant level of funding. This program contains elements of urban design as parts of a wider range of urban, social and economic interventions.

Conclusion

The public space in Athens today, hence the squares are parts of the crisis of space. The desperate search for identity through the European neoclassicism of the 19th century divides the former Ottoman Greek-Christian. The image of the urban area for the modern Greek citizen is pretty much a fantasy of the European philhellene to come into direct conflict with the Ottoman and Byzantine past.

The naming and the sculptural decoration refer to the ancient glory (Kondylis, P., 2007: 32). We have squares with ancient symbols and names. The modern movement in urban planning of the city does not come until after WW2. This modern movement has probably never been accepted apart from a small class of intellectuals and artists. The error is repeated with the contests by imposing images of globalization (electronic Monitors and abstract solutions, fashionable modern architectural sceneries, etc). In short, the squares of the Modern Greek capital reflect efforts of Hellenization in terms of modern imported trends.

The central government and municipalities lack the resources for effective qualitative interventions in the city, and the squares have become places of immigrants (illegal and non-) (see Victoria Square), or urban mega-recreation areas (Kerameikos).

The efforts for a new bioclimatic "landscaping" cannot answer the key issues in the public space that now escape from urban planning and assume a major social character. What is needed now is to understand that modern complexity cannot wait for the solution

of problems through urban design, or rely on it, but that urban design is merely one of the tools (as important as it might be) of comprehensive planning.

TRYING TO BE "SUSTAINABLE" AND "GLOBAL": AHMEDABAD AND THE SABARMATI RIVER FRONT DEVELOPMENT PROJECT

Gloria Pessina [1]

Abstract

The recent celebrations for the 600th anniversary of the foundations of the city of Ahmedabad in 2011 represented a crucial moment during which a reflection on the past of the city was combined with a strong push towards future changes. While the city centre was proposed for the nomination as a UNESCO heritage site, new large development projects started to appear both at the core and in the outskirts of the largest city of Gujarat. The Sabarmati River Front Development Project represents one of the most important investment sites for both public institutions and privates, as well as a translation on the ground of the city vision to become both "global" and "sustainable". Combining a large body of interviews with current debates about globalisation, politics of scale and political ecology, the paper aims at highlighting different narratives and their role in shaping the future Ahmedabad. The paper pays particular attention to the importance of the State in the creation of "new state spaces" (Brenner, 2004), thus contesting its loss of relevance in the age of globalisation and in the "space of flows" (Castells, 1996).

1. Ahmedabad, an aspiring global city

In its 600 years of existence the city of Ahmedabad in Gujarat (Western India) has faced any sort of challenge and changed its role in India and at the international level, but some elements have remained incredibly stable through time. One of the main features is represented by the strategic position that the city has always had through history: as a matter of fact it has represented the crossing point between the Silk Route and the Spice Route, as well as one of the gateways of India (Yagnik, Sheth, 2011), as it still is thanks to its international airport. The relevance of the geographical location has been playing a significant role also in promoting a sort of "mercantile ethos" (*ibidem*) within large part of the population, not only of Ahmedabad, but of Gujarat in general. It should not surprise then the dynamism of the economy in that part of India, which has always been considered one of the richest: still today Ahmedabad is the seventh Indian city in terms of GDP[2]. A further element that has proved to be constantly relevant throughout history is the relation between the city of Ahmedabad and its river, the Sabarmati. As it is described by the fifteen-century poet Hulvi Shazi, the myth of the foundation of the city by Sultan Ahmed Shah is strongly bound to the river: "The Shah, while on a gracious walk,/ stopped at the bank of the river Sabarmati/ The ground was clean and charming,/ the water pleasant, the air pure./ On seeing these attractions, by the grace of Allah,/ he

[2] www.rediff.com accessed on 20 March 2012.

dreamt of a wondrous city" (Yagnik, Sheth, 2011). Along the river several institutional as well as educational and religious buildings or open spaces rose, the most famous of which are probably the *ashram* created by Gandhi in 1915 or the Mill Owners' Association building realised by Le Corbusier in 1955. It is therefore not surprising that also nowadays the future of the city is both reflected in and promoted by the developments occurring within and along the Sabarmati.
The Sabarmati River Front Development Project initiated in 1997 by the Ahmedabad Municipal Corporation (AMC) through the newly created Sabarmati River Front Development Corporation Limited (SRFDCL), is actually listed among the main projects to achieve the municipal vision of a "Vibrant Ahmedabad – Vibrant Gujarat" or of a "Greater Ahmedabad" (fig. 1)[3].

Figure 1. One of the visualisations of the future of the Sabarmati presented to the public by HCP in December 2011 (Pessina, 2012)

Further major projects are the sixty-meter-wide and seventy-six kilometres long Sardar Patel Ring Road, the Bus Rapid Transit System (BRTS), the Gujarat International Finance Tec-City (GIFT) between Ahmedabad and Gandhinagar, as well as the opening of the Tata Nano plants in the southern outskirts of the city. Despite the difference in terms of uses and nature of the different projects, they are all characterised by bigness, both in spatial as well as in economic terms and tend to be aligned with (and hence funded by) the Jawaharlal Nehru National Urban Renewal Mission (JNNURM) which is mainly promoting large infrastructural projects. The issue of bigness is once again stated in the vision for a "Greater Ahmedabad" also in terms of population: the AMC in facts foresees a consistent

[3] Ahmedabad Municipal Corporation and Ahmedabad Urban Development Authority with Technical Support from CEPT University, 2005, City Development Plan 2006-2012, Ahmedabad.

growth of population by 2030, rising from the current 4 million inhabitants to more than 10 million.
All those projects pose questions of globalisation in large cities of the South, as well as of scales and distribution of powers among actors, but the case of the Sabarmati River Front Development Project differs from the others because of the presence and relevance of the issue of “sustainability” in its implementation.

2. The Sabarmati River Front Development Project: facts and figures

The idea to develop the natural banks of the river inside the city of Ahmedabad has a longer history than the ongoing project: the first proposal was formulated in 1961 by the French architect Bernard Kohn which suggested to reclaim 30 ha of land on both the banks of the river in order to develop a mix of commercial, recreational and residential activities in some points of the river, mainly close to the major bridges. The feasibility of such proposal was studied and confirmed in 1966 by a commission appointed by the government of Gujarat and a further proposal was done in 1976 by a group of local professionals including Ahmedabad Study Action Group, the architect Hasmukh C Patel and K B Mehta Builders. The group agreed on the reclamation of land and proposed the strengthening of the Pirana Sewage Treatment Plant in the south of Ahmedabad and the construction of retaining walls to protect the city from floods and to give space for development. The need to improve the sewerage system was confirmed also in the National River Conservation Plan of 1992 for the interception and diversion works, the construction of trunk sewers, the desilting of storm water drains and the provision of sanitation infrastructure in the river bank slums.
A last proposal was formulated by the CEPT University of Ahmedabad just one year before the currently implemented project was submitted: it envisaged to add to the 30 ha to be reclaimed 20 more meters along the west bank and 10 along the east bank to develop publicly accessible open spaces and recreational areas connected by walkways and promenades.
Although several projects have already been proposed since the Sixties only in 1997 the Ahmedabad Municipal Corporation decided to finally implement a plan and therefore created a specific public body, the Sabarmati River Front Development Corporation Limited (SRFDCL Ltd.), for the supervision of the process.
The proposal was commissioned to the Environmental Planning Collaborative (EPC), which in 2002 merged with the HCP Design and Project Management Pvt. Ltd., responsible for the urban design of the project. The works started in 2005 and are still ongoing.
The project regards a stretch of 9 km of the river comprised between the Subhash Bridge and the Vasna Barrage within the city of Ahmedabad and its main features are the following:

- the reduction of the riverbed from a variable width of 600-300 m to a fix width of 275 m, thus reclaiming 185 ha of land;

- the construction of RCC diaphragm walls (10-20 m depth) and anchor slabs (10 m) to prevent the riverbanks from erosion. After the finishing the anchor slab is turned in the so-called lower promenade;
- the construction of interceptor sewers on both the riverbanks able to prevent the waste water to flow directly into the river and diverting it to the two sewage treatment plants of Vasna and Pirana;
- the construction of RCC retaining walls (2.5 - 9 m) to protect the city from flooding. The height of the walls is determined by the 100-year flood level. An upper promenade is created on top of the retaining walls (figure 2 and 3);
- the dredging of the river bed in order to provide soil for the filling of the space behind the RCC retaining walls. At least 67.500 cubic meters are required for the filling;
- the relocation of slum dwellers and the provision of better living conditions to them. The amount of families initially considered was 8000 but the number was increased to 15000 after further surveys in 2002. The first proposal was to relocate them in three sites along the riverbanks, but the plan has changed afterwards and the relocation sites are now far from the river.
- the use of the reclaimed land for private residential and commercial developments with a view on water to be sold to finance the project (the percentage has decreased from 20 to 15% because of the high increase of the land value), two major roads, one on each riverbank (30%), gardens (26%), promenades (6%), informal market (3,6%) and the rest for other public facilities.

The main declared goals for the implementation of such actions are:
- the elimination of the danger of floods in the current context of climate change;
- the establishment of better hygienic conditions through a new sewerage system;
- the ground water recharge through the storage of water within the river bed;
- the improvement of the living conditions of the slum dwellers.

The expected cost of the project is 15 billion indian rupee and it will be covered by the sell of parts of the riverfront (15%) to private investors, as well as by funding from the JNNURM programme.

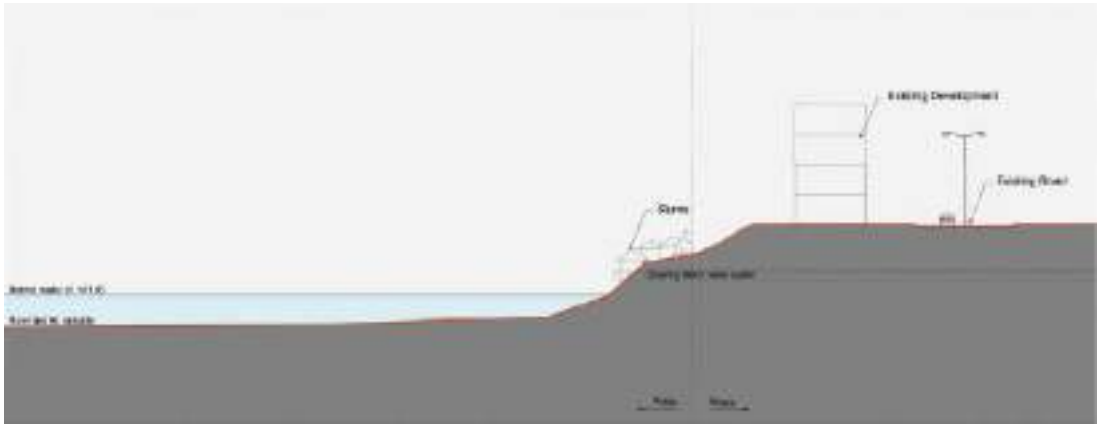

Figure 2. the riverbanks of the Sabarmati before the project (SRFDCL and HCP, 2008).

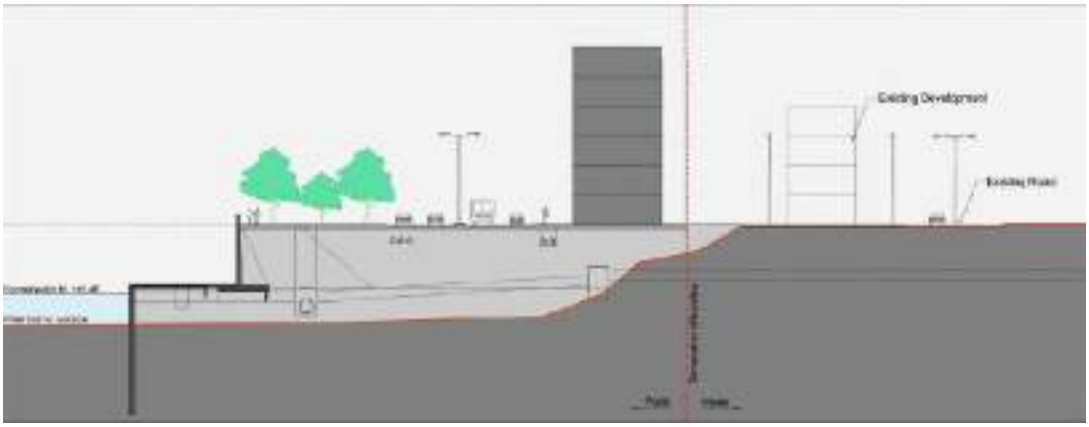

Figure 3. the riverbanks of the Sabarmati after the project (SRFDCL and HCP, 2008).

3. Narratives around sustainability

Looking at different descriptions of the project, one issue is quite recurrent, that is to say the importance of the environmental concerns. Among the different possible sources a couple of them are quite noteworthy given their capacity to reach wide audiences: one is the case of an international landscape architecture journal, while the other are public speeches by the politicians who mainly promote such project.
In an article published in 2009 on the TOPOS journal the project was described in this way: “though implementation will be challenging, the city hopes that this integrated environmental project will be a model for the nation” (Fenk, Schaffer, 2009), particularly stressing the capacity of the urban designers to deal with flood protection, sanitation as well as development.
Interestingly, the project is also mentioned several times in official speeches by the Chief Minister of Gujarat as an example on the ground of the current state policy of “climate justice”, meant as a “convenient action” against the “unconvenient truth” of climate change (Pessina, 2011).
Both examples relate in different ways to recent developments in the debate about sustainability started in the early Seventies. Moving from a definition of sustainability as a challenge to standard growth models (Daly in: Scoones et al., 2007) to “the ability of systems to bounce back from shocks and stresses and adopt stable states” (Holling in: Scoones et al., 2007), more recent debates focus on issues of risk management, as emerged in the United Nations Conference on Climate Change held in Copenhagen in 2009. In the water domain, the issue of risk is often identified with floods due to climate change, as it is in the case of the descriptions of the Sabarmati River Front Development Project given its political supporters. Among the tools for risk (and especially flood protection) as well as for an achievement of sustainability in general in the water domain, the Integrated Water Resources Management promoted in the Nineties by the Global Water Partnership seems to be still one of the most popular, as the words used by the TOPOS journalists seem to confirm.

While in theory the narratives of risk protection and integrated resources management (and integrated design) seem to work very well, looking at the specific case of the Sabarmati river some issues seem to be overlooked.
As a matter of fact, none of the official studies nor the wide spread articles seem to stress the dynamic nature of the Sabarmati, a non-perennial river, fed by the uneven and infrequent rain occurring during the monsoon between July and October and is therefore dry for large part of the year. The Sabarmati basin has traditionally been known as a good agricultural production area where cultivation was carried out being very careful towards water. A pattern of villages were developed along the course of the river with respect to the floodplain and paying attention to leave the silting areas for agriculture. After the heavy floods that occurred in 1973, the Dharoi Dam was created in 1974 at the feet of the Aravalli chain in northern Gujarat in order to regulate the Sabarmati and to provide water to the city of Ahmedabad. Downstream of Ahmedabad the water started to be retained through the Vasna Barrage. Since large amount of the water is diverted for agriculture directly from the Dharoi dam itself, the dry condition of the Sabarmati for most of the months became even more evident and the floods decreased in their intensity and frequency.
The legitimacy of the project, aiming officially at reducing the flood risk, is thus significantly reduced, as pointed out by an hydrologist based in Ahmedabad “Floods are unlikely to happen but in case they will take place the covering of the riverbanks with concrete will affect the capacity of large part of the city to absorb water and let it percolate in the soil. Moreover the channelizing of the river for such a long stretch will affect negatively the areas both upstream and downstream of Ahmedabad where the flood will be more violent. Ultimately such sort of canal will act as a funnel” (Pessina, 2011).
It seems clear therefore that the use of words is not neutral and large part of the environmental policies put in place in recent times are the result of specific discourses strongly bound to different forms of knowledge. Some consolidated and often institutionalised discourses can become “environmental orthodoxies” (Leach and Mearns in: Forsyth, 1993) that are hard to be contested. In the case of water the debate seems to be shaped mainly by major global players such as the World Bank, the Global Water Partnership, the World Water Council etc. (Forsyth, 2003; Mehta et al., 2007; Karpouzoglou and Zimmer in: Nicol et al. 2012;). As in one of the latest contributions on political ecology it is stated “it is not science as a specific and useful form of knowledge production that is questioned [...]. Instead, it is the way specific forms of ecological knowledge are selected and validated [...], what assumptions and practices become normal and internalized for people” (Peet et al., 2011). Political ecology represents for some scholars an attempt “to establish the political forces behind different accounts of ecology as a representation of biophysical reality” (Forsyth, 2003). In acknowledging the political nature of environmental policies and projects some recent contributions define therefore Sustainability (differently than sustainability) as a “contested, discoursive resource – a boundary object – that facilitates arguments about the diverse pathways to different futures” (Scoones et al., 2007). The idea of sustainability in the case of the Sabarmati seems to be highly contested not only in terms of narratives around flood control and protection from

risks as a declared aim, but also on a large number of other issues raised by several actors.
(1) One of the main features of the project, its high level of engineering (Khavthekar in: Pessina, 2011), represents also one of the main concerns of academics, practitioners and local dwellers: the use of concrete for the embankments of a long stretch of the river, in fact, strongly affects the environment and seems to have counter-effects to the expected protection from floods, especially downstream (Vasavada, Chayya, Choudhuri in: Pessina, 2011). (2) Hydrologists and representatives of environmental movements point out that the dredging of the riverbed to get sand for the earth filling on one hand represents an attempt to reduce distances to bring materials for the construction works on site, but on the other hand is dramatically affecting the nature of the river, thus increasing the speed of the water, promoting the erosion and endangering the stability of the bridges (Vasavada in: Pessina, 2011) (3) Slum dwellers organisations, NGOs as well as some academics active in the fields of sociology and urban planning are suspicious also towards the declared “economic sustainability” of the project, meant as sale of part of the land. Many of them are actually afraid that the effective public use of most of the project area could then be restricted just to part of the population through the introduction of fences and of entry fees as it happened in other cases in the city of Ahmedabad as Kankaria Lake (Pathan, Patel in: Pessina, 2011) (4) Economists and academics point out that as a result of the start of the Sabarmati River Front Development works, the prices of the land have already increased dramatically, thus endangering the affordability of the city (Chayya in: Pessina, 2011). (5) Slum dwellers organisations, human right protection organisations, advocates and activists have also pointed out that one of the most controversial points is represented by the relocation of slum dwellers. While the need for better housing conditions cannot be questioned, both the relocation sites and the housing typologies seem to affect the possibility of the slum dwellers to carry on with their usual activities. Looking at the former uses of the river, it is evident that many of the seasonal activities that used to take place within the dry river bed and that are still present upstream and downstream of Ahmedabad have disappeared now within the city, thus depriving many people of their source of livelihood and their possibility to sustain themselves (Pathan, Patel in: Pessina, 2011).

4. The politics of scale

Questioning one of the core issues of the Sabarmati River Front Development Project - the origin of water - a whole range of new issues come into the picture. As already pointed out in the previous paragraph, the nature of the Sabarmati river is that of a non-perennial one, dry for most of the year. Quite surprisingly after the creation of the embankments in 2006, water became a constant feature of the river.
Such interesting and apparently strange phenomenon becomes clearer when looking at aerial views of the city (fig.4): the water is actually present only in the stretch of the river within the city of Ahmedabad, interestingly appearing just a few hundred meters southern than a canal.

In the relation between the river and the canal the relevance of the scale issue becomes evident: as a matter of fact, a connection has been created between the Narmada Canal, stretching from the eastern to the western border of Gujarat, that is to say, between the Sardar Sarovar Dam (or Narmada Dam) to the arid region of Kutch, at the border with Pakistan.

Figure 4. Aerial view of the city of Ahmedabad (source: Google Maps, 2011).

Again, the legitimacy of this action is questioned by lawyers: “Now they want to beautify the Sabarmati, therefore they want to take water from the Narmada. Legally speaking they cannot use Narmada water for Sabarmati [...].There was a longstanding dispute between Maharashtra, Madya Pradesh and Gujarat about this Narmada water and about the Narmada Dam. So ultimately there was a tribunal for deciding the distribution of water and the height of the dam and that dispute went on for a number of years, from 1960 to 1980s. So that Tribunal has allotted a certain amount of water to Gujarat, but it is mainly meant for agriculture [...]. In the map that has been prepared by the Tribunal Ahmedabad is not in the picture. Because Ahmedabad will get the water from the Dharoi Dam. So this Narmada water was not meant to Ahmedabad” (Patel, G: in Pessina, 2011).
A part from the question around legitimacy, the issue of water clearly shows the interconnectedness of different territorial scales (fig.5), which are not mentioned and apparently not taken into account in the Sabarmati River Front Development Project.
The different scales does not seem to be connected only through flows of water, but also and probably more significantly by “flows of power” (Worster, 1985).
The case of the Sabarmati river shows therefore the “politics of scale” (Smith, 1984) around which a large debate has risen in the last two decades.

Figure 5. The city, the river basin, the Narmada canal (authors elaboration on Google Maps, 2011).

While introducing such concept, Smith actually redefined scales as socially constructed, historically contingent, politically contested rather than related to fixed boundaries. One of the most engaged authors who tried to summarise the debate about scales (and the 'politics of scale') is certainly Neil Brenner (1998; 2004) whose works mainly aim at questioning the mainstream literature about globalisation and at investigating the transformation of various scales (especially the scale of the state) under contemporary capitalism. Even though large part of the literature about globalisation and world cities tends to depict the State as a weak actor that is retrenching and ultimately losing its power in a growing "space of flows" (Castells in: Brenner, 2004), Brenner argues that the State is actually just changing its (spaces of) actions, as suggested by Lefebvre already in *The production of space*: "Each new form of state, each new form of political power, introduces its own particular way of partitioning space, its own particular administrative classification of discourses about space and about things and people in space". Such process is thus defined *rescaling* (Brenner, 2004; Swyngedouw, 1999; 2004).
As Swyngedouw wrote (1999), "the preminence of the 'global' in much of the literature and political rhetoric obfuscates, marginalises and silences an intense and ongoing sociospatial struggle in which the reconfiguration of spatial scales of governance takes a central position". According to Brenner (2004), such globalisation rhetoric masks "the national state's own crucial role as a site and agent of global restructuring processes".

Referring mainly to Western Europe and to the United Kingdom, Brenner acknowledges the rise of new actors mainly operating at different scales than the one of the state mainly after the 1970s crisis: on one side global corporations, international organisations and cross-border institutions play a decisive role, while on the other side more powers are decentralised to the local level. Nevertheless he stresses the re-scaling of the state as "a key accumulation strategy" (Jessop in: Brenner, 1998) through which "cities throughout the world economy are being promoted by their host states as locational nodes for transnational capital investment" (Brenner, 1998).
It is evident that the role of the state, and its space of action, has significantly changed from the time in which it represented the main producer of welfare and the main mediator of spatial inequalities, nevertheless, the production of a "spatial fix" (Harvey in: Brenner, 2004) seems to be still needed, or maybe even more, in the age of globalisation.
Among the "new state spaces" Brenner lists "science parks, conference centres, waterfront development schemes and enterprise zones" that differ from the infrastructure that Keynesian states used to build after World War II in terms of aims and shapes: while in the past the State was mainly aiming at promoting an equal spatial development of national territories, nowadays such infrastructures – usually implemented by private investors but still requested by state authorities - are often "splintered" (Graham and Marvin in: Brenner, 2004), aiming at enhancing the global competitiveness of just some areas within national territories. A clear example of this trend is represented by the Thatcher policies to promote the primacy of London (and the South East of England) as a main financial centre through the (re)development of areas such as King's Cross, the Isle of Dogs, Canary Warf and Thames Gateway, while other parts of the country were becoming poorer.
Against the literature that sees the retrenchment of the state as a necessary outcome of globalisation, Brenner quotes Swyngedouw (2000) in order to highlight the growing role of various newly created state controlled agencies in planning and managing these local mega-projects as it is the case – particularly diffused in the Thatcherite policies – of the Urban Development Corporations or think tanks such as London Forum and London First. As a matter of fact, through the process of state re-scaling, not only exceptional spaces but also exceptional actors – that are not elected, nor responsible towards the citizens - enter into the arena. As Swyngedouw writes in 2005, "in fact, it is the state that plays a pivotal and often autocratic role in transferring competencies (and consequently in instantiating the resulting changing power geometries) and in arranging these new networked forms of governance" in which "the internal power choreography is customarily led by coalitions of economic, socio-cultural or political élites".

The case of the Sabarmati River Front Development Project seems to clearly support the theories that show the centrality of the state even (or maybe, especially) in a context of globalisation. As a matter of fact, the State of Gujarat represents one of the main promoters of the Sabarmati project and considers it one of the strategic actions on water in Gujarat, alongside with the construction of canals and dams. Moreover, the river front represents an "exceptional space" (Brenner, 2004) within

the city in terms of design, foreseen uses and scale and as it happened mainly in the context of UK an “exceptional agency” (ibidem) - the Sabarmati River Front Development Corporation Limited (SRFDCL) - has been created by the AMC under the request of the State of Gujarat and is therefore strongly bound to the state.
Looking at the state at a broader level, the National Government of India is contributing to the project through the JNNURM programme, while multinational companies are attracted by the real estate opportunities on the riverbanks, thus creating a not clearly accountable “governance-beyond-the-state” (Swyngedouw, 2005)

5. Conclusions

The case of the Sabarmati River Front Development Project in Ahmedabad shows the power of narratives around sustainability and ecology (Mehta, 2005; Scoones et al., 2007; Swyngedouw, 2010) in the promotion of the aspirations towards development and globalisation. Exceptional spaces such as the Sabarmati River Front Development Project, mainly managed by newly appointed institutions, seem to represent the new necessary “spatial fix” (Harvey, 1985) for the production of capital and power at multiple scales, not excluding the State one, often neglected in the literature about globalisation (Brenner, 2004).
Such case shows also the contested nature of sustainability (Scoones et. al., 2007), through some of the voices of dwellers, practitioners, academics and in general persons affected in different ways by the project.
These elements would not be enough to justify the interest of the case and the will of the author to go back to Ahmedabad in order to further explore the issues so far emerged, if it was not considered a replicable example throughout India: “Whatever the outcome, the project is a leitmotif in the context of river and waterfront redevelopment projects now popping up in Indian cities like Mumbai, Delhi, Calcutta and Lucknow. Ahmedabad is breaking new ground, both literally and figuratively, in the redevelopment of Indian cities” (Fenk, Scheffer, 2009).

Acknowledgments

The author is a PhD Student in Spatial Planning and Urban Development at Politecnico di Milano (Italy) and currently a Visiting Research Student at the Institute of Development Studies (UK). She has also been a Research Fellow at Vastu Shilpa Foundation for Studies and Research in Environmental Design (Ahmedabad, India) between November 2010 and January 2011. The author would like to thank the Vastu Shilpa Foundation and Consultants and in particular Shri Balkrishna V. Doshi, the founder of the office, for his wise suggestions and for the stimulating questions and Arch. Rajeev Kathpalia, the director of the office, for his acute observations to the work. A special thank to Arch. Piyas Choudhuri that introduced the author to the Sabarmati during the workshop *“The river, future of a territory”* organized by Les Atelièrs in Cergy-Pontoise in 2009 and helped her during the research both with the work he has conducted for his award-winning master thesis (*Re-structuring the development along a non-perennial river. Case: Sabarmati River,*

Ahmedabad, CEPT University, 2009) and with his support during some interviews and field visits. A thank to all the architects, urban designers and interns working at Vastu Shilpa Consultants for their continuous interest for the research and for their questions. The author would like also CEPT University (Ahmedabad) for the support and in particular Prof. Neelkanth Chhaya, the Dean of the Faculty of Architecture, and Prof. Vasavara, the Head of the Centre for Conservation.
Further reflection upon the case study were stimulated by Prof. Antonio Tosi (Politecnico di Milano) as well as by Prof. Lyla Mehta (Institute of Development Studies) and Prof. Erik Swyngedouw (University of Manchester). The author is also grateful to the STEPS Centre for having organised the "Alternative Pathways to Sustainability" Summer School, during which the importance of narratives has become a crucial point for the research.

THE SPATIAL DIMENSION OF ENERGIES: URBAN PATTERNS AND ECO-STRATEGIES

Eugenio Morello [1], Stefano Pareglio [2], Silvia Ronchi [3], Silvio Rispoli [4]

Abstract

The outcomes of an experimental urban design studio named "Energy and urban Planning" offered to graduate students enrolled in the Urban Planning and Policy Design master programme are presented in this paper. The goal was to recognize the importance of the role that the urban planner can play in assessing both the suitable energy scenarios and the spatial dimension of energies on the territory by introducing a set of disciplinary references and a toolkit for action. A number of tools for the analysis and the design of energy-conscious urban master-plans were offered to students with limited competences on environmental and energy topics.
The case-study area chosen for the design was the metropolitan region of Milan, Italy, characterized by a temperate climate and a variety of morphological configurations, for simplicity grouped in three main categories, namely what we call the Compact City, the Edge-City and the Diffused City. In particular, seven samples of that territory were selected, investigated by seven teams of students, and proposed solutions were given.
Outcomes of the studio show that the contribution of the urban planning discipline can be relevant in assessing alternative energy scenarios, both in terms of quantification and evaluation of design solutions. For instance, taking into account energy and environmental aspects from the beginning of the design process, highly impacts on the concept solutions and the final physical layout of the built environment (in terms of land use and morphology). Hence, energy-conscious urban planning might lead to significant energy savings. Moreover, the scale of action, i.e. the small town or the district level, reveals to be a proper dimension in order to apply urban ecology principles.

1. Introduction: objectives of the studio

It is evident that different urban configurations present different energy consumption implications. Which is the contribution of the urban planning and design discipline in addressing sustainable future scenarios for the city is a crucial question. We believe that urban planners' expertise can inform the debate on energy in three ways as

[1] Laboratorio di Simulazione Urbana «Fausto Curti», Department of Architecture and Planning, Politecnico di Milano, Milano, Italy – eugenio.morello@polimi.it
[2] Centro di Ricerche per l'Ambiente e lo Sviluppo sostenibile della Lombardia, Dipartimento di Matematica e fisica - Niccolò Tartaglia, Università Cattolica del Sacro Cuore, Brescia, Italy – stefano.pareglio@unicatt.it
[3] Department of Architecture and Planning, Politecnico di Milano, Milano, Italy – silvia_ro@hotmail.it
[4] Department of Architecture and Planning, Politecnico di Milano, Milano, Italy – silvio.rispoli@mail.polimi.it

follows: firstly, in assessing the spatial dimension of energies within the urban landscape, thus acknowledging the physical layout as a key component of environmental sustainability. Secondly, in measuring and quantifying urban sustainability indicators, according to the increasing demand for evaluation and monitoring of urban policies; thirdly, in proposing innovative design solutions for the built environment (both the fabric and the open areas), which optimize the use of energy and mitigate environmental depletion. This latter aspect should be intended as a long term research perspective aiming at informing the debate on new urban design and planning theories.

The objective of the studio is twofold: first, to provide a basic knowledge on the topic of sustainability at the urban scale (policies and design) and second, to explore possible future scenarios through a design project that intentionally considers the implications of the different urban forms for the construction of site-related strategies and actions (eco-zoning). In particular, we explored two main ways to achieve more sustainable urban environments: one is related to the policies that the city can adopt in order to promote more environmental-friendly practices; the second one is related to the physical design of the urban environment and how this can influence sustainability.

2. Research context

During the class we referred both to the scientific literature and to international policies and standards. In particular, scientific literature gives a global picture of innovative approaches and the rhetoric of different disciplines, whereas policies enable to frame the political context and the targets of our actions for the next decades.

Punctual scientific references on energy come from several areas and the urban planning discipline should extract those relevant clues that have a direct feedback on the practice. One area of interest can be named “urban energy transition” according to the book edited by Peter Droege (2008), and refers to a series of studies focused on energy planning and metabolism towards a renewable, carbon-neutral city. In this sense, the type of investigation is related to the assessment of available and future clean technologies and the policies and strategies of diffusion (Mega, 2010) with a scarce feedback on the physical dimension of the territory.

A second set of references can be grouped under the umbrella of “urban ecology”, which originated from ecology studies (Odum, 1963; Odum, 2001). In particular, the introduction of the Ecological Footprint concept by Mathis Wackernagel and William Rees (1996) was a first attempt to relate ecology to the spatial dimension of human impacts. The more recent debate on sustainability strengthened the issue of the limited natural resources on Earth. However, the concept of sustainable development appears to be contradictory to some authors (Latouche, 2006), who reject the argument of growth in a finite world and support the paradigms of scarcity and self-sufficiency. According to this latter vision, the first aim of the design studio

was to reduce human impact on the territory through energy savings and efficiency, and only in a second step to produce clean energy on site.

Finally, "energy-conscious spatial planning" and "sustainable urban design" represent the most pertinent research contributions for the design studio, because they argue the importance of the urban planning discipline in sustainability issues. A critical approach to recent sustainable urban design contributions was required to students, and the use of tools derived by that research stream were proposed and applied during the studio.

Energy-conscious planning originated from urban ecology considerations, and proposes a physical declination of energy scenarios in relation to the type of territory and the possible synergies and dependencies among different patterns, whereby the built and un-built territories are intended as components of an eco-system that should work – and survive – with closed cycles, stressing off-grid solutions and the reduction of the ecological footprint of urbanized areas. The "Second Law thinking" reminds us that during each transformation, a certain amount of useful energy (i.e. exergy) is transformed to a less useful energy (i.e. entropy), thus we have to save high quality forms of energy (Stremke & Koh, 2010; Van den Dobbelsteen, et al., 2011).

The second discipline is rooted in the New Urbanism and Smart Growth movements (English Partnership with the Housing Corporation, 2000; Farr, 2007; Duany, et al., 2010; Haas, 2012) and reached a large audience and success due to the capacity of structuring a series of sustainability principles related to the physical design of the urban environment, and delivering simple guidelines, rules and certification systems for professionals (U.S. Green Building Council, 2009).

Reference for this work are EU policies promoting effective tools and programmes to achieve sustainability and energy self-sufficiency, in particular the 20-20-20 targets and the recent Roadmap 2050 for a low-carbon Europe. The Covenant of Mayors with the introduction of the Sustainable Energy Action Plans (SEAP) represents a useful framework for addressing objectives, strategies and actions at the urban scale (The Covenant of Mayors Office, 2008). Significant Action Plans delivered by big European cities were consulted and compared in terms of proposed actions and sectors of investment. Nevertheless, we noticed that most of the plans were conceived as guidelines with a lack of urban design solutions and scarce reference to the spatial dimension of the territory in general.

3. Case-Study areas

The metropolitan city represents a mosaic of fragmented urban environments, each of which shows different opportunities in terms of environmental and energy scenarios. In particular, an urban transect crossing three main typologies of settlements was recognized as the object of investigation at the studio. Hence, we distinguished among three types of urban environments: firstly, the Compact City,

i.e. the urban cores characterized by a significant mix of uses; secondly, the so called Edge City, i.e. the in-between places that host relevant services for the management of the entire city and were built without a coherent vision; thirdly, the Diffused City, which represents the flourishing low-density, car dependent sprawl, where land consumption has already exceeded acceptable limits in terms of environmental preservation. Seven teams were asked to work on seven samples of the territory considering the different critical issues and opportunities they have.

For the Compact City, two areas with totally different character were chosen. The first site, the Ortomercato (the wholesale vegetable market for the city) represents the occasion of the conversion of the current function into a new neighbourhood on the east side of the city; the second area, on the other hand, is the re-appropriation of a large surface currently occupied by the freight railroads in the centre of the city, thus primarily reconsidering the reconnection and the renewal of the existing fabric.

The three sample areas selected to describe the Edge-City conditions are not enough to cover the variety of the typologies we can encounter. For sure that is the transect which offers more occasions of transformability, because of its recent history with low value interventions and scarse coherence with the surrounding. The first site is the city waste management headquarter at the east periphery of Milan, a typical troublesome function relegated close to the boundaries of other municipalities. Nevertheless, this portion of the city is still facing an agricultural land, which might represent an opportunity to work with in terms of urban ecology. The second sample is the Baggio district, an old historical nucleus in the west periphery of the city. Dealing with the already established urban fabric with few occasions of redevelopment, forces us to conceive new ideas to achieve sustainability. The last area is a free agricultural site in the municipality of Rozzano, south of the city, where the new city plan expects to build a new high density and mixed uses neighbourhood, with serious problems of connectivity to the existing street network, due to the presence of a canal and two highways on the boundaries.

Finally, the Diffused City was well represented by two areas that show different characteristics. The first area, i.e. the town of Lainate, is the typical urban agglomeration that can be found in the northern part of the metropolitan region. In fact, Lainate is the result of the grouping of different small communities which go without solution of continuity on the territory. Housing and production are mixed; islands of residential neighbourhoods are interspersed with heavy transport infrastructures. The second town, Melzo, on the contrary, is a compact settlement located in the eastern part of the region characterized by a strong agricultural land use.

4. Methodology and design process

4.1. Research by design

The goal of the studio is to come up with a design project at the district or urban scale that envisions possible future scenarios for a number of different cityscapes.

Students are asked to work in groups of three people; each team should be composed by students with different backgrounds, in order to integrate their skills.

Encouraging ‘research by design’ is part of the methodology of the studio. This will be investigated through the introduction of tools for the analysis and the design of future conditions. Students are asked to explore at the same time urban re-composition strategies and the introduction of eco-strategies and actions suitable for each different urban environment.

The series of lectures is offered to the students and has the goal to introduce the topic of sustainability applied to the urban planning and design discipline. The lectures aim at covering the two main topics, namely one is related to the policies that the city can adopt in order to promote more environmental-friendly practices; the second one is related to the physical design of the urban environment and how this can influence sustainability. The first series of lectures is called "Energy, climate change and local action to reduce greenhouse gases (GHG) emissions"; the second one, deals with the topic "Energy, environment and the city form". In particular, the first series introduces the policies (mitigation and adaptation) towards carbon neutral cities and analyses issues related to energy sources and the market to figure out possible scenarios; the second series of lectures investigates how urban designers and planners can work on the physical layout of the urban form in order to improve the overall sustainability of cities and reduce the environmental footprint of ecological cycles, by improving the efficiency of mobility and energy management (savings and production based on a short energy chain).

For simplicity and due to evident organizational reasons of a one-semester long studio, the design process was structured in three phases: the analysis, the concept-plan with the identification of general eco-strategies and the master-plan with the localized eco-strategies. Of course, we recognize that the process can never be linear, but the given path represented a helpful framework to organize and deliver the different tasks during the studio.

Four themes directed our observations on site and were used as lenses during the whole design process: energy (energy efficiency and renewable energies), environment (environmental quality and comfort, water, waste, permeability), accessibility (sustainable mobility, smart linkage of places, way-finding) and people (place-making, sustainable lifestyle and policies for sustainability). The proposed themes were deliberately broad to encourage an interdisciplinary approach, were interrelated, could overlap and be understood as an opportunity to focus on specific actions that can inform design. In order to guide the exploration and to inform the students about the variety of actions they can implement, the delivery of a “glossary of common terms” was assigned. For instance, each team had to give the definition to a number of terms (actions) and provide a synthetic sheet with description, pictures and references. The glossary was structured according to the four themes introduced above. Once finalized, the glossary was shared among the students and used as a checklist to identify suitable design strategies.

4.2. The analysis

In the first step, a deep analysis of existing urban patterns, available cartography, plans and programs (also environmental and energy plans, if any) were investigated to achieve a baseline for the design. In particular, we referred to available cartography and plans from public datasets[5] with the following targets: firstly, to get a comprehensive picture of the programmatic context above the city level in order to verify the compliance of planning options; secondly, to investigate the energy and environmental guidelines established at the regional level, which are necessary for the planning of territorial development policies; thirdly, to manage datasets and spatial information, useful for the territorial understanding of the study areas; finally, the investigation of the environmental framework.

A series of samples extracted from the map were analysed and described, focusing in particular on the shape of the urban fabric and the street network. For instance, a series of clues derived from the shape of those places defined the strengths or weaknesses of the urban tissues and represented the design elements for rethinking more sustainable future scenarios.

A series of maps describing the current situation and conceived as a support for the following design phases was assigned to students as listed below.

- Map 1, Superimposing the case-study area over the centre of the city.
- Map 2, Recognizing patterns (both urban and rural). An interpretation of land use patterns recurring on the territory was asked. Categories had to be provided by identifying morphologies and approximate year of foundation (Figure 1).
- Map 3, The "hard" and the "soft" patterns (Figure 2). The chart gives back an interpretation of those parts of the physical context that can be considered as unchangeable and those parts that might be transformed in the near future. A range of degrees of transformability in between hard and soft can be introduced.
- Map 4, Main land use and soil permeability (Figure 3). This is a map where the three main land uses are indicated: covered areas (buildings) in black, paved open spaces (streets, squares and infrastructures) in grey, and permeable surfaces (green areas, water, non-urbanized areas in general) in white.
- Map 5, Densities on site. Urban morphologies are identified and a qualitative density to macro-areas is assigned, considering groups of blocks.
- Map 6, Street network hierarchy and mobility routes. The existing street network is highlighted and the hierarchy of streets identified. The network of public mobility (train, buses, subways, etc.) is included on the map.

[5] Main sources used: Piano stralcio per l'Assetto Idrogeologico (PAI); Rapporto sullo stato dell'ambiente in Lombardia 2009-2010; ARPA Lombardia; Rete Ecologica Regionale (approved with DGR n. 8/10962 on 30 December 2009); maps and geo-referenced data from the GEOportale di Regione Lombardia; Piano Territoriale di Coordinamento della Provincia di Milano together with the Valutazione Ambientale Strategica; Piano Territoriale Regionale (PTR) with the Piano Paesaggistico (PPR); Piano Energetico Regionale.

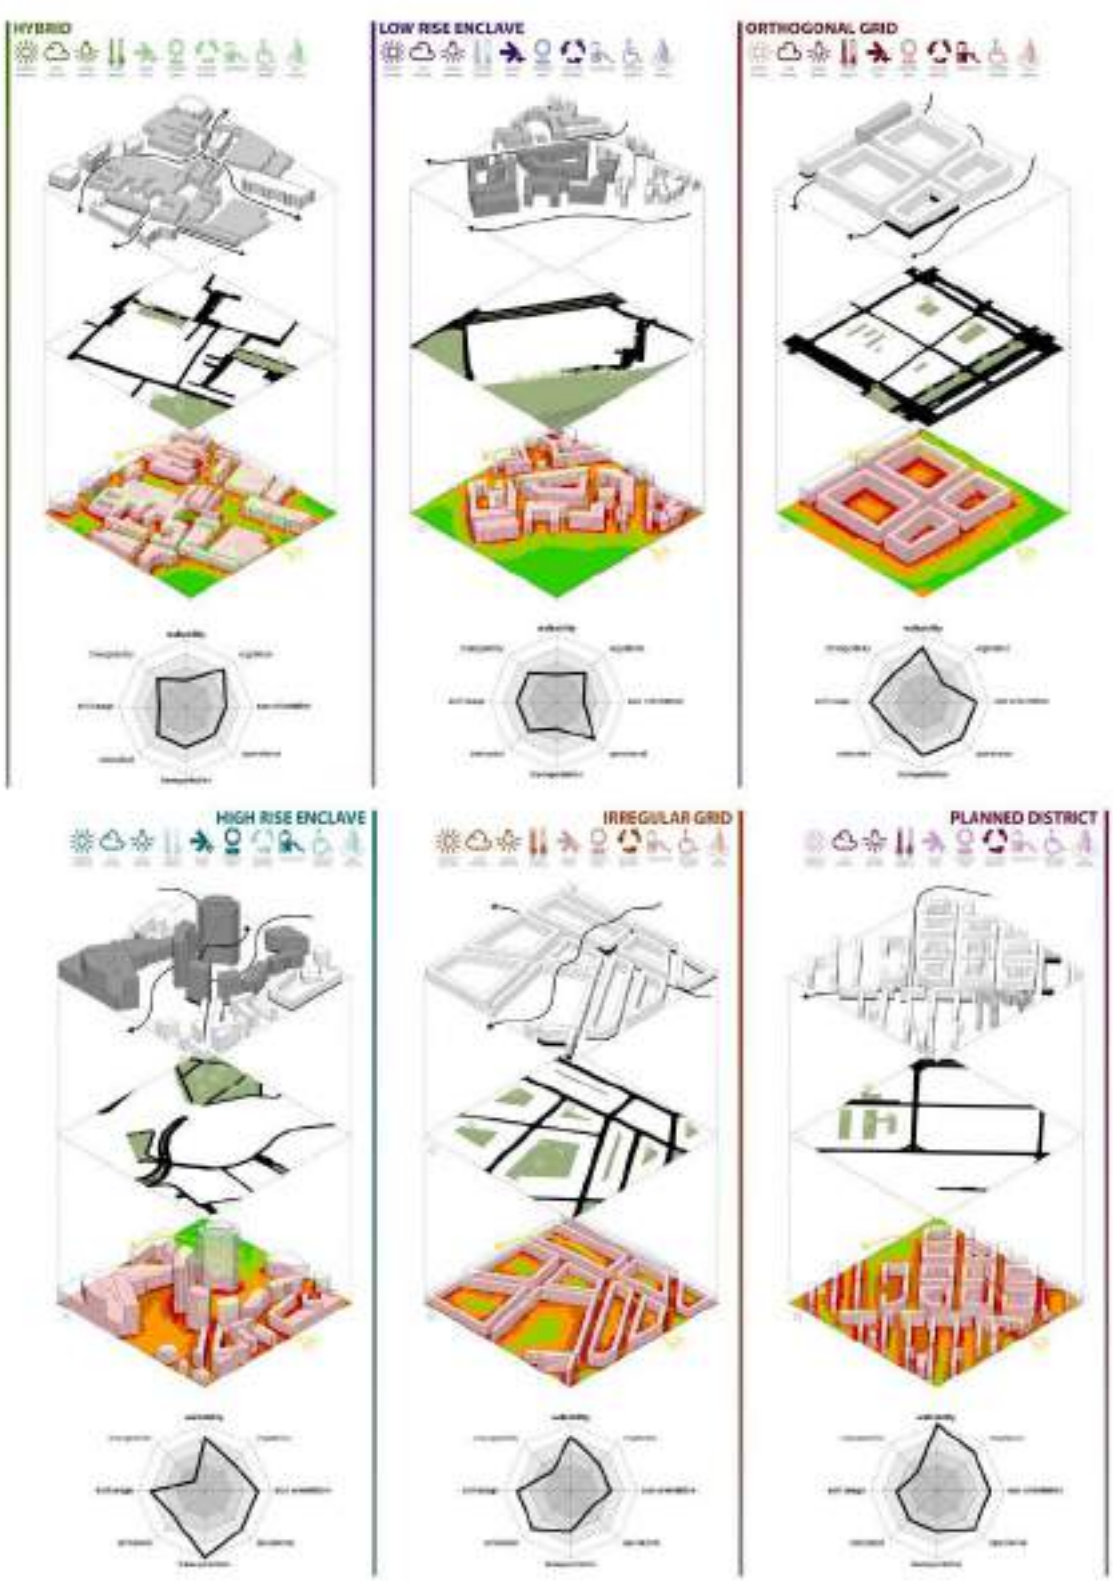

Figure 1. Recognizing urban patterns and investigating urban environmental quality aspects related to the urban form.

Figure 2. The “hard” and the “soft” patterns: the east periphery of Milan where isolated districts coexist with open agricultural land and infrastructures.

Figure 3. Land use permeability samples showing different conditions through the transect from the city centre to the periphery.

- Map 7, The natural green structure. Public and private green areas are defined and urban parks, pocket parks, ecological corridors, big regional parks and similar are identified. Moreover, forests and areas with a high vegetation density, rivers and bodies of water, if any, have to be mapped.
- Map 8, Existing urban services and facilities, both public and private, are identified according to a given set of categories. The main areas and axes of commerce and retail should emerge on this chart.

4.3. The concept-plan with the eco-strategies

The concept-plan is intended as a preliminary design that includes observations at a higher level in order to understand the role of the urban district in its larger context (hierarchies among districts, specific characteristics that define the identity of places) (Figure 4). The four themes (lenses) introduced above supported students in structuring possible strategies and finalized actions to define design solutions. In particular, we focused on those sustainable technological and infrastructural solutions that have a direct feedback on the design of the urban form, both at the building scale and at the territorial scale (

Figure 5). This phase was informed by the previous work on the glossary of common terms.

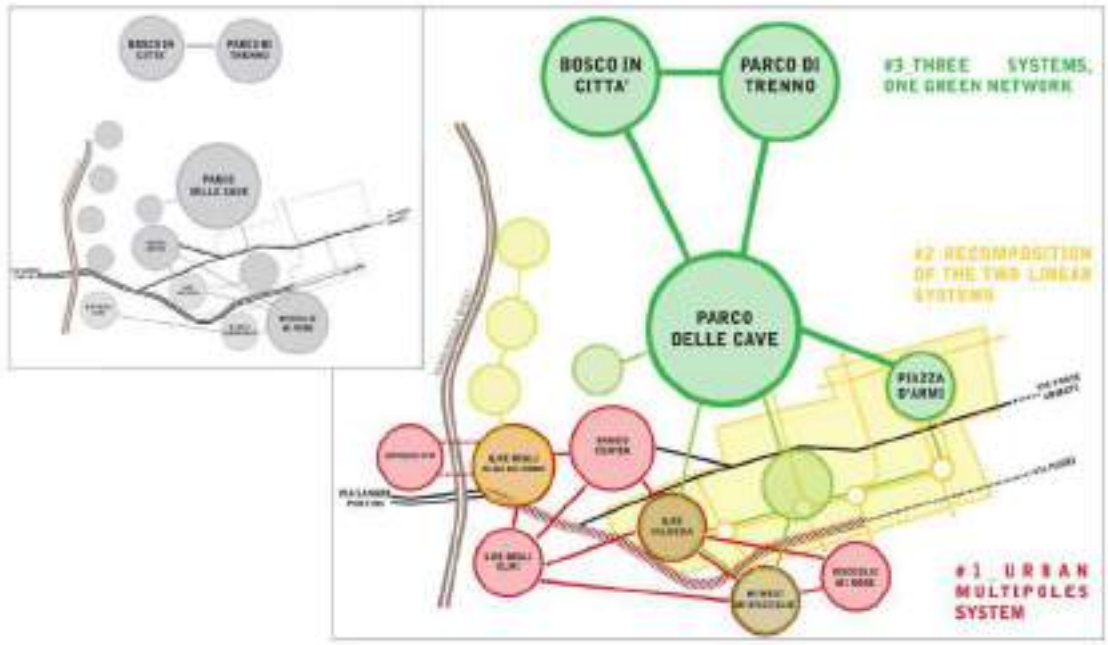

Figure 4. The re-composition of the urban districts in the west periphery of the city: the establishment of new hierarchies and connections among the neighborhoods, the streets and the big urban parks are considered together.

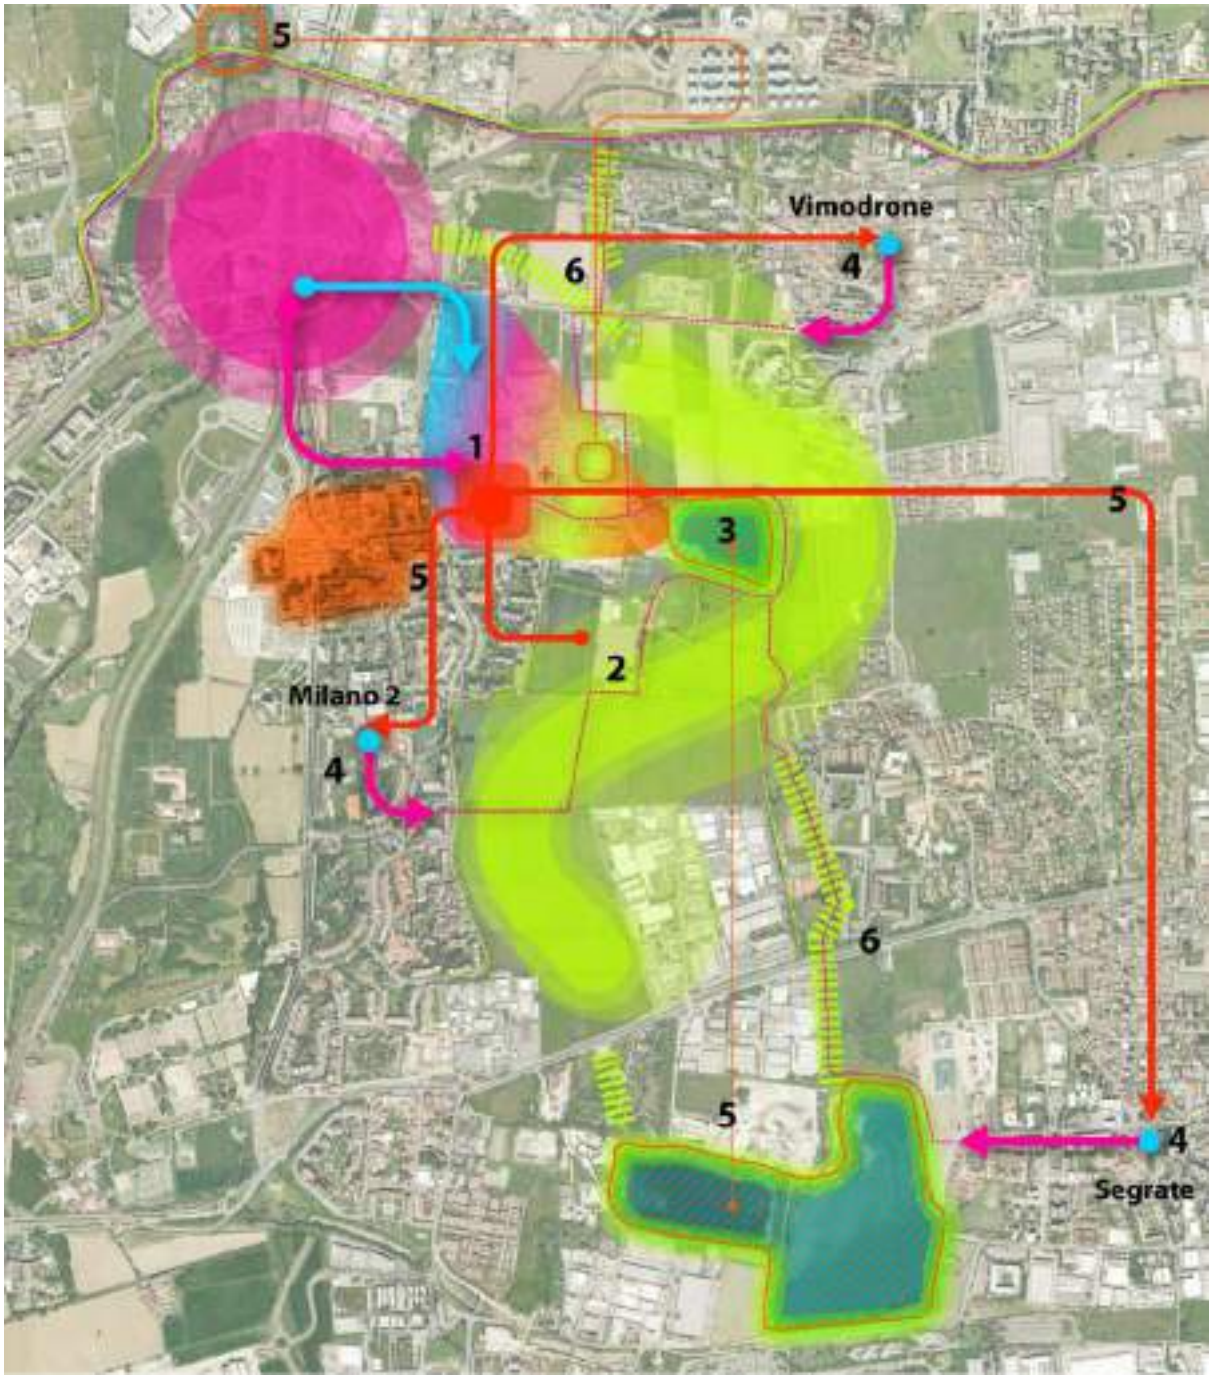

Figure 5. The energy concept-design for the Energy Park in the eastern periphery of Milan: (1) The new energy-oriented centrality; (2) The "Golfo Agricolo", a green connective tissue with a suburban forest; (3) Quarries, a geothermal source of heat; (4) The existing city with district heating; (5) The improvement of the energy network between the hospital and the other mono-functional districts; (6) Establishment of new green connections.

Moreover, we worked on the implementation and application of simple tools for modelling urban environmental quality (UEQ) and energy indicators in urban planning and design (solar accessibility, connectivity and accessibility, soil permeability). These tools enable to evaluate between alternative scenarios, to verify design schemes and to establish rules for mitigation and compensation. In particular, indicators and maps were used as comparative studies, to assess the changes introduced with the design schemes (before and after intervention). In fact, UEQ indicators are helpful if used as a design tool to evaluate among alternative solutions (Figure 6). For example, the study of the solar accessibility of different urban blocks was used as the basis for the re-invention of a suitable urban block with a higher performance that combines passive architecture needs (solar access on facades) and active architecture requirements (solar access on the roofs for the production of solar energy).

Figure 6. Connectivity analysis of the urban texture: left, the current situation; right, the proposed design scheme improves the overall connectivity by introducing a new central district and reducing the number of cul-de-sacs.

4.4. The master-plan with the eco-actions

The final step was the delivery of the masterplan, which in this case gave back a vision of a possible future for each specific case-study area. In this last insight, the actions related to the four themes (energy, environment, people, accessibility) have been made visible through a spatial localization and sizing, and some clues that an answer to more sustainable urban futures is possible emerged. The vision was supported by the theories and readings, and by the previous phases of the design.

The masterplan consists in a plan (1:2.000 or 1:5.000) on which a meta-design of the built volumes and the street design is clearly visible (Figure 7). For instance, the level of detail goes down to the scale of urban design: the layout of the street with traffic calming solutions, the size and depth of buildings (blocks and plots included).

On that map, the location of the eco-actions is reported and some insights on the proposed solutions attached.

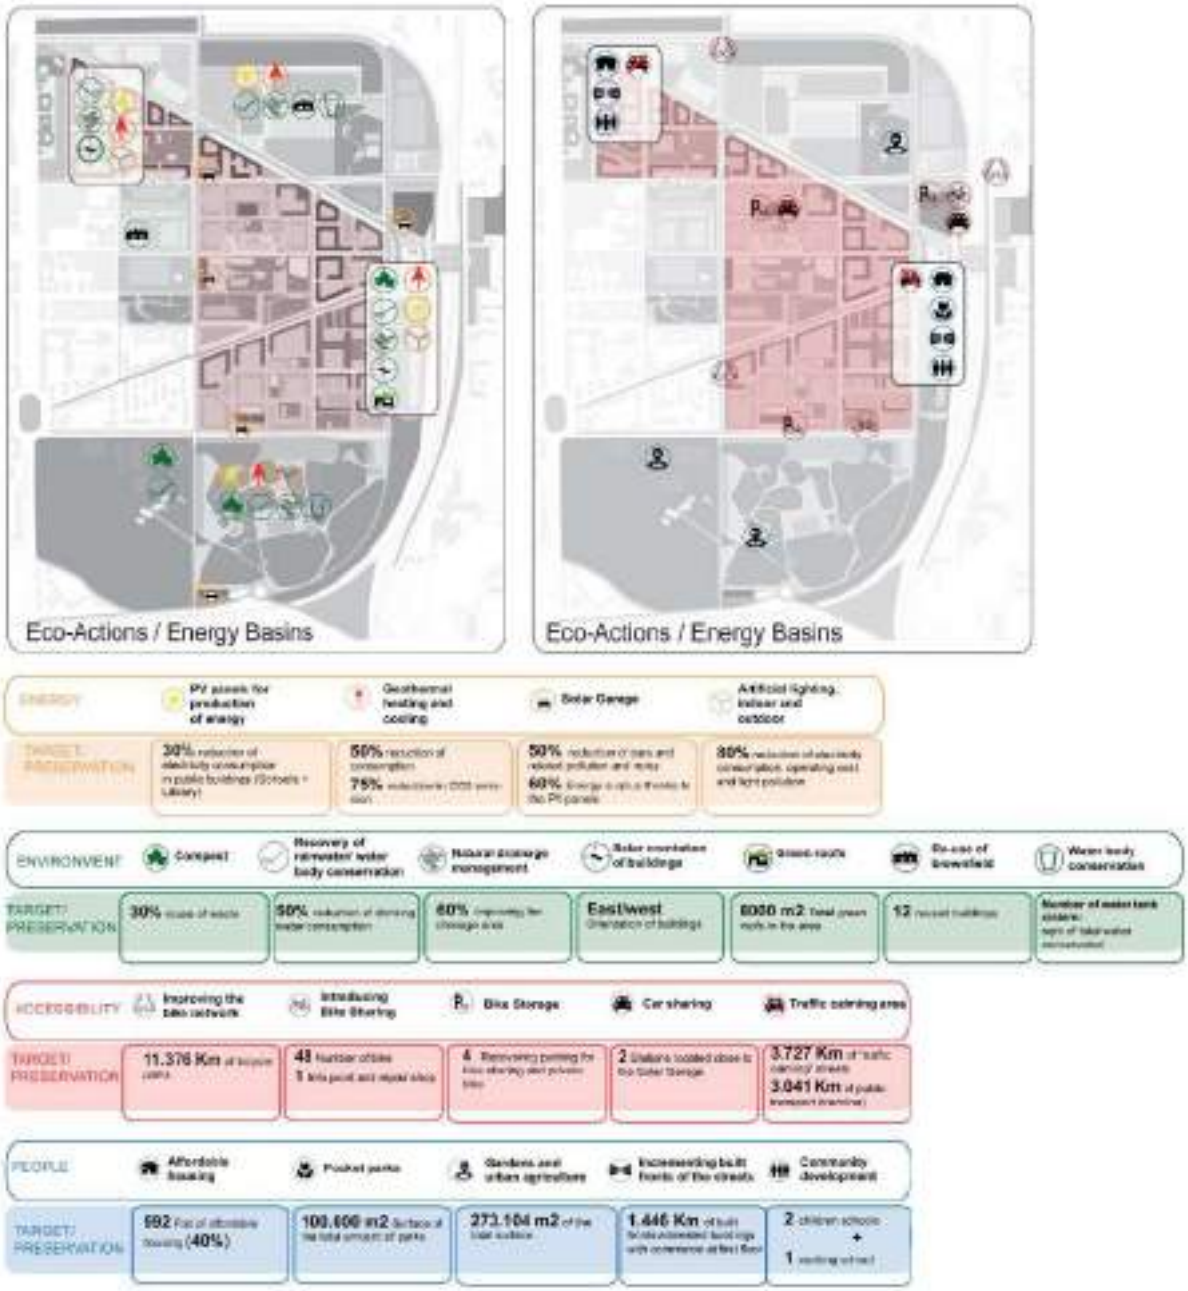

Figure 7. The eco-actions distributed over the masterplan according to the four themes, namely energy, environment, accessibility, people.

5. Outcomes

Different samples of the territory show different potentialities in terms of energy savings and clean energy production. The proposed design schemes try to combine urban planning strategies and energy aspects. Beyond the scale of the building where

green technologies are widely used, urban master-planning offers the possibility to scale up energy efficiency if properly taken into account from the initial concept design. A series of design solutions are presented below and analysed through the four themes of the studio (energy, environment, accessibility, people).

5.1. The Compact City

Concerning energy issues, we faced two main areas of investigation for the Compact City: retrofitting the existing urban fabric (buildings) and layout (street network) and proposing new neighbourhoods with carbon-neutral solutions. The idea is to introduce site specific rules and incentives at the scale of the district or even the block. Depending on the age of the buildings, for instance, different policies can be applied. The large stock of buildings from the ‘50ies and ‘60ies requires heavier intervention (from insulation of the walls and the replacement of windows, to the redesign of the urban street fronts which is often missing), as opposed to older or more recent buildings. Only after the retrofitting of the building envelope, the remaining energy needs can be satisfied through the installation of solar energy technologies (photovoltaic and solar thermal as in Figure 8) and geothermal solutions. A small cogeneration plant might be an option in the presence of a critical mass of users. District heating is also a solution and already provided in some parts of the city. Hence, the choice of the most suitable technology to achieve the energy self-sufficiency of the built environment depends on the cityscape (in terms of density and shape) and the quantification of different productions is a crucial aspect.

A relevant aspect of the compact city is permeability of the soil and wastewater. The presence of large paved surfaces and roofs was clearly highlighted from the permeability analysis. The existing urban fabric does not have many possibilities to improve the situation, but new neighbourhoods and urban parks are the occasion to adopt the proper infrastructure to separate wastewater on site and reduce the load of the sewerage system. The master-planning phase has to take into account the location and the sizing for street design solutions with innovative drainage solutions.

In both cases, the inner city of a metropolitan area offers a unique occasion for implementing an efficient sustainable mobility. For instance, public transport and bike lanes represent the basic solution to achieve energy savings in transport; further strategies like car-free neighbourhoods, car-sharing and policies for the introduction of private electric vehicles (dedicated parking areas and solar garages) were proposed. Again, all the mobility strategies have to establish a strong link to the physical design of spaces: in fact, without a proper design of both the street network (in terms of hierarchies of paths) and the built form (distribution of densities and land use along transportation nodes), mobility strategies might fail. Moreover, the proposed analysis on accessibility had the aim of improving pedestrian movements on the territory by providing more paths and hence a larger catchment area (the so called ped-shed). Creating pedestrian friendly environments is not just a matter of quantity but also quality: traffic calming solutions, attractive fronts and the presence of services are key factors for successful streets. All the buildings have to be

reachable within a five minutes' walk in order to avoid the use of private vehicles and enable the introduction of car-free districts.

The city is the best place to trigger behavioural change and to gather people with common interests. A dedicated program for a solar community that shares the diffused renewable energy produced on site, the introduction of a series of initiatives for improving a sustainable lifestyle (bio-market, sharing of facilities and co-housing), mixed uses and diversification of population are only few samples. In fact, the paradigm of mixité has also energy implications: the coexistence of different typologies of citizens and urban functions means different lifestyles and energy peaks in time. A smart mix of energy uses can lead to site-specific policies aimed at smoothing peaks.

Figure 8. The analysis of the solar potential on new roofs: above, the quantification of available roofs, and below, the suitable areas to be connected in a closed network.

5.2. The Edge City

The periphery of the city offers the most diversified catalogue of land- and cityscapes. The presence of large areas susceptible to transformation, the balanced mix of built spaces and natural environments (mostly residual green areas) represent the most intriguing challenges for future city scenarios. In that physical context, the application of urban ecology strategies is possible and desirable. For instance, the presence of a pond obtained from a quarry is the occasion to exploit the temperature of the water body to produce energy through heat pumps that can be activated through electric energy generated from photovoltaic modules installed on roofs (Figure 9). In another case-study area the rich agriculture and farm production close to the city can provide biogas and biomass for a small local plant (Figure 10).

Large natural areas can be converted into parks or preserve the agricultural function, if any. Those parks can represent the showcase to implement sustainable agriculture

or biomass plantations (short rotation forestry). Sustainable strategies for water management can be implemented as well.

Concerning accessibility issues the edge city is the place where interchange of transport systems happens. Investigating new solutions for the design or interchange nodes will improve sustainable mobility. Innovative solar garages for commuters with dedicated solutions to encourage the use (and ownership) of electric vehicles in the city and car sharing programs can drive a significant change in the urban mobility. From an urban planning perspective, the edge city was mostly built as a juxtaposition of segregated functions with little interconnections among each other. In fact, the proposed concept-plans aim at establishing new hierarchies and legibility among closed districts.

In terms of social strategies, the general aim on the sprawl city is to provide a stronger urban character to places, thus reducing the need to move to the city and creating a stronger sense of belonging: mixed use, mixed densities, social mix, environmental diversity, access to abundant natural areas, transit oriented districts are the key actions to be implemented.

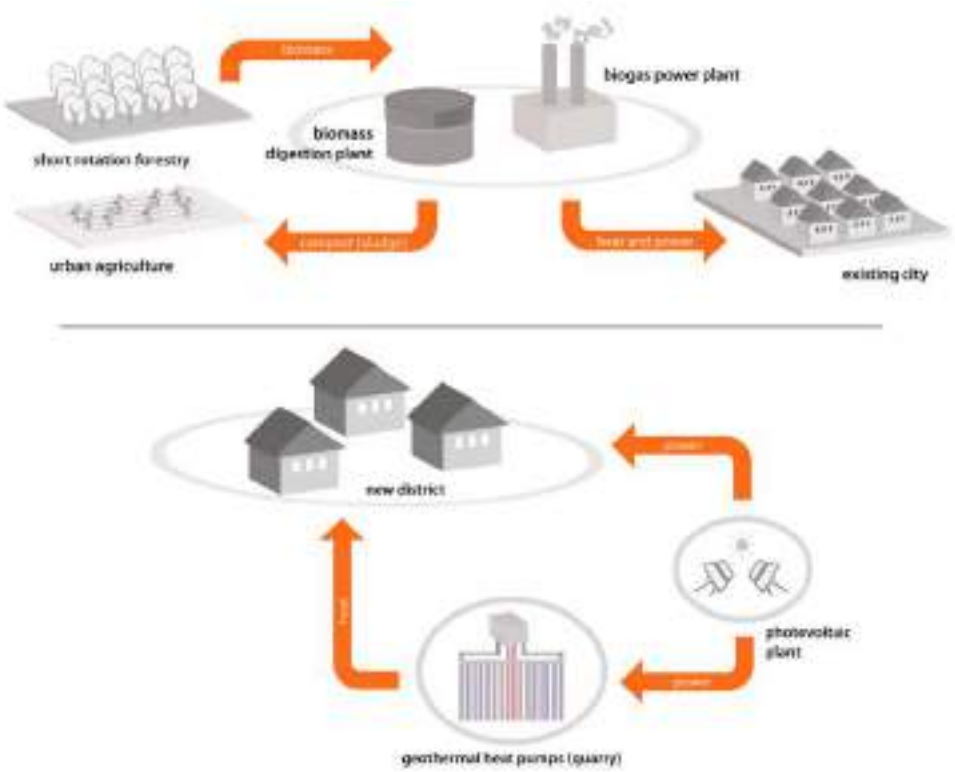

Figure 9. Energy cycles on site: above, the introduction of a biomass cycle with a short rotation forestry plantation in the park and the installation of a biomass digestion plant to produce compost for urban agriculture, plus a biogas power plant to provide heat and power to the existing urban fabric. For the new district (below) geothermal heat pumps work with the water of the flooded quarry. PV panels on roofs provide the power for the pumps that generate heat and cool for the buildings.

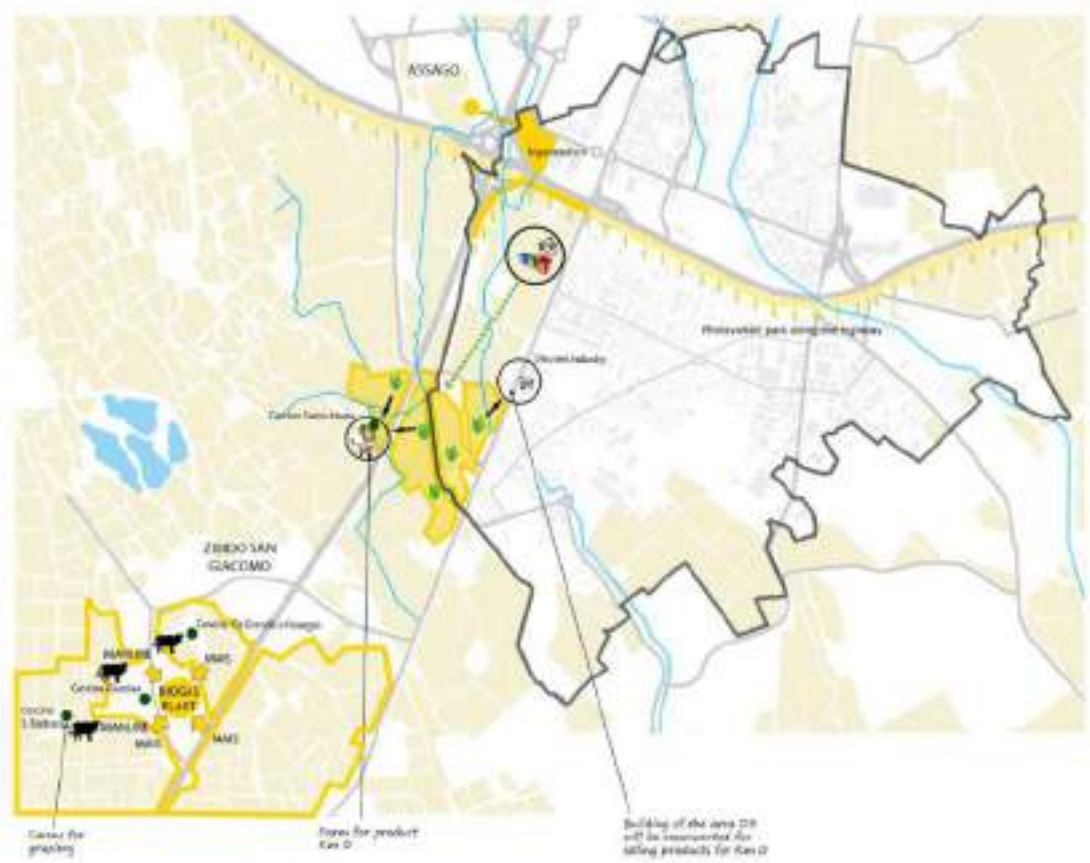

Figure 10. The renewable energy framework aims at reaching a self-sufficient production for the new development. For instance, agriculture and farm production provide useful material for a small biogas plant to be installed on site and serve existing neighbourhoods. The energy for the new district will be provided by a trigeneration plant and the installation of a linear PV park along the highway.

5.3. The Diffused City

A low-density city form encourages to look for energy solutions at the small scale. For instance, the carbon neutral building equipped with eco-technologies is the easiest strategy to pursue in the absence of more effective urban planning solutions, like urban infilling (densification of the urban form as proposed in Figure 11). In the northern part of the metropolitan region, the diffusion of industry represents an occasion for the replacement of part of the production with more sustainable retrofitting strategies (using roofs for solar energy production or green roof technologies for drainage and thermal mitigation of the urban environment). For instance, the role of industry should be converted from energy consumer to energy producer. In particular, the deep interrelation between household and industry on this territory can be intended as a resource in terms of mixité, thus it might be convenient not replacing industry with residential areas but with other forms of production (clean energy) and workplaces (services and tertiary). Another key-element on the territory is the presence of large transport infrastructures that cross and divide places.

Railways and motorways together with the residual spaces they create could be reinvented as energy conducts, thus having a positive feedback on the territory (Thün & Velikov, 2009).

Environmental actions aim at improving and increasing the open space and green structure by insisting on ecological connections and wooded areas (re-composition of natural patterns). This supports the maintenance of a high degree of permeability of the soil to be complemented by the development of a system for the rainwater management, which requires a strong link to the physical master-planning of places. Moreover, weak residual agricultural areas could be converted for local production by introducing dedicated policies.

Accessibility remains the big issue of the sprawl city. Promoting the polycentric city with transit oriented developments matches the most popular urban design approach. Nevertheless, that strategy had scarce success in the recent past, if we consider the vast use of the private car and the economic costs to sustain an efficient public transport in these low-density territories. The diffusion of electric private vehicles could be a solution if scaled up and supported by clean energy. For sure, a crucial option is to work on the improvement of the street connectivity and design, therefore ensuring a better access for pedestrians.

The actions related to people comprise the creation of areas in which promoting social practices. For instance, the reuse of industrial areas for new activities (also directly related to energy production) and the creation of new centralities (district centres with services and mixed uses) in order to improve the identity of places (place making strategy) are the principal solutions to be explored.

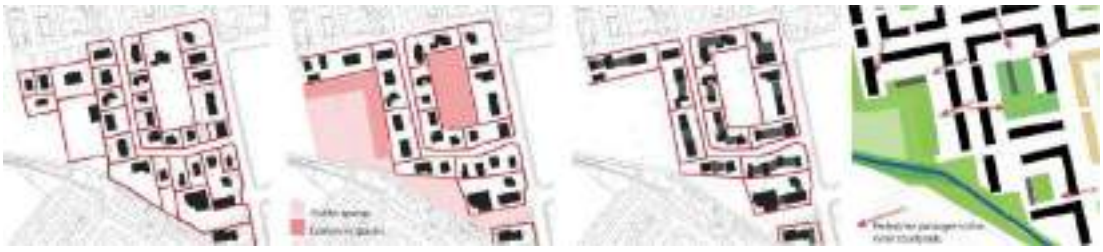

Figure 11. A long term strategy: from the current block fragmentation (1), through a process of property matching and increase of public and common spaces (2) and consequent densification (3), to the reconstruction of urban courtyards (4).

6. Conclusion and future work

Outcomes of the studio show that the contribution of urban planners to sustainability implications of the territory can be relevant. In fact, anticipating energy strategies during the master-planning phase is crucial, because the physical layout of both the urban fabric and the street network have an unquestionable importance in assessing energy consumption. The results of the studio show that not only technology can give an answer to sustainability, but also the configuration of the physical space, in particular the relation between land use, urban density distribution and street

hierarchies. Promoting proximity through a proper urban design with high quality is the first action in order to achieve reduced energy cycles on the territory.

Moreover, the scale of action, i.e. the small town or the neighbourhood reveals to be a proper dimension in order to apply simple strategies of urban ecology. Action-plans promoted by numerous European cities represent a general framework of strategies, but do not have a strong link to the different urban configurations (and hence to the different energy potentials). On the contrary, we focused on the implications of the built environment in assessing sustainable actions.

The relevance of the work to planning education will be enquired, in particular how considerations on energy and environmental quality can affect the design process and the physical layout of the final scheme.

For the second edition of the studio, a series of improvements are under investigation, also according to students' feedback. Of course, the limited time-budget of the studio (one semester-long class, which means about 14 full days of workshops) is an issue: for instance, introducing new activities will happen at the expense of others.

For sure, the quantification of energy savings will be explored with a deeper insight during the class, because students have shown to be interested in getting more validations and quantifications about their design schemes and energy scenarios. For instance, assessing the reduction of CO_2 emissions with easy calculation methods in order to compare alternative design solutions is fundamental, in order to offer a draft measurement and evaluation of concept design solutions. The SEAP experience with the Baseline Emission Inventory (The Covenant of Mayors Office, 2008) might represent a good starting point.

Moreover, we would like to improve the quality and quantity of the data to be used for the guiding the design and building the energy scenarios. Data acquisition was always a big hurdle, even if students in urban planning are quite trained in searching for data and cartography, especially from public geo-portals. Nevertheless, the aim of the studio was not to spend too much time in collecting and organizing detailed data, but rather to work on hypotheses based on the estimation of energy demands and energy production on the territory, even with limited data and resources.

Finally, beside the delivery of theoretical knowledge through lectures and readings and the glossary of common terms prepared by the students, a systemized investigation of best practices will be explored. For instance, the application of innovative clean technologies at the large scale or the introduction of successful policies can be collected and shared among the students as a reference for their design projects.

Acknowledgments

First of all, we are indebted to all the students of the design studio for their commitment and the originality of their proposals. We also have to thank the School for the launch of the studio and for supporting our activities.

Title: Translating disaster resilience into spatial planning practice in South Africa: challenges and champions

Author: Willemien Faling

Institutional Affiliation: CSIR Built Environment, and PhD student at the African Centre for Disaster Studies, North West University, South Africa

Address: Council for Scientific and Industrial Research, Meiring Naude Avenue, Pretoria, South Africa

Email: wfaling@csir.co.za

Abstract
Well-run cities can be among the safest places in the world from the impact of disasters, but in reality many cities in the world are the most dangerous places on earth. It is highly likely that hazards and extreme climatic events will in future occur more frequently and will become more severe, increasing the vulnerability and risk of millions of poor urbanites in cities in developing countries. Poor households that are concentrated in increasingly unsafe spaces bear the brunt of the disaster losses as they find themselves on the wrong side of the growing risk divide. Disaster resilience aims to reduce disaster losses by equipping a city to withstand, absorb, adapt to or recover from external shocks. In South Africa issues of development take precedence over issues of sustainability, environmental management and disaster reduction. This is illustrated by the priority given to 'servicing' spaces compared to the opportunities offered by 'transforming' spaces through post-apartheid spatial planning. The City of Durban's quest in adapting to climate change hypothetically demonstrates that if disaster resilience were to be presented as an issue separate from what planners are already doing, then planners may become more aware of it, but would see it as insignificant compared to addressing the many developmental backlogs and challenges. If however disaster resilience is regarded as a means to secure a city's development path while simultaneously addressing sustainability and resilience, then it is more likely to be translated in spatial planning practices in South Africa.

Key words: disaster resilience, spatial planning, developmental challenges, South Africa, Durban

1. Introduction

Well-run cities can be among the safest places in the world from the impact of disasters, but in reality many cities in the world are the most dangerous places on earth. 'The signs of our vulnerability to urban risk are everywhere' (IFRC, 2010 p.

8): earthquakes bringing critical urban infrastructure and assets down with tragic consequences (for example the earthquakes in Haiti and Chile in 2010, and Japan in 2011); volcanic eruptions throwing city airports across the world into chaos (for example the volcanic eruptions in Iceland in 2010 and Chile in 2011); the drug trade turning inner cities into war zones; epidemics turning into pandemics in the developing world; and streets turning into open sewers during seasonal flooding in the slums of developing cities.

Over the past 40 years, 80 000 people have been killed on average each year and 200 million people have been affected by natural disasters (UNISDR, 2010b; World Bank & United Nations, 2010 p. 23). Of greater concern than the current trends, is the increasingly clear prognosis from the United Nations International Strategy for Disaster Reduction (UNISDR) and the Intergovernmental Panel on Climate Change (IPCC) that hazards and extreme climatic events will in future occur more frequently and will become more severe (UNISDR, 2010a; IPCC, 2007). Many international development organisations (IFRC, 2010; ALNAP & ProVention, 2009; IPCC, 2007; UN-Habitat, 2010; UNISDR, 2010a; World Bank, 2008) and several researchers (Wisner, et al., 2009; Puppim de Oliveira, 2009; Pelling, 2003) warn us that as urbanisation and other global processes continue, a 'strange new urban world' (IFRC, 2010 p. 8) is developing – one that is increasingly at risk of experiencing natural, social and/or industrial disasters beyond many urban authorities' experience and ability to manage and control (ICLEI, 2010). The consequence are bigger losses more often, but also shifts in environmental conditions that are bound to have long-term implications for human settlements – settlements, particularly in the developing world, that are already challenged by a range of socio-economic development stresses (Parnell, et al., 2007 p. 359).

'An emphasis on resilience, rather than just disaster response and recovery has become a mainstream idea in disaster reduction' (Collins, 2009 p. 103). Whereas disaster reduction seeks to identify and reduce vulnerabilities and risks, resilience is also partly defensive, but more creative in implying coping and adaptation. Planning for resilient cities involves more than being occupied with minimum standards or widely-accepted spatial designs, and involves robustness, resourcefulness and pro-activeness (Collins, 2009 p. 104).

This paper questions whether disaster resilience is likely to be translated into spatial planning practice in South Africa given its developmental priorities and challenges. The paper starts by considering what risk, vulnerability and resilience means conceptually; then discusses the planning context and spatial planning practices in post-apartheid South Africa; and concludes with a case study on the City of Durban to demonstrate how a 'new' policy paradigm has recently been mainstreamed into local planning practices in spite of the developmental and intergovernmental challenges.

2. Conceptual framework

2.1 Definitions

A ***disaster*** is when a progressive or sudden hazard or event occurs that causes injury or disease; damage to property, infrastructure or the environment; or loss of lives and livelihood that is beyond the capacity and/or resources of the community to cope with (RSA, 2002; UNISDR, 2009). Disasters are caused by the combination of a hazard and vulnerability (Oliver-Smith, 2002).

'The ***risk*** (R) of disaster is a compound function of the hazard (H) and the number of people, characterised by their varying degrees of vulnerability (V) to that specific hazard, who occupy the space and time of exposure to the hazard event: R = H x V' (Wisner, et al., 2004 p. 49). Risk is thus the anticipation of a catastrophe (Beck, 1986 p. 33).

The United Nations International Strategy for Disaster Reduction (UNISDR), which is the strategic framework for reducing disaster risks as adopted by the United Nations Member States in 2000, defines ***vulnerability*** as the combination of socio-economic, political, physical, and environmental conditions people find themselves in that make them susceptible to the impact of a hazard (UNISDR, 2009). Not everyone suffers equally in a disaster due to their vulnerability: the conditions of inequality and subordination in a society rather than the geophysical features of a place explain why this is so (Oliver-Smith, 2002 p. 27).

The UNISDR defines ***resilience*** as 'the ability of a system, community or society exposed to hazards to resist, absorb, accommodate and recover from the effects of a hazard in a timely and efficient manner, including through the preservation and restoration of its essential basic structures and functions' (UNISDR, 2009). Urban resilience indicates the inherent capacity of a city to maintain core functions in the face of hazards, threats and the impacts of disasters, and to rebuild itself when necessary (UN-Habitat, 2011 p. 18).

Spatial development planning is 'a process by which a national/central [or local] government seeks to consciously plan for the spatial development of the territory of a country [or city] by using the location, timing, nature and scale of infrastructure investment and development spending to stimulate, support, strengthen and discourage growth and development in specific spaces/places' (Oranje, 2010 p. 55).

2.2 Urban disaster risk and vulnerability

The vulnerability of people to disasters is progressively increasing, and, if left unchecked, will augment the local disaster risk burden of the world's urban poor (Laukkonen, et al., 2009). An urban risk divide is developing in cities as they become increasingly unjust, polarised, divided and fragmented: the well-connected elite barricade themselves in well-serviced and regulated high-security villages (Watson, 2005 p. 286; Todes, 2011 p. 116), while some communities struggle to

survive along the fault lines of urban risk (IFRC, 2010 p. 8). The poor are largely priced out of safe areas and are concentrated in severely vulnerable and unsafe spaces – most often in informal settlements that are low-lying or steeply-sloping, flood-prone, close to pollution sources, often at highest risk of fire and disease, cauldrons of social tension and crime, with inadequate or non-existent services, and lack of protection from extreme climatic events. Hazards interact with each other to produce compound hybrid hazards, and as everyday disaster risk grows, it undermines the coping capacities of communities (ALNAP & ProVention, 2009 p. 4; Laukkonen, et al., 2009 p. 287; Pelling, et al., 2009 p. 4; World Bank, 2003; Freeman, et al., 2002 p. 5; Parnell, et al., 2007 pp. 357, 361). As everyday risk becomes an acceptable part of life, it lowers people's coping threshold and makes people less willing to prepare for catastrophes. Each succeeding event erodes the resources of a household to cope with and recover in time for the next shock, resulting in a 'ratchet effect' of vulnerability (Pelling, 2003 p. 16; Oelofse, 2002 p. 43; Faling, 2012).

Addressing urban disaster risk and vulnerability is critical in protecting the lives and livelihoods of people, as well as the infrastructure and development gain. Resilience offers a perspective on reducing disasters and everyday risks, as well as making people and places more robust and adaptable to changes and shocks.

2.3 Resilient cities

'Cities are among humankind's most durable artefacts' (Vale, et al., 2005a p. 5). Resilience is perhaps a new metaphor to many disciplines to describe and frame a counter-response to threat, but resilience has always preoccupied the inhabitants of cities as they sought to defend and secure their interests. The rise of resilience is ascribed to a growth in political action against a number of perceived threats and events such as climate change related events, disease pandemics and global terrorism (Coaffee, et al., 2009 p. 1; Todes, 2011 p. 118).

C.S. Hollings introduced the term resilience for the first time in 1973 to the analysis of ecosystems. It emerged as a concept in ecosystems theory to explain how ecological systems cope with external shocks, or how to interpret its stability (Coaffee, 2009 p. 85; Ernstson, 2008 p. 17). Ecological resilience was defined as: 'the amount of disturbance that an ecosystem could withstand without changing self-organized processes and structures' (Coaffee, et al., 2009 p. 112). The range of application of the term resilience has since then broadened in theory and research. In recent years resilience has become a trans-disciplinary concept that integrates socio-political and physical aspects (Coaffee, 2009 p. 87) and is becoming a common frame for the policy goals of socio-ecological systems such as cities (Hamin, et al., 2009 p. 239; Coaffee, et al., 2009 p. 114).

Resilience is popularly understood as the capacity to accommodate, absorb, bounce back from, or adapt to some kind of perturbation (Vale, et al., 2005b p. 335; World Bank, 2008 p. 32; Hamin, et al., 2009 p. 239). If resilient, a system has a degree of

elasticity to withstand a shock and reorganise itself when necessary (World Bank, 2008 p. 32) and is thus forgiving of external shocks (Hamin, et al., 2009 p. 239). Resilience is indicated by the continuation of particular functions at an acceptable level (Pelling, 2011 p. 42). Moreover, it includes the ability to learn by continuously adapting to the constantly changing risks and vulnerabilities (Collins, 2009 p. 106; Hamin, et al., 2009 p. 239).

The goals of a resilient city need to be built into the everyday practices of urban planners (Godschalk in Coaffee, 2009 p. 87). However, urban planning has so far played a limited role in consciously reducing vulnerability to disasters or everyday risks; and resilience is little understood (Biesbroek, et al., 2009). The International Council for Local Environmental Initiatives (ICLEI) sums up the reason for the lack of action: 'while the changing nature of disaster risk is well analyzed and increasingly addressed at international and national levels of debate and decision-making, efforts to provide direct and practical guidance to local government policy-makers and planners on how to reduce exposure and increase resilience to disasters have been few' (ICLEI, 2010 p. 1). Because resilience is not made practical, planning practices are often unsustainable – in fact, our everyday decisions could even increase people's exposure to risks and hazards, as opposed to building resilience (Pelling, 2003).

Most planners would agree that building resilient cities is of great consequence, but many countries have major development challenges – compared to which the pursuit of resilience seems like a 'nice to have'. The next section considers if, given its challenging planning context, resilience is likely to be translated into spatial planning practice in South Africa.

3. Contextual framework

3.1 The South African planning context

Apartheid had purposefully and systematically restricted black South Africans from meaningful participation in the economy. The assets of the majority of people were directly and indirectly destroyed and access to skills and self-employment was racially restricted (The Presidency, 2009). Despite solid and consistent economic growth for most of the past 18 years, and numerous policy and legislation changes, the resilience of urban settlements in South Africa is endangered by spatial inequalities, fragmentation, urban sprawl, inequalities between rich and poor that is deepening, the overload on basic infrastructure and services, congestion on roads, social exclusion, increased crime, and pressure on ecosystem services. Despite having one of the largest public housing projects in the world, decent shelter near employment opportunities remains elusive for most people, for many do not have access to housing or security of tenure, quality social services, public facilities and amenities, economic opportunities and livelihoods, and basic services. The South African space economy is thus characterised by the coexistence of formal and informal economic activities, housing and transportation systems, and a dualism in

quality of life, levels of incomes, education, skills, accessibility, density and access to service delivery (Biermann, 2011 pp. 14, 16; Oranje, 2010 p. 59; World Bank Institute, 2012). The stark inequalities in the country threaten the fragile social cohesion, and have given rise to an increasing number of violent service delivery protests and xenophobic attacks. There are furthermore huge territorial disparities between rural and urban areas (Van Huyssteen, et al., 2010 pp. 24-25, 35).

3.2 Planning in South Africa

With the rise of democracy in South Africa, expectations of the eradication of socio-economic imbalances, including equitable development and access to basic services, were high (Carmin, et al., 2012 p. 21). A new path of reconstruction and development was cut out for a post-apartheid South Africa in the form of numerous green and white policy papers, acts and regulations. Simultaneously a new intergovernmental system was established with a strong focus on the process of inclusive planning rather than planning products. Nevertheless, after many decades of comprehensive blue-print planning during which 'planners were perceived as having been instrumental in designing and maintaining the apartheid space economy' (Biermann, 2011 p. 15), spatial planning was regarded with suspicion and thus neglected – if not abandoned. This adversely affected planners' ability to perform spatial planning. Furthermore, many planning positions in government were filled with people who were not qualified planners, causing a loss in skills and institutional knowledge (Biermann, 2011 p. 15; Oranje, et al., 2011 p. 8).

Integrated Development Plans (IDPs) that promote the developmental government paradigm became the dominant planning instrument in post-apartheid South Africa. These plans focus on stakeholder processes and institutional coordination but neglect the notion of using space to restructure settlements. Watson calls this the 'marginalization of the spatial' (in Biermann, 2011 p. 12), while Oranje, et al (2011 pp. 6-7) describes post 1994 development planning in South Africa as characterised by a conflict in intent, action and outcome between service delivery and transformation. 'Servicing' is ensuring a rapid response to a lack of housing and basic services. As such, it has a 'very near-future perspective', concerned with the number of houses completed and services delivered in areas where people live 'now' and often with future re-election of politicians in mind. Oranje, et al (2011 p. 6) argue that the outcome has not necessarily transformed the post-apartheid space economy, but only addressed the symptoms. 'Transformation' on the other hand is concerned with the restructuring of the entire space economy 'through the pursuit of shared, sustainable, equitable and inclusive growth'. However, much more emphasis has been placed on servicing, which means that many communities may have houses and basic services, but the expansion of the economy into these 'serviced' areas has been minimal and people remain far from economic nodes with their accompanying jobs, social amenities and economic wealth.

Spatial planning re-emerged as an important component of planning with the publication of the National Spatial Development Perspective (NSDP) in 2003.

However, local spatial development frameworks are often driven by widely accepted concepts such as nodes, corridors and urban edges, without much insight into how spatial planning ought to respond to movement patterns, long-term economic prospects, the property market, or how space is used. It is often assumed by planners and politicians that it is possible through state intervention in the economy – notably though infrastructure investment – to change the spatial pattern of economic growth and development. The result is a disjuncture between conceptual spatial planning and quantitative infrastructure planning that contributes to misaligned service delivery. The absence of credible data on changing demographic and economic patterns, municipal governance and urban sustainability further impedes sound decision making (Biermann, 2011 pp. 12-14; Oranje, 2010 pp. 57-60).

Municipalities furthermore face a number of challenges in overcoming the apartheid spatial legacy: lack of funds; lack of technical, managerial, financial and planning skills and capacity to take up the developmental role; institutional transformation issues because of the amalgamation of municipalities; economic woes inherited from apartheid; huge service delivery backlogs; and intergovernmental misalignment and complexity (Van Huyssteen, et al., 2010 p. 27; Oranje, et al., 2011 p. 8).

3.3 Translating disaster resilience into spatial planning practice in South Africa

Before 1994, environmental management, disaster reduction and sustainability among other concerns, received very little attention in South African policy. This changed after 1994 as the process of democratisation resulted in a revised development agenda (Roberts, 2008 p. 521). But the simultaneous, parallel development of many policies resulted in duplicated development application processes, competing bureaucracies, interests and agendas, and differences in training, discourse and practice (Todes, 2011 p. 123). There was also a growing tension between the need to expedite development to address inequalities, and the need to introduce sustainability concerns such as environmental management and disaster reduction into planning. As described above, development won out as the priority, so that long-term issues were of less immediate concern. This tension has still not been resolved, and has, in many cases, intensified due to the range of immediate and severe development challenges (Roberts, 2008 p. 523). For this reason Faling, et al (2012) have found that planning for everyday disaster resilience is not a priority among planners in South Africa. It is not even deemed part of the planning process, but part of what the ‘environmental people do’.

What follows is a case study of the City of Durban in South Africa – a metropolitan city facing typing development challenges – and how they have started to mainstream climate change adaptation into their everyday planning. This serves to hypothetically demonstrate that the mainstreaming of disaster resilience in spatial planning can be accomplished if approached in a way that it is seen as part of the planning agenda and integrated into existing planning strategies.

4. Case study: Climate change adaptation in Durban

Durban is a coastal city with the largest port on the east coast of Africa. The eThekwini Municipality manages the 2 300 square kilometre municipal area that hosts a population of 3.5 million people and that is South Africa's third biggest urban economy (Carmin, et al., 2012 p. 20; Roberts, 2008 p. 521; SACN, 2012 p. 37).

The City of Durban faces typical post-apartheid challenges as described above. It also experiences severe weather events such as flooding, storms, droughts and tornadoes. To this extent, a report commissioned by the Municipality on climate change suggests that over time Durban would experience minimum and maximum temperature increases; and rainfall would become more infrequent, but more severe – causing flooding and high tide levels. The report also indicates that the sea level is rising by 2.7cm per decade. These changes in the climate and sea level will affect numerous sectors in the city such as food security, health, infrastructure, water security, biodiversity and the economy, and many people will become more vulnerable to disaster risks (Carmin, et al., 2012 pp. 18-21; Roberts, 2008 p. 528). At that time few strategies in eThekwini engaged proactively with each other to reduce the risk for disasters due to extreme weather events. Moreover, the disaster management sector was mostly responsive to emergencies, not focussing on proactively planning to minimise exposure and susceptibility, relocating people and infrastructure away from high risk areas, or on developing early warning systems.

As severe weather events started to cause more damage to the city during the last decade – notably the 2007 severe flooding and coastal erosion that caused significant damage to the coastline around Durban – the Municipality started to wake up to the consequences of these events, and realised that many of the post-apartheid development gains are already being undermined or lost, and will be further exacerbated by climate change. Climate change adaptation or resilience-focused interventions, started to achieve prominence in Durban for the potential it offers for 'development-linked co-benefits that are responsive to a context of poverty and underdevelopment' (Roberts, 2010 pp. 398-399; Roberts, 2008 p. 532; Carmin, et al., 2012 p. 23).

It still took some time and trial and error for Durban to be recognised today as one of the leaders in climate change adaptation. First, the Environmental Management Department commissioned the development of an adaptation strategy, published in 2006, which summarised general adaptation actions that could be taken by sector departments. It was an important document to further the debate on climate change in the city, but it did not act as a catalyst for action – in part because it did not specify goals and actions for specific departments, and partly because many departments were dealing with work backlogs and overloads, as well as a lack of funding and capacity. In 2008 the Environmental Management Department, whose name changed to the Environmental Planning and Climate Protection Department (EPCPD) – to indicate the priority given to climate change in the city – realised that to gain widespread support for an adaptation plan, they have to shift the emphasis from the

threats climate change present to presenting adaptation as a means to realise development priorities. Work was started on individual plans for specific sector departments by embedding adaptation planning into existing business plans and development objectives. These plans formulated measures and protocols to maintain or improve the functioning of municipal systems, services and infrastructure given the projected impacts of climate change. 'Essentially, the goal was to build increased resilience one adaptation intervention at a time' (Roberts, 2010 p. 401). Climate change consideration were also factored into the overall long-term plans and budgets of the municipality (Carmin, et al., 2012 pp. 21-23; Roberts, 2008 p. 533; Roberts, 2010 p. 401).

Three endogenous factors seem to have driven the adaptation initiatives in Durban. One is the efforts by a champion who pushed the adaptation agenda and creatively navigated the minefield that is local government. Two, the city came under the impression of the gravity of climate change impacts and the danger their residents were in if it became more severe. Three, the municipality realised that climate change adaptation was a means to secure the city's development path while simultaneously addressing sustainability and resilience (Carmin, et al., 2012 p. 28). eThekwini found ways to link adaptation to existing policies and plans to 'demonstrate that this is not an unfamiliar or inconsequential issue but one that was already part of current citywide priorities and initiatives' (Carmin, et al., 2012 p. 29). Adaptation came to be seen as integral to the on-going work of municipal departments.

Roberts (2008 p. 527) identified four markers that indicate the successful integration of climate change in the day-to-day operations, planning and decision making of the Municipality. These are:

- The emergence of a champion(s);
- The appearance of climate change as a significant issue in municipal plans;
- The allocation of dedicated human and financial resources to climate change issues; and
- The incorporation of climate change considerations into political and administrative decision making.

If the City of Durban could manage to integrate climate change consideration into their various sector plans, then surely other South African cities can attempt to mainstream disaster resilience into their spatial planning practices?

5. Conclusion

It is very likely that losses to lives, livelihoods, assets and infrastructure will increase in future as more people migrate to cities and as the effects of global process such as climate change increase communities' vulnerability and disaster risk. Many of the implications will be beyond the capacity and experience of local governments to address, wiping out development gain and diverting scarce funds towards relief and

reconstruction. Developing countries will suffer most from these impacts, increasing the risk divide within and between nations.

Disaster resilience attempts to reduce these losses by mainstreaming physical, social, economic and environmental measures into planning practices to allow urban systems to accommodate, absorb, adapt to or bounce back from shocks to the urban system. Spatial planning is critical in building this resilience. By managing growth and change in cities, spatial planning can promote liveability, sustainability and inclusion (Todes, 2011 p. 128). By mainstreaming disaster resilience into spatial planning practices, these development endeavours can be protected from future losses.

Post-apartheid spatial planning has had 'far more of a life on paper than in practice' due to various fears and concerns and inabilities concerning implementation (Oranje, 2010 p. 66). Planning in South Africa is burdened with addressing housing and service backlogs; fragmented and sprawled spatial patterns and inefficient transportation systems that result in unequal access to urban functions and the economy; challenges of intergovernmental coordination; and so forth. To add another burden – that of building resilient cities – would be met with contempt or despair. The Durban experience shows how planners and officials can be entrepreneurial and innovative in seeking to promote an emerging policy domain. By presenting disaster resilience as a means to realise a city's development priorities whilst protecting the development gain, it is more likely that resilience would be translated into spatial planning practice in South Africa, than if it were presented as a policy paradigm inconsequential from what planners are already doing.

The role of *models for reality* in the transition period of communities especially in the aftermath of crises: The Kurdish experience in Northern Iraq

Author

Hasan Sinemillioglu, Dr. rer. pol., TU Dortmund University, School of Spatial Planning, hasan.sinemillioglu@tu-dortmund.de

Abstract

The formerly deported people in Kurdistan in Northern Iraq were turning back to their devastated villages after the Kuwait crisis in 1991 and began to reconstruct their villages. Their former socio-cultural life-world (Habermas 1992) had been fully destroyed between 1975 and 1988. Before repatriation the deportees were forced to construct a new life-world in the alien environment of collected villages or exile, in which they were forced to live. After repatriation the returnees were under the strong influence of their newly established modern life in collected villages and/or exile; nevertheless traditions of their former village life were still determining their behaviour and minds as a model of reality (Geertz 1973).

The political environment in 1991 was fully uncertain; in the aftermath of crisis state failure caused a vacuum of power. No rules and no regulations – total freedom? The non-existent sphere of power (Weber 1998) was a source of uncertainty and chaotic development. It could not contribute to future orientation in the sense of creating a new and appropriate model for reality (Geertz 1973). Without having future oriented policies and social and financial resources (Weber 1998), reconstruction of the new villages was not future oriented, and the new villages did not become an integrated and dynamic part of the settlement system. The food distribution policy of the UN agencies further aggravated the difficulties of shaping a new model for reality because it seemed no longer reasonable for the new villagers to engage in farming activities. As a response to missing services such as schools and health care, the returnees in the newly reconstructed villages began to emigrate back to larger settlements like former collected villages and the three large cities of Dohuk, Erbil and Sulaimaniya.

The returnees were composed of different subgroups with the younger ones interested in modern life (electricity, roads, water, schools – but also radio and television) and the elderly dreaming of their former village idyll. Lack of organisation was hindering the returnees to articulate their interests; communicative action (Habermas 1992) through interaction of different actors was not possible. In this general frame of anomy (Gerhardt

2002) the international actors were not interested in the establishment of a new order and new political powers, while the local actors were not able to develop policies for future orientation.

The transition period after crisis is a period with strong impulses for social change which can be defined as a period of liminality (Turner 2008). The challenges of this period are huge but they include also chances and opportunities as the experience in Northern Iraq illustrates.

Keywords: Crisis, state failure, social change, reconstruction, regional development

Background

In the aftermath of the war against Iraq in 1991 the political situation in the region changed dramatically. The focus of development was no longer the liberation of Kuwait but the very political future of Iraq after its army had been forced out of Kuwait. The change in US politics towards the Saddam regime and the use of military helicopters against Shiites and Kurds caused a humanitarian catastrophe at the borders of Iraq with Iran and Turkey. Hundreds of thousands of people from Iraq fled to the neighbouring countries. Almost one and a half million Kurds were trying to seek security in Iran and Turkey, turning major cities into ghost towns. From Dohuk's 100 000 inhabitants at the time, only 400 people had remained while all the others were fleeing through the mountains towards Turkey.

After the intervention by the UN in 1991 in Northern Iraq once more a safe haven had been defined in order to protect the Kurdish population and to try to convince them to turn back home. Back home? Rather an odyssey! One should go back to the seventies and eighties and have a closer look at the developments in Iraq.

Socio-political development in Iraq in the seventies and eighties

The dispute between the Kurds and the central powers of Iraq dates back to the times of the British mandate after World War I. As Iraq was constituted in 1932 the Kurds were seen as a part of the Arab Kingdom of Iraq (Sluglett 2001, 23ff) and all attempts of the Kurds to obtain autonomy were in vain. General Qasim was the first to attempt to solve the dispute in 1958 after the proclamation of the new Republic of Iraq. The representative of the Kurds, Molla Mustafa Barzani, was called from his Soviet exile. 'The Kurds should obtain autonomy' was the proclaimed aim. However, the Kurds did not obtain autonomy and the struggle between the Kurds and central government continued. In 1970 there was a new attempt to solve the conflict. An agreement between the ruling Ba'th party and the Kurdistan Democratic Party (KDP) regulated the new approach for getting autonomy for the Kurdish people. In this agreement

„The [Iraqi] government promised Kurds full recognition of their nationality and autonomy within four years. The Kurdish language was made the primary language in the Kurdish areas, and also an official language which would be taught in addition to Arabic throughout Iraq" (Jawad 1982: 50).

And as Sluglett points out that

"(...) the new (provisional) Iraqi constitution of July 1970, stating explicitly for the first time that 'The people of Iraq is formed of two principal nationalities, the Arab nationality and the Kurdish nationality'." (Sluglett 2001, p. 142).

This was encouraging and a set of measures were foreseen to be implemented in that new political sense.

As the aim of the agreement had not been realised after four years, the Kurdish side started a rebellion. Interestingly, the Kurdish rebellion was supported by the USA through the Shah regime in Iran. Probably their aim was to weaken Iraq because of its alliance with the former Soviet Union. This support strengthened the Kurds so that they could withstand the Iraqi forces. The situation changed when Iran signed an agreement with Iraq in Algeria in 1975. The agreement stipulated that Iran stops its support for the Kurds and, in return, was given half of the Shatt-el-Arab, an important premise for its oil exports. After losing the support of Iran, the Kurdish rebellion was defeated and Iraq regained control over the Kurdish regions, especially in the border area to Turkey and Iran.

The political force and destruction of the rural settlements in the Kurdish region: impacts on the socio-economic life of the rural population

Iraq began in 1975 to reshape its politics towards the Kurds. The core of this policy was to obtain full control over Kurdish regions and to obstruct assumed support of the Kurdish villages in the mountainous areas of the North and Northeast to the Kurdish rebellion. As Farouk-Sluglett and Sluglett point out, "(...) the entire populations of villages situated close to the frontiers with Iran and Turkey, where the regime set up a *cordon sanitaire* between itself and its neighbours in order to 'prevent infiltration'" (Sluglett 2001, 188) were removed and the inhabitants deported. The deportation policy began in autumn 1975 in the Barzan area. It was continuously implemented until the end of the war against Iran. The peak of the repressions was the so called *al-Anfal campaign* against Kurds, during which up to 200.000 of Kurdish people were killed also by chemical weapons (Meiselas 2008: p 308; Sluglett 2001, pp. 269-270). At the end of 1988 most of the Kurdish villages had been destroyed (Table 1).

There are no statistics about how many inhabitants have been deported. The author estimated that the deported rural population must be about 720 thousand inhabitants (Sinemillioglu 2011, 25). The deportees have later been resettled in so called collected towns comprising the population of up to 20 villages strongly controlled by the security forces. The deportees were dispossessed and not able to continue their former agricultural life. In the words of Farouk-Sluglett and Sluglett "(...), those who were made to live in them [collected towns] could no longer continue with their traditional

agricultural or pastoral way of life" (Sluglett 2001, 188). The collected towns were strongly controlled settlements, which did not allow for any economic activity. The destruction of the rural regions and accompanying deportations was nothing else than the destruction of the social and economic structure of this society.

Table 1: Settlements in Northern Iraq, March 1996

Governorate	Cities / towns	Collective towns	Total Villages	Destroyed villages	Resettled villages
Dohuk	14	35	1,200	867 (72%)	600 (69%)
Erbil	22	28	1,238	1,025 (83%)	868 (85%)
Suleimaniyah	41	15	2,021	1,994 (99%)	1,004 (50%)
Total	77	78	4,459	3,886 (87%)	2,472 (64%)

The crisis of 1990 and the war of 1991: reversal of deportations, returnees in the destroyed rural regions

The invasion of Kuwait in August 1990 by the Iraqi army caused a heavy crisis in the Middle East. The UN Security Council responded immediately with the Resolution No. 660 (SR660) of August 2, 1990. With the SR661 of August 6, 1990, Iraq was put under international sanctions. After negotiations remained without any results, the UN mandated international force troops intervened in January 1991 and the Iraqi troops were forced out of Kuwait. The aftermath of the War, known as Gulf War I, was dramatic. By the end of March 1991 almost one and half million Kurds and approximately one million Shiites from the southern Iraq fled to Turkey and Iran. The UN reacted by deciding to form a "safe haven" in Northern Iraq so that refugees could return to their homes (RS688 of April 5 1991). From now on it was possible for the international community, for the UN Organisations and for humanitarian NGOs, to enter into the crisis region.

Some of the returnees who had been deported from their villages went directly to their former villages, especially those who had been living in Turkish or Iranian exile for many years, i.e. those who fled in 1975 and in 1988 from Iraq. They returned to Iraq as homeless people – roughly about 600,000 returnees (Sinemillioglu 2011). These former refugees started to rebuild their destroyed villages under extremely difficult conditions

and without any assistance; the only capital they had was their enthusiasm and their will to reconstruct their former homes (Sinemillioglu 2011).

The vacuum of political power in parts of Iraq and international response: the policy of *do nothing*

The UN resolution SR688 had created a completely new state of affairs: In Northern Iraq central government had completely lost power. The loss of their *sphere of power* (the expression is from Weber 1998) allowed the opposition to take over power immediately after the UN resolution. This was not fully recognised by the international community, but not fully denied either. The newly emerged Kurdish opposition proclaimed to install a democratic administration. The democratic orientation in one part of the state of Iraq was contradicting central power, possible through the policy of *do*

nothing at the side of the allies and the United Nations (Sinemillioglu, 2011, pp. 125-128).
The main actor during the aftermath of the crisis surely was the UN managing the humanitarian disaster and organising humanitarian help. Doing this the UN was bound by obligatory agreements with the Iraqi central government because the UN can be active in a member state only if the concerned country accepts this. According to the Memoranda of Understanding (MOUs) between the central government of Iraq and the UN the main goal of UN interventions was defined as humanitarian intervention, and for its actions the UN had to take into account the "sovereignty of Iraq and the national unity of its population." (MOU, 20 May 1996, from: Sinemillioglu, 2011, p. 101).

Interestingly, the UN Organisations continued their humanitarian work as though nothing new had happened in 'the three northern Governorates', as the Kurdish region used to be addressed in UN jargon. The UN agencies even negotiated officially with the new Kurdish administration, but the political orientation of the Kurds was fully neglected.

The obvious result of this policy was that also the allies accepted the situation in the North of the country but did not have any policy to control, to prevent or to influence the developments in these three Governorates. The following statement of the American Colonel R.M. Naab shows that the allies did not recognise and/or were not interested in the political processes in Iraq regarding the political development in the Kurdish region:

"In May 1992, Iraq was having an election. I said, „What is this going to solve?" And in fact, while Kurds participated in it very actively, the U.S. gave very little help officially. It didn't make the problem of the rivalry between two major parties go away. I mean Jalal and Massoud are still at it. It still goes hot and then cold for a while. It gives people in the West the opportunity to say, "Well, there they go again. They're all tribal. They can't manage their own affairs. They're killing each other." That's too bad for the Kurdish people" (Meiselas, 2008, p. 342).

The result of this policy was that the UN was allowed to bring back the returnees without organising any assistance beyond humanitarian help. The returnees were free to do what they wanted: Return to their destroyed villages and try to create a new *life world*.

Crises accelerate social change

Social change in general is a part of the transformation of societies (Zapf, 1996). In traditional societies this transformation occurs under the conditions of political and cultural pressure, i.e. inputs from 'outside' (Parsons, 1961). Political pressure can also

be identified in the process of state and nation building (Rokkan, 1969, p. 233-234). In the case of Iraq the process of state and nation building indeed created continuous political pressure accompanied by crises almost through the whole history of the country (Sluglett, 1991). The continuous struggle between Kurds and central government in this process caused the almost complete destruction of the rural space in Kurdish regions. This was done 'in the name of modernization' (Sluglett, 1991; Rohde, 2010).

In the literature there is a vast amount of publications about crises, nevertheless post-conflict situations are not deeply considered, as Herrero points out:

"Despite common elements, postconflict situations differ significantly from one another. Most of the existing literature does not address the immediate aftermath of the conflict – the emergency phase. (...) The security, political, and administrative vacuum resulting from conflict, as important as it is, is often neglected." (Herrero 2005, 43).

The "shattered society" (HRW, 1993) of the Kurds in Iraq in the aftermath of the GW I is a good proof for this observation. The very unique situation in Iraq shows that the unexpected change in the social and political environment, especially the change in state affairs, challenges the international community because the affected people obviously are not able to manage their own affairs.

Development after crises and the model of reality versus the model for reality

The will of returnees to reconstruct their former villages was not an easy task. In the aftermath of the crisis of 1991 the situation of the returnees was almost the same as it has been after the deportations, this time in the opposite direction. Arriving in their former and now devastated villages the returnees were confronted and challenged with a new environment fully different from their newly created life world under the conditions of collected villages or exile. They still carried elements of their rural life world in their minds, and as they started reconstruction of the villages the driving force was this cultural background. In the words of the renowned anthropologist Clifford Geertz *cultural patterns* or *models* out of their former life.

Geertz distinguishes two main concepts: models of reality versus models for reality (Geertz, 1973, pp. 93-94). Models of reality describe the forms, behaviours and traditions of the existing life world. For future orientation and plans models for reality are of importance. Most development can be in general described as a pendulum between these two models with a latent or open competition existing between the two.

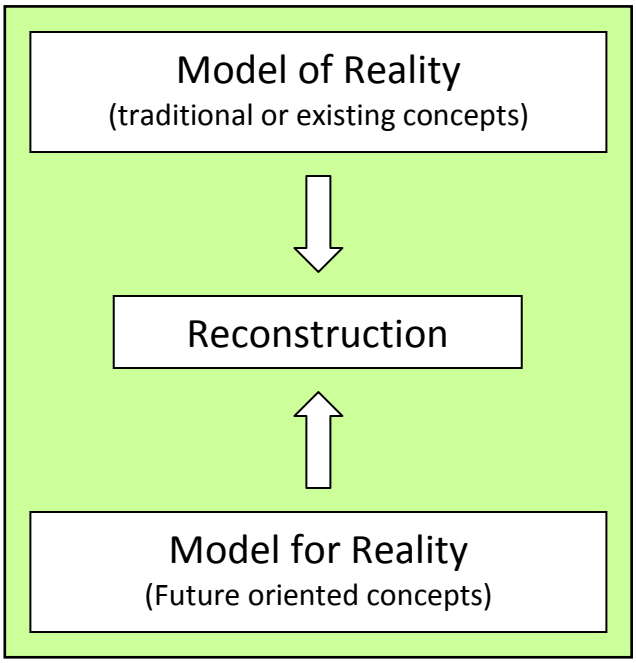

Figure 1. Concepts influencing future action: the field of reconstruction
Source: Sinemillioglu, 2011, p. 65. Translation by the author

Applying this approach to the reconstruction activities of the returnees, it is obvious that returnees were driven mostly by the existing models of reality. These were derived from their former village life, but to some extent mixed with new elements of their recent life world, i.e. life in collected villages including modern social amenities like schools and health services, technical infrastructure like flowing water and electricity in the houses, modern communication and transportation systems etc. Sinemillioglu describes five groups, especially the group of youngsters who want modern services in the villages, and the group of elderly people who strongly adhere to former rural life (Sinemillioglu, 2011, pp. 143-144). Traded values in the minds of elderly people like resistance to change and glorification of the past are strong hindrances especially if there is no future oriented assistance such as concepts and institutions and the missing "material, i.e. the social and financial, resources" (Max Weber).

Reconstruction? Is it possible to reverse the destruction and have a beginning at the point of destruction? The rapid change in social life of rural groups caused by the full destruction of their life world is a complex issue and it is nearly unmanageable. This is a potential risk in the development process.

Rapid social change and the demand for future policies: The role of external actors

The developments in Kosovo (Herrero, 2005; Sinemillioglu, 2011), and in Timor-Leste (Sinemillioglu, 2011) after the crisis describes the international aid for institution building, without which overcoming the critical phase would not possible.

The same should have been done in Kurdistan. The reasons, why this was not the case are manifold. The most important reason is the ambiguity of the approach "keeping Iraq together, otherwise all the Kurds in the region will want to have the same" (Sinemillioglu 2011). Out of many other reasons the international assistance was delimited with the humanitarian aid.

The main issues raised after the crisis of 1991 in Kurdish Iraq especially until the second Gulf war in 2003 were concentrated on two main fields: the reconstruction of the rural villages and the establishment of a new Kurdish Administration. The reconstruction of the villages could not be approached appropriately due to the lack of administration capacities since there were no governmental politics for reconstruction policies. The re-establishment of the rural regions, therefore, was merely understood as the construction of houses, better shelters, for homeless people. The reconstruction of the villages was not included as such in the programmes of the UN agencies or other international humanitarian agencies. And the policies of the Kurdish politics were not going far beyond the wish of *the reconstruction* of villages. Especially the ownership of land was not clarified. The confiscation of land by the Iraqi central government was de facto no more accepted, but there were no new regulations in that regard.

Under these preconditions the reconstruction of the villages was a chaotic process, which was not allowing a future oriented sustainable re-establishment of the rural regions. Especially the economic activities of the newly emerging settlements and the provision of the main public services were fully neglected.

In the sphere of the economic activities two main hindrances were determining the developments. One was the lack of material resources. Especially the lack of financial resources didn't allow establishing the farming activities. The savaged agricultural land, the lack of equipment and live stock, destroyed irrigation systems needed to be rearranged. Also the necessary social resources like skills for agricultural work were missing, not to mention the non-existent marketing structures.

The other hindrance was the international sanctions and the related food distribution. The sanctions were fully applied also to the Kurdish regions, which hindered the import of necessary machines, equipments and spare parts. The food distribution did additional difficulties, because the farming products could not be sold in the market – the wheat flour for example was imported from Australia.

In the field of social services the demand was tremendous. Every settlement was in need of schools, health services, and technical infrastructure like streets, communication means and electrification. The water supply and sanitation were non-existent, posing a considerable danger to people's health, especially to that of the children and elderly. Missing financial means were not the only reason for this situation. Especially the small scaled construction of the villages constituted a major problem since an effective support and sufficient organisation of the services was very difficult. Some villages were inhabited by just a few families, which simply couldn't be supplied. Many villages without far beyond road access emerged near main roads far away from their original locations. However, families in these locations had difficulties reaching their farming lands and couldn't start farming activities.

Furthermore not all of the returnees were able to start their life in their old villages. Many hundreds of thousands returnees had to resettle in different locations; in the former collected towns or in the cities, especially in Dohuk, Erbil and Sulaimaniya. As an example the population of the former collected town Shela Dize, 40 km east of the historical town and district centre of Amadiya, has been grown from 6,000 in 1991 to 22,000 in 2009 (Sinemillioglu, 2011, pp. 137-139). Repatriates from Turkish or Iranian exile had caused this rapid growth. These returnees were not able to reconstruct their former villages because of many different reasons. One of them was the missing transportation infrastructure; the other one was the ongoing conflict between Kurdish rebellion and Turkish army at the Iraqi borders with Turkey, scaring off the returnees to resettle in their former villages located in these areas.

The example of the region of Welati Jeri

DhK (Dortmunder helfen in Kooperation e.V. / Citizens of Dortmund help in Cooperation, registered association), a humanitarian organisation from Dortmund, Germany, supported the returnees in their villages in many different ways. The focus of the work of DhK was establishing the farming activities and supplying the returnees with social services, especially with schools and health care. Doing this DhK paid attention to participatory planning in the region. For the reconstruction activities the villages were not handled as separate units but groups of villages were bundled and considered as a small region. The work in the region of Welati Jeri (WJ) is a relevant example for the integrated and participatory bottom up approach of DhK.

The work of DhK in WJ started in spring 1992 and ended in 1995. The region is located in the North of the mountains Ciyaye Shirin and is cut off from access to the road by the river Reshin, a side arm of the Greater Zap. Facing this obstacle the nine villages in the region were obliged to act concertedly. This was the basis for DhK to negotiate with the

representatives of the nine villages. Very soon after the first contacts the negotiations ended with an organised *communicative action* between DhK and the representatives of the villages, which very soon turned into a *regional development committee (RDC)*. After clarifying the responsibilities between both sides, the communication was smoothly functioning. It was no more necessary to talk to single families; instead, it was now possible to consider the whole region as an entity. The needs of the separate villages were adapted to the needs of the region. The RDC and DhK organised regular meetings in each village with the men and women – even if these meetings were held separately. It was seen as normal that the decisions were made only by the men, especially by the elderly. Nevertheless, DhK was able to organise meetings with the women as well and discuss the needs from their perspectives.

Together the RDC and DhK defined the most important measures for the region. Access from the road to the villages, i.e. the construction of a foot bridge over the Reshin River, was defined as the most important measure since the missing access roads in the region made it impossible to transport the necessary goods for construction activities. Therefore, as a second measure, mules were bought for the transportation of goods. After these two measures were taken the reconstruction activities increased rapidly. More and more families from the Iranian exile and from the collected town of Qotchtepe returned to the region. In the following months and years the joint activities of the RDC and DhK included one health centre, five schools, two water mills, agricultural tools, seeds and seedlings and the distribution of oxen and sheep. The region began to grow; the agricultural work had been extended and the RDC became an important institution for the development of the region.

RDC was consisting out of the Muxtars, the mayors, of the nine villages. The muxtars traditionally are the elder authority in the village. Getting them together in a committee responsible for the whole region was an important milestone for the self-organisation and community development in WJ. This new organisational element combined the traditional function of the muxtar with the new institutional set up. In that way it was possible to combine and adapt the interests of the villages with the development of the whole region.

The example of Shela Dize

Despite this encouraging example of WJ the whole process shows strong deficits of policies especially in the sphere of spatial structure. Missing policies and financial resources didn't allow the sustainable reconstruction of the villages. The question of the settlement structure combined with the role of regional centres, which could have been market places for the agricultural activities in the catchment area, was not answered. The former collected town of Shela Dize is a typical example for this unbalanced

development. Shela Dize is a former collected town including the deportees from about 20 villages of the Rekan tribe. The town rapidly grew after the GW I. Before the war n 1991 the town had a population of about 6,000 inhabitants. After the war Shela Dize grew continuously; in 2009 its population reached 22,000 inhabitants. As map 1 shows the town has reached more than four times of its original size (Sinemillioglu, 2011).

Map 1: the former collected village of Shela Dize, 2009
Source: The municipality of Shela Dize, 2009, in Sinemillioglu, 2011, p. 138

Shela Dize is a residential neighbourhood; apart from small retail shops and school services there are no major economic activities. There are different reasons for this development. Besides the lack of financial resources many returnees couldn't return to their villages because of the crisis at the border to Turkey. The insecurity across the border hindered the reconstruction of many villages in the region. Another reason simply was the missing public services in the newly reconstructed villages. Especially the lack of schools and health services forced many families to partly leave the villages. These families had been divided into two parts; one part established a new household in the towns or cities while the other remained in the village.

Conclusion

The policy of "do nothing" left the state affairs in Iraq to its own dynamics. The politics in the north of Iraq were not able to define the necessary policies for a sustainable reestablishment of the rural regions; the political power in that region, on the other hand, had no necessary means and capacity. The political uncertainty determined the development until the war in 2003.

The policies of the UN agencies like food distribution and constructing only the shelters without support for the necessary economic development, the missing infrastructure for the agricultural activities and the failure of marketing mechanisms didn't support the agricultural activities of the returnees in the villages. The cities and towns and the former collected villages were covering the housing for the returnees and internally displaced persons without disposing of economic activities. Nevertheless, these locations had been the target of emigration from the reconstructed villages for years.

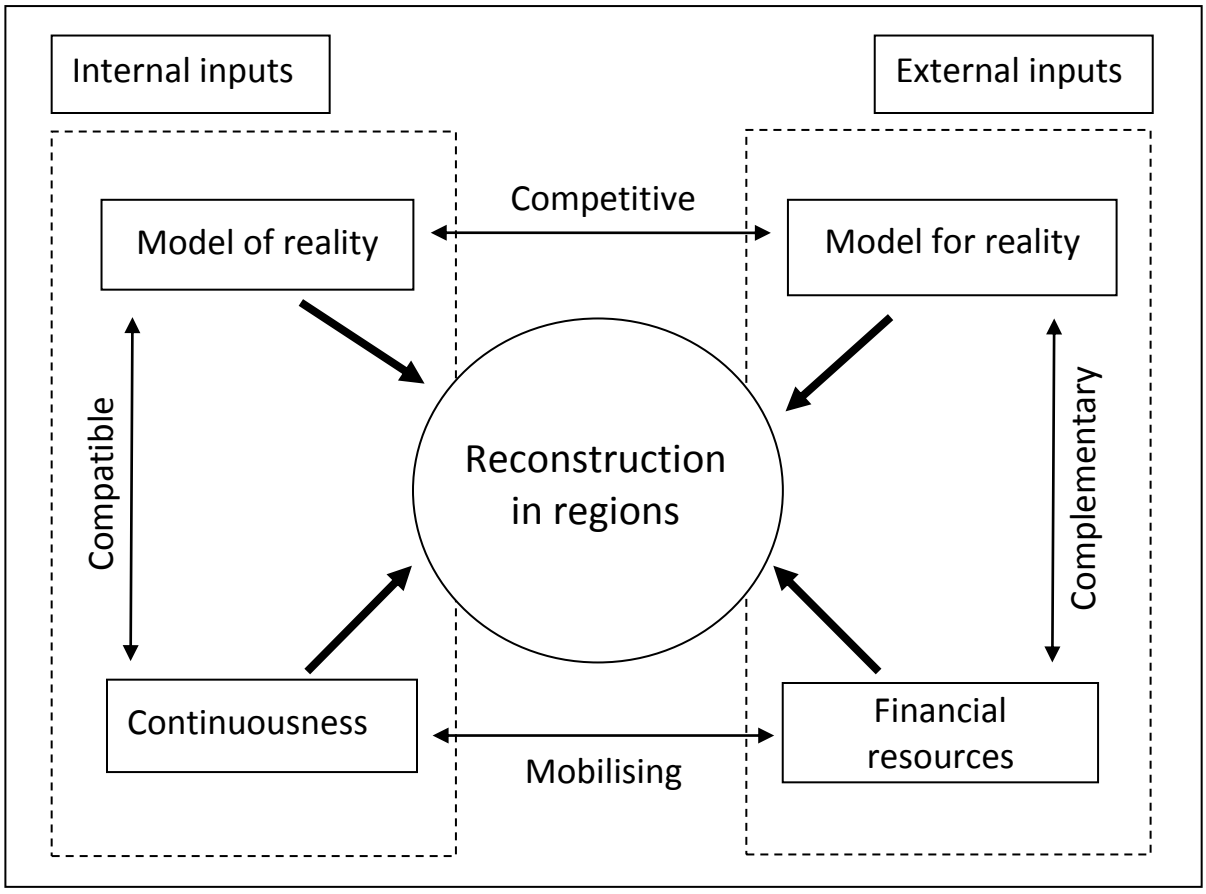

Figure 2: External and internal factors influencing the field of reconstruction
Source: Authors own construction

The development in the Kurdish regions of Iraq shows that the state failure challenges the future orientation in different ways. The spatial development after the crisis needs clear policies in different fields. Especially the missing institutional set up doesn't allow

developing future oriented policies; if there is no state and no functioning administration there are two options only. The first one could be observed in the Kurdish regions between 1991 and 2003. In that case all the chaotic developments do not allow people to create a sustainable future oriented environment.

The second one can be seen as an organised assistance by external actors as it was the case in Kosovo or in Timor-Leste. Figure 2 demonstrates this assistance for the reconstruction activities. Especially the relations between the models of reality and the model for reality are crucial to the external assistance. Obviously after the crisis the lack of financial resources is an important hindrance for the reconstruction process. The necessary inputs and a good management can mobilise the persons affected. This would support the communicative dialog between the external actors and the affected target groups, which is of great importance for the participatory planning activities.

CONSERVATION OF RELIGIOUS FACILITIES AND SURROUNDINGS: CONTRASTS BETWEEN BUDDHIST, ISLAMIC AND CATHOLIC COMMUNITIES IN BANGKOK, THAILAND

Pornsan Vichienpradit[1]

Abstract

In Asian countries, religious facilities are important urban cultural heritages, as we can recognize temples, mosques and churches as cities' landmarks. Bangkok is a city where visitors often perceive strong urban images from those appearances of religious facilities in downtown area. To protect these facilities, government takes a big role in conservation of religious buildings, especially if they are declared as monuments. Religious organizations themselves are also crucial authorities in term of managing and providing financial support to maintain facilities, even some differences between religions could be seen. And at last, communities always serve traditionally full support, since residents are believers and common users of those religious facilities.

But in administrative conservation system, there is no standing point for communities. By the law, cultural heritages protection is claimed to be duty of Fine Arts Department and each owner of properties, which means religious organizations in case of religious places. This can be interpreted that people cannot protect their local cultural heritages themselves even if their religious places are threatened, nor they have rights to report any destructive actions to the police. It is quite curious that people are excluded away from the mechanism of current conservation system, even communities have been supporting religious facilities for very long time.

Religious community is a traditional urban community formed together with religious place. We can find many of them in downtown Bangkok. Temple, mosque or church is the most important element for this kind of community, because it is taken as community's center. Even nowadays, lives of residents in these communities are still connected deeply with religious facilities, not only by the ritual but in everyday life. Systematically participation in conservation of these communities might be a good way to improve process of protection, and to prevent further heritages destruction; which sometimes found expanding as social conflict.

[1] The University of Tokyo, Tokyo, Japan - pornsan@ud.t.u-tokyo.ac.jp

This study will clarify the potential of each religious community in conservation term. Buddhist, Islamic and Catholic communities have different mechanism to manage and control their facilities. This study is based on interview information gathered from residents from several communities in the same neighborhood area of Thonburi and Bangkok-Yai district; the west side of Bangkok. Settlements in this area are well-known for traditional religious communities that still remain effective today.

The analysis will be made with case studies on points of “How the religious facility is managed”, “How the properties (land, buildings etc) are controlled”, “How the religious community role has changed”, and then “How much the community can participate in conservation process”. The results of this analysis should be compared between cases of different religious communities to figure out some hints to complement administrative mechanism, which communities have not yet been considered to play any role in conservation of their heritages.

1. Introduction

Bangkok was established to be the capital of Siam[i] in 1782. It has grown up as a multi-racial and multi-religious city where people from nations of Southeast Asia, China, India, Middle East, Western Countries and anywhere else live together. Since there were many ethnic communities, some of important urban heritages which remain today are religious facilities. Most of them are Buddhist temples, but there are also amounts of Islamic mosques and Christian churches locate here and there. In downtown Bangkok, visitors can find that memorable skylines of the city are mainly created with these religious facilities' buildings. (Figure 1)

Figure 1. Skyline of Bangkok is composed with sihouette of religious facilities.

How many religious facilities are there in Bangkok? According to Bangkok Metropolitan Administration (BMA) data[ii] in 2007, there were totally 755. The number can be broken down to 449 Buddhist temples, 169 Islamic mosques, 59 Christian churches (Catholic and Protestantism), and 78 other religious places. (Figure 2) From the ratio of nation-wide Thai people's belief of 95:4:1 for Buddhism, Islam and Christianity, we can say that diversity of religious beliefs in Bangkok is quite more outstanding than the rest of the country.

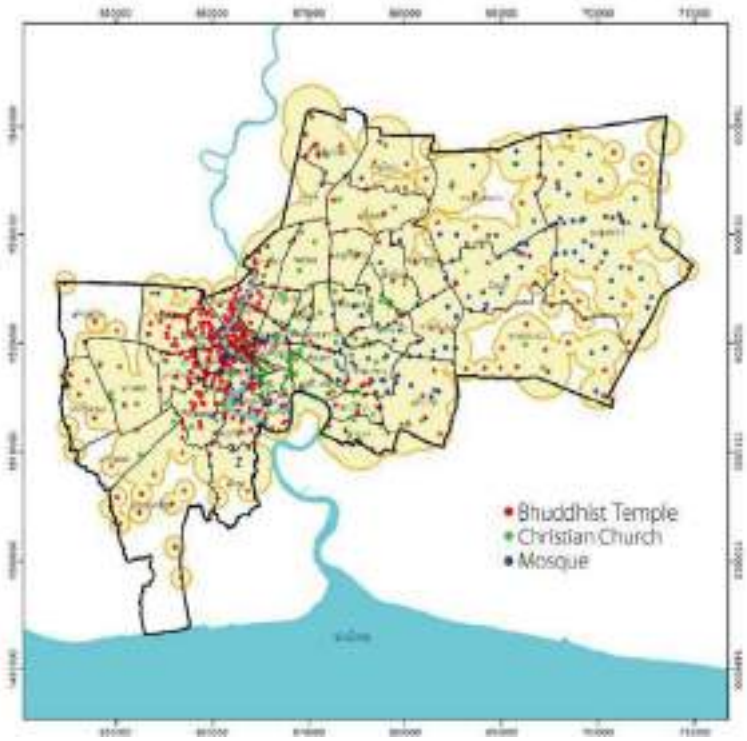

Figure 2. Distribution of religious facilities in Bangkok (Chulalongkorn Univ.:2010)

By the way, how do Thai people and government consider these religious facilities as their cultural heritages? According to the declared monuments list of Fine Arts Department (FAD), the governmental authority[iii] which has a very duty of cultural heritages protection, there are 191 places of monuments[iv] have been declared in BMA area until the year of 2009, and the number of religious places is 84[v]. This high percentage shows that religious facilities/buildings are really important parts of urban heritages in Bangkok that should be well protected and handed over to coming generations.

In fact, religious places are quite different from other monuments. If a declared monument is public, the responsibility of management and maintenance would be at public authority that the property belongs to. If it is a private property, it is the owner's responsibility to take care of the monument under administrative control of FAD. How about a religious one, which is not completely taken public or private?

The crucial partner is of course the religious organization itself. But Thai government also has some financial support to religious facilities maintenance, especially for Buddhist temples even they are not declared as monuments. And citizens might be the other important partners of the issue, as they are common users and supporters of those facilities.

Figure 3. Local people go to temple in a religious festival.

Traditional urban communities in Bangkok are always religious-facility-centered. We can find this kind of communities quite easily in downtown of the city even nowadays. For example, around a Buddhist temple, there is a Buddhist community that related to that temple. Community members always use temple's facilities in their religious ceremonies and also in any events of their lives. (Figure 3) Spaces in the temple are used as public open spaces for community. The land that the community locates usually belongs to the temple, and people have to pay their rental fees actually. Temple's management expenses are regularly from assets utilization like above, and also from donations of believers and the community. Mosque and church have similar system in order to get budgets for their facilities operation too.

By the way, the conservation system today seems to make light of community's importance. System is created to deal only with religious organizations, who are often legally owners of the properties. In historical context, community can be considered as important as religious place itself, so that should be included in some processes of this kind of conservation. This study will find out how people can now participate in current conservation system from laws and regulations review and interviews with key-persons of each religious community. Then possibilities of community participation in processes would be clarified for better religious facilities and surroundings protection, as they are important urban cultural heritages.

2. Scope of Study

2.1 Study Questions

Questions which this study tries to answer are as follow.

(1) What is the mechanism of religious facilities conservation in urban area now?
(2) How does community participate in religious facilities management process?
(3) Are there any differences in process/mechanism between religions?
(4) How can we apply existing potentials of communities in order to protect our urban religious heritages?

2.2 Study Targets and Methods

This study focused on downtown area of Bangkok, where traditional communities with religious facilities still exist. The Thonburi side (West Bank) of Chaopraya River was selected as the target because existing land use is still mainly residential even it is considered as a part of downtown area, so it is appropriate to see functional urban communities in this neighborhood. Precisely 3 communities of the districts[vi] of Thonburi and Bangkok-Yai were chosen to be study cases, since they are in the same neighborhood, and given conditions and circumstances are similar. Wat Kanlaya Community is the sample for Buddhist, Masjid Tonson Community is the one for Islamic, and Kudeechin Community is decided to be Catholic case-study community for the study. (Figure 4 and Table 1)

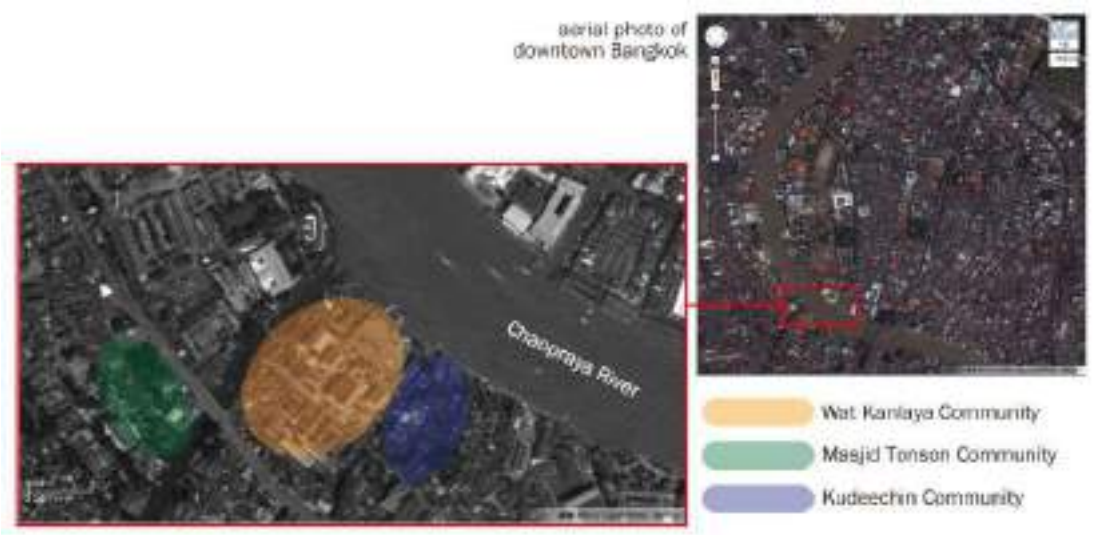

Figure 4. Location of Study Cases

The study started with review of literatures, laws and regulations which related to conservation of religious facilities. Then, Interviews of key informants[vii] are held in order to understand each study case situation. Collected information and data were reorganized to explain how different between each community and its mechanism. The conclusions would come at last that what should be done with communities to strengthen the conservation system in Thailand, as the results of discussion from case studies.

Table 1. Abstracts of Study Cases

	Appearance of Community	Religious Facility	Brief History of Facility
Wat Kanlaya Community		Wat Kanlaya	- Built in 1925 by a high officer and given to the King later. - Located by the bank of Chaopraya River - 2nd class royal temple. - Famous for its Great Buddha.
Masjid Tonson Community		Tonson Mosque	- Originally formed in Ayutthaya Period. - Historical evidences of community settlement can be back to Thonburi Period. - Former mosque was built of bricks. - Current mosque was completed in 1954.
Kudeechin Community		Santa Cruz Church	- Established in 1769 on given land by the King of Thonburi. - Once rebuilt in 1836. - Rebuilt again in 1916 and still in use until now.

2.3 Literatures Review

There are several researches related to this topic. Some of them are about religious facilities in Bangkok[viii], usually focusing on Buddhist temples, and suggesting how to protect them in good environments. But they scarcely explain roles of communities in existing mechanism of conservation. This study would be a fundamental research to clarify the real state of community participation in religious heritage management, and find possibility to involve it into the conservation system in the future.

About religious organizations in Thailand, there are also some researches in fields of religious studies and cultural anthropology[ix]. Some Japanese researchers mention about "State Buddhism[x]" in Thailand that affects the country's governance system. This should be considered in term of heritages protection administration too. By the way, some studies on Islamic societies and communities[xi] are also found, but there is no current study on Catholic communities in order to refer.

3. Existing Systems of Religious Facilities Conservation

3.1 Cultural Heritages Protection

Nationally valuable objects, buildings or places are fundamentally protected by "Ancient Sites, Ancient Articles, Art Articles and National Museum Act 1961" hereinafter "Monument Act". Section 7-13 in this Act mention on Ancient Sites (Monuments), which are divided into "Declared Monuments" and "Undeclared Monuments". Both are targets of preservation in this law, but differences are levels of penalties when there is a problem such as a destruction of monuments.

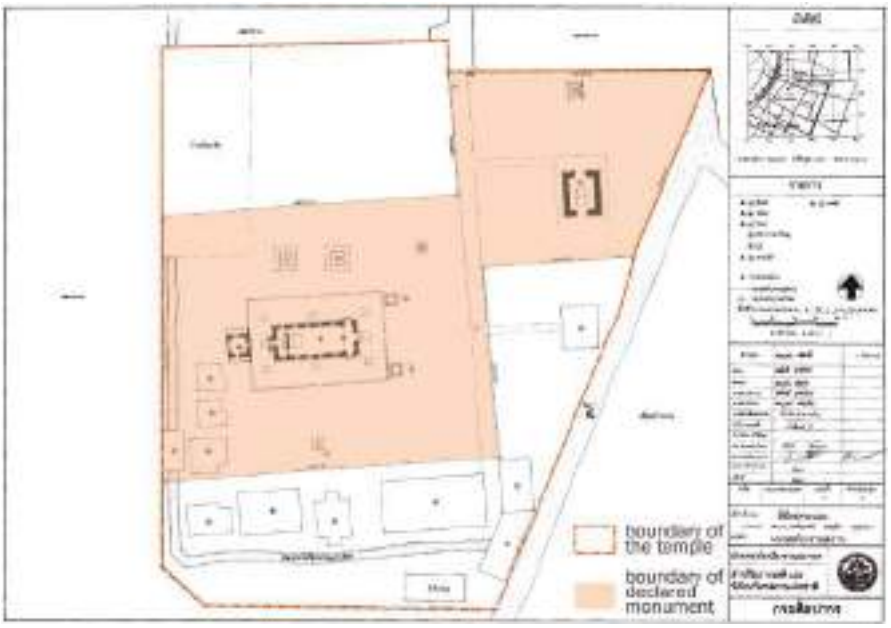

Figure 5. An example of monument declaration map

Once a monument is declared, the proprietor has to report and get permits from the Fine Arts Department (FAD), governmental authority which legally has a duty to take care of monuments, before having maintenance or any other kind of constructions that may change its values, structure or appearance. This is the only step added to the procedure for proprietor to proceed before taking any actions, but many people still misunderstand this point. They consider that their properties will belong to FAD after declarations, which is not true. FAD is just an organizing authority that helps protecting national properties by the law. Therefore private properties are comparatively declared in small number as we can observe from the list of monuments in Bangkok.

3.2 Religious Organization Control

In Thailand, there is no national religion cited in the constitution. People have full freedom of religion. Department of Religion Affairs (DRA) have approved 5 of them; Buddhism, Islam, Christianity, Brahman-Hinduism and Sikhism as religions most believed by Thai people[xii]. In fact, around 95% of population is Buddhist, and Theravada Buddhism[xiii] is practically taken for grant to be nearly national religion.

There are 2 laws mentioning about religious organization. One is for Buddhism, and another is for Islam. "Sangha Act 1962" stipulates the structure of national Sangha organization that has a hierarchy of management power. Anyway, every Buddhist temple is independent, and exists as a juristic person itself. The abbot of each temple is a representative by this law, and has full power over temple's properties. If the temple is declared as a monument, the abbot has to act like the proprietor and proceeds procedure in order to have physical change to the monument.

On the other hand, "Islamic Organizations Management Act 1997" is created to organize religious power structure of Muslims. According to this law, each registered mosque is also a juristic person, and independent. There must be a group of people called "Committee of Islamic Mosque" to operate mosque's activities, and this committee is the representative. Members of committee have to be chosen by registered members[xiv] of the mosque. There is no one act like the proprietor of mosque. Actions have to followed agreements of the committee indeed.

3.3 Urban Planning Regulation

Religious facilities are considered as public buildings as same as ones of governmental authorities, so that they can get exceptions of some building controls[xv] according to "Building Control Act 1979".

In local government level, Bangkok Metropolitan Administration (BMA) has regulations to protect and control environments around selected religious facilities. For examples, one is made for the pagoda of Wat Arun, a famous temple nearby

Chaopraya River. Height-control zones are created as a concentric circle around the pagoda (Figure 6 - left). Another example is a regulation made to be forced in high-density commercial area outer fringe of downtown Bangkok. Buildings within 50 meters from the borders of religious facilities in this area must be constructed under 16-metre height control (Figure 6 - right).

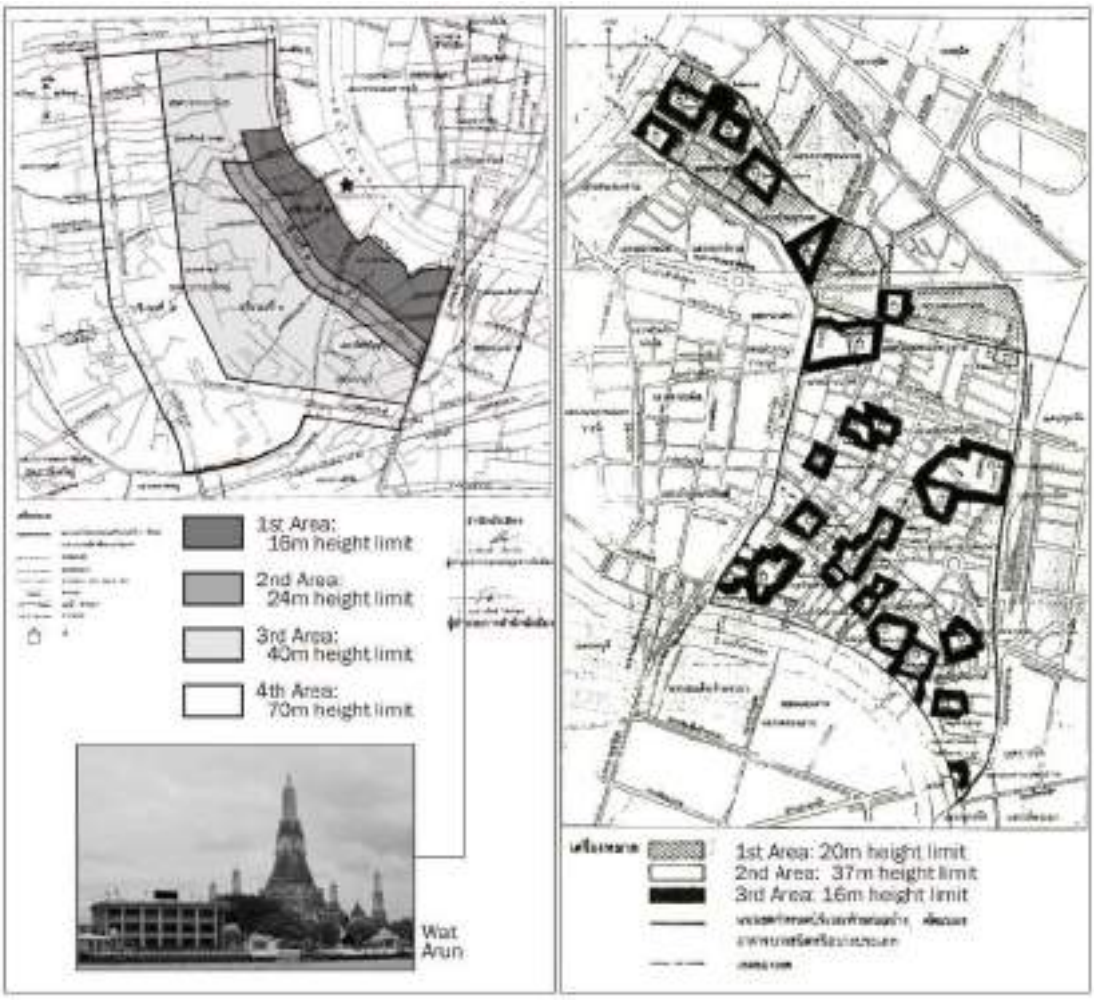

Figure 6. Description maps of BMA regulations related to religious facilities
Left: Height-control Zone around Wat Arun (1996)
Right: Height-control Zone in Outer Fringe of Downtown Bangkok (1999)

We might say that these existing regulations of BMA is considered to control and protect only vista or view of religious places, and they might be not enough to keep these kinds of urban cultural heritages in good environments.

4. Interview Results

Key informants interviews of 3 religious communities enabled us to understand better how responsibilities and powers actually exist in religious facilities. Relations between each communities and religious places are also clarified. This information should be really useful in further thinking of conservation process improvement, which is a main subject of this study.

4.1 Structures of Religious Community

Fundamental structure of each traditional community is composed with area of residences and the religious facility. Educational institute is often added if the community size is large enough. It is common to have an elementary school in Buddhist temple's site. Catholic missionary traditionally operates private schools nearby churches. But in Islamic community, it turns to be a religious school, which teaches the doctrinal contents of Islam to children who live in neighborhood.

One element that is unique for Islamic community is the grave. Muslims have to bury the corpse within 24 hours after someone's death, so it is necessary to have kind of facility in their community. We can also see places for funerals in Buddhist and Catholic communities too, but it is not an integrant element at all.

4.2 Origins of Religious Community

Urban Buddhist communities commonly emerged after temples had been constructed or renovated. Commonly, when temples were once completed, citizens moved to live around because traditional lifestyles needed to have temples nearby. Temples can be separated into 2 types, royal temples which are built of modified by Kings, noblemen or high officers, and private temples which are constructed purely by citizens. However ordinary people can normally use facilities of temples even they are royal ones. In the past, there was also a system of temple's slavery that government could dispatch slaves to Buddhist temples, but it was abolished in the reign of King Rama V. Therefore as places of liveliness, residential communities were naturally formed around temples.

Formations of Islamic and Catholic communities are different from above. Both religions were considered to be foreign beliefs even they had been propagated in Thailand for hundreds years. Residential areas for foreigners were separated from local residents since the Kingdom of Ayutthaya, and also had been carried on after establishment of Bangkok. The areas were always given by Kings, and the ethnicities can have their residences around there. When they founded communities, religious facilities were actually needed, and they had constructed themselves. The Tonson Mosque (of Masjid Tonson Community), and Santa Cruz Church (of Kudeechin Community) are also settled by local believers through this process.

4.3 Users of Religious Facility

There is no strict condition to use any religious facilities, if users are believers of the religion. Wat Kanlaya is traditionally used by local community people, but it is also nationally famous for the great Buddha's divine favor[xvi]. (Figure 7) Visitors from all over the country and also many foreigners visit the temple every day.

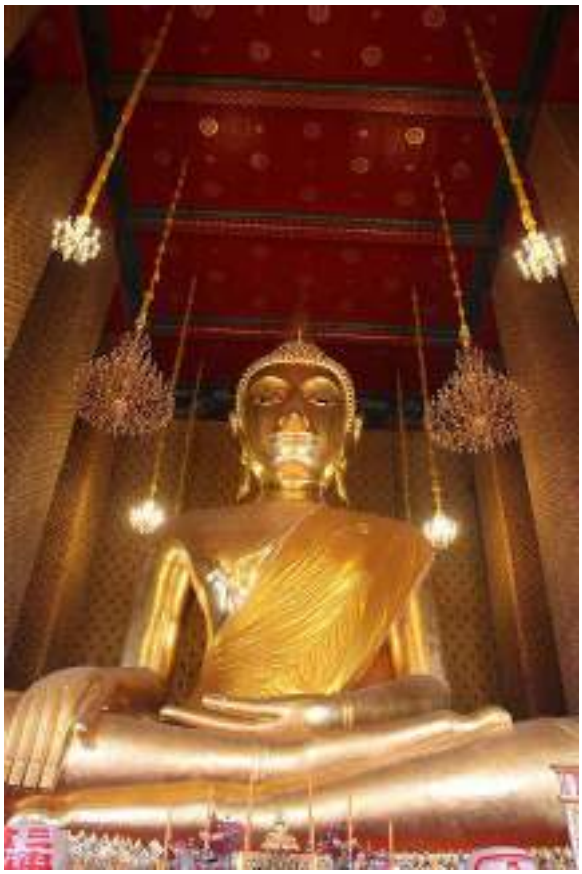

Figure 7. The Great Buddha of Wat Kanlaya

Mosque has a system of registration. By Islamic Organizations Management Act, Muslims have to be registered to a mosque, and in a place like community of Masjid Tonson, community members are always registered to the mosque. By practice, it is not necessary to go to the registered mosque, but most of people do. By the way, mosques have ceremony of worship every Fridays, and Muslims have duties to attend.

For Catholic community, there is no system of registration. Christians can attend Mass of any churches as they want. But as a result of interviews, it is said that people living nearby Kudeechin community, most of them are actually in the community, use Santa Cruz Church for their religious ceremonies.

4.4 Organization Structures of Religious Facility Management

From laws review, it is clear that Buddhist temples and Islamic mosques are considered as juristic persons, and have complete rights on their assets. How about Catholic churches? All Catholic churches in the city is under control of the Roman Catholic Archdiocese of Bangkok, and not completely independent. Any constructions, except little maintenances, of churches have to be approved by the committee of Archdiocese in principle.

In term of representative, abbot is the one who has full power over a temple. And "Committee of Islamic Mosque" will be the representative for any other mosque. Both have full responsibilities in managing religious assets and taking care of circumstances of the facilities. The difference is how decisions are made. In Buddhist temple, the abbot is the only one to make any decisions, but in Islamic mosque it should be the decisions of believers' group, since the committee is from registered members.

4.5 Tops of Religious Facility

Linked to organization structures, how tops of each facility are selected is also an important aspect to understand religious facility management. The abbot of Buddhist temple comes from monks' selection in case of private temple, and is sent from Sangha central organization[xvii] if the place is a royal temple. There is no restricted term for abbots, so they can be in the positions until the end of their lives.

Islamic mosque has no top in management. There is a committee in responsibility as explained. The committee also has head position for "Imam" who is a worship leader settles in each mosque, but power in decisions is at the committee, 6-to-12-people group, which is selected from the mosque's registered believers who are always in the community.

Top of a Catholic church and its community is the priest. The Catholic organization is hierarchical, and the priest of each church has to be dispatched from central. The term for a priest is 5 years, and he has to move to the other communities, or the other Catholic operated facilities such as schools after the expiration of duties comes.

4.6 Incomes and Budgets of Religious Facility Management

All religious facilities in this survey have incomes from donations and their assets leasing. The amount and ratio between sources of incomes is vary from place to place, and often unavailable to public. Actually, in case of a famous religious place with a great number of visitors, amount of donations is so much that is not comparable to anything else.

Santa Cruz Church also gets incomes from operation of a private school too. In contrast to this point, elementary schools in Buddhist temple's sites always belong to BMA, and do not make any direct income to the temples. Similarly, Religious schools in Islamic communities are also operated without any commercial consideration.

There are some budgets for religious places provided by Department of Religious Affairs (DRA) in order to maintain decrepit facilities. Fine Arts Department (FAD) has some for them too, if they are declared as monuments.

4.7 Assets Possession

According to Sangha Act, it is said that there are 3 types of land belongs to temples. One is land in use of religious facilities and monks' residences[xviii]. The other is called "Thorani Song" which is a part of land directly belongs to temples but it is leased for financial profit, in order to use those benefits in religious activities. In some cases, temples build buildings on Thorani Song and lease them instead of land. The last type is called "Kalapana" which is private properties of believers promised to give profits of land to temples. The concept of Assets Possession of Buddhist temples emerged around 100 years ago, when the country turned to be a modern state, and supports of the King and royal institutes got weaker[xix]. Temples had to have their assets management to survive in modern society.

Islamic and Catholic communities also have similar land leased to people which profits given to religious facilities. Sometimes the leasing land does not locate around mosque or church, but it is in downtown commercial area where can get very high profits[xx]. Anyway, there is also an example of mosque[xxi] that lease land to community without any charge too.

4.8 Land and Properties Tenancy

Contracts of leasing are regularly for 1 year in every study cases. It is set to be convenient for religious facilities to get their land or properties back if they want them to be in new usage of religions. By the way, communities borrowing them are usually traditional ones and have been exist there for long times as traditions, so problems always occur when religious facilities try to get them back to have further developments.

In Catholic Kudeechin community, there is a selection mechanism for new residents who are coming to live in management area of the church. Church committee, leaded with the priest, has duty to select new comers to live in the community, and the priority is given to those who are Christians.

4.9 Leaseholds Management

Post-leasing management system is only found in Catholic community case. The church committee, formed with church, school and residents representatives, plays the role of this process. Renovations or reconstructions of buildings in large scale within the community area have to be discussed in the committee in order to give permits to residents who want to have those projects. This mechanism is considered to help community to be kept in good condition of environment.

Table 2. Summary of Differences between Religious Communities

Communities	Buddhist Community	Islamic Community	Catholic Community
Structure of Religious Community	Residences + Temple + School	Residences + Mosque + Grave (+ Religious School)	Residences + Church (+ School)
Origins of Religious Community	Settlement comes after establishing of temple	Mosque construction comes after community settlement	Church construction comes after community settlement
Users of Religious Community	Local residents Visitors	Fundamentally registered members	Fundamentally local residents
Organization Structures of Religious Facility Management	Temple is a juristic person with the abbot as the representative.	Mosque is a juristic person with Committee of Islamic Mosque as the representative	Church is under control of the Roman Catholic Archdiocese of Bangkok.
Tops of Religious Facility	Abbot: Selected by monks (private temple), Sent from Sangha Central Organization (royal temple)	Committee of Islamic Mosque: Selected from mosque's registered members	Priest: Dispatched from the Roman Catholic Archdiocese of Bangkok
Incomes and Budgets of Religious Facility Management	Donation Assets leasing	Donation Assets leasing	Donation Assets leasing Operation of school
Assets Possession	Leasing land	Leasing land	Leasing land
Land and Properties Tenancy	1 year contract	1 year contract	1 year contract New comers selection process
Leaseholds Management	none	none	Church Committee: Post-leasing management

5. Conclusions

We can see similar and different points between communities in term of religious facility managements from this study. It can be said that to keep religious facilities and surroundings in good conditions is not only the duty of government or religious organizations, but it also has parts to deal with communities that are users and supporters of each religious place. What more is the area where communities exist is again the surrounding which can increase or decrease worth of these kinds of urban cultural heritages, so it is important to consider roles of communities when we think of conservation of religious facilities.

One of similar points for all religion is that assets management can be found in order to take incomes to operate religious activities, and to maintain their facilities. The system is created to have religious facilities be self sufficient, and get less helps from the government or central religious organizations. Communities get merits from this as they can have places to stay, and have facilities nearby to complete their rituals and ceremonies. Temples, mosques and churches can get rental fees from people in communities, and additionally some money from donations, to use for religious activities and facility maintenances. The balance collapses when donations become the main incomes of religious facility when it gets very popular that amount of rental fees collected from community means nothing. Or in the other case that occurs when the facility exists in the downtown area, the pressure of urban development around affects religious organization to utilize their assets in commercial use instead of use for community. These facts often cause conflicts between religious facilities and surrounding communities when new developments happen to occur. (Figure 8)

Figure 8. A development perspective image of Wat Yannawa, which was in conflict

To conclude the study, merits and demerits of each religion's current system should be summarized. First of all, in a Buddhist temple the whole power is at the abbot who is a representative of temple juristic person. A good point is that the right of any decisions is completely at one person so operation of assets management should be held smoothly. But on the other hand, how could people be sure that the abbot's decisions are always correct? There are some cases show conflicts on new developments, both inside and outside of the temple, between communities and abbots. Furthermore, the data shows that many royal temples have been declared as monuments, and by rules of Sangha, abbots of these temples have to be sent from central organization of Thai Buddhist monks. These abbots might have had high Buddhism education, but it is not mean they understand local culture of each temple. Gaps between senses of traditional value would occur between temples and communities, and appear to be serious conflicts if developments are still continued without agreement of community.

In an Islamic religious place, the power is at "Committee of Islamic Mosque" which is formed with representative believers of it. The decisions are not made by any single person, but they have to be results of committee discussions. This system seems to be quite democratic, and in a traditional community where most of people are registered with the mosque, decisions of the committee would be equal with decisions of the community. The merit is what people wish can easily take action. But in fact, there is no declared monument which is a mosque in Bangkok even many of them have enough value to be declared. And there seems to be lack of people's interest to have their religious facility to be a declared monument too.

At last, in a community with the Catholic church, the power to decide big issues is not there, but exists in upper level organization; the Archdiocese Committee. The priest's role is like a manager of church and community to report things upward, and has limited right in decisions. Anyway, there is a church committee which has duty of newly coming resident selection and post-leasing assets management, and this is very helpful to keep surroundings of the religious facility in good environment. This after care system is unique from other religious communities that should be adopted widely.

However, if we compare numbers of Buddhist temples and other religious facilities in the declared monuments list, "State Buddhism" seems to have some effects in the field of conservation too. Government should pay more attention to these other religious facilities because they are also important elements that show history of multi-culture, which is the identity of Bangkok.

By the way, we can see different degrees in potentials of communities in conservation of religious facilities and surroundings. Islamic community takes a big part in operating mosque and managing its assets. Catholic community is together with representative from church and school in the church committee screening new comers and taking care of changes in environment of the facility and around.

Participation of Buddhist community is the least because there is no place for its members in facility and assets management system. If we consider these religious facilities as living urban cultural heritages, communities should be the most important partners as well as supporters that are really helpful in management, protection and conservation, since they are users who get the most merits if the facilities are kept in good conditions. People in communities are ones who suppose to have consciousness of possession and protection awareness in religious facilities in order to handle them to coming generations.

Anyway, Constitution of the Kingdom of Thailand (2007) has a section mentioned about Community Rights. The sentence[xxii] is as below.

Section 66: *Persons assembling as to be a community, local community or traditional local community shall have the right to conserve or restore their customs, local wisdom, arts or good culture of their community and of the nation and participate in the management, maintenance and exploitation of natural resources, the environment and biological diversity in a balanced and sustainable fashion.*

It means community has actually right to protect what its members consider to have value representing their customs and culture. We can see religious facilities as urban heritages, and at the same time they are appearances of tradition and wisdom of local communities. But the system now doesn't let communities take much role in the process of protection and conservation of these heritages. We should consider how to apply potentials of current mechanism of each religious facility in order to make conservation system better and to conform to community rights clarified in the constitution. For example, Buddhist community and temple should set a committee to control or harmonize any development that may occur in both temple or community area, and work together with FAD to protect cultural properties and surroundings if there is any monument existing there. As well as, after-leasing care mechanism should be applied in Buddhist and Islamic communities, because it seems to be helpful in keeping the quality of community and protecting conflict that might occur, as we can observe in Catholic community nowadays. However, related government authority such as FAD should realize importance of communities that may help heritages protection in long term.

People's-based organisations in Düzce, Turkey: moving from disaster recovery to building resilience

Cassidy Johnson [1], Julia Strutz [2]

Abstract

There is a growing body of literature from the fields of development studies and also from disaster studies that highlight the roles of people's-based organisations and civil society in building resilience to natural hazards and climate change (IFRC 2010; Dodman and Mitlin, 2011); a potential that is also recognised with the Hyogo Framework (UN-ISDR, 2005). Local residents hold contextual knowledge about the place and about risk and that social capital can be potentially powerful catalysts in bringing about the type of transformation that can reduce risk to natural hazards and build resilience (Scolobig, Castán Broto and Zabala, 2008; Pelling, 2010). It has also been shown that risk reduction is most effective when the state can provide an enabling environment to support people's-based or civil society action (Maskrey, 1989; Satterthwaite, 2011). However, in practice, many civil society organisations operate outside of local government support, and must act in opposition to the government in order to achieve their goals (Johnson, 2011).

This paper explores how people's-based and civil society groups are engaging in resilience-building activities in Düzce, Turkey, a small urban centre that was devastated by massive earthquakes in 1999. Some of the groups, which formed in the wake of the earthquake, are still active, in some situations still engaged in disaster recovery that has taken many years to achieve, and in others they have become engaged in a wider range of development activities, or resistances to proposed developments that threaten the resilience of the built and natural environments. This paper also explores these group's relations with the local and central government and the potentials and problems around support and partnership.

The research is based on a cross-case analysis of three civil society organizations that were active in Düzce. The study is based on a qualitative methodology that uses in depth interviews and participant-observation both of the organisations' leaders and people within it, as well as with local government in Düzce. The researcher's findings are being reported back to the organisations and their leaders who have had a chance to comment on them and to provoke more discussion of the issues.

[1] University College London, United Kingdom - cassidy.johnson@ucl.ac.uk
[2] Catholic University of Leuven, Belgium – julia.strutz@ees.kuleuven.be

Initial findings show that while the community-based initiatives working in this area have built up the capacity of groups to demand change and support from the government, the lack of government support has meant that these groups have not been able to effectively act in partnership or cooperation with the government, which has impacted on their ability to scale up.

The work is particularly relevant to planning on two issues: 1) is to give voice to the inclusion of people's based activities and perspectives into the debate about resilience and risk mitigation planning and 2) to provide evidence of the practices in Turkey (based on Düzce case-study) of relations between people's-based groups and local government.

1. Introduction

The two earthquakes that devastated the Marmara and Bolu regions of Turkey in the latter half of 1999 offered a window of opportunity for civil society to take a greater role in shaping development of the region. The earthquakes and the destruction they caused exposed the deficiencies of the government in protecting its people from harm and being able to help them in their moment of need. Most of the almost 18,000 deaths and more than 50,000 serious injuries resulting from the two earthquakes were attributed to improperly built mid-rise construction, the quality of which should have been ensured by the government. This, coupled with the government's inability to effectively respond to people's immediate needs in the weeks following the earthquakes, necessitated that civil society, in all of its different forms, step in to take immediate action to rescue people and assist in meeting basic needs for shelter, medical attention, food and livelihoods. The government did eventually take control of the situation and exerted its power over the organizations, effectively curtailing their roles in many cases.

As the earthquake recovery progressed, there emerged a continued need for civil society initiatives that could address areas of the recovery where the government was lacking. The government's approach to reconstruction was to focus on large-scale infrastructure projects and mass housing targeted at homeowners. But there was a need also for social programmes that supported people's livelihoods and also for support to tenants and people who lived in dwellings without clear legal tenure and who were thus left out of state programmes.

Following the earthquakes, scholars drew attention to the fact that they opened up a place for civil society initiatives in development, and there was a lot of discussion about whether or not civil society's place at the table would be sustained over the long term (Özerdem and Jacoby, 2006; Jalali, 2002) It has been 11 years now since the earthquakes, and there have been many changes and fluctuations in Turkish politics and the economy at the macro level, including a change of government to the mildly-Islamic Justice and Development Party (AKP) in 2002, many legal reforms to meet EU accession demands, both in terms of human rights and government procedures, the economic crisis in 2000, and then steady and sustained economic growth over the

decade.

This paper looks specifically at three of the civil society initiatives in Düzce, one of the towns that were impacted by both the 17 August and 12 November 1999 earthquakes. The purpose is to draw out what these groups have been able to achieve in the 11 years since the earthquakes and, specifically, to consider their challenges in working with the government and how this has affected the scaling up of these activities. This paper argues that, while there are kernels of civil society activity related to resilience that have been sustained since the earthquakes, the scaling up of collective processes at grassroots level into something that could meaningfully contribute to building resilience in the region is stifled by a lack of local government support.

How states and civil society respond to disasters provides insights into the political nature of their relationship. A disaster event brings about an opportunity to change the structure of society–government relations and, in some instances, these new relations can bring about more effective forms of community governance. For example, Cuny (1983), notes that:

> "…a disaster traumatically brings into focus all the basic problems in a society. It reduces all issues to their fundamental level and strips away the ancillary issues that obscure or confuse the fundamental questions that must be faced […] For the society, disasters often bring changes in the structure of community leadership. New organizations may be born out of the necessity to deal with the disaster and remain to continue work of bringing economic change to the community. New leaders often emerge […] to replace those who have proved ineffective or unable to cope with the aftermath of a disaster." (11-13).

Disaster recovery and risk reduction are most effective where the state supports and complements community action through devolution of power and resources to the local level (Maskrey, 1989; Pelling, 2003; Dodman, Mitlin and Rayos Co, 2009; Wamsler, 2007). However, in order for this to happen, civil society requires an enabling environment from the state and from local government that is strong enough to support communities' visions and involvement in resilience building (Twigg, 2009). A wider engagement of civil society with the political and institutional structures of the city opens up important political space for community level groups to make changes (Pelling, 2003).

In order to address the needs of all people, it is necessary that state–civil society relations are both **collaborative and adversarial** (Jalali, 2002). Mechanisms need to be in place that allow organizations to have partnerships and collaborations with the state. Also, civil society needs to have the space to confront the state and check state power where it is necessary to ensure that the needs of all people are met.

Understanding the traditional power relationships and how they are being challenged

and permanently altered through civil society action is key to understanding how civil society is contributing to resilience.[3] Power manifests itself in different observable and obscure ways (Gaventa, 2006). Thinking about aspects related to power, the following questions can be posed. Did civil society involvement really open up spaces where a multiplicity of civil society groups could have an influence in shaping recovery and risk reduction? And have these contributions simply re-legitimized the status quo or is it really contributing to transforming patterns of exclusion and social injustice and to challenging power relationships?

2. Methods

This research starts by looking at civil society groups that were involved in the earthquake recovery in one town, Düzce, which is where the author has been involved in research and work since 2000 (Johnson, 2007; Arslan and Johnson, 2010). The three groups selected here are ones generally well-known to be active in Düzce, and were chosen because they have been active not only in one aspect related to recovery, i.e. housing or livelihoods, but have expanded their activities toward building resilience in all of its different facets. The length of time since the earthquakes allows for a long-term perspective on recovery, a viewpoint from which very little has been published, especially in English and related to Turkish cases. Two of the groups are grassroots organizations, initiated and led by the people. The other group is an Istanbul-based NGO that initiates and advises locally based groups, which then become autonomous organizations.

The research included seven in-depth interviews conducted between August 2010 and February 2011 with group leaders and group members. The interviews were open-ended, yet based on a standard set of questions about the groups' activities, relationships with the state and other actors, politics and internal functioning. The information derived from the interviews was supplemented by published material based on other empirical research on the same groups. The case studies presented here are a reconstitution of the interviews coupled with data from these other publications (as referenced). The method is not comparative in nature across the cases but, rather, compiles the cases to develop a general narrative about the landscape of civil society involvement in resilience. The discussion draws together the findings across the cases and also brings in findings from other published case studies on Turkey and civil society, providing analytical insights into civil society–state relationships, cooperation and plurality among civil society and the importance of information and transparency. The conclusions make links back to the general literature, reflecting on the sustained changes in power relations and the capacity of the state to encourage and enable community action.

---

[3] The word "resilience" is used because it puts emphasis on the overall capacity of all the systems to cope with any type of event, including emphasizing what communities can do for themselves, in addition to and in cooperation with the capacities of the state.

3. Case Studies

3a. Case 1: DepDer Düzce[4]

DepDer Düzce is one of seven disaster-affected people's associations (DepDer in Turkish) founded in the months after the earthquakes. Like other DepDers, which were founded in the surrounding towns of Kocaeli, Gölcük, Adapazarı, Değirmendere, Halıdere, Yalova and Avcılar, DepDer Düzce is a civil organization struggling for housing rights of people affected by the earthquakes. It was formed in response to a situation where people felt that the state was unable to solve their problems. DepDer Düzce currently has about 1,000 members, about 100 of whom are regularly active and are the driving force in the association. The central focus of DepDer Düzce has changed over the years, and those who are now left are people wanting to be part of the association for political reasons, or those without property, or those who lost someone in the earthquakes.

Many of the first members of DepDer Düzce were property owners before the earthquakes, and the initial work of the association was to ensure that the proper legal procedures were being followed and also to help people gain access to the new government-provided housing. However, two years after the earthquakes, there were still many families living in prefabricated houses or tents. These were people who used to be tenants before the earthquakes, or who had lived in informal settlements and therefore did not qualify for the government-provided post-disaster housing. In 2001, when the municipality began demolishing the prefabricated houses without solving the housing problems of their inhabitants, the role of DepDer Düzce shifted to defending the housing rights of those who were not owners. Together with DepDer Kocaeli, they questioned the government's policies, which only considered those with housing assets or property to be "victims" of the earthquakes, while renters and those from informal housing were sidelined in the government-aided recovery process. These people, whom the associations call *evsiz* (without house), held a mass demonstration in Ankara in 2001. One of the solutions proposed was to work together to get cheap land and also loans from the government, and to build cooperative housing. They founded the Disaster-affected Homeless People's Cooperative (Evsiz Depremzederler Kooperatifi), and members of the association stayed in Ankara for 75 days to meet the necessary politicians and responsible people, a process which ended with the detention of some of the members. During this time period (2001-2002) three other cooperatives were granted large plots of well-located land on which to build houses for non-owners. At one point, the municipality promised the *evsiz* a piece of land that had been given to the

[4] The information for this case study is based on interviews with Ayşegül Şenol , lawyer and member of DepDer Düzce, and Şener Sıddıka from the Steering Committee of the Disaster-affected Homeless People's Cooperative (Evsiz Depremzederler Kooperatifi). Both interviews were conducted by Julia Strutz in August 2010.

municipality by the Ministry of Housing. However, it ended up being turned over to the Mass Housing Administration (generally referred to by acronym TOKI).

Thus in September 2003, the cooperative began a lawsuit contesting the fact that other associations had better access to land and that the distribution of these resources was not equal. In early 2011, after a long struggle, a positive verdict was delivered – they had won their lawsuit, and are to be awarded by TOKI a piece of land with infrastructure, enough for 570 houses. The positive evaluation of their lawsuit was not only the first time non-homeowners were granted the right for disaster compensation in the history of the country, but it also opened a legal opportunity to form a housing cooperative that owns the land collectively. Indeed, the members of the cooperative commit themselves to work one day a week in the building process and are "productive" in this sense as a cooperative. In the years before the verdict, activities were generally quite slow and sometimes it was difficult to maintain members' interest in the cooperative. Most members suffer from economic hardship and live as tenants or in villages far away, and thus it was difficult to keep up regular meetings. Since the negotiations have led to more concrete outcomes in the last months and there is finally a plot of land they may own collectively however, the organisational capacity of the *evsizler* cooperative shows its strength again. Almost all the initial members of the cooperative founded 12 years ago join meetings again and prove verbally and non-verbally their belief in the project. Without any further support from the government – they even have to pay for a state certificate that proves the state-allocated plot to be earthquake secure – the self-building process of the houses, will depend solely on their capacity to act together and allocate funds to start the building process.

Besides these activities for the *evsiz*, DepDer Düzce is also engaged in local disaster risk reduction initiatives. For example, they are working to shape the current land use plans prepared by the municipality, with the aim of improving the city's resilience. The association is active in collecting information about their neighbourhoods and they organize meetings in the neighbourhoods to discuss the fact that the interests of property owners and the need for a resilient city are not always compatible. The municipality now comes and observes these meetings. The association also stands against on-going practices that they oppose, for example TOKI's construction of five-storey houses on land that is deemed to be unsafe. The aim of DepDer Düzce is for the city to have a central information centre on disaster risks and building, which they foresee could be managed either by the municipality or by Düzce University (the university in Izmit is involved in a similar project).

DepDer Düzce has good partnerships with other civil society organizations. They regularly work with the DepDers in Kocaeli and Gölcük and also with the Chamber of Architects and the Chamber of Civil Engineers. However, the relationship between DepDer Düzce and the municipality has not been an easy one. Generally, they feel that the municipality has tried to suppress the association (and in general people who wanted to do something about earthquake risk), by not listening and by

ignoring them for a long time. The municipality's reluctance around discussion of the earthquakes had to do with illegalities in the distribution of the money and also with inadequate disaster management prior to the earthquakes. However, with the new municipal government (elected in 2008), this has changed; the government in power doesn't feel responsible for what happened after the earthquakes and there is no longer any interest in money. This opens a window to begin discussing prevention and risk management once again. However, generally the organizations feel that the municipality is too slow and lacks the necessary staff to properly manage safe development. (In part this is related to the fact that Düzce only became a province after the earthquakes). In 2009, with a directive from the central government, the municipality founded a Disaster Directorate (Il Afet Acil Durum Müdürlügü) and a Civil Defence Unit (Sivil Savunma). With this new municipal government and dedicated staff, the association can now obtain information more easily, for instance about progress on a GIS that is being developed for the city.

3b. Case 2: Solidarity (IMECE)[5]

IMECE was formed after the earthquakes as a grassroots rebuilding initiative for three villages (Aksu, Çayköy, Hacisüleymanbey) in the Düzce region. In total, 57 houses were built between 2002 and 2005 in "solidarity" style (*imece* in Turkish) – meaning a collective process of villagers working together and with people from outside the villages. The process was much more straightforward than the work of the cooperative described above, because the land on which the houses were built belonged to the villagers prior to the earthquakes. The construction of each house cost Turkish Lira (TL) 3,000 (US$ 8,500) and was financed by a government subsidy of TL 6,000 (US$ 3,500) per house with additional funding from international sources secured by IMECE.

The driving forces behind the construction of IMECE houses are both external and local. There were external volunteers, from Istanbul, who came to assist, and one in particular who acted as a champion for the project. There were also international volunteers who came to the village to help with construction. Local women played an important role in the process – they attended meetings, took part in the decisions and also helped to build the houses. The villagers decided collectively who was going to have an IMECE house (one voice per household) and also worked together on the design of the houses.

The houses were finished and the infrastructure rebuilt by 2005, so the project's aims were achieved. However, this did not offer a sustainable solution to livelihoods. Many of the villages' young people finished university just after the earthquakes, yet remained unemployed for a long time due to the ensuing economic crisis in 2000.

---

[5] The information for this case study is based on interviews conducted by Julia Strutz with the *muhtar* (village headman) of Çayköy and with Erbay Yücak (one of the active members of the association), and informal interviews with the villagers during one of their meetings in August 2010.

Now they are leaving the village, as there is little chance of earning a living through hazelnut farming. Basically, the public institutions provided tents, food and credits after the earthquakes, but did not support any local initiative for recovery and strengthening of livelihoods. Thus there are some unfinished projects that IMECE sees as integral to the recovery process, yet they continually run up against various barriers, especially related to government support, which prevent these projects from being realized.

For example, to help the recovery process after the earthquakes, one of IMECE's ideas was to strengthen the local economy, which is largely based on hazelnut farming. The price for one kilo of hazelnuts prior to the earthquakes was about 6.50 Lira; this dropped to 2.50 Lira in 2004 (a state company bought the hazelnuts prior to 2004, but it was privatized) and now hazelnuts are sold at about 3–4.50 Lira a kilo. The idea was to develop direct links to European markets and to produce organic hazelnuts. For example, one hazelnut producer had made attempts to sell them to the Netherlands directly, but a lack of state support meant that this idea has not yet been realized.

Another project is the social centre that IMECE constructed, which was to house a hospital, a library, a guesthouse and a meeting room to do work with children and women. When asked why the building was standing empty, the local leader (*muhtar*) explained that they did not manage to get it through the bureaucratic process for political reasons. Even though the building has been built, the local government did not support the project so the necessary permissions for use have never been granted.

Generally, members of IMECE are frustrated with having to deal with the state to obtain permissions (for the hospital–social centre) and generally they are not interested in working with public institutions anymore. They say that even for the housing project it would have been better neither to have used state funds nor worked together with the state at all. Perhaps what also contributes to this perception of the state is that many of the villagers belong to an ethnic minority from the Georgian Republic and Abkhazia, which came to the region after the Crimean War; they feel that significant barriers are constantly being raised against them, and they experience racist behaviour.

Although IMECE is no longer an active organization, it did create an informal space for engagement. Many of the people who participated in IMECE are now active in other organizations, either trying to get proper housing for *evsiz* people or mobilizing against the hydroelectric plants planned for the valley where all the villages are located.

Currently, there is a plan for five hydroelectric power plants to be built in the valley where the earthquakes took place, with one of the plants actually being built on the fault line of the 1999 earthquakes. Resistance to the project now dominates discussions in the villages. It will take away 90 per cent of the water that flows through the valley, which is both drinking water and water for agriculture. It will also

create deforestation, leading to erosion and flood risk; in fact, increased flooding has already occurred in the areas that have been cleared. Villagers also believe this will eventually lead to their displacement, because the villages' livelihoods (agriculture and small-scale forestry) will become impossible.

The links established between the villagers are strong; the community is still undertaking a lot of activities together and many people have a very positive memory of the IMECE construction process. Since the earthquakes, the political power of the villagers has been awakened; they are going to meetings, discussing their common needs, working together in solidarity, meeting and linking with people from abroad. This interest and experience is visible in the action against the plans for the hydroelectric power plants – and meetings on these are clearly dominated by the three villages and by people who know each other from the "earthquake time".

Although they are not interested in working with the government, they do have partnerships with other organizations. Recently, the group has formed a positive partnership with Düzce University – whose scientists did an analysis for them of the impacts of the hydroelectric power plants project. Düzce University will probably also move into the unused IMECE social centre.

3c. Case 3: Foundation for the Support of Women's Work (Kadin Emegini Degerlendirme Vakfi – KEDV)[(6)]

The Foundation for the Support of Women's Work (Kadin Emegini Degerlendirme Vakfi – KEDV) was established in 1986 as a civil society organization with the mission to provide "…*support to poor women so that they could organize to respond to basic needs and to develop the capacities to improve their own lives and communities*" (Yönder, Akçar and Gopalan, 2005, p. 21). Prior to the earthquakes the organization had experience in operating child care centres in several low-income neighbourhoods, with support from the Social Services and Child Protection Administration (SHÇEK) and also from the Bernard Van Leer Foundation in the Netherlands. Immediately after the earthquakes, KEDV emerged as an organization that was capable of helping the women to organize and assist in the response. Sengül Akçar, Executive Director of KEDV claimed that the earthquakes increased the visibility of the organization and also its networks: "*Our approach was acknowledged and we had the opportunity to try out our strategies*."

In the days and months following the earthquakes, KEDV set up centres, first of all in the tent cities and then in the temporary settlements, where women could have a place to come together to share information and offer mutual support. As KEDV had

---

[6] Information for this case study is based on interviews conducted by the author and Julia Strutz with Sengül Akçar and Berrin Tenice, leaders of KEDV, in January and February 2011; also Yönder, Ayşe, Sengül Akçar and Prema Goplan (2005), "Women's participation in disaster relief and recovery", *SEEDS* pamphlet series No 22, Population Council, New York, 37 pages.

an ongoing partnership with SHÇEK and also because they had in the past signed a protocol with the regional administration, KEDV had a high degree of legitimacy already, which helped speed up the bureaucratic procedures for obtaining access to space. The idea was that these centres could help women to play a role as key agents in the relief and recovery process. The women used the centres as living rooms, workspaces, to receive guests and to run support groups. It quickly became clear that generating income was their main concern in the weeks following the earthquakes, as many needed to earn money to support their families. They became involved in the centres in many very practical activities, especially around income generation. For example, they organized teams to sell collectively made products to local merchants; they secured downtown stores from municipalities, and obtained stalls in two national chain department stores. They set up woodworking shops where they made wooden toys, and also screens and windows for doors, which were in high demand in the settlements. In response to the need for repairs and services, the centres trained women to become plumbers and electricians, to service the temporary housing settlements.

During the reconstruction women became concerned about the earthquake safety of the new permanent housing and also about the lack of inclusiveness in the way the government-run projects were being carried out. Following a visit from a women's NGO from India (Swayam Shikshan Prayog–SSP), the women systematically started mapping information about the people in their settlements, about the housing subsidies they were receiving, about people's livelihood concerns and other settlement-related problems. Collecting and owning this information, which the government did not have, provided the women with an asset they could use in negotiations. At one centre they discovered construction errors in some of the new permanent housing blocks in their district. This contributed to their concern that some of the new housing developers were the same ones who had built the buildings that had collapsed during the earthquakes, calling into question how the government was selecting contractors.

In time, each of the women's centres established its own formal identity as an autonomous women's group, so they could continue negotiations with authorities and access resources on their own without relying on KEDV. By early 2003, six of the eight women's centres were consolidated as autonomous service production cooperatives and four of these cooperatives are still active today. The situation after the earthquakes was extraordinary and full of movement; many things were possible and there was a clear gap to be filled by the women. Now, things are more or less back to normal but the cooperatives that still exist are important sources of livelihoods for the women involved. While the cooperatives are autonomous, they do keep in contact with the main KEDV office, which supports them in things such as writing funding proposals.

Sustained leadership has been a problem for the continued viability of the cooperatives. Once the women had moved into permanent housing they were less compelled take part in the cooperatives' activities; also, once the temporary housing

had been dismantled, the women who were renting moved into the city centre in search of housing, making the cooperatives, which were located on the periphery, too far for them to reach easily.

Change in government leadership since the earthquakes has also limited the cooperatives' activities. After the earthquakes, the central state was responsible for the recovery, not the local government. Post-recovery, when responsibility for development was back with the local government, the support structures, networks and contacts changed completely. This weakened civil society organizations such as KEDV, which had been strongly allied with the central government, as they were no longer supported in the same way by the local government. Today, the cooperatives are struggling because some of the municipalities want to take back the land and prefabricated buildings that they had allocated to the cooperatives' centres, because it has become valuable for redevelopment. In Düzce, and other towns, the municipalities want to redevelop the sites for other uses and are not recognizing the importance and value of the buildings' social function.

Furthermore, by 2003 women from the KEDV autonomous service production cooperatives had also established four separate cooperatives for housing in three of the disaster-affected provinces. As with the other housing cooperative discussed in Case 1 (the Disaster-affected Homeless People's Cooperative - Evsiz Depremzederler Kooperatifi) the idea was to build housing for tenants who were not included in the government's housing programme. These cooperatives had to be very pro-active and vigilant to obtain land and funding for the housing, however, they had several advantages over the organizations described earlier in this paper:

> "For example, during their visits to public agencies, the women learned that the Ministry of Public Works and Housing was considering auctioning off land in temporary housing settlements to cooperatives that had been set up by tenant groups for building apartments. Even though site selection would be based on each settlement's tenure composition, the women had already gathered this information and could supply it to the ministry. One outcome of this process was a promise from the regional coordinator of the Ministry of Public Works to give the women's cooperatives priority in land allocation" (Yönder, Akçar and Gopalan, 2005, p.26).

KEDV has also recently become active in disaster risk reduction activities, particularly in two Istanbul districts (Kartal and Kağıthane) where there were already active women's groups associated with KEDV. One of the women's activities in the neighbourhoods is to undertake a community needs assessment, which all the women's groups in all the neighbourhoods do when they first come together. What has been added to this process in Kartal and Kağıthane is mapping the environmental risks and the livelihoods at risk in the neighbourhoods. Once the risks have been mapped, the idea is to take this information to the planning stage, working with municipalities. In Kartal district, the women's groups were already managing green spaces and parks, and so had already established a good relationship with the mayor.

The mayor supports their interests in working together on planning for resilience and risk reduction, although they are at the very early stages of cooperation. KEDV is also cooperating with Istanbul Technical University to prepare a manual about risk assessment and community needs assessment that all the groups can follow, which will reduce the training time needed for each of the women's groups.

The idea is to develop mechanisms for community-based resilience as an alternative or complement to the technocratic disaster planning currently being carried out by municipalities. KEDV points out that household level preparedness has been prioritized over collective initiatives; for example, the Istanbul Seismic Mitigation and Emergency Preparedness Project has piloted a project for disseminating information to the community about preparing your household for disaster. What is absent, however, is information about the risks that need to be addressed by the collective. For example, the greatest risks identified by the community have been: petrol stations close to housing areas; lack of space to gather in case of evacuation; knowledge about safe construction techniques; and small businesses at risk. Most of the risks are related to preparing for earthquakes, but people are also thinking about chemical explosions and, more recently, about flooding, as this is becoming an increasingly greater risk in Istanbul.

Although they are in the initial stages of this process of integrating risk reduction into their work, KEDV foresees that the greatest challenge for scaling up will be that the municipalities will fail to see the connections between this approach of community-based resilience and the more traditional approach to disaster management centred around response strategies, such as fire brigades and search and rescue. Despite taking part in training sessions offered by Istanbul Technical University, municipalities either do not recognize the legitimacy of community-based resilience or are not equipped to integrate it into their institutional processes:

> "Local, community-based initiatives, such as those by autonomous women's groups, do not get any support from disaster agencies. Disaster mitigation is still considered to be an area of technical expertise and a matter of training individual 'heroes', rather than community organizing and development" (Yönder and Turkoğlu, 2010)

When asked about how they could improve this situation, Sengül Akçar of KEDV explained:

> "First of all, we think the partnership with the university may be helpful, as it is more likely that the municipality will listen if it is the university talking; secondly, there is a need to have good examples to show how this approach can work, pilot projects, which is what we are trying to achieve now. Third is the need to have a presence to legitimize our approach. We have 30,000 women in Turkey as members of the cooperatives, so this lends some power."

4. Discussion

4a. Relationships with the state

Özerdem and Jacoby briefly characterize the relations between civil society and the state in Turkey as follows:

> (The state) is not a Leviathan that harasses society, historically the image of the Turkish state has been that of a distant and omnipotent system that ordinary citizens would do well to avoid at most times. Simultaneously, though, it is also assumed to have infinite means and resources to distribute through benign largesse giving it an overall ambivalence revealed in the paternalism of the commonplace term *Devlet Baba* (Father State). The result is, for many commentators, a 'passive–exclusive' state whose internal contradictions and weaknesses in regulatory and distributive capacities combine to form an administration which 'neither combats nor promotes civil society' (Kalaycıoğlu, 2001). In other words, *Devlet Baba* thus signifies both distance and authority through which the patrimonial attitude of the public sector has continued the centrist and elitist mentality of the Ottoman pashas thereby posing a considerable obstacle in the development of a *civil* society. Özerdem and Jacoby, 2006 p. 54).

The case studies presented here, and also supported by other published case studies about the 1999 earthquakes recovery in Turkey (Demirel, 2005; Ganapati, 2009; Yarar, 2005; Kubicek; 2002; Jalali, 2002), show that there are kernels of community-based and civil society movements, including initiatives for disaster recovery and risk reduction, which are challenging the mainstream actions of the strong central government in Turkey. However, the scaling up of collective processes at grassroots level is stifled by a lack of government support at the local level. While this lack of support may in some ways be related to political interests or the validation of the needs and rights of the groups, it is also related to local government capacity to effectively respond to civil society initiatives and demands.

The case studies illustrate that for the most part, neither the state nor the local government is providing an enabling environment in which civil society groups and community-based organizations can scale up their activities or act in partnership with the government. Associations and networks were formed after the earthquakes not because of an enabling state but, rather, as a reaction to the top-down recovery institutions and the approaches to recovery by state actors, which did not meet the needs of the people. Jalali argues that in this context, civil society acted mostly as adversarial to the state (Jalali, 2002).

At the same time, many initiatives, like KEDV, did successfully cooperate with the state, or at least worked within the state system to complete their projects. For example, when it came to access to land, either for the women's centres in the camps or for the cooperative housing projects, the organizations needed to work within the state system. If they were not able to do this to get access to what they needed, they acted in an adversarial way, targeting the central government, for example by staging protests in Ankara and with lawsuits. We note that some limited success has been achieved through this adversarial approach, while it has also proved important in building solidarity among people.

These case studies also make it clear that there are organizations that are **in favour** with the state and others that are **out of favour**. In fact, several other published case studies make reference to the many privileges enjoyed by civil society groups with strong connections to the state (Ganapati, 2009; Kubicek, 2002; Yarar, 2005). Özerdem and Jacoby explain that, in legal terms, there are two types of civil society organization: professional organizations and private associations (*dernekler*), with trade unions representing an intermediate typology. However, in practical terms, they explain, there is a different dichotomy. On the one hand, there are organizations that are based on Kemalist and pro-western visions, or that have a neo-liberal vision, and are promoted via considerable state patronage and ties with government, some even acting as semi-official state institutions. Then there are those that maintain minority identities (such as Alevi, Kurdish or Roma) or have strong Islamist identities or leftist political perspectives, and thus are outside this system of state patronage and have considerable difficulty in carrying out activities. Ganapati (2009), in a case study of civil society groups in Gölcük, (another affected town in the region) observed that municipalities did offer logistical support to associations but favoured some networks over others due to ideological preferences. From the case studies presented here, there is a marked difference between what KEDV has been able to achieve and what the other two groups have been able to achieve. KEDV, through close ties to state officials and using existing networks within the state, was able to create the women's centres and crèches and carry out many programmes, with support from the state, regional governments and also international organizations. The other two groups (IMECE and DepDer Düzce) have been limited in their capacity to act by being outside the system of state patronage and thus have only been able to act in confrontation with the government.

Recently, since the last municipal elections in 2009, there appears to be some shift in this system of state patronage. For example, in Istanbul, several of the district municipalities have elected mayors from the Republican People's Party, based on a populist platform of support for the minority groups living in informal settlements (*gecekondu* in Turkish). In Sariyer municipality of Istanbul for example, a union of neighbourhood organizations has been formed, which represents 17 *gecekondu* neighbourhoods within the district. The union meets regularly with the municipality to promote the needs of the neighbourhood associations directly with the district mayor. In Kartal district, on the Asian side of Istanbul, the central government has planned to replace several of the informal settlements with projects developed by the

Mass Housing Administration (TOKI), which will displace the existing residents. The district municipality of Kartal (the same one that is working with KEDV on community-based resilience) has joined with the neighbourhood associations to resist and to negotiate with the central government regarding the upgrading of informal settlements. In April 2010, the municipality also granted legal tenure to 150 households located on lands under municipal ownership.

In addition to the system of state patronage, the case studies suggest that **pre-disaster networks** and contacts, or established links with the state, influenced what groups were able to do after the earthquakes. KEDV was able to achieve a lot in a short period of time because of established links with the regional and national governments before the earthquakes. Local grassroots leaders built on their pre-disaster civic and political experience to help people mobilize for collective action after the earthquakes. Pre-earthquake networks or political parties helped IMECE to find international and domestic donors to support their activities. Thus, for IMECE, and also the DepDers, despite the lack of enabling state institutions and policies, the fact that they were already familiar with procedures and practices of civil life helped them in their efforts to establish post-disaster initiatives. Ganapati's (2009) case studies in Gölcük also back up this finding, showing that people who had previously been involved in civic networks (such as sports clubs, civil defence organizations or labour unions) or political organizations/parties were the ones who came forward as leaders after the disaster.

Patronage systems with the local or district level municipalities, biased as they are, will change direction if the new draft Law on the Transformation of Areas under the Risk of Disaster (Afet Riski Altındaki Alanların Dönüştürülmesi Hakkında Kanun) will come into operation. This new law transfers all state-owned land to the authority of the Ministry of Environment and Urban Planning (Çevre ve Şehircilik Bakanlığı) and rules out all lower strata of the local or district municipalities and their responsibility for risk reduction. If an area is declared as risky in terms of location or housing stock by the Ministry of Environment and Urban Planning, the whole area will be demolished and re-built by the Ministry's executive TOKI (and probably subcontractors). The legal owner only has three options: 1) sell the housing for market prices and leave, 2) acquire an apartment of similar size in the new project and pay the difference in value to the Ministry or 3) acquire an apartment of much smaller size in the new project. In all cases, the Ministry is not bound to built the new project in the same or a close-by location; the owner will have to pay for the demolition of the risky property and hand over the ground plot. A drop-out from negotiations is liable to prosecution, tenants and inhabitants of informal settlements are excluded from the process anyways. Only in Istanbul, an estimate of 2 Million housing units will be demolished.[7]

[7] Kentsel dönüşümde tuzağa düşmeyin (Don't fall into the trap in urban transformation), April 21st, 2012, http://www.ntvmsnbc.com/id/25342196.

Seen in the light of the practice of urban transformation in Turkey today, this draft law is discussed as a legal armament of the central state to force homeowners to sell their property and gather bigger plots for the urban renewal project of TOKI and its subcontractors. Communities will have to negotiate directly with the Ministry of Environment and Urban Planning and will be dispersed in most cases. Whether this operation will contribute to safer housing conditions with all the harm done to social structures and livelihoods, probably depends on the future actors involved: as it is the case already today, the Ministry and TOKI will not shoulder the amount of demolitions and construction works alone, but will be supplemented by a variety of subcontractors. Their quality standards, site selections and the will to control them will determine whether the newly constructed houses will be inhabitable and safe – especially in 30 years time.

4b. Cooperation and plurality among civil society

All the groups consider cooperation with other groups to be an important element in enabling their activities and building the strength of the movement. DepDer Düzce was strongly aligned with the other DepDer organizations in the region and used this linkage to share information. Both IMECE and DepDer Düzce have linkages with Düzce University, which has been supporting their activities with technical expertise. KEDV formed a network of women's centres and these centres have acted together closely, sharing information, experience and strategies when needed. The groups have also cooperated with external organizations, which has been helpful for funding and also for building solidarity; however, it is cooperation with local organizations that has been important for building the capacity of the groups.

It appears that the associations and organizations choose to cooperate with somewhat selective groups. They were more likely to cooperate with groups that had similar political outlooks, or that are aligned across ethnic or gender lines. Kubicek (2002) points out that civil society in Turkey is very pluralistic and deeply divided along political and ethnic lines; for instance, there are liberals and conservatives, secularists and Islamists, nationalists and Kurdish activists. This pluralism means that civil society is fragmented in terms of its aims; groups do not have a collective ideology about what they are fighting for and thus civil society does not stand as one mass of people against the state. This hampers the ability to push for broad social and political change. Furthermore, the lack of a singular focus means that the state can play favourites and collaborate with non-threatening groups.

Yarar (2005) comments that DepDer Düzce was the most controversial and challenging movement in Düzce after the earthquakes and was thus criticized by main power groups and homeowners who did not believe tenants and others should have rights to housing in the earthquake recovery. This echoes similar debates in Istanbul, where state and private housing developments are displacing informal *gecekondu* settlements based on a rhetoric that denies informal settlers any occupancy rights (Gündogdu and Gough, 2008).

4c. Information and transparency

One of the main issues for an enabling environment for risk reduction is the availability of information about planning and development, and mechanisms to share this information across state and civil society groups. In Turkey, there appears to be a need for better access to information and greater transparency in government processes. The lack of access to information about planning and building and about disaster risk was highlighted by all of the groups. The main goal of many of the DepDers was access to information and education of the public. They wanted to represent the poor, disabled, women and renters and to act as pressure groups on the local governments. KEDV became involved in developing and sharing its own information among its members (and sometimes the state). Transparency was also an issue after the earthquakes, and continues to be an issue. The allocation of land to cooperatives was not transparent. Information about the hydroelectric power plants project in Düzce and about plans for urban development in the region are not made public. Relevant to this concern is the DepDer's intention to develop a central point for information about earthquake risks, planning and building that would be available to the public.

Information available at the local level and two-way communication about planning was further hampered by the fact that the local government was not responsible for the recovery. Normally, local and provincial governments are mandated to prepare local level settlement plans within their jurisdictions. However, Article 8 of the Development Law No 3194 allows the ministry to intervene in the preparation and revision of plans that relate to disasters. Within days of the earthquake, the ministry invoked the authority granted by this article, announcing that it would prepare local level plans as well as plans for permanent housing areas in the earthquake zone. This meant that local government officials and civil society groups and community-based organizations who were nearest to the disaster location and who knew the local conditions the best, were divorced from the planning processes.

5. Final reflections: unpacking the limitations to scaling up

The initiatives described in this paper, although they have been very important for the people involved in them in terms of building solidarity, networks and capacity to act, remain quite small in scale. It seems necessary to reflect on three points introduced earlier in the paper in order to understand what limits the capacity to scale up. First, Twigg raised the issue that in order for the (local) government to provide an enabling environment for community participation in resilience, the government needs to be sensitive to the perspectives, needs and rights of the people concerned.This is one of the crucial issues here because it appears that the government is failing to legitimize or validate the perspective of the groups, sometimes because they are too controversial. For example, the demand for housing for renters, as put forward by the DepDer, is contradictory to the basic principles of the housing market in Turkey. As Yarar (2005) points out: "*For them, if the state begins to distribute houses to the tenants and poor, this becomes a starting point for*

everyone living in Turkey to make the same claim from it" (p.17) The women's groups that are active in Istanbul with KEDV also have difficulties having their perspectives validated by the local governments.

The second point is that for the state to engage meaningfully with civil society, it needs the institutional systems and capacity to do so. The new laws regarding citizen councils is a positive step, but still, government needs capacity to really address this in a meaningful way. It seems that municipalities in smaller urban centres, such as Düzce, generally lack the capacity to interact with community-based organizations or to develop better forms of communication that would enable more participation in the development process. However, to be sure of this, more research needs to be done in Turkey, focusing on the local government capacities to engage with civil society, especially around the areas of urban planning and risk reduction.

The third point is around power. Certainly, in terms of challenging the power relations, these groups are adept at acting in an adversarial way to demand change. But has this transformed the patterns of exclusion and social injustice? It appears that while there have been some small steps, this has not yet happened in a meaningful way. Have the groups opened up spaces where they can influence recovery and risk reduction? There have certainly been attempts by all of the groups to do so, whether through demands for sharing information or attendance at meetings. However, generally, the groups still lack open and influential forums where they can engage with the government in decision-making.

ABSTRACT

In England over the last decade a new approach to planning has been pursued, referred to as spatial planning. Despite being broadly accepted as the country's progressive theoretical and professional currency, the terminology has become politicised following a change of national government and as a result has fallen from prominence. An often overlooked component of the spatial planning approach is the decision making and implementation function, development management; and yet this concept is potentially very relevant to the challenges facing planning in England today. This paper will consider the current relevance of the development management approach; its impact to date, and the potential for it to support the current government's agenda, which is based around a concept of 'localism' whereby communities and neighbourhoods take on new planning functions.

The development management concept, in contrast to the reactive process orientated DC approach of the past, is based around operating a multi-faceted end-to-end delivery and implementation orientated process utilising implementation tools/mechanisms, organisational approaches, front loading, monitoring and feedback with an emphasis upon skills and culture change within the profession.

Development management is intended to focus upon *outcomes* (i.e. meeting needs) rather than *outputs* (the implications of permitting/refusing development through the determination of a planning application - normatively related to the regulatory development control ("DC") function.

The paper reflects upon the evolution of the development management approach and its theoretical underpinnings. We question the reality of development management, critique its impact in practice, and consider the value of the concept to planning today. The paper will also explore the approach's significance in the context of proposed neighbourhood planning and participation methods currently being introduced in England.

1. Introduction

The spatial planning approach was introduced in England in 2004 by the Planning and Compulsory Purchase Act. It made *"substantial reforms"* to the English planning system and has provided for a *"widened scope"* of interest (Nadin, 2007:43). Notwithstanding this extended remit, the national guidance of the time, Planning Policy Statement 1 (PPS1) 'Delivering Sustainable Development' (ODPM, 2005, paragraph 31), stated that *"development plan documents form the framework for taking decisions on applications for planning permission"*. This reinforced the retention of the plan led approach which has historically underpinned the English system, including the discretionary methodology for decisions on individual planning applications. Since 2004 questions have been levied at the concept of spatial planning and its application in practice. This paper will specifically critique the impact of the attempts to reform the decision making process for new development proposals (the 'Development Management' (DM) process) and will consider the current relevance of the development management approach, its impact to date, and its potential for the future.

2. Controlling development

The English planning system is plan-led. Development plans set out policies and land allocations to which decisions on individual planning applications/proposals should conform. Development control (DC) is the process whereby proposals to carry out development (including engineering operations and changes of use of buildings or land) are assessed by local planning authorities (LPA) to determine their suitability in a given location. When considering a proposal decision should be made in accordance with the development plan, unless material considerations indicate otherwise, an important factor which underpins the discretionary approach utilised in England. DC is fundamentally therefore a regulatory function that reacts to the submission and content of applications for planning permission. The requirement to apply for planning permission in this manner was introduced by the 1947 Town and Country Planning Act and the system today remains based upon these foundations.

The origins of the British planning system can arguably be found in the Assize Courts and the Assize of Nuisance from 1275. Historically control such as this over the use of land sought to prevent nuisance between neighbours, rather than pursuing a "*vision of public interest*" (Booth, 2003, p.9). Public benefit was largely related to practical issues such as preventing fire, safeguarding public health and ensuring

appropriate width of carriageways. The modern (post 1947) planning system, conversely, operates to safeguard public interests of acknowledged importance as opposed to providing a mechanism for protecting private concerns – although the distinction between the two is notoriously ambiguous and the impacts of one neighbour onto another can constitute a wider public interest issue, with value-laden phraseology such as 'protecting amenity' being used to justify decisions.

Post war redevelopment gave planning an *"elevated status… reflecting its ideological status as part of modernity and social reform"* (Tewdwr-Jones, 2008, pg.673). However, by the 1950s planning was already being seen as a restrictive activity by the incoming Conservative Government. The spread of urban areas during the 1950s led to a battle between town and country, which was further exacerbated by increased mobility through rising car ownership (and with it the new road-building programme). In response, the green belts circular (1955) sought to halt outwards urban expansion.

Since the 1970's the focus of DC has been on speed of determination: resolving delay in the system to the detriment of all else (Booth, 2003). However, what constituted 'delay' was not defined (the eight week deadline originating in 1933 failed to take account of how the function had since changed). DC was seen in the context of managerialist efficiency i.e. problems arose through administrative failures rather than any elemental weaknesses in the design of the system. The mechanics of the systems were the focus, not the *nature* of the system.

Planning in the 1980s was characterised by the theme of removing barriers to economic development. Development control was seen as a reactive, administrative and bureaucratic process that was a barrier to economic growth and new development, a criticism that was also levelled at the planning system as a whole in some regards. However, Cullingworth & Nadin (2006) argue that in the prioritisation of economic development and the relaxation of planning controls to achieve this was in many cases largely rhetoric, with politicians' actions not matching their words. Indeed, by the late 1980s the Conservatives' paternalist intentions to the environment were heralded which would result in a greater amount of restriction placed on development that affected 'green' interests and subsequently those relating to built heritage. Development control, despite some minor alteration, ultimately emerged from this period effectively unchanged and unchallenged.

During the labour administration of the late 1990s an increased role for regional government attempted to give planning a more strategic overview, particularly in terms of housing land allocation, whilst at the same time seeking to increase community involvement. This was compounded during the first decade of the 2000s by the addition of a regional tier to the development planning system. The intended consequence of gaining greater strategic control across local authority boundaries was not matched in ambition by the resources made available to the regions for such an important role and the wider limitations of this top-down approach was frequently exposed, particularly in the context of housing. Significantly however, during this

period the development control approach was given greater scrutiny than it had arguably witnessed previously. This was as part of what was presented as a step-change in the manner in which the planning system operates:

'We want a system that is capable of reaching decisions that command public confidence and which is seen to be open and fair. A system that underpins our desire to improve productivity by being capable of reaching a proper balance between our desire for economic development and for thriving communities. A system that is clear and comprehensible, that comes to robust decisions in sensible time frames... It is time for fundamental change'
(DTLR green paper, 'Planning: delivering a fundamental change', 2001, paragraph 1.8)

This was to become known as the spatial planning approach and the associated 2004 Act was the key driver for change at this time. Although the focus arguably remained elsewhere, this Act did also effectively underpin the emergence of the development management approach. It was significant that when the Labour government introduced spatial planning into England and Wales in 2004, they also sought a culture change in the way planning delivered its 'product'. The regulatory framework has evolved rather than been comprehensively redesigned since its introduction, with the fundamental workings of the decision making process broadly unchanged from those introduced in 1947. It was noted at this time that the development control function was too reactive, based on regulatory function, and do not actively seek to engage with those outside of the 'silo'. Development management was the solution to this issue.

It would be wrong to solely associated the last Labour administration with a top-down approach to governance, indeed much was achieved in increasing community participation and empowerment in this period, and yet in some respects this has been lost in the politics of the last election and the emergence of the 'localism' agenda under the Coalition Government. Spatial planning, as a term at least, has become politicalised and although the principles of this approach remain in most cases, the terminology has fallen out of favour alongside Core Strategies and other matters that emerged out of the 2004 Act. Where, then, does this leave development management?

3. Development management in a new world order: Decision making in a world of spatial planning

Prior to the 2004 Act there was, perhaps, a prioritisation given to plan preparation without explicit consideration of the implementation tool. Given that the planning system is 'plan-led' this is appropriate. However, a plan won't, in itself, make anything happen: *"Development control isn't a second order activity - it's what makes things happen. Actual forward planning and LDFs don't make anything happen"* Andrew Whitaker, head of planning, Home Builders' Federation). Delivering on the plan, implementing it, is clearly key. This implementation is

achieved, in part, through the delivery of new development, supported and approved through the development control/management process. It is therefore the necessary mechanism through which sustainable development, economic growth, environmental protection and sustainable communities are delivered.

The former Labour government's agenda to join-up services, to link 'outcomes' and to apply the spatial planning approach can be seen as central to the emergence of development management as opposed to a system based on control. Writing about the emergence of the spatial planning approach Nadin (2007:43) reflected on the goals of planning reform*, "to put planning at the centre of the spatial development process… as a proactive and strategic coordinator of all policy and actions".* The interrelationship between policy areas is an important facet of spatial planning. Nadin neatly sums up the difficulty of policy integration stating that making *"broad policy statements is one thing, application of these principles is another"* (2007:53). The intention was for DM, as a part of the post-2004 spatial planning approach, to empower the spatial planning approach to be enabled throughout the process of development, embracing the application decision making process and the associated elements occurring prior and post decision.

The central government department for Communities and Local Government (CLG) defined DM as, *"…end-to-end management of the delivery chain for sustainable development"*. The Planning Officers' Society provide a little more clarity in their definition, *"…an integral part of the spatial planning process; it puts spatial plans into action and seeks to achieve good design and sustainable development",* but again this requires a fair bit of explanation. Put simply DM is the delivery mechanism for putting 'wish-lists' into practice.

In the context of making planning decisions upon individual development proposals, the development management concept was intended, in contrast to the arguably reactive process orientated DC approach of the past, to be based around the operation of a multi-faceted end-to-end delivery and implementation orientated process utilising implementation tools/mechanisms, organisational approaches, front loading, monitoring and feedback with an emphasis upon skills and culture change within the profession. Development management was intended to focus upon *outcomes* (i.e. meeting needs) rather than *outputs* (the implications of permitting/refusing development through the determination of a planning application - normatively related to the regulatory DC function.

Development control, in its simplest form, consisted of the following:

Figure 1. Development Control

By contrast development management is presented as involving a range of other functions. It is something more; something bigger. The CLG (December 2009) consultation paper on Development Management sets out seven key elements that a DM service should involve:

1. Convening role - Proactive discussions with landowners, agents, developers, community groups, parish/town councils to provide the foundations for partnership and constructive relationships
2. Links matters which can be considered in the determination of planning proposals more closely to the community's vision for the area – look to see if additional benefits can be gained from the proposal that meet the dev plan vision
3. Pre-applications – communication, consultation, negotiation, advice to derive community benefits and timeliness in decision making
4. Proportionate approach – effectively manage limited resources within planning authorities
5. Engagement - wider liaison and partnership working with parties to achieve holistic solutions. Link to convening role of local authorities
6. Proactive delivery - focus upon delivery, not process and targets – greater use of masterplans and site briefs and a more cautious or restrained approach to the use of conditions, particularly pre-commencement conditions.
7. Monitoring implementation to continually develop best practice and ensure delivery of desired outcomes. Enforcement, to reinforce the legitimacy of the system and instil public confidence

The set this against the former development control approach it can been seen that development embraces a broader remit:

Figure 2: Development management

The additional aspects, often outside of the DC team and often their department, introduced by the development management approach are presented as sitting around the core regulatory 'DC' element.

Critiques however might argue that development management actually just represents best practice in development associated regulatory control activities and it is of note that the current government continue to see issues with the planning system and again, as in 2011 as in 2001, *fundamental reform* is being spoken of:

"Instead of planning being seen as the forum and the discipline whereby people can shape the places where they live for the better, it has become a crucible for controversy and acrimony…This Government is proposing fundamental reform… we have proposals which go back to first principles - not just tinkering with processes, but rebooting the way we think about planning altogether." (Greg Clark MP Minister for Decentralisation and Cities – Speech 2/2/11).

With further reforms being promoted now is a pertinent time to consider where we have come from. What was the reality of the development management approach?

4. Development management in practice

The introduction of the development management approach was largely given to the Planning Advisory Service[1] (PAS) to champion. It was emphasised that development management was not just a new name for development management; it was something new, something bigger, something significant. The previously mentioned concept of 'end-to-end' delivery suggested that development management would break down the silos within local authorities and move to an arrangement where the regulatory process is a mechanism, not the core driver, within the approach. Despite this, the fundamental regulatory framework remained relatively unchanged. As such it can be argued that this was further evolution, despite the rhetoric of fundamental change. This is effectively acknowledged in the PAS approach deployed with evolution rather than revolution sought through a transition from *controlling* development to *managing* it. This was seen as a matter of embracing 'soft' (culture) change rather than instigating 'hard' (regulatory) measures. The clearest evidence of the development management approach can therefore be found where new approach and techniques are utilised, but working within the extant legislation.

4.1 Flexibility

Local Development Orders (LDO) allow for discretionary local variation in permitted development rights. Wycombe District Council prepared an LDO (July 2010) to encourage economic regeneration in an historic area of High Wycombe that was experiencing high shop vacancy rates. The LDO, which covers a 0.7 hectare area of the town's historic centre, allows for material changes of use of ground floor premises without requiring planning permission. The area has been suffering from high vacancy rates and the order, which has a three year life span, allows businesses to change between retail, professional and financial services, café, bar, restaurant, office and institutional/public uses without the need to secure formal approval from the planning authority as would normally be required. The intention is to provide a more flexible approach within the defined area, allowing the market to lead on the future proportion and distribution of occupancy types. It has received strong support from Members. Although twelve months later all changes in use have involved retail uses, which would have been permitted anyway, it is suggested that this system sends a strong message to businesses of the Council's willingness to adopt a proactive approach to utilising tools to increase flexibility where appropriate. There are clear parallels between this approach and the current government's proposed Neighbourhood Development Orders which are envisaged to be deployed in a similar manner, but would be instigated by the Parish Council, rather than introduced by the higher level local authority.

[1] The Planning Advisory Service is a government programme funded by the Department for Communities and Local Government.

4.2 Community involvement and responsibility

As well as simply changing permitted development rights in a given area, an LDO can also be used as a tool to support community engagement and empowerment. Using the existing LDO mechanism, Cornwall Council led a pilot scheme with Feock Parish Council to enable the parish to direct minor development within a defined geographical ward (Carnon Downs). The LDO extends residential permitted development rights for proposals that comply with the requirements of a published design guide, produced in partnership by the two councils and the local community. The LDO came into effect in June 2011 with officers initially supporting the Parish committee in determining proposals, although in the longer term it is envisaged that officer time will be freed up to work on other planning matters. This approach has had the added benefits of: increasing transparency in decision-making through real community involvement in the planning process; increasing community confidence to meaningfully engage in pre-application discussions based on their design guide; and forging excellent working relationships between the councils with all parties learning from each other.

4.3 Project management

A key element of the cultural change is in the way in which proposals are managed, including through the formal planning application process.

Planning Performance Agreements (PPA) are effectively project management tools designed to facilitate the effective coordination of all aspects of the development proposal relevant to the planning process. They are designed to bring together all the key actors with an interest in the scheme together around the table, including in some instances appropriate community representatives, to manage the implementation process in accordance with an agreed timescale with marked significant milestones. Examples have already been seen in Bristol, Lancaster and Westminster, and the potential exists for more widespread use. The main hurdle to the acceptance of this approach for major developments is perhaps the issue of probity and transparency in decision making, as well as managing expectations. The agreement of a PPA does not, of course, imply an approval at the end of the process. However, what a PPA can do is support the effective management of the decision making process.

Seeing a planning application as a ‘project’ and a case officer as a project manager, combined with project management tools for the planning relevant elements of the process of development, can be argued to represent a significant shift in culture and approach.

4.4 Democratic accountability

Redcar & Cleveland Council have been working to ensure councillors can engage effectively at the pre-application stage. The issue of bias and pre-determination

makes involvement problematic, but the value of Councillor insight and input can be extremely valuable to the decision making process. A protocol for elected members has been produced to provide a framework to work within. Training was then provided for the relevant committee members – not all members are invited to avoid any risk of pre-determination, and the presentations are in addition to, rather than instead of, any of their wider pre-application consultation carried out by the developer. Presentations on proposals are managed by officers and are designed to allow member engagement with major development projects at the pre-application stage. for the. The protocol is clear that any subsequent discussions on each presentation is for issue identification only, rather than allowing any expression of views on the proposal. A similar approach is being operated by Chorley Council. Such an approach gives Councillors' confidence to engage in pre-application discussions without prejudicing themselves, thus improving democratic accountability in informed decision making.

4.5 Training, skills and organisational approaches

The emphasis upon cultural change carries with it a requirement to undertake wide-ranging organisational reforms and reskilling. At a fundamental level the transition from a land-use planning system to the spatial planning approach laid the foundation for this transition, providing a context that supported, perhaps even demanded, a parallel shift in the decision making and implementation functions of planning. Supporting this, organisation change, such as the merging of the national Housing Corporation and English Partnerships to form the Homes and Communities Agency provided for a coherent and coordinated organisational structure to support the wider change taking place. At the local level reorganisation and restructuring has occurred within a number of authorities creating major projects teams, delivery teams and/or undertaking internal reorganisation to integrate previously separate sections within their planning services, such as policy, development control, economic development etc.

A key further element that has been pursued is training and knowledge transfers. Led by PAS, training has been delivered for staff across not only local authorities, but also other public, private and third sector organisations who engage with them.

4.6 System changes

Although the core legislation that underpins development control/management has not been changed significantly, some key alterations have been made to bring about change. A significant area of focus this this respect is the introduction of a uniform system of application forms and submission arrangements. Previously, each local authority produced its own applications; now, a single form is used across England, unifying basic requirements. In parallel with this, e-planning initiatives have enabled electronic submissions of applications and consultation with stakeholders via emails and cloud systems.

Key mechanisms have also been revised, most significantly perhaps the parameters and approach associated with permitted development rights; those matters that are pre-determined and require only compliance, rather than needing a formal planning approval from a local planning authority following the submission of a formal application. The intention here has been to ensure that the system is proportionate, efficient and impact driven. An example of proportionality can be seen in the practices of the Planning Inspectorate, who have introduced a 'fast-track' planning appeals system for householder application appeals, streamlining the process associated with these minor cases and allowing resources to be focused where they are more required. There is an associated service improvement for those using the system through this strategy in addition to the internal benefits.

5. Impact

Although the previous section of this paper identifies good examples of best practice that have seen real benefit, it is argued that there are limitations which question the success of the DM 'project'. It is suggested that these can broadly be grouped as systems failures and failures in the profession:

Figure 3: Development management limitations

5.1 System failures

The value of Local Development Orders has been questioned for a number of reasons. In the first instance they have resource implications to establish. After being introduced there are on-going administration resource implications. To offset

there must therefore be clear benefit from their introduction, but is this the case? Where an LDO is introduced it is in circumstances where the flexibility offered is inherently acceptable. On this basis, any application that was to be submitted in the absence of an LDO would likely secure support and benefit from a relatively untroubled passage through the application process. Is certainty and flexibility therefore being formalised where it tacitly existed previously? For the local planning authority, the real cost is financial, each application now no longer required equates to a planning fee lost. There is therefore a financial cost for local authorities who can ill-afford the loss of revenue. Furthermore, the nature of an LDO is such that it will either be restrictive, or it will be flexible to an extent that is can only be deployed in a less sensitive area, such as an industrial estate or business park. Clive Dutton, who is executive director for regeneration, planning and property at the London Borough of Newham, has said on this: "I'm a little agnostic about LDOs because it's crucial to have integrity of design in the built environment, rather than letting any development of a particular use go through" (Townsend, S 2011). Potential benefits do therefore exist, but the financial model and potential environmental impacts will limit the application and value of this tool.

Planning Performance Agreements are also slightly troublesome in some respects. Although the concept of project managing a development proposal has significant merit, the use of a PPA is limited by the nature of the system within which it is required to operate. The inherent flexibility that exists within the British planning system means no certainty of a positive outcome is assured at any point during the process, arguably limited the attractiveness of the system to developer, whilst the perception of the agreement may still be unpalatable to other stakeholders. It is perhaps the approach that is at fault here, the introduction of a formalised process which sits above and beyond the standard processes and practices. Instead, greater benefit may have been found in a more flexible, less formal but universal employment of project management principles across all forms of application, with a scaled approach relevant to the application type. The key therefore being the culture change, not the introduction of a formalised process for certain types and scales of development.

The changes to legislation that have been undertaken, and in particular the revisions to the permitted development rights, have been a mixed success at best. Poor drafting, an absence of definitions, and a complex series of parameters with loopholes has unfortunately been the case, particularly for the householders permitted development review. These flaws have undermined what was a well-intentioned attempt to address a system with real issues. Unfortunately, the replacement system has been found to contain more issues than the original format. The suggestion that the transition was necessary because it took the system towards a 'impact based' approach is equally flawed; what was previous system based upon if not impact?

Finally, the dark shadow of resources limitations is cast over everything. With local authority budgets reduced and resources stretched ever further, the actual ability of

local authorities to actually bring about change is unfortunately limited, further compromising the potential impact, and indeed ability to introduce in some instances, the changes that can lead to the culture change required. Too often change continues to be driven by cost, not impact. Many have acknowledged how complex and divergent the new system could become and how few resources exist to enable it to be delivered. Rydin (2011a:32) considers that communities are likely to 'require considerable support' if they are to effectively use the localism powers that seem to be heading their way and, with the untimely cut to Planning Aid funding, it is likely that this task will fall to local authority planners. All of this has an associated cost implication, in terms of both time and resources, and there remains an unanswered paradox between the stated ambitions of the Coalition Government and the perverse spending cuts being passed onto local government, compromising their ability to support the new agenda (Hambleton, R. 2011).

5.2 Failure in the profession?

It is hard to escape the fact that issues may also exist in relation to the willingness, or the ability, of the profession to bring about change. Development Control departments remain in some instances in both name and operation, many developers continue to approach the process in the same manner, and a perception of rhetoric is attached to the development management approach.

The development management approach that appeared following the 2004 Act can be seen both as a response to criticisms about the perceived delay in determining planning applications with a positive outcome and also as a way of implementing a more proactive, community engaged spatial planning approach. PAS stressed that development management is not a new name for DC. This however clearly depends upon what is understood by these terms. Those seeking to explain the difference often emphasize DC's mechanistic and administrative functions in order to provide contrast with the theoretically more proactive and dynamic DM approach. The reality though is that the previous DC functions remain within DM, and many of the approaches promoted through the DM approach were previously possible, if not always employed, under the former development control regime and associated legislation. Many practitioners would argue that development management actually just represents best practice in development associated regulatory control activities (Croft and Sheppard, 2011). The profession has therefore arguably not responded to the introduction of development management, but conversely what were they actually responding to? And, having regard to the comments concerning resources noted above, did they have the ability to respond?

5.3 Approach and change management

As has already been highlighted, PAS were very clear that DM was not just another word for DC. This was a *fundamental change*. A new way of approaching the planning application process. But in most instances is it not DC best practice laced with government rhetoric? It would be understandable and reasonable for this

conclusion to be reached when one considers that in 1980 the following statement was published: “Development control must avoid placing unjustified obstacles in the way of any development…it is, and should be seen to be…part of the process of making things happen in the right place at the right time. Local planning authorities are asked therefore to pay greater regard to time and efficiency; to adopt a more positive attitude to planning applications; to facilitate development…” (Circular 22/80 (development control - policy and practice).

PAS noted that development management is the term that has been coined to include the range of activities and interactions that together transform the 'control of development and the use of land' into a more positive and proactive process that fits better with the ethos of spatial planning and better supports local authorities in their role as place shapers. The presentation of development management is therefore problematic because to a certain extent it is damned by association with development control. The suggestion that it could *replace* development control within planning is to associate it with the silo within which development control lived. Development management was therefore itself placed in a silo which compromised entirely its ability to be something more. By associating it with the implementation of policy removed its ability to embrace visioning, policy formulation and strategy, thus compromising the ‘end-to-end’ concept and effectively limiting it to matters associated with planning *applications* and thus development control. Promoting best practice within development control would have been one thing, to attempt to promote something more whilst constraining its ability to do so is quite another.

The approach to change failed to deconstruct the wider structures that existed, forcing development management to fit into an extant construct which prevented development management from being all that it could be.

6. Wither development management?

It is important to remember that despite the suggestion of a wider shift, the determining of planning applications remains an important aspect of the planning service and one that is set to continue for the foreseeable future. Consequently, any definition of development management needs to acknowledge this inherent regulatory function and the pressures (speed of determination, conflicting views, community interest etc.) associated with it. This, it is argued, is equally a limiting factor to the perceived impact and shape of development management. There still remains a legal requirement to process and determine valid planning applications. Consequently the regulatory function it fulfils should not be viewed as redundant and still requires appropriate resourcing.

One perspective is to see development management as development control best practice, and this has merit having regard to the benefits that can undoubtedly be seen when the system is used to its full extent and the process of development is

approached in a positive and proactive manner. But this is also to perhaps overlook the potential that the development management approach has.

The most important step is to uncouple development management from development control and instead to see the approaches and functions. It is suggested that if development management is seen as the operational implementation of the process of development within the spatial planning approach, transcending planning functions and genuinely representing an end-to-end methodology:

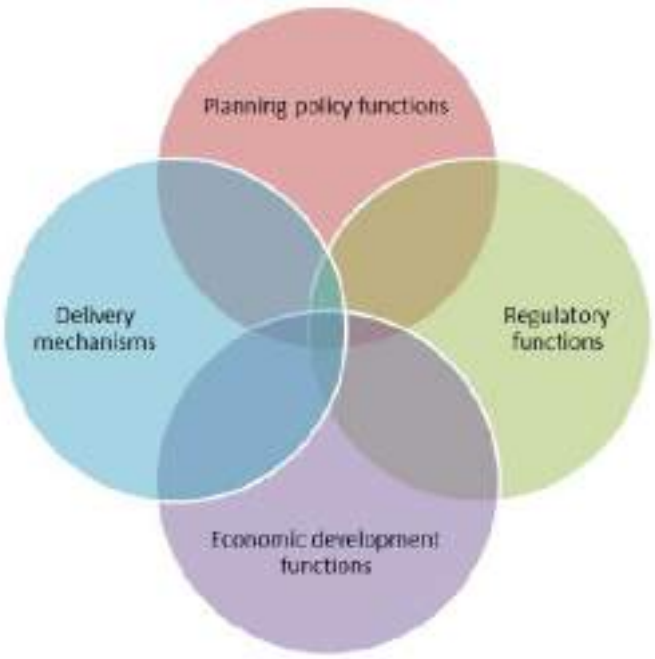

Figure 4. The development management *approach*

It is therefore suggested that whilst development management has clear limitations in the manner in which it was actually introduced, as an actual approach there is clear potential which has been somewhat lost as a result of the packaging, execution and resourcing. The development management approach requires a coherent strategy concerning the formulation of policy, the management of each proposal as a project, the coordination of activities, meditation between communities and other parties, and ensuring that the best outcome is realised.

In the context of the current localism agenda it will be necessary for many planners to further redefine their roles and work ever more closely with communities but the development management approach offers much in the emerging landscape and the best practice already seen should be championed. The development management *approach*, and the compatibility of the method with localism, should be further

explored and the true potential explored within a genuinely deconstructed approach to planning.

WHAT TO EXPECT IN 2030: THE IMPACTS OF FUEL PRICE AND FUEL ECONOMY ON LAND USE AND TRANSPORTATION

Sevgi Erdogan[1], Timothy Welch[2], Gerrit J. Knaap[3], Fredrick W. Ducca[4]

Abstract

The significant role of the transportation sector on land use, socioeconomic development and environment has led to new policies and regulations in the United States (US) that require planning agencies to integrate these additional aspects to be included in their transportation planning processes. This led to integration of macroeconomic, land use and environmental development models with long range transportation planning models. Integrating land use and transportation models in particular receive increased attention due to the significant relation between land use patterns and transportation. The cost of travel, which depends highly on fuel prices, can have a significant impact on the allocation of land uses, the amount of travel, the modes chosen for travel and the routes drivers select in a region. With the volatility of energy prices over the past several decades, the growing instability of energy supply both domestic and foreign, and ever growing demand, it is difficult to predict what fuel prices will be in the future. Reducing demand for fuel through advanced vehicle and fuel technologies by increasing energy efficiency and fuel economy have been one of the strategies to tackle with this problem. However, the market penetration of such advanced technologies in the future remains uncertain. To begin to grapple with such uncertainty, planners must understand the potential future impacts of energy prices. With knowledge of these impacts, better planning can be achieved to accommodate the likely outcomes. This paper investigates the impacts of increased fuel prices on future transportation system performance as well as travel behavior utilizing an integrated land use and transportation model. The developed scenarios build on national macro-economic forecasts of changes in household and employment allocations with future transportation network improvements and modeled in a multi-state integrated land use and transportation model for year 2030 in the Capital Megaregion area. The scenarios are conducted to measure the impacts of different fuel price levels on land use and travel patterns. As past research

[4] University of Maryland, National Center for Smart Growth Research and Education, College Park, MD, USA-fducca@umd.edu

suggests, high fuel prices yield increases in fuel economy. Therefore, the scenarios are designed such that both the impacts of fuel prices and resulting vehicle fuel economy (or vehicle mileage) on land use and travel behavior are captured. These scenarios can aid in understanding the issues regarding the rebound effect of increased fuel economy on travel. The analysis is conducted utilizing a modeling system that couples a four-step travel demand model exogenously with a land use model. The model results are analyzed compared to a baseline scenario considering various systemwide measures such as vehicle miles traveled, congested lane miles and emissions. The results show that increased fuel prices and fuel economy have a significant impact on land use and travel patterns. Increased fuel prices lead to a denser land use pattern and a reduction in automobile mode share and vehicle miles traveled even though fuel economy increases. However, the reduction is less pronounced if fuel economy increases significantly.

1. Introduction

Fossil fuel continues to be the main source of transportation energy in the US. In fact, 97% of US transportation energy comes from petroleum-based fuels (US DOT, 2010). Policies and regulations are in place in the US and elsewhere to reduce dependency on fossil fuels for various reasons such as volatile prices, dependency on foreign oil and related security issues and environmental concerns (e.g. Clean Air Act (CAA), 1970; the Energy Policy Act (EPAct), 1992, 2005; Executive Order (EO) 13423 and the Energy Independence and Security Act (EISA), 2007). Despite all efforts, fossil fuel is likely to remain the major energy source for the transportation sector for years to come. Research and development on alternative fuel and vehicle technology still requires much more time to develop and adopt. These technologies in practice will have many challenges as they become available. Thus, the unpredictable price of increasingly scarce fossil fuels will continue to impact the transportation sector and in turn land use patterns.

Early studies regarding the impact of energy prices on transportation and land use in the US primarily stem from the energy crisis of the 1970s and 1980s. Most of these studies focused on the impacts of fuel prices on either the transportation sector or on land use. Few studies considered the interrelation between transport and land use. Many of these early studies employed econometric methods to explain changes in travel demand with respect to various factors, including fuel prices (the primary concern of this paper). The relationship found between fuel price and travel demand was analyzed with an economics framework; using the term elasticity to describe the relation between the two phenomena. Many of these studies found that transportation demand is highly inelastic with respect to fuel prices in short-term, varying from -0.10 to -0.3 (Goodwin, 1992; Dahl, 1995; Espey, 1998). On the other hand, long-term price elasticity tends to be higher, varying from -0.3 to -1.06 (e.g. Dahl and Sterner, 1991a and 1991b; Graham and Glaister, 2002, 2004; Goodwin, 1992; Goodwin et al., 2004; Brand, 2009).

An increase in fuel price corresponds with an increase in transportation cost, which in turn leads to a series of travel behavior changes. A shift in travel mode, travel time or route is a short-to-medium term change. The common short-term response to increased prices is less personal vehicle travel. Eltony (1993) found that 75% of households' response to higher prices was driving fewer miles. Similarly, Bomberg and Kockelman (2011) analyzed the change in travel behavior in response to a gas price spike in 2005 and found that the respondents reduced overall driving and tended to chain together their activities. They also found that urban form plays a key role in individual responses, more than demographics. Hughes et al. (2006) compared short-term price elasticity of US gasoline demand between 1975 to 1980 and 2001 to 2006 and found that the elasticity is significantly more inelastic today than in previous decades. The significance of this result is that it reflects a structural change in the US market for transportation fuel which may be explained by changes in land use, socioeconomics or vehicle characteristics.

As the higher elasticity suggests, the response to a price increase in the long-term is more significant. Long term-responses include changing vehicle type (e.g. to energy efficient or alternative fuel powered vehicles), shifting to energy efficient modes (e.g. transit, ridesharing, non-motorized), reducing number of trips, lowering car ownership, and altering destination and location choices (e.g., Lutsey and Sperling, 2005; Litman, 2009, 2012). Another response found to be significant in the literature is a move towards increasing fuel economy (see for example Small and Van Dender, 2007; Johansson and Schipper, 1997; Brons et al., 2008). Similarly, residential and employment location choice can be influenced by increased fuel prices due to the change in travel cost. However, the literature suggests that the choice of employment location is not significantly impacted by changes in fuel cost for various reasons. Such explanations include the complexity and the transaction costs associated with a move which typically outweigh the small proportion of fuel prices in the total expenditures of many companies (Fisher and Mitchelson, 1981). Although the literature is limited in regard to the impacts of high fuel prices on land use, studies suggest that higher travel costs could lead to more compact and multi-centered (or decentralized) development (e.g. Romanos, 1978; Waymire and Waymire, 1980; Fisher and Mitchelson, 1981). Most past work has focused on fuel consumption in relation to city structure rather than looking into changes in travel patterns and land use (e.g. Mogridge, 1985; Newman and Kenworthy, 1989).

The interrelation between transportation and land use has been studied widely in the literature (e.g. Abraham et al., 1998; Rodier et al., 2002; Handy, 2005; Johnston et al., 2005; Pendalaya et al., 2012; Zhao et al., 2012,). This interest partially stems from largely accepted propositions about land use-transportation interaction including e.g. building highways will increase sprawl, building more roads will increase driving, transit oriented development will increase density and reduce automobile use and the like. Despite a large volume of research, it is not clear how this interaction works due to the complex endogenous relationship between the two and the numerous exogenous factors such as socioeconomic characteristics and political forces. Finding empirical data presents another difficulty in establishing this

relationship due to the long-term nature of land use changes. Therefore, coupling travel forecasting models with various land use models (e.g. Lowry (Lowry, 1964); MEPLAN, (Hunt and Echenique, 1993); UrbanSim, (Waddell, 2002)) has been the typical approach in the research arena.

Adding the influence of energy prices into an already complex interrelated system of transportation and land use has not received much attention. A limited number of studies have considered the potential impacts of energy prices on land use and transportation simultaneously. Mishra et al., (2011) and Ducca et al. (2012) investigated impacts of high-energy prices on the state of Maryland and the Chesapeake Bay Megaregion respectively. Although these studies reflected an increase in energy price differently (the former considered increases in crude oil price, agricultural commodity prices, federal defense spending, and employment in professional service while the latter considered only sudden increase in auto operating cost (AOC) in the target year of 2030), both utilized a national econometric model to estimate future land use given the change in transportation impedances. This paper builds on their work but investigates the sensitivity of land use changes with respect to different fuel price and fuel economy combinations instead of using the national economic model. This approach is selected to examine propositions inferred from the literature such as (1) an increase in fuel price causes small to moderate location changes, (2) the likely response to high fuel prices is increasing fuel economy rather than location changes, (3) the assumption of high fuel prices leading to more concentrated land use patterns may not hold if improvements in fuel economy and fuel efficiency are significant.

2. Analysis Framework

2.1 Model Framework

The modeling structure involves three main components that are loosely coupled: econometric, land use and transportation (Figure 1). The economic model uses national and regional economic trends for a variety of sectors to project household and employment growth and allocates it throughout the state (details of the economic model can be found in Inforum, 2011). The land use forecast is informed either by local zoning plans, which do not involve modeling, or by employing macro-level economic modelling data which comes from Inforum (2011).

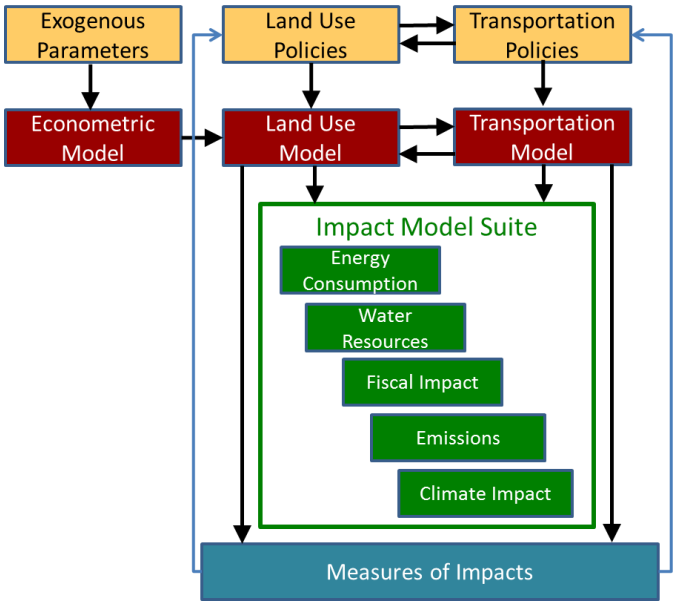

Figure 1. The integrated transportation and land use modelling system

The schematic of land use model that utilizes econometric modelling techniques to forecast future household and employment growth is depicted in Figure 2 (see NCSGRE, 2012 for details).

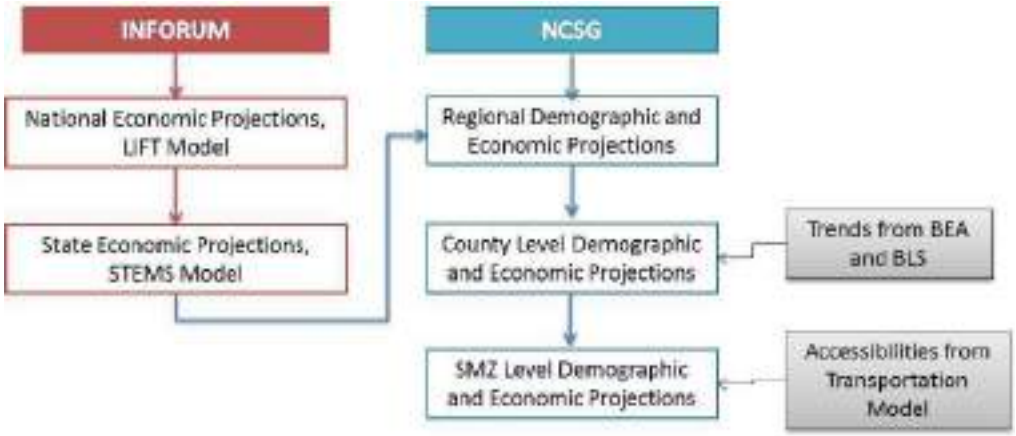

Figure 2. Land use model schematic

The land use model is integrated exogenously with the transportation model. The transportation model takes the socio-economic data from the land use model output and forecasts travel demand and the travel patterns for various future scenarios. The model is a three-level (national, regional and Metropolitan Planning Organization (MPO)) model that covers the entire 'Capital Mega-region', an area that encompasses the states of Maryland, Delaware, Virginia, Washington DC and parts of Pennsylvania and West Virginia (see Figure 3). The model also covers the remainder of the United States (primarily for freight, transit and tourism) but at a lower level of fidelity.

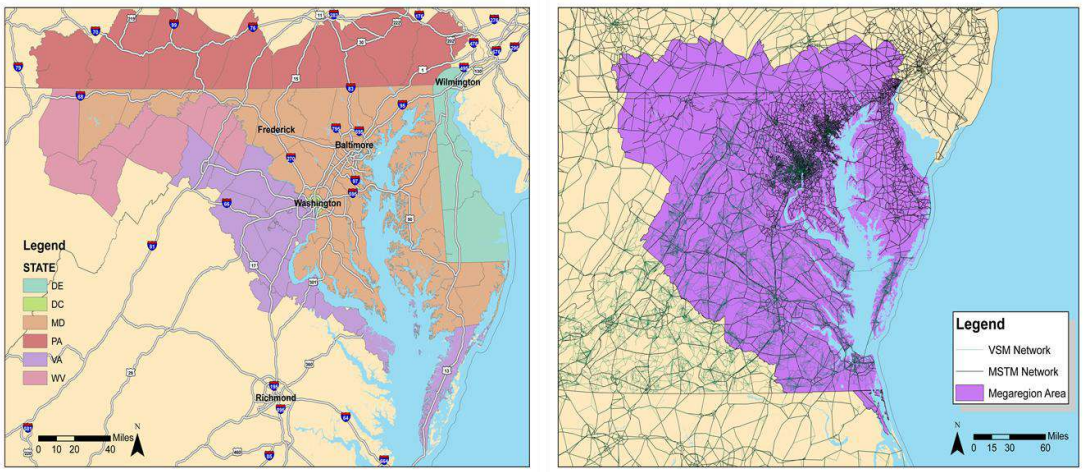

Figure 3. Capital Mega-region study area

2.2 Transportation Demand Model Formulation

The formulation employed in this study is based on the equilibrium analysis of transportation systems where an analyst tries to find traffic flows on a network at an equilibrium state given travel demand (represented by the trip matrix, or matrices) and supply (transportation network and services). The process is also called traffic assignment. The fundamental aim of traffic assignment process is to reproduce on the transportation system, the pattern of vehicular trips/personal trips which would be observed when the travel demand is assigned to the network by employing behavioral models. The traffic assignment model is based on the Wardrop equilibrium conditions (Wardrop, 1952). This principle is based on the fact that individuals choose a route in order to minimize his/her travel time or travel cost and such a behavior on the individual level creates equilibrium at the system (or network) level over a long period of time (Sheffi, 1984). Simply, for each origin-destination (O-D) demand pair, the travel-cost/travel-time on all used routes of the road network should be equal. Equilibrium, called User Equilibrium (UE), is reached when no traveler can decrease travel cost/time by shifting to a new path.

$$Minimize \sum_{a} \int_{0}^{x_a} (t_a(x_a)) \tag{1}$$

Subject to:

$$\sum_{r} f_{ij}^{r} = q_{ij} \quad ,\forall i,j \tag{2}$$

$$x_a = \sum_{i} \sum_{j} \sum_{r} f_{ij}^{r}\, \delta_{a,ij}^{r} \quad ,\forall a \tag{3}$$

$$f_{ij}^{r}, q_{ij}^{r} \geq 0 \quad ,\forall i,j,r \tag{4}$$

Equation (1) represents the objective function which minimizes the sum of the integrals of the link performance functions The term, t_a, is the travel time for link a, which is a function of link flow x_a. Equation (2) is a flow conservation constraint to ensure that sum of flow on all paths *r*, connecting each Origin-Destination (O-D) pair (*i-j*) is equal to the corresponding (O-D) demand. In other words, all O-D trips must be assigned to the network. Equation (3) represents the definitional relationship of link flow from path flows. Equation (4) is a non-negativity constraint for flow and demand. The travel time function $t_a(.)$ is specific to a given link 'a' and the most widely used model is the Bureau of Public Roads (BPR) function given by

$$t_a(x_a) = t_o\left(1 + \alpha_a \left(\frac{x_a}{C_a}\right)\right)^{\beta_a} \quad (5)$$

where $t_o(.)$ is free flow travel time on link 'a', and α_a and β_a are constants (and vary by facility type). C_a is the capacity for link a.

2.3 Model with Fuel Price Change

A change in the price of fuel results in a change in cost for highway travel. The effect of fuel price on user behavior can be represented as follows:

$$u_a(x_a, p_a) = t_a(x_a) + \frac{pl_a}{VOT.\vartheta} \quad (6)$$

where, p is the fuel price in miles per gallon, l_a is the link length in miles, *VOT* is the value of time in dollars per hour, and ϑ is the automobile gasoline efficiency in miles per gallon. Auto Operating Cost (AOC) is another component which is considered in the mode choice model in the next section (please see equation 9). A higher fuel price will result in a higher AOC and therefore will make auto travel more expensive.

2.4 Choice of Destination and Mode

The baseline scenario and all models also work on the choice of destination and mode depending on the respective cost functions. Because of varying cost functions, the destination and mode selected for different scenarios will change. This section explains how destination and mode choice are incorporated in the model, utilizing a random utility approach.

The destination choice model provides O-D demand for all trip purposes. The utility (U_{ijn}) of choosing a trip attraction/destination *j* for a trip *n* produced in zone *i* is given by:

$$U_{ijn} = S_j + \alpha L_{ij} + \sum \beta^k D_{ij}^k + \sum \beta^k D_{ij}^k N_n^k + \sum \beta^k Z_j^k + C_{jn} \quad (7)$$

Where, S_j is the size variable for destination zone *j*, L_{ij} is the mode choice logsum between zone pair *i-j*, D_{ij}^k represents the various distance terms (linear, log, squared, cubed and square root), N_n^k represents person, household or production zone characteristics for trip *n* and is used for creating interaction variables with distance terms, Z_j^k represents attraction zone characteristics (other than the size term), and C_{jn} is a correction term to compensate for the sampling error in the model estimation (i.e., it represents the difference between the sampling probability and final estimated probability for each alternative). The size variable may consist of several different terms; up to four categories of employment in addition to households were used. Weights (β^k) for each term in the size variable were estimated along with all other model parameters as follows, where E_j^k is employment of type *k* in zone *j*:

$$S_j = log\left(\sum \beta^k E_j^k\right) \tag{8}$$

A nested logit structure is used for the mode choice model, which is based on generalized utility functions for auto and transit travel. Separate utilities were developed to represent mode choice by trip purpose. The mode choice utility function is represented as follows:

$$\begin{aligned} U_m^p = \pi_m^p &+ \beta_{1_m}^p IVTT_m^p + \beta_{2_m}^p TET_m^p + \beta_{3_m}^p \times AOC_m^p + \beta_{4_m}^p PC_m^p \\ &+ \beta_{5_m}^p \tau_m^p + \beta_{6_m}^p WT_m^p + \beta_{7_m}^p IWTa1_m^p + \beta_{7_m}^p IWTb_m^p \\ &+ \beta_{8_m}^p NOT_m^p + \beta_{9_m}^p TF_m^p + \beta_{10_m}^p DA_m^p \end{aligned} \tag{9}$$

Where π_m^p is a mode specific constant for mode *m*, and purpose *p*; β in each term is the mode and attribute specific coefficient; $IVTT$ is the in-vehicle travel time, TET is the terminal time, AOC is the auto operating cost, PC is the parking cost; τ is the toll value, WT is the waiting time, $IWTa$ is the initial waiting time less than 7.5 minutes; $IWTb$ initial waiting time greater than 7.5 minutes; NOT is the number of transfers, TF is the transit fare; and DA is the drive access time. The mode choice model results in splitting O-D trip matrices into 11 travel modes (3 auto modes, and 8 transit modes). Three auto modes refer to Single Occupant Vehicles (SOV), High Occupant Vehicles with two occupants (HOV-2), and High Occupant Vehicles with three or more occupants (HOV-3+). Eight transit modes are combinations of walk and drive to bus, express bus, rail, and commuter rail.

3. Scenario Design

In this paper we measure two parallel phenomena related to fuel prices. The first is the elasticity of location decisions in relation to fuel prices. The second is the elasticity of travel decisions that result from fuel prices changes as well as the change in travel that occurs in response to changes in location decisions. The result is a complex series of behavioural responses that affect the nature of travel in the study area. Four scenarios were developed to model the effect of the possible changes in gas prices and technology on land-use and travel behaviour.

In the first scenario, we specify a baseline where gas prices are low but have steadily increased over time. In this case, gas is $3.88 ($US) per gallon before tax, resulting in an auto operating cost of $0.18 per mile. Land use response to this moderate travel cost change is assumed to be steadily growing from 2007 to 2030.

In the second scenario, we envision a case where prices for fuel have remained steady as in the baseline scenario, but due to policy requirements, specifically the 'Corporate Average Fuel Economy' (CAFE) standards for 2030 set out by the U.S. Environmental Protection Agency (EPA); average fuel economy has doubled from 27 to 54 MPG (miles per gallon). The result of the increase in fuel economy, with steady fuel prices on the auto operating cost per mile is a reduction to $0.09. This makes travel significantly less expensive. In response to the significant reduction in travel cost, the land use is less constrained and trends towards a slightly more diffuse urban pattern between 2007 and 2030.

The third scenario sets fuel economy back to the 2007 level, as if no improvement in technology was made and no policies were enacted to force increases in fuel economy. At the same time, we predict the price of fuel follows more historic world trends, absent policy intervention, the price of fuel is allowed to rise at the market rate resulting in a price per gallon of $15.52. At this price, the auto operating cost increases to $0.72 per mile. Land use patterns respond to the significant increase in price and future development patterns gradually move to a more concentrated urban form.

In the final scenario, policy intervention is again absent as it relates to fuel prices, allowing the cost per gallon to increase to $15.52. However, policy intervention and technology do adjust to this rise in prices. With the refined CAFE standards, average fuel economy increases to 54 MPG and the cost of operating a vehicle under these conditions reduces to $0.36 per gallon. Land use responds by moving towards a slightly more concentrated urban pattern than in the baseline scenario, where there was no policy intervention or technological improvements in vehicle fuel economy.

4. Results

This section contains the transportation demand model results from the baseline and three scenario models. Figure 4(a) illustrates the density of land use in the baseline (scenario one) for counties in the Baltimore Washington Metropolitan area. In this scenario, the region grows as usual with a standard rise in fuel prices. In the second scenario, where the fuel economy improves while the prices of fuel remains steady, making the relative cost of transport cheaper, the average density in each county decreases compared to the baseline scenario (Figure 4(b)). Figure 4(c) shows the relative change in land use density in the third scenario, when the price of fuel increases substantially and fuel economy does not keep up. In this case, land uses in the central cities and along main transportation corridors become denser. Figure 4(d) shows the land use density change under scenario four, where there is only a

moderate change in travel cost, resulting in some densification over the baseline scenario.

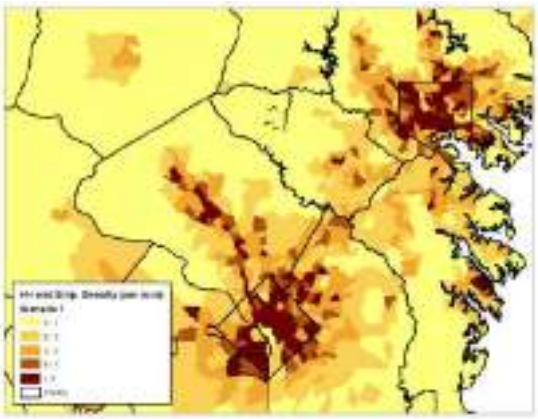

Figure 4(a). Baseline Land Use Density (Scn-1)

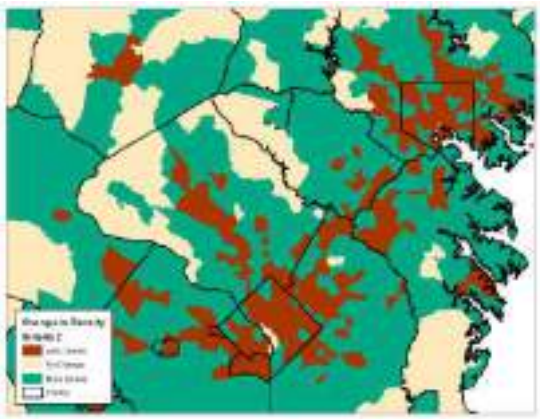

Figure 4(b). Change in Land Use Density (Scn-2)

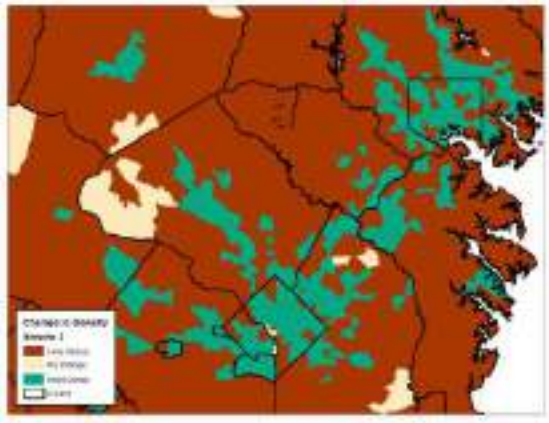

Figure 4(c). Change in Land Use Density (Scn-3)

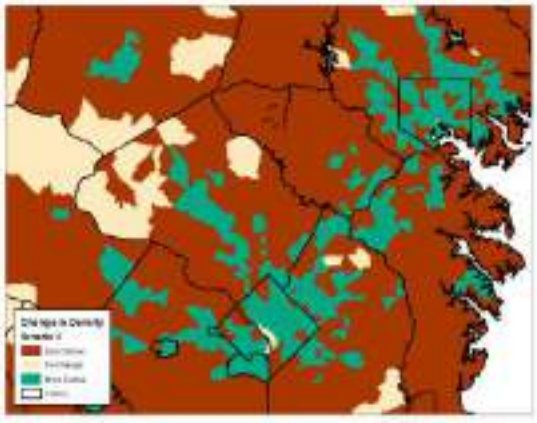

Figure 4(d). Change in Land Use Density (Scn-4)

Table 1 shows the effect each scenario has on mode share in the study area. In the baseline scenario, drive alone trips are over 70% of the person trips. When carpool trips are added, 91.61% of trips are by personal vehicle, the remaining trips are split between bus and rail modes. When the auto operating cost decreases by 50%, there is a 17.5% increase in private auto use over transit.

Table 1. Mode Choice

	Auto Trips		Transit Trips		Auto Share		Transit Share		Percent Change			
	Drive Alone	Carpool	Bus	Rail	Drive Alone	Carpool	Bus	Rail	Auto	Carpool	Bus	Rail
Scenario-1	807,778	240,858	34,363	61,672	70.57%	21.04%	3.00%	5.39%				
Scenario-2	1,002,293	230,510	29,454	53,005	76.20%	17.53%	2.24%	4.03%	24.08%	-4.30%	-14.29%	-14.05%
Scenario-3	601,560	489,526	66,235	104,845	47.66%	38.78%	5.25%	8.31%	-25.53%	103.24%	92.75%	70.01%
Scenario-4	788,537	373,489	46,315	80,232	61.19%	28.98%	3.59%	6.23%	-2.38%	55.07%	34.78%	30.09%

This indicates that there is an elasticy of the mode share with auto operating cost of about 0.35. When the price of transport increases over the base case by about 50%, there is a signficant increase in the non-drive alone trips. The share of drive alone trips decreases by over 25%, lending to a 103% increase in carpooling, a 92%

increase in bus and a 70% in rail share. In the final scenario, with a moderate operating cost increase, drive alone auto use declines just 2%, but results in a 55% increase in carpooling and over 30% increase in both rail and bus trips.

Highway assignment results for the baseline and three scenario models are presented in Table 2. Each model output is further categorized by major highway facility types for detailed analysis. The third column in Table 2 provides the vehicle miles travelled (VMT), followed by congested lane miles (lengths of road with a volume to capacity ratio of over 0.75, an aggregate statistic typically used for measuring the level of congestion), and the average speed on each facility type.

Table 2. Highway Assignment Results

Model (1)	Facility Type (2)	VMT (3)	Emissions (Tonnes) (4)	Congested Lane Miles (5)	Average Speed (MPH) (6)	Percent Change VMT (7)	Percent Change Emissions (8)	Percent Change Congested Lane Miles (9)

The results show the impacts of the change in travel behavior that occur as a result of changes in fuel price and economy on the highway usage measures. In general, the results coincide with intuition. For example, when the price of fuel remains low, and fuel economy standards increase, more travel occurs. While this is in part due to the more scattered nature of land use in the study region, it is also a result of the ability to make longer trips at a lower cost. For example, the 14.67% increase in VMT that occurs in Scenario-2, induced by the decrease in travel cost, leads to a 32% increase in congested lane miles and 2 miles per hour decrease in average speed along freeways. The significant increase in auto operating cost that occurs in Scenario-3 combined with improved fuel economy and the denser land use, results in a 19% decrease in VMT and a 50% reduction in congested lane miles. These results indicate that the fuel price has a significant impact on travel behavior. Despite the improved fuel economy, VMT and CLM decline significantly compared to the baseline.

Scenario-4 has a smaller impact on travel behavior relative to the previous two scenarios, with only a 4% decrease in VMT and a 16% reduction in congested lane miles. This indicates that if significant improvements are achieved in vehicle technology that increases fuel economy considerably (doubled in this study), the impacts of high fuel prices may not be as pronounced.

The combined effect of changes in fuel economy and price has a significant impact on total emissions. In Scenario-2 where fuel economy significantly increases and travel cost decreases, total emissions are reduced by 44%, despite the higher VMT. In Scenario-3 fuel efficiency is reduced and the cost of travel increases. As a result, emissions are only reduced by 22%. Scenario-3 sees the highest emissions reductions with a 53% decrease. This is the result of a combination of higher fuel economy and fuel price.

To test for convergence, the gap between assignment iterations in between the baseline and Scenarios -1 through -4, was measured. Gap is a function of change in assigned link volumes and cost between iterations. Therefore, as gap decreases the assignment gets closer to convergence, which indicates that a change in travel cost for a link does not produce a significant change in the entire network. For this study, the convergence criteria was set at a gap of 0.002 for the iterative assignment and 0.005 for the variable demand iteration. Figure 5 shows the iteration results in terms of the gap for fifty model iterations. In all cases the models reached the convergence criteria in less than 26 iterations.

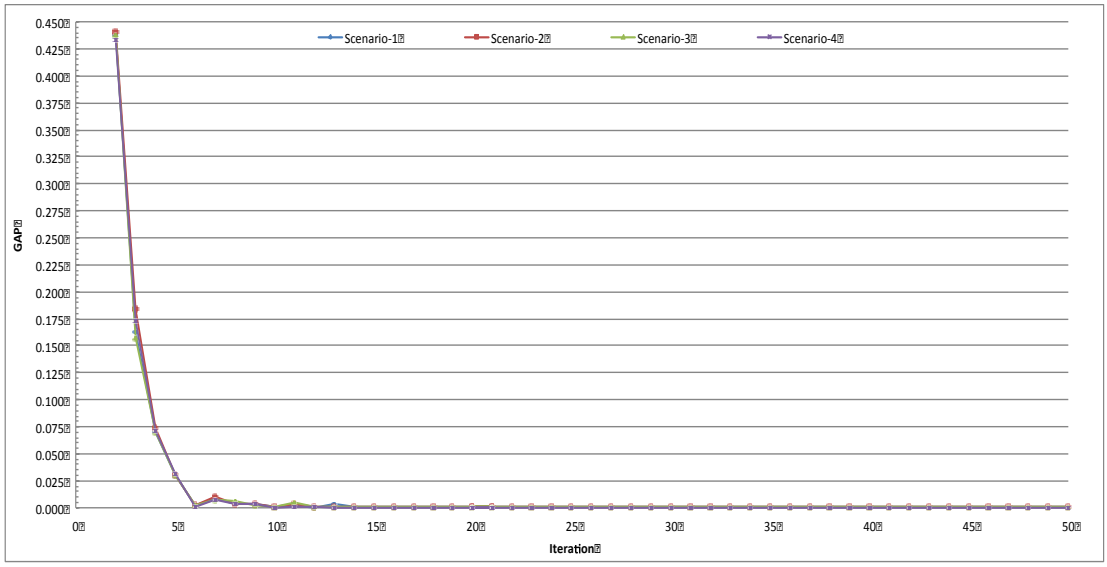

Figure 5. Convergence Results for Scenarios 1 through 4

5. Conclusions

The analysis conducted in this study sheds some new light on probable changes in land use and travel behavior in response to future changes in fuel prices and improvements in vehicle technologies. The analysis focused on two parallel phenomena related to fuel prices: the elasticity of location decisions and the elasticity of travel decisions that result from fuel price changes as well as the change in travel that occurs in response to changes in location decisions. A state-of-the art integrated land use and transportation model system, essential for such analysis, is utilized to analyze these complex series of behavioural responses that affect the nature of travel in the Capital Megaregion study area.

The results show that increased fuel prices and fuel economy have a significant impact on land use and travel patterns. The improved fuel economy causes a scattered land use change when the fuel prices remain steady. A substantial increase in fuel price can reverse this scattered distribution of land use with moderate improvements in fuel economy. However, if fuel economy increases significantly, the concentration of land use towards city centers and main transportation corridors occurs less. The results also indicate that the elasticity of location decisions is highly sensitive to changes in fuel prices and that improved fuel economy reduces this sensitivity. When technological advances lead to very high fuel economy in the future, it may be necessary for policy intervention to increase travel cost to meet planning goals that aim to prevent sprawl.

The impacts of changes in fuel price and economy on travel behavior and traffic measures are also remarkable. The results indicate that the elasticy of the mode share with auto operating cost is about 0.35. When the cost of transport increases, a significant increase in carpool and transit trips are observed. Similar to the land use response, when fuel economy increases significantly, a decline in the share of drive alone trips is not as pronounced. However, the increase in carpool and transit mode share is still significant. Highway usage measures also show similar behavior. For example, increasing fuel prices reduces VMT while increasing fuel economy standards and causes more travel. The results indicate that the fuel price has a significant impact on travel behavior: despite the improved fuel economy, VMT and CLM decline significantly. Emissions are also significantly impacted by gas price and fuel economy. Result show that increased fuel economy leads to higher emission reduction. The highest reduction in emissions is obtained when higher fuel economy and fuel price are applied in combination.

The approach followed in this study can be used to analyze alternative future scenarios and develop strategic policies. Despite the volatile nature of fuel prices and uncertain phase of technological developments, the knowledge of how the land use and transportation system will respond under different scenarios will help develop better informed policies and strategies. The results point to future research on different pricing strategies that would impact cost of travel in addition to fuel prices

so that the changes in land use and transportation can be guided towards a more desirable pattern.

Acknowledgements

The authors are thankful to the Maryland State Highway Administration (SHA) for their continued support in the development of models used in this study. The tremendous effort by the staff at Parsons Brinkerhoff in the data collection and model development is also greatly acknowledged. The evolution of integrated land use and transportation modeling system is a result of continued research for the last four years at the National Center for Smart Growth Research and Education at the University of Maryland. The opinions and viewpoints expressed are entirely those of the authors, and do not necessarily represent policies and programs of any agency.

ANTICIPATING THE IMPACTS OF URBAN DESIGN PROJECTS STARTING FROM THE PEDESTRIANS' EXPERIENCE

Barbara E.A. Piga [1], Valerio Signorelli [1], Eugenio Morello [1]

Abstract

The paper presents a four years study, developed by a university research laboratory, that deals with the anticipation of outputs of urban transformations. The main aim of the conducted investigation was to explore the ability of different tools to anticipate specific impacts of urban design projects in an interdisciplinary way. In particular, the general themes investigated concerned visual appearance (composition) and environmental conditions, i.e. shadowing condition, using simulations. In addition a specific point of view was used: how is it possible to anticipate the outputs of a design project from a perceptual point of view?
The research was conducted both in theoretical and experimental terms. For this reason a specific case study was analyzed. The required characteristic for the choice were: dimension and complexity (big urban project), importance for the city (centrality), implementation in a short time (project under construction). Besides studying the performance of the urban design project as a whole, we simulated it in order to clarify its output from an experiential point of view. To depict the perceptual impacts we used different typologies of simulations and we compared the possibilities and effectiveness of each one. Since this specific point of view was one of our main interests, a great attention was devoted to the tools that allow a dynamic description of the urban environment. Moreover, we were not focusing our attention on the functionality of the architectural projects alone, but on their cumulative effects on the urban environment. For this reason, we studied the output of the project starting from its local physical context (walking towards the project) and at the urban level (looking from a distance: changes in the skyline).
The use of a great number of different kind of simulations were experimented on the case study according to their proper characteristics. Since each one has its own limits and vantages, a combined use has been shown to be preferable for a more comprehensive understanding. In order to check the effective usefulness of the tools in a definitive way, we present a survey that allows to compare the real output of the urban project, which is almost completed, and the simulated one. The comparison gives an important feedback about the real capacity of the tool, helps to improve the entire approach and contributes to complete the theoretical framework. This will be the basis for future work on simulation, but it will also be an occasion to demonstrate the potentiality of this approach in depicting some relevant outputs. This could

[1] Laboratorio di Simulazione Urbana «Fausto Curti», Department of Architecture and Planning, Politecnico di Milano, Milano, Italy – eugenio.morello@polimi.it

improve the process of negotiation between public and private stakeholders, collaborating to the delivery of better public spaces.

1. Laboratorio di Simulazione urbana 'Fausto Curti' framework

This paper illustrates the results of the main researches activities developed by the *Laboratorio di Simulazione Urbana 'Fausto Curti'* (LabSimUrb) of the *Politecnico di Milano*. The research laboratory was founded at the beginning of 2007 by prof. *Fausto Curti* and prof. *Peter Bosselmann* with a threefold mission: to innovate, to experiment and to communicate. Using innovative methods of investigation and simulation to be integrated to more traditional methods of analysis, design and evaluation. Verifying through experimentation the outcomes of design alternatives in order to facilitate the understanding and to show the consequences of planning decisions. Effectively communicating the results of urban changes in order to facilitate the confrontation between planners, policy makers, developers and citizens (Laboratorio di Simulazione Urbana "Fausto Curti", 2011).

The research about Urban Design themes is conducted through the use of different kinds of simulations in order to predict some relevant outcomes, especially about perceptual and environmental impacts of new constructions. The first four years of the laboratory activities were devoted to set up the research methodology and to verify the proposed approach. In order to do this, we focused on a specific case-study area, the *Garibaldi-Repubblica* redevelopment project in Milan. The urban planning framework of the case study, and the first stage of the work, was presented at the ACSP/AESOP Joint Congress in 2007 (Arcidiacono et al., 2007), and in other several papers.

All the research works have been elaborated in collaboration with students from Architecture and Urban Planning, and part of the outputs presented here, are indebted to the theses that were developed at the laboratory on the ongoing research themes..

2. Perceptual and Environmental Simulation

The laboratory works both with conceptual (abstract) and perceptual (lifelike) simulations. The main interest is directed to the anticipation and the understanding, thorough simulation, of urban transformations and their effects on the experience of the city users. This is intended as a result of the correlation between the physical city structure with the generated dynamic conditions (visuals, shadowing, temperature and so on). In this sense, simulations are used as a basis for depicting in a realistic way the foreseen urban condition, and as a stimulus to which every user can react subjectively. From a perceptual point of view this means that we deal with photorealistic simulations that can guarantee an analogous interaction between the user and the simulation itself. As reported in the doctoral thesis of Barbara Piga (2010), each typology of simulation can address a different kind of interaction that can replicate, with a variable degree of equivalence, the actual one. From this point of view a tool that is able to describe the urban condition in a dynamic way, and that

can guarantee a certain degree of freedom of navigation and sense of immersion is the one that can better fit the real fruition of the environment; indeed, the urban experience takes place in time and space and our physical involvement gives us the sense of place. Despite this, each medium can help focusing on specific aspects of the described context, so that in our opinion it would be inappropriate to claim that one type is better than another. A video can well represent a walk in a street, while a panoramic image forces us to stop and focus on a specific point of view, exactly as we do when we live a city going from one place to another or we stop for looking around. Nevertheless, in both cases we are looking through the authors' eyes; this can be a benefit, because it allows to consider some important aspects of the urban projects, but at the same time it can be a relevant limit because the user cannot personally choose where to look at, and sometimes can even consider this as a lack of transparency: there is always the possibility that something is voluntarily hided. The same medium used in an interactive navigation can solve this problem, but cannot assure that all the representative points of view of the project are caught. Another modality of interaction can instead give the possibility to navigate the same place in different conditions, e.g. seasons or daytimes, or comparing project alternatives, and this can significantly enhance the comprehension. As it was shortly shown, it is important to understand what each tool can tell us. To better understand the proper ability of different mediums we tested different typologies of simulation on the same case study and we compared their potentialities and limits in depicting the urban condition from a perceptual point of view . In general, and if possible, a combined approach is preferable, and can increase the possibility that different (and related) ranges of implications are grasped.

Since the final goal is to enhance and to support the urban design process in all its phases, from the creative process to the evaluation one passing through public participation, it is important to understand in which way this approach can be a valuable framework and which are the more appropriate tools for the different needs. For this reason we tested the approach on the different design phases. In the first period of the laboratory activities we worked on the Garibaldi-Repubblica project in Milan; in this case the study was directed to analyze the use of perceptual simulation as a support for evaluation. After this phase we moved on, and we tested the same approach for developing guidelines to guide urban transformations. This experimentation was carried forward with the collaboration of students who developed their master design theses on the topic (Bulgheroni et al 2012) . The experimentation on some case studies helped us to focus on specific needs and always lead us to develop scientific methods to answer to specific purposes or demands.

This year we started to apply the approach for the design phase. In fact, a new master class linked to our laboratory activities started this March. For instance, students are asked to develop their design ideas starting from the perceptual point of view and with the support of different typologies of simulation, especially those that encourage them to think about the environmental and the urban experience as a coherent dynamic system. Another research branch at the laboratory deals with the theme of information and public participation. In this direction we started to develop a tool, the 'Tavolo Luminoso' with two colleagues, Laura Cibien and Francesco Secchi, and

its theoretical applicability on the topic of public participation became Laura Cibien's MSc thesis.

The work of the laboratory is now focusing on the previous mentioned different topics, as well as the research of new simulation tools that can support the improvement of the final outputs of urban design projects, both from the side of the designers and the decision-makers involved in the process.

3. Building an approach for urban simulation

The Garibaldi-Repubblica case study was chosen because of the following aspects: its strategic location for the city, indeed one of the last vacant and very accessible areas, close to the city center; the large amount of volumes involved in the urban transformation, because the total buildable floor area is over 330,000 sqm and the land utilization ratio is approximately 1sqm/sqm; the number of different stakeholders involved, such as several architecture offices, real estate developers, the public administration and the citizens, especially those already living in the area and who have reacted against the intervention. As it was already presented in other occasions (see the references above and the bibliography), we used different typologies of simulation in combination, in order to reach a more effective comprehension of the design outcomes. We started with traditional analysis, such as historical analysis, morphology, land use, infrastructure and green structure and then we move to perceptual and environmental studies. As a matter of fact one of the aims of the laboratory is to develop an integrated approach that can lead to consider how different aspects of the environment act together and which is their mutual influence. Sometimes the best solution is a compromise between several factors, that is the one that enables a positive balance between all the issues. For this reason we tend to work at least with environmental and perceptual impacts of projects, especially vision and hearing.

We started using simple tools, e.g. photomontage on single images, and then we moved on to more elaborated solutions that can better depict the design project effects in dynamic terms. To do that we used photomontages in sequences, renders, videos, Virtual and Augmented Reality. Having a photorealistic scale model at hand, the quickest solution for a first navigation in the transformed urban environment is to guide a micro-camera (Figure 1) within the model and look at the transformation from a subjective point of view (Figure 2). With a micro-car, developed by BetaNit for and in collaboration with our laboratory (Prati et al 2009), the area was explored and some representative point of views were individuated. The tool is really useful because it enables to travel through a large area in a relative short time, correlating the urban physical structure to the specific vistas of a pedestrian. At the same time it presents some limits, i.e. the height of the point view is fixed and proportional to the dimension of the camera and the scale of the model; in our case the model was in 1:500 scale, and this implicated that the point of view was six meters high, which produces a distortion compared to the 1,70 m assumed as the average height of a person. Nevertheless, the tool was appropriate to study the area in a quick way, and it

favored the collaboration and discussion on the projects among the colleagues. To study the individuated paths we used at first a sequence of photomontages, which was quite effective in depicting the future condition. Having a digital model of the area (Figure 3) it is not so complicated or time-spending to elaborate accurate images where the urban project is overlapped to the existing condition (Figure 4). Compared to the video from the scale model this solution enables to describe the vitality and the detailed richness of the area, even if it is related to the existing condition in a simple sequence of still events. To overcome this limit we decided to study, with a bachelor of science thesis (Secchi 2009), the applicability of movies techniques for urban design purposes. The output (Figure 5) of the superimposition of a video render of the project on the video of the actual condition, shows great potential of communication. The immediacy of reading the effects on the current situation and its strong recall of the real experience makes it a useful tool, not only for the evaluation phase, but also in the process of public information or participation, where the actors involved often do not have the technical skills to read and translate correctly what is represented in a map into the real outcomes that affect the daily life of the urban environment. The video produced was also presented in the Corriere della Sera, one of our major national newspapers, and this is emblematic of the communicative capability of this kind of approach.

Anyway, this kind of medium allows a fruition that is limited to a pre-selection of vistas. To overcome this limitation we decided to do a step further and to start to use simulation that could allow an interactive navigation. We started using pannable vrlm (Virtual Reality Modeling Language) panoramic images and then we moved on using game engine software for urban design purposes. Starting from the digital model we had, we created a virtual interactive simulation of the Garibaldi-Repubblica project and its surrounding.

In parallel to that step we started studying some environmental impacts on the area. The first step in this direction was the shadows analysis, that was approach as a laboratory research activity, and then was deepened with the MSc thesis of the author (Signorelli 2009). In this case too, we tested different typologies of simulation tool, both analogical and digital. We worked in combination with conceptual and perceptual simulations to figure out their effectiveness for the evaluation of urban comfort and energy efficiency, highlighting the potential and critical issues in relation to different stages of the processes of urban transformation. We worked with both a 1:1,000 scale model and a 1:500 scale model to study the shadow path generated by the intervention on the public space and on the facades of the building context; we did the same with the digital model and other simulation software. The results obtained were compared to evaluate the accuracy of the different tools used.
Vrlm permits to visualize interactively a panoramic image, developing a path composed by a series of these images. Nevertheless these types of simulations do not take in account the dynamic aspects of the urban environment and the interactivity is not so enhanced, if compared to the previous simulation tools presented. For this reason we decided to move on and use a game engine software. These products, commonly used for developing videogames, are increasingly used also in various

disciplines not closely related to a playful attitude (e.g. simulations in a hazardous situation that cannot be reproduced in a real environment without risk for users, such as in nuclear power plants or for virtual fire evacuation drills, improve the sightseeing of archeology sites and to develop virtual museums, and military simulators to recruitment and training). This has been made possible for different reasons: the increase of ease of use, the more realistic renders of the graphics engines, the improved interoperability among the software, the possibility to customize their components, and the affordability of the products.

Game engine are complex software systems characterized by different features. The most common components are a render engine for 2-D or 3-D graphics, a physical engine, a collision calculator and some frameworks (libraries) used for sound, animation and artificial intelligence. The level of detail reached by these products is extremely high, both in visual and physical simulations. Thanks to this software it is possible to provide a virtual environment, in which the user can roam freely, enriched with various dynamic elements and other components that give the possibility to the user to interact in real time with the simulation. By way of summary, the Game Engine permits not only to provide a static visual simulation of the urban environment but, acting on its components, it allows to include in the virtual environment the dynamic aspects of the urban fabric (e.g. simulating the alternation between night and day, and seasons, visualize the traffic flow and insert the various sound events etc.).

Nowadays there are manifold products, each one with specific characteristics, strengths and weaknesses. We choose to use Unity3D because it presents a user-interface similar to many commonly used software for tridimensional modeling; it allows us to import sound and readymade digital models, complete with textures, materials and animations in various formats; it includes an internal tool for recreating vegetation. Furthermore, it allows us to manage and change the point of view of the camera and finally permits a high customization, thanks to the ability to use different types of programming languages (C #, boo, javascript).

After we have inserted the digital model of the Garibaldi-Repubblica project and its surrounding in the game engine, we enriched the simulation adding the vegetation, using a software that permits to change dynamically the model of the tree used, according to the seasons and to the growing period; the animation of the public and private transport that will be refined using a multi-agent software to provide a more realistic simulation; some sound sources recorded in the real urban environment (but we have to point out that to date the game engine does not provide a physical based simulation of the acoustic environment); the various project proposals provided by stakeholders; and finally the sun, which can be moved in real time to see the shadows' impact of new urban projects on themselves and on the existing context.
As we said, the software permits to the users to walk interactively into a dynamic virtual environment, changing in real time the project proposals to understand their impact on the existent urban environment. For this reason we started to use this software also in a course held by our research group in order to compare the various

projects proposed by the students. This approach allow them to verify the perceptual outcome of their design process and it encourage them to think at the urban transformation in dynamics terms.

The capabilities of these instruments need more insights. The possibility to provide quantitative and qualitative information layers, in a virtual interactive environment is worthy of being investigated. Despite this, the product still has a weak user interface, which was developed for videogames and constitutes a hindrance in the usability of the product for a large part of users.

The game engine chosen was also used to develop the 'Tavolo Luminoso' tool (Figure 5), which was intended as an occasion to merge different topics and mediums together. The tool uses a physical scale model in combination with digital interactive simulation. In fact, on the base of the table an interactive visualization of the ground is projected in real-time. Using Augmented Reality it is possible to link the physical volumes to their relative digital ones, and it is possible to project on the table surface a simulation of the base with a simulation on it, i.e. the projected building shadows or other environmental conditions such as the wind condition (represented as particles that flow in the area).

4. Conclusion

A comparison between the simulation (photo and video montages) we produced and the real output of construction is now under development. Nowadays, the Garibaldi-Repubblica transformation is almost completed, and some considerations about the validity of the work done is possible. The first phase of comparison (Figure 6), demonstrates the general validity of the approach and also allows to highlight some limitations. Part of the gap between the simulated environment and the real condition is due to the fact that the projects have changed from the first (approved) hypothesis we have modeled. Especially, few buildings are in reality higher than it was defined with the first project approval. In general, the last solution is taller than the previous one. In some cases also the shape of the project has changed. This should lead to consider if, with a complex project like this one is, the planning tools and the required documents are enough for the municipality to direct the overall urban transformation and to verify the cumulative changes that occur during the process. In this respect, it is also particularly interesting to notice that it is quite common that the visualizations presented by the developers represent the project itself rather than the project in relation to its local or urban surrounding, while it emerges quite clearly that this kind of transformation, with high-rise buildings, has an impact on the entire city. As a matter of fact, considering as an example just the visual aspects, it is

immediately evident that the transformation will change the skyline of Milan (Figure 7) and some views from the street level.

Even if the simulated project and the built one are not exactly the same, it is quite evident from the comparison that the simulated views depict in an efficient way the urban condition. Moreover, the best comparison is the onsite one. Even if the building site is not completely concluded it is already possible to say that the general impression we had from simulation is comparable to the real one. Nevertheless, a further examination, especially after the conclusion of the building site, is necessary to completely evaluate strengths and weaknesses of the method. This review will also drive the development of our research on the topic. The quality of the render we superimposed to the photo of the actual condition is not that high, we just modeled simplified volumes and we treated their textures merely featuring solid and transparent materials: is this enough or this will imply a distortion that will be misleading for the evaluation process? Another aspect to be considered regards the vitality of the area. Obviously in photo e video montages we grab the situation of the existing condition. Even if it is quite difficult to anticipate correctly this aspect, which is due to many factors, it is anyway important to study which is the rate of bias introduced by this. Also other elements, such as the importance of the soundscape, will be investigated. This ongoing research will help to better figure out the limits of the approach and to identify which of these can be overcome.

Parallel to this, we are developing another study that analyzes the simulation of completed urban projects, produced by the developers, in comparison with photos of the realization taken from the same point of view. This research will give not only the possibility to highlight the gap between simulation and reality, but also to identify a trend in the professional production of this kind of products. Having this analysis at hand the final goal is to quantify the typology and magnitude of an eventual distortion. This will give the opportunity to reflect on the role that this kind of mediums, widely used, have on decision-making processes.

RECYCLING THE PAST: THE CASE OF THE INTENSIVE TRAINING PROGRAMME IN URBANISM "RADI RIGU!" (CREATE RIGA!)

Helena Gutmane [1], Jan Schreurs [2]

Abstract

This paper traces the etymology of the case in continuing professional education (CPE), restoring its historical societal roots, and discusses advantages which an integrative approach offers to planning education, to the urban planning practice and urban development in general. The narrative is drawn from the initiative of a multidisciplinary team of practitioners and scholars in the fields of planning, architecture, landscape architecture and transport engineering. The project RADI RIGU! – a number of innovative workshops undertaken in 2011/2012 - actualized the role of urban public spaces in social revitalization processes, the communicative and procedural character of the urban project. It made an effort to place the idea of spatial strategic planning in post-Soviet mindset as well as to elaborate new, more communicative tools and an "emotionally rich language for planning" (Sandercock, 2001). Finally, it introduced an integrated three-dimensional format of continuing professional education, amalgamating lifelong learning, urban action and implementation-aimed outcome. The methodology of the programme is inspired by a series of workshops on public space on the Belgian coast (Schreurs, 2007). It is also based on the reconstruction of the "*talka*" methodology, the popular form of volunteer work in the USSR.
The paper introduces the notion of social heritage and declares its ultimate place in the "ecology of planning" (Schreurs, 2012).

1. **Introduction:** three perspectives

> Olden times are settled for us in a perspective, where a lot of circumstances are shaded, direct lines dominate, and we are disposed to take them for conclusions, for the simplest contours of evolution. And partly we are right: historical memory passes by the insignificant facts, holding only those that are fraught with a further development. However, historical memory can be mistaken, in these cases the new that has to be observed, is a gauge for the old, lived over out of our experience (Veselovskij, 1989)

[1] Latvian University, Riga, Latvia/Catholic University of Leuven, Belgium – helena@alpsapce.lv

[2] University of Leuven, Belgium – jan.schreurs@asro.kuleuven.be

Being placed in the centre of urban triangle "real world"– professional practice – professional education, we observe three (evidently) interrelated perspectives.
The first - "real world" – is at the moment in the process of crossing the "post-bridge" from not yet fathomed past into a difficult, unfathomable future. Like in post-colonial or post-dictatorial environments, post-Soviet space is revising its own "social" past: right now an overwhelming revelation of the "historic facts", as well as their reconsideration and interpretation, is taking place. Society is waking up after a twenty-year long "shock therapy" of wild capitalism. Confused collective memory is trying to allocate itself in unknown surroundings, looking for help and answers in the past. All realms of life – art, economics, politics, social life, education – are going through external and internal revision of processes: both "in the wild" (Hutchins, 1995), and within their own fields. Cinematography shapes the form of „historical memory"[3], endowing "with a poetic value that which does not yet possess it" (Aragon, 1918, Hammond, 1978, pp.28-31) in order to transfer into present public images of feelings (Geertz, 1973).
Searching for new forms of relationship with society, politicians brandishing poetical images of Harmony[4] and Integration are undertaking attempts to restore and apply some tools to collective work used effectively in Soviet time.

Secondly, mirroring the processes "in the wild", the academic world related to the realm of human settlements nowadays is searching for new, more integrated and interdisciplinary, forms of education. These forms strive to reflect the needs of different overarching fields, growing demand for all kinds of participation, interdisciplinary and interdepartmental collaboration and international co-operation. It is possible to trace similar tendencies in Latvia as well. However, intellectual and structural damages in the system of education, especially high education and research, practically paralyzed this field for two decades, and the recovery probably will require much time and financial resources. Combined with a wild and chaotic urban development caused by the spreading of private ownership, the heavily bleeding education and research in architecture have been laying in a coma. City planning as a discipline had died.

Thirdly, unlike the professional education, last years' professional practice evidently reacts to the chaos created by financial capital based on a dogma of holy real estate (Redbergs, 2012) by alerting people both in everyday city making and professional education about the existing "dead ends". Young professionals in architecture,

[4] "Saskaņas centrs" [Harmony Centre] is the name of the popular Latvian political party, which has declared overcoming ethnical and social conflicts their main goal.

planning, geography and sociology are successfully experimenting with new creative initiatives, promoting social revival in different ways. Challenging the prevalent black-and-white picture of the Soviet past (Rozenvalds, 2010) in the 1990s, when the terms "social" and "collective" were coloured dark black, they create "Socmap"[5], "*Ideju talka*"[6], "*Pagalmu talka*"[7], SPP[8], involving inhabitants, children, students, city departments, real estate developers and politicians in debates and action.

Urbanism as an approach is frequently on the agenda of city makers, but urban activism becomes a form of implementation of urban innovations. New NGOs which promote urbanism are appearing in the Baltic States - *Linnalabor*[9] in Estonia and Urban Institute Riga (2011) in Latvia. There are two significant features which characterize public urban action today. First, it obviously functions on a regional level, building tight and creative cross-border cooperation (e.g. Est-Lat urbanist days 2011 in Kabli, participation of *Linnalabo*r in RADI RIGU! Forum and others). Secondly, it declares and exercises a shift from protest-based action to trust-building action. In this respect the comprehensive RADI RIGU! programme delivers convincing results.

2.1. Planning status quo: pre-Soviet, Soviet and present-day Latvia

When trying to understand today we turn to yesterday and consequently to the day before yesterday. This "day before" draws some surprising parallels with today. Geopolitical cataclysms throughout the centuries as well as national renaissance shape the "seismic landscape" of the country which at that moment did not yet have own statehood and was a part of the Empire of Russia. Mental environment of nascent national consciousness sensitively responds to the processes in European cultural life and especially to the rise of modernism. We can read this today in the built environment of Riga. At the turn of the 20th century Riga created its own unique ensemble of Art Nouveau, which nowadays has become a spectacular part of the

national heritage. The garden city idea made Riga one of the nicest and earliest (1901) examples of this movement in Europe (Dāvidsone, 1988)

One may argue that at the end of the 19th and the beginning of the 20th century Latvia was in the avant-garde of modern planning and architecture developments, following other European cities like Berlin, Munich, Copenhagen or Saint-Petersburg. Some milestones of professional history mark rapid development of and about architecture, synchronized with the building of Latvian national identity in that period. Among them are the opening of the Polytechnic School in Riga in 1862 akin to those of Karlsruhe (1825) and Zurich (1855), creation of the building department in 1869. There is a remarkable difference between the activities nowadays and those of the first generation of Latvian civil engineers and architects in politics, cultural life and education: a civil engineer A. Anderson became Lord Mayor of Riga (1921-28), professors of architecture founded the new Faculty of Architecture in the University of Latvia (1919) and the Union of Latvian Architects (1924). (Le Bourhis, 2010, p.47)

The fight for independence following the First World War resulted in the first years of independence in the history of Latvia: in 1918 The Latvian Republic was proclaimed. It was a time of building national identity. After gaining the status of capital city in 1918, Riga started to develop the features of monumental character in architecture, monuments, memorials and also in planning (Redbergs, 2012)

The reflection on the city favoured the introduction of international knowhow. Urbanism (elaborated by *pilsētu būvniecība*, a copy of the German *Städtebau*), being a discipline taught in Riga since 1917, kept the tradition of the beginning of the century of the cultural exchange between cities. After 1920, the city of Riga, strong in having a heroic and sensible part in European debates on the city, did not renounce urban growth. Riga, convinced of having a national and international exemplary mission, tried to form a „Great Riga", promoted by Latvian architect-urbanist Arnold Lamze (Le Bourhis, 2010, p.47)

World War II ended for Latvia with annexation to USSR in 1945. That was also a start of intensive economic, industrial and building development as well as a rapid increase in population due to immigrants coming from all Soviet republics. Soviet Latvia was presented as a "model Soviet republic" to the Western world, and the geographic position of Riga determined its position as a "borderland avant-garde", administrative centre of the Baltic region (Redbergs, 2012) Three planning events crucial for the present situation were carried out: nationalization of land, followed by organized deletion of the notion of "private property" and the system of centralized planning adapted to the "one landlord".

After the collapse of the Soviet Union in the 1990s Latvia regained sovereignty and established a free market. The effect of an "avalanche-like" transition from a rigid system of central planning to a free market economy in its wildest, uncontrolled form on

social as well as emotional and mental environments can be compared to an effect of a military intervention: a significant part of society was not able to adapt to the new unknown, obscure and, more importantly, alien order of rigid capitalism. Not for the first time and not only with us, history "played a bad joke": striving for independence and departing from the "prison" of Soviet Union with an extreme enthusiasm, we found ourselves in the middle of storming water[10] without an appropriate boat or necessary skills. Used to free services and rights guaranteed by the state – work, education, recreation, healthcare and housing - we were not able to understand the new meaning of "my private property" concerning own living place.

The inhabitants' small concerns about their own and common physical environment, low social activity and participation in urban development, explicit apolitical behaviour, inability to act in the urban space, absence of understanding and culture of communication in the new economic conditions were the side effects of the gained "freedom". These were the general feelings of the common people in the 1990s, and it was no different for professionals of urbanism. Knowledge about these aspects of "life of feelings" (Geertz, 1973) at that time is crucial for understanding the processes in city development today.
Booming real estate, becoming a major force for urban development, required quick solutions for the conflict zones. Shortly after 1991[11] an elaboration of the Riga development plan for 1995-2005 started. Its author A. Roze called this time a „time of metamorphoses" which completely changed the art of social life of the last 50 years Riga had to transit from the industrial type of social city to the post-industrial model of spreading agglomeration which consequently led to structural changes.(Redbergs, 2011)

Professional society met this "time of metamorphoses" without the necessary skills and education in planning. There are two reasons for this. First, the system of centralized planning was destroyed and together with it the Soviet system of planning institutions became obsolete. Second, the few planners who had been active in Soviet times, had started their professional careers after the Second World War, and in the 1990s had reached the age of retirement. (Le Bourhis, 2012) Culturally and professionally attached to the Soviet period they were neither skilled for the planning of a free market environment nor able to communicate with a new type of political leaders. Furthermore, the "volume architects" could not rescue the situation because of their concentration on the aesthetic dimension of architecture.

[10] Interesting embodiment of the 'water" metaphor appied to the first post-Soviet decennia is presented in the documentary about the former owner of Yukos Oil Mikhail Khodorkovsky. Film "Hodorkovsky" "tells the drama of Khodorkovsky's Odyssey, all the way from socialist believer to perfect capitalist and subsequently becomes the most known Russian prisoner...." http://www.khodorkovsky-movie.com/ [Accessed 1 May 2012].
[11] The year when was internationally accepted the state status of Baltic countries.

As a result, the "workshop-kind" and "spot-kind" planning and design became very popular. The well-known (Gehl, Kolhaas, Forster, Meinhard von Gerkan etc.) foreign specialists were invited to consult and to create representative architecture. However, unlike the post-social cities of Central Europe like Berlin, Budapest, Prague or Warsaw, Riga implemented only a few of their projects. A significant number of international workshops, seminars, contests and *plain-airs* were organized to develop large-scale real estates and to provide expertise in urban development.

Despite these activities, their actual impact on the built environment of the city remained insignificant. The weakness of the planning structure, absence of comprehensive approach to city development and political interest in public space, land-use based urban development regulations are the main reasons for the inefficiency of the existing system. The Riga Spatial Plan 2006-2018 is in fact a transition between the Spatial Structure Plan and a land-use-based planning document (Geldof, De Vriendt, Gutmane, 2009), but strategic approach to public spaces is not present in any form and in any kind of planning documents (Gutmane, 2010).

However, two more reasons of organisational character should be mentioned. One is undeveloped expertise and extreme shortage of good professionals in project management as well as a lack of understanding of it importance. In the last 20 years Riga has not realized any remarkable public space projects, and all of the few ongoing projects are struggling with the designing process as well as communication within different departments and with inhabitants.

The second is negative attitude towards any form of participation within city administration and politicians, based on insufficient knowledge about this trust-building instrument. Existing regulations for public discussion provide a legal platform for participation. However, because of the dominating mistrust and fears of negative reaction among politicians and city officials, these regulations usually are fulfilled very formally. Participation and involvement of all relevant actors is not deemed either necessary or very effective for the outcome of the project. Therefore these actors are not integrated into the planning and designing process on a regular basis.

The idea of integration as a two-way process is often stressed as the idea of cooperation and the necessity for both sides to overcome mutual mistrust and a feeling of being threatened.(Kunda, 2010, p.61)

2.2. Education: historical "conceptual gross section"

Although implementing modern planning ideas in practice from the beginning of the 20th century until the Second World War, in the realm of education professional society in Latvia remains focused on the aesthetics of built environment and does not develop its own school in planning. This tendency became a tradition which one could call a

"school" or "volume architecture" oriented look on urban environment in Riga. A comprehensive approach to city development, which requires serious research in the fields related to built environment, is also absent due to the repeatedly mentioned influence of the fall of the Soviet system.
In the Soviet Union the functions of education and research were delegated to different institutions, however, they were not separated. The dense and multilayered (and also well-financed) network of the Научно-Исследовательский Институт (NII, scientific research institute) ensured development of scientific research in different spheres related both to theory and practice. The realm of architecture and planning had and still has its own scientific organizational body – Российская академия архитектуры и строительных наук (the Russian Academy of Architecture and Built Sciences) A significant amount of work in scientific research was elaborated in high schools. The post-graduate researchers (doctoral candidates), whose research was attributed to the high schools, were the "binding layer" between universities, the NII and the practice. Russia to a large extent has kept this system nowadays, adapting it to the current economic situation (Сабитов [Sabitov],, 2002).
The situation in Latvia after the fall of the system built in the Soviet times was antipodal. After the demolition of industry, the system of field-specific scientific research and following academic layer of scientific education that had functioned so well before was completely destroyed: research institutions were closed, post-graduate education was left without financing, and demand for scientific research decreased considerably.

All aforementioned phenomena – transition to a free market economy, collapse of the Soviet planning and education system and traditionally aesthetics-based school in professional education, determined the current status quo in planning education. Despite the fact that the Faculty of Architecture and Planning in Riga Technical University includes the word "planning", systematic knowledge in planning has not been provided.
However, the evident changes of socio-economic situation all over the world, rising awareness of urgent necessity of integrated approach to urban practice and education do not leave much space for pure aesthetic issues. Growing quality of education in landscape architecture in Latvian University of Agriculture, on a regular basis provides comprehensive to planning and design of open spaces, opening of the alternative programmes in architecture, urban design and planning and active interaction between the students from different universities influences the interests of the new generation. Good illustration of this was the recently (February 2012) organized exhibition of the diploma projects of the Riga Technical University alumni, "40 jauno arhitektu stāsti" (Stories told by 40 young architects). The majority of the projects deal with public and open space issues rather than with pure architectural subjects.

Thus the professional environment in today's Latvia, especially in Riga, seeks to obtain skills, knowledge and professionals with a comprehensive mindset appropriate to the rapidly changing environment. The education field does not provide enough possibilities either for young people or for practitioners. The latter, having more urgent need of urban knowledge, are especially "deprived" - in Latvia there is not one possibility of lifelong learning in urban planning which would give chance to gain information and skills without leaving one's own practice.

2.3. "Subbotnik"– a sustainable form of social co-operation?

> Participation in networks is an important form of social capital. In times of need it can be activated, and under certain circumstances it can be transformed into economic capital.(Rajevska, 2010)

Riga's rich cultural heritage[12] forms the basis of the qualitatively built and successfully functioning system of built heritage protection. However, there remains an equally rich social heritage which is currently underestimated, unexplored and therefore not used in urban practice. The history of Latvian society provides us with unique examples of collaborative creation of the built environment already in the beginning of the 20th century. We compare two historical social events in Latvia - one from the times of the Russian Empire in the beginning of the 20th century and another from the Soviet social practices.

The first took place in the area of Riga's garden city *Keiserwald* (germ., old), today's Mežaparks (latv., Wood Park) in 1913 as an initiative on laying out a new public park. The action was organized by the recently founded public organization *Latvijas Izglītības Biedrība* (Latvian Association for Education) which was indented to promote and develop Latvian schools, kindergartens, libraries and reading rooms. The process of building *Saulesdārzs* (Garden of Sun, latv.) was organized as a common action, with the participation of Latvian businessmen, intelligentsia, inhabitants and city officials. The private property was bought with donated money; the design and implementation were created in a participative way (Neimane, 2012, p.9) Today *Saulesdārzs* has kept its public function in a reduced form (albeit an attempt of its privatisation was undertaken) as well as its historical composition. However, its most important quality, which nowadays is discussed as element of sustainable urban development – its significant role as a facilitator of social activity, national identity, collaborative design and economic activity - is completely lost.
A different phenomenon, appearing in recent urban practices, is *Subbotnik* (from *суббота* – Saturday, rus.), the form of volunteer work developed during the Soviet time. This contemporary legend was drawn from Lenin's articles "*О героизме рабочих в тылу. По поводу «коммунистических субботников*", (1919, About

[12] Historical centre of Riga is protected by UNESCO

heroism of the workers in the rear: the case of communist *subbotniks*) and "*Великий почин*", (The Great Initiative, 1920), and based on the real event of volunteer work on Moscow's railway in spring 1919. The success of the first event and its enormous positive impact on the mood of the people determined the following systematic development and popularisation of the initiative during the whole Soviet period. Although the form of the event has changed, shifting from the industrial sphere in the beginning of the USSR to the works on public space towards the end, the mental and (one may argue) also emotional positive image of *Subbotnik* has remained deeply rooted in the mentality of the Soviet people.

Under circumstances of general instability and bewilderment in the years of financial crisis Latvia has restored (2008) the initiative of *talka* (Latvian equivalent for *subbotnik*) in its later form – as an "*Lielā talka*" or Big clean-up day (one might draw the parallel with Lenin's "Great initiative" in 1919) of outdoor space. Officially *Lielā talka* was initiated by the President of Latvia at that time V. Zatlers with an overarching aim of "making nature garbage-free, allowing it to recover and urging people to take care of their environment." (www.talkas.lv, 2012) In 2010 the new dimension - of upgrading public spaces – was added as an initiative of social workers and landscape architects. This new form, gaining more and more popularity by inhabitants as well as by professionals, this year gathered professionals and students of architecture, landscape architecture and art and had huge success as socialization act with visible results of improved living environment. The format of *Pagalmu talka* (Courtyards' talka) includes workshop based student competition, competition based selection of the courtyards and principles of public private partnership in implementation.

2.4. CPD as an instrument for urban development

By the year 2010 an international group of professional planners and landscape architects working in Latvia started to explore the possibility to apply the principles of Talka to urban planning and design. A scope of several factors worked as the driving impulse: the aforementioned lack of political interest regarding public spaces, insufficient professional knowledge and experience in urban planning and design, passive societal attitude, growing mistrust, aggression and segregation between all social groups – politicians, professionals, inhabitants, city departments and businessmen. A year later an intensive training program *RADI RĪGU!* (Create Riga! 2011-2012) for practitioners in city planning, architecture, landscape architecture and road engineering was launched. The subheading and main subject was "public space as lever for social revival". The broader aim was to bring to the "round table" as many stakeholders and shareholders of Riga's development as possible, in order to activate discussions about an integrated approach to city development and to create trust among professionals, politicians and inhabitants. This defined the heterotopian nature of the programme.

2.4.1. Professional training + urban action + implementation

"RADI RĪGU!" had a 3D aspiration – as a professional training programme in urbanism, as an urban action and as an at implementation aimed research by design. All three dimensions of the programme were interwoven with a strongly expressed socially interactive and communicative character.

2.4.2. Professional training

The training programme RADI RĪGU! had the intention to provide experience in all stages of planning and design, from project definition to project management, for a multidisciplinary team of practitioners: architects, landscape architects, city planners and road engineers. Despite objective and subjective difficulties – a rather high price for training in a time of economic crisis, the large amount of time required, a very vague idea about the issue of spatial planning, project management, participation and involvement – 25 professionals working in Riga's architectural bureaus, among them in Latvia well-known professionals, responded to the call. A multidisciplinary, multi-aged and international group started training in April 2011 and worked together in nine workshops during one year.

High-level professional expertise was guaranteed by the international team of coaches from University of Leuven (prof. J. Schreurs and prof. Jef Van den Broeck), Free University of Brussels (prof. Marc Martens), Belgium and experts from Copenhagen (Tina Saaby, city architect), Barcelona (Jordi Farrando, architect) and Moscow (Anna Schtetinina, architect, leader of "Arhistojanije") were invited to participate in different phases of the work.

The workshops were organized in three phases, each aimed at a different stage of project processing.

Phase 1	**Phase 2**	**Phase 3**
• Project preparation	• Concepts	• Strategies
• Project definition	• Sketches	• Management

In order to provide exercises in the beginning stage of urban project participants were invited to select cases – spaces in Riga's neighbourhoods. Before the start of the programme the participants decided to work on city neighbourhoods rather than the city centre. They were motivated by the necessity to pay professional attention to the periphery of the city, left out of professional interest for the last 20 years.

From twelve spaces offered for selection they had to choose five according to the following criteria, given by the coaches:

1. Strategic character of the neighbourhood
2. Large involvement of inhabitants
3. Ownership
4. In favour of local authorities
5. Complexity
6. Shining example

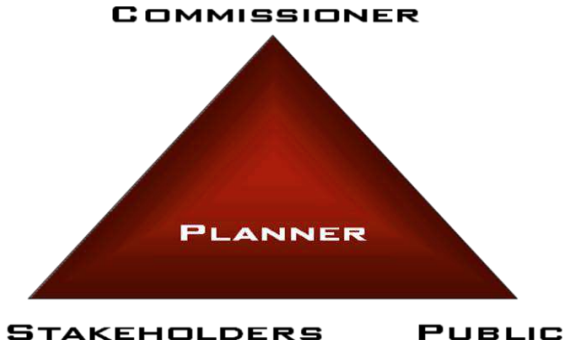
Selections were made in an interactive role-based way. One of the stages of selection included voting. The interesting fact is that by voting the chosen cases were re-evaluated guided by emotional attitude, which was influenced by feeling of social justice or, in other words, social sympathy: mono-social and identity-lacking neighbourhoods built in late Soviet time were preferred instead of spatially and socially more diverse ones which was more interesting for planning and design.

Instruments like mental mapping, analysis of different scales ("from space to place" method), visits of the sites, cross-evaluation and diversity games, combined with theoretical information given in the lectures by coaches, helped to receive and to adapt significant amount of new information as well as to apply the principle of integrated approach in the workshops and own everyday practice.

2.4.3. Urban action

RADI RĪGU! has made an attempt to build the trust by bringing public space users and policy makers closer to each other in co-operation. The call "City makers are on the street!" was the non-written slogan of *RADI RĪGU!*

The ultimate task of the intensive programme, disclosed in its title "CREATE Riga", is to make participants assume the role of mediators between decision-makers, stakeholders and the public.



The traditional soft PR campaign tools were used: a website (www.radirigu.lv), information in public media and open lectures given by the external experts. Two public conferences were organized during the programme: a mid-review of the results during the second phase and a two-day closing conference in the City Hall, which brought

together most of the important actors: politicians, decision makers, inhabitants, professionals, foreign experts and urban activists.

An effective tool for getting closer to users and city administration was "moving workshops". Started in the House of Architects, participants worked in all selected neighbourhoods, in the schools or district administrations, involving the local people. It created a platform for effective communication with inhabitants and local authorities.

Between the seminars participants did their "homework" on participative design, organizing workshops for children and involving different departments, real estate developers, NGOs, police and port authorities.

The integrative approach, applied as a methodology to all levels of the programme - aim, structure of the workshops, preparation of the process, selection of the cases, branding and implementation of the results, doubtlessly served as a strong communicative platform.
The integrative approach also determined multiple, layered aims of the project, which can be articulated in eight flows:

DISCOVER LEARN REALISE COOPERATE INVOLVE MARKETING LINK CREATE - RIGA!

1	2	3	4
DISCOVER	**LEARN**	**REALISE**	**COOPERATE**
the world of planning	**about a design process** from order to project definition from project definition to concept from concept to design from design to project	**real projects:** - on short term -relatively cheap -substantial -eye catching examples -pilot projects -best practices	all stakeholders and actors in all stages of the process: - decision-makers city administrations (national level) -district officials -external actors - NGOs
the importance of public spaces in all stages of the process	**project and process management** from idea to project from project to realisation from realisation to governance **to cooperate with:** stakeholders, actors, inhabitants **to preserve** spatial qualities during the whole process	-projects that improve daily living conditions in own neighbourhood	

5	6	7	8
INVOLVE	**MARKET**	**LINK**	**CREATE RIGA**
inhabitants in all stages of the process, including realisation and governance	integrate several stages of the process into public events: -happenings -exhibitions -design contests for children	link the project and its process to parallel events and programmes: - RIGA 2014 - Talka - Apkaimes	hand over a set of tools to the City of Riga in order to develop a real Public Space Policy: - methodologies, guidelines - motivated staff - skilled professionals - enthusiastic people

As an example one can mention communication with city officers at the early stage of the programme, which was organized not as passive information, but as active involvement. They were also invited to evaluate the variants of the programme‘s logo, which added an informal note to the communication process.
This preliminary friendly communication helped to create interest, understanding and personal engagement of the city officials invited to the discussions. Indeed, during the process they changed their positions from “observers” to “participants”. Initially discussions were not aimed at gaining permission or “financial support” (the project is partly financed by the ESF programme and participants themselves) but sharing opinions about questions such as “Is it necessary for Riga?”, “What do we need to make Riga better?” and “Which are the tools to achieve it?”.
All these activities definitely placed *RADI RĪGU!* on the public stage of the city. However, it must be admitted that the PR programme planned by the organizers was not entirely successful due to financial and time shortage. The biggest contribution to the successful “RR-story” concerning “best practice” public image was made by the well-organized and broadly popularized last conference in the City Hall as well as the FORUM –format of this event.

2.4.4. Implementation

Despite the great number of different workshops organized in Riga in the last two decennia, there was a lack of practical results: very few ideas found their path to realization. Therefore *RADI RĪGU!* and the city administration agreed (by signing a contract with the city development department) about possible implementation of the programme’s results.

It is worth mentioning that this agreement was an encouraging step and a sign of trust from the side of the city administration and politicians, because of a rather vaguely defined outcome and unknown result of the whole event. Moreover, the agreement was closed with a programme which was just an urban action, without any legal status. One

can argue that *RADI RĪGU!* is a unique example of (positive) collaboration between city authorities and urban activists, built on mutual trust.

3. Results? Results!

Before articulating the outcome of this heterotopian one-year-long urban action/training programme, it is worth briefly describing the initial emotional landscape of the story. Rereading the negative comments on the article announcing the start of *RADI RĪGU!* in the archive of the interactive architecture platform A4D (www.a4d.lv), remembering scepticism and mistrust, even resistance from the side of politicians as well as professionals, one would wonder if there ever was hope for (positive) results. There was, however, a shared space of enthusiasm, eagerness for new knowledge, love for one's own city and a rare air of creativity mixed with friendship. It was exactly this mixture that delivered results which were officially and publically approved on the *RADI RIGU!* Forum in March 2012.
The first and most important result is the fulfilment of the main goal, namely, to raise awareness of the need for a comprehensive approach to city development. During the year *RADI RĪGU!* activities – communication with inhabitants, public lectures, discussions with city officials – attracted enthusiastic people who joined the groups and worked on the projects together with the participants.
Due to its 3D character the training programme turned into a common event. Students and professors of three Latvian universities, civil servants, district authorities, Ministry of Environment, police, schools and inhabitants were all involved in the action.

The "homework" in communication and participative design resulted in the foundation of NGOs in two of the five programme's neighbourhoods.

The most mistrusted and (even among the coaches critically discussed) intention, to deliver practical results for the City in order to implement them, is in the stage of possible realization at that moment. Decision-makers publically announced their willingness to further develop the programme for neighbourhoods and particular projects created by *RADI RIGU!* The city development department has officially started to work on the proposals.

As a continuing professional development this programme fulfilled its task most successfully: all practitioners and students who participated in the training programme emphasized the high importance of the gained knowledge and skills for their further professional careers and understanding of the processes in the city.

The *RADI RIGU!* initiative has also gained international interest. Recently there have been discussions about possible collaboration with Umea within the cultural capital programme in 2014 and launching a set of parallel workshops on resilience, urban policies and community building in Latvia and Flanders.

However, the most important outcome of the programme, which was meant as a positive and constructive action of the professionals, may be that it is a demonstration "for" rather than "against". It is the first step in building trust and mutual understanding between participants of the urban project in its broader sense.

4. Conclusions

Searching for the more effective methods of professional education, the social aspect of learning appears not less important as the methodology. In this concern historical perspective of social life comes forward with forms of co-creation rooted in local culture. Together with material cultural heritage and not-material ones like song festivals, carnivals or religious rituals, the social heritage as ritual of spatial co-production has a capacity of being transformed into new forms of urban planning practice and education. The case of *Talka*, its shift from industrial production to spatial co-production provides us with valuable information and methodologies.

Contemporary urban development more and more turns into mass creativity and mass innovation, but urban co-production requires interaction of all actors. Learning in architecture and planning, having creativity at the bottom (Schreurs, 1986), has to become a platform for urban development as open source and co-creation ("yes, you can use my ideas"). As much as urban project "in the wild", the "laboratory" of urban education as mayor task has to provide professional training in co-existence, non-aggressiveness, tolerance. The programme *RADI RĪGU!* with its evolution from shared mistrust and resistance to shared enthusiasm and willingness to co-operate, offers a convincing methodology for creative learning.

RADI RIGU! has a heterotopian character and combines learning, urban action and the aspect of implementation. As such it was like heterotopias often are (Dehaene, M., De Cauter, L. 2008), a "reaction on crisis". It complies with a planning cycle which analyzes an existing situation, develops a vision about a better future, implies transformations and evaluates these in the light of a next cycle (Schreurs, J., Moulaert, F. 2012) and marks a shift from ecological approach to planning education.

Planning for Natural Gas Fracking in the Barnett Shale, Texas: The Legal and Regulatory Framework And the Role for Local Governments

Rachael ***Rawlins***

Hydraulic Fracturing for natural gas is booming in Texas. According to the State's regulatory agency, of the 15, 466 new drilling permits issued in 2010, approximately 85% of those wells were hydraulically fractured. [1] Rigs are literally pulling up in neighborhoods. Faced with minimal state and federal regulation, Texas cities are on the front line in the effort to figure out how best to balance industry, land use and environmental concerns. Serious concerns include chemical toxicity, air and water quality impacts, and correlation to earthquakes, visual blight, traffic and infrastructure concerns, and the adequacy of water in this drought stricken state.

The focus of this study is the Barnett Shale Formation which underlies 5,000 square miles of the Dallas/Fort Worth area of Texas to depths of 6,500 to 8,500 feet.[2] The Barnett Shale in the Fort Worth basin of North Central Texas is by far the most active shale gas play in the United States,[3] and one of the largest drilling programs ever undertaken in an urban area. [4] Although, the effort is not without considerable controversy, the public in the area have been identified by some Texas attorneys as "the most accepting and accommodating of any urban or suburban population concerning drilling," likely due to the fact that many of the citizens own the mineral rights beneath their land. [5] Historically, this area produced oil and gas from conventional reservoirs, but there are now over 8,000 wells producing gas from the Barnett formation. [6] Gas production increased over 3,000% from 1998 to 2007, from 94 million cubic feet per day to over 3 billion cubic feet per day.[7]

Fracturing employs high-pressure jets of water and a mix of chemicals, including carcinogens and endocrine disrupters, to fracture rock and release natural gas. [8] Additives are used to reduce

friction (as the fluid is injected), to prevent bacterial growth (biocide), to prevent mineral precipitation (scale inhibition), to prevent corrosion, to prevent swelling of expandable clay minerals (clay stabilization), as gelling agents to support proppants, as surfactants to promote fracturing, and as cleaners.[9]

Depending on the properties of the formation, the fracking fluids may be water-based, oil-based or acid-based, and sometimes also include nitrogen and carbon dioxide to help foaming.[10] First, a hydrochloric acid solution is pumped down the well to clean up residue left from cementing the well casing. [11] In the deeper, high-pressure shales, operators then pump slick water (a law-viscosity water-based fluid) and proppant. Nitrogen-foamed fracturing fluids are commonly pumped on shallower shales and shales with low reservoir pressures. [12] The fracturing fluid both opens the fracture and to transports the "propping" agent. [13] The fluid is pumped under pressures up to 8,000 psi, enough to crack shale as much as 3,000 ft. in each direction from the wellbore. Several treatments may be used to produce multiple fractures at different depths, or further out into the formation in the case of horizontal wells. [14]

Fracking fluid chemicals and wastewater can leak or spill from injection wells, flow lines, trucks, tanks and holding pits. Most of the injected fluids, 60-80%, are returned to the surface as "flowback" water which typically contains proppant, chemicals, and trace amounts of naturally occurring radioactive elements from the geologic formation.[15] Concerns include the possibility that chemicals injected, naturally occurring substances disrupted, or toxins spilled at the surface may make their way into drinking water supplies. The USGS estimates about 15,000 gallons of chemical additives of waste in a three million gallon frac job.[16] Storage and transport are both a concern.

One issue of particular concern in the Barnett Shale is the adequacy of water supplies. Increasing water use due to growing population, drought, and Barnett Shale development has heightened concerns about water availability in North-Central Texas.[17] Hydraulic fracturing well can use 1.2 or up to 3.5 million gallons of water for a horizontal well. [18] One fracture treatment can use more than 500,000 gallons of water, almost as much as an Olympic size swimming pool (660,000

[18] Id. at 33, citing Railroad Commission of Texas, Water Use in the Barnett Shale, July 30, 2008

gallons).[19] Sixty percent of the water used in hydraulic fracking comes from groundwater in the Trinity and Woodbine aquifers. [20] In the Barnette Shale, flowback water is primarily disposed of in underground injection wells.[21] Water is thus removed from the hydraulic cycle. Many rural communities rely on groundwater from the Trinity Aquifer as the sole water source. [22] In 1990, the Texas Natural Resource Conservation Commission designated the Trinity region to be a Priority Groundwater Management Area (PGMA), defined as an area where a critical water shortage is occurring or can be expected to occur in the next 25 years.[23]

Another concern is controlling air quality during both during drilling and fracturing . Emission include nitrogen oxides and volatile organic compounds (VOCs) from wellheads (natural gas leaks), flared gas (gas that escapes from the well during drilling and fracturing and is burned), equipment used for drilling, fracturing, and dehydrating gas (equipment exhaust), pipelines (natural gas leaks), flowback water tanks and pits (evaporating volatile organic compounds), and compressor stations (when natural gas leaves a well, it is sent to a gathering station and the gas is then compressed by an internal combustion engines and conveyed to a processing facility via pipeline).[24]

Drawing lessons for planning practice, this interdisciplinary law and planning paper reviews the status of both the science and the law related to hydraulic fracturing in Texas. Given trends in environmental law, the demand for energy and the importance of oil and gas industries in this state, the regulatory balance is unlikely to favor precautionary measures. This paper will consider the extent to which the risk is known, and whether the law requires industry to internalize the risk and the cost of this vast experiment. This paper will research the common law and regulatory framework at the federal, state and local level governing hydraulic fracturing in order to explore opportunities and constraints for local government.

I. Federal and State Regulations: Water

There is no state or federal regulation, nor any requirements for disclosure or testing of the chemicals that can be injected during hydraulic fracturing. Clearing up any confusion on this issue, the U.S, Energy Policy Act of 2005 included a specific amendment to the definition of "underground injection" under the Safe Drinking Water act to exclude "the underground injection of fluids or propping agent (other than diesel fuels) pursuant to hydraulic fracturing operations. [25] The EPA does retain some authority under the Safe Drinking Water Act to order

remediation. However, as discussed below, there are legal questions concerning EPA's burden of proof that may prove problematic in the context of hydraulic fracturing.

Following intense lobbying from the oil and gas industry,[26] the federal government also exempted wastes from oil and gas exploration and production operations from the Resource Conservation and Recovery Act (RCRA), our "cradle to grave" hazard waste regulatory system which regulations the generation, transportation and disposal of hazardous wastes. [27] The exemption covers all wastes "intrinsic to and uniquely associated with primary E & P operations,"[28] which means all waste that has been brought to the surface during oil and gas exploration and production operations or waste that has "otherwise been generated by contact with the oil and gas production stream during the removal of produced waster or other contaminants from the product." [29]

In the Barnette Shale, flowback water is primarily disposed of in underground injection wells[30] where standards are set by the federal government. [31] The Railroad Commission of Texas operates a federally delegated program to permit underground injection wells which is reviewed by the Environmental Protection Agency every two years.[32] There are also some minimal federal standards that require best management practices to control stormwater during site construction for a well pad and access road that is one acre or greater.[33] The primary responsibility for water resources related to site operations site otherwise falls to the Texas Railroad Commission and local government.[34] However, other than limited disclosure regulations, discussed below, there no regulations established by the Texas Railroad Commission (RRC) that apply uniquely to hydraulic fracturing. [35] There are permit requirements for all oil and gas operations. [36] The RRC also has set standards for casing, cementing, drilling and completion.[37] However, unlike some

other states, Texas has no restrictions on the proximity of drilling to sensitive receptors, and no lining requirements that pits (apparently including flowback water impoundments). [38]
In so far as water supply is concerned, the Texas legislature has recently adopted legislation that requires the RRC to promulgate rules to require fracking operators to provide information on the total amount of water used in the operations.[39] Signs offering oil field water for sale can be seen on the highway and on internet sites that cater to the shale industry. [40]

Surface waters in Texas are governed by a permitting process based on upon a showing that it is not subject to prior appropriation, and it will not impair existing water users or become a detriment to the state or public welfare. [41] Groundwater use, however, remains unrestricted for hydraulic fracturing. The general rule for the use of groundwater resources in Texas is the rule of capture. [42]This rule can be modified through the creation of local groundwater districts with authority to limit groundwater production. However, the Texas legislature has also created an exemption for temporary water supply wells that service oil rigs from any regulation by groundwater districts.[43] The term "rig" is interpreted broadly so as to include workover rigs and other implement of well completion, which includes those related to hydraulic facturing. [44]

II. Texas Railroad Commission: State Law, such as it is, May not be Enforced

The RRC claims that the state rules for well construction have prevented even a single documented case of groundwater contamination from injected fluids.[45] However, according to a 2010 review by the Sunset Commission Advisory Commission, a legislative body that reviews state agencies to identify and eliminate waste, duplication, and inefficiency in government agencies,[46] the RRC has a particularly poor enforcement record and limited enforcement capacity.[47]

[47] Id.

More than 60,000 wells were drilled from 2003 to 2008, representing an increase in production of 75%, however, inspectors and inspections rose only 6%. [48] Of the more than 80,000 oil and natural gas production-related violations found in fiscal year 2009, field staff forwarded less than 4 percent to the agency's central office for enforcement action.[49] There were 18,000 reports of water related violations, but the RRC took enforcement action on less than 1 percent of these violations. [50] Moreover, according to the Sunset Advisory Commission, the RRC was unable to say with certainty that there were no serious violations in the roughly 17,900 water pollution violations that did not go to enforcement. The RRC relies solely on the discretion of each district office to determine which violations should be forwarded for enforcement action,[51] and it fails to track data on operator violations in a way that would reveal the effectiveness of its enforcement efforts.[52] The Sunset Advisory Commission concluded that the Commission's enforcement process is not structured to deter repeat violations.[53]

According to the Sunset Advisory Commission, the RRC has not formally adopted any penalty schedule, and lacks any process to gather public input on what penalty levels should be for violations. [54] Moreover, the Railroad Commission conducts all of its enforcement hearings with in-house staff where the majority of participants (the administrative law judge, the attorneys who bring the charges, and the staff who investigate the violations) are all Commission employees. [55] The relationship between the judges, attorneys, and staff provides the opportunity for inadvertent ex-parte communication and may allow the Commission's staff (a party) to exert an unfair amount of influence over the administrative law judge's decisions.[56] The agency is also arguable compromised by its structure that includes a full time three member elected board (an anomaly in Texas) that relies on campaign contributions from the regulated industry. [57]

III. The Real Job Falls to Local Governments

Given the state of affairs at the federal and state level, most of the work is left up to the local governments. In Texas, concurrent state and municipal oil and gas regulations are widespread and have been recognized by Texas courts since the 1930's. [58] There are two categories of cities in Texas - home rule and general law.[59] General law cities are smaller cities whose powers are limited to those specifically authorized by state statute.[60] The Texas Constitution allows cities

with populations of more than 5,000 to adopt their own charters and become "home rule cities."[61] Home rule cities look to the state law only to determine specific limitations on their power.[62] The larger cities over the Barnett Shale have already taken the initiative to regulate many issues related to hydraulic fracturing, including addressing setbacks, well locations, green completions, closed loop systems, compressor locations, pipelines, waste disposal, truck traffic and noise regulation.[63] This paper seeks to identify some specific areas of concern where local governments could fill in the critical issues in the area of on-site water quality and air quality concerns that may be falling through the gaps at the federal level.

IV. Water Well Contamination, Hard to Prove

Allegations of water well contamination due to hydraulic fracking have been among the most prominent . Nationwide, there have been at least 36, and, in Texas, there have been at least seven, most in the Barnett Shale.[64] Most claims involve methane, chemical constituents (iron, manganese, etc.) and physical properties such as color, turbidity, and odor.[65] Proving causation, however, is difficult. The industry stridently denies any problem. According to one shale gas proponent, a university professor, speaking to a Congressional Committee: "the hydraulic fracturing process is safe, already well regulated by the various States" and that "the hysterical outcry over this process is completely unjustified."[66]

According to a University of Texas Energy Institute Report, some of the properties and constituents found in water wells may have been present before shale gas development began, but often there is insufficient baseline (pre-drilling) sampling or monitoring to establish the impacts of drilling, fracturing, and other operations.[67]Iron and manganese are common naturally-occurring constituents in groundwater, and, particularly in areas underlain by gas-producing shales, methane migrates out of the shales under natural conditions and moves upward through overlying formations, including water-bearing strata (aquifers).[68] It is also possible that water quality changes may be due to vibrations and pressure pulses disturbing constituents that were already present in the casing wall and bottom of the well the rather than by hydraulic fracturing fluids or leakage from the well casing.[69]

Another possible explanation, at least for contamination in the Barnett Shale, is that the water wells were drilled into the gas formation (as opposed to gas wells leaking into the water bearing formation). The theory is that the gas in the water wells naturally exists in the shallow Strawn Sand, beneath and intertwined with the Paluxy Sand aquifer in the far South Parker County area. This gas purportedly exists in discontinuous zones or puddles. Some older gas wells purportedly

produced natural gas from relatively shallow depths of 216 to 214 feet before hydraulic fracking begain.[70]

V. Trade Secret Protection Dominates Disclosure Rules

According to a University of Texas Energy Institute Report, "None of the water well claims involve hydraulic fracturing fluid additives, and none of these constituents has been found by chemical testing of water wells."[71] The Report specifically dismisses the "finding of acrylonitrile in a water well in West Virginia," noting "no evidence has been found that this compound has ever been used in fracturing fluid additives."[72] In that case, a resident of rural Wetzel County, W. Va., claimed that the water from her wells smelled like "industrial-strength cleaning solvent" and pointed to nearby hydraulic fracturing in the Marcellus Shale.[73] Tests by the state Department of Environmental Protection identified leaked gasoline as the source of the contamination, not process of drilling the gas wells. However, upon commissioning unofficial tests, she found high concentrations of acrylonitrile, in addition to benzene, and styrene. The local gas company denies that it used acrylonitrile, but has never fully disclosed what chemicals are in its fracking fluid.[74] Another drilling company, Haliburton, has listed as acrylonitrile or a compound including it on two U.S. patents for frack additives.[75]

Some statues, including Texas, have now started requiring some disclosure of fracking fluids. At the end of last year, the Railroad Commission of Texas adopted a limited disclosure rule that applies to fracking treatments of wells in Texas for which the Railroad Commission has issued an initial drilling permit on or after February 1, 2012.[76] The rule generally requires the supplier (the entity who provides additives for use in fracking treatments) or the service company (the entity that performs fracking treatments) to provide the well operator (the person responsible for the physical operation and control of a well) with the identity, the CAS number,[77] and actual or maximum concentration of each chemical ingredient intentionally added to the fracking fluid within 15 days of **c**ompleting fracking treatments.[78]

[78] Id. at 3.29(c).

On or before the date a well completion report is submitted to the Railroad Commission, the operator must then complete a Chemical Disclosure Registry form and upload it on the Chemical Disclosure Registry, known as FracFocus, a publicly accessible national fracking chemical registry website.[79] This form requires information on each additive that includes the trade name, supplier and intended use, as well as each chemical ingredient, the CAS number, and the maximum concentration of each chemical used in the hydraulic fracturing treatments that has a Material Safety Data Sheet (MSDS, pursuant to federal regulatory requirements), but only a simple list of chemicals that do not have a MSDS.[80] However, there are four categories of chemicals for which disclosure is not required, chemicals:

(1) not disclosed to the supplier, service company or operator; (2) not intentionally added to the fracking treatment; (3) that occur incidentally or are otherwise unintentionally present; and (4) eligible for trade secret protection.[81]

The trade secret exception is particularly problematic. A supplier, service company or operator can simply elect to claim trade secret and will not be required to publicly disclose detailed information on the fracking chemicals unless their claim is challenged and the Texas Attorney General or a court determines that the information is not entitled to protection.[82] If an entity withholds information about a chemical ingredient, it is only required to disclose limited information to the Commission on the chemical family and the properties and effects of the chemical. Only landowners on or adjacent to the property where the wellhead is located, or a department or agency of the state[83] may challenge a claim of trade secret protection. In commenting on the draft rule, the City of Dallas unsuccessfully requested changes that would also allow municipalities to appeal a claim of trade secrets.[84] The City did note, however, that municipalities may generally fall under the category of "adjacent land owner" in light of adjoining public rights of way.[85]

There is a limited exception requiring the disclosure of trade secrets to health professional or emergency responder (specifically defined as someone who needs information in order to provide medical or other health services to a person exposed to a chemical ingredient)[86], who must then keep the information confidential, with limited exceptions for diagnostic or treatment purposes.[87] As explained by the City of Dallas, this provision does not include any exceptions for

[79] Id. at 329(2)

[87] Id. at (c)(4).

incidents where hydraulic fracturing chemicals are spilled on property. [88] The City of Dallas also raised concerns about the timing of the disclosures, noting that providing notice only after the hydraulic fracturing process has been completed is not an effective tool for dealing with incidents that occur during the hydraulic fracturing process. [89]

Not only does the rule severely circumscribe the possible challengers to claims of trade secret, but any challenge is subject only to consideration of industry concerns, with no weighing of the public interest. "Trade secret" is defined as any "formula, pattern, device, or compilation of information that is used in a person's business, and that gives the person an opportunity to obtain an advantage over competitors who do not know or use it."[90] The following six factors are to be considered in determining whether information qualifies as "trade secret:"

(A) The extent to which the information is known outside the company,
(B) The extent to which it is known by employees and others involved in the company's business;
(C) The extent of measures taken by the company to guard the secrecy of the information;
(D) The value of the information to the company and its competitors;
(E) The amount of effort or money expended by the company in developing the information, and
(F) The ease or difficulty with which the information could be properly acquired or duplicated by others.

VI. Local Government Act Could Assist EPA, Shore-up Common Law, and Expand Disclosure Requirements

EPA Administrative Orders, Range Resources

In the Barnett Shale, there has been one loud and particularly fierce debate, including a tussle between the state and federal government, over cause of methane and other contaminants found in drinking water near hydraulic fracking by Range Resources (the company). In late 2010, homeowners who lived near drilling complained that their tap water was bubbling and even flammable.[91] EPA specifically noted that the well (drilled in 2005) did not begin to show signs of natural gas contamination until after the conclusion of drilling and hydraulic fracturing activities.[92] EPA was also aware of at least one instance in which a private water well drilled into the Trinity Aquifer produced some gas during or shortly following drilling operations.

[92]United States' Memorandum in Opposition to Defendants' Motion to Dismiss, at 3, http://www.epa.gov/region6/6xa/pdf/2011-05-09_range_plaintiffs_memorandum_%20in_opposition.pdf

Later, EPA also learned of elevated levels of methane, ethane, and propane in another nearby residential water supply well and earlier signs of effervescence in the water.[93] Initial water samples showed elevated levels of benzene, toluene, ethane, and a high level of methane, measured initially at that time at 7,810 μg/L, and later at even higher levels, 20,100 μg/L. EPA also sampled the production gas from the gas well, and performed compositional and isotopic fingerprinting analyses. [94] Isotopic fingerprinting is a method for determining the ratio of different isotopes of a particular element in a material such as gas.[95] Based on the results of the investigation, EPA determined that the presence of gas in the well is likely to be due to impacts from gas development and production activities in the area." [96]

Concluding that "methane in the levels found by EPA are potentially explosive or flammable, and benzene if ingested or inhaled could cause cancer, anemia, neurological impairment and other adverse health impacts," and that the contaminants "may present an imminent and substantial endangerment to the health of persons," EPA issued an Emergency Order on December 7, 2010[97] to the company to:

> (i) to notify EPA whether it intended to comply, (ii) to provide potable water to two residences, (iii) to install explosivity meters in two residences, (iv) to conduct a survey and limited sampling of water supply wells in the area, (v) to submit plans for additional soil gas surveys and indoor air concentration analyses of two residences, and (vi) to submit plans to identify gas flow pathways, plans to eliminate gas flow if possible, and plans to remediate impacted areas. [98]

The company denied culpability and the very next day, the Railroad Commission of Texas scheduled a hearing to evaluate whether the operations were causing or contributing to the contamination of the wells. Range maintains that their activities did not cause the contamination in the affected wells because they were drilling to depths of five thousand feet and the wells terminate about two hundred feet below the ground. [99] On January 19-20, 2011, the Railroad Commission of Texas (RRC) held hearings (during which EPA and the well owners refused to participate) and issued a final order on March 22, 2011 concluding that the hydraulic fracking operations had not and were not causing or contributing to contamination of any domestic water wells. [100]

[100] Brenda Clayton, *The Future of Regulation in Hydraulic Fracturing*, 7th Annual Texas Energy Symposium, February 10, 2012, at p.11.

EPA's position was that it may exercise special emergency authority upon receipt of information that a contaminant "may present an imminent and substantial endangerment,"[101] and that there was no requirement that EPA demonstrate that a respondent caused or contributed to the endangerment as a prerequisite to issuing an Emergency Order.[102] EPA took the position that it did not have to prove causation to the same extent as would be required in a common law action. EPA relied on its emergency powers under Section 1431 of the Safe Drinking Water Act, 42 U.S.C. §§ 300f – 300j-26 (the "Act") and argued that the claim is complete without any assertion of violation of some statutory or regulatory provision or ongoing harm to a particular individual. EPA explained that this authority allows EPA to issue orders to "any other person whose action or inaction requires prompt regulation to protect the public health," id., and is intended to reach beyond those who violated the particular statute or who failed to comply with a regulation.[103]

In response the company's claims of a violation of procedural due process, EPA explained that the company was not without recourse. It may seek immediate federal judicial review by filing a petition under the arbitrary and capricious stand for review in the United States Court of Appeals.[104] However, the arbitrary and capricious standard of a review is a "highly deferential" standard of review, and EPA may need only to plead "a rational nexus" between the company's conduct and the potential endangerment in this case,[105] not actual causation.

Following an unfavorable, but not directly related, Supreme Court decision concerning a challenge to an EPA compliance order issued under a different federal statute, the Clean Water Act,[106] in March 2012, the EPA decided to drop it's case against Range Resources. In exchange, the company agreed to monitor groundwater. [107] Politically, the case was further complicated by antics on the part of the a landowner who created a deceptive video for the news media and the EPA where he hooked a water hose up to a gas vent (not a water line) and lit it on fire. [108]

VII. In Depth Study, still mired in Politics and Uncertainty

Pavillion, Wyoming

The U.S. Environmental Protection Agency's (EPA) first report firmly linking hydraulic fracking to drinking water contamination was filed in December 2011[109], but only in "draft form," for public comment and submission to an independent scientific panel. The research was prepared in response to a request residents in Pavillion, Wyoming. EPA detected synthetic chemicals, like gylcols and alcohols consistent with gas production and hydraulic fracturing fluids, benzene concentrations well above Safe Drinking Water Act standards and high methane levels in deep monitoring wells. EPA also re-tested private and public drinking water wells in the community which it generally found to meet established health and safety standards. However, given the area's complex geology and the proximity of drinking water wells to ground water contamination, EPA expressed concern about the movement of contaminants within the aquifer and the safety of drinking water wells over time.

EPA cautiously noted that the chemicals in the water wells and that the conditions may be unique in that the fracturing is taking place "in close proximity to drinking water wells," and that production conditions are different than in many other areas. Nevertheless, the results are hotly contested with industry arguing that EPA's study did not "adequately distinguish between potential natural impacts and those from gas drilling activities."[110] Obviously wary of political ramification, in March of 2012, the EPA committed to additional investigation together "with a group of stakeholders." [111]

Although largely ignored in the public controversy, also identified were contaminants in the shallow portions of the aquifer, including benzene, xylenes, gasoline-range organics (GROs), and diesel-range organics (DROs). The report identifies at least 33 surface pits as likely sources for the contaminants detected in shallow groundwater. The pits were used for disposal of drilling cuttings, hydraulic fracturing flowback, and water produced from the formation.[112]

VIII. Common Law, and the Burden of Proof

In Texas, there are multiple lawsuits arising from fracking operations in the Barnett Shale involving alleged contamination of water wells. [113] Potential difficulties in relying on the common law in the context of hydraulic fracking include the ability to track chemicals to the source, and standards of care that incorporate forseeability. Claims typically include nuisance, trespass, negligence, and sometimes strict liablity. [114]

Texas courts have defined a nuisance as "a condition which substantially interferes with the use and enjoyment of land by causing unreasonable discomfort or annoyance to persons of ordinary sensibilities attempting to use and enjoy it." [115] Three types of conduct may be considered a nuisance: 1) intentional invasion of another's interests; 2) negligent invasion of another's interests; or 3) other conduct, culpable because abnormal and out of place in its surroundings, that invades another's interests. [116]

Where the tort is "intentional," the defendant will only be charged with responsibility for the "substantially certain" consequences of any actions that the defendant intended to take (even if the defendant did not desire that those actions would result in harmful consequences).[117] A trespass is also usually regarded as an intentional tort in the sense that it involves an intent to commit an act which violates a property right, or would be practically certain to have that effect, although the actor may not know that the act he intends to commit is such a violation. [118] The obvious difficultly for plaintiffs bringing intentional tort claims for damages associated with drinking water contamination is that defendants will be able to argue that hydraulic fracturing is not (yet anyway) known to cause drinking water contamination. Negligence is no easier. A person can be liable for negligence if he causes harm to another by failing to exercise the care of

a reasonable person. [119]Again if the risk is unknown to the "reasonable person," the defendant can hide behind the current state of knowledge. Other claims, such as for the storage and disposal of drilling wastes, noise or air pollution should not prove as difficult. [120]

Strict liability is more promising, but it is unlikely to be available in Texas. The common law has historically recognized a theory of strict liability for defendants who engage in "ultrahazardous" or "abnormally dangerous" activities. The doctrine can be traced back to Rylands v. Fletcher, 3 H.L. 330 (1868), an English case where the defendants were mill owners who had constructed a large reservoir in which they stored water on their land. The water broke through material used to poly an abandoned mine shaft and flooded the plaintiff's coal mine. The House of Lords ruled that the plaintiffs did not have to prove negligence and held that the defendant can be held strictly liable for an abnormal and inappropriate use of his property. However, the Texas Supreme Court refused to follow the doctrine and required proof of negligence in a case where an oil company had constructed large, artificial earthen ponds to store polluted salt water generated by oil wells. The water escaped the ponds and flowed about six miles onto the landowners' property and into the water sources the landowners used to water their livestock. The court reasoned:

> [I]n England there are no oil wells, no necessity for using surface storage facilities for impounding and evaporating salt waters therefore. In Texas the situation is different. Texas has many great oil fields, tens of thousands of wells in almost every part of the State. Producing oil is one of our major industries. One of the by-products of oil production is salt water. Which must be disposed of without injury to property or the pollution of streams. The construction of basins or pounds to hold this salt water is a necessary part of the oil business. In Texas much of our land was granted without mineral reservation to the State . . . the right to mine in the usual and appropriate way, as for example, by the construction and maintenance of salt water pools . . . incident to the production of oil, were contemplated by the State and all of its grantees and mineral lessees, that being a use of the surface incident and necessary to the right to produce oil.

Despite this case, and its progeny,[121] however, the Texas Supreme Court has never ruled on whether hydraulic fracturing could be considered an abnormally dangerous activity, and there are plaintiffs are pushing forward with this theory in ongoing cases. [122] According to the modern abnormally dangerous activity doctrine, as "restated" in § 520 and of the Restatement (Second) of Torts, in determining whether an activity is abnormally dangerous, the following factors are to be considered:

---

[119] See Restatement (Second) Torts §283.

Devon Energy Prod. Co., L.P., No. 3:10-cv-02554 (E.D. Tex., December 22, 2010); Holly Vandrovec, The Fight over Fracking: Recent Hydraulic Fracturing Litigation in Texas, Texas Bar Journal – May 2011, citing also Mitchell v. Encana Oil & Gas (USA), Inc., Parr v. Aruba Petroleum, Inc., et al.

(a) existence of a high degree of risk of some harm to the person, land or chattels of others;

(b) likelihood that the harm that results from it will be great;

(c) inability to eliminate the risk by the exercise of reasonable care;

(d) extent to which the activity is not a matter of common usage;

(e) inappropriateness of the activity to the place where it is carried; and

(f) extent to which its value to the community is outweighed by its dangerous attributes.

In Doddy v. Oxy USA, Inc., a concerning alleged health problems of landowners who lived near an oil well, the 5th Circuit Court of Appeals, reasoned that it is "somewhat unclear whether *Turner* can be read broadly to reject strict liability for abnormally dangerous activities. For one thing, *Turner* relied heavily on an earlier case, *Gulf, C. & S.F. Ry. Co. v. Oakes,* 94 Tex. 155, 58 S.W. 999 (1900), which involved the spread of the defendant's Bermuda grass to the plaintiff's land. It is doubtful that the escape of (apparently oil-contaminated) saltwater or the spread of Bermuda grass are "abnormally dangerous," at least as contemplated by the classic formulation in § 520 of the second Restatement of Torts." Doddy v. Oxy USA, Inc., 101 F. 3d 448, 462 (5th Cir. 1996). The Court further explained that it had previously interpreted *Fletcher v. Rylands* as a repudiation of strict liability in "cases where substances that are harmless and unobnoxious within themselves are stored or impounded upon one's land;" [123]and a repudiation of the "doctrine of strict liability for damages from impounded waters."[124] However, after examining other Texas Supreme Court Opinions, the 5th Circuit ultimately concluded that the Texas Court *has* rejected the abnormally dangerous strict liability tort.[125] The 5th Circuit also noted that the lower state courts have consistently refused to create strict liability for abnormally dangerous activities.[126]

Even if Texas were to apply the doctrine of strict liability for abnormally dangerous activities to hydraulic fracturing, liability may still be somewhat complicated by forseeability as strict liability is limited to the kind of harm, the risk of which makes the activity abnormally

dangerous. [127] The industry may still argue that water well contamination from hydraulic fracturing activity was not foreseeable at the time of the claim. A more viable option may be negligence per se, a concept in which a legislatively imposed standard is adopted by the civil courts as defining the conduct of a reasonable and prudent person.[128] An administrative rule or regulation can also be used to create the standard for negligence where the purpose of the rule is to afford protection to the class of person to which the injured party belongs from the hazard involved in a particular case. [129]

IX. Needed are Local, Site-Specific Regulations for Water

One proposal to deal with the difficult burden of proof is to require a "pre-permit" application process that involves an in-depth analysis of site specific conditions including sampling and chemical analysis of area wells both before and after a fracturing operation.[130] Home rule cities in Texas could follow Pennsylvania's lead. Pennsylvania reverses the burden of proof by establishing liability for water contamination by creating a rebuttable presumption that the well operator caused the contamination within 1,000 feet of the well and requires the operator to replace water supplies.[131] The operators must ensure that the new supply is as "reliable" and "permanent" as the previous water supply, and that it not require "excessive maintenance."[132] Also requires are "pluming, conveyance, pumping or auxillary equipment and facilities necessary for the surface landowner or water purveyor to utilize the water supply." [133]

Other regulatory measures in effect in other states include time limits on how long flowback water may remain on the site, specific limitations on the disposal of flow-back water, reuse and recycling, distance requirements from sensitive receptors, waste disposal plans, restrictions on roadspreading or landspreading, and design, maintenance and pit lining requirements. [134]
Some cities overlying the Barnett Shale have already adopted some regulations to deal with surface contamination. Fort Worth requires a "closed-loop" system wherein wastes from drilling and fracturing are stored within tanks, although it allows earthen lined pits for operations that are on open space of at least 25 acres and not within 1,000 feet of a "protected use." [135]Arlington requires a similar closed loop system with above-ground steel tanks for waste for gas drilling operations unless the Texas Railroad Commission provides a different directive.[136] Further

analysis is necessary to evaluate the adequacy of these regulations. Enforcement is, of course, also a concern.

Local government should also expand the disclosure requirements to minimize uncertain as to the source of any chemical contamination. Local governments could ask for more but must be wary of property rights arguments (this issue warrants further discussion and analysis, but is currently beyond the scope of this paper). Local governments could also engage in water supply planning and consider any limitations as may be necessary.

X. Air Quality, Federal and State Regulation

When an oil or gas operator drills and fractures a well, air pollutants, including nitrogen oxides and volatile organic compounds (VOCs), may arise from the following sources:

- wellhead (natural gas leaks)
- flared gas (gas that escapes from the well during drilling and fracturing and is burned)
- equipment used for drilling, fracturing, and dehydrating gas (equipment exhaust)
- pipelines (natural gas leaks);
- flowback water tanks and pits (evaporating volatile organic compounds); and
- compressor stations ("When natural gas leaves a well, it is sent to a gathering station and the gas is then compressed by an internal combustion . . . engine(s) and conveyed to a processing facility via pipeline."[137]

Pursuant to a 2010 Court entered consent degree, following a lawsuit filed by Wildearth and San Juan Citizens, [138] EPA recently adopted new standards for operators of new fractured and re-fractured natural gas wells that will require that they use technology capable of meeting the emission standards. The standards include both "new source performance standards" for criteria pollutants (a few common pollutants), and national emissions standards for hazardous air pollutants.[139] Under the Clean Air Act, oil and gas, like other industries, may also be subject to regulation through State Implementation Plans, as the discretion of the state, as may be necessary to meet health based National Ambient Air Quality standards established by the federal EPA.

Heath Based National Ambient Air Quality Standards are established only for a few common "criteria" pollutants - particle pollution (often referred to as particulate matter), ground-level ozone, carbon monoxide, sulfur oxides, nitrogen oxides, and lead - these are monitored on an area-wide basis.[140] The Fort Worth area in the Barnett shale has been designated "non-attainment" for ozone under the CAA, which means that the National Ambient Air Quality

[137] UT Energy Institute Report at 193.

standard is not met for concentration in the atmosphere. The role of VOCs in forming smog and their contribution to the elevated levels of ozone one the reason for the focus on VOC emissions from shale gas activities.[141]

Oil and gas production facilities can also release more than 50 toxic air pollutants from a variety of sources, including "venting, dehydration, gas processing, compression, leaks from equipment (fugitive emissions), open-pit waste ponds, and land application of volatile wastes."[142] EPA originally tried to regulate "hazardous air pollutants," pollutants that are known or suspected to cause cancer or other serious health effects, such as reproductive effects or birth defects, or adverse environmental effects through health based standards, [143] but the experience was a failure. EPA explains that the health effects of hazardous air pollutants are potentially very serious:

> People exposed to toxic air pollutants at sufficient concentrations and durations may have an increased chance of getting cancer or experiencing other serious health effects. These health effects can include damage to the immune system, as well as neurological, reproductive (e.g., reduced fertility), developmental, respiratory and other health problems. In addition to exposure from breathing air toxics, some toxic air pollutants such as mercury can deposit onto soils or surface waters, where they are taken up by plants and ingested by animals and are eventually magnified up through the food chain. Like humans, animals may experience health problems if exposed to sufficient quantities of air toxics over time.[144]

In its original attempt to promulgate health based standards for these pollutants, EPA managed to develop standards for only seven hazardous air pollutants. Difficulties in standard setting were complicated by the fact that these pollutants threaten to cause very grave health effects at minimal exposure levels.[145] Many are considered to be "nonthresold" pollutants, meaning that no human exposure to them is safe, and there is limited data and high uncertainty in determining a "safe" exposure. [146] Moreover, some ambient standards must be so stringent that the controls may be exceedingly expensive, and, in some cases, not yet known. [147]In 1990, Congress largely abandoned the harm-based approach to HAP's and substituted a technology-based approach that called for the employment of MACT. The legislation identified some 180 substances to be regulated by that method.[148]

[146] Id.

[147] Id.

[148] Id.

Under section 112 of the Clean Air Act, EPA publishes emission standards for hazardous air pollutants (NESHAPS) for "major sources," that is sources that emit or have the potential to emit 10 tons per year or more of a single HAP or 25 tons per year of more or any combination of these HAP. For major sources,[149] these technology-based standards must reflect the maximum degree of emission reductions of HAP achievable (after considering cost, energy requirements and nonair quality health and environmental impacts) and are commonly referred to as maximum achievable control technology (MACT) standards. [150] MACT standards are to reflect application of measures, processes, methods, systems or techniques, including, but not limited to, measures which, (1) reduce the volume of or eliminate pollutants through process changes, substitution of materials or other modifications, (2) enclose systems or processes to eliminate emissions, (3) capture or treat pollutants when released from a process, stack, storage or fugitive emissions point, (4) are design, equipment, work practice or operational standards (including requirements for operator training or certification) or (5) are a combination of the above.[151] CAA section 112(d)(2)(A)–(E). For new sources, the MACT floor cannot be less stringent than the emission control that is achieved in practice by the bestcontrolled similar source. [152]
The MACT floors for existing sources can be less stringent than floors for new sources,
but they cannot be less stringent than the average emission limitation achieved by the best-performing 12 percent of existing sources in the category or subcategory (or the bestperforming five sources for categories or subcategories with fewer than 30 sources). [153]

Especially given that the federal standards for hazardous air pollutants are not based on any determination of "safe" levels of pollutants, and that they can be affected by cost considerations, cities should think carefully about distance limitations between these hydraulic fracturing operations and housing, schools, daycares and other sensitive receptors. Some municipalities have established setback requirements, others, like Fort Worth, have also imposed air quality requirements on gas wells and their associated facilities, such as pits and tanks.

XI. Conclusion

If local governments are to protect their citizens, they must adopt regulatory measures. When it comes to protecting public health both federal and state standards fall short. There is no state or federal regulation, that regulates the chemicals that can be injected during hydraulic fracturing. Texas has adopted chemical disclosure requirements, but unless trade secret claims are challenged by a landowner, they are largely optional. Texas does have some regulations that govern oil and gas drilling, but given the dismal enforcement record of the state agency in charge, they cannot be relied upon to protect the citizens of Texas. Since there is generally no testing to establish baseline conditions, it is very difficult to hold the industry responsible for

[149] A major source includes "any group of stationary sources located within a contiguous area and under common control" that emits a certain number of tons of regulated pollutant annually
[150] Proposed Rules Vol. 76 Federal Register 52738, 52741 Tuesday, August 23, 2011, http://www.epa.gov/ttn/atw/oilgas/fr23au11.pdf

[153] Citing section 112(d)(3),

contamination. Unless local governments establish testing standards, their citizens will likely bear the cost of any contamination. Given that Texas courts are unlikely to classify hydraulic fracturing as an abnormally dangerous activity subject to strict liability, it may also be particularly useful for local governments to adopt standards of care that can be used to establish negligence per se. Given uncertainties in the state of the science, it will nevertheless be very difficult for citizens to win a legal action under the common law. If local governments want to ensure that hydraulic fracturing does not suck them dry, it will also be up to them to establish water use restrictions. Finally, given that federal air quality regulations for the most hazardous of pollutants are not determined on the basis of safety to protect public health, local governments should establish as much distance as possible between hydraulic fracturing and the place people live work and play.

AN INQUIRY ON THE EVOLUTION OF URBAN PLANNING IN TURKEY

Serap Kayasu[1]

Abstract

The aim of this paper is to present an inquiry on the evolution of urban planning based on economic, political and social changes that have taken place at different periods in Turkey. Legal and institutional reforms with regard to urban administration and planning reflect main characteristics of economic, political and social background of different transformation periods. The spatial pattern of urbanization have evolved throughout these reforms.

1.Introduction

When the evolution of urban planning in Turkey is overviewed, we can observe its impact on the built environment and spatial planning. The institution of urban planning has been neither effective in policy outcomes nor successfully implemented. We have to face the fact that urbanization processes have not always been administered appropriately in Turkey.

In order to comprehend the processes of urbanization and accompanying planning efforts, approaches to spatial planning in Turkey are reviewed in five different periods. The first period is from the establishment of Turkish Republic to aftermath of the Second World War (1923-1945); whereas the second period refers to the transition period from the Second WorldWar to the beginning of the economically and sectorally planned period of Turkey (1945-1960). The third period can be considered as the planned period (1960-1980); while the fourth period involves the implementation of neo-liberal economic policies, namely Structural Adjustment Policies of Turkey after 1980. Finally the period after 2000 can also be regarded as a transition period to Strategic Spatial Planning, following a wide range of legal and administrative restructuring processes.

Problems related to urbanization processes had occurred in Ottoman cities as early as the mid-19th century. Some preventative measures had been taken with regard to the provision of public services particularly in Istanbul. In the early 1930s, however, all urban administrative procedures and reconstruction laws dating from the Ottoman period were changed. A number of international planners had been invited to participate the competitions designed to plan the cities of newly formed Republic. The period between 1930 and 1950 can be indicated as a significant period in terms of city development. After the 1950s, however, due to the mechanization of

[1] Middle East Technical University, Ankara, Turkey – kayasu@metu.edu.tr

agricultural production, rapid urbanization stemming from rural to urban migration brought the urban problems to the forefront at an unprecedented level. Beginning of the planned period in 1960 marked the significance of planning; however, was accompanied by deepening economic and spatial problems ranging from housing and transportation to the provision of public services.

2.From the Establishment of Republic to Aftermath of the Second World War (1923-1945)

The prevailing aim of this particular period was to create a new nation state within the framework of modernization project. The selection of new capital city, i.e. Ankara; the distribution of industrial areas to different parts of the country; the connection of different areas to each other through newly formed networks were among the priorities of that period in terms of spatial planning.

The problems of a new and growing capital city have given impetus for the concept of city planning from the 1920s onward. Preparing a development plan for Ankara was necessary. The law no. 1351, The Establishment and Responsibilities of Ankara Reconstruction Directorate , was enacted in 1928. According to this, Ankara Reconstruction Directorate had been created for the tasks given by the Ministry Council. The Directorate was to prepare an existing landuse and a reconstruction plan of Ankara. *Sehremaneti*, i.e. a municipal institution, was established in 1924 with the aim of implementing related legislations. Two local reconstruction plans were prepared in this period, i.e. one was Izmir Development Plan by French planner Rene Danger; the other was for Ankara by Heussler. Carl Lörcher also prepared a plan for Istanbul during this period.

Previous urban administrative procedures and construction laws dating from the Ottoman period were changed by the Republic during this period. The Law no. 1580 of Municipalities was issued on April 3, 1930. Municipalities were also to prepare landuse plans for five years according to the rules of The Law of Buildings and Roads no. 2290. However, with the enactment of Law no.1580, *Sehremaneti* in Istanbul has been abolished and municipalities have been established in cities. This was the emergence of provincial administration along with the establishment of municipality in Istanbul. One of the basic features of the law was the fact that a large number of functions and responsibilities has been given to municipalities including the provision of the public services. The allocation of responsibilities was coupled with the national policy of buying out foreign companies, including those that had provided public services in Istanbul. As a result responsibilities were transferred either to the municipality itself, or to joint venture companies within which the municipality had a share (Tekeli,1994).

Municipalities were preparing landuse plans for five years according to the Law of Buildings and Roads no. 2290. Plans were prepared with a vision of 50 years, and approved by Ankara Reconstruction Directorship between 1930-1933. Due to the fact that 50 years was a very long time for projections and predictions, most of the

plans which were prepared during this period could not be implemented (Yavuz,1952).

The Ebniye Law which had been in effect for the previous 50 years had already been abolished. On the other hand, new legislation was very detailed and consisted of the means that are meant to force municipalities to conform with a contemporary image of city. In addition to the preparation of city plans, projecting future population and setting certain landuse standards were among the contents of the Law of Buildings and Roads. Public decisions would be made by the Council and the population projections would be made for 50 years (Duyguluer,1989). According to this law, ownership of those areas designed for public services was in the jurisdiction of local authorities and the Treasury. Moreover foundations could be transferred to municipalities by a decision of the Council of Ministers. During reconstruction operations in a city, compulsory replotting (Addikes Rule-Hamur Kurali) could be applied. According to this, municipalities were able to take up to 15 percent of land free of charge (Aksoylu, 2003). During the 1930s, when those laws that were expanding the authority of municipalities were passing, the need for a separate legislation to generate income for municipalities that was consistent with their new functions became quite obvious. In this context the Bank of Municipalities was established in 1933.

The municipality of Istanbul and then the Municipality of Ankara organized international competitions among well-known international city planners. Herman Elgötz who was a German planner and planner of Essen, French planner Alfred Agache who designed Dunkerque, Rio de Janeiro and Brazil, Jack H. Lambert and Henry Prost have been invited to enter the competition for Istanbul Development Plan, and the first prize was granted to Elgötz. Although Elgötz won the competition, his plan was not implemented. Subsequently, German planner Wagner was invited to prepare a plan for Istanbul. He carried out his studies in 1936 and 1937, and prepared the landuse plans of the historical peninsula of Istanbul as well as Beyoglu district. Immediately afterwards, master plans for other districts in Istanbul were also prepared.

An international competition for the plan of Ankara was designed in 1928 and German planner Prof. Hermann Jansen won this competition. He completed the Reconstruction Plan of Ankara in 1932. Prof. Jansen prepared the Development Plans of Mersin, Adana, Ceyhan, Gaziantep and Izmit between 1930-1939. Furthermore French planner Lambert prepared a reconstruction plan for the new settlement areas of Erzurum during this period. These plans were prepared solely for municipal boundaries without considering the regional context. They were mainly oriented towards beautifying the cities without socio-economic research, data and map.

3.The transition period from the Second WorldWar to beginning of planned period (1945-1960)

The most significant aim of this particular period was to control the transformation process from the World War II conditions to planned development. With the help of Marshall Plan mechanization in agriculture was initiated, and as a result the need for labor in agricultural production decreased. Therefore rural to urban migration accelerated, and in large cities squatter housing problem become an important issue. The early indications of rapid urbanization could be observed after 1945 and throughout the 1950s in Turkey. The increase in the construction of squatter settlements was noteworthy during the 1950s in large cities such as Istanbul, Ankara and Izmir. Governments have enacted amnesty laws for squatter settlements due to populist politics. In addition municipalities focussed their efforts in infrastructure and started to bring some of basic services. As squatter areas within municipal boundaries expanded, they started to gain legal status due to amnesty laws, and municipal departments were established in each of them. However, existing capacity of the country in terms of recently established institutions proved to be inadequate in the face of emerging problems.

Throughout the transformation period, confronting squatter housing problem and developing a new set of legal and institutional regulations emerged as a necessary task. First, the Bank of Municipalities was converted into the Bank of Provinces, i.e.Iller Bankasi, in 1945 by Law no. 4759. This helped to extend the limits of public borrowing by the municipalities. In addition a strong technical assistance board, which would support planning efforts and the design of infrastructure systems of municipalities, was created. The Bank of Provinces has been assigned to carry out reconstruction plans as well as developing existing landuse maps.

Municipal Income Law no. 5237 passed in 1948. By way of this law, municipal revenues were increased for the first time in the sense that while the revenue of the big cities has increased once, that of smaller cities increased three times as much (Tekeli,1981). However, due to the increasing rate of urbanization, such interventions could not be sufficient.

Rapid post war urbanization coupled with the fact that the supply of housing almost came to a halt during the war, which resulted in the development of squatter housing neighbourhoods.
In this context the area of jurisdiction of Law no. 5218 passed in 1948 for the city of Ankara was extended to cover all of Turkey by Law no. 5431 issued in 1949. With this law licence was to be given for existing constructions, with a charge four times as the usual, in case of a violation of the existing building codes. Licences would be issued for those constructions that did not conform the land use plan and technical regulations only upon the fulfilment of legal requirements (Aksoylu, 2003).

The Law for the Encouragement of Construction (1948) gave the responsibility for providing building plots to municipalities so as to enable them in controlling the

physical development of the city. According to this law, the municipalities could buy treasury land at a price calculated on the basis of its land tax value which would be paid back in ten years in equal installments. These plots would then be transferred to those who do not own a house, without seeking fulfilment of the requirements of the Tendering Law (Arttirma-Eksiltme ve Ihale Kanunu). Those who received land had to complete the construction of a house within two years. The building would then be exempted from tax for ten years and the owners could obtain credit from the Real Estate and Credit Bank which would cover up to 75% of the cost of construction with 5% interest (Tekeli, 1981).

Failures in the implementation of reconstruction plans that had been prepared according to the Law no. 2290 and changing conditions of the cities have resulted in the enactment of new Reconstruction Law no. 6785 in 1956 (Artukmaç,1975). Modification of the Law of Buildings and Roads no. 2290 had been on the agenda ever since the First Building Congress held in 1948. The most important characteristics of the Law no. 6785 were giving the responsibility of planning and development in adjacent areas to municipalities so as to control the speculative developments in these areas and constitution of the transition from city scale planning to regional planning; classifying the cities into two groups such as population greater than 5000 and less than 5000, and differentiating the types of plans that municipalities will prepare as master plan and implementation plan; abolishing the obligation of long planning and projection periods. A Regional Planning unit has been actually established within the Technical Board of Urban Planning within the Ministry of Public Works in the same year. This facilitated transformation from a rigid approach of the city planning to a more flexible and positive policy which can be adapted to the scientific and technological developments (Aksoylu, 2003).

According to the Expropration Law no. 6850 (1956) expropration decisions of the municipality could be made by the Municipal Council; approved by sub-prefects in the districts and by governors in the provinces. Expropration could be conducted through the granting of easement rights if this was appropriate from the point of the current objectives.

The evaluation of expropration operations by the Prime Minister as a major political activity of the government led to the establishment of the Ministry of Construction and Settlement by the Law no. 7116 issued on 14 May 1958 (Tekeli,1981). Urban , rural and country planning, housing policy, building materials, research and analyses for regional planning with the participation of other organizations, construction of houses for rural migrants, to take precautions before and after the natural disasters were the duties of this Ministry. The Ministry of Construction and Settlement had been established to carry out research and planning functions rather than act as an executor or investor.

4.The Planned Period (1960-1980)

Due to the economic and spatial ramifications of rapid urbanization during the transformation period, policies regarding to economic development and industrialization proved to be inadequate. Unbalanced population growth in large cities constituted the main characteristics of urbanization despite the fact that there were limited opportunities for formal employment and housing. The definition of metropolitan planning was being discussed, in the face of the emergence of metropolitan areas. In addition to development planning approaches to economic and sectoral development, regional structure analyses and socio-economic development indices were being developed. The need for a 'National Physical Plan' was being discussed in academic and professional circles. The main mission of this period was to place emphasis on development plan making processes and the establishment of State Planning Organization.

One of the most important legal and institutional regulations in this period include the establishment of State Planning Organization in 1960. This institution introduced the First (1963-1967), the Second (1968-1972) and the Third (1973-1977) Development Plans and regional planning agenda during this period. In addition to the Antalya Project (1959), Doğu Marmara Planning Project (1960-1964) and Çukurova Regional Project (1962-1963), DPT also made developmental programs for eight areas identified as a result of analytical studies at the national scale in 1960-1970. There were no obligatory rules for preparing regional plans at the time in Turkey. This is one of the reasons for the fact that the number of regional plans has been quite limited.

Taking planning practice under the umbrella of Ministry of Construction and Settlement and giving responsibility about that to other central administrative institutions is the most important change in the organizational structure from the 1970s to 1984 (ODTÜ, 2000).
The establishment of Master Plan Offices in 1965, with the decree that was prepared according to The National Security Council's decision number 86 the master plans for Istanbul, Ankara and Izmir have to prepared by the offices under the Ministry of Construction and Settlement, and for this purpose in Istanbul, Izmir and Ankara Master Plan Offices were established (Tekeli,2001). Another important change in this period, according to municipal bill of the 1970s, municipalities were classified by their size and municipalities have more than 100000 population were called 'Greater Municipality'.

The Squatter Law no. 775 was enacted in 1966. At the beginning of the planned period, squatters were considered as being a physical problem. In 1966, well known 'Squatter Law', which was the first legislation specifically concerning squatters was enacted for the first time. By the way of enacting this particular law dual structure of the housing stock was accepted, i.e. the planned and modern housing areas as opposed to the squatter areas. On the other hand the Law No.775 used the concept of 'Gecekondu '(squatter) in its title and implied the acceptance of this as a social

phenomenon. In addition to these regulations municipalities would define the provision of services, upgrading and cleaning areas of squatters, and prepare the maps and plans of reconstruction and improvement along with the Ministry of Construction and Settlement that had the authority to control them (Uzel, 1987). In order to implement these decisions management guidelines in the areas of municipal administration were also necessary. The Squatter Law and other regulations did not comply together regarding these arrangements and, thus, none of them was realized at that time except for the title deeds that were given to the squatter householders. This signified the first time that squatter houses gained legal status.

Sixteen years of implementation of the Reconstruction Law no. 6785 revealed certain shortcomings in planning practice especially in large cities. A new law dated 11 July 1972, number 1605 was enacted. This law changed several articles of the Law number 6785. One of the most important changes, in relation to metropolitan cities was the granting of the authority to the Ministry of Construction and Settlement to prepare metropolitan master plans without requiring the approval of the municipalities (Law no. 6785/1605). With this decision, a new terminology on 'metropolitan master plan' was introduced into development and reconstruction legislation in Turkey for the first time. Another important change was related to adjacent areas (mücavir saha). These areas would be defined and designated in accordance with the proposals of municipalities by decision of the provincial administration board and the approval of Ministry of Construction and Settlement. By way of this change, areas which were included under the jurisdiction of Reconstruction legislation expanded (Aksoylu, 2003). This law also introduced the concept of territorial conservation instead of conservation on the basis of single buildings. If an area outside the adjacent areas was considered important from the regional planning, touristic and industrial development, transportation network perspectives, they could be taken into the sphere of the provincial supervision upon a proposal by the Ministry of Construction and Settlement and with the approval of the Council of Ministers (Tekeli, 1994).

The Third development plan covering the period between 1973 and 1977 aimed to determine the natural resources and human capital of the settlements in order to trigger the development and to solve the problem of uneven development in regions. Within this context, the State
Planning Organization specified the constraints, problems, opportunities and infrastructure utilities of particular cities. In the first two development plans the main approach was regional planning for underdeveloped regions. However the Third plan put emphasize on development priority zones (Keleş, 1993). Regional development approach maintained its significance until the second half of the1970s and urbanization was seen as a phenomenon that needs to be supported by economic and social development. In regional development plans physical and spatial dimensions were highligted more than social aspects.

5.The Period of Neoliberal Policies (1980-)

The 1980s were a distinct period in the planning history of Turkey. Tekeli (2009) indicates that the capital and population were redistributed in urban space in a different way as a result of rural to urban migration, urbanization andindustrialization after the1980s. The policies of this period. The concern for economic integration of Turkey to international economy and being a part of worldwide cyberspace telecommunication infrastructure was rapidly developed, new institutions such as free capital market and free zones were developed through a series of structural reforms. All these reforms resulted in the change of settlement patterns. Istanbul became even more powerful in economy; its population increased to 9 million and the industry decentralized in the Marmara region.

The effects of globalization on new production processes and spatial patterns could be observed in global cities. The relations between local and global along with an emphasis on local authorities and governance were among the main features of this period. The Greater Municipality Law no. 3030 (1984) defined metropolitan areas as Greater Cities and in the country's administrative system they were considered in a distinct category. In order to be defined as Greater city, cities had to have more than one district within the boundaries of municipality**.**

The Amnesty Law no. 2805 (1983) has been issued by the commission of the Consultant Assembly and National Security Council. This law pertaining to procedures related to unlicensed buildings brought about a general building amnesty. With this law the regularization process of unlicensed buildings in areas for which master plans existed was simplified whereas in areas without master plans, elaboration of Construction Improvement Plans (Imar Islah Plani) was required. With this law new planning terminology on Construction Improvement Plans and Upgrading Plans has been introduced in Turkey. The law regularized all of the squatters constructed before the National Security Council declaration of 2 June 1981, and prohibited further squatter construction (Aksoylu, 2003). Construction Improvement Plans were required to regularize constructions on shared plots of land. If plots on which squatters were located belonged to the Treasury of the State or to the provincial administration, and was within municipal boundaries or adjacent areas (mücavir alanlar) then their ownership could be transferred to the municipality. If they were outside municipal boundaries, in that case ownership would pass on to the provincial administration.

The New Building Amnesty Law no. 2981 specified the ways to legalize unauthorized buildings, including not only squatters but also those in the planned areas. As an important differentiation from the previous law, this law aimed to speed up the process of legalization of unauthorized buildings (Aksoylu, 1994). Existing buildings would be conserved as much as possible, but the density could be increased 2-3 times by increasing the existing storeys of houses from single storey to 3-4 in the upgrading plans. The ways in which upgrading would take place in terms of financial, institutional and technical aspects were not defined in the law.

The Construction Law no. 3194 (1985) indicated that Development Plans, of which structure and content are defined in planning legislation, are the main planning control tools. This is the main law directly related to the production of urban built environment. The Construction Law defines two kinds of plans in the planning system, i.e. Regional Plans and Development Plans. Regional plans are prepared by the State Planning Organization in case of a need to determine socio-economic trends, development potential of settlements, the targets of sectors and distribution of regional infrastructure. Development plans are prepared in accordance with regional plans to make decisions regarding the settlements and land use such as housing, industry, tourism and transportation. In practice, however, urban development is generally regulated by the developmental planning approach at municipal level, generally without any strategic frame defined by upper scale plans at regional or provincial level.
With this law authority and supervision were to be left to the jurisdiction of local governments. According to this law preparing plans for those cities that have a population greater than 10.000 was compulsory and the municipalities will prepare , approve and implement the plans within the boundaries of municipality and adjacent areas. This law increased the rate of transferred land to 35 percent, which will be taken free of charge by the municipalities during the compulsory replotting (Çeçener, 2000).

The Tourism Encouragement Law no. 2634 (1982) induced many private and public entrepreneurs to undertake large amounts of fixed investment in tourism by building hotels, yacht ports, swimming pools and so on through a wide range of fiscal and monetary incentives. It also allocated State-owned land plots for tourism development; reduced bureaucratic formalities for tourism investors; relaxed restrictions on the employment of foreigners in the tourism sector; introduced vocational education and training development projects, and gave precedence in communication services. These incentives were given to tourism investments that took place in tourism zones and tourism centers that were specified by the central government with a special legislation, even though clashes could occur between the central and local governments' long term vision for a particular area.

6.The Transition Period of Strategical Spatial Planning (2000-)

The 2000s have been the years when comprehensive changes have taken place in terms of public administration and planning in Turkey. Legal and institutional transformations realized in the last decade have strongly modified the contents of public administration and planning in the country, and have revealed new expectations. At this point, both urban planners and local governments have started to review their point of views about planning. Today, the fundamental actors of urban planning in Turkey query themselves and the legislators as to whether the concept of strategic planning can be accomodated in the planning system of Turkey.
Since the economic crisis at the beginning of 2000s Turkey's economy has exhibited growth tendencies. A large scale institutional reform has been accompanying the

economic dynamics. Even though the current global recession has been slowing Turkey's export sectors, the emphasis on institutional reorganizations has been strong so much as The Ministry of Construction and Settlement and The Ministry of Environment were combined towards the recent establishment of The Ministry of Urbanism. Three significant laws were issued in 2004 regarding urban administration and planning in the context of a Local Administration Reform Package.

In the case of The Law of the Greater Municipalities no. 5216 the latest form of this law has been approved in 2004 with several revisions in the responsibilities and powers of the authority of greater municipalities. Since it is approved, greater municipalities are obliged to prepare Strategic Plans, which are essentially socio-economic in nature as opposed to physical development plans that had been prepared for many years. Other prerogatives given to these authorities include the preparation of both Environmental Plans between the scales of
1/50000 and 1/25000 and Master Plans between the scales of 1/25000 and 1/5000. Furthermore they have the right to approve Detailed Plans in the scale of 1/1000 prepared by district municipalities. They are also responsible for the preparation of plans concerning disasters, designation of locations of premises used for the processing and storage of explosive and incendiary materials. Other than those, greater municipalities are entitled to provide preservation, maintenance and restoration of cultural and natural assets and historical values.

Planning and urban development had been detrimental in general for greater cities. However, redefinition of the territories of greater municipalities by the last law has eliminated the privileged status of sub-district municipalities and collected the management and control of all district and subdistrict municipalities within one hand. With this law territorial authority of metropolitan municipalities are enlarged, and at the same time metropolitan municipalities are given authorization for the preparation of large scale plans. By this law greater municipalities have also chance to establish stock corporations within the realm of their authority. In addition they can accept grants for their expenses.

The Municipalities Law no. 5393 had been revised twice in 2004, and has taken its latest form in 2005. Those municipalities including the district and sub-district municipalities in metropolitan areas are first responsible for plan preparation for their areas. In addition to the task of plan preparation, they are also responsible for the protection of natural, historical and
cultural assets. Municipalities are also entitled for land development and housing provision. They can exercise compulsory purchase for the purpose of land development with infrastructure or for the purpose of housing provision (production, selling and renting); and institute firms, borrow capital; issue shares and paper assets. By this law, municipalities have also chance to establish stock corporations within the realm of their authority. They also can accept grants for their expenses.

Further from above statements, the most important addition of the latest revisions made in the Municipalities Law is that those municipalities of districts with a

population of 50.000 and above has obtained the power to delineate areas which are deteriorated within the current urban context and designate those areas for the preparation of 'urban regeneration and development projects' and for the purposes of risk reduction as well. These projects may be prepared for redevelopment purposes or rehabilitation of specific old and historical quarters of the city or prepared particularly in areas subject to high earthquake risks. However, in many cases, municipalities used the authority given by this law for the preparation of urban regeneration, rehabilitation and redevelopment projects in a way to gaining rent from land. By increasing the construction rights they can transfer the potential profit.

The Law of Special Provincial Administration no. 5302 is also empowered to carry out several responsibilities including to cover costs of infrastructure, construction, maintenance, and to cooperate with other local authorities and bodies in regeneration projects. It also gives Special Provincial Administration the power to make necessary expropriation in accordance with the annual tasks program. Special Provincial Administrations have the opportunity to create unions with other local administrations. Especially in Istanbul and Kocaeli, where the borders of greater municipalities overlaps with that of provincial administrations, creation of such unions will contribute to the implementation of urban regeneration projects simultaneously with the Environmental Plan of the city.

By the legal arrangements, local government's authorization areas have expanded in terms of planning and related services. This situation can be considered as being improvement for governance, participation and transparency. However, the wide range authorization of municipalities by the latest legal and institutional reforms may have certain pitfalls. Clearly a new set of regulations should be developed towards cooperation among municipalities and the Ministry of Urbanism, given that all of these institutions and their administrators are equipped with unprecedented power schemes.

The new legal arrangements adopted strategic planning as a main goal. Although the concept of strategic planning started to be discussed in the Turkish planning environments during the 1980s, the definition of the strategic plan concept was included for the first time in the Bill of Basic Codes for Public Administration in 2004. This bill has not been legally issued as yet; however, the Local Administration Reform Package have been prepared in conformity with the principles of this draft bill. In the bill a Strategic Plan is defined as being a medium that enables public institutions and enterprises to reach their basic principles and policies, goals and priorities as well as performance criteria through a set of methods to be adopted. The definition of the concept involved in the bill is an institutional strategic plan. The Law of Metropolitan Municipalities, the Law of Municipalities and the Law of Private Provincial Administrative Authorities, which came into effect inaccordance with the principles and approval of this law, emphasize, however, spatial strategic plans. For instance, according to the Law of Metropolitan Municipalities, preparation of strategic plans of the metropolitan municipality along with the preparation and implementation of master zoning plans of all scales ranging between 1/5.000 and

1/25.000 on the condition that they conform to the higher scale plans that are also among the duties and authorities of metropolitan municipalities. The Law of Municipalities refers to a strategic plan and a performance program. According to this law, the municipalities and local governments are responsible for preparing a development plan and a program as well as a strategic plan in conformity with the regional plan if there is any, within six months after the general elections and also for preparing an annual performance program before the beginning of each year. It is indicated that the strategic plan shall be prepared by also taking into consideration the opinions of universities, vocational chambers and related nongovernmental organizations. The preparation of strategic plans is not mandatory for municipalities with populations of less than 50,000. The Law of Private Provincial Authorities on the other hand, mentions the necessity of a discussion on a strategic plan, and adopting a decision about it is considered as being among the duties and responsibilities of Provincial General Assemblies. According to this law, the Provincial Environmental Plan prepared under the coordination of the governor, together with the metropolitan municipalities in metropolises, provincial municipalities and Private Provincial Administrative Authorities in other provinces as a large scale plan, in which spatial goals are specified. In this context studies for the preparation of strategic plans will be organized by the Head of the Research and Planning Coordination Department of metropolitan municipalities.

The Istanbul Metropolitan Municipality, included among the Municipalities within the framework of this study, started its strategic planning activities as the largest planning office along with the Istanbul Urban Design and Metropolitan Area Planning Office that it established within its structure with a team of 500 people. A number of academicians, planners and architects officiated in the three Urban and Regional Planning Departments located in Istanbul. In the case of Izmir Metropolitan Municipality, the Master Zoning Plan Office for the whole of Izmir started its activities right after Istanbul. Strategic plans are conducted in this city in the Master Zoning Plan Office, which is the planning department within the structure of the metropolitan municipality. Kayseri Metropolitan Municipality also started strategic plan activities recently. A strategic planning team comprising of 20 people was established with the cooperation of Strategic Planning Coordination Office and Strategic Planning Management within the structure of the Municipality. Joint studies are conducted with the State Planning Organization. Strategic planning activities have commenced very recently in Samsun Metropolitan Municipality as well.. Its activities are conducted through the Municipality Company SABEG. In a number of other metropolitan municipalities, including Erzurum and Gaziantep for example, preparation for a strategic plans is in progress.

7.Conclusion

Central governments have placed considerable significance on urban administration and planning in Turkey. In this sense economic, political and social background of different transformation periods have been reflected in legal and institutional reforms of that particular period. The spatial pattern of urbanization have evolved throughout

these reforms in such a way unbalanced growth and uncontrolled urban expansion constitutes one of the main characteristics of Turkish cities. The reasons for the unsuccessful implementation of planning processes and ineffective policy outcomes should be searched partly in an understanding that view urban planning as being more of a physical process as opposed to a spatial process intertwined with economic and social contents.

The plans are are prepared either for an already existing built up area or for developing areas sometimes with unsufficient consideration for their impact on the totality of the urban area. Elaboration of larger scale plans is not obligatory. Plans offer short term solutions and because of this the problems are accumulated in the long run and they become bottle-necks blocking development at the city wide level. Rapid urbanization processes could not adopt to a rational land policy. Neither could it control this process through the proposals of planners whose urban images and aspirations were quite inconsistent with the economic situation. As a result Turkey fell into an uncontrolled urbanization process and public services could not be realized due to the high rate of expropration cost of the land. This led to the emergence of a dual structure, consisting of both legal and illegal housing stock in the city. Lack of regular and sufficient funds to develop urban infrastructure, land speculation, populist tendencies in the allocation of capital resources and the development of the cities, restricted capacity of the administration are the factors affecting the failure of the urban planning.

Defining the integration principles of country, regional, urban and rural plans, incorporation of urban planning concern into economic development planning and budgeting, strengthening existing capabilities and income generating activities of municipalities, initiating effective land policy and programmes, co-ordination and corporation of the different organizations are necessary for the planned development of the cities in Turkey.

From rapid growth to sustainability: predicting China's future urban spatial growth policies by comparing with United Kingdom's

Abstract: Research of urban growth management started in western countries, and aimed to set up policies and reduce the negative effects of urban sprawl. It was introduced to China in the late 1990s. Empirically, the planned sizes of most future Chinese cities, especially small cities, are much larger than moderate scale they would need, while without explicit growth management strategies. That would lead to a waste of resources, and inequitable development between urban and rural.

With rapid urbanization, resource-conserving and environment-friendly society strategies in China, single-sided pattern of urban spatial growth is being transformed into an exterior-expand/interior-renewal mode. Therefore, new policy instruments, leading to sustainable development in transitional China, are required to meet the requirements of Urban Spatial Growth Management (USGM). According to present studies in China (Chen et al, 2009; Liu and Zhang, 2007; Wei and Wang, 2008), it is widely accepted that most developing Chinese cities need spatial growth management. However, since the technique of USGM has not been formulated in China, such research merely concerned with qualitative not quantitative analysis. Thus, the issue of USGM in China needs to be tackled from the perspectives of institutions, policies and techniques.

This paper answers the following research questions: a) what USGM policy tools are needed in China; b) what kind of USGM policy in the UK could be used for reference; c) how these tools are utilized. By reviewing researches of urban growth management in both China and the UK, the author recommends China's USGM research being proceeded by two main aspects: a) to set up environment-oriented system of USGM accompanied by Chinese characteristics, and b) to utilize modern techniques to examine the effectiveness of USGM.

Key words: urban spatial growth management; policy tool; sustainability

1 Introduction

According to the worldwide recession from 2007, Chinese government recognized the significance of urbanization development for driving the domestic economic growth. In 2010, the level of China's urbanization has already amounted to 46% with 1% of the annual average growth since the reform and opening-up policy (Zhang, 2009). However, with the increased level of urbanization, the rapid expansion of the urban construction land space results in substantial decline of agriculture area. In order to ensure the quantity of cultivated land, China's government has carried out strict land control policy.

At the mean time, the Chinese economics and social developments gradually became more resource-conserving and environment-friendly . Moreover, the current Chinese urbanization combines the extensive expansion and interior regeneration to bi-directional growth. Therefore, the urban spatial growth management (USGM) must adapt the economics growth for urban expansion. On the other hand, the need of economics structure adjustment for urban regeneration must be satisfied. In addition, the transformation of national strategy, for instance, the resource-conserving and environment-friendly society strategy, has a special requirements for USGM. It has been agreed by most researchers that USGM is the process guidance for controlling urban space（Chen, 2009）. Moreover, various political tools must be used to control and guide the urban spatial growth, in order to create an environment-oriented system of USGM.

This paper discusses the USGM in contrast to urban growth management (UGM) in China. It does not create a new concept but focuses more on spatial management， since the UGM's substance is to manage urban spatial growth and to maintain the sustainable development of the urban economy, community and environment, of which ultimate objective could be achieved by urban space. Furthermore, UGM was proposed to cope with urban sprawl, which is an issue of urban space. Thus, UGM could be better combined with urban planning with aspect of urban space. In this paper, the system of UGSM in the China is firstly summarized . Then, the problem of the current system and its causes are analyzed with respect to sustainable development. By studying the experiences of British growth containment system, this paper proposes some novel concepts of reconstructing the sustainable USGM system in China.

2 Literature Review

The original research on USGM was to deal with a series of problems of the economy, environment and the society in United States. After World War II, housing options in the United States increased considerably along the significant economics growth, elevated consumption, as well as the stimulus provided by the federal mortgage loan acts and the rise of the automobile. As the result, the rapid development of suburbs and the continual decline of downtown areas drove more and more people to the suburbs. This situation brought problems of traffic, infrastructure provision, public

services, conservation of natural resources, and damages to farmlands and forests. Consequently, these issues seriously impeded the planned developments in cities. Therefore, it is a major concern to adopt varied measures to respond to economic growth and environmental protection policies, and to accelerate the sustainable developments of cities for both State and local governments.

In the US, the current debates on UGM focus on several aspects, including the definitions, policy instruments, efficiency of policy instruments. UGM is generally defined as the management of urban developing capacities, circumstances, locations and characteristics. However, there has been no agreement on itsdefinition (John M. Levy, 2002). Benjamin (1990) indicated that growth management is not a simplex growth control. In his opinion, it is designed to maintain the dynamic balances between development & protection, development & supporting infrastructure, growth-generated public service demands & financial supply, and progress & fairness.

Bengston et al. (2004) deems that UGM policy tools can be classified into three categories: public acquisition of land, regulatory approaches, and incentive-based approaches. In addition, some researchers indicate that the government structure and electoral rules have a crucial impact on the selection of approaches, such as establishing service boundaries, incentive zoning, the transfer of development rights and so on (Feiock, et al, 2004).

From the technology index and policy rules, Nelson (1999) analyzed different states with or without UGM. He found that the states with employing UGM principles exhibited more reasonable development under certain conditions such as controlling urban sprawl, preserving farmland, providing more accessibility by car and other forms of transit, less energy consuming, and minimizing tax increases. Carruthers (2002) considered that only the states with mandatory and consistent requirements and strict operation mechanisms were successful in preventing urban sprawl. Otherwise, the sprawl might have become severe.

Comparing to the US, in 1970s, the agricultural area declined slightly as well as the urban area growth in the UK. Moreover, there seemed no urban sprawl problem in the UK, as the policy worked well by using brown land and improving density of occupancy (Bibby,2009). Although urban expansion does exist in British cities, the current situation shows that urban expansion could be managed to improve efficiency of city land-use by strict policy of UGM, which inhibits local development on the other hand(While et al, 2004). For instance, the growth crisis of Cambridge subregion growth, it caused by State’s reluctance to manage or redistribute in South East. Moreover, the growth crisis leads to localized pressures on housing markets, the land-use planning system, infrastructure, and the environment, intensifying struggles between progrowth and antigrowth in certain places. Overall, it has long been thought that the green belt is the key to manage the UGM (RTPI, 2002).

UGM was introduced to China in late 1990s. From available search indexes, the information indicates that some researchers focus on reviewing western UGM and mainly recommend its concepts and practice (Liu, 2005; Jiang, 2007; Lu, 2005; Zhang,

2002; Fang, 1999). In addition, other scholars have extended their perspective to integrate UGM with the unique conditions in China (Wei, 1998; Zhuang, 2005; Li, 2005; Zhu, 2006; Chen, 2006; Liu, 2007; Feng, 2008). They proposed that UGM in China should be concerned with the system of property rights, the system of land management, the legislation of UGM, and so on.

Chinese researchers suggested that UGM could be applied in China. Nevertheless, most researchers pointed out that UGM would be an essential measure to guide sustainable urban development or participate in regional competition.

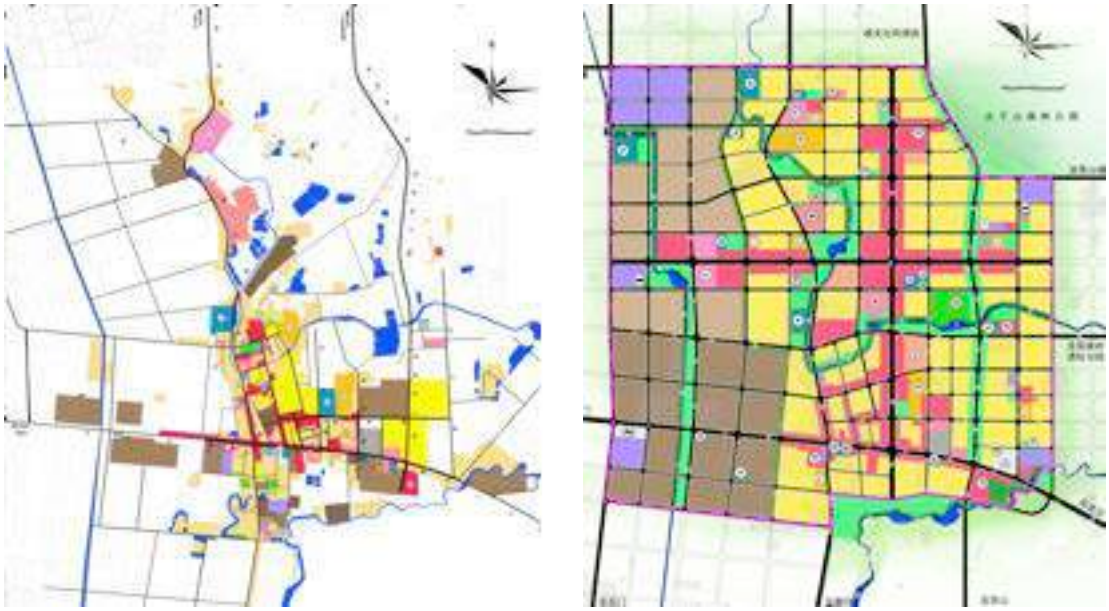
3 Recent China’s USGM System

Due to the unique regime, current Chinese USGM has to rely on local planning system to achieve USGM. More specifically, this system consists of a group of related departments, such as Development and Reform Commission (DRC), Land and Resources Bureau (LRB), and Urban Planning Bureau (UPB). In terms of structure, the planning system is formed by the State Economic Development Plan, the Land Use Plan, and the Urban Plan, which are drawn by DRC, LRB, and UPB respectively. Initially, the national target of social and economics developments are decided by the State Economic Development Plan. The Land Use Plan regulates sizes and ranges of land-use in agricultural developments and urban constructions. Additionally, the plan provides suggestions for expansion of urban construction while guaranteeing the agricultural lands are not affected. The Urban Plan organizes the urban construction with the other two Plans' functions. For Chinese USGM, the Land Use Plan and the Urban Plan could be used straightly because of direct relationship with urban space. From reform and opening-up in China, especially in the 1990s，the function of the Chinese USGM system was only to set the economic growth as the first purpose under rapid urban development. However, the problem seems to be exposed with the USGM system under the double pressures of social and economic transformation.

4 Disadvantages of China’s USGM and Experience in UK

Wang and Zhang (2010) presented that most of the Chinese large and medium scale cities were facing problems of urban sprawl by evaluations of thirty-five cities. Comparing to large and medium scale cities, the issues in small cities and towns were more critical. Empirically, the land-use scales of these cities, decided by planning, are consistently much larger than the moderate scales they would need. Particularly, a small city planning practice, in middle part of China, could be studied as an example for Chinese urban planning. According to the statistical results in 2010, the city’s population were 24461, and the occupied urban development lands were 3.42 square kilometers. However, according to the planning, by 2030, the population will increase to 120,000, and the scale of urban development land will become 13.20 square

kilometers (Figure 1). This analysis indicates that there is still space to improve. On the contrary, problems of the Chinese USGM do exist according to the data.



(a) (b)

Figure 1: (a) Current scale of urban used land, and (b) urban development land in 2030.

As previously mentioned, the Chinese USGM mostly relies on the Land Use Plan and the Urban Plan. Many researchers studied these two plans' problems, which are the inharmonious of law's foundation and executive methods, and conflicts of interest among the departments (Wei, 2011, Cao and Xu, 2004, Wang and Du, 2004).In conclusion, there are two main problems existing from the vision of building sustainable system of USGM.

Firstly, absurd land-use model, like examples above, connive low efficient usage of land resources due to lack of control measurements. Based on the system of the Chinese USGM, scale of the urban construction lands should be controlled by the Land Use Plan to maintain the size of agricultural land. Meanwhile, the Urban Plan should have coordinated with the Land Use Plan according to the City Planning Law of the Peoples Republic of China (2008). Moreover, due to the Chinese financial policies, local governments usually obtain development funds by selling land leases therefore extends the scales of urban development lands managed by the Urban Plan (Construction Plan). Therefore, size of urban construction lands is always out of the local government' control.

On the other hand, environment issue has already been ignored through the process of system's establishment from China's USGM. Furthermore, the Land Use Plan is to the primary control of the scale of urban developments. However its purpose is to control scopes of urban development spaces and protect the agricultural land exclusively. Therefore, it is necessary to build an appropriate mechanism for China's USGM to protect the environment entirely.

China’s USGM could not copy the UK’s totally due to differentiation of policy system and period of social development. However, sustainable concept and measurement of green belt in UK could be learned by China. As mentioned before, USGM appeared with urban sprawl in US. However, compared with US, there is no serious suburbanization existing in UK. Therefore, green belt is the core point of UK’s urban containment policy. Although the green belt policy is argued in reality, it does control the urban problem and protects environment, even leads to sustainable society(Hanley and Knight, 1992, Amati and Yokohari, 2006, Susannah, 2007, Thomas and Littlewood, 2010). Besides, planning policy statement 1 (1970), from process of UK’s established urban plan policy, expressed the intention of planning. In detail, Planning determines the places where people live and work and the country we live in and it conducts a main role in supporting the Government’s wider social, environmental and economic objectives and for sustainable communities. Moreover, concept of sustainable development and foundation of law would be introduced and understood well under the system. In comparison, China’s USGM and urban planning have not focus on sustainable development deeply while they pays more attention on economic development. Therefore, the ignorance of sustainable development in legislation and operational process brought the unsustainable act like former examples.

5 Recommendations on restructuring China’s USGM System

The basis of restructuring China’s USGM system is socialist public ownership of land under socialist market economy. Because of sustainable development’s problem, China’s USGM system has to be restricted with experience of UK’s urban control policy. Moreover, the reform should include four parts, which are fundamentals of law, organization structuring, control measures and supervised mechanism.

Fundamentals of law have to be improved firstly. The law needs to be legislated to protect the legal status of USGM in restructuring system. In addition, the concept of sustainable development must penetrate entire management system. With legal protection, USGM should be shown the nature of public policy mainly. This system should not have timing limitation and can be used for government, corporations and public, and even be the foundation of planning practice.

Secondly, related USGM departments’ function seems to coordinate mutually. Particularly, improving related functional organization could enhance the guide function of local governments. For local government, the functional combination of LRB and UPB ensure the efficiency of land use and planning management through concentrating land management and planning management. For related departments, financial tools, like taxation, would lead and coordinate local planning practice to promote the local departments’ own function and corporation. Nevertheless, departments’ decisions must be foreseeable, judgment and practicable on finance.

For control measures, containment policy, like green belt, should be introduced and conducted. In detail, green belt can be planned and controlled to improve the environmental sensitivity area protection under the foundation of protected agricultural land and eco-environmental protection. Overall, urban development model focused on creating compact and economize city by control measures.

Finally, it seems to be necessary to enhance inspection mechanism of special growth management with improving the strength of public participation, which is core part of implementation process. Moreover, all of parties' suggestion has to be considered for establishing each USGM's measures to avoid that the system is on behalf of single party's interest. Meanwhile, it is non-substitutable that all different parities and non-governmental organization supervise the results and correct unreasonable requirement during the implementation process of USGM system. Therefore, public participation is one of the most important forces to achieve the USGM.

6 Conclusion

In summary, China's USGM has individual methods, problems and measures, due to China's political system is different with western countries. In reality, urban sprawl has already appeared in Chinese cities, thus Chinese urban development needs USGM to guide the procedure (Wang and Zhang, 2010). However, there is a series of non-negligible problems, like absence of special management measures and eco-environmental concept, existing in current China's USGM system. In addition, these problems exist not only on operational level, but also bring furthering reflection. Particularly, capital shortage would affect urban development because of China's financial policy and government's examining standards always ignore the environmental notion.

According to experience from UK containment policy, China's restructuring USGM system should focus on sustainable development as a premise. At first, urban development activities should follow the USGM system through improving related legal system. Regarding the organization structuring, procedure of spatial planning management should be simplified. Moreover, duplicate administration could be avoided through combination of LRB and UPB. Subsequently, urban constructional land should be used efficiently by means of green belt. Specifically, green belt can be border of urban expansion forcibly to avoid urban sprawl. Finally, in aspect of supervised mechanism, environment impact assessment and public participation both should be used frequently to examine the USGM system and add concept of sustainable development to USGM. In the future, USGM research would pay more attention to supervised mechanism and local financial policy to distribute the financial power fundamentally.

URBAN PLANNING IN THE SERVICE OF THE QUALITY OF LIFE OF CITIZENS

Alex Deffner [1], Eva Psatha [2]

Abstract

With deep roots in the ancient Greek philosophy, the issue of well-being and quality of life (qol) has been steadily in the focal point of the modern philosophical thought since the 18th century. The improvement of qol, regardless the definition of the term, is considered to be a natural tendency of humankind, and a standard pursuit for human beings. Thus, what finally defines the level of the qol in a society is the adequacy of the living conditions. In this view, urban planning plays a critical role in the configuration of the collective level of the qol, since it interferes in the very core of the living conditions of people, which it actually targets with its actions. In fact, cities constitute the scene of everyday life for the 75% of the global population, shaping the environment for living. Thus, the effect of the city in the living conditions of citizens is something obvious. The form, the structure and the complex functions of the city determine significantly human functions as well: they determine the space and time of citizens with direct impacts on labor, health, rhythms of urban life (fast or slow), 'discretionary' time, leisure and interpersonal relations of citizens. For all the previous reasons, the improvement of the quality of urban life (qoul) can always be found among the targets or objectives of most urban planning projects, regardless the scale. From mega projects, which are considered to contribute to the competitiveness of cities, to minor regeneration projects, the amelioration of the qoul is always present as a causative factor. However, urban planning interventions often fail to succeed in this objective and sometimes even undermine (involuntary) the qoul. This 'heretic' induction is reflected on the environmental, socio-economic and structural problems of modern cities which (especially in Greece) usually tend to be attributed to the inadequacy, or even lack, of urban planning. However, they are often derived from wrong, or out of date, planning decisions endangering the sustainability of cities. This happens partly because the qol in general, and the qoul in particular, remain undefined terms – in spite of their continuous invocation – and the relation of the urban parameters to the qoul determinants is still confusing. And yet, qoul can only be defined on the basis of its determining factors, while referring to the living standards of all people, including the less favored citizens. In this paper, the main determinants of the qoul will be analysed, highlighting those factors which can be affected – or even configured – by urban planning. The empowerment, or the undermining, of the qoul determinants through time by urban planning initiatives will be discussed, with an emphasis on the contemporary era. Finally, urban policies contributing to the improvement of the qol of citizens will be proposed.

1. Introduction

Urbanisation, either emerging as a result of social transformations, or as a consequence of productive restructuring, creates an unforeseen concentration of people in a limited urban space. The urgent demand for housing, which inevitably arises, and the attempt for maximum exploitation of the space available can lead to malfunctions and failures. These issues have come to be the focal point of urban planning over time, notably since the end of the 19th century (Bartetzky and Schalenberg, 2009a).

Focusing on contemporary cities, recent trends in urban planning and management, along with new urban policies, cause a realignment of people's perceptions and attitudes towards the city, when considered as a field of social activation and interaction. Current urban issues, such as environmental degradation, the amplification of social inequalities and their reflection on urban space, the depreciation and privatisation of public space, raise critical questions about the quality of life (qol) of the residents, which mainly concern the objectives and practices of urban planning.

The environment in general, and in this case the socio-economic environment defined by the city, although external to the individual, forms the context in which each person is placed and can organise his/her life, and in which groups of people act, interact and function collectively. On the basis of this theory, the individual characteristics of urban residents which can define their qol, are of great interpretative importance for urban function, while, on the other hand, information concerning the urban function directly influences people's everyday lives. In other words, the individuals in the city constitute dynamic entities that continuously interact with the urban environment (Maggino, 2006).

Under the previous perspective, the factors which determine people's satisfaction with their everyday life, their neighborhood and/or their city, are in direct relation with the determining factors for a person's subjective well-being and come under the wider objectives set by the quality of urban life (qoul) research.

In fact, satisfaction with home, neighbourhood and city partly depend on a number of variables, which are sometimes recorded by official procedures and are organised in systematic information resources, e.g. during the population census. They also depend to a significant extent on less-studied factors: factors which are usually ignored by urban policies. Such factors include home ownership, security, urban public transportation, quality of public space (with the condition of streets and pavements included) and the accessibility to green spaces (IDB, 2010).

The comprehension of the previous factors and the relationship between these factors and urban policies are of crucial importance in order for urban planning to remain focused. And the focal point of urban planning should be nothing more than the

amelioration of the living conditions for the city's residents and users. The complicated relationship between the qoul - in terms of its determining factors - and urban planning constitute the subject of the current paper.

2. Quality of one's life and quality of urban life

The most challenging issue when dealing with the qol evaluation concerns the specification of the determining factors. Although this issue has been the subject of theoretical research for many years and many different approaches can be found in the literature, the factors taken into account are far from being standard. The efforts to reach a commonly accepted set of determining factors are hindered by the underlying subjectivity of the concept, which also makes difficult to define the term.

A basic distinction to be made concerns the level of examination: the individual or the collective level. Qol in a community or a city cannot be considered as the average qol level of the residents. For example, even if the residents of a city evaluate their own qol as high, this finding does not imply directly that the city is characterised by a high qoul level. There are many factors which can determine a person's qol without spatial reflection (e.g. state of health or marital status). There are also spatial factors which play an important role for the qoul, which are not usually considered when evaluating subjective well-being (e.g the weather conditions). However, when examining the qol in cities we have to start from the subjective well-being of the citizens.

Although defining the qol determinants is a difficult task, many scholars from various disciplines have undertaken it, either by asking people directly about their perceptions (as in European reports about the qol of European citizens), or by setting them in advance in an objective and quantifiable way (e.g. the WHO studies), in order to confront directly the issues of subjectivity.

From the first attempt to record and measure qol on a large scale that took place in Scandinavia during the 70's (Comparative Welfare for Scandinavia, 1972), various researchers have dealt with the qol determinants. Cummins (1996), Diener and Lucas (2000), Frey and Stutzer (2000), Verlet and Devos (2009) are among those who have proposed different sets of factors for evaluating qol at the personal level.

The recent findings of the 'Second European QOL Survey', which evaluates subjective well-being in all European countries, are of special interest, as it is a collective work based on a large-scale project. This research has used the overall satisfaction with life as the basic index for evaluating the qol, while recording important personal characteristics and different aspects of everyday life of the interviewees, in order to highlight those which play an important role (European Foundation for the Improvement of Living and Working Conditions, 2010). Findings of this research are presented in Table 1.

Table 1. Factors which influence an individual's QOL

Order of significance	*Life Domain*	*Relative Facets*
1	Financial status	Income Material well-being/lifestyle deprivation Employment
2	Health	Age Health status/disability Social support
3	Employment status	Employment Unemployment Retirement
4	Education	Education Level
5	Marital status	Marriage Divorce Widowhood
6	Practical/moral support	Family Friends Institutions
7	Public Services	Quality of services Accessibility

Source: 'Second European Quality of Life Survey', 2010 (own elaboration)

After concentrating and organising the different variables which emerge in the literature as qol determining factors, in order to decide in the qoul determinants, Psatha et al have proposed the qol determining factors which are presented in Table 2.

Table 2. QOL Determinants

s/n	*Main QOL Determinig Factors*	*Facets incorporated in the main factors*
1	Physical health	Energy, absence of pain
2	Mental health and psychology	Positive feelings, trust in myself
3	Happiness, self-esteem, self-actualisation	Emotional well-being, spiritual well-being, challenges, prestige
4	Family environment and personal relationships	Marital status, giving and earning love and tenderness, understanding and solidarity
5	Social relationships and friendship	Friends, being needed, interpersonal relationships, understanding and solidarity
6	Income	Material well-being, financial sources
7	Employment	Productivity, unemployment, Satisfaction with one's job
8	Education and lifelong learning	Level of education, personal development
9	Distinctive time and Leisure	Recreation, humour, relaxation, leisure opportunities
10	Security and tranquility	
11	Freedom and variety of options	Challenges, capabilities
12	Social Inclusion	Position in the community or society, social participation
13	Factors concerning the wider environment	Satisfaction with the neighbourhood, housing, natural environment, political situation, public services, etc.

Source: Psatha et al, 2011

When it comes to a city's residents, the factors classified in row 13 concern mainly the neighbourhood and the wider urban environment. These factors are the focus of the next chapters.

3. Determining factors for the qoul

Qoul has to do with the capabilities and chances offered to the city residents in order to obtain a good personal qol. Thus, those cities which cultivate the factors in Table 2 are the most probable to be characterised by a high qol level. The level of achievement of these factors in the city level largely depends on infrastructures and urban planning (Psatha et al, 2011).

An individual's qol determinants can lead to the most important qoul determining factors. These include health services, urban green spaces and recreation areas, quality of urban environment, employment opportunities, social networks, education opportunities, leisure resources, urban crime and socio-economic structure (Psatha et al, 2011).

There are also further issues which influence the qoul. These include circulation conditions, the level of efficiency of public services (which was highlighted by the 'Second European Quality of Life Survey'), the quality of public space (which is

mentioned by many scholars and researchers as a critical factor for the QOUL) and less obvious issues such as the weather, the accessibility of public spaces particularly for disabled people, and the social infrastructures for vulnerable groups.

One of the most important issues concerns urban green spaces, whose role vis-a-vis the qoul has extensively been proved by many researchers. There is a plethora of references for the documentation of the positive relationship between green spaces and the qol in cities. Most of them originate from health sciences (Morris, 2003; Pretty et al., 2005) but references from urban economics (e.g Mansfield et al., 2005; Arvanitidis et al 2009), urban planning (e.g. Swanwick et al., 2003; Lake et al., 2010) and environmental disciplines (Bird, 2007) can also be found.

Circulation conditions and accessibility of urban facilities can have an equally important impact on the qoul, since they formulate the number of alternatives and capabilities a city can offer to its residents concerning housing, employment and leisure. They can change the time balance and everyday life of citizens in many ways (Cramer et al., 2004; Nuvollati, 2009).

After having projected the qol determinants from the personal level onto the city level, Psatha et al evaluated and incorporated the significant factors that can be found in the literature, proposing a set of 12 categories that constitute qoul determinants suitable for European cities. See Table 3.

Table 3. General categories of QOUL determinants for European cities

Economic Environment Employment opportunities, employment structure, average income and income distribution, living costs, etc.	*Social Environment* Crime, social inequalities, social exclusion, networks and infrastructures
Natural Environment Air quality, water resources, waste management, suburban natural environment, accessibility to areas of natural beauty, weather and climate	*Built environment* Building density, housing conditions, public monumental buildings, building stock, neighbourhoods, etc.
Urban and suburban green spaces Total area and rate per resident, condition, allocation, accessibility, usage, etc.	*Public spaces –Public buildings* Area, quality, condition and maintenance, accessibility, visiting rates, etc.
Culture - Leisure Cultural resources, tourism infrastructures, recreation areas, leisure activities, entertainment capabilities, cultural life, available choices	*Demographic data* Marital and family status of adults, age rates, level of education
Education Education units, quality and maintenance, attendance per education level, private schools, etc.	*Health care* Health services, accessibility, social welfare for the disadvantaged, etc.
Democratic Institutions Democratic regime, election of local government, voting rates, etc.	*Traffic and transportation* Traffic conditions, parking spaces, efficiency of public transportation and level of transportation services, accessibility of districts

Source: Psatha et al, 2011

4. Quality of urban space and quality of urban life

As previously mentioned, probably the most highlighted issue of urban space relating to the qoul concerns urban green and open spaces. From this central premise, other side issues arise, concerning the adequacy, the accessibility, the quality and the condition of green spaces and also of the urban public space in general. These issues also emerge in the literature as qoul determinants (Beck, 2009; Minton, 2009; United Nations - HSP, 2011). The importance of the quality of the urban space extends to the economic function of the city. It seems that well designed and well maintained public spaces of high quality can attract business and touristic activities, enhancing the competitive profile of a city (Rogerson, 1999; Florida, 2002; Psatha and Deffner, 2012). In addition, well maintained public spaces assign a positive value in the hosting cities, from a social, economic and environmental aspect. According to CABE Space (a U.K. consulting organisation on public space issues), public spaces

of high quality generate positive economic values in the long term. They are actually considered to be a unique case of public infrastructure, offering many benefits to the city (Beck, 2009).

On the contrary, abandoned or inadequately maintained public spaces have a strong negative impact on their neighbourhoods, as they provoke antisocial behavior, further vandalism and delinquency. This kind of public space disperses the impression of a decadent urban area, which repulses potential residents and investors (CABE Space, 2005a). When public spaces are characterised by a low quality level, they are used by neighbours only out of necessity, for the necessary activities (e.g walking in the street under sufferance in order to go to the bus stop but never going for a walk), leading to deteriorating social isolation. On the contrary, well tended public spaces cause several social activities, giving the impetus for more sophisticated and fruitful social interaction (Gehl, 2008). Thus, the presence of the appropriate public spaces contributes to the generation of powerful and long-lasting local communities in the city (CABE Space, 2005b).

Despite the importance of public spaces in the qoul, their neglect is a common occurrence in European cities. However, the regeneration, amelioration and adequacy of public space are also a matter of equity. It is usually the less privileged communities that suffer from a low quality public space (Beck, 2009).

In general, the aesthetics of a city has been proven to affect the residents' satisfaction of the urban area and the economic performance of the city. The aesthetics of urban space in combination with economic and social factors form a strong impact on the qoul, while it also acts individually as a determinant for the satisfaction of the neighbourhood (Widgery, 1982; Florida et al, 2011).

For all these reasons, European Ministers responsible for urban development consider the creation and good maintenance of urban public spaces as a critical factor for the enhancement of the attractiveness of the European cities (European Commission, 2009):

> Public spaces play an important role in the living environment of urban populations and can attract industry, businesses, tourism and workforces. Being a mix of architecture, infrastructure planning and urban planning, high-quality public spaces should be understood as 'the sum of all the cultural, economic, technological, social and ecological aspects influencing the quality and process of planning and construction.

Focusing on the spatial level of the neighbourhood, it has been found that the latter plays a critical role in the satisfaction with life level for urban residents, participating by 10% in the formulation of the relevant perceptions. The spatial characteristics of the neighbourhood play the most prominent role in the levels of the overall satisfaction, compared with the neighbours or the relationships with them (Verlet and Devos, 2009). This finding is compatible with the conclusions of previous research, according to which satisfaction with the neighborhood correlates strongly with the

overall quality of one's life, regardless of personal factors (e.g marital status, age or education level).

Satisfaction with the neighbourhood and its impact on the qol, passes through the social networking and the fear of urban crime (Adams, 1992; Rojas, 2010). Additionally, when residents are well integrated into their neighbourhood community, they have a better perception of their neighbourhood and they enjoy a higher qol (Baldassare, 1982).

The extent to which urban planning interferes with the satisfaction about the neighborhood, has been a subject of research for many years. Wirth was the first to propose a model according to which neighbourhoods with high density and population levels suffer from isolation and social unrest which undermine directly the qoul, in contradiction with the old and homogeneous communities on a smaller scale (Wirth 1938, as referred by Baldassare, 1982; Adams, 1992; Parkes et al, 2002). This old hypothesis has also been proven, more recently (Adams, 1992), and is usually referred as: the 'Wirthian approach'.

According to other researchers, however, satisfaction with the neighbourhood depends less on the urban characteristics and more in the social inclusion of the individual. Relatives, friends and the opportunity for social interaction are the main determinants. Under this perspective, people who live in urban areas with high population density are not inferior to satisfaction with their neighbourhood, under the condition that they have obtained an adequate social networking (Kasarda and Janowitz, 1974 as referred by Parkes et al, 2002).

In conclusion, despite the acknowledgment of the importance that satisfaction with the neighbourhood has for the qol, there isn't yet a commonly accepted theoretical background as far as the determining factors for this satisfaction is concerned. The most important difficulty lies on the existing correlation between the neighbourhood characteristics and the socio-economic ones. The underlying social segregation that exists in different extents in most cities causes the characterisation of urban residential areas, according to the social or income profile of the average resident.

The question relating to the factors that can determine the urban residents' satisfaction with neighbourhood and urban life, although critical for planning and policymaking, is not adequately answered by existing research, because of the large number of and differences between the factors that are taken into account and between the population samples used. There are, however, some common findings. The fear of crime, for example, is always the most prominent factor for the satisfaction with the neighbourhood (Adams, 1992; Rojas, 2010; Parkes et al, 2002).

5. The role of urban policies and urban planning to the qoul

5.1 New urban policies vs the qoul

Public open spaces have always been considered as a medium for the improvement of the living conditions in cities. The availability of public spaces helps inter-personal relationships to develop, enhancing the social capital of urban areas. Thus, their provision had been a target point for local governments for many decades. Cities used to 'proudly' promote the use of public spaces and urban residents used to incorporate this use in their daily routine, converting public space into a field for social participation and interaction. However, recently cities tend to pursue the privatisation of public spaces (Muehlman, 2005).

Recreation places are increasingly considered as commodities that can be exploited on the basis of their economic potential, rather than facilities which can enhance the qol at large (Lloyd and Auld, 2011).Pursuing economic development, however, cannot always guarantee the maximisation of qol for all residents. The increasing commercialisation and privatisation of urban public spaces led to the attraction of those people who can afford– and are willing to pay– to visit them and for obtaining the leisure experiences offered, while for many residents the access remains problematic or even impossible (Crane, 2000 as referred by Lloyd and Auld, 2011).

Security against crime along with cleanliness are usually the rationale for 'developing' extensive urban areas, mainly in former industrial or degraded entities. Malls and residential complexes emerging in those cases display cleanliness and safety as their major benefits in their attempt to attract the potential buyers and users of the new places (Minton, 2009). Private common spaces, however, can contribute to the degradation of the public character of open spaces, through the limitation of social interaction, the restrictions on free access and the exclusion of certain groups of residents (Nemeth and Schmidt, 2011).

Another issue related to the previous urban policies, concerns the competence of urban governments. In many cities, especially in the U.K. and the U.S.A., the 'traditional' responsibilities of local governments (e.g cleaning services and the maintenance of public spaces) have been transferred to the private sector, raising serious issues concerning the quality of services and the function of democratic institutions. The new urban policies include the concession of local tax management on private companies which undertake regeneration projects in the city centres in order to enhance commercialism. The relevant policies are often criticised for the kind of the public spaces they generate, as the only citizens to be acceptable are the potential clients, while the other residents are eventually excluded (Minton, 2009).

Picture 1. Homeless shelter in San Diego[3].

Source: http://www.kpbs.org/news. Photo by Ana Tintocalis.

Although regeneration projects beautify the degraded areas and can bring them back to the scene of economic urban activity, their contribution to the qoul is not straightforward. In regenerated urban areas, homeless people are undesirable and they are usually kept away by several policies, including regulations for specific areas, which prohibit begging and sleeping or loitering in public places (U.S National Coalition for the Homeless, 2012). There are references to the fact that in New York, after the regeneration of the central but degraded areas of the 90's, 100,000 homeless people had to move to other areas, away from the centre. This phenomenon was repeated in other U.S. cities, such as San Diego, where a specialised camp was created on the city's outskirts (Smith, 1999).

5.2 The role of urban planning

Many scholars have examined and documented how urban planning affects the ways in which people use public spaces. Different urban forms can play different roles in the structure of the public-private relations within the cities. This is predictable, because public spaces from their origination and design are composed by factors which act as limits between functions, directly affecting their own use and social exploitation.

[3] The homeless population in the area has reached 9,800 individuals in 2011, according to The Regional Task Force on the Homeless (http://www.utsandiego.com/)

Whyte has discerned some design characteristics which encourage the concentration of people in the public spaces. The qualities related to the natural environment (sun, water and vegetation) come first, as they can beautify and soften the built environment. Important factors for the attraction of people are food sites, sitting facilities and resting areas. Art of various types (e.g. sculptures, or street artists) can also be important. Other factors are those characteristics which affect the attraction of people to the surrounding area, including parking facilities, commercial or business activities and public services (Whyte, 1980).

The planning and design of public spaces plays an important role in the social interaction in cities, as public spaces shape the capabilities for audiovisual contact and meeting together, providing a motivation for social communication (Gehl, 2008). Meeting a neighbour, a colleague or even a stranger in a public space (street, park or square), contributes to closer social relationships and intensifies the social bonds, while it offers the chance for motivations and inspiration (Lloyd and Auld, 2011). The simplest form of social interaction, just seeing and listening to other people seems to remain the most important attraction of public spaces for all (Gehl, 2008).

The attraction of people to the public space, however, relates directly to the matter of safety. As Jacobs has pointed out, vivid and crowded streets seem to be, and actually are, safer than over-guarded streets. On the contrary, in places where order is obtained through the police instead of people's presence, this order is fragile (Jacobs, 1961).

These fifty-year-old remarks remain timely and can still be applied in cases of city centres like in Athens. Having followed a concentrating model of urban development, Athens has faced a city centre on the saturation line, during the 80s. The problems of congestion and air pollution were in part assigned to the over-concentration of activities and public services in the city centre (Prevelakis, 2002). The issue of decentralising ministries and public services to other city areas is coming to the scene from time to time. Nowadays, however, although the relative proposals have only been applied in part (e.g the Ministry of Education and several university buildings were relocated), there is a serious skepticism concerning the purposefulness of these policies. The population mixture and land uses have dramatically changed since the 80s, so keeping public services and ministries in town is often countered as a measure against the degradation of urban areas which used to be vivid, although it can contribute to the coveted presence of citizens in the streets only during the working hours (White Paper for Governance, 2012; www.cityofathens.gr; http://www.tovima.gr).

The current phenomenon of gated communities also is also linked with the issue of safety. Behind the development and promotion of this trend lies the depreciation of public space and the prevalence of fear in the urban domain, as urban residents pursue to 'hide' behind walls in order to feel safe (Atkinson & Flint, 2004).

Picture 2: Omonoia Square[4]

Source: http://athensville.blogspot.com

Although gated communities are supposed to enhance the feeling of security, which is important to subjective well-being and the quality of one's life, in fact, their very existence discloses the feelings of fear which dominate urban life in many cities, something that acts as a degrading factor for the qoul. In addition, those communities could worsen urban crime, because they enhance and highlight the existing social inequalities and the rivalry between the social classes in the city (Gadecki and Smigiel, 2009). The recent case (February, 2012) of the American teenager who was shot dead by a gated community's guard, shaking the U.S. population's perceptions

[4] Omonoia Square and the streets around remain unfrequented in the evening, despite the recent enlightenment projects. The most centralised square of Athens used to be crowded all day long in previous years.

concerning the purposefulness of this residential arrangement, has tragically confirmed the relevant skepticism.

6. Conclusions

Recent trends in urban planning and urban policies redefine the function of the city as a dynamic complex of constant social interaction, while the relations between urban residents and the city are reconsidered. But as cities form the scenery for the everyday life of billions of people worldwide, both current urban issues and the attempts of planning to confront them have a major impact on the citizens' qol. Issues such as the quality of the urban environment, the available green spaces, public spaces, crime and circulation conditions along with the corresponding urban policies, do not simply affect qol of a city's residents, they can actually define it.

Regarding qol, one the most challenging issues for the relevant research concerns the specification and the definition of the term. This procedure mainly depends on the selection of the most appropriate determining factors. Although there have been many notable attempts to scientifically define and systematically study qol, including the suggestion of various sets of determining factors, there isn't yet one commonly

accepted composite index. This indeterminacy is reflected at the city level, concerning also the qoul, for which the determinants are not standard either. On the other hand, there are also many urban parameters which by common consent influence the qoul, undoubtedly forming the major relevant determining factors. These include the socio-economic characteristics, the quality of the urban environment, urban green spaces, recreation resources, public spaces and crime.

Among the previous factors, one of the most important but on the same time often neglected ones, concerns the quality of the urban environment and more specifically the quality and accessibility of public spaces. Current urban practices and the relevant types of urban space have controversial impacts on the qoul. Either because social transformations are some times faster than policymaking and the application of policies, or because the applied policies often target specific groups of the population, neglecting others, there are cases where planning interventions undermine, instead of advancing, the qoul. New policies for town centres, management policies for public spaces and the phenomenon of residential development through gated communities, are among such cases.

Better comprehension of the issues related to the qoul and unequivocally establishing the determining factors of the latter can be the key to avoid biased or ill-targeted interventions and possible urban policy failures, in order for urban planning to remain well-focused on the constant amelioration of living conditions in the city for all residents.

THE ROLE OF HERITAGE IN RURAL REGENERATION: THE CHALLENGE AND POTENTIAL FOR RURAL HERITAGE TOURISM DEVELOPMENT IN THE COUNTRYSIDE AROUND SUZHOU, CHINA

Yi-Wen Wang[1], Giulio Verdini[2]

Abstract

Rural areas have served as a vast reservoir of cultural heritage as rich as that in urban areas. Man-made structures in the countryside, together with their adjacent cultivated land and natural surroundings, have been the long-lasting receptacle of agricultural practice that chronicles the history of mankind. Similarly, heritage tourism has long been associated with urban heritage. Beyond urban areas, however, rural heritage can also be a main source of cultural tourism and bring added socio-economic values to local communities. Particularly, in the last two decades, rural tourism has been seen as a remedy for rural communities to combat the declining agrarian economy and diversify the multi-functional roles of agricultural land. In this trend toward agri-tourism, places of historical interests begin to take an increasingly prominent role in rural regeneration.

This paper aims to identify the issues of rural heritage management in China and explore its potential for rural heritage tourism development. Due to the country's relentless pursuit of economic growth, rural heritage in China is under threat of incremental destruction and gradual dilapidation. The perceived threats toward rural heritage are mainly posed by peri-urbanization expansion, the decline of population and, above all perhaps, the government's recent initiative on rural development, 'Building a New Countryside', due to which traditional countryside houses are either demolished or modernized at the cost of original morphological and architectural character. This research takes a form of a case study on the countryside around Suzhou City in Jiangsu Province. While the city has often been dubbed 'Venice of the East', its rural areas are also characterized by canal-scape and features clusters of vernacular buildings and agricultural structures. The paper examines how rapid urbanization and the government's initiative encroach on arable farming land and threaten the continued existence of rural heritage. Drawn from empirical materials from field survey and interviews, it further illustrates the desertion of tangible heritage assets in the countryside.

[1] Department of Urban Planning and Design, Xi'an Jiaotong-Liverpool University, Suzhou, China – yiwen.wang@xjtlu.edu.cn
[2] Department of Urban Planning and Design, Xi'an Jiaotong-Liverpool University, Suzhou, China – giulio.verdini@xjtlu.edu.cn

The paper argues that the truly rural 'heritage' is the everyday life setting in the countryside that provides local communities with a stage to development eco-tourism in the countryside.

1. Introduction

The diversification of the functional uses of agricultural land has grown in importance since the concept of sustainable development became a matter of concern all over the world. Multi-functionality of agricultural land often refers to the production of other goods, services or values in addition to crop and livestock, such as food security, leisure activities, recreational opportunities and cultural tourism (Daugstad *et al.*, 2006). Arguably, rural tourism has been considered as one of the most effective tool to diversify economic activities and generate additional income for the rural community. It has played an important role in regenerating the declining economy of the countryside as a result of intensive global food trading (Sharpley & Vass, 2006). Certainly, the term rural tourism has been perceived and interpreted in various ways, ranging from generally leisure activities to hands-on farming practice. It is, however, the role of 'cultural heritage' in the current trend of rural regeneration in general and tourism development in particular that this paper seeks to examine.

Whereas the focus of rural development initiatives in the 1990s appears to be on agricultural reform and economic growth, the first decade of the 21st century has witnessed a growing interest in the heritage values of rural landscape and the employment of heritage tourism as a key strategy for rural regeneration. The idea of 'heritage-led rural regeneration' has received a rising popularity in Western Europe and North America in the recent years (English Heritage, 2008; Lincoln *et al.*, 2010; Mayes *et al.*, 2010). While heritage-led rural regeneration appears to be a new trend and attracts more and more attention in practice, appreciation for the heritage value of agricultural landscape hardly can be seen in China and the recognition of its tourism potential is yet to be developed.

As a result of the country's relentless pursuit of economy growth, agricultural lands on the urban fringe often bear the brunt of rapid urbanization and are quickly disappearing. Original tranquil rural landscape is under threat of destructive development and irreversible transformation. Part of the aim of this paper is to unlock the heritage value of existing agricultural villages and their characteristic landscape on the fringe of Suzhou. Certainly, the evolution of discourse on rural regeneration in relation to heritage tourism and the recent pioneering initiatives undertaken in the developed countries may afford remedies for the problems of tourism development in China (Y.W. Wang & Verdini, 2011). The examination of the rural planning policies and the current socio-cultural and economic circumstance of deprived rural areas in Suzhou, however, are indispensable for identifying the range of issues before promoting heritage-based approaches towards rural regeneration.

It may be worth noting that the term 'rural heritage' employed in this paper refers to the tangible agricultural structures and their surrounding open spaces and, also, the

intangible traditional skills and cultural expressions historically associated with agricultural practice. The tangible built heritage that this research focuses on is the unassuming, low-visibility heritage that is modest in appearance, mundane in function and often, though not always, made up of relics of the relatively recent past and not statutorily protected. A basic position taken by this research is that places like these are of lesser significance so have a greater flexibility in making changes to their physical structures to meet contemporary needs, hence a greater potential to stimulate local economies and promote sustainable tourism with the involvement of local communities. Another assumption of this research is that, compared to impressive architectural monuments and archaeological sites, unassuming agricultural structures and vernacular buildings can better reflect the lives of ordinary people in the past and, therefore, better communicate with people at the present time and facilitate their understanding of the past.

2. External Threats to Rural Heritage in Suzhou

The major threat to rural heritage in Suzhou is mainly posed by the rapid peri-urbanization expansion and the government initiative launched in recent years – Building the New Countryside,

2.1 Urbanisation of Agricultural Land

The main driving forces of peri-urbanization – i.e. the inward migration of low-income labours or the gradual encroachment of green-field development on urban fringe – are essentially situational. Yet this phenomenon has become rather typical of cities in China considering that nearly half of the country's growth in the next quarter century will be in peri-urban areas. This continuing expansion of built up areas consequently results in the incorporation of former rural villages and agricultural land into 'cities'. Whereas the urbanization of agricultural land is clearly observed everywhere in China, it can be argued that it has brought about a catastrophic effect on the existence of rural heritage, particularly, in the regions of Pearl River and Yangtze River Delta.

The two regions currently experience the highest rate of economic growth but, historically, they flourished because of the fertile arable land in the region that had rich natural resource and produced abundant crop. This means that there is a relative wealth of cultural heritage that is closely associated with agricultural practice as well as the unique inland waterway in the regions. The research conducted by Bosselmann *et al* (2010) exemplifies the threat of urbanization towards the cultural landscape of the water villages surrounding Foshan City in the Pearl River Delta. A similar episode of 'countryside urbanization' can now be observed in the Yangtze River Delta, which experienced economic reform about half a decade late than the Pearl River Delta (Figure 1).

Figure 1. Yangtze River Delta generally refers to Shanghai, southern Jiangsu province and northern Zhejiang province of China.

The irreversible transformation of rural landscape brought about by rapid urbanization and industrialization of the countryside in Southern Jiangsu Province, has caused concerns. The depletion of arable land, the disruption of ecological balance and the loss of rural heritage and character too are of great concerns to many scholars (Liu *et al.*, 2010; Verdini & Wang, 2011; Yang & Huang, 2011).

2.2 Rural Policy: Building New Countryside

Another insidious threat to the continued existence of rural heritage is posed by a series of rural planning policies and initiatives that are proposed to accelerate the modernization and development in rural areas. This is best exemplified by the government's recent campaign – Building a New Countryside. The idea of building a "new" countryside is a derivative idea of the overarching and highlighted theme of planning policy – the integration of urban and rural development. The campaign was launched against the backdrop of the widen gap in income and livelihood between the urban and rural population. Long *et al* (2010: 459) summarize the salient features of the government's 'new countryside' campaign into five aspects: 'advanced production, improved livelihood, clean and tidy villages, a civilized social atmosphere and efficient management'.

One point particularly relevant to this research is 'advanced production' which is concerned with the optimization of production and circulation of agricultural produce. To optimize the farming system, land consolidation becomes the primary means to resolve rural land-use issues. Many rural villages rent the farming land to contractor if the community committee agrees so. The new problem emerges, however. The employment of land-loss farmers becomes the burning issue.

The other relevant point is to break the traditional stereotype of countryside as poor and dirty and to transform it into ‘clean and untidy villages’. While this brings a substantial amount of financial incentives and supports to regenerate rural villages, it also has destructive impacts on the character of rural landscape. The problem stems from, on the one hand, the mistaken belief that rural areas should be ‘developed’, instead of ‘regenerated’, into something similar with those in urban areas in order to provide local residents with a reasonable standard of modern amenities.

On the other hand, the problem has to do with the approaches adopted to implement the initiative. Modernization of the countryside is often associated with re-cladding or rebuilding the existing houses (Figure 2). Admittedly, upgrading domestic comfort of existing dwellings should be essential to the initiative. Way too often, however, rural villages and agricultural structures are modernized at the cost of losing the original morphological and architectural character. Instead of adopting modest refurbishment or conservation approaches, radical transformation and destruction of historical structures has become the norm for the ‘new’ countryside.

Figure 2. Recently refurbished houses and new build in the Suzhou countryside

3. Internal Deterioration of the Suzhou Countryside

Another perceived threat to rural heritage in Suzhou is the demographic decline in the countryside that has directly or indirectly resulted in the dereliction and dilapidation of tangible heritage in rural areas. Despite the fact that the official census is conducted periodically, it is difficult to ascertain the actual number of rural residents and unoccupied houses in any given rural areas. This is mainly because the rigid household registration system set up to prevent unauthorized rural-to-urban migration in the 1960s, has nowadays adversely resulted in an enormous number of ‘floating population’ – migrants from rural areas living in cities where they are not entitled to enjoy any social welfare but can earn more money to sent back home.

While the actual figure for rural population loss is unclear, it is certain that there is a significant increase in aging population in China's countryside as many other countries in the world. This means that, while a substantial number of historical houses and agricultural structures are left abandoned, a large group of elder people, some of who may master traditional skills and handicrafts, are also left behind in the countryside.

To better understand the current physical and socio-economic conditions of the Suzhou countryside, several field trips, face-to-face questionnaires and semi-structured interviews were conducted during the period from July 2011 to March 2012 for the research project supported by the Suzhou Social Science Programme 2011 (11-B-08) and as part of the undergraduate teaching programme of Xi'an Jiaotong-Liverpool University in Suzhou. With its focus on rural heritage and its tourism development potential, this paper mainly reports some findings on the physical environment of rural villages in Suzhou and addresses partly the social-economic conditions. A more detailed report on the social-economic transformation and its relation with rural land-use conversion is presented in a parallel track of the conference.

During the period between July and October 2011, the research group went on four field surveys across the urban-rural fringe of Suzhou and eight study cases were selected and analyzed (Figure 3). The routes of the fieldtrips mainly crossed the southern part of the prefecture Suzhou, including Suzhou Industrial Park, Suzhou New District, Xiancheng and Wuzhong District and the Kunshan and Wujiang counties (Figure 4). The southern part of Suzhou is relatively less urbanized and industrialized as it is farther away from Shanghai. In addition, this part has a greater natural resource for tourism development because of its close proximity to Tai Lake. For the above reasons, Southern Suzhou was considered strategically important to this research.

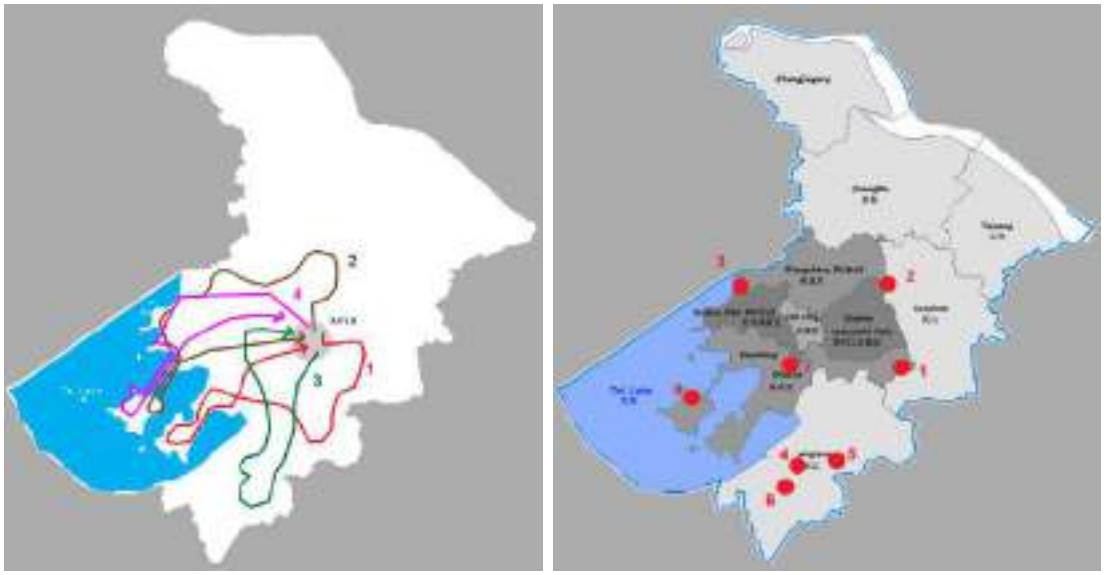

Figure 3. The routes of four field surveys and the locations of eight study cases.

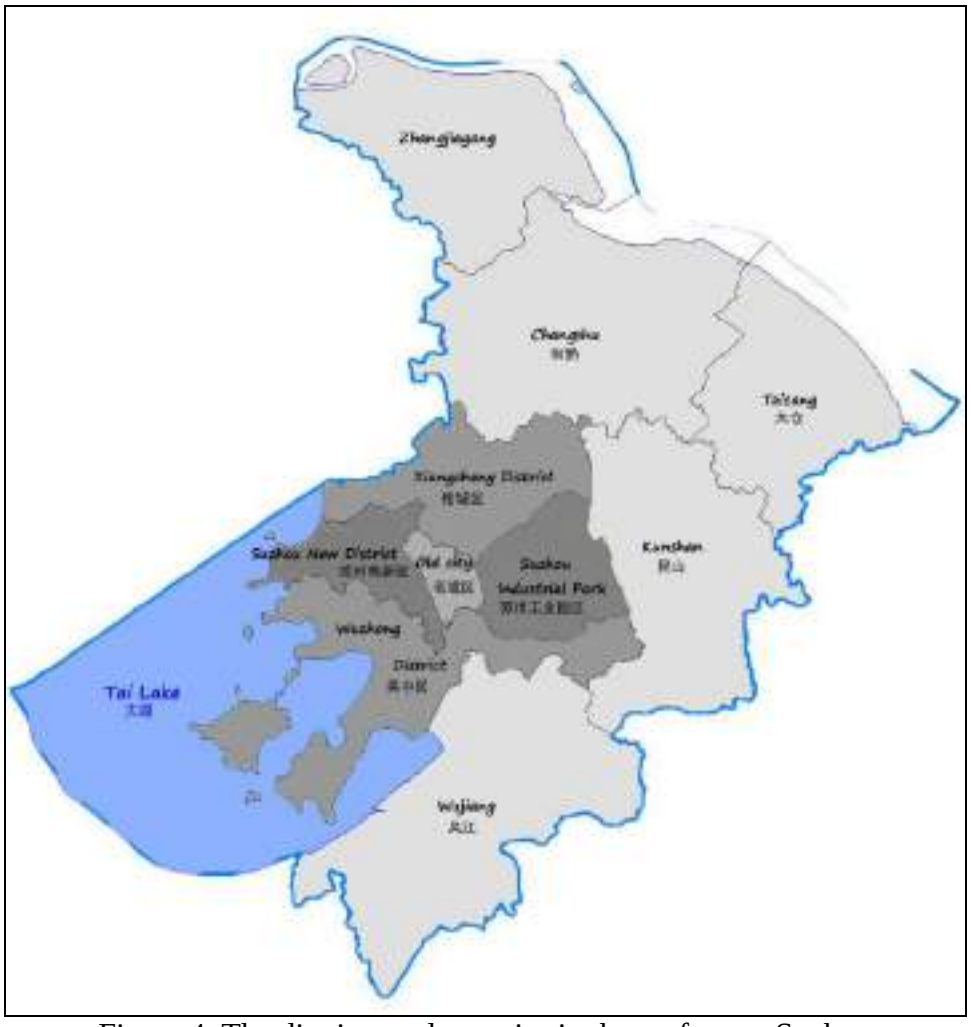

Figure 4. The districts and counties in the prefecture Suzhou

3.1 Desertion of Built Heritage

Many industrial developments were allocated in a disorderly, anarchic fashion in the survey areas. This problem mainly stems from the development of township and village enterprises that the government has promoted and supported since the 1980s. Modern factories were built, sometimes, adjacent to or mixed up with residential buildings and, sometimes, in the middle of farming land or nearby rural villages. In part, because of the phenomenal growth of rural enterprises, yet also because of the decline of agricultural economy and the rise of secondary industry, many old houses in former agricultural villages are abandoned and become derelict.

The survey on the Study Case 3, Jinshi Villages, revealed the degree of abandonment and dereliction in the water villages in Suzhou. Jiinshi Village is a linear settlement

located to the east bank of Tai Lake. The village consists of many clusters of commercial and residential buildings erected in different period of time and lying along a canal connecting to the Lake. The centre of the village features a continuous row of shop houses built in the 19th century (Figure 5). Not having undergone sweeping redevelopment, the village retains much of its original typo-morphological features as well as townscape character.

Currently, there are about 500 households and 1700 people living in the village. Around 35 houses are located in the historical high-street area, one third of which are unoccupied and only one of which retains its original commercial use – as a retail shop selling snacks, processed foods and daily products. Regardless of whether they are occupied or not, most of the houses are in a state of dilapidation, and some are practically inhabitable (Figure 6 & 7). The village did not undergo redevelopment as the residents have been dissatisfied with the compensation policy and refused to sign the agreement. The historic structures in the high-street area are left largely intact mainly because the residents hold the view that the government will resolve the disagreement in compensation costs at some time in the future and developers will bulldoze the area and develop it into a holiday resort or an upscale neighbourhood.

Figure 5. Aerial photo of the historical high street of the Study Case 3, Jinshi Village

Figure 6. Unoccupied shop-houses in the high street (left) and detached house (right).

Figure 7. Dilapidated and abandoned houses in the Jinshi village.

Whereas most of the historical buildings in Jinshi Village cluster together in the centre, the old houses in the Study Case 5, Nankun Village, scatter over the settlement. The Nankun Village is located in the Wujiang County which has been the major production centre of silk industry. The county appears to be extensively industrialized since silk production is a highly profitable enterprise and most of former rural households have turned themselves into entrepreneurs embarking on the new venture. Nankun Village is one of few villages in the county that retain much of the original rural morphology and character because of their remote locations.

Figure 8. Aerial photo of Study Case 5, Nankun Village

Houses in the village sit across the bay and form a crescent shape (Figure 8). With different heights, sizes, styles and locations, the residential structures erected in different periods of time reveal the track of historical development in the village. Short rows of houses form a right angle with the crescent-shape bay. Standing in between the 19th-century houses are the 20th-century structures that, in most cases, were built in the open space of existing old houses to accommodate new members of the extended family. As the new two-storey structures are higher than the one-storey old ones, the view toward the bay is dominated by the new (Figure 9). Although the old houses are being sandwiched by the new and not really noticeable in the bay view, they have a fairly strong presence in people's spatial perception when walking on the access road. All the old houses, however, appear to be unoccupied and used as shed to storage crops or tack firewood (Figure 10). They are left derelict simply because the cost for modernization and refurbishment is high and there is no growing pressure for space as before. Due to the decline of agricultural industry, the younger generations tend to leave the countryside to seek better employment.

4. A Possible Stimulus to Rural Economy: Rural Tourism Development

Although the Suzhou countryside is under the renewed threat externally from urbanization and rural policy and, internally, of the economic decline, demographic change and physical deterioration of agricultural villages, the rural Suzhou, with some external stimuli, still holds great potential to rejuvenate itself. It has been argued that one of most effective means of regenerating the countryside is the promotion of rural tourism.

4.1 Rural Tourism Development in China

While the rural farmers still constitute about three quarters of the country's total population, China remains to be the largest agricultural society in the world. It is not surprising that it began to venture into rural tourism development fairly late if compared with other economically advanced countries. However, also due to its

large number of rural population, the country's modernization programme has largely depended on the socio-economic aspects of regeneration (Su, 2011). The highlighted need to alleviate poverty in the countryside has been often linked to the diversification of farming activities as well as the promotion of tourism industry (Zeng & Ryan, 2012). Similarly, on the more ideological level, the connection between rural tourism development and the "Building a new countryside" policy is also accentuated (S. Chen, 2006; Peng & Li, 2008).

Since the early 1990s, the role of rural tourism has taken on an increasingly important role in the social-economic regeneration of China's countryside. Beginning from 1998, the China National Tourism Admiration launched a series of initiatives to promote the rural tourism development and assist the 359 exemplary tourist resorts and sites in the countryside nationwide. This shows that the China government, by now, was perfectly aware of the enormous range of cultural and natural resource in its vast countryside and began to direct its focus of attention to exploit these (Su, 2011).

Currently, the international and domestic tourism industries are booming in the three major regions: Pearl River Delta, Yangtze River Delta and Beijing Capital Region. It is suggested that the rapid development of tourism in the three regions has to do with their high economic growth rate and the clustering effect of historic cities in these regions (Zhang *et al.*, 2011). Certainly the tourism boom in the regions is mainly fuelled by the rich cultural heritage in the historic urban cores of these cities. However, for the Pearl River and Yangtze River Delta, it can be argued that the rich cultural heritage in the rural areas is easily comparable to that in the urban areas. Historically, the two regions thrived because of fertile farming land and rich agricultural production. On the account, man-made structures, cultivated land and natural surroundings in the two regions have been the long-lasting receptacle of agricultural practice that chronicles the history of mankind.

4.2 Rural Tourism Resource in Suzhou

Situated in the Yangtze River Delta that enjoys overwhelming superiority in developing rural tourism (J. Chen, 2006; Guoqing Wu, 2008), Suzhou is one of the historic cities that have long-lasting link with traditional agricultural practice. There is a substantial body of literature addressing rural tourism in Capital Beijing and Chendu City in Sichuan Province, but relatively little on Suzhou. (Guo *et al.*, 2008; W. Wang *et al.*, 2009; Su, 2011).

Generally speaking, rural tourism activities in China can be classified into three broad themes: agriculture, folk culture, natural resource and holiday resort (Guo *et al.*, 2008; Peng & Li, 2008). Among the four, agricultural tourism is the most popular one, and it is often known as "*Nong Jia Le*", meaning 'Joy of Farmer Home'. As Su (2011) and Guo *et al* (2008) note, the joy-of-farmer-home tourism originated in the 1980s when individual farmers tried to generate additional income by providing

authentic countryside cuisine and overnight accommodation in the farmer's home or a place to camp in the farm. In a sense, it was a type of full broad and lodging that targeted at customers who were often individual urban residents coming from the cities nearby and liked to spend a weekend away from the hustle and bustle of city life. In other words, the early form of rural tourism in China was an embodiment of 'green' or 'eco' tourism that is completely opposite to mass, one-off, theme-park-like tourism that is currently dominant in the domestic tourism industry. The profit that these individual economic activities could generate was quite modest. It is not surprising that, two decades later, it has turned into a tourism product that is capable of providing lodging and service to masses of tourists at the same time – typically in Labour Day, National Day and Spring Festival holiday. To attract repeat visits and also visitors from other regions and even foreigners, it has also evolved into a comprehensive holiday package encompassing all sorts of leisure activities or hand-on experiences, such as hiking, rowing, fruit-picking, fishing, cooking, knitting, pottering etc. A wide variety of hand-made products or traditional craft works are sold in the theme-park-like farms.

What role does 'heritage' play in the 'joy of farmer home' or, generally, rural tourism? The wide range of activities taking place in the joy-of-farmer-home tourism have involved both natural and cultural heritage. For the latter, it also includes both tangible historical settlements and houses and intangible folk customs and skills. Specifically about the built heritage, they can be the scenery or the scene for the leisure activities in the country side. While the statutory protected 'Heritage' like ancient water towns often serves as the scenery for rural tourism, it is usually the non-statutory protected 'heritage' like framer's houses or barns provides authentic rural scenes for leisure activities to take place. It is this 'heritage' – in lower case – that has the potential to promote and turn to eco-tourism in the Suzhou countryside, and to stage the 'joy-of-farmer-home' tourism in an authentic rural setting.

5. The Cultural Heritage Assets and Community Involvement

A question has to be asked is whether the existing cultural heritage assets, and the local communities too, can support and sustain responsive rural tourism.

5.1 Cultural Heritage Assets

Mundane and unassuming maybe, farm houses, animal shelters and storage sheds, together with rice paddies, fish ponds, vegetable patches, fruit orchards and canals characterize the rural landscape of Suzhou. As a result of abundant natural resource and fertile fields in the region, Suzhou has an exceptionally rich agricultural heritage that spreads across its rural areas. The mundane rural 'heritage' and agricultural landscape of Suzhou provides picturesque and tranquil settings that are as idyllic as the renowned water towns in the region (Ruan *et al.*, 2002; Zhou & Ma, 2007; Ruan & Yuan, 2011). Rural villages in Suzhou often exhibits a well thought out spatial arrangement, in which man-made built environment seamlessly blends into its

natural surroundings. They can provide places and host events for the 'joy-of-farmer-home' tourism in a more authentic fashion (Figure 11 & 12).

Figure 11. View of Study Case 1, Xitang Village

Figure 12. View of Study Case 3, Jinshi Village

The Study Case 2, Chuodunshan Village is an illustrative example that mundane rural 'heritage' is capable of staging eco-tourism. Instead of allocating the money from the 'Building a New Countryside' project to individual households to renovate private houses, the community committee used the government subsidy to improve the public spaces in the village. The local government consequently chose the village to be the site to pilot an environmentally-friendly water purification system. The overall quality of the public realm was significantly improved, although the spatial

configuration of the village was slightly altered to enhance accessibility and convenience (Figure 13, 14 & 15).

Figure 13. Aerial photos of Study Case 2, Chuodunshan Village, taken before and after the improvement of public realm. The outer service road and the footpath on the south bank of the east-west canal were added.

Figure 14. The public spaces in Chuodunshan Village

Most of the buildings in the villages were rebuilt in the 1980s. Some of them are in fact quite contemporary. In other words, no buildings in the village are of heritage value or 'historical' interest. Despite lacking backing from historic buildings, the local restaurant owners make the most of rural setting in the village and run their business in an ingenious way. The restaurant draws customers at some tourist sites or bus stations and attracts them by offering a free cruise along the waterway by motor yacht (Figure 16). Customers do some sightseeing within and around the village when the restaurant is preparing meals. Most of the ingredients used are sourced locally. There is a large tract of land to the southeast of the village, and many small patches in front of houses too, where the local residents grow various kinds of seasonal vegetables or breed livestock. The amount of local produce has not only proved sufficient for the consumption of local residents' consumption but has also provided the restaurant local ingredients. The restaurant seems to do good business in

the area as many customers also come to the restaurant by private car. The restaurant gives a fascinating example of how to use the picturesque settings and agricultural landscape of rural villages to brand its countryside cuisine.

Figure 15. Canals and footpaths. Many daily activities of local resident, such as cleaning and chopping vegetables and washing up are taking place along the canal.

Figure 16. The restaurant (middle) provides customers a free cruise along the canal and arrive the village by motor yacht. It also sources most of its ingredients locally.

5.2 Community Involvement in Rural Tourism

To promote eco-tourism in the countryside, it is essential to have the rural communities to support and sustain. The policy of ‘Building a New Countryside is a double-edged sword for rural communities. Under the policy, the implementation of land consolidation optimizes agricultural production but many farmers were, in a sense, made redundant. Also under this policy, China’s countryside has gradually transformed from an agriculture-based society into one with a mix of different industries. The promotion of rural tourism is beneficial to a smooth transition from primary industry to the tertiary. Loss-land farmers can take part in the development of rural tourism. Certainly, the existing theme-park-like tourism models also help resolve the he surplus of rural labours. However, as Su (2011) points out, if rural tourism industry is intended to expand its market and move toward high-quality,

personalized services, the government and competent authorities should provide training, finance and marketing support to rural communities. It is also noted that some younger generations of formal rural residents begin to move back to the countryside and start up small-scaled enterprise related to rural tourism development.

On the other hand, the older generations also have an important role to play. Traditional crafts, customs, cuisines and farming techniques, for instance, are the intangible assets that suffer from decline. Much of the traditional handicraft products in Suzhou, such as embroidery and bamboo weaving are produced in rural areas as home-based enterprises. Whereas the term 'rural heritage' denotes an attractive combination of natural and cultural heritage, the term 'cultural heritage' also encompasses both tangible and intangible assets. The importance of intangible rural heritage should be equal to the tangible (Zheng & Zhong, 2004).

6. Conclusion

The paper has examined the external threats to rural heritage posed by the rapid peri-urbanization expansion and the government's 'Building a New Countryside' policy. It also explained the internal factors that caused the desertion of tangible heritage. The current development of rural tourism industries in China was also reviewed to understand the potential of Suzhou for promoting such economic activities. The paper argued that the truly rural heritage that Suzhou has is the everyday life setting in the countryside that provides local communities with a stage to develop responsive and eco-tourism in the countryside. It is this 'heritage' in lower case that better reflects the lives in the past and communicates the present generation. It also has a greater flexibility in making changes and a greater potential to stimulate local economies and promote sustainable tourism with the involvement of local communities.

Implementing A Regional Sustainability Plan With Scenario Based Planning

Robert Paterson, Elizabeth Mueller Michael Oden, Barbara Wilson and Ming Zhang,

The University of Texas Centre for Sustainable Development

Abstract

A great many regions and communities in the US and Europe have invested heavily in the development of regional plans to promote more sustainable community development. The transition from plans to plan implementation is often difficult as buy-in among regional stakeholders is not always uniform nor always positive. In recognition of such problems, the US Department of Housing and Urban Development initiated a Sustainable Communities Grant program which allowed regions of the US to compete for funds to undertake collaborative plan implementation processes.

The Central Texas region was a recent recipient of one of those US HUD Sustainable Communities Grants engaging a broad spectrum of regional stakeholders in the development of scenario planning software to explore the creation of sustainable activity centers in the next 30 years in urban, suburban and rural settings. This paper describes efforts to create a second generation scenario based planning software system that better enables communities to make informed choices about the creation of more sustainable land use patterns. The great promise of scenario based planning is that it provides an immediate feedback loop to participants on "what if" land use scenarios so that inappropriate or incompatible development can be avoid or minimized. The new software program also strives to be educational in that it provides design solutions and choices when adverse effects arise in its indicator report system. The paper describes the current regional collaboration and network of partners that are developing the software suite. It details the sustainability indictors being developed for the analytic software suite. The paper concludes with a discussion of long term objectives for the software on an open source platform with internet browser accessibility.

Implementing A Regional Sustainability Plan With Scenario Based Planning

Robert Paterson, Elizabeth Mueller Michael Oden, Barbara Wilson and Ming Zhang,

The University of Texas Centre for Sustainable Development

Background

In June 2009, the Secretary of the US Department of Housing Urban Development, Shaun Donovan, announced the Sustainable Communities Planning initiative coordinated within the Federal government's Interagency Partnership for Sustainable Communities. The Obama Administration is seeking to transform the way federal grants and programs facilitate sustainable development practices in US metropolitan regions by creating better interagency coordination and cooperation, and providing planning and implementation grants to regions that propose to collaborate and define a shared vision of sustainability through regional planning. That initiative led to the creation of a new *Office of Sustainable Housing and Communities* within HUD to coordinate the initial $100 million grant program. Three federal agencies--the US Department of Transportation, the US Environmental Protection Agency and US HUD--have committed to focusing their grant and infrastructure investment efforts to help advance six overarching Livability Principles to help American families gain better access to affordable housing, more transportation options and lower transportation costs, while protecting the environment and reducing energy dependence on fossil fuels. In 2011, HUD expanded the initial planning grant program to include a second category of grant recipients--*Detailed Execution Plans and Programs* for those regions that already had completed and adopted a regional sustainability plan.[1] An additional $67 million in grant funds became available for the second year of the program. Seventy four regions were recipients of the Sustainable Community grants (see figure

1 below), however the Interagency Partnership for Sustainable Communities boasts $3.5 billion in directed support to metropolitan regions in the US.[2]

Figure 1: Sustainable Communities Regional Planning Grantees (2012)

The overall objectives of the 2011 round of grants are to: (1) support metropolitan areas and multijurisdictional partnerships to adopt integrated plans, strategies, and management tools; (2) create strong alliances of residents and regional interest groups able to maintain a long-term regional vision and simultaneously support incremental sustainable development practices; (3) build greater transparency into planning efforts and assess progress toward national goals by identifying best practices and performance; (4) expedite implementation of the Livability Principles through changes in local zoning and land use that remove barriers to sustainable development; (5) assist regions that have shown a long-term commitment to sustainability to prepare for implementation and demonstrate on-the-ground results; and (6) identify how Federal agencies can better support local and regional planning and reduce redundant and conflicting Federal requirements.

A consortium of Central Texas governments, NGOs and interest groups received one of the 2011 Sustainable Communities Partnership implementation grants. The Consortium proposed to build off the region's successful regional planning venture and develop a next generation scenario based planning software suit to help the region's 20+ cities and five counties to implement their preferred regional vision adopted through the Envision Central Texas process. This paper describes the Central Texas regional collaboration and network of partners that formed and are developing the software suite which will be completed by the end of 2013. The software suite will be public domain and freely available to regions through the US and world. The paper describes the sustainability indictors being developed for the analytic software suite as well as additional software capabilities. The paper concludes with a discussion of long term objectives for the software on an open source platform with internet browser accessibility.

The Capital Area Texas Sustainability (CATS) Consortium and Partners

The Capital Area Texas Sustainability (CATS) Consortium is a broad-based collaboration of public, private, academic and nonprofit stakeholders in the Central Texas region (Austin-Round Rock MSA) that seeks to build on the region's previous sustainability efforts and to implement the region's plan and vision for sustainable development. At the start of the project the core members and partners of the consortium included:

- Capital Area Council of Governments (Lead agency)
- Capital Area Metropolitan Planning Organization (CAMPO) (the regional transportation authority)
- Envision Central Texas (ECT) (a 501(3)(c) nonprofit organization for regional planning and implementation)
- City of Austin, including its planning, housing, transportation and economic development departments
- City of Round Rock
- City of San Marcos

- University of Texas at Austin, The Center for Sustainable Development (lead), The Texas Advanced Computing Center, and the Center for Transportation Research, the University of Utah, Metropolitan Institute
- IBM, through its Smarter Cities program (IBM later dropped from the team due to licensing concerns)
- Fregonese and Associates, HDR Associates and Criterion Planners (replacement firms for the IBM role)

The foundation of the CATS Consortium sustainability implementation effort is the regional vision and preferred growth scenario developed between 2002-2004 by Envision Central Texas (ECT), a broad-based regional nonprofit with extensive community participation by more than 12,000 Central Texans (see figure 2 below).[3] The physical plan reflects efforts to concentrate substantially more growth in largely existing community centers and to move regional transportation infrastructure investments toward more multimodal choices include transit, biking and pedestrian systems.

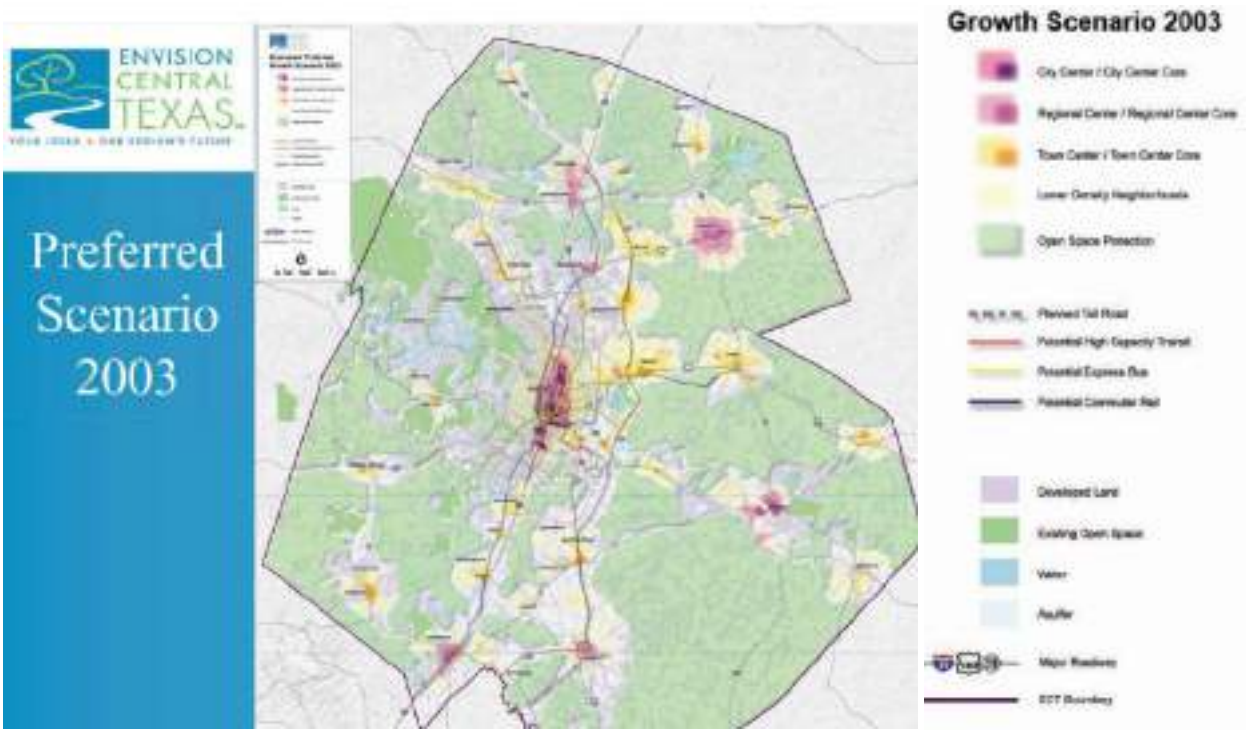

Figure 2: The Envision Central Texas Preferred Growth Scenario (2005)

Source: Accessed at:
http://envisioncentraltexas.org/resources/resources_74_Preferred_Scenario_2003_illustration.pdf

The core elements of the regional vision include:

> ***An effective transportation system that improves mobility throughout the region, increases transportation choices, including roads, rail, trails and bikeways, and is coordinated with land use planning.***
>
> ***Protection of our environment and natural resources so we will have the open space, parks and trails that people cherish, preserve our ecologically sensitive land and ensure sustainable clean water and air for future generations.***
>
> ***A diverse and thriving economy with a robust base of businesses and quality job opportunities for citizens and a distribution of jobs throughout the region.***
>
> ***A variety of housing choices, affordable for everyone in the region and offering a mix of styles, such as neighborhoods with pedestrian-friendly streets or housing that is within walking distance to transit and stores.***
>
> ***Preservation of our region's unique character by protecting and enhancing or neighborhoods, towns, rural areas, historic sites, and special sense of place.***
>
> ***An understanding that social equity and racial harmony are core values that strengthen us and actions that foster respect, civility, and opportunities for all.***
>
> ***A region -wide understanding that our fortunes are tied together requiring planning, participation and collaboration by stakeholders throughout our region to ensure a successful and livable future for Central***

In 2008, ECT undertook a progress assessment on regional efforts to implement the adopted plan and vision, and concluded that while there remained strong support for the regional vision and the need for coordinated land use and infrastructure planning, a major barrier to implementation was that many localities lacked the resources to plan and implement plans in their own jurisdictions.[4] Many localities lacked the staffing and technical support to craft activity center plans, CIP programming and land development code modifications to implement the preferred scenario in their own jurisdictions. However, despite these limitations in terms of local efforts to

advance the vision, two important accomplishments were completed in the years immediately following the ECT plan that added both credibility and stronger coordination of regional planning efforts: those were the ***Central Texas Greenprint*** and the ***CAMPO 2035 Long Range Transportation Plan***. [5]

Between 2006 and 2009, the Trust for Public Lands, CAPCOG, The University of Texas, and City and County governments in the Central Texas region undertook a Greenprinting process (i.e., open space and preservation lands suitability mapping) taking into account lands necessary to protect water quality (especially riparian zones) and quantity (i.e., karst recharge areas); ecologically sensitive areas such as endangered species habitat; prime farmlands and ranches; important recreational resource lands; cultural and historic sites, and scenic corridors to assist localities in defining priority lands for protection from land development. The project created an interactive GIS map system that enables state and local governments to query land development and infrastructure development proposals against the regional open space maps to prioritize protection programs and measures; to avoid water, sewer and transport infrastructure decisions that would conflict with the green infrastructure plan, and to enable acquisition of the highest priority lands as development in the region proceeds. [6]

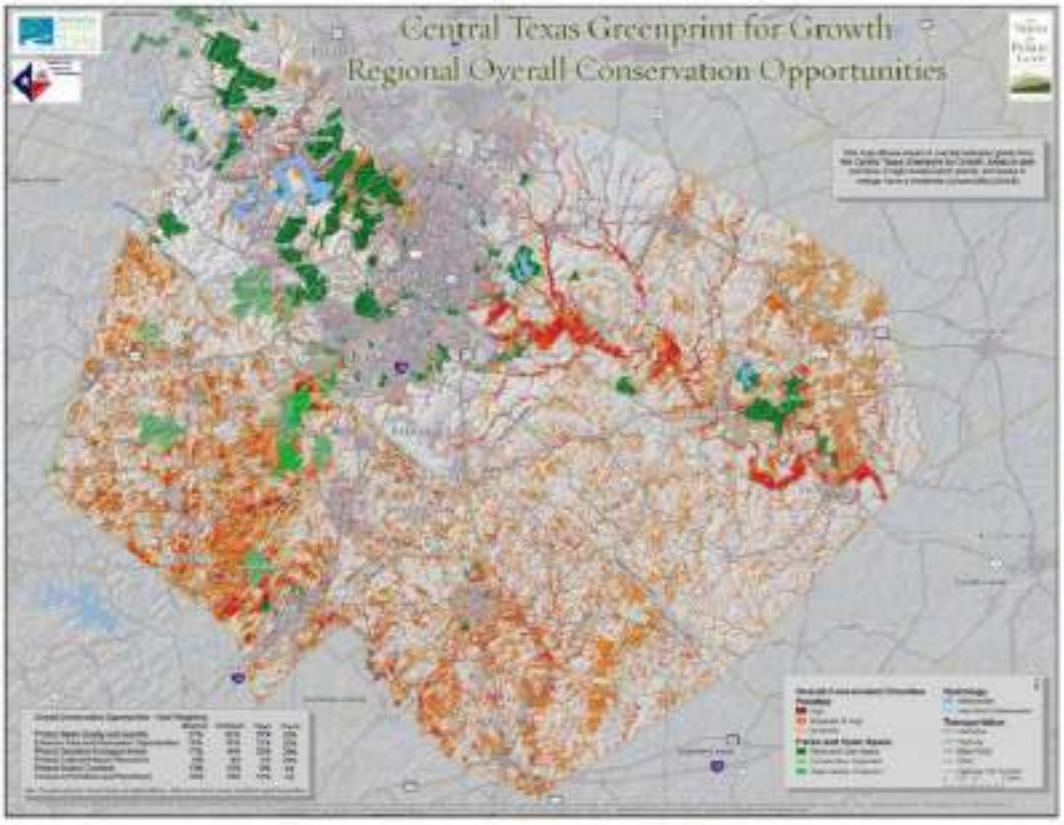

Figure 3: The Central Texas Greenprint

The ECT vision and preferred growth scenario and Greenprint in turn informed the creation of CAMPO's 2035 Long-Range Transportation Plan, which envisions future regional growth being accommodated in a network of 37 mixed-use, mixed-income, walkable, connected and transit-supportive Activity Centers that provide a balanced mix of jobs, housing and services, primarily within the context of existing communities (see figure 4). The Activity Centers concept is designed to improve the region’s livability outcomes in such areas as transportation system performance, air and water quality, and social equity and opportunities for revitalization.

Under the Centers Concept, funding is targeted to expand the region’s public transit system (including buses and rail), to implement a network of high capacity roadway lanes, and to build new arterials serving the mixed use centers. CAMPO intends to create a specialized program that

sets aside 50 percent of future Surface Transportation Program Metropolitan Mobility funding for projects that support the activity centers shown on the Centers Concept map. Those funds would be available to a wide range of projects to enhance transportation and livability in Activity Centers, including bicycle and pedestrian improvements, travel demand management projects, transit projects, and planning studies. Project selection is expected to be based on the extent to which the transportation project would leverage local planning and investment resources to create a successful mixed use activity center over time.

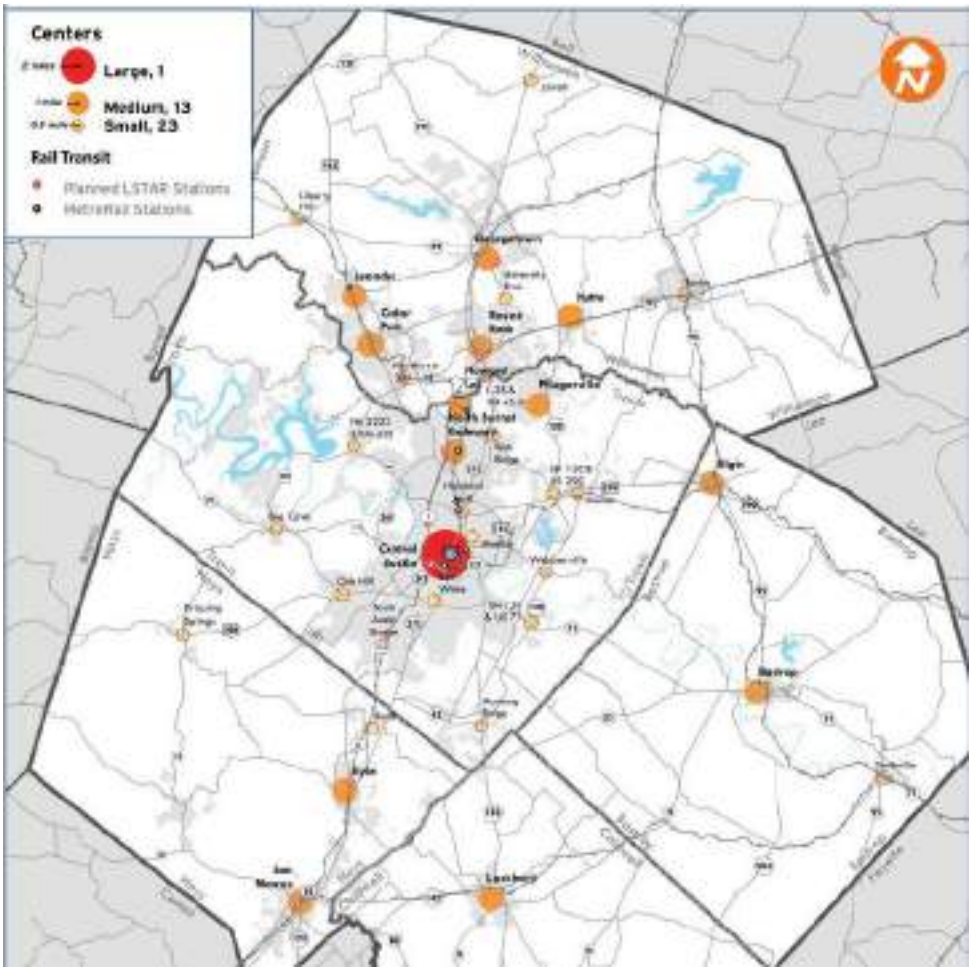

Figure 4: The CAMPO 2035 Long Range Transportation Plan Growth Concept Map (2010)

The HUD Regional Sustainability Planning Grant has enabled the CATS Consortium to focus on innovative and practical strategies that will help bring the Activity Centers concept to fruition within the context of Central Texas, where the power to make the key planning and investment decisions necessary to implement the concept belongs almost exclusively to local communities. The strategies include:

1. Development of a **Sustainable Places Analytic Tool** in partnership with the University of Texas partners and contractors that allows for scenario based planning at multiple levels with sustainability metrics that are responsive to local values and concerns within the host localities and their Activity centers.

2. **Demonstration Projects** (applying, testing and refining the analytic tool) at selected Activity Center sites to implement best practices for and overcome obstacles to compact, mixed-use, mixed-income development with balanced jobs and housing linked to the local and regional multimodal transportation network.

3. Broad-based **community engagement** (along with focused engagement around Activity Center demonstration sites) to build awareness and consensus around the Livability Principles and sustainability strategies.

4. Development of, and ratification of a **regional Compact** between cities and other jurisdictions committing to the adoption of common planning elements and supporting the coordination and integration of local comprehensive plans.

The remainder of the paper focuses on the analytic scenario software system that will be beta tested at the demonstration site communities.

The Sustainable Places Project Analytic Tool Suite

One of the more important developments in US physical planning over the last 15 years has been the increased use of scenario-based planning approaches at regional and local levels where land use and transportation decision making and their interrelated impacts on community

sustainability issues can be iteratively explored with indicators that provide the all important feedback loop on decision making. According to Bartholomew and Ewing (2010) the birthplace of this emergent area of planning practice can be traced back to two projects in the late 1980s and 1990s that looked at land use planning and transportation investment choices in a systemic manner: Montgomery County's Comprehensive Growth policy Study and the 1000 Friends of Oregon's LUTRAQ project. Both projects led to better consideration of the impacts of alternative land use and transportation development scenarios.[7] Since that time Bartholomew and Ewing (2010) have documented 74 regional scenario planning projects in the US. Often times these scenario planning efforts fall under the rubric of Blueprinting or Regional Visioning projects.

Some of the more notable success stories that have used scenario planning to inform public opinion and garner support for more sustainable land use and transportation investments include: the Portland Metro 2040 Vision; the Sacramento Blueprint, Envision Utah, and the Wasatch Choices 2040 plan.[8] The Envision Central Texas vision and preferred growth plan also built on that tradition, working with the planning consulting firm Fregonese and Associates using ARC GIS based scenario planning tools in development of the regional plan. The scenario planning process and software enabled the region's citizens and public to more realistically evaluate future land use patterns and their potential impacts on the region’s transportation system, land fragmentation, housing supply, farm and working lands, jobs-housing proximity and balance, as well as environment and natural resources impacts (among other measures).

As a result of the persuasive effect that scenario planning had on the Central Texas regional planning efforts, the CATS Consortium believed that one of the most important ways to help Central Texas localities realize plans to design and create more livable activity centers would be through the creation of the next generation scenario planning software. As defined by the

Consortium, the next generation of scenario planning software would need to meet several pressing needs, including: (1) minimizing the GIS data collection import and cleaning operations that would be needed to use the software, (2) allow for creation of land use scenarios that are based on market realities and not just land use class distinctions, and that can operate at a district or neighborhood scale, (3) enable scenarios that offer a host of metric and indicators that can be matched to local interests and value as opposed to what a technical planner might say is most important, (4) scenario software that serves more of a learning and solutions function than the current generation of software offers, (5) software that serves both the planner/ consultant works but also that some accessibility for officials and the public, and (6) software that links alternate development scenarios to visualization and on-line preference ranking to expand public dialogue away from the charrette or planning workshop.

To that end, the Consortium and its partners assembled a team of planning academics and consulting firms to accomplish those tasks to create the next generation of scenario planning software. The remainder of this section highlights each of the core components of the software project development and partner contributions.

A. The Sustainable Place Project Data Schema and Wizard

During focus groups with the Central Texas region's local planning directors, we learned that one of the more significant barriers to the use of scenario planning software at the local level are the substantial transaction costs associated with getting ARC GIS data layers needed to do the analysis, ready for use and imported in a compatible format with the software. Although a great deal of land use, economic, social , demographic, environmental, and infrastructure data is readily available in ARC GIS compatible formats, a number of issues can arise and require data

cleaning and other forms of manipulation (e.g., differing coordinate and projection systems) to be compatible enough with the ARC GIS software to be accurate and usable for scenario planning purposes. The CATS Consortium has contracted with Criterion Planners Inc., who are the creators of scenario planning software package known as INDEX, to create a standardized data schema and data quality wizard to (1) reduce time loss due to uncertainty about GIS data formats and fields, and (2) to provide automated routines to correct common data cleaning problems such as removing bad geometries (e.g., null, self-intersecting, irregular polygon slices, etc), street-centerlines-to-parcel-rights-of-way alignment checks, multi-part demographic parcels split issues, proper boundary-to-land-use topology and technical design coordination to ensure the software can be ported to an open source platform as those GIS options become more viable in the coming years. Data schema and wizard is designed to reduce uncertainty, increase transparency and ease of use for the new software system.

B. The Sustainable Places Project: Envision Tomorrow Plus Software

The CATS Consortium considered a variety of alternative software products that we could work with that were already considering going open source so they could meet the terms of the HUD grant. After meeting and discussing the project with multiple software vendors the CATS team selected the Envision Tomorrow (ET) software package created by Fregonese and Associates because it came the closet to meeting many of the CATS consortium objectives. First, as a result of an existing collaboration with the University of Utah Metropolitan Institute, the ET software was already undergoing changes in terms of modeling land use scenarios from a building typology instead of a land use or place based typology. By basing land use planning scenarios on a building library, it becomes possible to create development pro formas for each building type to ensure that market feasibility is built into the model from the beginning. Typically a

library of 30-40 buildings with a pro forma for each building type is created as back ground work to scenario development with a series of focus groups with area developers. Once that step is completed land use classes or place types can be constructed from a cross section of building types, reflecting variations in land use densities and intensities for urban, suburban and rural market conditions. This called the *Return on Investment Analysis System* which is an interconnected group of excel spreadsheets that are linked to the ARC GIS attribute tables.

A second major advantage of the ET software was the interplay between excel building information and sustainability indicator formulas. Thus, once a design workshop begins and alternative land use and transportation alternatives are being painted in ARC GIS, the results are being dynamically relayed to the spreadsheets enabling on the fly calculations if sustainable community metrics that can be viewed in parallel format with the scenario development. This enables real time learning of the consequences of multiple land use choices through an interactive display. The University of Texas at Austin, the University of Utah and other partners are creating a new suite of sustainability analytic tools and indicators that can be selected by localities to explore the consequences of alternative development schemes depending on communities values and interests. It expected that somewhere on the order of 40-45 sustainability indicators can be toggled on or off by the user. A major enhancement over existing software packages is the addition of pop-up windows for each sustainability indicator that explains the theory behind each indicator, the connections between the indicator and livability concerns, and links to design solutions via hypertext links to online sources and a bibliography.

Additionally, several special analytic capabilities are also being created that required considerable local or regional calibration to be useful in other regions such as a fiscal impact

model that accounts for variation in land uses and development densities on infrastructure costs and local operating and capital budgets. A 7D transportation travel estimation application that provides instant feedback on a variety of transportation related indicators during the scenario creation process. The tool will estimate travel behavior (auto, transit, walk/bike) from land use scenarios.. A housing and transportation costs estimator will allow analysis of the interplay between the two elements, and estimate the combined housing and transportation costs from different scenarios. An air quality and green house gas estimator will be created based on changes in VMTs and mode shifting from alternative land development scenarios. A public health estimator will build off the 7D estimator building on a meta-analysis to predict public health implications from the travel behaviors and recreational opportunities that derive from alternative land use scenarios. Rates of obesity and associated health outcomes (coronary heart disease and Type 2 diabetes) may also be estimated based on research findings. Other estimators are under development with the idea being that the software will ultimately function like an apple iphone where with open source code access additional analytics can be add like "apps" on an iphone.

C. The Sustainable Places Project Browser and Participatory Engagement Template System

Once a community has completed a design workshop process and created 2-4 alternate development scenarios for its downtown or other focal area, the question is how does a community get by-in from its public to that envisioned future, and engage the public in a dialogue on those planning results in a meaningful way. To address this issue, the CATS consortium contracted with the Texas Advanced Computing Center to create an on-line public engagement software system where products from charrettes can be easily ported to a web template for on-line public participation. A second objective is to take the ET software in a more

limited fashion into a web based browser environment so citizens can explore "what if" scenarios themselves for their city. It is hoped that eventually the project will be able to engage with ESRI city engine modeling system to enable high quality 3D visualization as well. However, this is a long term hope that is not included in the project's current grant scope.

D. The Sustainable Places Project Into The Future

Perhaps the most important part of this project from the CATS Consortium perspective is the shared interest in growing the software system well beyond the end of the HUD grant period in 2013. It is hoped that the system will continue to evolve and grow eventually into the open source GIS environment. There is strong interest among the Consortium members to seek out additional grant funds to refine and improve this evolving software system.

WHAT MAKES THE OLD CITY STICKY? RETHINKING THE ECONOMIC GEOGRAPHY OF ISTANBUL'S JEWELLERY SECTOR

Yiğit Evren[1]

Abstract

This paper examines the structure of Istanbul's jewellery industry and its locational dynamics. It focuses on the old city jewellery cluster which is one of the oldest and the largest urban industrial districts in the city. This cluster is characterized by large number of small scale artisanal producers relying on outworkers for almost all stages of production. The paper illustrates the vital role of place in jewellery making by examining the extent to which agglomeration within the old city contributes to this sector's creativity, competitiveness and sustainability. The paper also provides some policy implications within the context of various threats and opportunities in the jewellery sector.

1. Introduction

Jewellery industry has frequently been regarded in economic geography as a noteworthy exemplar of the complex relations between spatial clustering and economic performance. A classic study of the jewellery quarter in Birmingham provides substantial support for the significance of local linkages between firms and the specialized urban-industrial concentrations (Wise, 1949). Most of Wise's observations were echoed in a series of more recent works. A group of researchers led by Lisa De Propris in Europe, for instance, have investigated the structure of the jewellery industry under the umbrella of the debate on the link between the governance of local production systems and the development of localities (Propris and Wei, 2007; Propris and Lazzeretti, 2007; Propris and Lazzeretti, 2009). Across the Atlantic, we have been witnessing that this sector has been discussed in the context of the social bases of industrial agglomeration (Scott, 2000). Since the re-discovery of clusters as a competitive advantage in the mid 1990s and as an inevitable response to the so-called cultural turn in economic geography in the early 2000s, the jewellery industry has received considerable interest from various disciplines (Carnevali, 2003; Pollard, 2004a; Pollard, 2004b; Wood et.al., 2004; Bagwell, 2008).

The common message from the vast writings in economic geography literature on jewellery industry seems to be that this sector has a craft-based and labour-intensive

[1] Yıldız Technical University, Istanbul, Turkey - yigitevren@gmail.com

character and as in the cases of Birmingham, London, Los Angeles and Bangkok, the production occurs in dense networks of interfirm linkages underpinned by social and cultural settings (Scott, 2000). Furthermore, producers tend to locate in geographic space in the form of localized urban-industrial districts and these industrial districts are in or close to the centre of most cities.

Nevertheless, there is no single deterministic relationship between particular forms of organization of production and their geographies as Hudson (2000) rightly contends. In this context, more empirical evidence from relatively less explored localities will improve the present structure of jewellery making. Bearing these issues in mind, this paper examines the structure of Istanbul's jewellery industry and its locational dynamics[2]. The paper is structured as follows. Part 2 sets out the theoretical concern of the paper. It provides a review of the literature on the spatial organization of jewellery making. Particular emphasis, here, is placed on clustering. The following part provides a background to the empirical study by focusing on the significance of the jewellery industry to Istanbul's local economy and its changing structure. Part 3 discusses the role of place in jewellery making. It examines the extent to which agglomeration within the old city contributes to this sector's creativity, competitiveness and sustainability. The paper concludes with the main discussion point of this research and provides some policy implications within the context of various threats and opportunities in Istanbul's jewellery sector.

2. Spatial organization of jewellery making: lessons from the clustering literature

Why do jewellery producers cluster in cities and why they do so in inner city areas? This has been, not just in the context of jewellery making of course, perhaps one of the most popular debates in the economic geography literature. Let us begin with the conventional view of agglomeration, which is based on the concept of external economies of scale or scope that flow from firms locating in the same area. This is originally Alfred Marshall's (1890) view of agglomeration and it indicates that by co-location firms reduce their costs with respect to the accessing of specialist skills, supporting industries and knowledge spillovers. Furthermore, firms overcome the limitations of short term contracts by developing personal relations and engaging in active cooperation.

According to Dicken, the subsequent growth and cumulative development of a localized economic cluster tends to be based upon two sets of agglomerative forces, namely traded interdependencies and untraded interdependencies (Dicken, 1998: 11). The former represents the desire of firms performing different but linked functions in

[2] Part of this paper draws on the sectoral analysis report (Evren, 2010) which I submitted to the Istanbul 2010 European Capital of Culture Agency as part of the "Istanbul Inventory of Cultural Heritage and Cultural Economy Compendium" Project funded by the Agency and the Turkish Academy of Sciences (TÜBA).

a production chain to reduce their transaction costs by locating close to each other. The latter represents the less tangible and mainly socio-cultural benefits derived from geographical clustering. These are face-to-face contact, social and cultural interaction and the enhancement of knowledge and innovation. This is the socio-cultural basis of agglomeration as Dicken puts it, enabling firms to maintain trust, establish partnerships, develop rules of behaviour, track innovations and thus provide rapid responses to changes in demand patterns.

Maskell and Lorenzen (2004), however, conceptualise clusters as market organizations, arguing that geographical proximity is derived from firms' efforts to achieve resource efficiency, especially under the conditions of uncertainty. According to this view, if markets, or more precisely customers, suppliers and products are unstable, firms tend to form clusters by engaging in two main types of interaction with each other, both of which can also be considered as distinctive agglomerative forces. The first one is, as Maskell and Lorenzen name it, project relations and it arises if ambiguity in industry prevails and firms regularly need to redefine the specifications of their products. The second one is flexible relations established by firms which frequently need to expand or reduce their output or adjust their product range to provide variety due to high levels of industrial uncertainty (Maskell and Lorenzen, 2004: 995). In both cases geographical proximity between firms sharing the same value chain is a prerequisite for their survival.

Indubitably, the above-said explanations in clustering literature provides a useful theoretical stepping stone for understanding the locational dynamics of jewellery producers. Nevertheless the importance of urban dimension in clustering, more precisely the role of inner city areas, deserves a closer look since geographical concentration of this sector in urban industrial districts is the norm not the exception. In this respect, Porter (1995) identified four key advantages of the inner city. These are strategic location, local market demand, integration with regional clusters and human resources, all of which make the city centre attractive for various economic activities. According to him, inner city areas are surrounded by central business activities, an entertainment zone and well-established logistical infrastructure. These areas are the places in which close linkages are shared between different businesses, the local market can hardly be saturated and residents eager to work for relatively low wages.

Lorenzen and Frederiksen (2008), on the other hand, refer to the concept of urbanization economies to explain the tendency of creative sectors to locate in cities. 'Urbanization economies' denotes the gains acquired by firms from being located in a city. These positive externalities, as Lorenzen and Frederiksen argue, arise from the regional diversity in cities. First of all, cities are the places in which co-ordination between unrelated knowledge bases can take place. In other words, by locating in cities firms producing different products can get the opportunity to establish temporary collaborations and create novel products. Secondly, urban areas are the places of overlapping labour markets. These rich skill pools underlie innovation and competitiveness. Finally, cities accommodate a wide palette of institutions and

infrastructures both of which serve as pipelines to global markets and knowledge networks.

3. Jewellery industry in Istanbul: an overview

For over 500 years Istanbul has been one of the most important centres of Turkish jewellery production. The key trigger to sectoral development in the city was the granting by Byzantine Emperors of tax exemptions to jewellery makers (Akın, 2008). However, it is argued that the placement of Armenian manufacturing jewellers in the Istanbul's old city and the establishment of the Grand Bazaar by Fatih Sultan Mehmed II in the mid 15th century were the two most important milestones in the history of jewellery making in Istanbul. Thanks to palace demand for jewellery products and the interest shown by several Ottoman Sultans (e.g. Yavuz Selim and Süleyman the Magnificent) in jewellery making, the sector grew continuously in this period. This laid the foundations for Istanbul, the historical peninsula in particular, to become the primary centre of jewellery production in Anatolia.

At present, the Istanbul sector comprises 79% of manufacturing firms and 85% of all employment in the Turkish jewellery sector. It has been estimated that more than 18,000 people are employed in approximately 5,000 workplaces in Istanbul. Furthermore, the local jewellery sector in Istanbul generates 96% of national jewellery value-added (Köroğlu et.al. 2010). In 2009 the total value of exports realised by 733 Istanbul-based jewellery producers was 931 million dollars, which is around 95% of all jewellery exports in Turkey in that year. It is clear from these figures that Istanbul has indubitably played a key role in the Turkish jewellery sector becoming, in 2008, the world's third largest global producer after India and China, with 183 tons of jewellery made.

Over the past two decades Istanbul's jewellery sector has experienced a structural transformation from small-scale artisan production to mass production (Evren, 2010). The changing conditions of the Turkish jewellery market and intensified competition in the global jewellery sector have encouraged some local producers to standardise their products and use vertical integration strategies in order to realise economies of scale. We have also witnessed the internationalisation of the local jewellery sector; several large scale producers have set up their own retail stores abroad or established liaison offices and offshore production facilities in order to penetrate various international markets such as China, Russia and the United States (Gereffi, 2007).

These developments have led to some important changes in the traditional jewellery value chain. On the one hand, small workshops, which are unable to adapt to changing conditions and therefore cannot compete against large-scale producers, have been severely affected. At present, craftsmen doing relief-work, engraving or enamelling appear to be experiencing the greatest struggle for survival in the market. Hence the number of artisan producers as such has fallen substantially. Conversely, jewellery design, which was predominantly an in-house activity of small workshops, has become a creative profession pursued by specialist designers rather than

craftsmen. The author's previous investigations indicate that there are at least six types of jewellery designer in Istanbul who differ from each other according to the size of production and power of their brands (Evren, 2011).

In some circles within the sector there is growing optimism about the possibility of Istanbul to becoming a world leader in jewellery production. Nonetheless, as far as the overall industry is concerned, the sector still fails to set new global trends and is associated with the production of relatively low value-added designs and products.

4. Unpacking the old city jewellery cluster

In Istanbul, the jewellery industry is clustered in three different localities within the metropolitan area. One of these clusters is Kuyumcukent, a recently finished complex just outside the Atatürk Airport at the western end of the city. Kuyumcukent is the largest goldsmith complex in Turkey, consisting of more than 650 small and medium-sized jewellery manufacturing workshops as well as several wholesale stores, factory-type workshops and retail stores. The other cluster is in a vast urban area stretched alongside the E-5 Highway on the European part of Istanbul between Kuyumcukent and the old city. There are about 100 large jewellery factories in this cluster, many of which utilise contemporary production technology.

Yet, the sector is predominantly located in the old city. Today the Grand Bazaar, in which the sector was first established and locally clustered, houses around 400 traditional jewellery producers (Köroğlu et.al., 2009; Eceral et.al., 2009). Taking other artisanal producers located within the immediate environment of the bazaar and the *District of Hans* into consideration, the total number of producers comes to around 2100. Such a figure indicates the significant clustering of small-scale jewellery production in the old city of Istanbul. Istanbul's old city is also the home to a number of jewellery-related institutions, notably İKO (Istanbul Chamber of Jewellery) and a School of Jewellery. These institutions, together with a wide palette of producers operating in different segments of the highly disintegrated value chain, and a great number of supporting cast including importers, wholesalers, retailers, designers and machinery and tool manufacturers comprise a place-specific economic diversification which lead to industrial synergies in Istanbul and a unique manufacturing culture in the old city.

In light of these comments, now we can turn our attention to the logic of agglomeration. What makes the Istanbul's old city sticky for different actors of traditional jewellery making? I will try to answer this question by providing three different views on agglomeration. In doing so, I will draw up-on over 70 in-depth interviews which I have conducted with various goldsmiths and silversmiths, designer-makers, gemstone and bullion dealers and other jewellery-related traders in Istanbul since 2009. Here I quote only three of them.

The first view belongs to a goldsmith who has been working in one of the workshops located just outside the Grand Bazaar since the early 1980s. According to him the

"glue" of the old city is its unique business ecology which allows firms producing similar products to compete and collaborate. On the one hand, co-location provides the opportunity for jewellery producers to watch their competitors closely, and thereby compare their own performances. On the other hand, the old city represents a dynamic market with full of unexpected opportunities:

> "About a moth ago, a talkative friend [also a competitor] popped in my workshop. During our chat, he saw one of my latest earrings and wanted to borrow a sample. I was very busy at that time and wanted to get rid of him. So I gave him a pair to leave me alone. Two weeks later he came back and told me that he had signed a fat juicy contract that will make us both rich! Since then I have been working to meet that order day and night. You see? There is trade in downtown's air. In every corner you run into a friend and you never know when an ordinary greeting can lead to new business opportunities."

The second view is from a retailer who sells affordable gold-pieces for low-volume markets in the Grand Bazaar. During the interview, he talked about the advantages of locating with the same cluster with small-scale producers which are able to meet their highly fluctuating demands. In this context, the old city jewellery cluster facilitates easier and faster access to specialised inputs making it preferable to other localities in the city.

> "Foreign tourists are our main customers. Normally this type of customer has limited time for shopping. This means that you have to be ready to make any kind of modification [changing the size etc.] on your products in accordance with our customers' preferences. This requires most of us to work in close collaboration with a goldsmith nearby. In cases as such, my assistant takes the product to the goldsmith's workshop, have it modified within minutes and brings it back. Meanwhile, my mission is to keep my customer in the store as long as possible."

The third view comes from a charge hand who works for a polishing house. This interview illustrates how production and exchange within the sector are supported by complex and place-specific social settings. Behavioural patterns, norms, accepted rules, conventions and other institutional arrangements constitute the institutional dimension of the old city jewellery cluster. One of the pillars of the social bases of agglomeration is the master-apprentice relationship which requires mutual trust and dedication.

> "I was ten years old when I started working in this sector. The Grand Bazaar is a kind of a school you know and we name it the University of Grand Bazaar. Your master does not only teach you the basic skills required in jewellery making but also show you a certain way of life and even how to make practical jokes… I cannot forget my first week. One day my master told me that he would teach a secret technique in polishing and asked me to bring him some minaret shadow! Some minaret shadow? He looked very serious and I was too young to believe this. After all, he was my master, you know, you have to do what he says without questioning. Anyway I walked around the Grand Bazaar for about an hour, even went to the Nuruosmaniye Mosque. I couldn't ask to anyone of course [laughs]."

These different views indicate territorialization is a significant component in the organization of jewellery making in Istanbul. However, in 1995 the local planning authority took a decision to move the small scale workshops from the city centre to its peripheries (Evren 2012). The main reason for this decision was to reduce the so-called negative environmental effects caused by jewellery producers. Nevertheless, this decision has never been officially implemented partly because of the on-going negotiations between the local planning authority and those traditional manufacturing jewellers who are keen to continue their businesses in the old city. According to my in-depth interviews with these jewellers, the municipality's attitude to the sector's locational preferences is problematic. A silversmith commented:

> "The municipality has always put the same argument on the table: jewellery makers pollute the environment! How can this be true? There is silver in our waste and we don't throw it away, we refine it in an environmentally friendly way…Look, we may be small in scale, but we are in great number. Therefore, it is not that easy to clear the old city from jewellery manufacturers. That's why the municipality always wants to show us they keep the whip hand. That's why they don't re-issue our licences… A long time ago, I received a letter from the municipality saying I have to stop production within two weeks. I did nothing about it. Two weeks later we found a seal on our main door. This was a kind of a message you know, because they sealed the door knob, not the lock! Therefore we entered our premises without breaking the seal. Look, after all those years it is still there."

Undoubtedly, these intimidating tactics have created severe uncertainty whether the jewellery production will continue to cluster in the old city of Istanbul. Most of the producers feel the pressure of decentralization. This situation prevents them to expand their businesses in the cluster. Furthermore, the overall physical quality of the premises allocated for jewellery production is quite low and the buildings are poorly maintained.

5. Some conclusive remarks on the policy implications nexus

The jewellery production in Istanbul is agglomerated in three different urban industrial districts. The old city cluster is the oldest and the largest one which is characterized by large number of small firms, employing fewer than 10 people. Most of these producers rely on outworkers (gem setters, casters, engravers, polishers etc.) for almost all stages of production.

The case of the old city jewellery cluster indicates a wide palette of agglomerative forces on various actors of jewellery production have been at work. In other words every actor, be it a producer or a retailer, has a unique reason to locate within the old city. Producers, for instance, highlight the importance of a unique business climate in the old city, in which firms operating in the jewellery sector learn from and compete with each other. Retailers, however, emphasize the role of information flow, face-to-face relations and trust in the survival of small scale jewellery business. From this point of view, the information and communication ecology in the old city, where

firms are automatically exposed to news and recommendations, play a vital role in the sector's existence.

With respect to the conflict between the local authority and the manufacturers, we must acknowledge small scale jewellery production in the old city is an asset for Istanbul. Traditional jewellery making is a very important part of the old city's industrial and cultural heritage. The sector does not only contribute to the local economy of Istanbul, but also improves the image of the city and more importantly helps make the city centre more attractive. Furthermore, the sector nurtures a creative and innovative environment in the city. The international success of a small number of entrepreneurial jewellery designers is an example to a younger generation of up-and-coming designers, and encourages them to set up their own businesses. In this context, the old city's future in jewellery production lies in preserving the artisanal manufacturers in their own habitats, improving their working conditions and creating channels through which these small scale producers can access wider markets.

SIGNIFICANCE OF ECOSYSTEM SERVICES MAPPING FOR THE INTEGRATION OF SPATIAL PLANNING AND CLIMATE ADAPTATION*

Azime Tezer[1], **A. Ceren Onur**[2], İlke Albayrak[3], Ö. L. Şen[4], A. Özgür Doğru[5] Necla Uluğtekin [6]

Abstract

Recent global concerns are focusing on biodiversity loss (species and ecosystems) and global climate change especially in regard to sustainable urban development. Global warming, rapid urbanization and environmental degradation are closely related to the challenges of present urban settlements and mainly these are affecting the well-being of ecosystems and their services (Millennium Ecosystem Assessment-MEA, 2005). The need for better understanding of urban development and its impacts on ecosystems where these developments occur should be carefully assessed for the sustainability of the functions provided by natural systems. Meanwhile, the existing spatial information is concentrated on land cover and land use information. On the other hand, ecosystem services (ESs) may provide better understanding and more efficient spatial development in the process of spatial planning design and policy development (Daily 1997). Recent transnational organizations and EU institutions are also focused on the integration of ESs into spatial planning (EEA 2010).

As a result of the complexity of urban systems and ecosystem functions together with the limitations on the consistency of spatial information, the key ESs can be used to identify ecologically sensitive areas. In this approach, it is aimed that relevant mapping of ESs will be a key step to lead rational spatial development policies. Therefore, mapping of ESs and the socio-ecological drivers of space can be a relevant tool to achieve more sustainable development strategies by integrating ESs and urban socio-economic dynamics to the spatial decision making process. This

approach can be a rational tool to implement climate change adaptive policy development as well.

This paper aims to integrate ecosystems and their services into spatial planning through relevant mapping of ESs to be utilized for climate adaptive spatial policy development process in the Istanbul case. Istanbul is an exceptional geography for the biological diversity with its location when compared with other settlements in the region. On the other hand, the urban development dynamics of the metropolitan area have a significant role for the well-being of ecological units, biological diversity in other words its life support systems such as drinking water sources, forests, coastal and riparian corridors, wetlands and heathlands which are the representatives of the major habitats of Istanbul Metropolitan Area (Ozhatay et.al. 2005, Tezer 2005, Tezer 2008).

1. Introduction: Climate Change and impact on cities

Global GHG emissions due to human activities have grown since pre-industrial times with an increase of 70% between 1970 and 2004 (IPCC, 2007). A projection of current trends as represented by a number of different scenarios, gives global surface temperature increases of about 1.8° to 4° C by the year 2100. Sea level is expected to rise between 18 and 59 centimeters. Climate change foreseen impacts are ocean warming, rise in sea level, increase in continental-average temperatures, extreme weather events like cyclones, tornados, change in precipitation, heat waves, natural threats such as drought, flood, spread of diseases (IPCC, 2007). Cities especially the developed ones, are major contributors to climate change by producing greenhouse gas emissions, mainly through energy generation, vehicles and industry (Pimm and Raven, 2000).

Climate change and urban dynamics-based impacts are expected to cause vulnerabilities in urban areas by decreasing accessibility to urban services and natural resources like water and food. Existing urban dynamics-based problems can be triggered by climate change impacts as well. The vulnerabilities of settlements with the results of these impacts should be re-assessed by mitigation and adaptation tools and strategies to achieve more resilient and sustainable urban areas. Defining vulnerabilities is a complex and uncertain issue as both urban dynamics and climate change and their future impacts are uncertain and based on projections and foresights. It is important to be able to foresee future climate change risks and identify main drivers of urban vulnerabilities (Hallegatte et al., 2011).

The dependency of vegetation on variations of rainfall and temperature are studied in many studies. Rise in temperature and change in precipitation are expected to change also the land cover especially the green cover (c). Thus key ESscan be also affected by these impacts. Desertification can be a good explanation for defining the land degradation in arid, semiarid, and dry sub-humid areas resulting from climatic variations and human activities. Change in main ESs components like forests, agricultural areas, pastures, scrubs, water bodies etc. can cause loss in their qualities. Existing species may be replaced by other species that have less economic importance and also this may cause a loss in the productive, regulative and

supportive capacity of the earth (UN, 94). Millennium Ecosystem Assessment (MEA, 2005) claims that especially deforestation may cause a decrease in precipitation. As forest existence depends on precipitation level, its change can cause a change in forest cover as well.

Pollution (land, air and water) due to the impacts of urbanization increases greenhouse effect and accelerates climate change. Insufficient capacity of infrastructure and heat island effect of built up areas are also considerable outcomes of urbanization. As Cadenasso et al. (2007) indicates; land cover, density, used materials and the morphology of urban landscapes cause differences in local air temperatures. Climate change based vulnerabilities like change in temperature, precipitation, hydrological cycle, food chain and land cover/use (forest, agriculture etc.) are expected to have more severe impacts in urban areas as a result of their dynamics and needs. Therefore climate change impacts, unexpected natural risks may cause insufficiency in infrastructure, problems in food and water accessibilities. These impacts may threaten quality of life as well as environmental quality and future prosperity.

Millennium Ecosystem Assessment (MEA, 2005) put forward that climate change will have very sudden impacts on ESs in the following 50-100 years. According to the report, climate change is a direct driver that affects ESs and human well-being. But, at the same time it can complicate the management and assessment of ESs to be more complex in all scales. Beside that, as a result of human activities and climate change, the degradation on ESs cause a contribution to greenhouse gas emissions which has effects not only in local but also in global level.

2. Spatial Planning and Integration of Ecosystem Services (ESs)

Planning and urban design professionals have been always related with questioning and establishing better “nature” and “development” interactions since far back to post-industrialism with the severe and sudden impacts of rapid industrialization and urbanization. The first reaction of urban settlements to early problems of industrialization has been widely researched and well documented. “The City Beautiful Movement” and “The Garden City Movement” at the beginning of 1900’s were related movements of urban planning and nature interaction (Platt 2004). Later, Ian Mc Harg (1969) had significant influence of ecology and urban design interaction with his prominent work of “Design with Nature”. They were the relevant stepping stones of ecologically sensitive spatial planning practices in the last century. Ultimately, today, the need for having better interactions of urbanization, nature and community is beyond beautification efforts, but is an urgent necessity especially with the growing concern of climate change impacts.

The Millennium Ecosystem Assessment (MEA, 2005) brought new approaches to nature and human relations and the issue of ecosystem services (ESs) accelerated the efforts for the integration of planning processes. From 1990 to 2010 more than 2,000 scientific articles were published on this subject. The majority of these publications were related to ecology, environmental sciences and studies, economics and biological diversity conservation. In these publications, the integration of spatial

planning with ESs is not very common and has a small figure with 47 counts (Tezer et al, 2011).

Although the ESs issue has become an increasingly important subject in scientific literature and at the global level policy making processes, the lack of inventory regarding to the services leads to disconnection between planning and policy-making domains. In addition, existing planning models for policy development are oriented by land use and sectoral information (Willemen et al., 2008). In this context, to be able to integrate the ecosystem approach to planning, the principles of ESs based planning approach will be relevant to review its content and characteristics. These features can be summarized under five main headings:

- ESs-based planning approach is holistic and interdisciplinary
- ESs-based planning approaches focus on relationships and processes of the ecosystems and society.
- ESs-based planning approaches include the appropriate purposes related to spatial and temporal scales.
- ESs-based planning approaches aim for the equitable sharing of benefits and resources for every segment of the society in order to foster participation in the planning process.
- ESs-based planning approaches use adaptive management activities.

On the other hand, the identification of relevant planning tools and the clarification of commonalities of the two approaches' principles will be beneficial for identifying a framework to integrate ESs into spatial planning process. In this context, the conceptual framework of MEA (2005) clarifies the links between ESs and human well-being while then again it presents a draft framework to be applied to the planning process from global to local level scales with an analytical approach. The key tasks are defined in this analytical process, such as (MEA, 2005):

- Definition of ecosystems and categorization of the services provided by them,
- Identification of ESs and the links with society,
- Identification of direct and indirect factors changing ESs,
- Identification of the indicators of factors changing ecosystems' services, structures and human well-being,
- Assessing past trends of ESs,
- Uncertainty analysis, projection of changes on ESs and human well-being under specific scenario analyses, and
- Definition of basic outcomes and development of future policies after comprehensive assessment process.

Conversely, the strategic spatial planning can be a relevant tool for sustainable planning of ESs with its multi-dimensional and multi-stakeholder nature. This approach may provide the development of land use decisions under resource protection, action-based multi-dimensional governance, sustainable investment decisions, coordinated and long-term spatial development policies (Gedikli, 2010).

ESs-based spatial planning can be developed in four phases (Albayrak, 2012). First phase is the definition stage where existing ecological, socio-economic and administrative characteristics are put forward. In this stage, ecosystems and their services, sensitive habitats, direct and indirect factors changing ecosystems are defined with local ecological knowledge. Additionally, existing planning policies and tools are identified in this stage with the support of ownership patterns, socio-cultural characteristics, public and private stakeholders who may have role in the planning process of ESs. Second stage, entitled as identification, is where key ESs and their trends are identified. The key ESs are the ones which have significance on the planning decisions. In this stage, their sustainability indicators and status are assessed together with previous trends to direct planning decisions. The third phase measuring, assessing and mapping is the stage where spatial, socio-cultural and economic analyses put forward; and scenarios analyzed under past/present trend analyses. The final phase is the decision making and modeling stage where spatial, institutional and legal frameworks of planning process is set under the outcomes of previous stages (Figure 1).

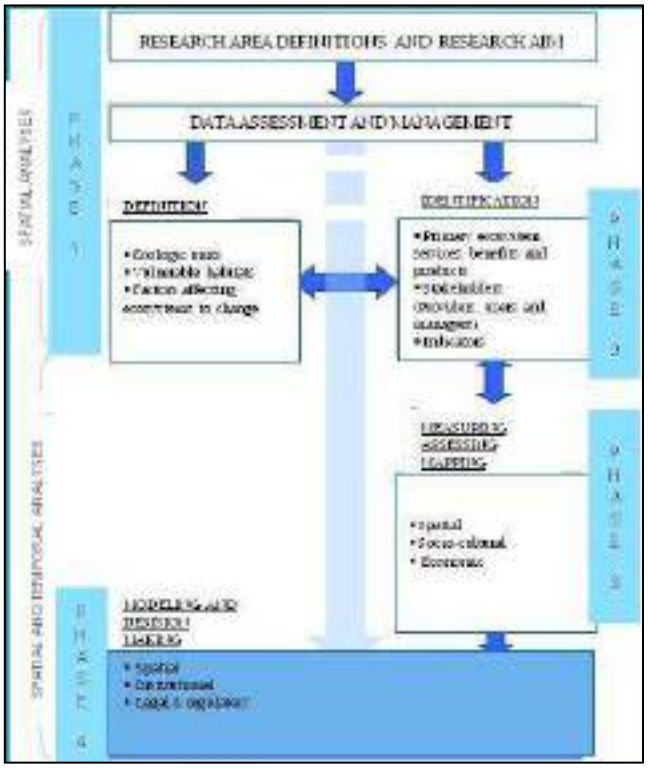

Figure 1. Stages of ESs integration with spatial planning (Albayrak, 2012)

2.1.Mapping of ESs

Geographically referenced data of GIS have to be defined at a selected common coordinate system for using the GIS capabilities effectively. On the other hand, maps, which are used for communication of the information obtained as a result of the analyses executed with decision makers and end users in GIS, add another

dimension to this technology for being so popular (Ulugtekin et al., 2009). Because of the above mentioned characteristics, GIS is often used by several disciplines to find solutions to global problems through a systematic approach. Therefore, it is considered as a multi-disciplinary tool and is used for different variety of applications, such as transportation, disaster management, navigation, medicine, city planning, agriculture, and etc. In this research, GIS was effectively used to organize, manipulate, retrieve and present the spatially referenced data obtained from different sources related to ESs and land cover/use data. In this context, the vector data obtained, produced or derived from existing maps, remotely sensed images and GPS surveys were firstly imported into a GIS database as layers and then all vector data were reorganized by identifying them at a common coordinate system that is Universal Transverse Mercator (UTM) Projection. Additionally, European Datum 1950 (ED50) was also considered as the defined datum of the system in this case. A GIS database on which spatial analysis can be executed properly were obtained by the definition of the vector data at common coordinate system. As the following step of the study; relations between non-geometric and geometric data were provided based on the relational database principles. As a result GIS database is prepared for executing queries and analyses and also for mapping their results thematically. Positional, thematic, temporal analyses were used in the analyzing process of ESs of Istanbul case. In this context:

- Positional analyses were executed by comparing different parts of the study area at the same scale to introduce general characteristics of the study area.
- Thematic analyses were executed for investigating different themes in the same area at the same scale comparatively.
- Temporal analyses were executed for comparing the data of the same area collected at different dates of the study area were determined based on temporal analyses.

Finally, results of these analyses were visualized as thematic maps indicating the several characteristics of ESs in Istanbul.

3. Evaluation of the main ESs integrated with climate change in Istanbul

Istanbul, covering 5344 km^2 area with 12.915.158 people and the urbanization ratio of 90%, is located on a unique ecosystem location by combining two continents and the climatic regions of both Mediterranean and Black Sea climates with diverse flora and fauna characteristics. Bosporus and the Marmara Sea have also very significant role in the natural structure of the city. The existing pressure of increasing urbanization, growing population and rapidly emerging economical activities are expected to increase in the future. Unplanned urbanization, residential areas of the internal immigrants with infrastructure deficiencies, location choices and plans conflicting with the natural characteristics interfere sustainable urban development of Istanbul.

The pressure on this vulnerable natural environment is expected to continue by the impacts of climate change (Figure 2). Addressing the impacts of climate change on

ESs and urban area, determining the vulnerable areas and developing strategies to increase the resiliency can be a relevant policy development tool to achieve sustainability in Istanbul. Therefore in this research, terrestrial and climatic features of Istanbul are mapped to produce ESs based spatial knowledge for future spatial policy development.

Evaluating actual land cover and land use with projected changes in primary climate parameters (e.g., temperature and precipitation) can help understanding the vulnerabilities on urban functions and ESs. Other climate parameters such as evapotranspiration, runoff and wind should be also integrated to understand the possible impacts on ESs.

3.2. Mapping of ESs in Istanbul

In this research Istanbul Metropolitan Area Boarders' land cover and land use data is studied at regional scale. Main land cover and land use data are determined as artificial surfaces, urban green areas, urban unused areas, forest areas, agricultural areas, scrub and herbaceous vegetation. Beside these, beaches, dunes and rocks, wetlands as marshlands, water bodies and main transportation axes (TEM, E5 and railway) are included in the assessment of existing ecologic and built up area characteristics.

According to the Millenium Ecosystem Assessment (MEA) 2005 Report; ESs are classified as supporting (nutrient cycling, soil formation, primary production), provisioning (food, fresh water, wood and fiber, fuel), regulating (climate regulation, flood regulation, disease regulation, water purification) and cultural services (aesthetic, spritul, educational, recreational). In this study, ESs of Istanbul are intended to be classified according to MEA, 2005 classification as shown in Figure 3.

These services can be developed more in details especially to address the socio cultural characteristics of Istanbul.

3.3. Evaluation of the ESs in Istanbul

In this research, ESs addressed for Istanbul Metropolitan Area are tried to be evaluated for integrating with climate change scenarios. Increase in temperature and change in precipitation are expected to have impacts on existing ESs in Istanbul. In order to increase resilience of Istanbul and develop appropriate spatial planning policies and strategies; these impacts should be addressed. Above some of the estimated impacts of climate change are mentioned. Additionally the impacts of CC on the ESs should be clarified. Hence further assessments have to be evaluated with the integration of the two.

Soil Formation: Increase in precipitation should be taken into consideration especially for low drainage soil formations like hydromorphic and vertisol soils. The high quality soil can be protected and avoid from urbanization.

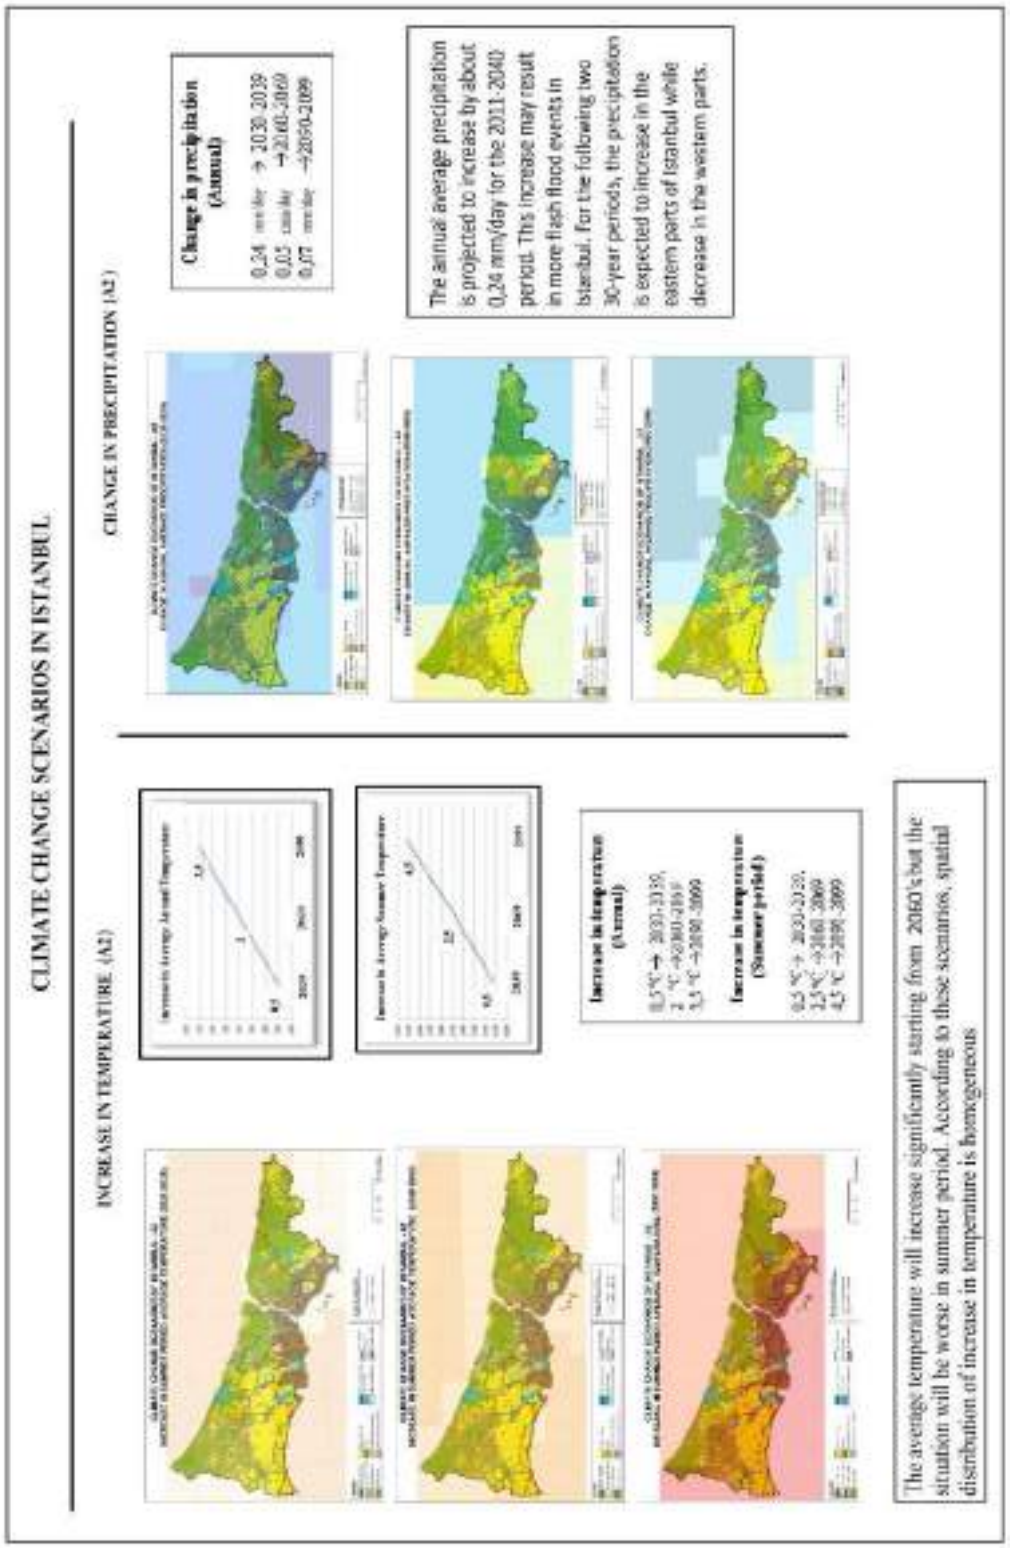

Figure 2. Projected changes in climate parameters in Istanbul (based on A2 scenario simulation of ECHAM5 Global Circulation Model)

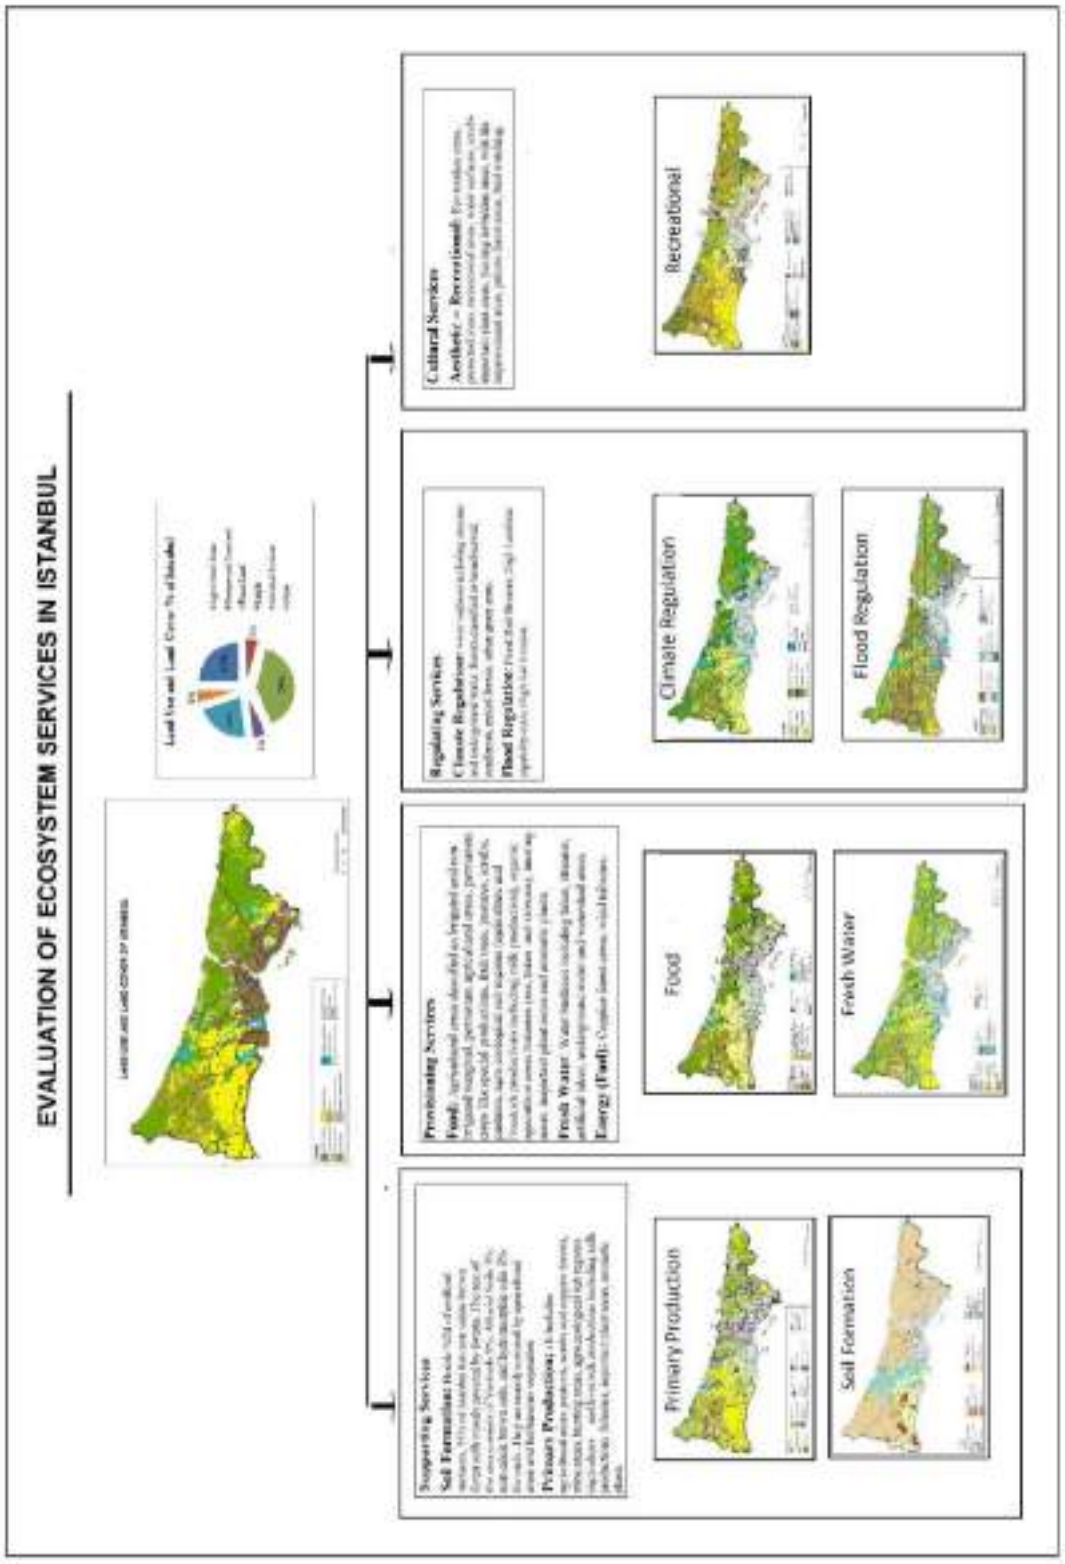

Figure 3. Evaluation of Ecosystem Services (ESs) in Istanbul

Primary Production and Food: Temperature rise can affect all agricultural areas, forests, agro ecological sub regions and their products, all plants, fisheries etc. Beside that decrease in precipitation in the west part of Istanbul after 2060's, drought can be seen and primary productions like agriculture, forest, livestock etc. may be replaced with other land uses and land covers like from forest areas to agriculture areas, from permanent agricultural areas to marginal agricultural areas or built up areas etc. These changes may cause significant losses in ESs and on the economy which is strictly related to these ESs.

Fresh Water: One of the most affected services is expected to be fresh water services. It depends on atmospheric changes like precipitation and evaporation. Actually, the water demand of Istanbul urban areas is higher than the local water supply and there are new projects for supplying water demand from other locations. According to climate change scenarios, this situation can be worse especially in the European part.

Fuel: Coppice forest areas can be destroyed as a result of rising temperature and decrease in precipitation especially in the west part. Wind turbines can be good solution for decreasing the greenhouse gas effect and dependency on external energy sources like natural gas.

Climate Regulation: As a result of damages on forests, green areas and water surfaces, this service which is also very important for climate change mitigation may function very slow and inefficiently.

Flood Regulation: Flood risk can be very high especially in the east part and both urban areas and primary productions can be under risk. Due to previous experiences in Istanbul, this may cause an enormous pressure on economy and human well being.

Aesthetic – Recreational: Increasing temperatures and decreasing precipitation will enhance the stress on the flora and fauna in the recreational areas, and may result in the adoption of more resilient species

These impacts and more should be well addressed in order to determine the vulnerabilities. Most vulnerable services are determined as fresh water services, primary production and food services, climate regulation, flood regulation, aesthetic services and fuel services respectively. Strategies among these services in order to increase the resilience for economical growth and human well-being should be integrated with spatial planning tools.

4. Conclusion

This study tries to develop a new methodology for the integration of climate change and ESs. This approach may help to figure out with the uncertainties related to climate change and urbanization dynamics. For sustainable cities and ESs not only the existing situation but also the future vulnerabilities should be addressed. Therefore this study will be developed more in details and further research and analyses will be done. In this study only the main ESs are intended to be evaluated.

At the following stages, beside taking ESs into consideration, urban built areas' physical, socio-economical issues will also be evaluated. Scenario analysis is the tool preferred here to develop and to lead future urban development policies (Figure 4).

In order to achieve this, the land use scenarios should also be generated and integrated with climate change scenarios. Land use scenarios are necessary to be able to understand the change in land cover, the impact of land cover change on ESs, how the ESs will change due to land cover change. Then, integrating with climate change scenarios, climate change impacts on actual ESs and future ESs can be evaluated.

As it is shown in Figure 4, in the first stage of the research; main ESs are intended to be identified by mapping of the spatial distribution of these services. In second stage; climate change scenarios based on temperature and precipitation are developed and the spatial differentiation of these scenarios are indicated. As a result of these stages; climate vulnerable ESs are identified. These vulnerabilities may clarify the actual vulnerabilities under the view of climate change scenarios. As climate change scenarios are made for future, beside actual situation also future ESs should be addressed by developing land use scenarios. With this perspective; the future vulnerabilities of ESs can be determined and spatial planning decision making process can be supported according to these scenarios. As a result; in order to create climate resilient cities in the future, appropriate spatial planning strategies and policies can be created and main actors and their roles can be identified. Increasing the resilience of ESs can be the most feasible and rational mitigation tool for combating climate change.

Can youth participate in the city even if adults don't?

João Armando P. Gonçalves

CITTA – Centro de Investigação de Território, Transportes e Ambiente
Faculdade de Engenharia da Universidade do Porto - Portugal

Abstrat

Is a participative environment a prerequisite for having young people to participate and have an influence on the territory? Or, if seeing it from a different angle, can youth participation be the key to open community to a more collaborative context? Inspired by and using some of the tools and techniques from the general field of youth participation, an experiment was carried in Proença-a-Nova, a village of 5000 inhabitants, located in inland Portugal. The aim of the project was to test a number of active tools and techniques that municipalities could use in the context of the current planning framework, not only to engage young people but, potentially, to gather meaningful input from other segments of the population. At the same time, it was expected that relevant suggestions could be collected from the young people involved and, through that, raise their profile in the context of the community.

Key words: youth participation, education, citizenship, collaboration

Obrigado por nos ouvir[1]

1. Introduction

1.1. The background

The possibilities open by the participation of children and young people in the life of the city has been addressed since the 70's when Kevin Lynch, Roger Hart and others, started exploring the relation between young people and the city environment, and their potential participation in shaping it.

Since then, many experiences have been held and a historical overview of the evolution of children's participation in planning can be seen in the analysis done by Francis and Lorenzo (2002). This analysis highlights the different backgrounds and motivations for bringing young people into the discussion of urban issues that might affect them, directly or indirectly. From the *romantic* approach of having children as planners, through the *advocacy* phase and the *needs-based* one, followed by the view of *children as learners*, the always present *rights-based* field, and ending with the *Institutionalization* realm and the *Proactive* one ("planning with children").

[1] Thank you for listening to us

During these 40 years, two particular international initiatives/movements have enhanced the debate and raised the awareness about the possibilities and benefits of involving young people in city issues. These were the *Growing up in Cities* initiative (sponsored by UNESCO) and the *Child-friendly Cities* movement (by UNICEF).

The emphasis given, in the recent years, to communicative planning has opened a new window of opportunity by raising the "hope that regional and urban planning will no longer remain the exclusive domain of experts and the government, but will become a playground for all – even for young people" (Horelli, 1997).

Currently, one may ask *"Why should we make any effort to have young people participating?"* The number of reasons has been growing as the result of those different experiments and the associated discussions. It's not only because of the size of this particular group of population (for example, adolescents 10-19 represented 18% of the total world population in 2010). It's also the fact that any decision taken now, in terms of planning, most likely will have far-reaching implications for the following generations (Frank, 2006). This touches the very essence of the concept of sustainable development (Chawla, 2002).

But other benefits can also be identified, for the young people themselves, for planners and policy-makers, and the community at large. These include a better knowledge of the community and the democratic processes, acquisition of new skills and fresh views, development of wider citizenship spirit and a stronger sense of community, better informed decisions, more inclusive mindsets, etc (Driskell, 2002). Tonucci and Risotto (2001) even mention young people as being "sensitive environmental indicators" meaning that if we take their opinions and wishes in consideration, we'll be meeting the entire community's needs as well. Weston (2010) argues that young people should be the citizen for whom cities are designed because the area of the brain related to spatial perception and analysis is still developing in them. However, despite all the benefits that are recognized, there is still a great need for studies that document the long term effects of children's participation (Knowles-Yánez, 2005)

Actually, the understanding of young people as citizens today (and not only in the future) is of crucial importance to make that effort of bringing them to the table when planning or improving the spaces. As Simpson (1997) refers, the manner in which young people are viewed has historically hampered their inclusion in the process of planning and urban design. Seeing them as competent citizens who can create community change (Checkoway & al, 2003) is still an unusual starting point and challenges the predominant views of children as "adults-to-be" (Torres, 2009).

Changes are needed not only in terms of mindset but also in terms of processes and structures. In what relates to planning and the inclusion of youth concerns, processes and methods continue to be legalistic, reactionary and dominated by economic

interests (Knowles-Yánez, 2002, cited by Frank, 2006); certainly not very youth-friendly.

It is encouraging to see the growing numbers of governments and international institutions advocating for a greater involvement of children and young people in community life; institutions like the United Nations, UNICEF or the Council of Europe (with its Charter on the Participation of Young People in Local and Regional Life). However, there are still challenges to be overcome in terms of planning practice: on the decision-making processes, on the procedures for engagement, on the recommended settings, and on the duration and age-appropriateness of activities (Knowles-Yánez, 2005), to mention a few.

The inclusion of young people within this communicative turn requires new methodological "tools" which can enable young people to take part in varying arenas of urban planning and the use of different enabling methods which are not usually included in the traditional sphere of "science" (Horelli, 1997). The exploration and implementation of some of these "tools" and methods were at the centre of the action-research project carried in Proença-a-Nova (Portugal) which is presented in this communication.

1.2. The context

In Portugal, hard rationality is still the background for planning and the participation in the planning processes is generally very institutional and passive. When developing a plan, the public participation is concentrated mainly in two periods: when the process starts (the "preventive participation") and after having a "final draft" of the plan (the "successive participation").

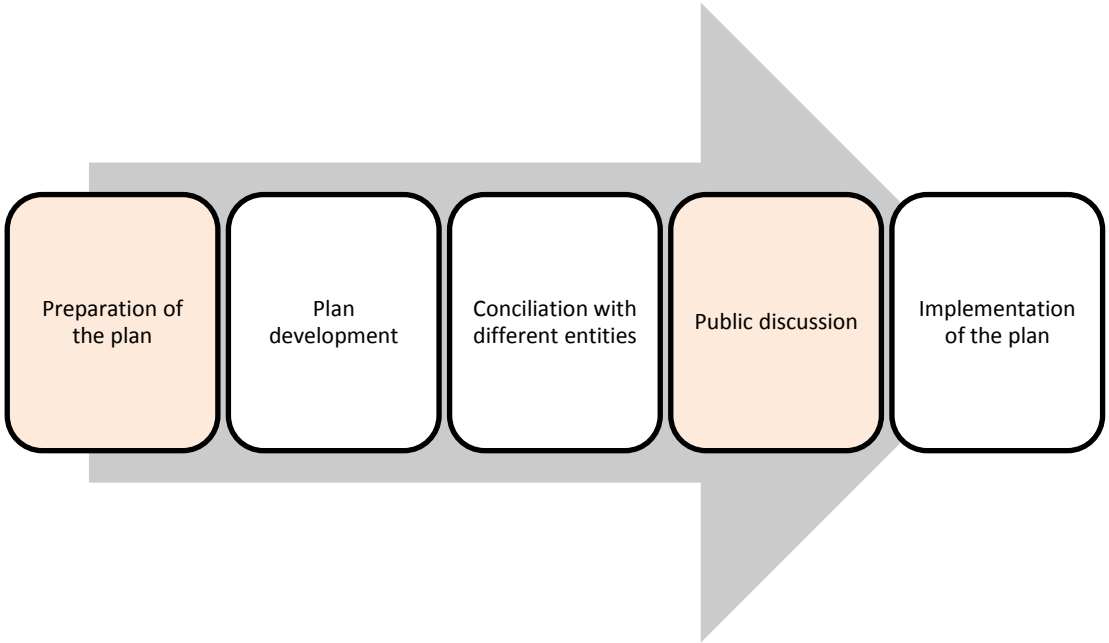

Figure 1. The planning process in Portugal and the public participation opportunities

The approaches rely mainly on spontaneous inputs from citizens or public hearings. These are not very well attended, and often the focus shifts towards very specific and personal problems raised by those who dare to stand and speak. The good examples of participative experiences in a few municipalities aren't enough to hide a weak culture of collaboration and constructive participation, but also a general lack of creativity when it comes to select the best tools and techniques to engage citizens.

In this unfavorable context, to bring young people to the debate on public participation may seem misplaced and risky. However, the issue can be seen from another angle: can youth participation be the key to open to a more collaborative practice? And what could be the reaction of decision-makers and the community to the proposal of hearing what young people have to say? More importantly: would young people be able to provide information and suggestions that could be relevant to municipal authorities on planning and managing the town?

2. Analysis (methods & materials)

2.1. Approach

In order to test the possibilities of involving youth in urban issues (namely planning processes) in Portugal, a project was developed in Proença-a-Nova, a small town of 5000 inhabitants, located inland (Figure 2). The project, which was called *Cidadãos 2.0*[2] lasted from September 2011 to May 2012 (including 4 initial months of preparation).

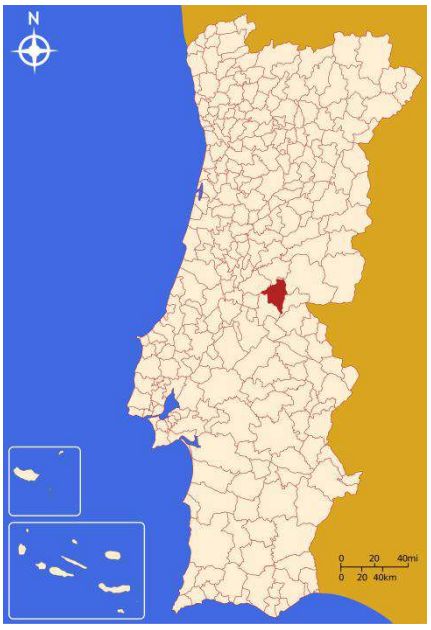

Figure 2. Municipalities in Portugal and the position of Proença-a-Nova

This town was chosen not only because it belongs to a particular sub-region which has been experiencing a decrease on youth population in the past decades (which could constitute an extra challenge), but also because of its size, which could enable a stronger sense of "community" (more difficult in bigger settlements) and, therefore, a stronger link between youth and the territory.

The starting point of the project was the existing planning framework and the opportunities for public participation which are currently provisioned (mentioned above). The aim was to test different techniques which could be used,

[2] Citizens 2.0

with young people, in the context of the "preventive participation" phase. Therefore, a strong emphasis would be given to youth participation in community evaluation (Checkoway & Richards-Schuster, 2003)

The target group was young people in the adolescent age range, and there were a number of reasons for that option. First of all, it was felt that, at that age, young people have already a degree of maturity that enables an interesting critical view of the urban environment, but they still possess the capacity to think "out of the box", in a creative way. This was to be balanced with the capacity to absorb the learnings from the experience, and maximize its impact in terms of citizenship education. Another powerful reason was the fact that in the international literature is less common to find experiences with this segment of the population (Passon & al, 2008); in particular, in Portugal, the experiences of involving adolescents in urban issues are very rare or non-existent.

Besides the two mentioned major options, there were other decisions that shaped the entire experiment, such as:

a) It should be a project to be run during a number of sessions in order to enable a deeper analysis and a better connection between facilitator and participants;
b) The study area should be limited in scope and normally "used" by young people. This would enable a better evaluation from them, based on their own personal experiences;
c) In order to ensure a truly collaborative approach, the process needed to be open and flexible enough to adapt to local conditions and to accommodate inputs from participants or key partners;
d) The participation should be done on a voluntary basis (basic requirement of true participation);
e) The local high school needed to be a key partner because the "recruitment" needed to be done there, where young people are and spend significant part of their daily time. This option had, naturally, pros and cons which were well taken into account;
f) The project needed to go beyond the mere test of a number of approaches and techniques; it should be meaningful and useful for each participant and also the key stakeholders involved (in particular the municipality and the local high school)

Based on the mentioned premises, a basic "Road Map" was designed, incorporating a number of major phases which included Introduction, Preparation, Promotion, Implementation, Presentation and Evaluation (Figure 3)

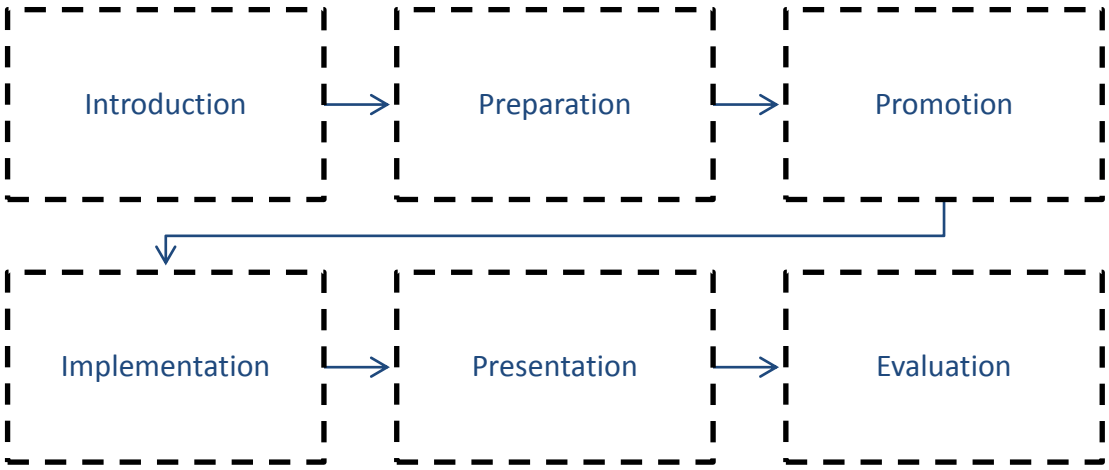

Figure 3. The Road Map of the *Cidadãos 2.0* project

2.2. "Introduction" phase

Since no previous links or contacts existed in the municipality, specially with those considered as the key stakeholders (municipal council and local high school), the first phase consisted in presenting the idea, raise the awareness on the topic, collect feedback and relevant information (namely on existing opportunities), and the assessment of the existing local conditions which could enable such a project to be feasible. This was done through a number of meetings with decision-makers of both key stakeholders and implied the production, beforehand, of a number of communication materials such as letters, a summary brief and leaflets.

One important aspect when approaching these 2 stakeholders was to indicate exactly what was expected from each of them. In particular, for the municipal council, one essential requirement for the project to be possible was the availability to, at the end, to receive the young people and consider their proposals.

2.3. "Preparation" phase

Once the realization of the project was agreed in principle, it was time to prepare it, by increasing the level of detail and incorporating the specificities of the particular context in which the project was to be developed. This phase included three major steps (Table 1)

Table 1. The "Preparation" phase

Step	Objectives	With whom	Means & techniques
Analysis of the context	_ To understand the municipality in terms of	_ Municipal council contact person _ High school contact	_ Interviews _ Data collection and analysis

	demography, youth habits, etc _To adjust the project proposal to be submitted to partners	person _Relevant individuals _Representatives of relevant associations	
Negotiation	_To agree on the project outline (including time reference)	_Decision-makers in key stakeholders	_Meetings
Resource mobilization & preparation	_To collect relevant images and documents _To prepare presentations and promotional materials _To train potential volunteers to support implementation _To prepare the sessions (to be run with youth) and materials	_Contact persons	_Capture of photos _Documents' reading _Working sessions

Among the number of meetings and other contacts that were held, it should be mentioned the ones done with the planning officials of the municipality. Besides the information about the different plans in place, it was confirmed that quality public participation was not common practice and certainly not when it comes to young people. The only experience in this domain was a small survey done to 22 young people (10-15 years old) on the occasion of planning a new park, asking them which kind of "playing facilities" they would like to have. The participation of citizens in contributing for the formal spatial plans had been very limited; however, when interventions were planned in public spaces, meetings were organized, prior to the construction phase, to inform about the changes to be.

Also the "negotiation" with the high school principal was of great importance. Due to the large number of classes (throughout the different grades) in the high school, there was the need to select a few to do a targeted presentation to. The selection was done together with the principal, who provided useful information about the commitments and projects already existing for the different grades, as well as opinions on to which grades this kind of project could be more useful. That led to select the three classes of the 8^{th} grade and one of the 11^{th} grade (which had a specific interest in geography issues and specifically in urban ones).

2.4. “Promotion” phase

The promotion aimed, in one hand, to inform different stakeholders (and the public in general) about the project but, more importantly, to attract young people’s interest in order to encourage them to volunteer to be one of the active participants. Being such an unusual practice (the participation of young people), such a phase was particularly important. Besides, since there were different publics and different levels of involvement, the key messages, the materials and the techniques had to be diversified and adapted (Table 2)

Table 2. The “Promotion” phase

Step	Objectives	With whom	Means & techniques
Presentation to relevant stakeholders	_To present the project, in general _To promote the project in the target group environment (creating momentum) _To collect reactions and feedback _To involve potential contributors	_Formal or informal youth groups _Students’ association _Parents’ association _Teachers	_Meetings with presentations _Announcements in every class _Flyers & posters in the high school _Posters in the offices of formal youth groups
External communication	_To promote the project _To increase credibility of the project by making it more visible	_General public	_Articles in local press and on the municipality website _Local TV
Targeted presentation	_To present the project, in detail _To have a youth view on local practice in terms of participation _To make potential participants to experience what the project may be _To encourage enrolment _To identify potential collaborators (amongst youth)	_Students in the age range	_Presentation session in class (45m) using active methods and educational activities

The presentation sessions in class turned out to be crucial in the entire process of promoting and "recruiting" participants. In these sessions there was a special focus on what was the purpose of the entire project and special attention was given on linking to local reality (places and situations they knew or used regularly). That was an important approach to try to establish a sort of "emotional link" between the young people and the project. This could only be done in this kind of face-to-face opportunity, in which empathy could be explored.

The above mentioned approach turned out to be very effective since that, despite the general promotion that has been done in the entire school and among formal and informal youth groups, all the members of the final group of participants belonged to one of the classes in which a "live" presentation was done.

Besides the two key stakeholders (municipality and school) who had an enthusiastic reaction from the beginning, the feedback from other stakeholders was diversified: some of them showed interest and expressed willingness to contribute and others were just happy to be informed.

2.5. "Implementation" phase

This phase was important, not only from the point of view of observing young people's reaction to the proposed activities (therefore testing the possibility to use them in a formal planning exercise), but also because there was this aim of producing concrete results that could be relevant to the partners (therefore proving the benefits of adopting such an approach in the future). So, attention had to be given not only to the process and methods but also to the content. Regular checking was done on the results to confirm how relevant they could be in terms of the normal content of urban plans. Therefore, during the entire process, there was the need to manage this double role as a scientist and as an agent (Horelli, 1997).

When planning this phase, the steps were kept as simple as possible, also with the aim of having the process easily perceived by the participants (Table 3).

Table 3. The "Implementation" phase

Step	Objectives	With whom	Means & techniques
Participants' mobilization	_To have young people enrolling and involved	_Student's association (receiving forms)	_Online and paper forms _Facebook group
Situation assessment	_To map the current situation from the young people's point of view	_Young participants in the project (max. 20)	_One "face-to-face" session using different activities _Questionnaire

Analysis of results	To analyze the information gathered and synthesize the main trends		One "face-to-face" session using different activities
Proposals	To gather a number of concrete proposals to be presented to local officials		One "face-to-face" session using different activities

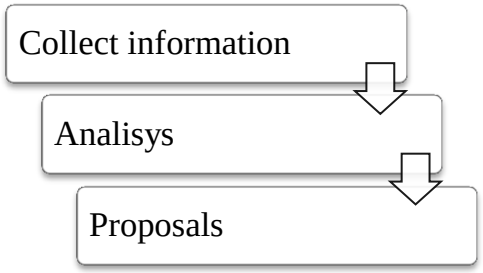

Figure 4. The work model

The model proposed to the participants was a very simple one (Figure 4) and it was planned to be based on three "face-to-face" working sessions with the duration of 3 hours, ideally during a free afternoon. The reality showed that this was not possible and adjustments had to be made. Actually, from very soon, it was understood that flexibility needed to be one of the key words to have in mind when planning sessions, timing, etc. And that makes sense in a participatory approach: there is always need to have some room for young people to incorporate their own inputs and find the best conditions for things to work. This is part of using youthful styles of working (Frank, 2006)

The implementation started with the enrolment of participants and their involvement. This was done mainly electronically by filling an online form (hard copies were also available at school) and/or joining a dedicated Facebook group. The target number for the number of participants was 20 and there were 18 registrations. After the first session and during the implementation phase the group became stable with 15 members. It's important to note that the enrolment was totally done on a volunteer basis, which was a key requirement from the beginning.

One of the main challenges of the entire project was to find available time from participants to run the sessions. Since they were coming from different classes (and different grades), their school timetables didn't match and it wasn't possible to find a slot of time, during week days, in which all of them were available at the same time. In the first scheduled session (planned for 3 hours) there were young people attending the initial sections and then needing to leave, while others were just arriving (after finishing other school commitments). This led to plan the following sessions in a more flexible way and adapting to this new reality by using some "walk-in" style of activities. Afterwards, following the suggestion from participants, sessions started to be run at weekends (Saturdays).

On the other hand, it became clear that it would be very difficult to keep the three sessions only. Instead, the focus shifted to the results; the sessions would continue until the 3 stages were completed (Assessment, Analysis and Proposals). So, at the

end, there were 7 working sessions (the first two being in a walk-in/walk-out system), representing, in average, 14 hours of work per each of the 15 participants.

The activities used in the sessions were very diversified and adapted to the stages of development of the process itself (Table 4).

Table 4. Participative techniques used

Stage	Techniques	Source
Setting the scene (general techniques)	• Ice- breakers • Ground rule-setting • Personal mapping (What expectations and personal qualities do I bring?) • Daily activity schedules	Several Save the Children, 2005 Sustainable cities International, 2009 Driskell, 2002
Situation assessment	• Where we live: Like & dislike • Pictures in time • Community mapping, focusing on 4 main issues: safety, mobility, shopping, leisure) • Focus group • Interviews • Questionnaire • Urban photo safari	Save the Children, 2005 Save the Children, 2005 Sustainable cities International, 2009; Wridt, 2009 Driskell, 2002 Driskell, 2002 Driskell, 2002; Canadian Institute of Planners, 2000 Driskell, 2002; Save the Children, 2005; Cook, 2006
Analysis	• De-coding themes (PAR_) • Creating a focus • Prioritizing the Issues • Guided tours • Public space assessment	HeartWood Centre, 2004 Save the Children, 2005 Save the Children, 2005 Driskell, 2002 PPS, (…)
Proposals	• Manual crafts (My right to information) • Video interviews • Create your own Community Charter • World Caffe • 10 ideas for Proença-a-Nova	Save the Children, 2005 Driskell, 2002 Canadian Institute of Planners, 2000 Save the Children, 2005

Regarding the questionnaire, it was designed by the group and submitted to 90 colleagues from different grades, in the high school. The content was based on some aspects that had been dealt in the sessions and the intention was to validate the opinions that had been expressed there.

During the sessions, attention was given to build capacity of the participants in terms of participation (different levels for different situations, as stated by Hart, 1992) and planning (instruments, process, and municipal structures). Again, this was done mainly through active methods.

Figure 5. Activities in the implementation phase

2.6. "Presentation" phase

For the sake of results to be presented, the local stakeholders were more interested on the content (the opinions expressed by the young people) and not necessarily on the process and how the different techniques have been used or if they were successful or not.

In terms of presentation of these results, there was again an "internal audience" (all those more directly involved) and an "external" one (the wider public). Therefore, the key messages and the media had to be adapted to each of these audiences (Table 5)

Table 5. The "Presentation" phase

Step	Objectives	With whom	Means & techniques
Preparation session	_To organize the results to be presented and prepare materials _To develop participants' presentation skills	_Young participants in the project	_Workshop _Role play _Visit to the town hall
Presentation	_To present the results of the project _To exchange views on some of the conclusions	_Political decision makers _Key decision makers in the high school (principal) _Youth groups _Other people involved	_Session in the town hall (with ppt presentations, videos, posters, etc)
External presentation	_To inform about the results of the project _To enhance credibility of young people's contribution _To provide an example of a participatory process	_Wider public	_Press release _Local TV
Technical presentation	_To present the results from a technical point of view	_Municipal officials from the planning departement	_Meeting

The high point on presenting the results was the session with the mayor and other members of the municipal council, run in the town hall, to which other stakeholders and key partners have been invited. The idea of running the session in the town hall came from the Mayor, the rational being that he wanted to give importance to the project and to the opinions of the young people. In any case this idea was not accepted until the participants agreed with it.

Special care was given to participants' preparation in order to make them feel as "at ease" as possible. A rehearsal was done one week before the presentation and a visit to the hall where the session would take place was carried.

After that more "political" presentation, a meeting was held with the municipal planning officials for a more "technical" one. The main focus this time was to "translate" the results from youth language into a more technical/institutional one.

2.7. “Evalution” phase

Evaluation was present in several sessions and not only at the end. In fact, for a number of sessions evaluation activities were carried to assess the level of satisfaction of the participants but also to understand some of the learnings that the project was providing.

In any case, the evaluation is still ongoing because, besides the immediate one, a medium term evaluation is planned to happen later in the year.

The immediate one will be conducted in another session with the 15 participants and will focus on the process, the personal learnings and also the proposals in terms of initiatives which will be able to ensure that the youth voice is heard when the urban environment is to be changed.

The medium term evaluation will have an emphasis on the key partners, specially the municipality. In this case, the focus will be on the ideas that have been adopted and the changes that have happened or are planned to happen.

3. Results

Despite the fact that the total impact of the project is still to be evaluated in detail, there are some results which can be pointed as significant outcomes of this experience:

a) The voluntary involvement, for a number of months, of a group of adolescents in thinking and discussing the issues of their community, especially on those that directly affect their daily use of urban space and environment;
b) The confirmation that active methods enable, also in the Portuguese context, deep involvement and meaningful participation, especially if we’re dealing with young people;
c) The young people involved increased their awareness regarding the state of the urban space in their community as well as the processes, structures and bodies that plan and manage that space;
d) Such process enabled the collection of significant amount of relevant information about the reality, the needs and wishes of youth, their use of urban space, and their view on how it should improve or evolve;
e) Along the process, it was clear the growing interest that the project raised amongst different stakeholders: individual persons (teachers, municipal councilors, other students, parents…), local business companies or youth organizations. This enhanced the credibility of youth and their input and the one of the project;
f) The project provided the opportunity to bring together the young people, the decision-makers in the municipality and the public officials. Youth were able

to make their voices heard in a structured way and to get the commitment, from the municipal council, that some of the suggestions made would be implemented

These preliminary results reflect what was mentioned before about having different stakeholders and different interests. For the sake of the research, the aim was to test the methods and understand the possibilities and impact of such an experience. For the young persons more directly involved, the interest was on make their voices heard and, ideally, to make some real improvements happen. From the municipal council, there was a genuine interest in hear how young people feel by living in the town and what were their needs, wishes and ideas.

One of the practical outcomes of the project was a list called "10 ideas for Proença-a-Nova" which included: a proposal of building a pool and a bike lane (including a byke rental system); ideas to improve two particular public spaces (previously identified as problematic); the suggestion for programs and workshops for young people in rehabilitation and community issues; recommendations for retail shops and services; among others.

4. Conclusions

Young people are users of the city and, as such, they live their own daily experiences that shape opinions about how things work there. They are a particular group of citizens with particular views of the city, different from the one from adults (Torres, 2009) and this was something that this project confirmed.

To face this particular group of people as "persons" before seeing them as "young people" is probably one important starting point for processes that intend to hear them or to involve them more deeply.

Young people have things to say about the city and have particular ways to say it.
If, when targeting adults, a passive approach for participation (waiting for people to participate spontaneously) does not bring many results, when it comes to young people, the active methods are even more essential. Wanting to have young people's inputs requires to "go and meet them" in their own "territory". This goes both in the sense of the spaces they use frequently (school, clubs, public spaces…) and in the sense of the ways they prefer to act or interact (activities, games, debates, images…).

Besides the absolute need of active methods, there is another important reflection coming out of this project: the importance of school and the school system itself (Davidovitch-Marton, R, 2007). In Portugal, schools play an important role not only in transferring knowledge but in offering different types of other activities (sports, clubs, projects, etc). This implies that an extraordinary amount of young people's time is spent at school and, therefore, the "use of the city" (namely public spaces) is becoming limited. Especially for those that also have to do some daily commuting

(because they live far from where the school is based). This school commuting is becoming particularly strong in Portugal because a student centralization (Torres, 2009) policy is under way, closing small schools and building/developing big "educational centers" in the more important urban centers.

The mentioned trends related to school reduce young people's attachment to their neighborhoods (Torres, 2009) and their personal free time (also to engage in projects as the one that has been described).

Another remark should be made regarding effective communication which is one key feature of this kind of projects and essential to collaboration (Torres, 2009). Communication is at the background of any participative process but it is even more important when the people to involve are young people (and adolescents in particular). The need to attract participants (on a voluntary basis) and, afterwards, to keep the group together, demands that specific communication skills and techniques are developed and used. In particular, the use of social media was the one more effective in the current project.

Also, the communication between the different stakeholders involved (young people, officials, politicians, teachers, etc) is of great importance. There is a need to constantly "translate" the language that each group uses to ensure that the message goes through. In particular, in the different sessions held with young people, instead of using the "planning jargon", the starting point was the concrete experiences that young people had and that constituted their comfort zone. Then, from the information collected in the sessions, there was a need to try to fit it into the political and technical framework in which politicians and officials operate.

The final important reflection relates to flexibility. As mentioned before, when undertaking such kind of projects of active consultation of young people it is important that the process itself and the facilitator are flexible enough to adapt to local conditions or to unexpected events: less people attending, bad weather conditions, activities that last less (or more) than expected, suggestions made by the participants, etc. This demands constant adjustments to the project planning but also the knowledge about different techniques and to have the necessary materials (as "plan B" resource).

In conclusion, and referring to the initial question, this project showed that, even in the case that the participation culture is not so much developed, it is possible, with the right approaches, to bring young people to give their contribution to the development of their community and to translate that (if necessary) to the instruments that are provisioned in the planning framework. On the other hand, undertaking such a project with young people raises the interest in adults (being parents, teachers, officials, politicians…) and may trigger other broader participative initiatives. Also in this case, the idea begun to permeate both the school and municipal officials (Davidovitch-Marton, R, 2007). And even if the process is costly (mostly in terms of time), the immediate outcomes tend to add value to the urban

space and, on the long term, may bring a positive impact in terms of the participation culture. The challenge remains in adapting our planning practice, which also requires an evolution in the form of local governance.

From Industrial Zone to Housing: Which Consequences for Social Memory and Industrial Heritage? Project PAV in Geneva.

Dr. Nadia Capuzzo Derkovic

*** Please do not quote without permission ***

Abstract:

My paper will focus on the current Project Praille-Acacias-Vernet (PAV) in Geneva (Switzerland). PAV is a project of urban reconversion of an industrial site in many aspects symptomatic and whose stakes exceed those of a simple project of urbanization of the outlying areas of the city of Geneva.

The industrial zone Acacias-Praille was developed in the 60s to accommodate businesses, private companies, machine shops and warehouses. At that time, the site was located on the outskirts of the city (Praille and Acacias). Nowadays, these businesses are mostly still operating. Therefore, the PAV zone is not a brownfield site. Urban reconversion of a site even though it is still active will be analyzed through its impact on the changing image of the city and its industrial heritage.

Issues related to the displacement of these companies in other industrial sites, such as densification of existing industrial sites, will also be discussed. Indeed, the primary objective of PAV is to reorganize the existing fabric to make way for housing. Gentrification of these three districts is already visible in housing design. Inevitably, the move will not concern only the land and real estate, but also the economic fabric of three quarters, as the Cantonal authorities included in this project the nearby district Vernets. Industrial activities will consequently be fragmented – being relocated on other sites - and the fabric of social and economic relations will be profoundly changed.

What is at stake is to concentrate, to gather, to stack up companies which practice intensive use of space and generate nuisances under control... Some will see an analogy to Lego blocks and the infinite array of possible arrangements. Others will question the feasibility of such a project in the timeframe of 2030. What interests us, is the attention paid to the industrial heritage, its treatment and the place accorded to it in this project. Finally, an industrial area, active or not, is not just a field with walls, rails and railway tanks. It is mainly a place where a company and its workers have developed know-how, techniques, where trade union struggles have developed. These traces are those of the industrial memory of Geneva, the memory of workers. How important is this social memory today in this project?

1. Introduction

A new center for Geneva[1], *At the outskirts, and yet in the center*[2], *A new heart connected to the city centers of Geneva, Carouge and Lancy*[3]: it's in these terms that the big urban reconversion and development project of sector Praille-Acacias-Vernets (PAV) is described. To address the severe housing crisis that swept through Geneva for a little over a decade and to attract new business segments, Cantonal authorities are investing great hopes at the extent of the PAV area. Evoked in the inaugural address of the Cantonal government in 2005, the first architectural competition on the sector was opened in September 2011 at a place called *La Marbrerie*[4]; following the zoning status reclassification of the first 130 hectares from the 230 of the sector in June 2011[5]. The objective here is clear: to transfer an industrial site, hosting small businesses still in operation, from the secondary and tertiary sector, into a residential and multifunctional area.

Unlike other reconversion projects of industrial sites, the one of Praille is not a brownfield site but a site of approximately 230 hectares hosting on its area 1,800 companies. The aim of this paper will not to highlight the existing upgrading politics of this industrial heritage site, or not, nor to present reconversion initiatives contained or not in the agenda of this big project, but to reveal social questions raised by such a project. The specifics of the project and site features will be presented before addressing the notion of centrality highlighted in promotional materials, published by the Department of Construction and Information Technology (DCTI) of the Canton of Geneva, and its impact on the process of appropriation of urban space in the neighborhood (De Certeau, Giard & Mayol, 1994, p.9). Finally, beyond the politics of conservation of buildings reflecting the industrial development of Geneva in the 1950s and 1960s, this paper will question what makes memory: stones or uses of the place?, and what anchor territorially the identity. In this projective context, the lines of inquiry raised in this article are based not on observations made during or after completion of such a project but upstream.

2. Analysis

2.2. The site:

Along the Arve, adjoining the Plainpalais district and the municipalities of Carouge and Grand-Lancy, the sector Praille-Acacias-Vernets enjoys today a strategic position at the heart of Geneva, close to the historic center and the shores of Lake Leman. Historically, the industrial area of Praille was developed in the 1960s to house companies on land located at that time on the outskirts of the city. It is the transfer of slaughterhouses at Praille in 1943 and the completion of rail connection with the construction of a freight railway station in 1945 with the creation of an industrial area (Marti, 2007-2008, p. 5) that will mark the beginning of the site development (Brulhart & Deuber-Pauli in Barblan, 1984, p. 18). A brief review of the industrial history of Geneva shows that the displacement from the center to areas outside the city is not new but goes back to 1840s.

> "Even before the law of demolition of the fortifications (1849), the creation of the new town on the cleared terrain and the construction of the bridge of Coulouvrenière (1856-1857), the territory of Plainpalais was chosen to move out cheaply from the harbor and the historic city the industrial base at the time of technological change. (...) The transformations are accompanied by speculation of major projects related to urbanization of the area."
>
> "The urban growth is provided after the National Exhibition in 1896 in Plainpalais, confining in factory zone workers housing estate. (...) In the interwar period, the situation has stabilized and improved by the creation of banks of the Arve and the transfer of slaughterhouses at Praille in 1943, while construction of the viaduct Junction in 1943-1945 moves the rail link

Cornavin-Praille downstream from the neighborhood. Urbanization from 1960-1970 completes to make denser the habitat in Plainpalais to meet the urgent need for low cost housing. Once Plainpalais fully integrated into the urban center, the real estate and administrative influence is growing and putting pressure on industries (...). "[6]

Figure 2. Acacias street, low-rise worker buildings on the path Ternier, close-up: av. Eugene-Marziano. © Nadia Capuzzo Derkovic, February 2012

By the end of World War II and into the 1970s, a combination of factors explains the urban changes that will profoundly change the city. Installation of international organizations, in the wake of the implementation of the UN European headquarters, banking sector development and implementation of foreign companies (Marti, 2007-2008, p. 4-10) are at the heart of Geneva's growth. In parallel with this economic growth, population growth is spectacular. In thirty years, the population rose from 185,000 to 336'000 inhabitants (Marti, 2007-2008, p.5). Faced with this growth, several successive development plans localized on various sectors of the canton tried to meet the strong demand for housing.

Today, the PAV sector concerns three districts located in three communes of the

[6] Brulhart A. et Deuber-Pauli Erica, *op. cit.*, p.18. Author translation: « Avant même la loi de démolition des fortifications (1849), la création de la ville nouvelle sur les terrains dégagés et la construction du pont de la Coulouvrenière (1856-1857), le territoire de Plainpalais a été choisi pour déplacer à moindre frais hors de la rade et de la ville historique l'appareil industriel au moment de sa mutation technologique. (…) Les transformations s'accompagnent d'un mouvement spéculatif de grande envergure en relation avec les projets d'urbanisation de la zone. »
« L'essor urbain est assuré après l'Exposition Nationale de 1896 à Plainpalais, confinant dans la zone des usines les lotissements ouvriers. (…) Dans l'entre-deux guerres, la situation est stabilisée et améliorée par la création des quais de l'Arve et le transfert des abattoirs à la Praille en 1943, tandis que la construction du viaduc de la Jonction en 1943-1945 déplace en aval du quartier de la liaison ferroviaire Cornavin-la Praille. L'urbanisation des années 1960-1970 achève de densifier l'habitat à Plainpalais pour répondre au besoin urgent de logement à bon marché. Une fois Plainpalais complètement intégré au centre urbain, l'emprise immobilière et administrative s'accentue et fait pression sur les industries (…). »

district: the city of Geneva, Carouge and the Grand-Lancy. While Acacias host mainly housing, the Vernets, located on the other side of the Acacias street, mostly provides a base for sports facilities, including swimming pool and ice rink eponymous, office buildings (including Rolex SA) as well as service companies and wholesalers. Built in 1958, the barracks Vernets occupies an area of 48'190 m2 (parade, four buildings and parking) between Acacias street and sports complex Vernets. By 2016, the 5 acres now occupied by the barracks will be transformed into habitable zone. The Hans Wilsdorf Foundation, Rolex SA owner, has already unveiled and out of a feasibility study proposing the construction of six towers for thousand homes and a university center. In parallel, the Association for the conversion of ARV-Vernets, founded in 2008 in response to the disappearance of so-called alternative cultural venues[7], finalizes its draft KaZern[8]. This development project intends to propose a mixt project including the creation of a cultural center, public spaces, housing and activities on the perimeter of Vernets. It is therefore Praille industrial and craft activities that will be moved outside the city to make way for new urban center.

2.2. The project:

Situated right outside the historic center of Geneva, the neighborhoods of Praille, Acacias and Vernets, quickly became an area where urban densification can be developed in response to the housing pressure, with the movement of industrial and craft activities, which are there. Ace of agglomeration project France-Vaud-Geneva[9], CEVA[10] stops, the new stadium, all these factors make the proposed redevelopment of the area attractive. In this context, the Geneva Branch of the Federation of Swiss Architects (FAS) introduced the international competition “Geneva 2020” in 2005, the same year that the new government takes office in Geneva. The FAS call met a great success and plans submitted proposed innovative ideas of urban renewal, but the cantonal authorities did not follow them. In parallel, the authorities instruct studies from eight architectural firms for the production of a master plan. The office finally selected for its realization is the office Niklaus Fausch Ernst Architekten (ENF) form Zürich.

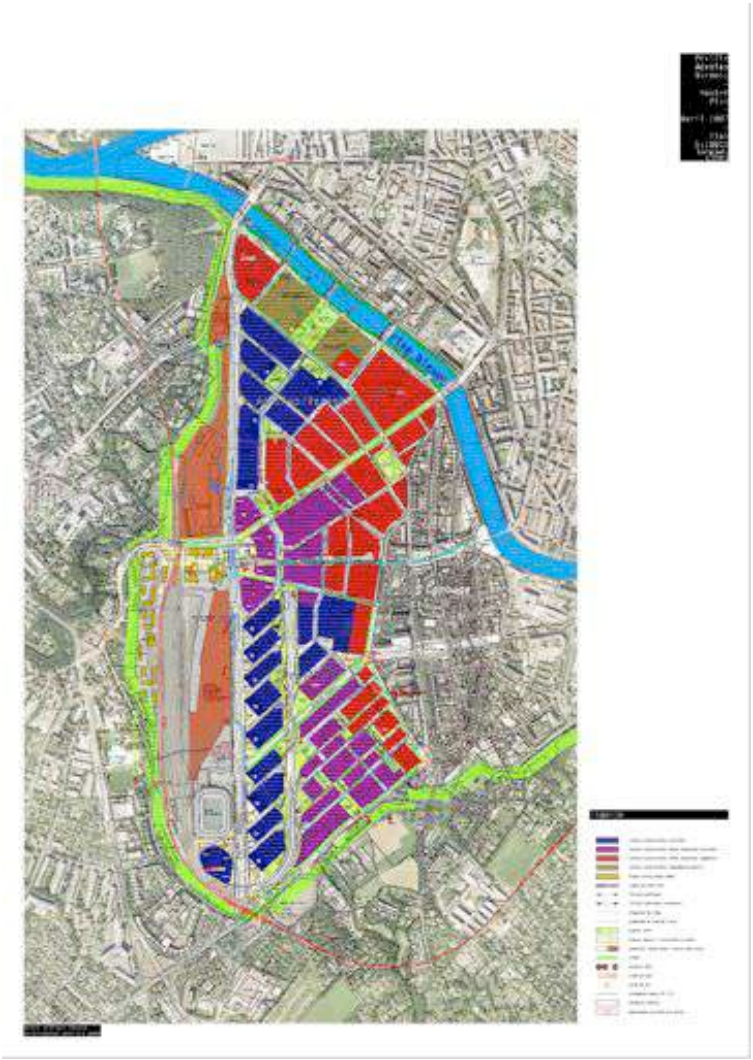

Figure 3. Praille-Acacias-Vernets Master plan, © Niklaus Fausch Ernst Architekten ETH / SIA gmbh, April 2007

The objectives of the master plan, as formulated by authorities, are indicative of the desired mutations in this sector. But these changes will not be without consequences on the spatiality experienced by residents, the composition of the social fabric and identity of the area and neighborhoods. Before discussing these consequences, here are the objectives of PAV, as set out in the master plan of Zürich architects.

"Increase the density of perimeter Praille, contained in an urbanized environment, close to downtown center, give it a new identity better valued.
Consider the vast multimodal accessibility of the site (existing and proposed) by promoting the formation of jobs, thereby contributing to urban sprawl and transportation policy environment friendly.
Develop the capacities of the site and enhance its attractiveness.
Improve the landscape quality of the environment, quality of life and green space planning, setting environmental objectives. "[11]

[11] Ernst Niklaus Fausch Architekten eth/sia gmbh, *Masterplan*, FTI, 2007, p.4. Author translation : « Densifier le périmètre de la Praille, enserré dans un contexte urbanisé, à proximité du centre centre, le doter d'une identité nouvelle, mieux valorisée. Prendre en compte la grande accessibilité multimodale du site (existante et projet) en y favorisant l'implantation d'emplois, contribuant ainsi à la maîtrise de

Important point, this is a concept master plan development that meets the request of authorities. In this sense, it merely provides a development project from existing structures while allowing opportunities for development, to allow "action at the various levels (political, economic, technical or environmental."[12]

This project is organized around six themes which include mobility issues, and logistics networks, the need to strike a balance between new housing, the maintenance and creation of new professional activities and development of public facilities, the creation of public spaces and their networking, and the mutation of an active industrial area into an urban center.

Figure 4. Model Master plan Praille-Acacias-Vernets, © Niklaus Fausch Ernst Architekten ETH / SIA gmbh, April 2007

If the first five themes are part of the urban development sector, the last, namely the transformation of an industrial area, will have repercussions in the peri-urban belt, even the rural area. The challenge is important because much of the 1,800 firms still in operation will leave the area if they are not compatible with neighborhood life (noise, traffic and pollution). From the perspective of land, forced the move will not pose major problem since 82% of land is owned by public authorities. However, the relocation of these activities will be exploded on several small-sized industrial zones outside the city and several towns. On a temporal scale, the movement of these activities will depend on the opportunities in terms of provision of land required. At the political level, "a constructive dialogue (should) be set up with actors land, the

---

l'étalement urbain et à une politique des transports favorable à l'environnement. Développer les capacités d'accueil du site et renforcer son attractivité. Améliorer la qualité paysagère de l'environnement, la qualité de vie et planifier des espaces verts, fixer des objectifs environnementaux. »

[12] Ernst Niklaus Fausch Architekten eth/sia gmbh, *Masterplan*, FTI, 2007, p.5

foundation for industrial land in Geneva (FTI) and the cantonal and communal services, in order to identify durable solutions internal and outside of PAV, which ensure a balance between activities of secondary and tertiary sectors. "[13]

Figure 5. View of the Praille from the municipality of Grand-Lancy, © Nadia Capuzzo Derkovic, February 2012

2.3. New central / new identity:

Beyond the political, the socio-economic and cultural development of PAV on Geneva urban development, whose construction is now planned for 2030, will be measured in terms of readability and centrality. Mutation and densification that will result from the implementation of the PAV will profoundly transform the image of the city. In terms of sense of belonging, spatiality experienced by residents and users will undergo profound changes. Located near downtown, that is to say in the urban belt, affected neighborhoods will gradually be in the downtown core if one believes the objectives and themes of the master plan. And reorganizing the space and offering a new urban composition, centrality will be redefined by breaking with the concept of concentric circles. This shift involves symbolic, thereby changing cultural uses of space. When discussing the concept of downtown, it is commonly referred to the historic heart, the original site from which grew the city. However, in this case, the notion of centrality is used to describe the desired changes in the Praille-Acacias-Vernets, which is not without consequences for current urban identity of the city of Geneva. In terms of readability and visibility, the spatial reference points that define the image of the city and the sense of belonging to both individual and collective level, will either be deleted or be integrated into a new architectural environment. It is important to note that the significance of these landmarks space is not necessarily

[13] PAV, « Foncier », *Projet Praille Acacias Vernets ou comment préparer la Genève de demain,* Le PAV s'expose, n°1, janvier 2011, p. 8. Author translation : « Un dialogue constructif (devra) être mis en place avec les acteurs fonciers, la Fondation pour les terrains industriels de Genève (FTI) et les services cantonaux et communaux, afin de dégager des solutions pérennes à l'intérieur et à l'extérieur du PAV, qui garantissent un équilibre entre activités des secteurs secondaires et tertiaires ».

defined by the function, aesthetics or heritage value of a building. Even insignificant, these spatial signs are all markers, constitutive referents of the sense of belonging.

> "Many places have meaning for individuals and groups of individuals have a reduced visual importance. They are known viscerally, so to speak, and not by the eye or critical thinking. " (Tuan Yi-Fu, 2006, p.164)

In this sense, the word from area users revealed by the vox pops conducted by BazarUrbain in March 2010 at the request of government, is indicative of the existence of a memory guaranteeing the historical continuity of the place. Indeed, the passages dealing with the word of the industrial world and people in the area reveals the identity of the industrial sector and the memory of the place.

> "The industrial part is less known, but the memory of the place is recalled by some residents of Acacias that evoke the location of certain activities and building missing in this sector, such as slaughterhouse and former warehouses of the Migros. "[14]

> "Fear of the disappearance of certain activities by relocating or fear of mono-functionality. For example, in the historically industrial area of Acacias, residents and users would rather like to see the settlement all sorts of diverse and complementary activities. Or fear of exclusion of population already settled thus favoring a gentrification and loss of the spirit of the place, especially the Acacias district noted for its multiculturalism, its popular atmosphere and the abundance of life it supports. The Acacias district returns for its clients and its people, just like a real life of a neighborhood feel as authentic and without "frills". "[15]

> "The craft and industrial world is not stated as an identity element, even if the nostalgia of another time is sometimes noticeable. Is the demise of this world revealing a modern reality or the working world does not built anymore as entities with their own rites and their solidarity and ultimately with the feeling of belonging to a family? "[16]

The impact of the erasure of industrial traces on the sense of belonging to place is

---

[14] BazarUrbain, *op cit.* p. 115. Author translation : "The industrial part is less known, but the memory of the place is recalled by some residents of Acacias that evoke the location of certain activities and building missing in this sector, such as slaughterhouse and former warehouses of the Migros. "

[15] BazarUrbain, *ibid*, p.122. Author translation : «Peur de la disparition de certaines activités par délocalisation ou peur de la mono-fonctionnalité. Par exemple, dans la zone historiquement industrielle des Acacias, les habitants et les usagers souhaiteraient plutôt voir s'implanter toutes sortes d'activités diverses et complémentaires.
Ou encore, peur de l'exclusion de populations déjà présentes favorisant ainsi une gentrification et une déperdition de l'âme des lieux, notamment pour le quartier des Acacias apprécié pour sa multiculturalité, son ambiance populaire et le foisonnement de vie qu'il abrite. Le quartier des Acacias renvoie, pour ses usagers et ses habitants, à l'image d'une vraie vie, d'un quartier ressenti comme authentique et sans « chichis » »

[16] BazarUrbain, *ibid*, p. 99. Author translation : « Le monde artisanal et industriel n'est pas énoncé comme un élément identitaire et moteur du lieu, même si la nostalgie d'un autre temps est parfois perceptible. Est-ce la disparition de monde-là est-elle le révélateur d'une réalité moderne ou le monde ouvrier et artisanal ne se construisent plus comme des entités avec leurs rites propres et leurs solidarités et au final avec le sentiment d'appartenance à une famille ? »

obvious reading these vox pops. In planning the movement of crafts and small industry, the urban fabric and the identification of the sector will be completely changed.

3. Conclusion: Clear or permanent traces industrial? :

To cope the danger of disappearing of industrial heritage, and thus the industrial history of Geneva, it is the need of night cultural sites that appears to save, at least temporarily, the most significant buildings. Like the Usine, old factory of gold roughing (UGDO, 1880) which became a self-managed cultural center since 1989, of the Bâtiment des Forces motrices (1886), historical monument since 1988 and hosting today as BFM cultural events and festivals, of Kugler factory (former Factory Gardy, bought in 1930 by Kugler) whose current assignment is the home of artist residencies and cultural projects on time, it is the factory Sicli which has just been converted into a cultural and festive venue, after being bought by the state. The conversion of the area's industrial heritage Praille-Acacias-Vernets seems to follow the same path as that present in the neighborhood of Junction in the previous movement of industries from the city center to the periphery.

Figure 6. Factory Sicli, designed by architects Constantin Hilberer and Heinz Isler, 1968, © Nadia Capuzzo Derkovic, February 2012

Constituting a special land reserve to boost real estate development (Veschambre, 2008, p. 161), it is the upgrading and densification of the existent that is privileged in the PAV. Here, the conversion, affecting an extended urban area, is a conversion of the functionality of the site from a mono-functional to a multifunctional area, breaking urban planning developed up to then.

> "What is at stake is to concentrate, to gather, to stack up companies which practice intensive use of space and generate nuisances under control (...), to

create voids in which group in turn to other companies and create housing. "[17]

Some will see an analogy with Lego cubes and the infinite array of possible arrangements. Others will question the feasibility of such a project in the timeframe of 2030. What interests us, is the attention paid to the industrial heritage, its treatment and the place accorded to it in this project. Finally, an industrial area, active or not, is not just a field with walls, rails and railway tanks. It is mainly a place where a company and its workers have developed know-how, techniques, where trade union struggles have developed. These traces are those of the industrial memory of Geneva, the memory of workers. How important is this social memory today in this project?

THE COMPETITIVENESS COMPULSION

Helen Carter
hflc@plan.aau.dk
Department of Development and Planning, Aalborg University, Denmark

Key words: competitiveness, urban policy and plans, local government, Denmark

Abstract

'Competitive' is something many cities strive to be today, and for many policy-makers this seems to be a 'natural' priority. A compulsion to compete seems to have been created by an industry of benchmarking, ranking and 'best practices' which surrounds urban governance today, and this influences policy-makers in cities in ways which are often diffuse and indirect. It is often assumed that wider trends, external influences and other levels of governance are pushing a neoliberal competitive discourse upon cities, and whilst this may partly be the case, this paper investigates the mechanisms within local government itself which contribute to reproducing the focus on being competitive. Through a case study of a small city in Denmark, this paper discusses the discourse of competitiveness, the lack of reflection on this discourse which exists amongst policy-makers, and the practices which promote a focus on competitiveness within the local government. In this case, these practices include comparisons and rankings of the city alongside other places in the local region, study tours for inspiration from projects in (often larger) cities, a focus on particular modes of urban development which prioritise 'creative' people and the development of 'experiences', and a general focus within the local government on striving to 'be the best' in a variety of areas. Through a combination of interviews with local policy-makers and document analysis of recent policies and plans, it will be investigated how these practices and more create a diffuse and indirect compulsion to compete, resulting in the institutionalisation of the vision of the 'competitive city'.

Introduction

In this paper I would like to examine the idea that local governments, particularly in small cities, are 'compelled' to act in a competitive manner through their policies and plans. The aim of this paper is to investigate how this 'compulsion' operates within a city.

Much previous literature on competition has focused on the wider creation of a competitiveness discourse, for example at international and national level, with little focus on how cities themselves are contributing to creating this discourse. This is where literature on neoliberalism, policy mobility and planning is of interest, as this is an area of literature which has put planning and policy-making within the city at centre stage. The contribution of this paper is its focus on neoliberal competition and how it operates within a city, placing focus on the role of local government in promoting competitiveness.

Through this literature, and specifically through a focus on disciplinary practices, such as benchmarking, and the creation of subjectivities through planning, I endeavour to investigate the 'competitive compulsion' within Vejle Municipality. This will illuminate the way in which local actors may be playing a part in the 'compulsion to compete' that is experienced in local government. Through the example of a local government in a small city in Denmark, I will seek to illustrate how this apparent 'competitiveness compulsion' is in part created in the city, rather than simply being imposed from outside.

This paper is structured as follows. Firstly I will present a theoretical framework through different perspectives on how competitiveness is propagated, including specific mechanisms such as benchmarking and the creation of subjectivities in planning. With a point of departure in this theoretical focus, I will draw on several examples from a case study of Vejle Municipality, Denmark, showing ways in the local government of a small city can play a role in creating a competitiveness compulsion in planning and policy-making. This will lead to a conclusion on the importance of the role of local actors in terms of their complicity in creating a neoliberal compulsion to compete, with this not simply imposed on cities by external forces. Even in the case of a small city it is evident how local actors play a role in an unreflective adoption of competitive perspectives in urban policy and planning.

Neoliberalism, Competition and the City

Inter-urban competitiveness is often mentioned in the context of neoliberal urban development, with competitiveness viewed as a "primary virtue" (Harvey, 2005, p.65) of neoliberalism. Within the critical analyses of Harvey and others, the "coercive laws of competition force individual or collective agents (capitalist firms, financial institutions, cities) into certain configurations of activities which are themselves constitutive of the capitalist dynamic" (Harvey, 1989:15). In a more recent analysis of neoliberal urbanism, Peck & Tickell (2002) refer back Harvey's ideas about the "powerful disciplinary effects of interurban competition" (2002, p.393), discussing the ways in which they conceptualise neoliberalism as reinforcing and normalising inter-urban competition. These include: promotion of a 'growth-first' perspective on urban development; naturalisation of market logics; neoliberal 'lock-in' in terms of an austere public sector and growth-oriented economic development; a narrow range of potential policies; funding provision to cities on the basis of economic potential rather than social need; cities at the forefront of both neoliberal governance and contestation of neoliberalism (Peck & Tickell, 2002, p.47-48). Therefore in these analyses of neoliberal competition, it is an overwhelming external effect, operating through a variety of mechanisms which force cities to make plans and policies in certain ways.

These political economy analyses focus on competition as a 'force', in particular in a neoliberal capitalist system, which both leads to and is constitutive of a wider system of entrepreneurial urbanism. The danger with this analysis can be its overarching nature. Larner (2003), for example, has expressed some concern that the term 'neoliberalism' is problematic in this respect, providing little explanatory power due to its all-encompassing manner. This type of critique has led to more recent focus on local forms, hybrids and peculiarities of neoliberalism at different sites and scales, as

a supplement to more overall analyses (e.g. Brenner & Theodore, 2002; Peck & Tickell, 2002; Peck, 2004). As Robinson states, urban policies are "highly contingent, dependent on local circumstances, and that their specific form is the result of the range of influences and connections at work in any given instance" (Robinson, 2011, p.29).

Robinson carries on this critique by pointing out that with the "broad academic consensus that there has been a neoliberal turn in urban policy internationally comes a temptation to assess localized urban policy developments as conforming to international trends" (2011, p.28), which can bring with it assumptions about power in terms of the weakness of local governments in the face of "external and more powerful actors" (Robinson, 2011, p.28). Therefore although these wide analyses of a global neoliberal system have their uses, it is important not to view the city exclusively in the light of these homogenising ideas. By examining the city more closely, it is possible both to focus on contextual specificities of neoliberalism, as well as view local actors in a more productive manner, instead of as powerless actors responding to powerful external forces and actors.

The Discipline of Benchmarking and Best Practices

A more detailed analysis of some of the mechanisms which reinforce neoliberal urban governance is evident in terms of discussions about 'best practices' and ranking and benchmarking. Sum (2009) has examined competitiveness as a "hegemonic 'knowledge brand'" (Sum, 2009, p.184), and in particular has investigated how "knowledge apparatuses" (Sum, 2009, p.185) such as benchmarking and indicators functions in the spread of the competitiveness discourse. Through examination of international benchmarking reports such as the *World Competitiveness Report* produced by the Institute for Management Development, Sum (2009) discusses how comparisons of different indicators and 'best practices' form a type of disciplinary power over countries, for example, the ranking of countries "operates as a disciplinary tool (or paper panopticon) with surveillance capacities over them" (Sum, 2009, p.193), with annual revisions of these rankings institutionalising a "continuous gaze through numbers" (Sum, 2009, p.194). Therefore in Sum's analysis, these forms of benchmarking and ranking are an important mechanism in the "treadmill of competitiveness" (Sum, 2009, p.194), and they are often used by various actors to support arguments, to express the need for certain projects, and to create fear over lost possibilities.

This is an idea which is also resonant at the city scale, and some of the recent policy mobility literature discusses similar concerns, whilst highlighting the importance of local government as an actor. McCann (2004) has underlined the importance of mass media in propagating the idea of 'best places', through his study of a number of cities and rankings in selected US mass media publications. These rankings, which he refers to as a "persuasive, widely accepted and powerful simplification of the world" (McCann, 2004, p.1914), create a great interest amongst policy-makers and local politicians. McCann investigates how these rankings inspire cities to focus on certain practices in order to move up this apparently desirable hierarchy, which he describes as being tied up with the "hegemonic, normative discourse of interurban competition that sustains and encourages relative ideological conformity over large

parts of the developed world" (McCann, 2004, p.1912). More recent discussions have placed focus on the manner in which various 'models' of urban development move between cities, highlighting the similarities between urban development in different cities under neoliberalism.

Robinson (2011), whose interests lie particularly on the relationships between so-called 'developing world' cities and 'developed world' cities, raises an interesting point in terms of assumptions of "creativity and mimicry as the preserve of wealthier contexts" (Robinson, 2011, p.22). This highlights the importance of assumed power relations in these debates, with the idea that some cities or actors are more 'powerful' to implement certain policies than others. Robinson (2011) instead calls for greater focus on the local actors in these seemingly global circuits of knowledge, highlighting the "potential for local agency to appropriate and creatively use (even mandate) opportunities for citywide strategic planning", which has "arguably been understated, especially in discussing the circulation of neoliberal policy" (Robinson, 2011, p.35). This harks back to the wider point being made about neoliberalism, that is, the importance of examining contextual hybrids, rather than focusing on a homogeneous model of neoliberal urban development.

These areas of research, into mechanisms which promote competitiveness at a global scale, as well as the processes by which models of neoliberal urban development are transferred between cities, and the role of practices such as benchmarking and best practices, all demonstrate the potential of investigating neoliberal urban governance within the city. Although there is undoubtedly a wider system within which these practices are perpetuated, there is a growing research focus on the specificities of particular places, rather than a constant focus on a universal nature of urban neoliberalism. This focus on the local and the individual city is one which is particularly resonant and evident in planning research, where case studies of particular cities and regions add some further perspectives to this conceptualisation of competitiveness as a locally-specific discourse, promoted through a variety of mechanisms.

Creating Subjectivities through Planning

Recent work on planning and neoliberalism has placed focus on the contradictions between these two 'objects', the most fundamental being the neoliberal ideological desire for less state control, but the simultaneous need for planning to regulate land use (Tasan-Kok, 2011). This 'contradiction' is mirrored in broader discussions of neoliberalism, which have recently distinguished between 'actually-existing neoliberalism' (Brenner & Theodore, 2002) as being distinct from 'pure' neoliberal ideology. Despite these apparent fundamental contradictions, the neoliberalisation of planning seems to be a reality. Baeten highlights how urban citizens have "become self-governing atomised entrepreneurs who have the obligation to pursue their own betterment and fulfillment […] in the city of endless choice and resource" (Baeten, 2011, p.207), a very particular kind of subject. This is a discourse which is difficult to contest, and creates an "impeccable logic of urban neoliberal subjectivity" within which it is "perfectly normal that cities in the first place dress up to seduce wandering neoliberal minds seeking that flawless urban landscape where they can capitalise best on their talents" (Baeten, 2011, p.207).

Peck (2010) discusses similar tendencies, placing more explicit focus on the 'creative class' thesis of Richard Florida (2002), which in recent years has been "hugely seductive" (Peck, 2010, p.192) for local policy-makers and politicians in many parts of the world. Peck (2010) highlights how the creativity trend in urban policy creates a "new generation of entrepreneurializing subjects" (Peck, 2010, p.223), with particular ideas about these subjects' work, free time, and perhaps above all, patterns of consumption.

Both Baeten (2011) and Peck (2010) underline the creation of specific kinds of neoliberal 'subjects' in cities today. Jensen & Richardson (2007), in a slightly different context, have discussed this issue in greater detail, investigating the "imagined mobile subjects" (Jensen & Richardson, 2007, p.137) created in a project around a trans-national corridor. This study adds a more detailed perspective to the general idea of the creative, entrepreneurial subject in the neoliberal city, in that it highlights the specific role of planning and policy-making in creating 'imagined' subjects, and in turn how these subjects are used "to make thinkable, and normal, proposed interventions such as new high-speed transport or communication infrastructures" (Jensen & Richardson, 2007, p.140). Therefore particular subjectivities, such as those Baeten (2011) and Peck (2010) are critical of, have consequences for what is normalised in planning and policy-making, that is, "when particular subjects are imagined in particular ways, this will play a more or less visible part in the formation of policies and plans" (Jensen & Richardson, 2007, p.140).

In this paper I will bring together these seemingly disparate areas of literature. Through examples from Vejle Municipality, I will show how systems of ranking and particular subjectivities are created within planning and policy-making. This contributes to the institutionalisation of competitiveness, and a lack of reflection from local government actors, as these mechanisms then make not just possible, but logical and necessary, certain types of urban development which are reflected in the materialities of the city.

The Case of Vejle Municipality, Denmark

Vejle Municipality is located in the east of the Jutland peninsula, west of Copenhagen and south of Aarhus, Denmark's second city. In the 20th century the city developed a number of industries, including textiles, metals, timber, paper and foodstuffs, also related to its harbour on Vejle Fjord. The majority of these industries have declined since the 1970s, and in recent years new industries, such as IT, service businesses and administration, including the headquarters of Region Southern Denmark, have taken their place (Becker-Christensen *et al*, 1996). Since a nationwide municipal reform in 2007 which increased the size and administrative duties of Danish municipalities, Vejle Municipality has been composed of the city of Vejle itself, and a number of smaller towns, villages and rural areas. Today the municipality has around 107000 inhabitants, with the city of Vejle itself having around 51000 people (Danmarks Statistik, 2012). There has long been an interest in urban development in Vejle Municipality, as seen for example in the creation of an architecture policy and annual architecture prize in the 1970s, and the

implementation of a permanent pedestrian area in the city centre in the 1980s (Brønfeld *et al*, 1998). In this article, the examples of some contemporary planning and policy-making practices in Vejle Municipality are intended to illustrate the local face of a 'competitiveness compulsion'. The practices are not viewed as unusual, at least in the Danish context today, and in that way Vejle serves mainly as a real-life example of a more widespread tendency for local governments to play a role in creating a competitiveness compulsion. The evidence used in this paper is taken from a wider case study of planning, policy-making and the competitiveness discourse in Vejle Municipality. This paper specifically draws on a number of interviews with civil servants and politicians, as well as a document study of municipal publications. Further more comprehensive research into these mechanisms is expected.

Best Practices and Rankings

Within Vejle, as in many cities large and small, there are various local practices which feed into the global trend for 'best practices', ranking and benchmarking. Local government officials and politicians in Vejle take regular 'study tours' to other cities and to see particular projects, both within Europe and further afield. The 'Technical Committee' in Vejle Municipality is the political committee most directly engaged with planning and architecture, and they usually take an annual tour to a larger European City. In recent years, these cities have included Barcelona and Valencia (2008), Oslo (2009) and Milan (2010). These tours are viewed as important in providing inspiration for developments in Vejle, and it is stated by a civil servant in the municipality that they have an important function in terms of showing politicians the possibilities there are in urban development. These tours are however not just about looking outward, or tapping into best practice in well-known cities, they are also about bringing projects and ideas back to Vejle. A politician on the Technical Committee refers to these tours as inspiring, but that there is also a need for Vejle itself to create such inspiring projects - "one has to get out and see what others have done to get some ideas to take further oneself" (interview, politician, 2010). This underlines the way in which the city is seen as a place which can potentially participate in these practices proactively, rather than simply being a 'receiver' of best practice or big city ideas. This is more generally evident in the focus there throughout the municipality on Vejle being 'known', both in Denmark and further afield, for its projects and practices.

More explicit measurements of city 'success' are also of interest with regard to Vejle. There is a great attention to various rankings with the municipality, although this is rather diffuse, with a variety of different indicators seen as important, from national to regional, and in terms of many different sectors, including retail, tourism, and quality of life. Yet as with the idea of being 'known' in terms of urban development, there is also a locally-created expression of the mechanism of benchmarking, illustrating how competitiveness is institutionalised within Vejle, rather than simply being monitored as something occurring 'outside' the city. The 'Growth Barometer' (*Vækstbarometer*) is a short quarterly report which compares Vejle to other cities in the local region in terms of a small number of indicators. These reports, collated in this form since February 2007, bring together data (mostly from Statistics Denmark) in the following areas: population; the local tax base; house prices; building projects; harbour

development; workplaces; business development; unemployment; new firms created; and hotel stays (Vækstbarometer, 2012). The initial reports loosely compared Vejle with nearby cities of Kolding, Fredericia and Horsens, whereas since 2008, a comparison with Aarhus has also been included (Vækstbarometer, 2008). These reports are also quite explicit in their presentation of tables comparing the performance of the five places in terms of the different indicators. Vejle Municipality is here defining certain ways in which it can measure itself through this local interpretation of a worldwide fetish for 'benchmarking', thereby contributing to their own apparent need to compete.

Imagined Future Residents

The other aspect of the 'compulsion' to compete which I introduced in the beginning of this article was the creation of particular subjectivities, which could then serve as legitimating factors for certain policies and plans. Within Vejle, a focus on 'creative', 'innovative' and often young people is evident in policies and plans from across the municipality. This is particularly in terms of their status as desirable 'future residents', people that need to be attracted to live and work in Vejle. As one interviewee states, this 'attraction' of new residents and businesses is quite important, being "something we very much focus on in Vejle, that is to be attractive, we focus basically on the more people we can get to live and invest here, put money into Vejle" (interview, civil servant, 2009). Yet at this overall level, the aim remains fairly unspecific, and the question of exactly what groups they are trying to attract in Vejle is an interesting one.

It is here that the 'creative class' is quite evident, for example in a publication from the Business Development section of the municipality, this group is referred to as "the ultimate resource for economic growth", and their presence should apparently create "great demand for culture and consumer opportunities and contributes to a series of positive effects in the local area - increase retailing, more restaurant visits and higher property prices" (Vejle Erhvervsudvikling, 2008, p.23). The general interest in Florida's thesis is also more widely evident in Vejle Municipality, including the fact that he himself was invited to speak in the municipality in 2006. This also resonates with a slightly more general focus on well-educated young people as a key group to attract to the municipality. This is mainly in terms of encouraging young people to 'return' after they have completed a higher education elsewhere, as there are limited opportunities for this in Vejle Municipality itself. For two of the interviewees engaged with the field of culture, this is where they conceptualise a focus on youth culture as important, in that giving children and young people a good experience in Vejle Municipality early in their lives would hopefully draw them back later (interview, politician, 2010; interview, civil servant, 2010). Again in a publication from the business development section of the municipality, there is a view that there is already a positive development in the city with regard to this group: "partly because businesses to a greater extent have attracted highly educated people, and partly because a focused effort has made Vejle Municipality especially an attractive place for highly-educated people to live and work" (Vejle Erhvervsudvikling, 2009, p.12).

Specific projects within the municipality are also framed in terms of these subjects, illustrating the connection between these desired future citizens and the materialities of the city. The redevelopment of an old Spinning Mill in the city centre to a mixture of office space for small businesses, space for sports clubs and culture, a museum, a cafe, and other facilities, is one such project, catering to both the work and leisure of the entrepreneurial and innovative creative people whom the municipality would like to attract. A civil servant working with this project states that the general focus on creativity and projects such as this one in particular would hopefully mean that "the business community will be able to attract some knowledge workers, who would not have chosen Vejle, because there was not an environment they could be a part of" (interview, civil servant, 2009). This illustrates the connection which is made in planning and policy-making between the desirable future residents and the types of projects which are then implemented in the city. A certain kind of ideal future citizen is imagined who is out there, waiting to be 'attracted', and it is then logical and necessary to create a certain type of city which is attractive to these citizens.

The Competitiveness Compulsion in Vejle

The short examples in this paper show the way in which a competitiveness compulsion can be created within a single small city. Although the practices which I have presented here are by no means unfamiliar from other cities, they also show something of the workings of competitiveness within a city. Rather than 'submitting' to overwhelming outside forces, in the form of powerful regulations, actors or the like, Vejle Municipality has been actively creating these forces within the city as well. Study tours are an important annual event, but they serve also as inspiration to how Vejle itself can become such a 'model' and create their own 'best practices' by which they will be known. Benchmarking and externally produced indicators are of interest, yet the municipality also creates their own indicators, willingly measuring their 'performance' against their neighbours and thereby subjecting themselves to their own form of competitiveness treadmill. Imagined future residents are created, in the somewhat predictable form of creative, entrepreneurial, well-educated and mainly young people, and the creation of these imagined future residents leads to an imperative for planning and implementing projects and forming the kind of city which they are expected to want.

Therefore the small city in particular should not be dismissed as a powerless actor in a competitiveness game which is occurring in at the international and national levels, or even in just larger cities. As the Vejle example shows, the local government and actors in a small city can form their own mechanisms which then promote local competitiveness.

In Vejle Municipality, I have looked at two ways in which a compulsion to compete is created within the municipality. Firstly there is the compulsion related to disciplinary mechanisms such as 'benchmarking', where the price of property, the tax base of the residents, and other elements are prioritised as ways of 'measuring' the municipality's success. Secondly there is a compulsion related to the creation of a particular type of 'future citizen' whom policies and plans are directed towards. These two elements of compelling the municipality to compete contribute to a process of the local government creating its own self-reinforcing 'compulsion to compete', in terms of the disciplinary practices they place upon themselves and the

subjects they create to serve in their policies and plans. These practices are highly institutionalised in the municipality, which is particularly evident in terms of the lack of reflection there is on these practices. It is generally seen by actors in the local government as a 'natural' priority to work in this way, and this is part of the self-reinforcing power of the mechanisms I have discussed in this paper. In this case, local government in a relatively small city is by no means a powerless actor in the face of a monolithic 'competitiveness' discourse, being imposed through external mechanisms. They are complicit in creating a compulsion to compete in their own city.

In the examples used, there is evidence of the "disciplinary tool" (Sum, 2009, p.193) of comparing various indicators between cities, as well as a focus on 'best places' (McCann, 2004). Although, as Robinson (2011) has highlighted, the examples also show the importance of not ignoring local agency when investigating such mechanisms. This is what the Vejle example shows most clearly - that although these practices are not unique or created in a vacuum, they are practices which are occurring within Vejle Municipality, showing the power of the local actors in contributing to creating their own "treadmill of competitiveness" (Sum, 2009, p.194).

The local creation of neoliberal subjectivities (Baeten, 2011; Peck, 2010) is also apparent, in terms of the creative, entrepreneurial and young imagined future citizens. As Baeten (2011) indicates, this mode of neoliberal and competitiveness-oriented governance more generally creates an ideal citizen who should be attracted to a city, where they unleash their entrepreneurial potentials and enjoy the consumption-oriented lifestyle expected of them. Following Jensen & Richardson (2007), this creates a logic whereby plans and policies are made "thinkable, and normal" (Jensen & Richardson, 2007, p.141) in terms of the necessity to attract these imagined future citizens. Together, the use of comparative indicators and the imagined future citizens contribute to a self-reinforcing 'necessity' to compete in Vejle. The two examples are also intertwined, in that a focus on particular indicators such as house prices and the new businesses in Vejle are supported by the imagined future citizens whom the municipality would like to attract.

The case of Vejle Municipality shows that local agency can play a role in creating a compulsion to compete for a city, rather than this being something which comes exclusively from external trends and forces. This is particularly interesting in terms of the small size and relative anonymity of Vejle, a type of place which might be assumed to lack this kind of local power. Yet it also shows the problematic nature of this situation, as the self-reinforcing and circular nature of the disciplinary mechanisms and the creation of particular subjectivities does not inspire reflection on these processes, rather they are institutionalised within the municipality. For local actors, their part in creating this compulsion is rather opaque, and the institutionalisation of these practices means that planning and policy-making in this way is viewed as a natural and logical course. Further work on the competitiveness compulsion at the local scale, in terms of more comprehensive study of the internal mechanisms which are at work, as well as greater focus on smaller cities, is necessary.

THE TERRITORY OF BELIEVE IN BANGKOK OLD TOWN: CONSERVATIVE NATIONALISM THAT INSTALLED TO CULTURE

SIRIPORN DANSAKUN[1]

Abstract

Town planning was created for many purpose of the reigning. Bangkok old town itself has 4 layers of town planning overlapped in 2011. All the layers has symbol of believe itself, and the development relate to how they definite "Thainess" as be loyal to "Country-Religious-the King." But if we look inside to the much more small scale, the town are full decorated with soft "ephemeral ornaments" by people. The hypothesis is this ornaments can tell us how success of the symbolization that the reigning had been dedicated. And in the same time it shown some missed believes that were ignored in the big viewpoint, small but priceless for users. The research focuses on the ephemeral decorated space. Collecting data from public places that have high dense of usage and full of people circulation. The evaluation of this community place is markets in the Bangkok old town, that inherited from generation to generation. From those markets we scope to the town zoning that is fulfilled with hard elements of town landscape that is a symbolic of believe. The purpose is to find the relation ship between permanent symbolic ornaments and ephemeral symbolic ornament, and the meaning of decoration to users. The methodology is snapping Bangkok town activities in the period of 2011-2012. Collecting data of decorated space. Categorize how to decorate. Clearify the structure of believe territory. Matching each category to each area in percentage. Interview about sense of value and users cognitive. Analyze people daily life interaction with spirits and force through decorated ornament. Though this study we find out that Bangkok permanent town symbolic clearly related to the political policy of each period, creating multicore philosophy that is mixed of Nation-Religion –The king. And if we

figured on percentage of decorating area the Nationalism believe “Thainess” created from the trial of “National Unification” cover area of decoration the most. The distribution of Nationlism believe and folk believe can separated into each level of public and private space. And in if we focus on the different view point of sustainable of meaning for decoration the folk clearly have much more value for the user in the long run. Its use very small area but effects to user daily life, being tools for interact with spirits and forces, and the small things itself created one more layer of town invisible town structure where force and spirits lives and having circulation in the users mind.

1. Introduction

Bangkok have 1568.737 square meters, with 6,784,529 population in 2008. 99% of citizen have Thai Nationality. 94.5% is Budhistsm, 4.1% is Islamic, 1.0% is Christian. 35.34% graduated primary school 30.39% graduated from high school and 26.39% graduated from university. The population in eduation generation 6-29 years old is 1,321,800 people.

1.1 The 5 layers of town planning overlapped on Bangkok Old Town.

Related to The study of Town mapping in Bangkok old town,Rattanakosin area,we can find four layers of town planning created in each era. Before Bangkok turn to be Main Capital of Thailand the map show only temple random around the area. And their suggest that people who live here was chinese and local people living nearby each temple. When the Rama 1st take Bangkok as the Capital their has two planning conceeptep used for first planning period, The Naga Theory and The diagram of Cosmos Theory. Then in Rama 5th the facilities linkage and zoning was adapped into cosmos theory to put the new function architecture into the old town. And the town ins spreading in line by economic growth.

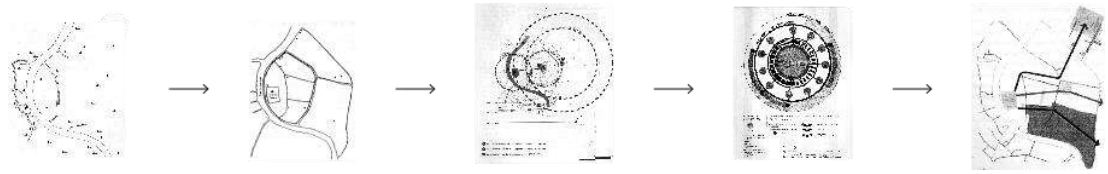

fig1.1.1 5 layers in the bangkok old town.

fig1.1.2 Bangkok old town and total area of Bangkok city.

1.2 Symbol of Believe in each Town Planning Time line.

All the layers concept can compared to the changing in flag design, Plitical issue, Cultural and lifestyle management , town symbolic elements, and ephemeral decoration ornaments controled by government. In Rama 1st the flag began to use royal monarchy sign. The building and custom was allowed to be well prepared only for Royalfamily and Nobleman. In that period Town planning have the spot only the relation ship between Palace River and Temple. In Rama 5th the Flag turn from Royal sign to be white elephant that means to the prosperity of King and Kingdom. People have custom in cross culture the facilities turn to be much more various kind. Almost was trying to make the unity of Thailand together,by bringing some craft from all over Thailand to mix and adapt to each other to make every one feel as in the same nation. Town decoration is crossed culture and using European way to pay respect to adapt for people to express their feeling of paying respect to Thai king. That time town planning concept still have cosmos linkage but input many facility that link people to government into the loop.

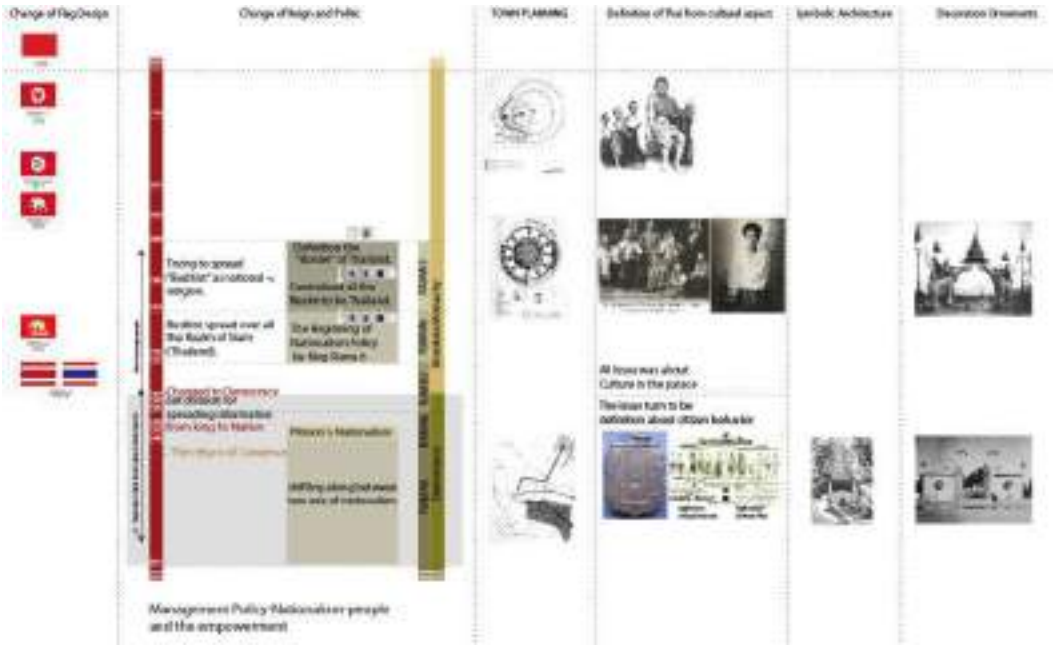

fig1.2.1 comparison timeline of flags design , Political issue , Town planning concept, Cultural written by the reign, Town Symbolic and ephemeral decoration by the reign.

1.3 The relation between Symbol of Believe and Thainess.

1.3.1 Definition of Thainess as Folk believe and Thai Nationalism.

This research separate Ornament that express believe into Folk believe that created by common people in their life and cross culture. And the Nationalism ornaments That country tried to install into town scape and the same purpose issue that is installated by people.

1.3.2 Town Symbolic as Folk believe and Thai Nationalism.

Town Symbolic as folk believe usually appear in spirits house, The holy Tree and House of God in Hindu Religious. The other symbolic in Nationalism is almost facilities and monuments that can separate to Royalist+Racist Nationalism and Liberate Nationalism. This expressing way also decorated in the ornaments statue, interior painting and ephemeral decoration densed in Bangkok old town.

If we see in the planning concept in each5 layers we also can find symbol of believe setting in each area too.

1.4 The Ephemeral decoration space.

To find how the political decoration turn to be believe ornaments, This research focus onto the ornaments decorated by citizen themselves. Specify into ephemeral things that they can take it off or set it to space anytime they want to. So we can measure the supply of decoration that support demand easily in town.

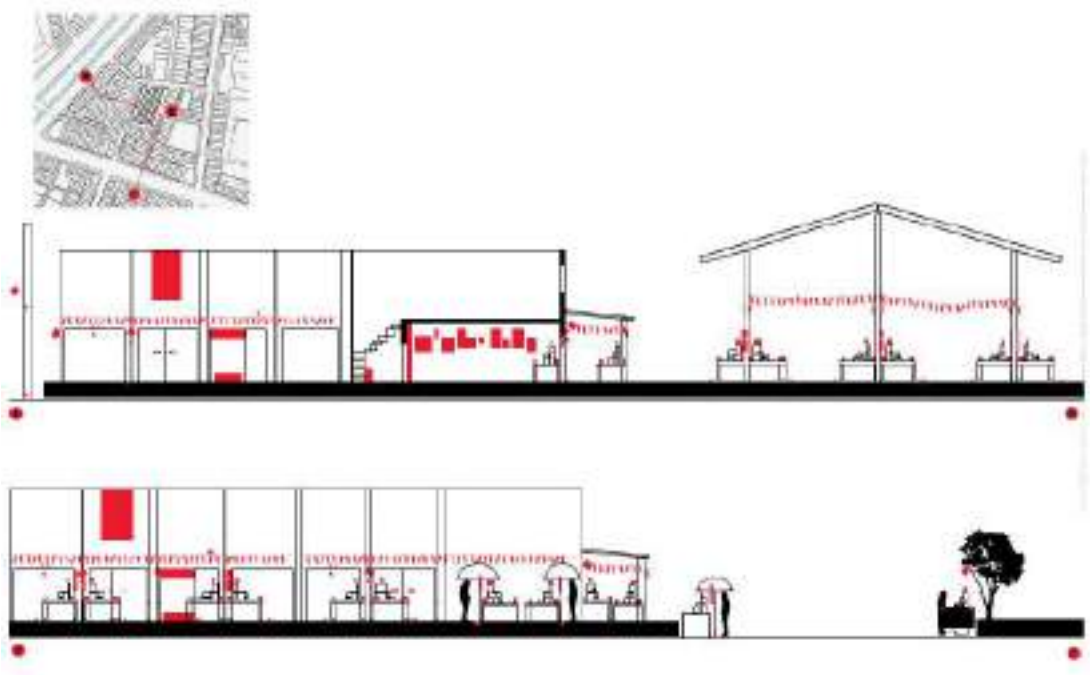

fig1.3.2 Kaset market's ephimeral ornaments decoration.

1. Scope of Study

1.1 Study Questions

Questions which this study tries to answer are as follow.
How Nationalism take roll as one kind of believe, among mixed culture.
How Nationalism absorb to everyday life.
How it spread into town.
How people take important about Nationalism as believe.

1.2 Study Targets and Methods

This study focused on market area of Bangkok Old town, The methodology is snapping Bangkok town activities in the period of 2011-2012. Collecting data of decorated spaces.Categorize how to decorate.Clearify the structure of believe territory. Matching each category to each area in percentage. Interview about sense of value and users cognitive. Analyze people daily life interaction

with spirits and force through decorated ornament.

1.3 **Literatures Review**

After research about Nationalism, Space decoration and folk believe, there are some of research that searching about Ghost Space, Ornaments of Believe in Temple and House Design. Nationalism and New Definition of Thainess. Thainess in Political and Management policy.

2. Site Selection

From background study this research focus in the Bangkok old town that have 5 layers of town symbolic and still have common life living from generation to generation. We focus onto the semi public place as market. The place that people can dominate their own territory but sharing it together in the same time. The place that open to all people to visit. The place that have densed circulation almost everyday trough the year.

2.1 Market in Old Town

The site selection begin with mapping all market that stay alive for a long run generation to generation. Then select the dense town symbolic zone. And pick up the well circulation place in the symbolic zone for case study.

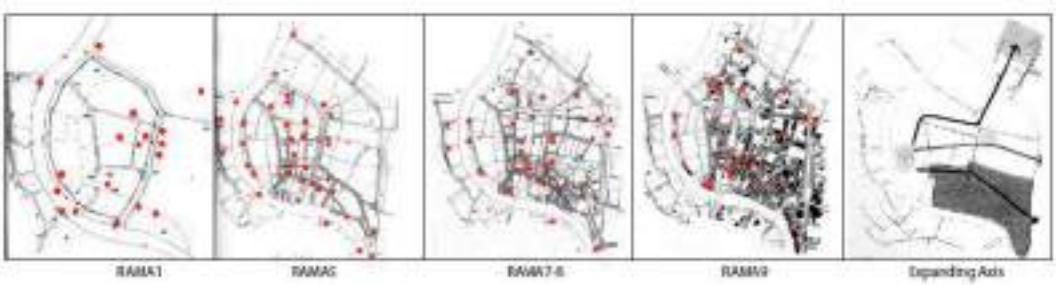

fig2.1 market formed in each era.

2.2 The physical Factors

Almost the market located in riversite spreading onto the pedestrian way of the maind road. Most are rental from owner. Someplace ownd by The Crown Property Bureau. Some own by one owner and sometimes change to new owner with some renovation and renewal zoning program.

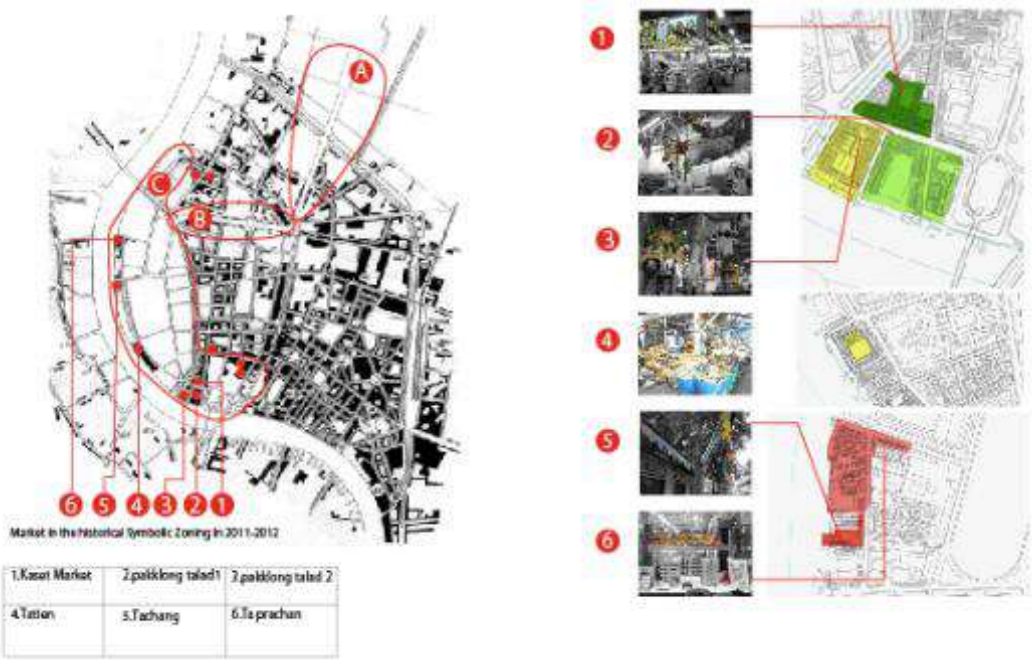

Fig2.2.1 old markets in the symbolic axes of Bangkok old town.

Fig2.2.2 Case study No.1 Kaset Market.

3. Definition of Ornaments

3.1 Ornaments in each Scale of Community

from liturature review field study research and interview result, The density of ornament on each scale of community will have different percentage. The sharing style and territory creating also happen easier inside the facility. And the way

relate to host is also depend to the shape of place. What is host definited in each scale and how tenant interact with the host, the space the place the land and their customer.

3.2 Typical of ornaments separated by purpose of believe.

From interview result we separate the ornaments into Thai Conservatinve Nationalism. Democratic Nationalism(messeage.) and Folk believe that appear as the figure below.

fig.3.2 believe ornaments separated for this research.

3.3 Town mapping of decoration.

According to town snapping. The ornaments can be separated in many ways as,

3.3.1 Hard Scape Symbolic

The hard scape symbolic created by town planning concept. History of people relate to that place. And the cultural issue.

3.3.2 Ornaments in Town Landscape scale

Almost town landscape ephemeral decoration is about the royal family espacilaly the king. Some is stand alone setting. Some is making as sign in the vista. Some is use for sirsle. Some is decorate as a bridge. And many road sign elements and some turn tobe façade of each building especially the builing of government, bank facilities and the building in each corner or the town.

fig3.3.2 ephimeral street ornaments.

3.3.3 Ornaments in Community Area Scale

3.3.3.1 Ornaments in total view of Market Facililty

ephemeral total view of market facility is some stand alone ornaments. Façade decoration flags and flags set that cover the pathway and arcade as a membrain.

3.3.3.1 Ornaments in pedestrian way

in the pedestrian way usually be the private decoration by people, sometimes sharing toether. Sometime is using as private. In the private ornaments they have lots interaction meaning in each position.

4.Structure of where to set ornaments.

4.1 defferents of spreading

among all kind of ornaments, there are the decoration of their believe that is their beloved. And the place they set placed for someone they respect have covered more than 70% of the displaying space in the market.

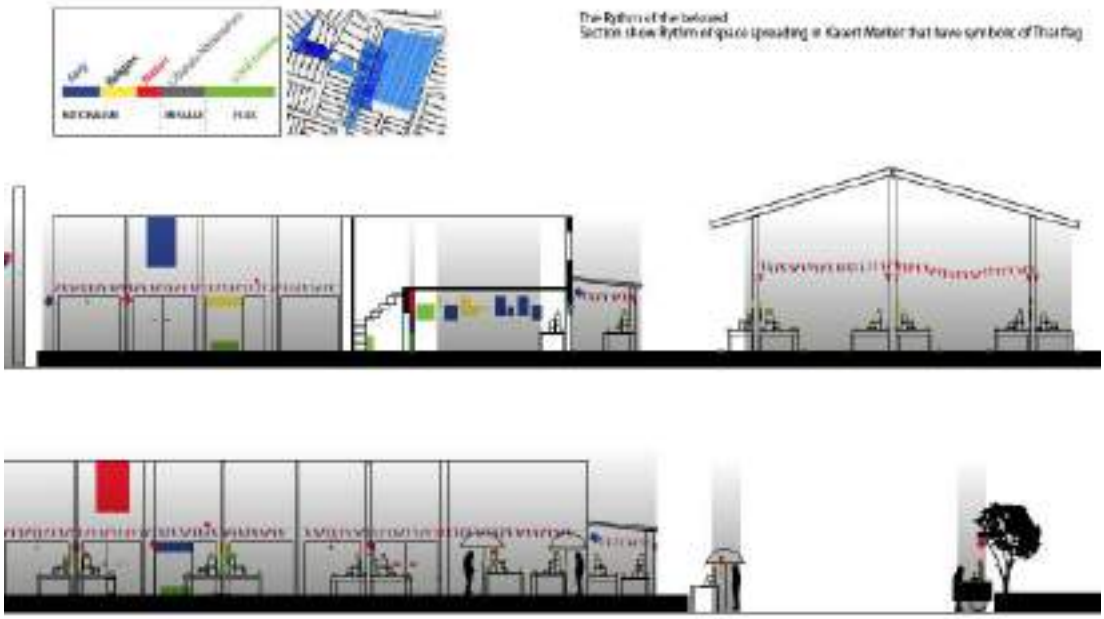

fig 4.1 The rhythm of the believe ornaments that express to someone they respect.

4.2 frequence of changes

The interaction folk believe somekind is changing daily and have the interaction with the tenant user more than twice a day. Not much ornament changed or interact monthly. The religious folk and nationalism all have much of ornaments that will be turn to the new one annually. For anniversary using usually be for the Nationalism ornaments. The fix use keeping along generation usually be for the folk ornaments that sometime they keep the ornament move together and ask the spirits to move to the new place with thwm and the moving believe ornaments. (This kind of ornaments sometime being in the case of stolen. But the most ornament stoled is religious statue. That turn to be one kind of rotation happen case by case.)

4.3 Zoning and the spreading of ornaments

The spreading of Nationalism ornaments can be spread easily because the shape is

easy for amature decorator to adapting to any design much more than religious and folk believe. But from the designer view folk believe also have many potential to adapt to design in veryinteresting way. And for the decoration for respect it is upper than 80 cm from floor and will be spread cover wider area, sometimes the ornaments itself got bigger when its going high.

fig 4.3 the zoning and spreading of element expressing repect.

5 Category of how to decorate

5.1 Territory creation

from measure and activities snapping, can find many way ornaments effects to meaning of territory.

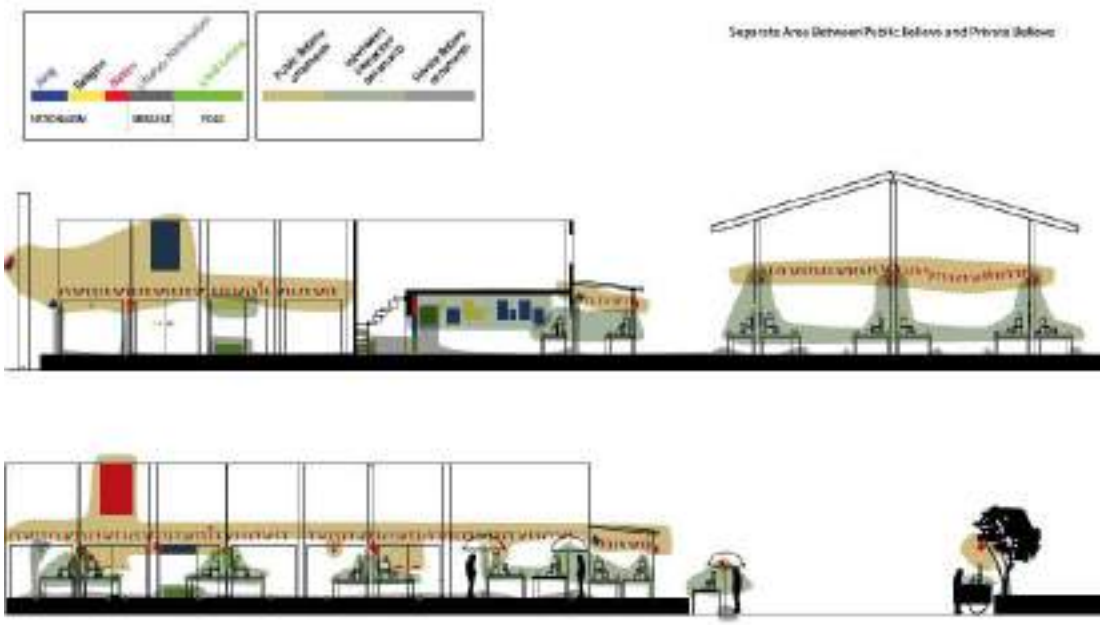
- wrapping volume.
- double layer effect.
- Unity of sharing space.
- Edge emphasis
- extension space
- sharing pattern (sharing belive)
- connect to host

6 Territory and perceive trough ornaments

from interview results and activities mapping

6.1 Public and Private volume or territory created by ornaments

The zoning of private and public ornaments are interesting in section plan. The more private the more linked to ground. The more public or want to express,the more they set it high.



6.2 The Connection to Spiritual Space.

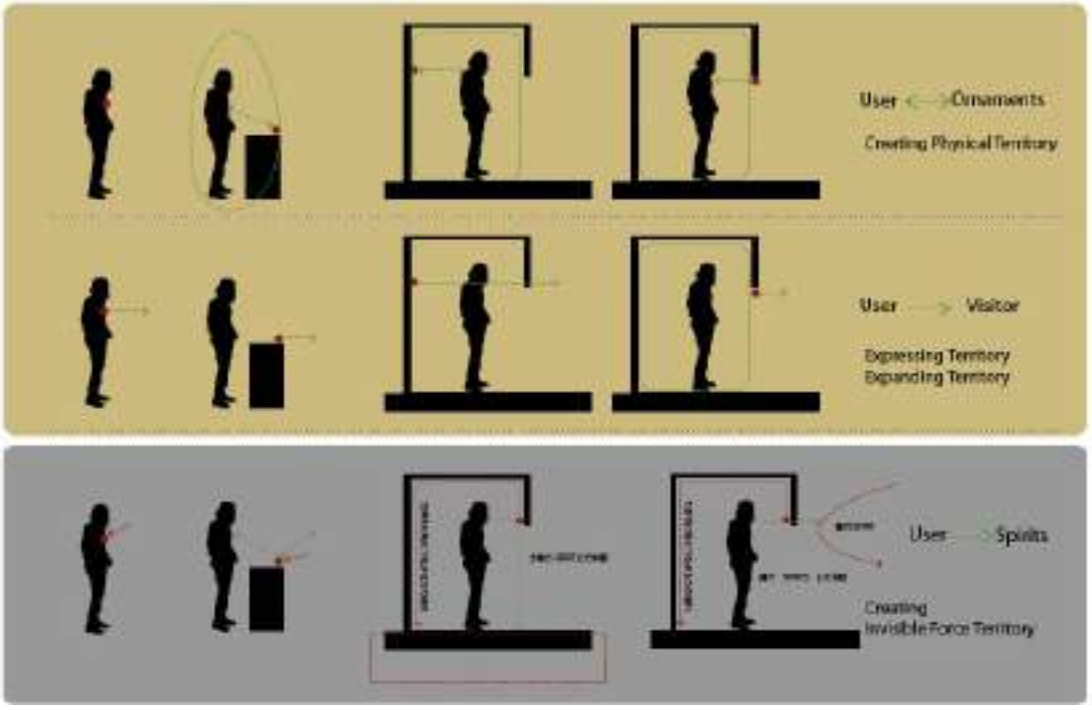
They are many kind of spiritual ornaments. Some connect to the total area. Some cover only the door way. Some linked the house to the tenant. Some link the street vender to the ground or the big tree. Some interact with the spirits keeping circulate trough the town. And the user pecieve each kind of spirits movements and the space the movesd in 3D.

6.3 Percieved space created by territory

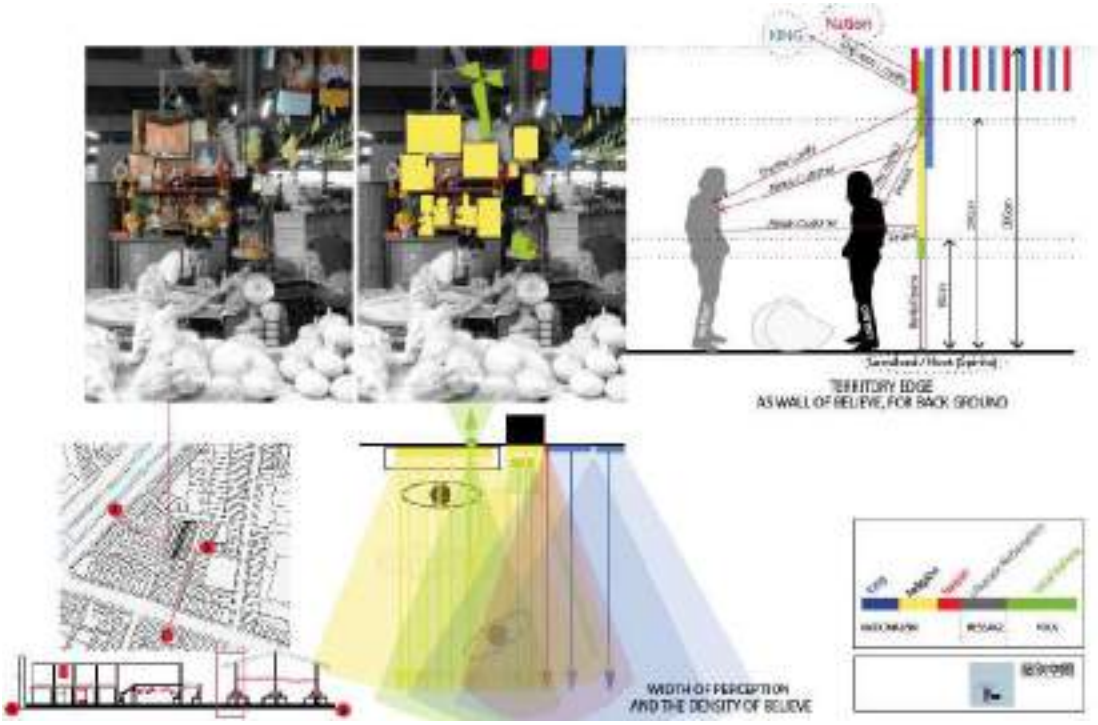
many space created by the territory itself. At the edge or the land mark of each territory they will put some connection ornaments and will perceive some space that can expand their territory or blur it more.

7. Ornaments'Interact

The ornament sometimes interact to the owner itself.



8. Adaptable to Design



9. Percieve of Value

9.1 as believe

9.2 factor of decorative selection(cultural activity, sense of place ,

9.3 Memorable

10.Conclusion

10.1 Nationalism is input to ornaments of believe.

Nationalism is input to ornaments of believe decoration by local people. It has a shape to let decorator pin up many idea of use but it still keep it own state in it s area that the other ornaments can not approach better. It keep it s position while turing position to the believe memorial and some kind of folk believe in some case. And in the same time the way of decorating input into people to make them feel as this territory crating style is the old way that feel nostalgic to the culture itself, also.

10.2 The Adaptation of ornaments itself

Folk and religious sometimes have interesting locating way. But its never change to design as easy as nationalism. But in the believe meaning nationalism still have no much potential to stick with user to every place as in the modern design. While folk believe can input into the very modern and contemporary interior space much more as the important elements that connect to spirits and spiritual space that user still perceive and want to get connected.

Creative Industries in City Spaces: the case of art in public places

Solmaz Khoshkholghi, Katharina Borsi

Abstract

Purpose: to survey the creative cultural industries impact in urban spaces and their quality in particular art in public realm in cities

Methodology: The article reveals the preliminary findings of the study of art in urban spaces and artists contribution in forming and transforming public realm of cities

Key Words: creative city; cultural industry; public spaces; quality of space; public art

Introduction

Cities are manifestation of the culture and traditions of a people, a historical period, a region, an environment and a climate. Therefore city, its architecture and features had an unbroken relationship with the culture of a society and people's lives and Changes in it often accompany changes in life style, views and art.

With the rapid scientific, technological and economic development, cities grew faster and unbalanced and unplanned development lead to design strategies affected from the paradigms such as mass production and standardization.

The consequences of modernist planning were responsible for homogenous urban fabric rather than heterogeneous urban texture, zoned land use instead of mixed land use, indirect communication rather than direct communication, space rather than place and most importantly segregation rather than integration. In other words, as some critics like Natrasony emphasize, modernist approaches and internationalist style caused placeless urban environments.

It is a well established argument now that Good architecture and environmental planning not only respects the natural environment, but also pays attention to the continuity of culture, highlights the local features and stresses the order of space organization. Every city should have its own character in which elements of politics, society, economy, history and culture directly affect the overall layout, image, structure and facilities of the city. Only when the city's unique features are defined can an excellent urban image be created.

Considering the impact of the quality of city spaces and public realm of cities on all the people of the city and moreover the fact that visitors of a city first see and are influenced by the city's look make the environment and public spaces' design of even greater importance. Paying enough attention to the design of the city environment and urban landscape helps to improve the socio-cultural fabric, the tourism industry and the national image overall, the main and most important influence however is on the quality of life of the residence of the city.

In this regard it is important to revise public realm concept, the importance of liveable successful in between spaces and its complication as well as the path urbanists have been through and theories experienced in order to achieve that immensely vital concept.

Public Space

In urban life the in-between space, public space, has an important role in terms of social interaction and behaviour. They are the vital parts of cities where social life, integration and communication between residents and strangers take place. Organization of this space embodies social interactions or vice versa. Sometimes a composed social phenomenology can shape this space.

Public space has a broad concern and defined by various authors as places accessible to all, used by all, activity nodes and gathering points, places where common or different beliefs are shared, where people meet each other or come into contact with total strangers. Madanipour (2003) defines public space as "a site for display and performance", "an arena of recognition", "an exploration of difference and identity", "the in-between space that facilitates co-presence and regulates interpersonal relationships" (Madanipour, 2003, p. 235). It is the place of common world, shared experience and where tolerance grows between citizens. It is a tool for managing pedestrian movement and it has a function for various purposes (Madanipour, 2003).

There are three aspects of the public realm which are considered by researchers to be spatial, managerial, and temporal. Firstly as a spatial aspect, spaces between places, left over spaces that are disregarded by policy and design supply amazing opportunities for social uses and the street life. Secondly as a managerial aspect, between public and private institutions; there is an overlap of different spatial control and access. Hence there should be negotiation among the users. Lastly as a temporal aspect, between tenancies; this implies the change of urban space in terms of its character and use when it is in the period between the occupations of different occupants. Hence urban design should reconsider the uncertainty and challenging opportunity of this in-between space (Stevens, 2008).

The concept of public spaces has a crucial impact on community. Successful public spaces are the tools for place making. Their design and form also have an impact on the coherence and continuum of the whole region. Vivid and usable public spaces are important for the healthy society and environments. It makes these urban components important in planning process and urban regeneration and to investigate the basic element that gives character to cities and its public spaces and tools that have been used during years to form these spaces. Morris (1994) says that it is the outcome of a process that is formed under the determining forces and classifies these forces under two; firstly geographical factors such as climate, topography, and local construction materials. Secondly, man-made determinants like socio-political and economical powers, culture, and religion. Creative class always known as the society's expressive engine and cultural industries as tools to express, form and transform the second group into spatial dimensions and more tangible features of cities and form the characteristics and identity of space through artistic expression. Acknowledgment of the creativity and creative city theories and attempt to understand the role of cultural industries in place making is the first step of a broader understanding of city spaces, public realm in particular, and how to achieve successful, livable public places.

Creativity theories and creative industries

The creativity discourse and creative city is not a new idea and different cities in the world been famous and flourished through being art and culture centres during the history, from Athens to Florence, Paris and Vienna (Hall, 2000). During last decades the new economy formed due to 'the shifts in technology, structures of production, labour markets and dynamics in locational agglomeration' (Scott, 2006)-so called 'creative economy'- changed the social, cultural and spatial aspects of urban development process through restructuring modern cities. Experts believe for successful cities art and creativity plays an important role in this restruction and they emphasize on the importance of investment on creativity, locality and cultural heritage (Sassen,2001; Sharp,2005; Montgomery, 2007).

Creativity

If creativity is 'any act, idea or product that changes an existing domain or transform it into a new one' it is possible to indicate the link between creativity and cities as 'a creative milieu is a place that contains the necessary preconditions in terms of hard and soft infrastructure to generate a flow of ideas and inventions' (Landry, 2000). This link becomes more important considering the strong correlation pointed out between creative places and economic growth and the link between creative industries and the development of creative urban regions become popular research topic (Durmaz, 2009). The concept of 'Creative city' developed by Landry by conceptualization of this link: 'a creative city is an entity that could only be

developed through well designed creative strategies (policy); with a strong presence of creative industries (economy); and by a creative community (society) (Durmaz, 2008).

Cultural and creative industries

Adorno and Horkheimer first used the term 'cultural industry' in critisizing commercial mass production of art and culture and lack of its independency from economic and political conjuncture (Adorno and Horkheimer, 1947). But it was a surprise that when governmental institutions started to use the term in 1980s as a policy circles vehicle, they used it to adress the whole range of cultural products and services people consume (Durmaz, 2009), in the way Adorno and Horkheimer critiqued. For adorno the contraditction of art and culture and economic activities was crucial whereas in this new conceptualization 'cultural industries' tiesd them together. In 1990s 'cultural industry' was the short way of 'defining various sectors with art-related outputs' (Montgomery, 1990).

The 'cultural industries' concept led to 'creative industries' by arriving of 'creativity' theories and 'creative city' notion and these industries include key sectors such as: 'advertising, architecture, the art and antiques market, crafts, design, fashion, film, crafts, performing arts, publishing, television and radio' (DCMS, 1998). This report though distinguishes cultural industries as artist centred from creative industries as technological reproduction and wide accessibility.

Creative industries are important part of creative cities, generating economic activity to the city. Landry reports that attention to creative industries increased between urban planners, policy makers and developers in recent years (Landry, 2000) and theories of creativity provided base for many cities' spatial and economic growth (Landry, 2000; Florida, 2002). Landry believes that creative industries also create positive images of cities, help social cohesion, attract talent and investment while contributing the liveability and quality of place and life of residents (Landry, 2000) and promote sustainable urban development and tourism (Richards and Wilson, 2007).

On the other hand Oakley express that the role of cultural and creative industries in economic growth of cities is exagerated (Oakley, 2004).
Roodhouse writes 'creative industries are wider definition of culture to encourage cohesion, participation and ownership' (Roodhouse, 2006) and Evans et al. indicates the importance of creative industries in enhancing place quality and formation of urban identity. And this is the link which makes creative industries, culture a and its

manifestation forms important in urban planning and place making. In order to be able to discuss the importance of these tools in urban related disciplines the understanding of the quality of place and its indicators is vital. And understanding of their mutual impact.

Place quality

In urban related literature the 'quality of place' refers to the assets that make a successful urban space where people prefer to live, work and play. Understanding the characteristics of such places and what makes a place successful and the destination to live, work and visit has been the focal point of urban research and forms an important part of it.

Montgomery argues that cultural industries and creativity should be an important part of planning strategies, particularly in providing infrastructure for qualitative improvement in the quality of life of residents and enhancing the experience of visitors. He believes in approaching higher quality of everyday life by cultural planning strategies using intangible values and characteristics of urban space such as diversity, choice, flow, safety, sense of place, identity, aesthetic quality and legibility as base to improve the quality of the place (Montgomery, 1990).

Landry indicates conditions for a place that it can be judged on: economical, social, environmental and cultural characteristics of the place. Florida introduces new dimension to the quality of place by using the creative city theories in definition and stressing that certain qualities of place which is defined as 'place quality' fosters creativity and attracts creative people and creative industries: big ticket amenities, easy access to outdoor activities, night life experiences, healthy environment, participated activities, social events, lifestyle activities, accessibility, active young people and the environment that they can fit in (Florida, 2005). Another approach to place quality is from urban design principles and management strategies aspect. This approach believes that there is three main ways to achieve place quality: planning, development and people (Parfect and power, 1997).

Considering different approaches to place quality in different disciplines and literature, it is possible to sum it up that the quality of place related to tangible and intangible assets that space offers and it is possible to present these assets in three different categories: built, social, and environmental assets. This categorization gives us a framework to assess and study different places and how cultural industries involve in this assessment.

The point that almost all literature agrees on is the fact that creating high quality places is crucial both to generate economic activity and providing spatial, aesthetic, cultural needs and well being of people.

As mentioned before one of the manifestation forms of the intangible assets of the space and the society is through cultural industries in particular art in city spaces.

Art in public realm

Art as a form of creative industry during urban history has been used as a tool to improve aesthetic of urban landscape and provide character and uniqueness to a place. Art in urban spaces have become increasingly central to the definition and experiences of the post-modern city, In particular, because it is such a powerful tool to address timely issues. Hence, it is time that art in public realm along with the importance of cultural industries role in creative cities become subject to such critical interrogations.

Public Art

During last few decades, traditional distinctions between sculpture, painting, drawing, photography and installation have blurred. Conceptual catholicity, openness, and flexible categorization have provided the base for the galvanization of a new art: the complex world of public art.

The term public art refers to works of art in any media that has been sited or staged in the public domain, accessible to all, often outside but also includes any art exhibited in publicly accessible buildings. It is possible to say different aspects of the built environment are seen as nominees as location for public art, including, street furniture, lighting and graffiti. Public art is not confined to physical objects; dance, procession, street theatre even poetry have proponents that specialize in public art. Architectural sculpture and even architecture itself in urban fabric is widespread form that fulfils the definition of public art.

In traditional urban fabric introducing art into everyday life has been seen as an inherently good thing and art has been placed in public spaces to enhance aesthetic, memorialisation and so on. The last few decades have seen a ‘renaissance’ of public art particularly in the cities of Europe and the USA.

Public art has been included in different urban regeneration programs and it has been advocated as contributing to the alleviation of a range of environmental, social and economic problems locating within the urban design process and the integration of artists into the urban regeneration. Goodey writes “Since the 1980s public art has been increasingly implicated in processes such as the rejuvenation of decaying urban

spaces, the development of flagship projects of urban regeneration, the stimulation of central economies and the enhancement or transformation of urban images" (Goodey, 1994).

It is possible to say nowadays mostly there are art works in major city centre regeneration programs that endorse 'official' views of the city, for example local authorities, which celebrate and enhance the spaces produced by these interests.
Critical writing on public art and its integration in urban regeneration process has derived from a number of perspectives: of artists, arts advocates, cultural theorists, and urban and cultural geographers. As Jones indicates artists and art advocates have been mainly concerned with examining the process of public art production (Jones, 1992). These works shows the concern of writers for quality in the production of public art works. Whereas critical writing from a cultural studies or cultural geography perspective mostly seeks to situate the specific iconographies of public art works in the multiple contexts of their production and reception and generally these critics have been critical of the involvement of public art in projects of urban regeneration (Miles, 1997). In their point of view public art is a part of broader processes of uneven urban development. They see public art within the politics of urban transformation, criticize how this on-going process has an uneven impact on the different social groups of social spectrum's lives and even call the culture and public art in this development process as a 'carnival mask' which is presenting selective versions of history, or myths of harmony, offering another layer in the composition of elite images of the regenerated city (Hall, 2003).

Reviewing the critical literatures on public art shows that the voices of the public are largely absent and writing on public art has focused on the meanings inherent in public art works and the influence of the contexts within which this art is produced but, they ignore the meaning derived from the incorporation of art into the experiences of the public's everyday lives.

Loretta Lees says: "this (semiotic) interpretation strips the built environment of the meanings it is given by the people who live in it and of the transformations, however modest, that they make. ... Contemporary architecture architectural geographies do not emphasize enough the fact that 'urban meaning is not immanent to architectural form and space, but changes according to the social interaction of city dwellers'". She argues that architecture (and urban design and regeneration in my point of view) is about more than just representation. Both as a practice and a product, it is performative, in the sense that it involves ongoing social practices through which space is continually shaped and inhabited.

Background

Many believe that the term 'Public Art' born in 1960s as a paradigm to reunion segregated modern art with urban spaces, It is possible to say public domain became more attractive for artists during 1970s, under-explored and even abandoned public spaces provided artists from different disciplines a pure, untouched stage to present their new works. They were experiencing new forms and media, their work moving out of galleries and museums into the public realm. So since the late 1970s interest in public art and the scale of local, regional and national commitments to it have grown considerably and contemporary public art started to have an increasingly visible presence throughout different countries in particular, Britain.

During this time expansive claims are made for public art. It is claimed to be a cultural investment, vital to the economic recovery of many cities; contribute to local distinctiveness; attract companies and investment; feature in cultural tourism; add to land values; create employment; increase the use of open spaces; reduce wear and tear on buildings and lower levels of vandalism. 'Conceivably as a response to preoccupations with architecture and the environment it is supposed to humanise and otherwise improve the environment; bring about safer areas and encourage greater care of areas by residents whose pride in their locality has increased' (Public Art Consultancy Team 1990:25). In 1988 the Cabinet Office endorsed its contribution to urban regeneration (Cabinet Office 1988:25) and officially public art became a tool in improving urban fabric in regeneration schemes.

Considering the lack of evidence about the impact of public art in Britain, it appears that many organisations in the public and private sectors promote public art and commit resources to it largely on the basis of traditional, social conventions.
However by the end of the 1980s some of the constituencies involved in funding and promoting public art were beginning to consider whether they should adopt a more critical approach to public art and at the same time local authorities were beginning to question their own promotion of public art, and started to develop 'new understanding of the true scope and function of public art and the link between cultural and economic regeneration' (Roberts and Salter 1992:8).

Walker (1989) and Dormer (1992) have asked what good public art does and in 1984, a Professor of Government examined the public funding of the visual arts, including art in public places, from the standpoint of its benefits to individuals and the public interest (Banfield, 1984). In 1987 Stalker and Glymour proposed that 'public contemporary sculpture does little or nothing to enhance the quality of life generally...

Whatever legitimacy there is to government support of such displays derives from the tradition of serving the special interests of a very limited group of citizens. But this justification is overwhelmed by the fact that publicly displayed contemporary sculpture causes significant offence and harm, and does so in a way that intrudes repeatedly into peoples' normal living routines' (Stalker and Glymour, 1987).

The 1841 House of Commons' Select Committee appointed 'to enquire into the state of the National Monuments and Works of Art in … Public Edifices', these should contribute to 'moral and intellectual improvement for the People'. 'Similar aspirations informed the funding of other cultural amenities in the public realm, such as the new museums, libraries and parks' (Conway, 1991). Galleries echoed 'civic aspirations, regional prosperity' and parks were built with statues, buildings, drinking fountains and sundials which celebrated 'royal visits and the achievements of local heroes and promoted local and national pride' (Selwood, 1995).

More than a century later, public art is not anymore consist of memorials and monuments to people, events and common aspirations and when it is, it often is inevitably imbued with ironies. Robert Melville believes that 'the significant statuary of our time' is unlike that of our Victorian predecessors, in that it 'serves no sacred, commemorative or symbolic purpose and has practically no validity as architectural decoration' (Melville, 1954). Art in our time is regarded as playing a part in urban improvement, If not as an integral part of it at least as a tool to planning process (Sudjic, 1993) and it is been assumed to have economic benefits, although several writers have declared doubts about the rhetoric of the economic impact of cultural approaches on urban regeneration where public art projects usually reveal (Booth and Bloye, 1993).

Gordon Hughes writes in his critique of John Myerscough's report on *The Economic Importance of the Arts in Britain* (PSI 1988) that Myerscough's attempt to 'measure the arts in terms of their success in the market are flawed both methodologically and intellectually, and their results exaggerated' (Hughes, 1989). He also challenged the 'value of measuring the economic value of the arts *per se.'* And writes: 'both odd and unconvincing if the strongest argument for public spending on the arts relied upon its employment impact', rather than its other, 'less tangible', benefits. He then introduces three ways to assess 'non-market value of the arts'. First, the arts' option values, 'people place a value on the opportunity to enjoy artistic activities, even if they choose not to take advantage of that option at given times'. Second, 'the benefits of the arts could be considered in respect to the externalities or spillover benefits which they generate' and the third, 'art as comprising merit goods - goods or services

whose consumption is thought to be desirable for the community as a whole' (Hughes, 1989).

Conclusion

There is a war going on between people who don't like Modern art pieces popping up in public spaces of our cities and people who accuse them of being culturally deprived. As mentioned before although the use of art and so called cultural industries was a common practice during the urban history taking part in providing, identity and character for the city in which elements of politics, society, economy, history and culture manifested through the overall layout and image of the city, with arrival of theories seeking to find a link between cultural and economic regeneration and development of new understanding of the scope and function of public art which led to its presence in most of the major regeneration projects particularly in current economic circumstances, the question of the priority in public expenditure fired up the ongoing debate in related urban disciplines.

Despite being a popular debate lack of research in the field and evaluation of projects after completion is evident and therefore a comprehensive understanding of the polemical paradigm of public art and the perceived social, cultural and Political benefits of its practice is not possible.

Reviewing the critical literature on public art shows that the voices of the public are largely absent and writing on public art has focused on the meanings of the public art works and the influence of the contexts within which this art is produced but they ignore the meaning derived from the inclusion of art into the experiences of the people's everyday lives. According to some critics it is reasonable that the origins of an objective critical approach to examine questions of meanings of public art, its roles and functions in the context of fashioning new cities might focus on the audience as a site of meaning and how they engage with it, rather than the contexts of production and the works themselves. (Hall, 2003; Miles, 1997; Burgess, 1988).
On the other hand, the strongest argument for public spending on the arts relied upon its employment impact and attracting investment which could led to economic recovery of cities. Whereas as Hughes argues 'it is both odd and unconvincing … measuring the economic value of the arts *per se*', rather than its other, 'less tangible', benefits (Hughes, 1989).

In the attempt to enliven dull and empty public spaces of modern cities, the reunion of segregated modern art with urban spaces could play a positive role but along with other factors contributing in successful place making. Relying on putting art

installations without considering context and the harmony of the environment or the spatial and semiotic function of the piece won't facilitate the liveable public space. After all, it is the author's personal opinion that public art's mission is rooted in a broad movement: to foster artistic experimentation, enrich public space and the everyday experience, and forefront artists as key contributors to democratic society and for an objective study of this complex world investigation of semiotics, socio-cultural meanings, professionals and audiences view is required.

Regulatory frameworks for reducing disaster risk through planning and building

Cassidy Johnson [1],

Abstract

Regulatory frameworks for building and planning should be one of the key tools for reducing disaster risk in the built environment. Indeed, in most high-income nations, good regulations, which define design loads, specify construction details and provide hazard zoning have been shown to minimise damage and save lives. However, thus far, in low and middle-income nations, regulations have been less successful in reducing risk. Drawing on case studies from four countries (Turkey, Iran, Namibia, Argentina) as well as wide range of literature, this research looks at how regulations for land, planning and building can provide an enabling environment for disaster risk reduction in low and middle-income nations. The research finds that many countries are developing good regulatory frameworks, however the difficulties lie in implementation. Local governments lack budgets, expertise and general capacity to do planning that is based on sound risk information, and competing priorities for development mean that development decisions do not always place hazard risks at the top of the agenda. Furthermore, building regulations are ineffective in informal building and many local governments lack the capacity to properly check plans and construction quality. The research finds that making safe land available for development and also enabling a 'compliance culture' in building are key elements to reducing risk in the built environment.

1. Introduction

In what ways can government action and regulation help reduce future losses from natural hazards? In answering this question, this study seeks to draw out evidence of how regulatory frameworks for planning, land-use management and building can provide an enabling environment for disaster risk reduction in low and middle income countries. The focus of the study is on which governance mechanisms are effective for the design and implementation of plans, codes and regulations in both formal and informal settlements, with reference to the political economy conditions that contribute to this.

Urban populations will continue to increase in coming decades, especially in low elevation coastal zones and in seismically active urban areas in low- and middle-income nations (McGranahan et al., 2007; Satterthwaite, 2007; Nicholls, 2008). Given that urban areas will be growing an expanding, it is vital now to

[1] University College London, United Kingdom - cassidy.johnson@ucl.ac.uk

institutionalise good planning and building practices that take into account disaster risks. Past experience has shown us that once land is settled on, it is very difficult to move people and nearly impossible to undertake large-scale retrofitting. Thus, action is needed now to avoid disasters in the future.
In addressing vulnerability in the built environment, there are two major approaches: the first is the location approach, which is to use planning to limit the amount of development in areas that are deemed to be at risk for hazards, which is usually done though some form of land use planning. The second is the design approach, which is to make development in hazardous areas safer by altering the way buildings and infrastructure are built, usually though the implementation of building codes (Burby, 1998).

Priority Action 1 of the Hyogo Framework for Action (HFA) outlines legislative frameworks as a key basis for integrating disaster risk reduction into development policies and planning: "Countries that develop policy, legislative and institutional frameworks for disaster risk reduction and that are able to develop and track progress through specific and measurable indicators have greater capacity to manage risks and to achieve widespread consensus for, engagement in and compliance with disaster risk reduction measures across all sectors of society' (ISDR, 2005, p 6). In relation to land management and urban planning this statement of the HFA means that legislation needs to specify that disaster risks be considered in land and development planning. This includes a multi-stage approach, first of all knowing what the multi-hazard risks are through risk and vulnerability mapping; using this knowledge as the basis for developing plans and policies for land management; ensuring that the local institutions, especially local and in some cases regional governments, are sufficiently capable to implement the plans and policies.

Under Priority Action 4, the Hyogo Framework for Action also specifies: 'Land use planning and building codes', stating: 'Encourage the revision of existing or the development of new building codes, standards, rehabilitation and reconstruction practices at the national or local levels, as appropriate, with the aim of making them more applicable in the local context, particularly in informal and marginal human settlements, and reinforce the capacity to implement, monitor and enforce such codes, through a fostering disaster-resistant structures.' Furthermore the 2010-2011 ISDR Resilient Cities campaign, which offers a ten-point checklist for reducing risk in cities includes building regulations as key component stating, 'Apply and enforce realistic, risk compliant building regulations and land-use planning principles.' (ISDR, 2010)

2. Methods

An earlier version of this paper was written for the 2011 Global Assessment Report for the United Nations International Strategy for Disaster Reduction, and synthesised the findings from five commissioned case studies and one expert meeting. The case studies commissioned as part of this study focus specifically

on the design and application of regulatory frameworks for planning and/or building in particular countries, cities and communities, including Turkey, Argentina, Namibia and Iran.The case studies, accompanied by other literature, are used to draw out the main issues and considerations of how planning and building regulations are contributing to disaster risk reduction. The excerpts from the commissioned case studies and other published works are used throughout the paper to present evidence of the findings. The paper has been published in Spanish in *Medio Ambiente y Urbanización, vol 75, no1, Dec 2011.*

The study is divided into two main parts, the first part is concerned largely with planning and land management and the second part looks at regulations for buildings and disaster resistant construction.

3. Planning and Land Management

The findings from the case studies indicate a number of common regulatory and governance issues with regard to urban planning and land management, including the importance of regional level coordination for disaster risk reduction, having multiple stakeholders involved in developing regulations and the differences between reactionary laws and strategic laws. The case studies also show that the effective implementation of regulations remains a major challenge for local governments and that the most important thing municipalities and governments can do in growing cities is to make safe land available for building.

3.1 Need for regional-level coordination

A level of regional coordination in planning is effective for enabling risk reduction, and in large urban centres this may entail the coordination of planning across metropolitan areas. This regional planning jurisdiction also aids in the preparation of uniform disaster risk mapping for earthquakes and in prioritising high-risk areas for intervention. For example as detailed in the Istanbul case study, enlarging of the municipal boundaries to match the provincial boundaries has enabled the municipality to plan for the larger region and to better coordinate its activities with the provincial-level administration. A United Nations University (UNU) study, which looked at social geography of urban disaster vulnerability found that out of the four megacities included in the study, Tokyo, Los Angeles, Manila and Mexico City, the municipalities with legally established, strong and well-financed metropolitan government structures, those being Manila and Tokyo, allowed for more inter-sectoral and intercity coordination for disaster mitigation planning (Wisner and Uitto, 2009).

For risk reduction, the acknowledgement of the region of the physical geography of risk is important, i.e. management of a flood plain in its entirety (Burby, 1998). The case study from northern Namibia offers the example of how a lack of regional level planning can result in the transfer of risk from one place to another. As it details, the

towns of Ondangwa and Oshakati each have their own plans for dealing with the flooding, but the plans for both towns are isolated, designed solely for the purpose of dealing with floodwaters in the locality of their respective areas. For example, the channel that is proposed to manage the floodwater in Ondangwa drains directly into a village south of the town, exacerbating the flooding there (Gold, 2010).

Multiple Stakeholders in planning

Methods for integrating risk reduction into planning outline the importance of combining local knowledge of individuals and communities at risk with scientific information and also highlight the importance of equality in participation in decision-making across genders, religious and ethnic groups (for example, Wamsler, 2008 or Maskrey, 1989). One of the common methods for gaining broad-based representation in planning for disaster risk reduction is having an advisory committee of the major stakeholders that can advise on legislation and policies at the national level and at the regional, local and district level may assist the governing body on developing and implementing land use plans or formulating projects related to disaster risk reduction (Burby, 1998; Pearce, 2003). An advisory committee would normally include representatives from government departments, representatives of community-based organisations and civil society, experts, and those representing private interests.

The case studies show that legislation and regulation regarding the participation of multiple-stakeholders in planning and development is becoming more commonplace. In practice, however, the preparation of plans and projects related to risk reduction still tends to be technical and is in most cases handled solely by government agencies. Although there are many positive examples, the inclusion of multiple stakeholders, such as advisory committees or community-based initiatives, is either limited or these perspectives are not yet implemented in the majority of urban areas.

For example, as documented in the Namibia case, in the Oshana region, a Regional Disaster Risk Management Committee was established from 2008, to co-ordinate the management of the flooding as well as supply of emergency services. This committee is centred on the ministries, regional and local government and it did not include the broader spectrum of stakeholders, such as representation by the informal settlements affected by the floods (Gold, 2010). Similarly in Turkey, a new legislation at the municipal-level regarding mandated citizen participation in urban development objectives through Citizen Councils (Kent Konseyleri) in district municipalities. However, in most cases, Kent Konseyleri is still only existing only on paper, or advertised on websites (Yönder and Türkoğlu, 2010).

Reactionary laws on land use vs. strategic guidelines for achieving risk reduction

Often, legislation that prohibits certain land uses in areas determined to be at risk have been reactionary, coming as amendments to existing laws in reaction to a recent disaster event that has exposed the risk in that area. For example, as detailed in the case study on Argentina, in 1957 following severe flooding in the region, the Province of Buenos Aires enacted a provincial law that established minimum distances and heights from water bodies for all developments. This was accompanied in 1977 by another law which created strict regulations for minimum plot sizes and

infrastructure. After these laws, the costs of purchasing the plots increased to such an extent that that large sections of the lower-income population could no longer afford to purchase plots (Almansi, 2010).

These reactionary laws enacted after a disaster are positive in that they recognize the risks as a land use problem and enact preventative zoning to regulate the development in high risk zones. However, these laws can have adverse effect on the poor, making it unaffordable for the poor to obtain legal land, because regulating land through zoning laws (which detail specific distances, sizes and heights, etc.) are very in-flexible in terms of accounting for other realities of development. These types of prescriptive laws do not account for increasing land costs or people's abilities to pay. Nor do they account for environmental variations in the possible levels of flooding or the possibility that it may be feasible to make some land habitable through other mitigation measures, i.e. drainage, pumping, embankments. Ideally, legislative frameworks that are more flexible in their application may be better for managing risk if they can be applied diligently.

More recent legislations regarding risk reduction and land-use, such as those described in the case study of Turkey, are less specific in terms of prescribing exact zoning regulations and thus have the possibility to offer more flexibility in terms of how legislation is implemented. Yönder and Türkoğlu (2010) outline how, in Turkey, the law requires that geological studies be prepared by the Ministry of Public Works and Settlements prior to plan preparations in order to help identify areas where no development is allowed. In municipalities over one million people, environmental plans must be superimposed on micro-zone risk maps.

This may have more positive impacts in terms of tailoring development to local needs and priorities as they change over time. However, this legislative approach requires a more sophisticated decision-making mechanism at the project or plan approval stage, and decision-making can become politically motivated. For example in Turkey it has been found that municipal council decisions may still allow development in unsafe areas or at higher densities than allowed in the plans. Such decisions have also in some cases been supported by the Central Government's Disaster and Emergency Management Authority –AFAD. For example, in 2010, a decision by the AFAD reduced the 150-meter wide no-construction buffer zone along the local fault line in Sakarya-Akyazı to 20 meters. Furthermore, in March 2010, the municipal council in Burdur rejected a development plan revision that incorporated the local fault line and the no development buffer zone into the plan (Yönder and Türkoğlu 2010).

3.2 Implementation of plans and regulations

Even though legal frameworks and plans that provide an enabling environment for risk reduction may be in place, it becomes the responsibility of the local/municipal government to implement the measures. From a multi-year study looking at land-use planning and hazards in the United States context, Burby (1998) comes to the

conclusion that the critical barriers to local government implementation of land use planning for risk reduction is based on two distinct, yet inter-related factors, those being commitment and capacity. Most local governments may lack commitment to disaster risk reduction because in their context other concerns such as basic infrastructure, unemployment, housing and education are much more critical. Local government are more willing to advocate measures if their constituencies suffer chronic losses from disasters. Most local governments struggle with having the capacity to implement measures, which is usually due both to a lack of expertise and lack adequate staff to undertake reviews and inspections.

In the past, there has been an operational and professional separation between urban and regional planning and disaster management. Although bridges across these disciplines are being made, a divide is still prevalent in most governments. Disaster management has been the domain of government civil protection units and has generally been focussed on contingency planning to respond to disasters. In the past, urban and regional planning has engaged little with aspects of disaster risk, except in the aftermath of a disaster. While government initiatives to mainstream activities for reducing disaster risk into urban and regional development is becoming more commonplace, there are still traditional divides between the ways the government departments are organised and also in the background and the training of the staff (Pearce, 2003). For example in Turkey, preparation of disaster risk maps is now conducted under the AFAD, but the Ministry of Public Works and Settlement oversees land use planning, development and building controls carried out by municipalities. Thus, in Turkey, as in many other countries, there are essentially two different Ministries carrying out the activities related to land use planning and to disaster risk reduction.

Another aspect illustrated by the case studies, follows on from the point made by Burby (1998) about capacity – that local governments are responsible for approving development projects and building plans and they are the front-line of risk reduction in planning and building. However many local governments, especially in smaller towns or poor districts, do not have adequate staff with the adequate technical capacity. Hardoy & Pandiella (2009) in a study looking at urban poverty and vulnerability to climate change in Latin America conclude that disaster risk is shaped by, “the long-evident incapacity of governments to address risk and to integrate development with the reduction of vulnerability. Meanwhile, within local governments, there is generally an institutional incapacity to address this issue or to control pollution and protect natural resources " (p.204). A study looking at flooding in African cities concludes, "local authorities are best placed to cope with flooding from small streams whose catchment areas lie almost entirely within the built-up area. They administer the regulations and by-laws concerned with land use planning and should be involved in local disaster management. However, most African local authorities lack the human resources and financial power to carry out such responsibilities effectively. They may be able to form partnerships with NGOs but they should be supported by national governments and regional agencies to map

flood risk areas, maintain urban stream channels, control building in flood channels and on floodplains and provide emergency assistance" (Douglas et al., 2008, p. 203)

In some localities, the need to satisfy short-term concerns for profits or for other development needs underwrites the decisions of municipalities to uphold disaster risk reduction measures, especially in localities where there are not frequent disaster events. In a study looking at earthquakes and urban planning in Turkey, Sengezer and Koç (2005) provide an interesting account of planning processes in seismically active cities of Erzincan, Adapazari and Avcilar (latter is now a district of Istanbul). In each of the areas, the earthquake risks where well-understood and urban plans accounted for risk reduction either by limiting building heights, types and densities or encouraging development in areas with more stable soil conditions. However in each of the cases, the pressures to offer higher densities as the populations expended, made it so that subsequent planning decisions allowed for relaxation of these regulations, even though the areas were at high risk (see Box 1).

Box 1: Tracing the development decisions that lead to risk in urban areas: case of Adapazari, Turkey

In another example in Adapazari, a city in the north-western Marmara region of Turkey, has suffered earthquakes in 1943, 1967 and in 1999. After the 1943 earthquake, the 'Adapazari City Development Commission Report' recommended that the city be expanded to the terrace areas to the south-west of the city, which it was observed had undergone less damage in the earthquake and delimited areas which should not develop due to unstable soil and high ground-water conditions, especially along the rivers. A plan produced in 1957 complied with these recommendations. In 1957 the population of the city was 65,000 and the density was 100 persons per hectare. After the earthquake of 1967, it was suggested that the height of buildings should be limited to three storeys, as it was the higher buildings that proved to be more vulnerable in the earthquake. By 1985 the population of Adapazari had reached 200,000. The development plan of 1985 called for development towards the riversides, violating the principles of the 1957 plan, which had prohibited construction in this area due to geological concerns for earthquake risks. In the 1990s, growth of industry in the city increased, including the opening of the Toyota automobile plant, and most of the industrial parks were located in the alluvial agricultural areas. By 1997, the population had reached 300,000 and the density was 350 persons per hectare (up to 600 persons per hectare in the city centre). In the 1990s, 'numerous modifications to plans, some of which where limited to an avenue, a street, or even a building lot, were made in order to increase building densities regardless of ground conditions and the risk of an earthquake' (Sengezer and Koç, 2005, p. 178).

3.3 Security of tenure, evictions and risk reduction

Security of tenure in informal settlements generally enables investment in infrastructure and in better housing quality, thus reduces risk to flooding, fires and other hazards. For example, the PROMEBA programme in Argentina, which

facilitates upgrading of informal settlements has been able to reduce risk in informal settlements through upgrading that enables legalisation of land tenure (Almansi, 2010).

However findings from the case studies indicate that regulatory frameworks may, in some situations, negatively impact on the security of tenure of informal settlements. In the cases presented here, there are examples of regulations that aim to prohibit development in hazardous areas (location approach), or seek to replace informal settlements by higher income uses in which the designs and new construction can be made to a hazard-resilient standard (design approach). In both of these situations, legal tenure cannot be granted to settlements already located in these areas and in some situations former tenure arrangements may even be revoked in an effort to reduce risk, meaning that those settlements cannot upgrade, or are removed or both. In most situations, given the choice, people would choose to remain where they are. Relocation often means that people are living in areas further from livelihood opportunities and do not receive just compensation for what they have had to leave behind (Cabannes, Yafai and Johnson, 2010).

The case study in Namibia explains that in Oshakati, subsequent to the master plan developed for the city by external consultants, the town council has prohibited permanent construction in Oshoopala settlement, as this settlement will be re-developed into middle and high-income housing. It is likely that the current informal settlement in Oshoopala will be resettled in another area (Gold, 2010). In Buenos Aires a similar situation is true. Legal restrictions for land use, building and hydrology make it so that informal settlements formed in areas in which development is restricted because of flood risk have not been able to achieve security of tenure (Almansi, 2010).

In Istanbul, Turkey, the earthquake mitigation strategy is to improve the resilience of the largely informally built housing stock through the demolition of these settlements and the construction of new buildings in their place. This is done under a newly established legal framework on urban transformation, which gives municipalities the power to rehabilitate urban areas based on disaster risk. However, under these urban transformation projects the new houses are unaffordable for the original occupants of that land, who are generally relocated to the periphery areas of the city. Even then many people cannot afford the price for the new houses that they are relocated to (Cabannes, Hasan and Baysal, 2008).

Work of the Philippines Homeless People's Federation illustrates that it is possible that people will voluntarily resettle to other lands if there current areas are at high risk and if they can negotiate or find good conditions for resettlement onto safe lands. Having a strong community-based organisation enables this kind of articulation of needs and negotiation. In Iloilo, Philippines after Typhoon Frank inundated many coastal settlements in June 2008, the Philippines Homeless People's Federation were able to negotiate with the municipality to relocate almost 2000 families to safer lands in San Isidro (Dodman, Miltin and Rayos Co, 2010).

3.4 Safe Land

Once people have settled on land, resettlement is often not possible because of social pressures for people to stay on the land that they have occupied for many years. Thus, as urban areas continue to grow, people need land to settle on that is safe from disasters. In many cities, the provision of safe land is the most vital aspect that local governments can undertake for controlling disaster risk in urbanising areas going forward. This entails developing the regulatory mechanisms that enable the urban poor access to land that is not in high-risk areas and regulations that allow them to have tenure security, both for business and housing, in an affordable manner.
In Windhoek, the capital city of Namibia, with a population of 223,000, a network of urban poor groups, Shack Dwellers International, has been working with the local government as well as NGO professionals to develop progressive regulations for land and housing policies, which is enabling people to access safe land in an affordable manner. In Windhoek, 26 percent of people are living in informal settlements and thus the policy revision came about in part because of the recognition that former housing policies were not working for the very poor and were making health conditions worse for them. Under the new policy, the municipality recognizes the different levels of affordability that households have and makes propositions for types of tenure based on affordability. Changes to the tenure laws allow the very poor to access land by making it possible to have more than one family sharing ownership of a plot. Plots sizes have also been reduced so people can hold titles to smaller plots, depending on what is affordable. One aspect that makes this policy possible is that there is no value placed on the land, and the municipality is only interested in cost recovery of the services it installs (Mitlin and Muller, 2004).

4. BUILDINGS AND CONSTRUCTION

In US, UK, Japan and Australia good regulations, which define design loads, specify construction details, provide hazard zoning have been shown to minimise damage and save lives (Spence, 2004). However benefits of regulations are less clear when concepts and prescription of advanced codes are transferred to countries less able to apply them rigorously. Another problem with the application of codes in many low and middle income countries is that attaining standards increase costs of building beyond what poor can afford.

In informal settlements for example, people prefer upgrading rather than construction on a new piece of land partly because they are then less constrained by building codes & planning regulations. In a new site, they must meet all these standards, but in incremental buildings these are not necessary, thus it is much cheaper to build there. In some instances, people are able to adapt their building methods in informal settlements to reduce risk for more frequent disasters (i.e. annual flooding in Dhaka, Bangladesh) (Jabeen, Johnson and Allen, 2010).

4.1 Appropriate codes and standards

While most countries do have building codes of some kind, the challenge is to develop codes that are appropriate for the local economic and environmental conditions and that respond to current building practices and technology.

Findings from a multi-country study by Practical Action, looking at the design and application of building codes in low-and middle-income nations concludes that codes need to be locally developed and related to the local system of design and building so that they match the capability of the local professionals or those who will be applying the code (Yahya et al., 2001). In many countries, codes have been directly transferred from the colonising country and few revisions have been made; building to the standards of the codes is not affordable by half the population. Very often they do not allow incremental development, going for a uniform solution that is trying to suit everybody. In other countries, each time there is a disaster event, new aspects of the code are added, and codes have become increasingly sophisticated requiring specialists to decipher them. In some cases, simple 'deemed to satisfy rules' whose application is obvious (e.g. limiting storey heights, prescribing positioning and size of openings) might be more appropriate than more complex performance specifications. It is generally easier to modify rules than to train and employ a cadre of professionals to apply and police codes that are unrealistic.

An example from Bangladesh shows how codes are in direct contradiction to what people actually live and build. The Bangladesh National Building Code (BNBC) identifies only government bodies or public agencies to be responsible for planning minimum standard housing development for the low-income people in urban areas. It defines the minimum standard housing to have a density of 75 units/hectare with average 5 persons/dwelling. The minimum plot size varies between 30 sq. m to 25 sq. m in dense metropolitan areas. Minimum width of walkways is to be 3 m while the requirement for infrastructure follows the regular development requirements. Individual plot can have maximum of 75% land coverage with 1.5 m open space at the front. Minimum size of the 1st habitable room is 9 sq. m and the 2nd, 6 sq. m making of 15 sq. m in total. There is no option of incremental development to improve living environment while still living in self built construction. Also there are no considerations about addressing risk varying in different locations (Jabeen and Mallick, 2009).

The photograph below shows an example of how people can realistically afford to live in an informal settlement in Mohammedpur, Dhaka. In these rental units, families averaging six to eight people in size are living in a 9 sq. m one-room dwellings cantilevered over the water (thus there is actually even no plot of land). The walkways are 1.5 metres and there is no outside space.

Figure 4: Informal settlement in Mohammedpur, Dhaka does not conform to Bangladesh National Building Code (source: Huraera Jabeen)

In Gujurat, two municipalities, Bhuj and Anjar, which were the worst affected in the 2001 earthquake, decided to simplify the rules for reconstruction, prohibiting all construction higher than two stories. The rational was that they were more accessible for people and could be simplified in terms of procedures (Spence, 2004). In the long term, this kind of standard may not be realistic given required urban densities, however it does illustrate the point that simple and achievable standards may be better at achieving risk reduction than those that are too sophisticated to be implemented properly.

4.2 Application and enforcement of building standards

The damage from many large-scale disasters, especially for earthquakes can be partly attributed to the lack of application of building codes-- the failure to enforce codes and to verify the quality of construction during the building period. Building supervision and site inspections of the building process can be marred by lack of capacity to do checks or sometimes corruption. This appears to be especially important when reinforced concrete is being adopted as a new building technology in urban areas, as we have witnessed from most of the intensive earthquake disasters in the last ten years.

In Turkey after the earthquake in 1999 in the Marmara region caused the collapse or severe damage of one hundred thousand buildings, it became apparent that a new regulatory system was required to ensure that buildings would be built safely. In the previous system, building plans are submitted to the municipal authorities with the signature of a design engineer who is responsible for code compliance. In practice however, municipal engineers were not able to check thoroughly all of the design calculations and workmanship because of their heavy workload or lack of professional qualifications. Under the new system it was proposed that a private firm charged with building construction supervision would assume the functions of the municipality in checking both the design calculations and the actual construction activity at the building site. In that regard the firm served as a public agent ensuring that materials, workmanship and detailing requirements were fulfilled. The firm needed to have a ten-year duration liability insurance coverage for each job that had been tasked to it. Even though there was a lot of momentum behind developing a accountable system in the wake of the destruction from the earthquake, interestingly, the new system ultimately failed to be passed into law, due to lack of support by some interest groups and the fact that such far reaching changes to the system also required changes to civil law, commercial law and insurance laws (Gülkan 2010). Thus even though there may be a strong commitment to making the necessary regulations for enforcement of codes, and ultimately for risk reduction, the political and economic realities of getting laws passed and implemented can sometimes cloud the good intensions.

Several case studies make the point that the process of obtaining building and planning permissions is extremely complicated, time-consuming and therefore expensive. The end result of these lengthily procedures are that builders prefer to construct outside of the official processes, and thus buildings do not conform to codes or standards. Of all the regulatory constraints, it seems that onerous administrative procedures are invariably one of the greatest barriers to conformity of building codes. In Peru, for example, in the historical centre of Lima, it was identified that to obtain an Automatic Building License requires an average of 222 working days (311 calendar days) under optimum conditions. Standards are so high and regulations so rigid that owners prefer to let buildings collapse (Payne, 2010).
A study about the experiences of the Philippines Homeless People's Federation in community-driven response to five disasters which impacted on low income groups in the Philippines (the Payatas trash-slide in Manila; the landslide in barangay Guinsaugon; the Mount Mayon mudflow and floods: the fire that devastated the Lower Tipolo Homeowner Association land in Cebu; and the flashflood in Iloilo) identifies that regulations are one of the limitations inhibiting community-based response. Stringent land use subdivision and conversion regulations inhibit local governments being able to make land available for people to settle on for temporary and permanent housing. Delays and difficulties in processing land and housing permits, obtaining clearances for developing relocation sites identified and acquired by communities, and getting agreement and official permission for needed actions that often require the agreement of many different bodies were some one of the difficulties that the Federation faced in the different disaster situations. The study

recommends that one of the important things it can do to help communities recover is to change government policies to streamline these processes into a one-step process to make it simple and faster for people to build (Rayos Co, 2010).

4.3 Advocating a 'compliance culture'

There is a general paradigm shift away from policing of building codes to developing a basis of awareness and education about safe building methods. The cultivation of a 'compliance culture' is being advocated by several international groups which have been working on the application of building codes in low and middle-income countries, including the Global Task Force on Building Codes (GTFBC) (de la Pomerai, 2010), Practical Action's work on Building codes in Africa, and by the Royal Institute of Chartered Surveyors (RICS) in the UK (Kataria 2010), the latter which has been doing work on codes in Haiti since before the earthquake. The case study from Iran also mentions these the need for a trained and skilled labour force as one of the major challenges for implementing the earthquake standard (BHRC, 2010). The major impetus behind this shift is that in order to 'police codes' it requires that buildings are built through formal means, obtaining the required permits, and that the institutional basis at the local government required for checking designs and construction is enough to cope with the demands of the on-going construction. As has been shown in this paper, all of these aspects are problematic due to the fact that local governments do not have the capacity to meet the demands of policing codes and regulating all building. Furthermore, a substantial amount of construction is informal and thus outside of any regulatory controls.

5. CONCLUSIONS AND RECOMMENDATIONS ARISING FROM THE STUDY

Some recommendations regarding the use of regulatory frameworks for achieving disaster risk reduction are clearly highlighted by this study:

Enabling access to safe land. Making safe land available for development so that people can build in areas that are less exposed to hazards. In the context of urban growth in hazard prone areas, the simplest solution is to make safe land available in the beginning, so that expensive structural measures (or resettlement programmes) are not required later on.

Adopting regulations that require less oversight from government. Municipalities and local governments have limited resources and competing priorities for development. Instituting regulations, which require less government control to supervise, yet result in risk reduction is a better alternative to complicated regulations, which cannot be feasibly followed up or implemented by local governments. Examples of regulations which require minimum oversight include: making access to safe land (if people are building on land that is already safe than building controls become less important), simple building codes and planning regulations, i.e. 'deemed to satisfy' standards,

and developing a culture of compliance to building standards through education about safe building practices for builders and for general public. Investments in stricter planning and building controls can then be instituted only for larger engineered structures, for public buildings and larger infrastructure works.

Need for investments in the capacity of local governments to plan for and encourage safe development. It is the local governments that are at the front line of decision-making and implementation for planning and building regulations, however, as the case studies have shown, regulations require technical expertise to develop and manpower to implement. In most municipalities in low- and middle-income countries, municipalities are lacking the capacity to plan, implement plans and encourage safe development. Laws and policies are required at the national level that enable local governments to take responsibility for planning and building and include budgets and resources that assist local governments do this.

More specifically, this study has highlighted a few areas where investments in capacity at the local level are necessary for disaster risk reduction in planning and building:

- Multi-stakeholder development of plans and codes: urban and regional plans and building codes or standards which respond to the needs of multiple stakeholders will be more likely to be adopted and result in overall risk reduction. This kind of planning or revision of codes requires sometimes a change of approach at the local level, a technical capacity to integrate the multiple perspectives and also requires time and budgets to undertake the activities.
- Supervision of building process for engineered structures: implementing set of regulations that enable accountability for the design and building of engineered structures. If this is local government, ensuring that local government has the technical and staff capacity to undertakes these checks.
- Safe building practices for non-engineered structures: increase the capacity of local government to raise awareness about safe building practices. This includes using media and pamphlets for raising awareness of safe building methods, investing in training at community-level and training of building professionals and across government departments. This kind of approach can also be implemented by non-governmental groups and supported by other levels of government
- Streamlining of permits and land development processes: The process of getting permits for building or land in many municipalities is time-consuming. The end result can be increased risk as more buildings are built outside the formal system with little application of building standards. Local governments need to look at this system and where possible revise the system to make it easier for people or for developers to obtain clearances for building.

Abstract

Together with a dominant demographic trend and an important component of global land transformations, the world's population has been concentrating in urban areas (United Nations, 1993). On the other hand, in addition to its global reach, growing populations, changing consumption patterns, expansion of urban areas and current unqualified lifestyles of urban context are seen as unsustainable in the long term (Karr, 1999) with a number of documented effects on natural systems. Within the urbanization process, humans became dominant on urban ecology and caused several alterations especially on riverine systems and their hydro-morphological and ecological structure. Therefore, presently it is more crucial to integrate urban natural systems and their functioning into urban development dynamics through social, economic and environmental dimensions.

From this point of view, in addition to functions and importance of riverine systems, the paper focuses on the problems and changes of urban riverine systems which collectively termed as 'Urban Stream Syndrome (USS)' and characterized by geomorphic and hydrologic alterations of a stream (Walsh et al., 2005). In this context, the importance of 'river health' requires special thinking of a riverine system as an ecological unit, not merely a channel that conveys water from the origin to the lowlands. The term of 'Healthy Rivers' constitutes the basis for re-naturalization of degraded riverine systems and directs the paper to investigate the criteria of healthy river characteristics not only for its functioning but also to demonstrate resilience in the face of environmental changes, including climate change, resource exploitation or other kinds of impacts resulted by human activities in urban areas. Therefore, the paper looks at urban stream syndrome from spatial planning perspective and put forward the method of 'Stream

Daylighting' as a tool for reclamation of buried and culverted riverine systems in urban areas and to better understand and integrate its functioning in to urbanization dynamics.

As is known, studies of ecology in cities have exposed environmental stresses, threats, and constraints that affect urban biota. From this point of view, the paper will focus on the significance of healthy rivers in urban ecology and their ongoing threats and challenges from urbanization dynamics together with human activities all will be discussed for better integration into spatial, social and economic development of urban settlements.

Key words: Urban riverine systems, urban stream syndrome, healthy rivers, re-naturalization, stream daylighting.

1. Introduction

Water has always played a central role in human societies (Biswas, 2008). However, according to the United Nations 2009 Revision of World Urbanization Prospects, 50.5% (3.5 billion) of the population on Earth is living in cities in 2010. Consequently, the ecological impacts of this population growth and its distribution are profound especially on water resources. With the acceleration of urbanization, as one of the essential components of natural processes, urban rivers are exposed the crisis of ecological deterioration.

In this context, "urban riverine systems" refer to those that originate from or flow through city proper, including some artificial canals and canal systems which have had the characteristics of natural rivers through the evolution of so many years (Lei and Guanghe, 2008). Riverine systems in urban areas occur at the land-water junction alongside the natural waterways and they form unique ecosystems that act as 'buffer zones' between uplands and downstreams (Lowrance, 1998). However, as a result of increasing anthropogenic activities, the functions of urban rivers are gradually weakened, the river channels are polluted, buried and the riverine characteristics have been lost. Urban rivers which were one of the zones where human activities and natural processes have had mutual benefits during the process of urbanization, have been profoundly affected through this process (Lei and Guanghe, 2008). Their functioning, structure and components were changed, degraded or lost.

From this point of view, re-naturalization and integration of buried or degraded riverine systems has become an important issue with a focus on providing mutual benefits and supporting the sustainability and integrity of riverine urban systems. Therefore, the paper analyses the current situation and problems of urban riverine systems within 'Urban Stream Syndrome' framework and proposes 're-naturalization' of these systems in order to develop their lost natural characteristics and functioning both from ecological and socio-economic perspectives.

2. Riverine Systems in Urban Areas

Throughout the civilization process, the lands around riverine systems have always been a suitable and preferred place for human beings. As can be seen from the early civilizations such as the Egyptian Civilization, Indus Valley Civilization and Mesopotamian Civilization developed near major perennial rivers (Biswas, 2008). These civilizations were all founded on their access to water by canal systems which provided the key not only to supplying freshwater, but also to agriculture, trade, transport and defense.

Although riverine systems make up 2% of all freshwater on Earth, they have an important role for the continuity of natural processes as part of the 'Water (hydrological) Cycle' which is essential for existence of freshwater resources on the land surface. Riverine systems serve as roads to carry water, organisms, important gases and nutrients to many areas. They also help drain rainwater and such dynamic systems provide a wide range of ecological niches supporting a diverse flora and fauna with providing travel routes and recreation opportunities for people in connection with nature (White and Keith, 2005).

Riverine systems also have an important role as part of the urban ecology. These systems in urban areas not only provide important source of water and material but also have an ecological importance with the riparian areas which are the hotspots of interactions among plants, soil, water, microbes and people (Lowrance, 1998).Therefore, if the integrity of each system is succeed then the urban ecology can be a better linkage among the three components of sustainable development (social, economic, environmental) (UN, 1987). Herein the integration of such principles in to practice has some challenges and requires scientific & pragmatic tools. One such pragmatic approach to apply this principle in to practice is that of 'ecosystem services', which describes the multiple benefits provided to people, both directly and indirectly by ecosystems and biodiversity (Daily 1997). These services were defined and grouped by the UN Millennium Ecosystem Assessment (MEA) (2005) into four categories: 'provisioning services' (extractable resources), 'regulatory services' (processes that regulate the natural environment), 'cultural services' (culturally- valued benefits) and 'supporting services' (processes essential to maintenance of the integrity, resilience and functioning of ecosystems). In this context, watershed areas including headwater streams provide important ecosystem services such as clean drinking water, habitat for aquatic life, and rapid processing and uptake of nutrients which can reduce delivery of nitrogen and phosphorus to downstream coastal waters. According to Elmore and Kaushal (2008), riverine systems in urban areas, as another component of this system, also serve as a variety of functions: urban drainage and flood management, public and community amenity (including linkages to open space), and can include special cultural and community significance (Table 1). In addition to the importance of their ecological functions, they also can integrate the history with modern city features and provide a

social cohesion among generations. Hence, riparian zones are foci for human-nature interactions and can serve as catalysts for ecological and socio-economic revitalization in urban systems (Groffman et al., 2003).

Table 1: Ecosystem services of riverine systems in urban areas

Ecosystem Services of Riverine Systems in Urban Areas	
Provisionary	Freshwater, Food, Fibre, Aquatic Habitats, Energy Production
Regulatory	Flood Management, Disease control, Water & Air Pollution Control, Urban Drainage
Cultural	Public & Community Amenity , Recreation, Aesthetic Value, Ecotourism
Supporting	Soil Fertility, Water Cycle, Material Carrying (Water & Sediments Carrying), Mass & Energy Exchange

However, even it has been recognized that water is an essential requirement for humans and ecosystems' survival; the ecological researches of terrestrial urban systems include many contrasts among economic development, social wellbeing and ecological conservation in urban areas. Hence, as the human population steadily increased over time and the range of the human activities also expanded, especially after the Industrial Revolution, and urban ecological systems are largely exposed to several pressures caused by anthropogenic impacts. Due to the growing demands of population especially for water resources, in terms of both quantity and quality of riverine systems started to come under increasing stress in many parts of the world than ever before (Biswas, 2008). Over time, many streams and river basins in urban areas were altered hydraulically, chemically, and biologically through navigation and flood control projects, wetland dredge-and-fill activities, industrial activities and waste discharge. According to Bernhardt and Palmer (2007), the most obvious and immediate consequences of urbanization are an increase in impervious surfaces resulted as the increased runoff to receiving streams, higher peak discharges, greater water export and higher sediment loads. As a result of increasing impervious cover in developing catchments, evapotranspiration and soil infiltration are reduced, peak discharges and flashier stream flows increased. The changes in channel morphology disconnect the stream from its flood-plain, decrease meandering, and homogenize stream profiles that increase flood risk and degradation of aquatic habitats and biodiversity. Therefore, an

altered hydrography with high peak flows and reduced base flows is the most obvious and consistent effect of catchment urbanization on stream hydrology (Walsh et al., 2005).

All these negative effects of urban areas on riverine systems emerged the term of 'Urban Stream Syndrome (USS)' (Walsh et al., 2005) which describes the consistently observed ecological degradation of streams draining urban land. It is also used to describe a consistent pattern of hydrological, physical, and biological conditions seen in aquatic ecosystems downstream of urban inputs. Although, urban-impacted riverine ecosystems are degraded due to the complex and multiple factors of the major anthropogenic impacts which can be ascribed in few large-scale groups including urban storm water runoff, land use, deforestation and pollution (Table 2). In this context, symptoms of the urban stream syndrome include elevated concentrations of nutrients and contaminants, altered channel morphology, and reduced biotic richness, with increased dominance of tolerant species, which result ecological, hydrological and morphological alterations and degradations on riverine systems (Walsh et al., 2005).

Table 2: Impacts of urbanization on riverine systems within (USS) framework

Drivers ……▸	**Symptoms** ……▸	**Results**
• Urban storm-water runoff • Land use • Deforestation (for riparian vegetation) • Polluters	• Water Quality (Nutrients & toxics increase) • Temperature (Temperature increase) • Hydrology (Altered channel morphology) • Physical Habitat (Biotic richness decrease & tolerant species increase)	• Ecological, Hydrological and Physical Degradation on Riverine Systems

3. Re-naturalization of Riverine Systems in Urban Areas by Stream Daylighting

Over the last couple of decades, river restoration has emerged as an important intervention to overcome the long-term deterioration effects of human manipulation on rivers (CRSSR, 2012). The earliest river restoration projects were launched in Europe. The US started the activities around mid 1970's, and later some examples took place in China. In Europe, the US, Japan and many other countries, there have been many restoration practices for small river ecosystems with mature restoration technology

(Zhao et al., 2007). Up to date, however, these practices have focused solely on stream channel design and mechanics with focusing on a specific area (site-by-site solutions) with a narrow scope. Such that, the main purpose of river restoration is to eliminate constraints to river's natural patterns or biodiversity, which caused by human activities (Ebersole, 1997), but not necessarily to rehabilitate certain natural structures and conditions of river ecosystems or keeping a state of ecological balance and the original status of the ecosystem. Therefore, a holistic approach for the restoration of riverine systems including groundwater exchange, geochemical cycling, establishment of appropriate ecological processes and systems including integration with urban systems (ecological and socio-economical systems) is required. According to Zhao et al., (2007), urban river restoration planning should be the trade-off of a consideration in river ecology, applied restoration technology measures and socio-economical supporting conditions.

Therefore, especially for the recent years, there is a growing concern on the upgrading of riverine systems' ecological status. Also, it is realized that the successful stream rehabilitation requires a shift from narrow analysis and management to an integrated concept of the interconnectedness of human actions and river health (Booth et al., 2004). Herein, the approach of 're-naturalization' constitutes a complementary role to reach beyond the 'good-status' to original ecosystem. In other words, the measures that help a system to go back to natural status in a naturalistic way are usually referred as re-naturalization with an aim which has evolved towards the concept of bringing watercourses 'close to a natural state' rather than creating a truly natural state (Table 3). This also can be explained by 'connectivity' approach which is an ecological term that describes the 'natural habitat continuum throughout the landscape as being the antithesis of the fragmentation'. Therefore, rivers and riparian corridors are connecting elements (or landscape corridors) between patches and serve as paths along which animals can move and plants can spread (Harrison, 1996).

Table 3: The shift from rehabilitation/restoration approach to re-naturalization

From Rehabilitation and Restoration ..... ▸ **To Re-naturalization**	
• Solely focuses on stream morphology or channel design • Considers precautions for flood damages • Causes changes & relocation of river bed morphology. • Aesthetic concerns are mainly prioritised • Lack of historical data usage (original situation & original status of the river)	• Holistic approach • Includes a broad framework of integration between ecological, social, economic systems • Considers connectivity between aquatic variables within ecosystem structure and functions • Aims to be 'Close to nature' in urban, semi-urban, rural, natural landscapes

The approach of re-naturalization indicates the importance of system health and is based on the 'healthy river concept' which refers a system whose social and natural functions can be balanced or compromised in terms of the socio-economic, ecological and environmental values associated with the river. According to Karr (1999), healthy rivers approach demonstrates good health by being resilient in the face of environmental changes, including climate, resource exploitation or other impacts of human activities. Also, it implies a long-term balance whereby the integrity of the natural system is preserved while meeting human needs and providing a system whose social and natural functions can be balanced or compromised in terms of the ecological, socio-cultural, and economic values associated with ecosystem services generated by the riverine systems (Table 4).

Table 4: Ecosystem services generated by healthy riverine systems in terms of ecological, socio-cultural and economic systems

Socio-cultural	Ecological	Economic
• Water supply • Clean potable water • Flood control • Recreation	• Riverbed (Favorable riverbed & energy exchange and transportation) • Water quality (Acceptable water quality) • River Ecosystem (Purifying water and nourishing river ecosystem) • Flow regime / Run off (Compatible runoff)	• Flood control • Land use patterns • Infrastructure • Navigation

In this context, the river health criterion should reflect the river's natural function status, which includes the riverbed, water quality, river ecosystem and runoff. However, the variety and quantity would be different for different rivers depending on different natural features and social background (Changming and Xiaoyan, 2009). According to Platt (2006), for a healthy riverine system, natural functions show the life signs of the system and ultimately determine the sustainability of human societies.

On the other hand, the riverine systems which are exposed to several impacts by human activities lose their natural functioning and structure mainly by channelization or culverting activities in urban areas. These increasing anthropogenic interventions mostly caused chain alterations on their ecological and hydro-morphological features and

resulted with a system failure including damaged & fragmented aquatic ecosystems. According to Buchholz and Younos (2007), in European and American cities prior to the mid-1800's, small neighborhood grids allowed for the management of water with a localized supply and treatment approach that included collecting rainwater in cisterns and designing useful channels in narrow roads and alleys. However, when the industrial revolution came to full force and it was no longer possible to manage city water flow using pre-industrial methods. Therefore, many riverine systems are culverted in to pipes, buried and covered with concrete or asphalt covers and so the development of cities continued over these forgotten underground ecosystems. Communities and decision makers mistakenly believed that they took the control of these natural systems to mitigate for future threats such as pollution, spreading diseases and floods.

According to Paul and Meyer (2001), the process known as stream burial (where streams are directed into culverts, pipes, concrete-lined ditches, or simply paved over) is probably the most extreme impact of urbanization on streams. It results in the destruction of the natural stream channels and contributes to downstream habitat degradation, aquatic habitat fragmentation, enhanced transport of polluted water and toxic contaminants, and reduction of ecosystem services such as nutrient and sediment retention (Walsh et al., 2005). Because they constitute the largest fraction of stream length and are the most economically feasible to bury, the smallest streams are among those most affected by urbanization (Elmore and Kaushal, 2008). However, with the beginning of the twenty-first century, a turning point is precipitated by the deterioration of industrial-era pipes that were built to capture storm water runoff and led to think and ultimately build a more holistic future for American cities. This situation brought awareness of the problem reflected by the development of a policy to prevent culverting or to promote the removal of these structures and to restore urban rivers back to a more natural condition.

Herein, the 'daylighting' activity has steadily increased especially across the United States, and it is even more widespread in parts of Europe. According to Pinkham (2000), Daylighting" as a new phenomenon, became perhaps the most radical expression of this change in intervention and implementation to surface waters. The term describes projects that deliberately expose some or all of the flow of a previously covered river, creek, or storm water drainage. In short, daylighting projects usually remove a stream from an underground pipe and restore the waterway to open air. In this context, removing culverts and daylighting projects has a high potential to improve aquatic and marginal habitats. Deculverting also could therefore significantly improve fish passage by removing migration barriers (Wild et al., 2010). In addition, it could provide aesthetic values with recreational opportunities and a new open public space for city dwellers and educational opportunities as an outdoor laboratory for students. Also, it provides to give a place a sense of identity. In general sense, the benefits of these removal & improvement projects in terms of socio-economic perspective is reported in several cases which were located in areas suffering from crime and a 'near-silent, pedestrian and

cycling environment is provided after daylighting riverine corridors. Other reported economic benefits include rising nearby property values and leveraging private investments (Pinkham 2000) or attracting new business nearby.

4. Assessment of Implemented Stream Daylighting Projects

The newly emerging socio-economic/ecologic intervention of urban stream daylighting is a distinctly valuable and viable tool for the integration of buried riverine systems in to urban ecosystems with the second chance it provides to be 'natural' again. Over time, many implementations are completed all over the world and miles and miles of riverine systems are turned back to their natural status (the closest status to river's original ecosystem functioning). In order to understand the 'daylighting' concept in depth and assess the implementations from different national backgrounds, ten case studies are selected and compiled according to their general features and characteristics.

These cases are selected from four different geographical regions (US, Canada, Europe-Switzerland and Korea) including different social, economic, legal and environmental backgrounds with various circumstances and results they face off. Six of the projects are selected from USA where this approach is emerged and one from other countries. The selected case implementations are indicated below (Table 5).

Table 5: Selected 10 case studies from implemented daylighting projects

Location	**Name of the Riverine System**
USA	1.Napa Creek- San Francisco Bay 2. Strawberry Creek- Berkeley 3. Jolly Giant Creek- California 4. Arcadia Creek- Michigan 5. Dunes Creek- Indiana 6. Castro Valley Creek- California 7. Thornton Creek- Seattle
Switzerland	8. Zurich Daylighting Programme
Canada	9. Taddle Creek- Toronto
Korea	10. Cheonggyecheon River- Seoul

The general assessment of the implemented projects consist of 6 main and 12 sub-issues including; the general info about each project, technical details, economic, social, legal,

institutional backgrounds and the results of the implementations. Also in detail the sub-issues are determined as: Project location, date, primary objective(s), length of daylightened corridor, implementation type, total cost & funding, land characteristics, legal support, stakeholders, challenges and benefits. Assessment of the general characteristics of the implementations provides an overview for the approach in each sub-issue to generalize and to bring out summarizing findings for future implementations. Therefore, the general assessment of different practices from different countries and backgrounds will provide a broad spectrum of implemented daylighting experiences including different contexts and backgrounds. It will also help to understand the details and general features of each implementation process including their positive and negative aspects which can guide the future practices both in rural or urban areas. This task is handled in the conclusion sub-title (Table 6).

5. Conclusion

The areas including riverine systems have always been important sites for human beings to settle and live with the utilities provided by water sources such as transportation, defense, irrigation or recreational amenities. As can be seen from many cities both from ancient times and present, the urban rivers have been always the foundation for settlements' existence, containing city's rich history and culture and embodying modern city's peculiar features and picturesque scenes. Riverine systems in urban areas have continued their role of to be the interaction zones between human and nature over the centuries. However, the modern era has not been kind to urban streams and riverine systems especially in urban areas where they are exposed to several anthropogenic impacts causing a chain of alterations on the whole system's functioning.

As a result of case study assessment, the results of implementations are determined with in a broad framework including urban infrastructure benefits (cost of sever system repairs), increase property values, in neighborhoods, creating an outdoor laboratory for students, improved air & water quality, temperature reduction, increased biological biodiversity, recreational opportunities, flood protection and increase public awareness & participation. In addition to these positive effects, each project indicates a number of situations that should be considered during the project process such as old infrastructure problems, combined sewer systems, challenges of densely urbanized areas, difficulty of establishing the channel geometry and consensus & collaboration between stakeholders. A variety of stream daylighting implementations are given in Table 6 where the main challenges, drivers of implementation, participation and legal backgrounds within different scopes and major results are presented including the most important results under each theme in grey background. The assessment demonstrates that the requirement of daylighting implementation for a degraded or forgotten riverine system

originates from similar conditions and problems in different places. Such that, many projects are taken into consideration according to the increased flood problems, ecological deterioration, decrease on water quality and aquatic species, pollution & sanitation problems and economic issues related with increasing amounts of water needed treatment. On the other hand, although the main goal of each implementation may differ from each other with its priority among generalized riverine corridor problems but they are dealt with a common perspective of 'ecological restoration and re-naturalization'. Many projects were supported by public authorities and local organizations with significant public involvement which was the key component for the success of each project. On the other hand, legal support for daylighting projects were inadequate as a result of its newly emerged but in two cases it was seen that, the efforts of daylighting could shape the policy tools (Jolly Giant Creek-New Drainage Master Plan) or the current water-related policies could support a city-wide daylighting project (Switzerland-Zurich Daylighting and Sewage Separation Program under 1991 Swiss Law). Although, it is a new concept which needs a multidisciplinary approach and support, the daylighting implementations are mostly resulted with a number of positive impacts in terms of social, economic and ecological aspects including improvement of aquatic habitats, water & air quality, social cohesion and increase of land property values.

In the context of this paper, it is clarified that the improvement and re-naturalization of degraded, buried or culverted riverine systems is feasible with the 'stream daylighting' method even in highly urbanized areas. The assessment of ten cases leads to generate an assessment of the projects under specific titles. In addition to general assessment, the implemented projects can also be analyzed and discussed with different themes. This assessment compiles the cases according to eight key themes which are determined according to the highlights and crucial points of each project and constitutes a route for understanding the key components of daylighting practices. Under each theme, the projects can be assessed with the features related to their scope & goals, drivers, feasibility, public participation, stakeholders, funding, legal background, positive impacts and results which will be anticipated as the major issues of future urban stream daylighting assessments and feasibility applications.

As a conclusion, the necessity, feasibility and the importance of 'daylighting' for damaged or lost riverine systems especially in highly urbanized areas are clarified by the assessment of cases from different backgrounds. The assessment demonstrates the applicability of the method including its positive impacts and beneficial results in each case. Moreover, through the analysis of implemented projects, it is seen that the daylighting method provides degraded riverine systems to reach the closest stage of their original status by 're-naturalization' approach which is based on the health of the ecosystem and requires to be supported by relevant legal tools, governmental and local authorities as well as by public involvement to be adopted and become widespread.

Table 6: Assessment table of implemented daylighting projects under key themes.

Implement -ation Year	1970's	1984	1988	1995	1997	1998	2005	2006-2009	2007	2009
Case Studies / Key Themes	**Napa Creek, San Francisco Bay Area**	**Strawberry Creek, Berkeley**	**Zurich, Switzerland**	**Arcadia Creek, Michigan**	**Jolly Giant Creek, Arcata**	**Taddle Creek, Toronto, Canada**	**Cheong Gye Cheon River, Seoul**	**Dunes Creek, Indiana**	**Castro Valley Creek, California, US**	**Thornton Creek, Seattle, Washington, US**
Primary Goals & Scope	'Re-exposion of a previously hidden stream ' (only cover removal without re-naturalization concerns)	Creek ecological restoration (archetype of daylighting projects)	'Sewer Separation' program on citywide	'Re-develop-ment of an unhealthy core area' (business centre) in Kalamazo city and reduce flooding	'Creating an outdoor ecology laboratory'	'To give new life to the hidden creek at the heart of the city'	'Preserv ing the unique identity of the natural environ ment and historic resource s of Seoul'	'Opening the entire Dunes Creek system to Lake Michigan and reduce the urban impact to the surrounding natural area'	'To increase the creek's capacity to carry a 100-year flood and restoring essential habitat for wildlife species'	Improving water quality and flood Protection also create public amenity
Drivers	Uncovering the waterway as a part of ongoing urban renewal project, Prominent landscape architects and urban planners envisioned protection of riparian corridors in Bay area	Creek is a heavily impacted bu urbanisation (erosion loss of fish species, flooding, decreasing of water quality, sediment contamina-tion)	Flow of stream waters in to sewer system and limited wastewater treatment plant capacity, need for natural environment in the city	Part of a major downtown re-development project, a national design competition for re-development zone of the city brought the idea of daylighting	Biology teacher in a high school proposed daylighting for biology courses (to create an outdoor laboratory for students)	Increased pollution levels, (complaints from residents) create concerns about public health	Sanitation and Safety Problems (traffic load, air pollution, aging road structures, unwholeso me-some environ-ment)	Enclosure of Dunes Creek, a tributary to Lake Michigan had been contributing to the presence of E. coli in the lake effects the beaches	The District saw opportunity to restore and enhance the library and improve the environment	Homeowners downstream of the Northgate mall began to note the deteriorating conditions of creek and marked increase in flooding incidents.

Feasibility	All projects in bay area was in densely developed areas has similar challenges (old infra-structure etc.)	As an first implemen-tation, the biggest challenge 'fear' is removed, lack of modern tools	Combined sewer systems in densely urbanized area+ large impervious surfaces	The Arcadia Creek watershed is mostly urban and a densely populated area	The biggest challenge was establishing the channel geometry in a floodplain and major effort is needed to remove concrete slabs (costly)	A very polluted creek in a highly built-up part of the city. Also creek run combined with sewer made daylighting difficult	Physical (resolv--ng inconve nience) and environ mental (rainy seasons) constrai ns.	Creek is heavily-modified also collapse of the the parking lot over creek due to the heavy rain, need to repair	The site's steep gradient presented challenges.	One of the most abused creeks in the city due to the intensive development of the watershed
Public Participa---tion	Local firms and groups supported the activity, designers have pushed hard for significant public involvement	High school students from low income families worked for maintaining tasks(paid)	The initiative of the neighbourhoo d was very important and helped to raise the money for the project.	Public involvement in planning, and preliminary engineering, campaigns	Many students have been involved in restoration and maintenance process	University o Toronto developed proposals fo daylighting project + community support	Intensiv e public involve ment program s were operated (Wall of Hope Program)	A live camera uploaded images on internet to alleviate public concerns and questions	Collaborati on with local agencies during the process	Citizen groups worked actively in the project
Stake-holders & Funding	For the following daylighting projects in the bay area, cooperation between government, business, non-profits and citizen groups play an important role	The entire park project was completed from city funds (City of Berkeley). Cooperation with Berkeley Youth Alternatives and University of California	Zurich City Council has a key role with the supports of all the relevant city departments , politicians, and the population	Downtown Development Authority funded and coordinated the project including engineering studies with its consultants, 'STS Consultants Ltd.'	-Humboldt State University, -Community groups - Government Arcata High School - Natural Resources Services Division of the Redwood Community Action Agency (RCAA)	- The Taddle Creek Watershed Initiative, - University of Toronto, - City of Toronto - Business, - Local envi-ronmental groups worked together	Operated by Seoul Metro-politan Govern-ment, recommend -dations given by KSCE, Funded by Federal Emergency Manage-ment	-The Indiana Department o Natural Resources, -Save Dunes Conservation -JFNew partnered and Funded by NOAA, (ARRA of 2009) and FEMA	-The Alameda County Flood Control and Water Conservation District, -Alameda County General Services Agency, the - City of Union City,	Thornton Creek Alliance Citizens for a Liveable Northgate Thornton Creek Legal Defence Fund

Legal Back-ground			1991 Swiss Law- 'Removal of clean water inputs to combined sewer system'		The efforts shaped the city policy 'New Drainage Master Plan' is prepared					
Positive Impacts	Offers urban infrastructure benefits (expensive repairs),Several daylighting projects followed in bay area, increase storm flow capacity	Property values in neighbourhood have increased, and an old place with high crimes turned to a family oriented area, and won many awards	Excellent example of citywide daylighting program 'Creek Concept' encouraged by city policies	An unhealthy (crimes, flood risk) area transformed to an attractive business centre (increased investments)	Increased pedestrian traffic by students and accessibility to the outdoor laboratory. Also a new natural public space is created.	Unfortunately the project could not realized because of the challenges which are difficult to overcome	Improved Air quality & Temperature reduction, Increased Biological Diversity and land property, Recreation &Restoring Historical Centre	Natural connection between large watershed and Lake Michigan and Improve water quality & aquatic habitat, flood protection, recreation	Water quality improvement, enhanced wildlife habitat, and public awareness and enjoyment (amphitheatre) playground, recreation park are built	The majority of water flows through the underground pipe but small amount is routed through channel to provide a constant flow of water
Results & Lessons Learned	Removing the cover did not fix the problems, a damaging flood occurred in 1986	Successfully implemented first project, inspired many other projects, and shows importance of public participation and reuse of materials	City policies can encourage creek daylighting projects	Daylighting used in very dense urban area, decrease crime and increase land properties, book published for children	Daylighting projects can help to shape city policies. Also an outdoor laboratory for the school and valued natural area for the community is created.	The project show that there is a multitude of options even for the same creek.	Daylighting projects c have positive impacts both economically, environ-mentally, physically and socially. & Importance of local communi-ties	A live camera that uploads images to the Internet every 15 minutes at NOAA.gov, project won many Awards	Second phase is completed in fall 2010. Increase public awareness The project highlights the possibilities for restoring streams in urban areas.	Community process led to large scale water quality project and major private redevelop-ment.

Dutch spatial planning laws and public private partnerships: increasing or reducing democracy?

Marcel Pleijte[1]

Abstract

The Dutch spatial planning laws and the structures of decision making in the Dutch planning undergo changes and innovations. The transformations in the spatial planning laws is to increase the implementation of projects (getting things done), to avoid administrative clutter and to mitigate the nuisance power of civil society to protest and appeal procedures which slow down the realization of regional development and urbanism. Besides changes in the Dutch planning regulations the spatial planning in the Netherlands is also characterized by displacement of politics to public-private partnerships. The public private partnerships have to realize regional development by urbanism.

According to Metzger (2011) is spatial planning in neocorporatist governance structures reduced to little else than pseudodemocratic window dressing of dominant corporatist interests. According to Healy (2010) is spatial planning not only a set of expert skills, but also calling for justice. Spatial planning has to offer processes and mechanisms that open up potentially controversial issues of spatial development for democratic debate and transparency (Healy, 1997). Healy pleads for designing court institutions within planning processes, not necessarily formal legal courts but also public hearing procedures.

In any democratic system have actors an option to go public with their grievances: through the media, internet-opinion-raising activities or direct action or civil disobedience (Metzger, 2011).

The central questions in this paper are:

How do the changes in the traditional planning instruments of the Dutch spatial planning acts and the public-private partnerships affect spatial planning practices in the Netherlands? Do they make the Dutch planning practice more efficient and effective and for whom? Do they make the Dutch planning practice more democratic, more open and more responsive for the Dutch society? Accomplish developments of

[1] Wageningen University and Research Center, Wageningen, The Netherlands – marcel.pleijte@wur.nl

spatial administrative centralization and decentralization in planning policy independently of each other, do they reinforce each other or are they at odds?

For answering these questions the background is showed behind the choices to change the Dutch spatial planning acts and the choice to introduce public private partnerships (section 1). Then a theoretical framework is offered where I first will look for the consequences for political and social democracy in terms of inclusion or exclusion of actors and issues. Then is explained that the Netherlands is a decentralized unitary state and after that three laws are introduced which have different assumes about interactions between governments (section 2). After that three case studies in the Netherlands are presented where a new planning instrument of law is combined with a public private construction, so we can see how this combination influences spatial planning practices in terms of democratic improvements or democratic deficits (section 3 till 5). At least conclusions are given and a reflection is made on the three laws and their application in the cases (section 6). The public-private partnerships and the changes in Dutch spatial planning laws in the case studies have the characteristics of democratically problematic neocorporatist governance structures and mechanisms, legitimated through sometimes quite shady consensus-building planning efforts (Healy, 1997).

1. Introduction

Discussions about the relationship between centralization and decentralization in spatial planning law and spatial planning policy are still going on in political-administrative and scientific arenas (De Gier, 2011). Spatial planning in the Netherlands can be characterized as public partnerships: national governments have to meet local governments when they prepare their spatial planning decisions, make spatial planning decisions and want to implement these. The history of Dutch spatial planning is strongly determined by the municipal role and responsibility (De Gier, 2011). In 1965, the Spatial Planning Act (WRO) enters into force in which zoning schemes of municipalities are introduced. The zoning scheme is the only plan that citizens can bind. The powers of the higher authorities were only in the sphere of supervision. Till 1985 the Spatial Planning Act (WRO) was one of the most decentralized law in spatial planning laws. In 1985, the WRO is revised because the government and the provinces want to ensure the indirect impact of their plans in the zoning schemes of municipalities. Municipalities need provincial approval for their zoning. Further ministerial appointment powers are introduced. In 1994, the Nimby-act (not in my back yard) is introduced so that the Minister of Housing, Spatial Planning and the Environment and provincial authorities get the power to enforce in projects of supra-municipal interest in municipalities, in extreme cases the national

and provincial governments can take the place of the local authority, without a planning-legal foundation based on a key planning decision or a regional plan. In 1994, the Infrastructure Planning Law came into force for the construction of major infrastructure (motorways, railways, waterways). Where previously the zoning schemes of municipalities could stop the infrastructure plans of the national government, the national government did now has the authority to ask to a municipality to change a zoning scheme. In 2000 the law was updated and a trace destination project was seen as a decision where no zoning change was needed. An administrative agency, the Ministry of Transport, could now devote about infrastructure themselves without interference plans of municipalities.

Since 1 July 2008 the new Spatial planning act (Wro) makes it possible for government, provinces and municipalities to fulfill a role as developer by their own. According to Witsen (2011) the new Spatial planning act makes a sharp distinction between legal interests which governments at various levels stand for: "In principle every government only makes plans and rules for their own interests. So they do not operate at each site and so is created an important prerequisite for a smooth decision-making. That's the theory" (Witsen, 2011). Discussions are still going on about the real effect of the new Spatial planning act: does it really mean actual acceleration and actual decentralization?

The new Spatial Planning Act (Wro, which took effect in June 2008, provides national government and provinces the possibility to use a Central government-imposed land-use plan (Nationaal inpassingsplan) or a Province-imposed land-use plan (Provinciaal inpassingsplan) excluding the municipal council in cases where national or provincial interests are concerned. The first experiences with the new Spatial Planning Act are moderately positive (PBL, 2010). There had until then been little tension between provinces and municipalities, the formal decision-procedure was shortened and the informal consultation was not noticeably longer.

According to the next Dutch cabinets it still does not go fast enough: the Crisis- and Recovery Act (Crisis- en Herstelwet; Chw) entries at 31 March 2010 into force and the Environmental Licensing Bill (Wabo) was into force from 1 October 2010. After the economic crisis a so-called Crisis and Recovery Act (Chw) was introduced, aimed at the acceleration of projects to the economic crisis and to combat its consequences. The Act includes temporary and permanent measures. Among the temporary measures the Act includes the restriction of the rights of local governments. Chw also makes it possible to take a project implementation decision that replaces licenses, exemptions and other decisions normally required. The Environmental Licensing Bill (Wabo) was introduced on 1 October 2010. Purpose of the Environmental Licensing Bill is a simpler and faster licensing and to offer better

public services. The Ministry of Infrastructure and Environment is currently working on a new Environmental Management Act, which should align plans and procedures with each other, leading to faster and better decision-making (Elverding Commission, 2008) and more space should be for local managers to make decisions.

The above sketch shows that throughout time the legislature (the government and the First and Second Chamber) have chosen for progressive centralizing developments in spatial planning laws (De Gier, 2011).

Since 2000, the Dutch cabinets also plead for decentralization of spatial planning policy (i.e. Position paper Letter from Camp, 2002; National Spatial Strategy 2004, 2006). The motto was: 'decentralization where possible, centralization where necessary'. When the report about Spatial Development Politics (WRR,1998) appears, the central government sought to recast the relationship between public actors and with other private actors. The Ministry of Housing, Spatial Planning and the Environment introduces concepts such as development spatial planning and regional development to encourage public-private partnership structures in regions. In the last Cabinet Coalition (VVD and CDA, 2010) is chosen for decentralization of spatial planning to the provinces and for decentralization of regional economic policy, the policy landscape and nature policy to provinces. Decentralization is therefore motto and trend in contemporary spatial planning policy and spatial planning policy in the recent past (last decade). The old Ministry of Housing, Spatial Planning and the Environment (VROM) and Transport and Water Management (V & W) have merged into the Ministry of Infrastructure and Environment, where the term 'spatial planning' has fallen away in the naming of the Ministry, which the Ministry stressed that the decision to decentralize the spatial planning policy is serious.

So where the Dutch spatial planning laws are in a continuing trend of centralization (De Gier, 2011), the central governments are promoting further decentralization of spatial planning policy to achieve a more effective spatial planning.

2. Theoretical framework

According to Metzger (2011: p 191) spatial planning can be seen as a displacement and delegation of politics into other realms of societies than the formal spaces of politics: "*This displacement in turn generates a need for a radical reconstitution of our ideas regarding the democratic legitimacy and accountability of planning work – and, further, the democratic- ethical responsibilities of the contemporary spatial planner in a situation where planning practice is all the more seldom guided by formal statues, guidelines or frameworks for democratic accountability, transparency and legitimacy. It is a matter of debate whether planning has ever been*

truly confortable with the idea of more direct involvement, control and steering." Healy (1997) has showed that traditional, regulatory planning systems lacked adequate spaces for nonadversarial dialogue. The only way for may interests was to contest technocratic domination through pursuing obstructive and confrontational tactics that generated unnecessary and unfruitful confrontations (Metzger, 2011).

Networks often have a very limited degree of transparency and democratic accountability (Allmendinger and Haughton, 2010; Swyngedouw, 2005). The building of such semiformal or informal networks as a form of decentralization of spatial policy and the centralization in spatial planning laws are brought as methods to avoid administrative clutter and getting things done (Allmendinger and Haughton, 2010). According to Marres (2005) political controversies in spatial planning are not failures of governance or of the political system but are 'occasions of democracy'. From this point of view another perspective arise about conflict, strife and opposition within the policy process: they are democratic important (i.e. see also Hillier, 2002 and Pløger, 2004). Healy (1997: pp. 224-228) has warned that "*overcosy informal relationships between key public and private stakeholders in spatial planning processes often will have a tendency to degenerate into the building of democratically problematic corporatist alliances, legitimated through sometimes quite shady consensus-building planning efforts*."

The Netherlands is a decentralized unitary state. The sovereignty rests with the central government, but which has certain powers under laws passed to lower organs (Deth & Vis, 2006). The Dutch Constitution has no provisions for the establishment of restrictive laws by the States General and Government together and can make any rules about which they agree. The Dutch Constitution obliges the legislature the establishment and administration of provinces, municipalities, public bodies to settle "by law" This means that the central government can also limit or eliminate power of other authorities by changing the law. Even the elimination of existing and establishment of new provinces or municipalities is only a matter of central government. (Deth & Vis, 2006: 94-95).

A decentralized unitary state is the form in which territorial units within a unitary state have independent powers. The highest lier is the Central government. The central government provides the unit by legislation and supervision. There are also territorial authorities which own tasks, responsibilities and powers. Local authorities are required to implement greater regulation of the Central government. This is also called co-administration. Decentralization refers to it that the central government has a number of tasks transferred to the provincial and municipal governments. State unit means that the emphasis is on the central government and that the power of provinces and municipalities is subordinate. Provinces and municipalities must

comply with national policy and can only make its own policy when it comes to matters that only relate to provinces or municipalities. Provinces and municipalities do have the power to (often set by the government limits) rule their own affairs: autonomy.
Terms such as unitary state, federation or confederation link according to Van Deth & Vis (2006) not to distinct types, but to countries on a continuum. This also applies to centralized or decentralized. France, for example, is a centralized unitary state: the national authority has a large degree of control in regions and cities.

Thorbecke, the Dutch founding father of the decentralized unity state, saw as the founder of the decentralized unitary state great dangers in the imposition of regulations by the central government to other organs and society (Toonen, 1989, 1990). Thorbecke did not want to create unity through national state authority, but by agreement between the constituent parts in order to achieve legitimacy and state authority (Toonen, 1989, 1990). This idea of an organic state led to the explicit recognition of their own powers of local authorities. Everything to the household of their own bodies is that they can rule by their self. This concept was called the Triple ring or autonomy doctrine, used to indicate that each level is competent in a particular area without interference. In Dutch practice, the separation between the three tiers of government is difficult: a complex system of contracts and cooperation between administrations is created (Van Deth & Vis, 2006).

In Dutch spatial planning there is no often autonomy of local governments or municipalities, but there is co-administration between the different tiers (De Gier, 2011). De Gier (2011) indicates however that decentralization is also co-government: it is the free space that a higher authority allows to a local government. To emphasize the equivalence between the various tiers or levels of government municipalities prefer that is spoken in political-administrative correct terms about *other* governments instead of talking about "*higher*" (central government and provinces) and '*lower*' (municipalities) governments, but from the powers, duties and responsibilities reviewed it is preferred here to use the terms higher and lower authorities.

In this paper, we considered three laws, which are all focused on interactions between governments. However, all these laws apply another assumption when it deals about the interaction between governments:

- The Crisis and Recovery Act assumes public-public opposition and gives no vocational law to municipalities;

- The Intermunicipal Statutory Regulations Act supposes public-public cooperation

and offers municipalities the opportunity to inter-municipal cooperation and collaboration with the province and the Water Board and extension of local government;
- The Spatial Planning Act presupposes a level of public autonomy, with each tier of government has its own roles, responsibilities and privileges. Above municipal interests (provincial interests or central government interests) provide provinces and central government opportunities to achieve their own interests, for example through a Province-imposed land-use plan or a Central government-imposed land-use plan.

One similarity is that all three laws want to decrease (or even an elimination) of local autonomy or jurisdiction of a municipality:

- a Province-imposed land-use plan or a Central government-imposed land-use plan makes it possible for national or provincial authorities to act (= override, take the place of) and to exclude the powers of the municipality (from original tier of government);
- Intermunicipal Statutory Regulations Act: mandate or delegation of powers (= transfer of powers to a public entity or perform on behalf of a municipality);
- Crisis and Recovery Act: government provides power to municipalities in order to relax environmental quality standards in exchange for no vocational law.

Yet this perception is too black and white:

- There is also talk of public-public cooperation in Crisis and Recovery Act: municipalities and provinces can bring by themselves projects they would like as development areas under the Crisis and Recovery Act. Relaxation of environmental quality standards and acceleration of procedures can be local reasons for municipalities to log in a project to the Crisis and Recovery Act. The Association of Dutch Municipalities expects that municipalities, provinces and central government through the Crisis and Recovery Act can more operate as a team in the development of complex projects.

- The application of the Spatial Planning Act involve both public-public cooperation and public-public opposition. In other words, there is less talk of autonomy for each level of governance than in the assumptions behind the Planning Act was provided.
- At the Intermunicipal Statutory Regulations Act (Wgr) is supposed public cooperation. In practice it may also occur opposition between authorities within the Wgr or they may have problems with the control and monitoring capabilities of the steering bodies in the Wgr.

The following sections describe the assumptions behind the three acts and show their application in three cases.

3. Province-imposed land-use plan and application in the case of Wieringerrandmeer

Under the old WRO opportunities for proactive development by provinces were limited. The role of the provincial council was especially judging: the province saw to it that the provincial policy of the regional plans were translated into binding municipal zoning schemes. The province did not have powers to adopt land use plans with a direct binding effect. It could happen in the past that provincial or municipal authorities could delay central governmental policy by not including it in local zoning. Government and the provinces were depended of the impact tot the smallest scale.

With the introduction of the new Spatial Planning Act changed this situation. A Province-imposed land-use plan or a Central imposed land-use plan in the Dutch Spatial planning act (Wro) is a zoning made by a provincial council or Central government, which can be legally recorded the destination of a particular area. This possibility exists since the entry into force since 1 July 2008. A Province-imposed land-use plan overrules a provincial municipal zoning scheme. It is one of the legal instruments by which interests by higher authorities still may be conducted even if this policy interests of a local government crossed.

Policy from a Province-imposed land-use plan should be implemented in a municipal zoning scheme. Municipalities are excluded for this part of making their own policy. A province can only make a Province-imposed land-use plan if there is a provincial interest. What this exactly means is not defined by the Wro, but is determined by the province itself. When a part of a plan is in conflict between a lower and higher authority about the legal status of interests it may be submitted to the Council of State.

The Province-imposed land-use plan makes it possible to a provincial council to develop and implement projects by themselves. That was not possible under the old law (WRO). In that situation the provincial council was only supervisor.

The motto behind the new Spatial Planning Act is: you go about it or not. Each layer has to realize its own public interest and a public interest of a higher authority justifies that this tier deals about it. Questions should be addressed at the level or scale on which they play (subsidiarity). There is thus a strong belief in clear roles, clear responsibilities and clear powers. If anyone is able to realize its own affairs it is

not necessary to cooperate with other tiers.

Application in the case of Wieringerrandmeer

Since 2004, the province works together with the municipalities Wieringen and Wieringermeer Wirense Lago and the private partner Lago Wierense in the spatial planning of the Wieringerrandmeer. In the mid-nineties there was aninitiative of the municipality of Wieringen to make an island again of Wieringen by creating a border lake. Around the lake more houses, businesses and recreational facilities and nature were planned. At the present land area, 30 farmers were established. Market Consortium Lago Wirense, Wieringermeer municipality and the province of North Holland want to continue with the development of plans for the Wieringerrandmeer. The municipality of Wieringen is not accepted. Reason for the municipality not to accept the plan is that no car bridge over the lake is designed in the plan. Despite several attempts at mediation from the province the municipality persists in its position. For the province reason to ask the provincial states to agree with a decision to prepare a Province-imposed land-use plan, so that the province can take over the initiative of the municipality.

A political party voted a year ago against the border lake plan and a spokesman announced on substantive grounds the value is still not visible. There is now still in the dropping of Wieringen. "*What has the provincial council to win to work with a reluctant partner together for thirty years.* " He warned: "*Especially since we save the path of an open end transit system which threatens the province to pay for all costs*." Hooijmaijers, a provincial governor, refuted the latter. "*Financial, nothing changes. Where the municipality is protected in the cooperation, it is now the province. Making the Province-imposed plan, we take over the role of the municipality*." During the debate especially Bruijstens (Elderly political Party) bothered to the fact that developer Lago Wirense the municipality has sent a letter which threatened to damage claims. "*The letter states that the municipality may be liable for millions if it persists in its view. I deeply regret that Lago Wirense use pressure in this unacceptable way on the decision by the municipality*." Bruins Slot (CDA political party) was not with him. "*It's a normal course of business as the company as a co-signer of the cooperation agreement is warned that this step will cost the municipality money?* " Hooijmaijers, a provincial governor, had the same opinion, especially since the company just has a legal duty to do this in time. An interesting detail was that the provincial council has received a letter from the lawyer of Wieringen and rejects all legal liability.

The financial interests and to ensure progress are reasons for the province to make a Province-imposed land-use plan. The Provincial Council decided in April 2009 for the area to establish a Province-imposed land-use plan.

4. Crisis and Recovery Act and application in the case of the former airport Soesterberg

Due to the economic crisis and occurring stagnation of economic growth and rising unemployment as a result, the Cabinet Balkenende provides to give incentives to the economy in 2009 by investments. Besides extra investment the government wants to reduce complexity and sluggishness of decision making, especially for large spatial and infrastructure projects that the growth of the economy could support.

The government charts which projects with a great effect on employment or the economy before 1 January 2014 could start if there are legal possibilities for these projects faster to run. The Central government also loos for the legal barriers threaten these projects. The Crisis and Recovery Act (Chw) now contains a number of temporary and permanent measures making procedures faster and easier to run, so projects can be implemented. Since 31 March 2010, the Chw entered in force. The act ends on 1 January 2014. Proposals have been made to make the Crisis and Recovery Act permanent. Fewer and faster procedures are possible by temporary adjustments of the General Administrative Law Act. Provinces or municipalities can contact the Ministry of I & M and request to bring an area under the Crisis and Recovery Act.

In spatial planning, it is not uncommon for local governments to challenge decisions of higher authorities by making use of vocational law. The Balkenende IV considers it undesirable that local governments against each other decide to appeal. Because in the past there was public-public opposition in the Chw is chosen to give municipalities no vocational law, what should give no delay. The Council of State has criticized this. The assumption that governing bodies are equivalent and that local authorities should be able to legally defend their legitimate interests is with the Chw affected. The government, despite the opposition of the State Council, has included no vocational law in the Chw. The Council of State is therefore invariably to the conclusion that neither a municipality may appeal against decisions. They are not the central government and are not to be regarded as the addressee of such a decision.

Spatial development and environmental regulation can be at odds with each other. The Chw offers opportunities for creative here to deal with. There is possibility to

redistribute environmental space to temporarily deviate from environmental quality standards (more flexible), such long-term hindrance companies are moving and adjacent housing can be realized. At the end of the plan period (up to ten years), again with the standards have to be met.

Application in the case of former airport Soesterberg

The former airport Soesterberg is transformed from hermetically sealed military area to an accessible area where nature and cultural history can be enjoyed. To afford this 440 homes will be built. Soesterberg North has the status of development area within the Chw. The municipality of Soest has asked and received that status with a clear goal. From a work-housing land to a housing-work area seems not so complicated. But if you want less business and more housing (such as for Soesterberg North) then it becomes more difficult. Companies have an environmental circle for noice and air quality, which under the existing rules may occur no housing. The relocation of North Soesterberg to another location will be phased to take place, and that phasing is not synchronized with the plans for the construction of new homes. By the status of development there may be homes built in the environmental circle (s) of companies, with the condition that the land after 10 years meets the environmental quality standards. This offers opportunities to build homes now and not have to wait until business moved. There are companies in Soesterberg North with a circular environment (noise or smells), in which no homes can be built. The municipality will ask these companies to cooperate to move their business, or to make the environmental circle of their business smaller. The latter may for example, by a higher chimney, a different place for supply, an additional valve or acoustic shields. If companies do not want to cooperate, then the company will be obliged to cooperate by the Chw.

Another reason for fastening the building of houses in Soesterberg is that the project of Soesterberg is a part of a program of 25 projects in the so called Hart of the Heuvelrug. The revenues of building the houses are used for a swap to other projects and to realize the development of nature.

5. Intermunicipal Statutory Regulations Act (Wgr) and application in the case of Oude Rijnzone

The Intermunicipal Statutory Regulations Act (Wgr) is a Dutch law which regulates partnerships between public entities such as provinces, water boards and municipalities. The current law dates from December 20, 1984. In 1950 the predecessor was already in operation. This law was especially critical because of the

limited democratic content of an association. Decisions are taken by a body, which was not directly elected. It operates as a fourth layer of administration. It took a long time till sounds to create new provinces disappears, but with the Memorandum Governmental Organization in 1983 was chosen for the renewal of local government and not for a fourth tier of government. Municipalities get in different ways influence on the Wgr.

Application in the case of Old Rhine zone

In the Old Rhine area public and private parties work together on regional development of the zone along the river the Old Rhine. In the area, new residential and commercial areas developed, restructured existing business areas and the water and nature qualities will be strengthened. Another aim is to improve accessibility.

In 2008, all municipalities, the provincial councile and the water board joint a Cooperation Agreement. One of the restraints of the Cooperation Agreement was to prepare a Business Case Oude Rijn Zone through the region and a decision by the Government on allocation of resources under the National Spatial budget. In May 2009 a Business Case Oude Rijn zone established in the steering committee. In June 2009 the government decided to release 30 million euro's grant to the Old Rhine Zone.

The granting of Spatial budget by the state was to the condition that the regional cooperation is in a more binding form in the implementation phase, more binding than in the existing Cooperation Agreement. The government has advised thereby further forms of cooperation and informed choice for Intermunicipal Statutory Regulations (Wgr).

The Old Rhine Zone Steering Committee prefers the Wgr over a private form of cooperation. The latter are well as a possibility in view of the implementation in clusters. In a private form, that brings everything in the implementation phase in contracts, the adjustment possibilities of the public parties are limited. This form is less appropriate for a complex program as the Old Rhine Zone. In the opinion of the steering committee than there is too little justice to the local responsibilities and interests within the practice in the Old Rhine Zone. In any public administrative theory is a public form preferable to a private form of cooperation, because in that situation, administrative transparency, democratic control and influence are greater possibilities. Wgr offers municipalities the opportunity to participate and they can always ask for information. Five municipalities are working together with the province in Wgr Old Rhine Zone. The city of Leiden, the Water Board and the Ministry of Infrastructure & Environmental are consultants in Wgr Old Rhine Zone.

6. Conclusion and reflection

When we compare the choose for the deployment of three acts in three cases, it is striking that in all cases public-private partnership structures indirectly or directly influence the choice of the three acts as a policy instrument.

At the deployment of the Chw at the airport of Soesterberg pressure from the public-private partnership structure plays a role because it allows the target of the red for green approach to the project of airport Soesterberg and also the financial deficit of the Program Hart of the Heuvelrug can be taken away. The motto behind the Chw is: regulations simplify and accelerate. The central government has this in advance necessary obstacles to the market removed, but that's no guarantee that the market actually boarding. The market decides, not the government, so the law will mainly be used when the market rebounds. Another option is that the government itself will behave as a market party and for example builds the houses themselves. By dealing with more flexible environmental standards for noise and any odors from businesses to homes, governments put no more heavily in their evaluative role, but their developing role. Thus, the reduced duties for promoters, but what does the more flexible standards mean for the rights of residents? Is carefully dealt with quality standards?

In Wieringerrandmeer is primarily pressure from the province and the companies of the public-private partnership construction. The province has a financial interest because it has a lot of land purchased in the area. when delay is a result the private parties threaten to come forward with claims. For the province this are reasons to apply the instrument of the Wro: the Province-imposed land-use plan.

In the Old Rhine Zone both the government and the authorities of the public-private partnership construction pressure to opt for a stronger form of cooperation between governments. The authorities prefer the Wgr over Public-private partnterships contracts because they estimate as to retain more influence. The government forces in exchange for money (30 million) so that the authorities increased cooperation issues through the Wgr. That the choice of the Wgr is not established only bottom-up by municipalities themselves illustrates the Old Rhine Zone. The Central government seduces a province and municipalities money to opt for application of the Wgr and obtains also affect the substantive planning. The government could in the Old Rhine zone also use a Province-imposed land-use plan, but did not. Now other governments and private parties willing to co-invest with the government. When applying the Province-imposed land-use plan the money under the PPP arrangement can fall away.

It can therefore be said that public and private parties can benefit from a continued centralization in planning law as reflected in the laws. Decentralization of the spatial planning completed as public-private partnership arrangements could be strengthened by continuing centralization in the spatial planning laws.

From a broader or different perspective be reflected, namely the perspective of parties who are not part of a public-private partnership structure or parties who left the public-private partnership structure, the centralization of spatial planning laws are in tension with decentralization of planning policy.

Finally, can be reflected on the centralization of spatial planning laws and the decentralization of planning policy from a still broader perspective. The discussions in the political-administrative and scientific arenas on spatial planning in the Netherlands seem narrowed to discussions about the planning law and planning policy, but the spatial planning in the Netherlands includes more. Apart from government decentralization can also be talked of citizens' initiative and entrepreneurial initiative of civil society. In short, besides decentralization of policy is also talk of socialization and commodification of spatial planning. The attention in the planning law and planning policy is strongly focused on interactions between governments. From this perspective, both spatial planning laws and spatial planning policy can be improved. Healy (1997) pleads for designing court institutions within formal planning processes, not necessarily formal legal courts but also public hearing procedures. According to Metzer (2011) this is not enough. In any democratic system have actors an option to go public with their grievances: through the media, internet-opinion-raising activities or direct action or civil disobedience (Metzger, 2011). Metzger plead for new methods to accommodate fruitfully dissensus already in an earlier stage within the planning process. According to Metzger (2011) it possibly could also entail "*a renewed interest in a rediscovery and reworking of advocacy planning theory to put it more in tune with the demands of contemporary society and the present challenge of confronting neocorporatist governance structures in which spatial planning is reduced to little else than pseudodemocratic window dressing of dominant corporatist interests*" (Metzger, 2011: p. 195).

Energy Transformation and Planning Conflicts: How to achieve the Transformation towards Renewable Energies in a Conflicting Environment?

Jörg Knieling,

Abstract

Against the background of climate change many countries, regions and communities have set up ambitious agendas regarding a shift from fossil fuels to renewable energies. In this transformation process several questions and challenges have shown up touching land use and spatial planning. Large-scale renewable energy projects like wind parks, solar fields or power lines cause complex land use conflicts that are difficult to handle with existing planning routines. Against the background of the ambitious goals of climate policies and corresponding European and national infrastructure programs regarding renewable energies these conflicts are even expected to further increase in the future.

In consequence achieving the climate mitigation agendas could be threatened if there are – besides existing formal procedures of coordination – no additional and innovative ways of conflict resolution. How could those solutions look like? How to solve multi-level conflict settings where different rationalities of the involved levels seem to be antagonistic? How to handle local or individual concernment versus abstract societal necessities? How to deal with complex planning processes? How to justify severe interventions into landscape or resident population's quality of life against the background of the uncertainty of climate change data? Which new ways of organizing planning processes might be possible? How do they fit into the legal setting of planning law? And how can they meet people's rising skepticism against big infrastructure projects that can be found in many countries?

From a German point of view the paper describes the problem, structures the conflict setting and deduces applicable conflict resolution strategies against different theoretical backgrounds. The topic is tackled regarding earlier findings on environmental conflict

resolution and aims at identifying specific characteristics of current conflicts due to energy transformation. The paper discusses formal as well as informal aspects of adjusting planning processes, including elements of communicative planning in formal and informal planning processes on the regional and local level.

The methodological basis of the paper is a literature review and experts interviews. Furthermore, the author is involved in different expert panels addressing the topic in research as well as in policy advice.

Keywords:
climate change, transformation, renewable energies, land use conflicts, conflict resolution

1. Problem and Background

Following the German federal government's Energy Concept of 2010 the share of renewable energy regarding the gross energy consumption is intended to increase to 30 % in 2030 and 60% in 2050, the portion of generation of electricity of the gross energy consumption shall rise to 50% by 2030 and 65% by 2050 (Bundesregierung 2010: 4f.). Comparable goals exist on the European level. The EU-directive on renewable energy sets binding targets for all EU-Member States, such that the EU will reach a 20% share of energy from renewable sources by 2020 and a 10% share of renewable energy specifically in the transport sector (EU Commission 2009).

Against the background of these political goals it becomes apparent that the extension of renewable energies will cause an increasing range of land use conflicts (Pfeil, Töpfer 2011). On the one hand there are conflicts around punctual energy infrastructure like wind energy plants, wind-farms, large scale solar fields or extensive biogas plants. On the other hands linear infrastructures like power lines are of interest including an even more complex conflict setting because of their far reaching spacious extension. In particular on the European level the question of linear infrastructures arises to connect water energy resources in Scandinavia or solar potentials in the southern EU Member States with the other energy consuming member states. The EU commission has underlined this challenge with its current multi-annual budget for 2014-2020 including infrastructure investments for Trans-European Networks (TEN), amongst others energy: "The energy sector can look forward to €9.1 billion being invested in trans-European infrastructure, helping to meet the EU 2020 energy and climate objectives. (…) The internal market for energy will be further developed through better interconnections, leading to security of supply and the possibility to transport renewable energy in a cost effective manner across the EU. (…) The money from Connecting Europe will act as a leverage for more funding from other private and public investors" (EU 2011).

The pressure of successfully implementing the energy turnaround leads to requests from politics and administration to connect the ambitious aims with more efficient planning processes. In particular they wish a speeding up of the implementation and fear that pro-

tests could become a severe restriction. For example, EU-commissioner Oettinger claimed that three years should be enough for planning and permitting a project whereas it can take up to 15 years nowadays. This claim for acceleration stands in contrast to latest public protests against big infrastructure projects that have been manifold regarding transportation, e.g. the enlargement of airports or the building of new rail-tracks, but also energy infrastructure. In Germany the notion of the "Wutbürger" has become the "word of the year 2011", describing angry or furious citizens whose protest against infrastructure projects is decidedly and well organized. How realistic can claims for acceleration be if they are counteracted by a new public self-confidence of opposing top down decisions?

2. Conflict Structure in Large-scale Renewable Energy Projects

What are specific characteristics of conflicts regarding energy infrastructure that are different from familiar land use conflicts? (vgl. Glasl 2010, Schiller 2009) On the one hand conflicts about energy infrastructure are comparable to other land use topics that deal with change or intervention into existing structures. They are mainly interest conflicts concerning a change for the worse from the point of view of affected communities, land-owners, citizens or institutions. In the case of the energy grid there is another conflict layer questioning if those projects are necessary at all and if they could be substituted by intelligent energy grids operating on a decentralized basis.

On the local level there are multiple critical arguments with regard to energy projects. For example, concerning high voltage transmission lines power health impacts of electro-magnetic fields or the impact on landscape and nature or forests are questioned. In this respect the possibility of under-grounding cables is discussed, but this solution can increase the costs massively. Quite often those aspects are criticized as NIMBY behavior (Not in My Backyard), meaning that affected individuals refuse to accept any change.

In Germany for some decades energy infrastructure has been a main political battlefield because of the severe conflict about nuclear energy. Environmentalists have been opponents of nuclear energy and claimed for alternative solutions. Now, the energy turnaround towards renewable energies sometimes leads to a complex conflict constellation. Whereas on the federal level environmental NGOs plead for the extension of renewable energies they can become opponents against infrastructure projects on the local level. This make the conflict structure quite complicated, accustomed constellations have to be reconsidered.

Furthermore, the economic side of renewable energies leads to new actors. Whereas energy provision for a long time has been a field of monopolistic resp. oligarchic semi-public business structures renewable energies have opened up new business fields for small scale energy producers or providers. In consequence, these new actors show up in the conflict pushing the installation of energy infrastructure. If they are integrated in the community or region, e.g. as citizen-energy plant or local provider, this might allow other compromises than in the case of anonymous investors coming from outside.

The whole discussion about the extension of renewable energies is overlaid by the basic dispute about the necessity of the energy turnaround and skepticism resp. uncertainty of the evidence of climate change. If local politicians or citizens are not convinced that climate change really happens or will affect them they will hardly be willing to accept disadvantages for their property or quality of life. A bit similar is the affect of the time-dimension of climate change. If the risks of climate change might show up not earlier than in 50, 70 or 100 vears many affected actors do not see the need for a compromise. Politicians fear to lose coming elections, and local people are afraid of suffering the loss of quality of life.

In the field of energy infrastructures another aspect can become important for conflict resolution. Energy planning is traditionally a technically oriented domain characterized by an engineering rationality. Involved experts are mostly socialized professionally in an engineering community that is used to identify the best solution from a technical point of view. From this respect, citizen protest appears to be disturbing and obstructing to select the preferred solution. This specific self-understanding of energy planning can restrict achieving a compromise between different conflict actors.

3. Conflict resolution strategies

Conflict resolution in the field of energy infrastructures includes approaches regarding existing formal regulations as well as additional informal procedures and instruments. In the following in particular informal approaches and their linkage to formal procedures are tackled.

The EU Commission's goal of shortening the processes of planning and permitting energy infrastructure, in particular the construction of the European network of power lines correlates with many actors' aims of successfully proceeding with the energy turnaround. But how can this ambitious goal be reached? – Concerning planning processes and administrative routines the past decades have been characterized by a "communicative turn in planning" (Fischer, Forester 1993, Healey 1992, 1996) underlining that hierarchical steering modes have to be reconsidered to include citizens' expectation of been able to participate and influence decision-making processes (critical Tewdwr-Jones, Allemendinger 1998)

In recent years in the field of large scale infrastructure projects attempts of including communicative elements of conflict resolution have indicated potentials and restrictions of such approaches. In particular in airport-projects, e.g. in Berlin and Frankfurt, mediators have been hired to moderate between conflicting parties in addition to the formal planning process. In some respects these efforts have shown good results as they have brought together many different actors and their interests. But they failed in reaching a binding compromise because in Frankfurt the political decision making process did not fully take over the results of the mediation and in Berlin later changes of the project annoyed the affected citizens. Nevertheless, both projects have proven that mediation has the potential to contribute positively to the planning process. If the politicians would respect the results more consequently mediation could function more positively.

Another prominent attempt of communicative conflict resolution has been the "Schlichtung" in the case "Stuttgart 21", the rebuilding of the Stuttgart railway station. Here, similar to a familiar procedure of conflict resolution in tariff conflicts, a mediator was involved as well. His competency was to work out a sort of dictum after having heard all arguments. Although the procedure that was even shown in TV offered a high degree of transparency and included a lot of conflicting parties the results did not lead to a real appeasement. On the one hand the project executing organization, here the railway company German Railway DB, did not really accept the dictum, on the other hand some of the citizen groups had left the process before its end. Nevertheless, Stuttgart 21 initiated a lot of discussion of new forms of conflict resolution besides the existing formal regulations in planning law (Böhm 2011; Selle 2011, Wulfhorst 2011).

Concerning energy infrastructure there have been similar attempts of conflict resolution by negotiation resp. mediation in the U.S.A. (Raab, Susskind 2009). Here, against a different formal background compared to German law allowing the closure of a mediation process with a binding agreement of all participating actors, mediation has already been discussed for cases of large-scale energy infrastructure. Like in Europe the spatial connection of energy production and energy consumption by building new power lines has been the initial cause: "The best solar energy resources in the U.S. are similarly located in the less populated Southwestern states. In the Northeast, there is also extensive debate about whether to build new transmission lines to bring renewable energy from Eastern Canada and Northern New England to population centers in Southern New England and New York City" (Raab, Susskind 2009: 1).

In the U.S. routines of conflict resolution have been evolved in different fields of large scale infrastructure. For example, the U.S. Federal Energy Regulatory Commission's (FERC) has implemented an ambitious integrative stakeholder involvement model. This procedure has originally been developed for certifying natural gas pipelines. A main element of the so called Integrated Licensing Process (ILP) is a "pre-filing environmental review process" which is intended to "facilitate maximum participation from all interested entities and individuals and to assist an applicant in compiling the information needed to file a complete application". In addition, each applicant has to file a "Participation Plan" for the further process (FERC 2006). In some cases the conflict parties can already reach an agreement on their own which is then checked by FERC whether it can be accepted or not. For more conflictual cases FERC offers another procedure, the so called Alternative License Process (ALP). This approach was developed against the background of conflicts in hydropower projects including FERC staff directly participating in the conflict resolution process (Raab, Susskind 2009: 6f.).

Nevertheless, these attempts have also been criticized as being not sufficient enough. Grounded on scientific and practical experiences, Raab and Susskind (2009: 9) propose principles for planning and implementing large-scale energy infrastructure projects addressing the procedural and communicative dimension (see table 1).

Table 1: Six Principles for Using Consensus Building to Improve the Licensing and Siting of Large-Scale Energy Infrastructure (source: Raab, Susskind 2009: 9)

	Six Principles for Using Consensus Building to Improve the Licensing and Siting of Large-Scale Energy Infrastructure
1.	Initiate stakeholder involvement process as early as possible and set realistic but firm timetables
2.	Include broad representation of legitimate stakeholder groups (including government agencies, and – for site-specific projects – citizen groups)
3.	Seek consensus, and consider using professional neutrals to facilitate collaborative decision-making
4.	Do not exclude contentious issues, instead seek ways to address negative aspects of any proposal (including compensation, contingent agreements)
5.	Consider incorporating alternative siting processes (such as voluntary processes, pre-approval, competitive solicitations)
6.	Structure stakeholder involvement processes to supplement but not supplant formal back-stop process, while modifying formal processes to better accommodate consensus building opportunities.

The principles underline the importance of early and broad participation, the inclusion of external neutrals as facilitators, consensus orientation and thus collaborative decision making as well as the necessary nexus of informal and formal processes (see also MacCallum 2009).

Ideas from the U.S. had been impulses for the German discussion earlier before, when forms of communicative conflict resolution and mediation in particular were discussed in the 1990s. The Harvard Negotiation Program was a prominent brain-pool for innovative approaches. After a period of optimism the implementation in Germany stagnated because of different formal regulations. Most notably the problem that mediation agreements cannot be binding but have always to be qualified by the responsible parliament hindered a successful implementation of mediation in planning cases. Nevertheless there are several fields of local and regional planning as well as project development where communicative forms of conflict moderation have been introduced (e.g. Siegel 2002, Battis 2011, Pitschas 2011).

4. Future Research

Considering the challenges of the energy transformation on the one hand and the restrictions of formal procedures of planning and implementing the necessary energy infrastructure on the other hand it becomes obvious that additional approaches of organizing the relevant processes could get decisive importance for coming discussions. Nevertheless, the description of latest references from Germany and the U.S. has shown that implementing communicative forms of conflict resolution poses a lot of questions in detail. Future research might be able to contribute to those questions.

One aspect of communicative conflict resolution is the point of time when to start with a specific form of participation or negotiation. Raab and Susskind claim to start as early as possible, but what does this mean in the formal process. Is it sufficient to start when the applicant for a project informs the administration or should he even start before this when he considers a new project internally? This might sound unrealistic but at the time an application is submitted to the administration main decisions have already been taken by the institution running the project. This problem is underlined by the saying "that participation always comes too late".

Who are the actors of a conflict resolution process? - Raab and Susskind propose to include stakeholders as broad as possible, sometimes the range is limited to the affected actors. What are the advantages and disadvantaged of those alternatives? Does a broad inclusion restrict the effectiveness of the procedure or are there instruments available that make it possible to handle a big group of actors in a communicative negotiation process? Is a restricted participation critical because of a lack of legitimization of the final agreement?

Another research topic is the nexus between informal and formal instruments. Serious participation makes sense only if its results have a chance to be included into the formal decision making process. How this can be achieved in a most productive way?

Some specific questions arise from climate change as the framing topic of the energy turnaround. Because of the far reaching time-horizon of climate change and its impacts on local stakeholders the NIMBY-phenomenon might be more relevant than in other planning conflicts. The conflict resolution needs to give answers how to tackle this problem. Another point is the uncertainty about climate change. This can make it even more difficult to convince opponents of the necessity of a project.

Another aspect has already been mentioned above but should be explored in more detail, the self-understanding of technical oriented energy planning and its comparability with social processes like conflict-resolution. This aspect addresses the social-ecological dimension of energy transformation which has hardly been discussed to date. The construction of power lines, wind-farms or solar-fields is still mainly seen as a technical and economical question. For the transportation sector "Stuttgart 21" has shown what results such ignorance can have, for the energy turnaround towards renewable energies it would be desirable to prevent this escalation.

Finally, this paper has discussed the challenges of energy transformation mainly against the background of the German political discussion and its administrative structures. Looking at Europe it will be necessary to differentiate and include the specific planning cultures of the EU Member States (Knieling, Othengrafen 2009). Such a discussion makes the research even more promising because it allows conceptualizing different models of conflict-resolution each depending on the respective national specifics.

TOWARDS RESILIENT REGIONS: SOME CONSEPTUAL AND POLICY ISSUES

Elisavet Thoidou [1], Dimitris Foutakis [2]

Abstract

In recent years resilience has somehow been rediscovered and introduced into the discussion on development and planning while it has its roots in environmental sciences. Ecosystem ecology once again constitutes the origin of this newly introduced concept, as it did with the concept of sustainable development. In its primary meaning, resilience of ecosystems is perceived as their ability to adjust to changing environmental conditions and survive. Lately, the concept of resilience is metaphorically used as a term which characterizes countries, regions, and cities as well as the various subsystems operating within them. The pursuit of resilience tends to take the place of the pursuit of sustainable development and competitiveness, which prevailed during the 1990s and 2000s respectively. Thus the question arises as to what resilience means if transferred to the context of spatial development. More particularly, from the viewpoint of spatial development policies and spatial planning a twofold question arises: first, what the specific content and relative importance is of this concept in view of the current economic crisis and the other challenges regions face; and second, what its implications for spatial planning are, especially in areas most exposed to current threats. This paper draws evidence from current experience in Greek metropolitan areas which are going through a process of updating of their strategic planning documents, and aims to consider the above-mentioned conceptual and policy issues.

1. Introduction

As contemporary societies face the challenges of globalization, climate change, and economic crisis, previous certainties about spatial development and spatial planning in terms of both theory and policy are being tested or even questioned. The role of factors pertaining to environmental threats seems to be crucial in this respect, first and foremost regarding their impacts on ecosystems, the economy and society. It is worth noting that despite the fact that these phenomena and their impacts are of a global nature, they have indispensable territorial dimensions thus leading to a transformation of spatial policies, namely spatial development policy and spatial planning, primarily in the context of supranational organizations such as the EU. Even in the UN context, which in principal addresses both climate change and developmental problems on a global basis, a strong territorial

approach has been developed. The UN has initiated the 'Down to Earth: Territorial Approach to Climate Change (TACC)' Programme with the aim to promote collaboration among UNDP, UNEP and eight associations of regions, and more particularly, to assist regional and local governments in developing countries with formulating integrated strategies and action plans, integrating climate change into sustainable development planning, enhancing the relevant institutional capacity of local governments and so on (UNDP 2011).

Growing consciousness about climate change and an acknowledgment of the need to address the problem of greenhouse gas emissions from various sources as well as to prepare communities and territories for coping with its results that is to promote mitigation and adaptation measures respectively, has brought the issue of resilience to the fore. According to the UN Intergovernmental Pannell on Climate Change (IPCC 2007) resilience is "the ability of a social or ecological system to absorb disturbances while retaining the same basic structure and ways of functioning, the capacity for self-organization, and the capacity to adapt to stress and change". It is within the UN context that the World Conference on Disaster Reduction (WCDR), in 2005, adopted the 'Framework for Action 2005-2015: Building the Resilience of Nations and Communities to Disasters' with the aim to "promote a strategic and systematic approach to reducing vulnerabilities and risks to hazards" (UNISDR 2005, 1). In practice, hazardous events with severe territorial impacts such as hurricanes, tsunamis, earthquakes, floods, volcanic eruptions, and wars have led the UN to launch a strategy towards precaution and recovery from such phenomena. For instance, tools on "good recovery practice" were drafted in the context of the International Recovery Platform which was conceived at the WCDR as a key pillar for the above 'Framework for Action'. These tools offer guidance on recovery on the following themes: Shelter, Livelihood, Environment, Gender, Public Infrastructure, Governance, Health, Psycho-social, and Climate Change (IRP 2011).

2. Conceptual issues

The concept of resilience goes in tandem with a variety of other concepts, all of which fall under the heading of 'planning for risk prevention'. In this context, concepts such as vulnerable and vulnerability as well as resilience and resilient, which are interrelated with the concepts of risk and hazard, have been introduced in the study of the impacts of the dramatic changes which have been caused or are expected to emerge from the above hazardous phenomena. On the basis of the assumptions and definitions adopted by the ESPON Hazards Project (Schmidt-Thomé 2006) these concepts and their relationships can be schematically described as follows:

> Risk is "a combination of the probability (or frequency) of occurrence of a natural hazard and the extend of the consequences of the impacts. ... Risk = hazard potential x Vulnerability...
> Vulnerability is the degree of fragility of a (natural or socio-economic) community or a (natural or socio-economic) system towards natural hazards. It is a set of

> conditions and processes resulting from physical, social, economical and environmental factors, which increase the susceptibility of the impact and the consequences of natural hazards ... Vulnerability = Damage potential + Coping capacity" (Schmidt-Thomé 2006, 11).
>
> Coping capacity "refers to the manner in which people and organizations use existing resources to achieve various beneficial ends during unusual, abnormal, and adverse conditions of a disaster event or process. The strengthening of coping capacities usually builds resilience to withstand the effects of natural and other hazards" (GTK 2003, 17).

It is obvious that coping capacity to a great extent is of institutional nature, in the sense that it represents the level of readiness of local institutions. This is also the case with resilience as it is closely related with coping capacity.

As current threats to the economy, society and the environment grow, resilience along with vulnerability are metaphorically used as terms which characterize countries, regions, and cities as well as the various subsystems operating within them. In addition, these notions have been introduced in studies on the various effects of dramatic economic and social changes pertaining to the global economic crisis on territorial systems. In searching for the way out of crisis-related problems, the notion of regional resilience is accentuated since it represents the ability of regions and territorial systems in general to adjust to changing circumstances and remain stable (Hudson 2010, CJRES 2010). Therefore, resilience is highlighted in the field of spatial development and tends to supplement and even replace widely established concepts such as sustainable development and spatial competitiveness. Thus the question arises as to what resilience means if transferred to the context of the economy and society and more particularly, what its implications for spatial policies are, especially in areas most exposed to current threats.

Several definitions of the term can be referred with their roots being in the environmental and ecosystem approach (Davies 2011), as resilience is linked to sustainable development (Ahern 2011). According to Walker and Salt (2006, cited in Ahern 2011) it is defined as "the capacity of system to respond to change or disturbance without changing its basic state". Dos Santos and Partidario (2011) describe resilient systems as being "more adaptable to change, ... more able to learn and … less vulnerable to disturbance and external shocks (e.g. natural phenomena, economic crises or political shifts)".

Of course, the concept of resilience should not be overestimated. Like other concepts of this type, it could arguably fall into the category of what Raco (2009) has called 'pseudo-concepts'. As with other notions related to territorial development (flexibility, sustainability, and globalization) it could be characterized as a 'fuzzy' concept according to Markousen (1999) and this could in part explain its success. Under specific circumstances the 'metaphor of resilience' could serve to shed light on regional changes and facilitate the

elaboration and implementation of various policies (Pentall et al 2010). It could lead to the rethinking of the core assumptions which have prevailed in the last decades and to the emergence of "alternative, less growth-oriented agendas" (Raco 2009).

In order to exploit this approach beyond merely environmental concerns, of particular importance is to identify the whole system of reference (e.g. a city), the type and source of hazards (e.g. economic crisis-related problems), the characteristics of the risk, and of course the "damage potential and coping capacity as the two main sides of regional vulnerability" (Schmidt-Thomé 2006). The very operation of resilience is crucial, as it can have different characteristics, with different focuses. Martin (2012, 5) identifies the following interpretations/types of resilience with different focus for each:

> " 'Engineering' resilience: Ability of a system to return to, or resume, its assumed stable equilibrium state or configuration following a shock or disturbance. Focus is on resistance to shocks and stability near equilibrium.
> 'Ecological' resilience: The scale of shock or disturbance a system can absorb before it is de-stabilized and moved to another stable state or configuration. Focus is on 'far from equilibrium' behaviour of system.
> 'Adaptive' resilience: The ability of a system to undergo anticipatory or reactionary reorganization of form and/or function so as to minimize impact of a destabilizing shock. Focus is on adaptive capability of system".

According to Foster (2010), when it comes to policy issues, time and space, among others are of particular importance. Questions arise as to the different recovery times that correspond to different variables and to the time "we give a region to demonstrate resilience" (ibid.).

Finally, among the issues raised by the regional resilience concept the following question can be argued to be relevant to the fundamental work on Political Economy, 'the Wealth of Nations' by Adam Smith (1776/2000), in which the main question is: what are the key parameters behind the ability of some regions or countries to succeed and prosper while others are not able to withstand external shocks and return to their previous state. From this point of view, there are no easy or timeless answers to questions about resilience, as the parameters of time and space are of decisive importance (Foutakis 2012).

In addition, among other problems inherent in the use of the concept of resilience beyond merely environmental issues, it is important to note that resilience-related priorities as set in relation to environmental risks differ from those pertaining to economic development, above all the pursuit of spatial competitiveness. Combating climate change and a transition to an economy free of fossil fuels requires a shift towards greater self-sufficiency of regions (Green New Deal Group 2008). The need for a re-localization of many economic activities, such as energy production, along with the pursuit of securing self-sufficiency by means of exploitation of renewable energy sources at the local level seems to be

inconsistent with several aspects of contemporary policies that aim to strengthen regional competitiveness. For instance, there is on the one side the need to put emphasis on the production of local goods that pertains to environmental resilience, and on the other the effort to strengthen international flows that goes in tandem with the pursuit of regional competitiveness and consequently of the resilience of regional economy. There is thus a tension between the policy priorities arising from the two different options of the concept of regional resilience, namely environmental and socio-economic resilience. In this respect it can be argued that the territorial level of reference is appropriate for addressing questions raised in relation to the concept of resilience.

3. Resilience and spatial policies

In the last few years the situation in several regions and metropolitan areas has been characterized by dramatic changes. In addition to the impacts of environmental threats, since the outbreak of the economic crisis in 2008 a number of parallel crises have come to light or worsened adding new challenges for regions and metropolitan areas. Yet it seems that the pursuit of resilience has lately taken the place of the pursuit of sustainable development and spatial competitiveness, which prevailed during the 1990s and 2000s respectively. Thus the question arises as to what resilience means if transferred to spatial policies. As with sustainable development, planning for resilience seems to be dependent not only on the content but also on the process of planning. In their elaboration of a particular planning model aimed at ensuring resilience, Dos Santos and Partidario (2011, 1529) argue that "Planning for resilience … is neither about creating new formal plans nor about introducing new orientations, but it is instead about how to raise awareness in relation to a more open-mind-to-change perspective, which is critical to deal under uncertain realities, even in more traditional planning contexts".

From this point of view, resilience-related planning principles are very close to those of established new strategic spatial planning practices (Albrechts 2011) in a twofold way: first their focus is on planning procedure, given that "resilience is a more strategic than normative concept" (Ahern 2011, 342) and, second, they are thematically structured instead of following an analytical sectoral approach. A third argument could be that as the new strategic spatial planning builds much on the upgrading and exploitation of territorial governance, it can enhance the institutional capacity of territorial systems, which means building territorial resilience. As already mentioned, coping capacity is of institutional nature, in the sense that it represents the degree of readiness of local institutions among which participation in the planning process is important. Some of its benefits are described as follows: "stronger commitment to jointly agreed planning measures, the horizontal and vertical integration of a community (building social capital and concrete response networks), and better public awareness of hazards" (Burby et al 2000, cited in GTK 2003, 96). Irrespective of any criticism of strategic spatial planning, the 'resilience metaphor' can provide it with updated planning concepts (Pendall et al 2010).

The above shifts are heavily dependent on the specificities of each individual country and region. In the metropolitan areas of the US, for instance, a new type of degradation of the built environment - and consequently the everyday life of citizens - has emerged, culminating in the 'foreclosure' phenomenon (Swanstrom et al 2009). As a response, specialized planning agendas have been set up, with the objective to promote regions' resilience capacity and to "build and sustain strong metro regions" (ibid).
