- As is common place in impact assessment, the application of the main methodological aspects of the approach is preceded by a screening stage. The aim of the screening mechanism is to narrow the application of the assessment instrument to only those policies where it could usefully contribute to the decision making process and thereby promote resource efficiency.

- Screening decisions should be based on the case-by-case judgement of a designated body with expertise related to the policy area under consideration and also to territorial matters in the member state. In most member states screening will therefore be led by the government department responsible for preparing the national position on the particular policy proposal, or for transposing the policy nationally, working collaboratively with other departments. In particular this will include the department responsible for spatial planning which should also seek to ensure consistency in the application of the approach across policy areas.

- In line with the study's conceptualisation outlined earlier, the application of TIA is likely to be particularly desirable in cases where a policy is perceived likely to have unintended or undesirable impacts on the territory that could be significant in terms of contradicting national and/or sub-national objectives or polices. Whilst screening is a flexible process and depending on the policy proposal may not always necessitate the application of specific techniques, the causal/logical chain approach and checklist approaches can be used optionally, in isolation or in concert, to facilitate decision making in this area. Employing these methods requires that important territorial dimensions are firstly established that relate closely to national, and possibly sub-national, policies or objectives to allow impacts to be evaluated. These constitute the criteria that form the basis of the checklist approach and can be used to focus the logical chain exercise.

2. Scoping

- Policies that receive a positive screening determination need to undergo scoping. This stage endeavours to further elaborate on the impacts that may have already been partly identified in the screening process and to lay the foundation for the subsequent assessment stage. Scoping

will necessitate the same degree of interdisciplinary expertise as required in the screening process and in the interests of efficiency it will often be appropriate for the same body to have both screening and scoping responsibilities.

- The scoping approach is structured around a mandatory checklist (Fischer & Phylip-Jones, 2008). Essentially, this is an extension of that used on an optional basis in the screening stage and is developed in the same way requiring the prior definition of territorial dimensions reflecting national and possibly sub-national policies or objectives which form the criteria in the checklist. Differing from the screening checklist, however, impacts are considered in more depth. The impact of policies can, for instance, be considered in relation to their individual constituent parts, or policy elements, and the types or features of areas where potential impacts could emerge geographically are considered.

- The completed checklist serves to inform the development of an Impact Assessment Matrix (IAM). This is formed from the assessment criteria and policy elements identified in the checklist and functions as the template on which the assessment is based, specifying for each of these interactions the dimensions of the impacts that should be considered. These dimensions, or characteristics, should be appropriate to enable the impacts to be sufficiently evaluated. Three characteristics are put forward below. These can however be supplemented with other dimensions if necessary (e.g. impact probability), or reduced as considered appropriate.

    - Magnitude: referring to the size or scale of the impact.
    - Orientation: this refers to an impacts direction of action, i.e. whether it will result in an increase or decrease in terms of a given criterion, e.g. ‘employment’.
    - Temporal distribution: this refers to the impacts duration, e.g. whether it is short, medium or long term.

- In the scoping stage the geographical extent of the assessment exercise can also be determined. Whilst it is preferable for the assessment to cover the entire territory in order to develop a comprehensive picture of the potential impacts, this will not always be feasible. The assessment exercise is conducted at the sub-national level and in some member states this may be hostile towards a comprehensive approach. In England, for instance, recent changes to the planning system mean that the TIA would most readily be conducted at the local administrative level. This geography encompasses over 300 units, the engagement of which would be impractical in a fit-for-purpose TIA approach. In these cases scoping can additionally incorporate the identification of specific case study localities that can serve to be indicative of wider potential impacts.

3. Assessment / Analysis

- The aim of the assessment/analysis stage is to identify potential change in a territory, or territorial unit, as a result of a policy. This stage is foreseen as a sub-national level activity and can be conducted at either the regional or local administrative levels.

- This exercise is structured around the IAM developed in the scoping process which specifies the impacts and the characteristics that should be considered in the locality. The completion

of the IAM should be undertaken in a participatory interdisciplinary setting based on the judgement of stakeholders familiar with the area concerned, drawing on available information and evidence whenever possible. Whilst top-down approaches to TIA have typically conducted the assessment based on NUTS regions, this approach necessitates the use of functional/administrative geography in order to engage agencies or bodies with existing operational familiarity with the sub-national territorial units in the member state. This in particular will include planning departments.

4. Evaluation

- The evaluation stage concludes the TIA process. This stage is concerned with synthesising the outputs of the sub-national assessments (e.g. mapping) and evaluating the significance of the likely policy impacts. Significance, as used here, is understood as being dependant on both the nature of the likely impacts and the context in which they occur. That is, whilst impact characteristics such as magnitude, probability, spatial distribution, and duration, etc, can be used to describe potential impacts, they alone do not determine whether they are significant (George 2010). The significance of the policy impacts is determined by looking at their characteristics in light of defined policy objectives (Fischer 2007).

- The evaluation exercise is conducted by employing an Evaluation Table. Here the collective impacts identified in the sub-national assessment exercise are interpreted in terms of their compliance with the policies or objectives on which the criteria used in the assessment stage were based. The evaluation is undertaken using a 5 point scale (-2, -1, 0, +1, +2), which indicates whether the anticipated policy impacts are considered to be positive or negative for a given objective and also their degree of significance in this regard (neutral to high). Whilst this is ultimately a judgement based exercise, the use of the Evaluation Table allows for a high degree of transparency with written justification required for each determination.

- In principle, the evaluation of a policy's potential impacts can be conducted at both national and sub-national levels. Whilst it should be seen as a mandatory requirement at the national level and will normally be led by the government body responsible for developing the member state's negotiating position, or transposition strategy, in collaboration with other departments. It can also be conducted at sub-national levels by the agencies engaged in the assessment stage, allowing for the evaluation of impacts against sub-national policies or objectives.

Conclusion

The TIA methodology has been developed in conjunction with stakeholders in the UK, Slovenia and Portugal and has been tested in each of these countries. Testing has shown that those with existing experience in impact assessment are likely to find the TIA methodology approach simple and straightforward to apply. Whilst inexperienced individuals will require more time to familiarise themselves with the approach, testing has also shown that once a person starts with the assessment, they usually find themselves handling the TIA methodology in an effective manner quickly.

Fundamental to the approach is expert judgement and, as part of this, collaborative working between government agencies across multiple sectors. Accordingly, one of the main barriers to the implementation of the approach is likely to include the resistance of different departments / administrations to co-operate in the manner envisaged. At the sub-national level, regional / local authorities may also be sceptical about the possibility to be able to influence the policy making process at the European and national levels, and may consequently be unwilling to invest even minimal resources in TIA. Getting around these potential issues will require that the approach is actively promoted and championed across government.

Whilst the TIA methodology has been shown to be a promising approach, further testing is still required. This includes applying it within the real time policy development process, to date testing has been confined to mock ex ante exercises, and also in other EU member states. How to deal with trans-boundary issues in the assessment process also needs further discussion.

Toward Integrated Flood Management in Kampala, Uganda

Dr. Richard Sliuzas[1]

Abstract

Many cities are taking initiatives to increase their resilience in the face of climate change. Despite considerable uncertainty about the nature, speed, and location of specific climate change variables municipalities need to be thinking about possible scenarios and developing strategies to mitigate climate change effects. In relatively poor cities, such as the Ugandan capital, Kampala, these are not trivial issues, as many resource constraints exist. The approach that is being developed for a new UN-HABITAT project on integrated flood management in Kampala under the Cities and Climate Change Initiative is described in this paper. Flooding is a major problem in Kampala that already has substantial effects on all aspects of urban life, and greatly affects the quality of life of the city's urban poor who are particularly vulnerable to flooding and related problems. A two pronged approach is adopted that deals with the vulnerability issues of specific communities as well as city wide flood risk assessment. The two levels of analysis provide insights that can be used for strategic planning and the identification of strategic interventions to enhance Kampala's resilience to flooding.

1. Introduction

Urban flooding may be fluvial (caused by rivers bursting their banks), coastal (due to tidal waves and storm surges), pluvial (due to overland flows caused by runoff rates that exceed the capacity of natural and artificial drainage systems), ground water floods, and artificial system failures. The causes of flooding are usually a complex combination of natural, technical and human factors but are often the result of an inability to satisfactorily deal with the concentration, transportation and discharge of surface water runoff (Jha et al., 2012). As severe or frequent flooding may have high and long lasting impacts and costs the adoption of good practices for sound surface water management to minimize flood risk is a critical component of urban sustainability. Moreover, it is becoming more important in those cities where climate change is associated with increasing amounts of rainfall and or increasing rainfall intensity.

[1] Faculty of Geoinformation Science and Earth Observation (ITC), University of Twente, Enschede, The Netherlands - sliuzas@itc.nl, r.sliuzas@utwente.nl

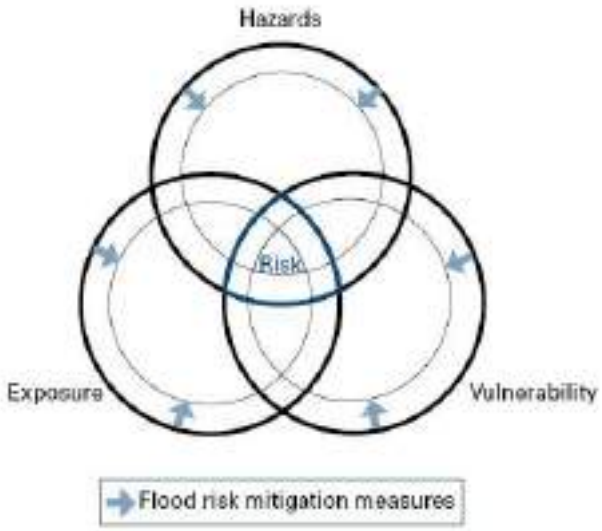
This paper examines on-going work to identify strategies to contend with flash flooding in Kampala, Uganda. Flash flooding, a form of pluvial flooding, is a widespread phenomenon in cities where extensive and intensive rainfall events that exceed the drainage capacity commonly occur. Severe storms that are occur in tropical cities are therefore likely to be problematic, especially in cities such as Kampala with relatively few technical, financial and human resources and a high degree of poverty and informal development.

Traditionally surface water management was seen primarily as an engineering problem. The classic response to flooding by civil engineers (and physical planners) was therefore to increase the capacity of artificial drainage systems to remove the surplus water as quickly as possible from the city and the affected neighbourhoods. Such approaches have though become the focus of increasingly critical discussion for several reasons. Engineering solutions are expensive to build, operate and maintain and are not easily adapted to higher rainfall regimes expected under climate change; the rapid discharge of massive amounts of water can create flooding problems downstream; ground water levels in urban areas may be depleted over time due to reduced infiltration as a result of increasing imperviousness, in combined storm water/sewer systems untreated sewerage may be discharged into natural streams causing pollution.

2. Integrated flood management

The integrated flood management (IFM) approach takes a more holistic view of flood management than the traditional engineering perspective. IFM is distinguished by its shifting of the focus from a reactive to a proactive response to flooding i.e. from flood control to flood management (APFM, 2006). In doing so it aims to develop an integrated package of instruments that target one of the three main components in any disaster event: the hazard itself, the degree of exposure or the degree of vulnerability (see figure 1). The management and hopefully reduction of flood risk therefore becomes a concern for all societal actors and not just the city engineers, though their expertise is certainly an essential element that should not be disregarded. Experience has shown that actors from all segments of society play various roles throughout the entire disaster management cycle with its three main phases: response, recovery and preparedness (Figure 2). Central to the approach is the distinction between structural and non-structural measures for flood management. Structural measures alter the physical characteristics of the flood phenomenon through water storage, upstream catchment management, channel modifications, levees and the operation of various hydraulic works and are typically the domain of engineers and physical planners who base their activities on the concept of Sustainable Urban Drainage Systems (De Bruin, 2006, Ellis et al., 2002) . Non-structural measures on the other hand are more directed at reducing exposure and vulnerability. For example by improved land use planning and development control in flood plains, better flood forecasting and early warning systems, stimulating flood

proofing measures by affected populations and businesses and offering other forms



of socio-economic assistance.

Figure 1: Construct of flood risk management and its reduction ((APFM, 2006)

Figure 2: Risk Management Cycle (APFM, 2008)

Spatial scale is a key issue in the IFM approach. Even if the main focus is a specific city's flooding problems (Figure 3), the nature of flood management is such that information will almost certainly be required for a much larger region covering an entire water basin. In some cases the water basin may require international cooperation, but almost certainly multiple administrative jurisdictions will be involved. Complex institutional settings may therefore complicate both the analysis of the problem as well as the search for affordable solutions.

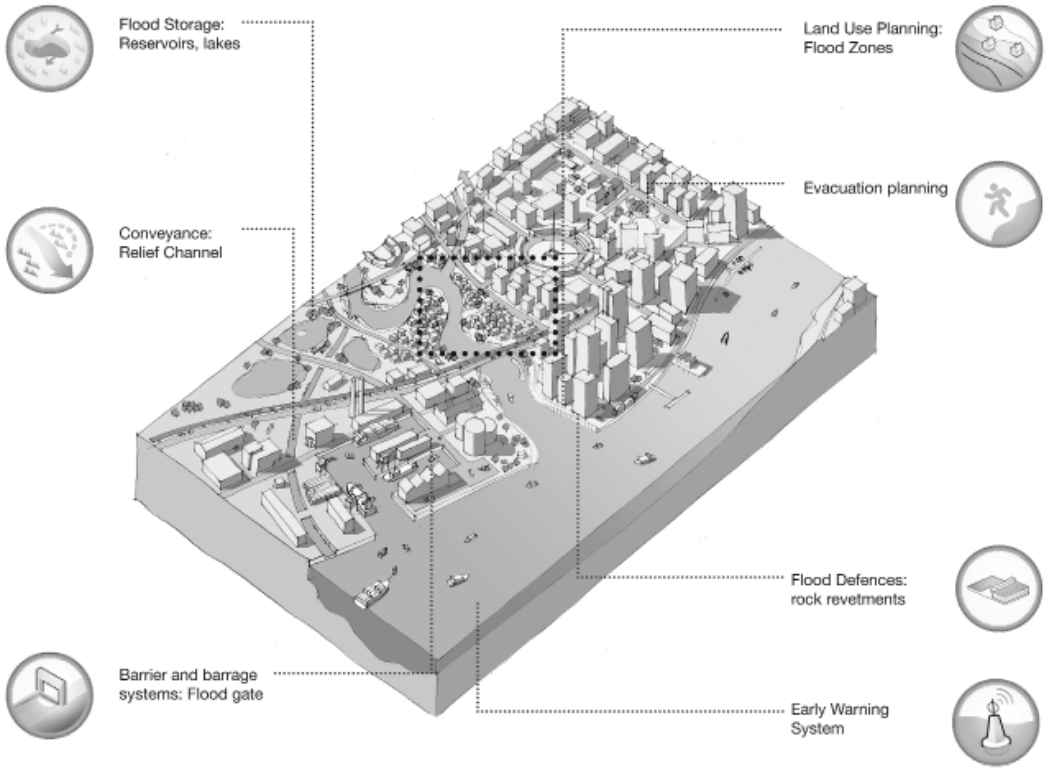


Figure 3: Overview of flood risk management measures at city scale (Jha et al., 2012)

3. Integrated flood management in Kampala

This section describes the specific setting in Kampala and explores some of the specific characteristics, the current status of the work there and some initial ideas for how an IFM approach might be implemented there.

3.1 Kampala and its flooding issues

The city of Kampala, Uganda's Capital, has been chosen as a pilot city for developing and demonstrating the use of IFM tools under UN-HABITAT's Cities and Climate Change Initiative. The city is located on the shores of Lake Victoria on terrain which is characterised by a series of hills that are separated by wetlands, some of which drain directly into Lake Victoria. Most of the original development of the city was concentrated on these hills which were interconnected through roads and

rail links crossing the wetlands at strategic places. The wetlands were also the natural urban drainage system. As urban development has proceeded the limits of natural drainage capacity have been exceeded and flooding problems have become more frequent and more severe. Currently the city faces regular flash flooding events in several locations around the city. Important contributing factors to flash floods are: significant increases in impervious surfaces leading to increased run-off rates, the lack of sufficient drainage systems (many primary drains located in the wetland areas are insufficiently maintained and under-dimensioned and secondary and tertiary drains are next to non-existent), an increasing amount of development has been allowed to take place in former wetland areas (this includes both planned and unplanned development as well as the recent construction of a major urban ring road and a new sewerage treatment works), the nature of the tropical climate with intense rainfall events which are expected to become more frequent and sever under the effect of climate change.

There are no major rivers passing through the city but flash floods occur regularly. These events are usually not of particularly long duration but they do cause significant disruption of social and economic life in the city, loss or damage to property and stock and in some cases life (Figure 4). Indirect effects include disruption of school attendance and health impacts related to the spread of feacal and other waste in flood affected neighbourhoods that rely on pit latrines for sanitation.

Figure 4: Flash floods in Kampala (source unkown).

3.2 Project approach

The project aims to develop strategies for introducing an IFM approach in Kampala at two spatial scales. The highest scale encompasses the entire administrative areas of the city supplemented by a detailed case study for one of the city's neighbourhoods known to have significant flooding problems. The whole process includes 4 main tasks (inception, data collection, flood modelling and analysis and strategy development) and will take about 15 months. The consultant team consists of a combination of Dutch and German experts with backgrounds in urban planning and hydraulic engineering and two local experts in spatial planning and climate change issues and flood modelling. During the kick-off mission the importance of

establishing a steering committee to ensure ownership and commitment from local bodies was realised. This committee includes senior staff from KCCA's planning and engineering departments, a local UN-HABITAT representative, a senior staff member of the Department of Disaster Preparedness, Relief and Management, Prime Minister's Office, a representative from the National Slum Dwellers Federation (NSDF) who provides a direct channel to the local low income communities in Kampala. Further, we have a representative from the Buganda Land Commission which is important because land rights over much of the wet lands in Kampala are held by the King of Buganda under the *mailo* tenure system, and although much of these lands are flood prone they have been allocated and settled for various uses. It is therefore evident that any actions to address current flooding problems and to prevent future development in flash flood prone areas must involve the Buganda King.

3.3 Current status of work

The team's initial focus has been on identifying the nature and extent of flooding problems, establishing institutional linkages and a project steering committee, identifying and obtaining access to useful spatial and other data for the two study areas, and undertaking some initial analyses on the basis of available data to test some assumptions about flood risk and possible IFM strategies.

Although the IFM envisages a multi-stakeholder approach in which technical expertise and analyses are combined with local perspectives and more qualitative analyses, flood modelling methods are required to provide a solid basis for dialogue throughout the project. High quality spatial data and non-spatial data is therefore required. Through the KCCA offices and other local actors it has been possible to quite quickly assemble a rich set of data for flood modelling and risk assessment. Particularly important sources of data are the Kampala Drainage Master Plan (KDMP) of 2002 and the work of the on-going Greater Kampala Physical Development Plan (KPDP) project. Initial euphoria has however been somewhat tempered by the realization that much of the available data is not available in GIS formats or has not been properly geo-referenced or is otherwise poorly documented. Although such deficiencies can usually be rectified they reflect a lack of concern for information management strategies within KCCA and other organizations, an issue which has been identified as a key success factor for GIS adoption by local government (Campbell and Masser, 1995, Masser and Sliuzas, 1999). Despite this concern, almost all agencies contacted thus far have demonstrated a readiness to share their data with the team and this is a very encouraging signal that data ownership is unlikely to become a barrier to progress.

The project will use a combination of quantitative and qualitative methods for data analysis. Rainfall run-off and flood modelling are data intensive activities that require a variety of inputs: the intensity and duration of typical rainfall events; current land cover and the built environment; terrain elevation; natural and artificial

drainage channels, etc. Much of the existing data will be updated using very high resolution colour orthophotos of the city and fieldwork. This work will be conducted together with students of Makerere University as part of an internship required in their study. In this way survey costs can be managed and combined with capacity development activities. A serious concern is the lack of high quality meteorological data for Kampala. Official meteorological data is outdated or only sporadically available. To compensate for this we have installed one low cost digital weather station at Makerere University and have started a programme of daily/nightly rainfall measurement with locally assembled rain gauges via local primary schools in flood affected areas. As many schools are in flood prone areas they are willing to assist our efforts and at the same time the collected data can be used by the schools for their own environmental education activities. The latest reading received showed that 3.8 cm of rainfall within 1.5 hours resulting in flood depth of 50 cm with waters remaining on the school for about 12 hours. The situation in nearby, more low lying areas was almost certainly significantly worse.

Stakeholder participation is a critical factor for the success of the project and any ensuing strategies. In the IFM approach stakeholders are more than victims of floods. Their behaviour is likely to be a significant factor in the level of exposure. Improper solid waste disposal for example is known to be a contributing factor in blocking drainage systems and therefore increases flood risk. Stakeholders also possess local knowledge about flood events, flood coping strategies and possible adaptation measures which could be replicated and disseminated throughout the city. Through workshops, focus groups and training activities the project will seek to engage affected communities and stakeholders in problem analysis, strategy development and implementation. Achieving and maintaining a high level of engagement will not be easy as the bonds between KCCA, Government agencies and low income communities are often fragile and easily broken. The NSDF is aligned with the International NGO Shack/Slum Dwellers International (www.sdinet.org) which promotes inclusive cities and high levels of emancipation and self-determination for low income communities. It is not yet clear to what extent the ambitions of NSDF will match with the ideas of KCCA and other project partners, but governance aspects will almost certainly be crucial to success.

Legal frameworks are another aspect of IFM activities to be addressed. Spatial planning law and development regulations for example set standard and conditions for development control and guidance. Typically such regulations adopt a one-size fits all normative approach to set backs form drainage channels for example. Restricting development within 30 or 60 metres of rivers and streams is certainly inappropriate and a gross simplification of reality. Determination of the extent of flood prone areas require a tailor made hazard assessment for each water basin, but will almost certainly generate resistance from those land owners who’s development rights and property values may be affected. Building and planning regulations too will be examined to identify opportunities for increasing rain water harvesting and infiltration options which will help to reduce the amount and speed of run-off, for example.

4. Future prospects

Although this project is in its initial stages the contours of the challenges to be addressed and some of the possible strategies are already beginning to emerge. The search for the *right mix* of options for the specific situation in Kampala will require a clear and open project governance approach. A range of IFM strategies have been identified and applied elsewhere (Schultz, 2006, Van Alphen and Lodder, 2006, van Duivendijk, 2006) and these and others can be valuable resources in the search of for approaches that are well suited to the Kampala case. Project governance will need to consider, manage and reconcile the interests of many stakeholders in the process. Given the limited technical and financial resources of KCCA and other partners, for example as indicated by the long lead time for the implementation for the KDMP, cost in terms of time and money will almost certainly be key elements of the strategy development and selection process.

Moving the existing city towards sustainability: the role of urban planning

Author: **Rosalba D'Onofrio**
Institutional Affiliation: SAD (Scuola di Architettura e Design "E. Vittoria") - Unicam, V.le della Rimembranza, 63100 Ascoli Piceno, Italy. rosalba.donofrio@unicam.it.

Abstract

It is not easy to imagine how the existing city to can be converted to the principles of sustainability, however, the need for innovation, which you can find in European acts on the planning and regeneration of the existing city, requires a pioneering phase which must necessarily address the main problems of rehabilitation of the operating models of the city, knowing that the current condition shows the almost complete unsustainability of actual current situation of urban models. In the awareness that the efforts made to improve the performance of the existing city will move the cities towards sustainability, but not to sustainable cities, the role of urban planning in this process will be to translate the stress of adjustment towards sustainability into strategies, rules and projects that combine different disciplinary contributions. In ordinary practice, urban planning has reduced the complexity of urban systems, because they are considered stable, under the illusion that the changes are predictable and controllable. Sustainability, is considered not as a dynamic course, but as a final stable state. In many cases, moreover, the search for possible solutions to fight the effects of climate change has been delegated by urban planning to other disciplines, obtaining sectoral responses with very limited effectiveness. Today, however, there is a growing awareness that the identification and implementation of policies and measures to promote the adaptation, resilience and reversibility of the existing city, require the contribution of our discipline. This breakthrough, which is primarily a cultural matrix, is present in some recent international experiences of "Climate Plans", in which the envisaged measures are closely interwoven with those of urban planning. As a result of these early experiences, urban planners are called upon to move their attention to scenarios concerning the evolution of urban ecosystems as a whole. These early experiences, provide some answers principle questions, such as: how the strategies to combat climate can be integrated in the instruments of the local government; what new and specific analysis must be introduced in urban planning in order to understand the issues of urban sustainability's and how analytical and project reasonings combine at different spatial scales. These strategies, together, will lead to an urban plan that has been developed in stages, representing a dynamic process, open to continuous audits and amendments. It will provide a verification process of sustainability and a validation process of the practices proposed by various stakeholders, wherein one learns as one goes.

1. Introduction

As of 2008, more than half the world's population now lives in cities and starting in 2025, our planet will house more than 5 billion people in urban contexts. According to the United Nations, almost 80% of energy consumption occurs in cities; in addition to energy, cities need a concentration of food, water and materials that nature cannot provide at current growth rates. The moment has come to start thinking about how to avoid leading tomorrow's city into collapse by activating a lifesaving procedure. We have probably arrived at a point at which even urban planning should start to take account of climate changes, above all when the search for better urban efficiency requires cities themselves to actively contribute to a possible response to local and global impacts. However, one should not fall into the error of refining the concept of sustainability with reference only to energetic terms and thereby err in evaluating the complexity of questions in the field with the risk of compromising development choices and the city's future itself.

For some years now, the theme of sustainability in urban development has actively entered the urban planning debate; but if even societies that seem, at least apparently, more prepared and more experienced in the pursuit of this objective are repeatedly thrown into crisis by devastating and unexpected environmental and climactic variations, it is necessary to ask what has worked only partially or not at all. In fact, in ordinary practice, the urban planning discipline has managed to reduce the complexity of urban systems, considering them substantially stable and deceiving itself that the transformations were preventable and controllable; it has thought about sustainability not as a process and constantly evolving course, but as a stable final state. The temptation has sometimes prevailed to limit intervention to a small scale, for circumscribed environments, for timely projects, for single architectures, imagining the reconstruction of the urban mosaic possible when starting from single pieces. Lastly, in many cases the urban planning discipline has delegated to other disciplines the search for possible solutions to contrast the effects of climate changes, favouring responses of a sectoral approach and with rather limited efficiency.

A series of experiments has descended from this cultural structure, of which only a few cases have produced mature results and concrete applications for improving the environmental and social quality of our cities. In fact, the experiments have often concentrated above all on technological innovations directed toward building sustainability and saving energy, omitting broader and more complex reflections on the contemporary settlement model and the lifestyle of the inhabitants.

The modest success of politics experienced up to now (primarily compared to the existing city), the global economic crisis and above all the energy crisis and environmental catastrophes, necessitate a radical rethinking today on the contents and means with which to trigger real environmental, social and economic

sustainability processes in cities. The same uncertain success of international politics, emerging after the failure of the recent climate conference in Durban, obliges those dealing with city projects to examine new principles of responsibility implicit in a broader view that is expanded to look for new configurations and the modification of current operational models. In the awareness and hope that cities can and should become places in which to experiment with new, more sustainable forms of living and working, new social relations, smarter ways of using one's time and a better quality of life – not necessarily associated to the growth of material consumption – and in the awareness that the effort necessary to improve urban performance will lead to obtaining cities transitioning to sustainability rather than sustainable cities, a reflection is required on the role of territorial and urban planning in managing this process and on its capacity to translate the anxiety of adaptation to sustainability into strategies, rules, and projects able to create synthesis between different disciplinary contributions.

Among the strategies to counter climatic changes, research on existing urban areas and politics defined on the local scale assume a greatly relevant role today; it is above all with reference to the existing city that a fertile exchange of different responses to sustainability objectives that cities have put at the centre of their agendas for some years is made necessary, serving as a compass to orient strategic choices for development and to achieve a rethinking of urban spaces within an ecological perspective. Starting from this heritage of experience, it is possible to identify some significant questions regarding urban planning, with particular attention to themes that seem to shift the terms of the debate and disciplinary research, opening up new occasions for learning and intervention.

2. Reflections for a work agenda

2.1 The need for a transdisciplinary approach and the integration between adaptive and mitigation measurements

If sustainable urban development is, as numerous studies and international reports suggest, primarily a process that is enriched by collective learning, the capacity for conflict resolution and the capacity for strategic design, it is also the result of synergistic integration and co-evolution between the large subsystems comprising the city (the economic, social and physical-environmental systems). To obtain the substantial evolutionary equilibrium of these subsystems, it is necessary to promote integrated intervention politics that confront the theme of urban sustainability with a transdisciplinary approach directed toward three principal goals: technology (primarily energy and transport), the environment and urban form, and the *habitus* (characteristics of the individual behaviours) (Camagni R, 1996). Urban planning will not be able to confront these principal paradigms of urban sustainability by making use of traditional analysis and evaluation instruments, but will have to resort to an overall dynamic analysis of the urban system, with contributions from multiple integrated disciplines, including thermodynamics, ecology, statistical mechanics, technological

sciences, economy, sociology and architectural composition, making use of innovative interpretive methods such as: the analysis of environmental cycles and networks in relation to the infrastructure, energy and settlement networks in the city; the analysis of urban growth limits in relation to carrying capacity criteria applied to the urban environment; the analysis of environmental comfort in relation to the quality of life in cities, etc. Through these new interpretive methods, the urban planning discipline is asked to promote politics and action that not only allow urban organisms to mitigate catastrophic effects, but also adapt themselves to climate changes, constructing new social, economic, and environmental responses to allow the city to withstand the urging of both the environment and history in the long term. The promotion of this equilibrium is among the new tasks of urban discipline, which is therefore called to act in an overriding way on the organizational and management models of the city. Up to now, the theme of mitigation has always been predominant; the reduction in emissions in the atmosphere has been, justly, much discussed, but there has been little about adaptation, or rather how urban organisms can absorb and counter the effects of climate change, above all with reference to existing cities. On other fronts, however, the joint application of politics for adaptation and mitigation is called for, along with the definition of a worthy strategic approach that is able to hold together different levels of management, from both the intervention and acting sectors, with the goal as well of resolving the inevitable conflicts between complementary but different measures. If, with respect to measures for climatic impact mitigation, an abundance of experience in the whole European territory is recorded, expressed through precise targets for the reduction of CO_2 emissions with respect to 1990 (the Kyoto Protocol reference year) – from Amsterdam, which foresees a reduction of 40% by 2025, to Berlin (-40% by 2020), to Barcelona (-50% by 2030) – the concrete experience relative to the operational and organic application of adaptation measures is instead still rather limited. Also, in the "SEAP"[1], the idea of adaptation is commonly only cited, whether in the scientific community or in official documents; but more importantly, programs and projects financed by the EU[2] demonstrate a growing interest in adaptation practices and the role that urban planning can play in their definition. Going further, the conviction that climate changes should be confronted in an integrated way and on different scales is spreading. This new approach has been pursued by the AMICA (Adaptation and Mitigation, an Integrated Climate Policy Approach) project, financed by the European Union within the Interreg IIIC Program. In the explanation of the program, the drafters maintain that "… choosing between mitigation and adaptation is analogous to the choice between

[1] The Sustainable Energy Action Plan (SEAP), promoted by the European Commission Campaign SEE (Sustainable Energy for Europe) within the "Covenant of Mayors" (D.C.C. 48/2009) is the document that communities undersigning the pact are obliged to create for reaching objectives in the reduction of carbon dioxide emission established for 2020.

[2] For example, the GRaBS (Green and Blue Space Adaptation for Urban Areas and Eco Towns) project is a network of leading pan-European organisations involved in integrating climate change adaptation into regional planning and development. The principal aim of the project is to stimulate and develop the adoption of AAP's (Adaptation Action Plans) through the application of good practices and guidelines.

repairing faulty brakes on a bicycle and buying a helmet. Functioning brakes help to prevent accidents (mitigation), while the helmet is designed to avoid disasters if an accident should occur (adaptation)."

AMICA proposes a new approach to territorial environmental politics that integrates long-term protection of the climate (a measure of mitigation) with short- and medium-term adaptation measures, improving the coherence of local development strategies and the allocation of financial resources, and promoting the projection, planning and operational capacities of local administration to confront threats of climate change and seize opportunities. From this double response method with long- and short-term measures, a different relationship with analysis and project scales also follows. If, in fact, politics and mitigation measures are similar in large part, adaptation measures should necessarily be oriented to the specific vulnerability of the territory. With such a goal, the program is aimed at motivating local governments to include climate protection and adaptation in their ordinary planning activities, favouring those synergies that are created when mitigation and adaptation measures are complementary and not alternative between themselves. For example, some interventions in land management, such as the planting of trees, act both as adaptation interventions to avoid soil erosion, and as mitigation interventions (forestation). Another meaningful example in such a direction is given by water conservation (adaptation intervention), which also translates into energy savings (mitigation intervention). Understanding possible synergies between adaptation and mitigation measures can soften conflicts and, in such circumstances, good planning can become very useful. For example, if it is true that a higher living density is a means to improve the overall energy efficiency of an urban area, it is also true that responding to climate change with adaption requires space in and around buildings. In this case, good urban planning can lead to a reduction in greenhouse gases and contribute to adaptation, offering the parallel opportunities of lowering carbon dioxide emissions and the recourse to an average density of settlements, their differentiated use and green areas.

The experience of the city of Lyon is of particular interest in such a scenario. Since 2005, the Urban Community of "Grand Lyon" began preparing a Climate Plan scaled to its territory (55 towns and 1,300,000 inhabitants). Three original aspects are immediately evident:

- the commitment of the urban community to the AMICA European Program;
- the search for adaptive solutions and innovative practices, above all in matters of managing green areas in the city;
- the commitment to synthesizing all of the objectives of climate effect reduction contained in long-term planning documents (PDU, PLU, SCoT).

The originality of the experience of Lyon lies mainly in the importance given to adaptation and the willingness to promote public action in climate matters that are not limited to emission reduction measures. In fact, a study was promoted that aimed to measure the vulnerability of the urban area in its entirety with respect to three types of risk: water resources, heat islands and flooding. This study showed that heat peaks caused the greatest vulnerability in the territory. With this in mind, the "Charte de l'Arbre"(Fig.1), created by the "Arbres et

paysages" service in 1994, on the occasion of its revision in 2005 decided to consider climatic warming on nature in the city through a deepening of knowledge related to the impact of vegetation on the urban climate. The case of Lyon, in addition, testifies to the variability of the reference scale in the definition of adaptation measures; if management on short timescales is undoubtedly favoured in the "Plan Canicule", the need to draw on long timescales passing through extensive urban policies is highlighted, where for example, the redefinition of the urban form occurs with the support of vegetation.

Figure 1. Lyon. Charte de l'Arbre

In addition, city governments can take a range of planning decisions related to urban development to reduce greenhouse gas emissions. They can be proactive in regulatory and educational measures and apply mandatory density and energy efficiency criteria. Cities can make a substantial long-term contribution to the prevention of motor traffic if they consider this aspect early in the planning process. Urban development planning is a key factor in the demand for mobility: whether it is a compact city where the various functions – residential and commercial, services, education and recreation – are located and how they interconnect, or whether public transport is available for newly developed areas, etc. For example, the State of California is currently a pioneer in what could be the next step against global warming: filing lawsuits to hold cities accountable for greenhouse gas emissions caused by poorly planned suburban sprawl.
There is, in reality, a lot of significant European experience in such a direction. One of these is in the PTCP[3] of 2009 for the Province of Modena, Italy. In this

[3] The "Piano Territoriale di Coordinamento Provinciale" (PTCP) is the provincial planning instrument in Italian urban legislation aimed at governing territorial resources through their protection and development. It is the planning act with which the province exercises its own role in territorial government, connecting and adapting

plan, the themes of sustainability were dealt with in a participatory course on the Agenda 21 model prior to drafting the PTCP. In particular, the participatory process has lead to sharing and to inserting the following adaptation measures into the definitive version of the plan:
- increasing the hydraulic security of the territory from flooding phenomena by reducing the vulnerability of residential and productive areas to the danger of flooding;
- stopping settlement expansion in relation to waterway flows increasing with climate changes and the impermeabilisation of the soil. With such an aim, the PTCP provides for an increase in urbanized area that does not exceed more than 3–5% of the territory urbanized as of 31 December 2006, requiring towns in the provincial territory to accomplish selected goals through the application of territorial adjustments;
- controlling atmospheric emissions of climate-altering gases by introducing rules for the energetic efficiency of buildings and the identification and regulation of provincial ecological networks.

2.2 Time variables and risk management

Thinking about urban planning within a global warming scenario leads to looking for responses to the impacts in solutions that are not only for civil protection and emergency, however indispensable these may be.
Within the plans, one should evaluate and consider how conditions for the security and liveability of different urban areas can change in time and, as a consequence, project any transformation hypothesis onto a scenario that considers risks and impacts linked to the climate, some already in place, others potential.
Two examples are interesting in such a sense: the climate plans of New York and Toronto, in which great importance has been given to the timely programming of operations to accomplish in relation to the hypothesised risks. Some action is identified as “short-term”, to be realised immediately and without passing through the planning instruments; others are defined as “long-term” because they are more complex and because only progressively can some necessary preparatory steps for their effective realisation be completed.
In the “Climate Change Adaption” of 2008, the city of Toronto foresees two types of action for adaption to climate change: short-term operations that make reference to existing programs regarding areas of the city in which vulnerability characteristics have already been noted, and long-term actions that will need systematic elaboration with the aim of identifying and evaluating vulnerability characteristics of determined urban areas and the consequent adaptation strategies (Fig.2). The short-term actions were immediately made operational and have dealt with already-financed interventions and adaptation measures recommended by the “Several City divisions and agencies”, which were able to improve existing programs and increase their resistance to climate changes. In

itself to territorial policies in the region, coordinating and directing urban planning at the community level and provincial sector planning.

contrast, the long-term actions enter into a global adaptation strategy that deals with urban infrastructure and planning, and which, in the identification of risk and the measurement of adaptation, should make use of knowledge to be implemented within a time frame that is established but susceptible to modification. Nine successive steps have thus been identified, programmed in general terms, but to be elaborated in detail with time; among them, the third step forcefully highlights the fact that "… Climate change will affect nearly all aspects of Toronto's life. As a result, it is important to incorporate climate considerations into the planning of most City operations and services. A description of the challenges posed by climate change for the city, and goals for both mitigation and adaptation should be incorporated into relevant plans, strategies and programs".

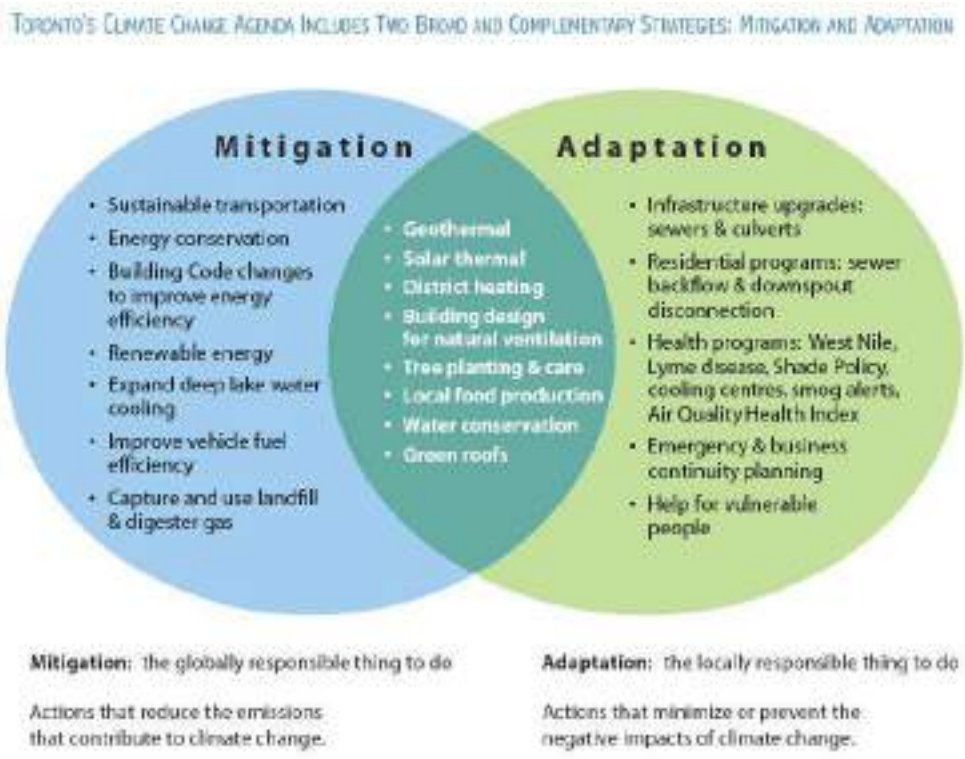

Figure 2. Green spaces as means to both mitigate and adapt to climate change

In addition, the document reports a list of the city's policies and plans that should include climate change considerations and explicit goals for adaptation.
Lastly, step eight establishes that once the city has identified and chosen overriding adaptation measures from among the different options, it should first incorporate them "…into major infrastructure projects that are expensive, long-lived and will have to operate under changing climate conditions".
The criteria that the city will use to identify the most-recommended adaptation measures may concern:
- the effectiveness of the adaptation action in providing protection for vulnerable populations;

- the extent to which the proposed adaptation options protect against loss of life or major economic losses;
- whether the adaptation option reduces stress on vulnerable systems;
- the cost of the adaptive action compared to the cost of alternative strategies, or to the potential cost of not acting;
- the extent to which adaptation options also reduce greenhouse gas emissions or provide other benefits that increase the sustainability and liveability of the City.

3. Diffusing a model of integrated urban planning that is multi-scale and flexible to accompany the transition toward sustainability

The tendencies emerging on a global level in recent decades have required cities to confront problems through a vision that integrates the three dimensions of sustainability – economic, social and environmental – and that is shared at the same time by the highest possible number of urban actors (citizens, administrators, interest carriers, etc.).
The need for an integrated approach is the unavoidable condition necessary to respond effectively to problems connected to the city's use and development and to ensure the joint confrontation of different but interconnected themes and problems: not only energy, transport and building, but also economic and competitive well-being, social inclusion and environmental management. These themes are normally managed in an isolated manner and by different public administrations. The integrated management model foresees interdisciplinary and sectoral cooperation capable of involving the different institutional levels – local, regional and national – and, transversely, the individual sectoral abilities involved in intervention politics. The instrument used to activate such a model is one that makes reference to a long-term planning strategy, which by putting into relation different politics and different administrative levels guarantees the coherence of development operations, improving their efficiency and eliminating the risk of contradiction. This model imposes a shift in the approach to defining politics and instruments aimed at assuring the sustainability of the transformations, calling for an approach to planning that renounces the prescriptive and deterministic vision of rationalist urban planning. The objective is to make the city able to respond to continually developing needs by forecasting flexible and adaptable scenarios, and anticipate knowledge where science still does not give reliable responses, above all regarding the possible environmental implications of land consumption, resource withdrawal, the rate of pollution, etc. In addition, sustainability dictates being ready to confront problems on different territorial scales, since problems extend from the planetary dimension, with climate variations correlated to the greenhouse effect or the effects of ozone reduction, to the continental dimension with the phenomenon of acid rain, down to the regional or local dimension with questions linked to urbanization. Identifying the most appropriate scale to deal with the different aspects of sustainability and the reading of environmental problems opens the door to personalized sustainable development solutions; this promotes the role of local administrations in the most appropriate areas for experimentation with the

integrated policies of adaptation and mitigation aimed at guaranteeing the sustainability of urban organisms, thereby reinforcing the European tendency to consider cities as fundamental and favoured territorial units of reference.
A particularly significant experience in such a direction is Rotterdam, with the RAS "Rotterdam Adaptation Strategy", which provides for the application of an adaptive strategy through continual adjustments to the definition of operations counteracting climate change as a function of changing circumstances. In particular, through the "Route Planner", the principal objectives are identified and the action and options for each task are confronted,[4] while the measures taken are evaluated through continual monitoring action, registering the effects that they will have on the speed and extent of the awaited change. On one hand, this procedure offers the possibility to weigh the measures adopted and, on the other hand, the opportunity to evaluate the possibly positive implications of the program with the additional goal of the city's greater attractiveness and added value from the economic point of view. The path toward resilience to climate change, different for each theme, is additionally incorporated within territorial planning.

4.Conclusions

From the most significant European and international experience, it emerges how cities today constitute one of the best opportunities to counteract climatic changes and that to advance in this direction requires adopting urban governance systems able to assume within them the theme of climate change, improve the cooperation among the different institutional levels and promote a multilevel system of governance that recognizes the role of regions and cities, entrusting them with real standardization and planning power and concentrating on them a good part of the resources destined to support the great change that awaits in the coming decades.
However, even if there is this awareness on behalf of public administration and planners, they often lack the instruments necessary to analyze and design concrete sustainability strategies. Innovative paths regarding adaptation and mitigation strategies can be constructed only starting from the integrated evaluation of urban systems in the awareness that the spreading of cities over vast areas of the territory beyond the administrative confines of the municipality, the mobility and logistics of merchandise and the contextual necessity of

[4] These are the tasks on which the Programme on Sustainability and Climate Change will focus during the period up to and including 2014:
- Leading the way in reducing CO2 emissions
- Energy savings
- Converting to sustainable energy and biomass raw materials
- Stimulating sustainable mobility and transport
- Reducing noise pollution and improving the air quality
- More trees and green areas in the city
- Increasing investments in sustainability and stimulating sustainable products and services
- Increasing public support for sustainability and firmly anchoring sustainability in education and research
- Preparing for the consequences of climate change
- Stimulating sustainable urban and regional development

maintaining and protecting natural resources urge linking urban transformations to integrated territorial government.

Faced with the challenge of governing the change, the necessity and utility of urban planning as a general approach is confirmed, even if completely renewed in its form and contents in the name of flexibility and resilience. This, in fact, represents a particular capacity for favouring adaptive action to reduce vulnerability and increase the resistance of urban organisms, but the knowledge, procedures, and instruments necessary are still largely inadequate to allow such planning to acquire the key role that was attributed to it more than a decade ago by the Green Paper "Adapting to climate change in Europe – options for EU action" [5].

In particular, given the fact that traditional planning instruments are not able to adapt to new conditions, the application of more dynamic procedures is spreading today, procedures that:

- make reference to a strategic planning approach capable of constructing more sustainable adaptive measures;
- make reference to different specific time frames;
- make use of a systematic multi-scale approach;
- require profitable collaboration among the different sectors of local administration and also between different levels of territorial government.

Thus renewed, the Plan will be able to configure itself as:

- an extraordinary "director's chair" of sustainability politics that organizes strategies in a flexible and dynamic way, monitoring developments with the possibility of modifying the objectives and instruments with respect to inevitable change in contextual conditions and with the assistance of diversified analysis and project scales;
- one of the essential instruments for constructing social and environmental quality if situated, as it should be, in the framework of politics and action of integrated government and based on realising sustainable development;
- a useful confrontation area to profoundly reform the methods and contents of public intervention and to adopt sustainable urban policies taking shape through genuine shared courses.

It is necessary, however, to be very clear that, next to the rules, clear principles, political addresses and governance at the height of the challenge of sustainable development, it is necessary and that each urban policy not be made in such a way that it is divorced from the people living, working and transiting in the territory as active users of the contemporary city.

[5] The green book on the urban environment from 1990 (COM (90)218) identifies the problems of cities and underlines the implicit existence of an urban dimension in many actions of the European Union. A subsequent resolution from February 1991 (C33/02) "hopes that the objectives defined in the ecological field will constitute an integral part of future urban planning strategies and will activate a European group of experts on the urban environment, formed from national representatives, independent experts and observers. Their task is to evaluate the methods for integration of environmental objectives into the planning strategies and instruments of the future city, to formulate recommendations to the Commission on the methods with which the urban dimension of the environment can enter into the vast European environmental politics and, coherently, to suggest the operational methods for contributing to the improvement of the urban environment in Europe.

INSTITUTIONS AND PLANNING: TOWARDS A MULTI-PERSPECTIVE THEORETICAL FRAMEWORK?

Carlos Oliveira[1], Isabel Breda-Vázquez[2]

Abstract

The paper aims to explore the relationship between institutions and planning. Using different 'new institutionalist' perspectives, it describes the several factors that contribute for change and continuity in institutional processes. This framework is then used in a brief analysis of recent developments in Portuguese planning governance, particularly concerning inter-municipal coordination. The paper concludes that as each perspective is endowed with specific strengths and weaknesses, an integrative, multi-perspective approach is not only defensible but also desirable. Rather than a 'chaotic' approach in a striking need of deconstruction, 'new institutionalism' may add value to planning research by criss-crossing conflicting and intersecting views.

1. Introduction

The relationship between institutions and planning has been 'revived' in the last decade. This may hardly be considered surprising as institutions - both formal and informal - provide the setting for planning (Verma, Ed., 2007). Yet institutional contexts may be looked from different angles and with diverse lens, as testified in the profuse literature on 'new institutionalism', a theoretical framework that has been gradually extended across different fields of social science (Della Porta and Keating, Ed., 2008). Planning, in particular, often values diverse, and apparently contradictory, institutionalist perspectives. Some writings focus the central role of institutions in lowering transaction costs, hence turning planning procedures more stable (Alexander, 2007). Other perspectives emphasize the significance of values, norms and practices in shaping the identity of actors, or at least in their strategies (Healey, 2006). Other studies focus the role of discourse and ideas in promoting change in urban policies (González, 2006). Nonetheless, there is a need for a more transversal approach of the relationship between institutions and planning governance, in order to overcome the main drawbacks of each specific perspective.

The paper centres this subject in the recent evolution Portuguese territorial policies, focusing the intermediate scales between the municipality and the nation-state. As

[1] CITTA – Research Centre for Territory, Transports and Environment, University of Porto, Portugal – carlosol@fe.up.pt
[2] CITTA – Research Centre for Territory, Transports and Environment, University of Porto, Portugal – ivazquez@fe.up.pt

complex socio-spatial contexts, inter-municipal territories, notably those located in metropolitan regions, provide a strong support for an institutionalist analysis of planning methods and practices. Portugal tries to renew its often crystallized institutional landscape, in order to respond to escalating social and economic challenges in a particularly delicate moment of the country history. By exploring transition and change from different institutionalist perspectives, we aim to conclude that a multi-perspective theoretical framework may strongly contribute to enlarge our knowledge of the relationship between institutions and planning.

2. Change and continuity in the 'new institutionalism'

At least since Thomas Hobbes, social theory has been dedicating strong attention to the role of social contexts in the behaviour of institutions. This influence has been theorized in different ways, however. Grannovetter (1985) argues that it often ranges from what he calls an *undersocialized* perspective of rational, independent institutions, only marginally affected by social relations, to an *oversocialyzed* perception of institutions as deeply embedded in their contexts. This debate achieved increased predominance during the 90s, with the diffusion of the so-called 'new institutionalist' literature (Hall and Taylor, 1996).

Nevertheless, the 'new institutionalism' is not a single, coherent theoretical approach, as three main perspectives may be distinguished; notably racional choice; sociological and historical institutionalism (Hall and Taylor, 1996). The so-called rational choice institutionalism may be compared with the *undersocialized* perspective identified by Grannovetter. Having its roots in several streams of the economic theory, this perspective describes political action as a succession of 'collective action' dilemmas (Scharpf, 1997). Rather than being compelled by social relations, each actor is predominantly driven by its own strategic calculations. Institutions are predominantly a product of their functions, and of the benefit these functions may represent to the involved actors (Hall and Taylor, 1996).

Racional choice institutionalism provides a systematized and often very precise theoretical model, supported on easily generalizable concepts. Game theory is among the most widely used tools of this kind (Scharpf, 1997). By reproducing actor preferences and expectations, game theory matrices and calculations aim to identify more or less predictable patterns of behaviour. Yet this variant of 'new institutionalism' is often criticized for oversimplification. Its conditions of use are often too restrictive and relevant aspects, such as subjective preferences, are disregarded. Rational choice institutionalism has difficulties in explaining why so many institutions persist, even though the functional reasons that lay behind their creation are not in existence anymore. Nevertheless, these drawbacks do not erase the obvious contributions of rational choice institutionalism. It brings one of the main problems of political phenomena – the management of uncertainty – to the core of social theory; it gives more space to the study of individual action at the expense of more structural variables such as 'culture'; and it avoids giving an excessive emphasis on contingent aspects (Scharpf, 1997).

Sociological institutionalism contrasts sharply with the rationalist variant, as it relates to what Grannovetter (1985) would classify as an *oversocialized* view of institutions. This branch of new institutionalism conceives institutions in a much broader way (Thelen, 1999). Actors are not just independent, individualist beings looking for the maximization of their benefits but also 'social beings' trying to adjust their patterns of behavior with the norms, values and practices prevailing in their social context. In this perspective, institutions are not just formal entities but also norms and procedures, symbolic systems, cognitive mechanisms and moral patterns in such a way that the devising line between the concepts of 'institutions' and 'culture' is often ambiguous (March and Olsen, 2005). Culture, rather than institutional functions, explains either the creation of new institutions and their persistence through time (Steinmo, 2008). They not only influence actor decisions but also their basic preferences and even their identity (Hall and Taylor, 1996). This, of course, does not mean that actors are not rational, simply that their rationality is socially constructed.

The strengths and drawbacks of sociological institutionalism often contrast with those of the rational choice branch. Unlike this last approach, it provides consistent explanations for the persistence of many institutions through time, and for the more subjective motivations of actors' behaviour. Nonetheless, using an inductive methodology that aims to clarify institutional phenomena by selecting one among several possible explanations, sociological institutionalism fails to provide a systematic, general theory (Jenson and Mérand, 2010).

Historical institutionalism introduces a temporal dimension in the study of institutions. These are conceived as the product of often long-standing trajectories of development, whose evolution may be explained either by functionalist or by cultural factors. Historical institutionalism is 'agnostic' concerning human nature (Thelen, 1999). Actors may be both 'individualistic' and 'social', in the sense described by the two other streams of thought. As a consequence, depending on the specificity of each situation, their action may be conditioned by their own self-interest or by social purposes (Steinmo, 2008). This perspective poses many epistemological problems. How to assess if, in each specific moment, their behaviour was driven by individual or collective factors? The answer to this question, according with historical institutionalism, resides in studying all the facts that lay behind each specific institutional trajectory. As Steinmo (2008:127) put it, in 'taking History seriously'.

The eclectic approach of Historic institutionalism provides an opportunity to combine two equally pertinent approaches of the relationship between institutions and individual action. Nonetheless, as the other branches of institutionalist thought, it is not exempted from drawbacks. The most prominent of them resides in the difficulty to provide an accurate explanatory model of institutional phenomena. If we conceive the mission of science as the development of theoretical models able to deliver adequate explanations to the majority, if not all, natural and social phenomena, then historical institutionalism methods are questionable, at the least (Steinmo, 2008).

Yet Historical institutionalists counter this concept of science as flawed, or at least limited to specific branches of scientific knowledge, such as Newtonian physics. In the social and even life sciences, absolute and invariant laws are simply ineffective, as their objects of study not only vary through time, as they are subjected to a wide range of complex and interdependent factors. The best way to deal with these difficulties, according with historical institutionalists, is by using comparative studies that embrace diverse institutional contexts. In the long range, especially if experienced by a multi-generational community of researches along decades, the combined results of a large sample of specific cases will produce more general models (Steinmo, 2008).

The three institutionalist branches present different explanations for change and continuity in institutions, which are described in the next two sections.

Institutional change factors

Change in rational choice institutionalism is strongly related with actors' strategic calculus. Certain actors are particularly motivated to promote change. This is especially true in the case of the *losers*, or actors marginalized by the political system. Having little to lose, they are in good position to challenge the establishment (Pierson, 2004).

Rather than concentrating on the strategic calculus of specific actors, sociological institutionalism approach of institutional change focuses wider, powerful forces that lead to change at the deeper level of the prevalent norms and values of each context. DiMaggio and Powell (1983) and other researchers sustain that institutions are endowed with a motivated behaviour that structures their action through systems of shared and more-or-less harmonized rules, norms, attitudes and taken-for-granted beliefs. Institutions may be coerced to converge, either by pressures from other institutions that hold the power to impose their standards, or by cultural expectations. They may try to reproduce successful models as a way to cope with uncertainty. Or they may integrate agents with different beliefs and values that will internally contribute for change. These three kinds of isomorphism, called *coercive*, *mimetic* and *normative* respectively, may work as triggers of institutional change. Usually, these processes are neither easy nor abrupt, as they involve change at the deeper level of cultural norms and beliefs, rather than shifts in actor's interests (Healey, 2007).

Historic institutionalism provides a wider range of explanations for institutional change. Pierson (2004) distinguishes between short and long term time horizons, either for causes or for outcomes. A process may occur rapidly but produce long-standing outcomes. Such is the case of what is often called 'critical junctures' (Mahoney, 2000), according to which one or more successions of causal factors converge in a specific moment in History, generating a 'legacy' of institutional transformations (Collier and Collier, 1991). Major shifts, such as the Industrial Revolution, may be analysed using this model. Goldstone (1998), for instance,

describes the invention of the steam engine as the result of the convergence of two chains of interrelated events, one of them related with environmental transformations and the other with social-cultural shifts. This 'critical junction' was at the origin of such deep economic and institutional changes that radically transformed Britain.

Change, according with historical institutionalists, may be the product of other kinds of processes, however. These may be long-standing, both in their causes and effects. Robert Putnam's work on social capital (2000) describes remarkably how an enduring phenomenon (the decline of social capital in the US, during several decades) is in itself the result of also persistent causes, such as urban sprawl and the massive consumption of television. Change may be instantaneous in both its causes and effects, although there may be a temporal lag between them. Some political studies, for instance, establish a link between economic development and democratization processes that, although both brief in time, are not immediately subsequent (Przeworski and Limongi, 1997). In other situations, as the 'threshold effects' model illustrates (Grannovetter, 1978), the causal factor (economic growth) may be long lasting, but not the democratic process.

Institutional continuity factors

As much institutionalist literature is predominantly focused on institutional change, the continuity of existing pathways is often neglected. This fact is regrettable as much institutional design destined to promote change is often harmed by not anticipated change-resistant factors. Institutional continuity variables are, nevertheless, presented in all the main streams of institutionalist research. Part of rational choice literature, for instance, is dedicated to the so-called 'veto points', or the aspects of formal institutions that provide opportunities to block, or at least retard, decisions. A high degree of compromise required to promote the change of rules, such as two-third majority in Parliament, may be considered an example of a veto opportunity (Tsebelis, 2002). Some federal systems are 'trapped' in a 'Joint decision' system involving different levels of government, may also contribute to institutional inertia (Scharpf, 1988). The same will happen with presidential or bi-cameral parliamentary systems.

Sociological institutionalism, on the other hand, is often concentrated on 'embeddedness' (Grannovetter, 1985), or the persistence in time of deep-rooted norms, values and beliefs. Putnam (1993) analysis of civic cultures across Italy emphasis this aspect, as he goes back to the history of the country's different regions since the middle ages, in order to explain diverse patterns of *civicness* in present days.

Perhaps the better-known Historic institutionalist continuity effect relates short-lived causes and enduring effects. Path-dependent processes are long-standing, self-reinforcing dynamics generated by an event produced in a specific moment in History. Once triggered, either by chance or as a consequence of a conscious decision, this event will generate a positive feedback process, meaning that each

stage along a particular trajectory will increase the attractiveness of that trajectory over time (North, 1990; Pierson, 2004). Path-dependence is a source of inertia in the long run, as the further we move in time, the harsher it becomes to change the course.

Table 1 synthesises the above-mentioned institutionalist factors for both change and continuity.

Table 1 - Institutional factors for change and continuity

Theoretical approach	Change factor	Continuity factor
Rational choice institutionalism	**Actors' collective action**: Change is promoted by local actors, either leaders or those marginalized from institutional arrengements who try to revert the situation in their benefit.	**Veto points**: Change is blocked when multiple actors are involved in decision processes.
Sociological institutionalism	**Coercive isomorfism**: Chang is driven by powerful external actors. **Mimetic Isomorfism**: Change is driven internally, by the will to replicate other institutional contexts perceived as more successful. **Normative isomorfism**: Change is driven by individual ('institutional entrepreneurs') or collective ('epistemic communities'), who bring with them diferente values from other contexts.	**Embeddedness:** Powerful beliefs, norms and rules are crystallized in the institutional context, blocking any attempt to shift existing traditions.
Historic institutionalism	**Critical junctions**: Change is the result of converging chains of events. **Cumulative causes**: Gradual changes are directly related with equally enduring causes. **Cumulative effects**: Short-term events produce long-lasting change. **Strutural processes**: Both causes and effects are brief, although temporally lagged. **Threshold effects**: A long-standing causes generates change a brief effect change.	**Path-dependence:** Events occurred in a more-or-less distant past triggered self-reinforcing dynamics.

3. Tangled institutionalisms: the case of inter-municipal coordination in Portuguese planning

Literature on 'planning traditions' usually portrays Portugal as a member of the Southern European 'family' of countries (Nadin and Stead, 2008), meaning that it emphasises regulation more than negotiation; That its local government is relatively weak, especially concerning its human, technical and financial resources. And that trust among public and non-public actors, as among actors belonging to different levels of government, is generally low, leading to cumbersome procedures and high levels of red tape (Breda-Vázquez and Oliveira, 2008).

Nonetheless, attempts to change this general setting have been recurrent in the last few decades. Yet the intensity and direction of change may vary strikingly between different aspects of territorial policies concerning the objectives, instruments and scales of public policy intervention. The evolution of territorial policies in Portugal in the last few decades may help to understand that this diversity of outcomes often derives from the mix of institutionalist factors existent in each context.

Among the most recurrent attempts to introduce institutional change were the rescaling of territorial policies through devolution of planning competencies to sub-national levels and the involvement of non-public actors in decision processes, notably territorial strategy-defining. Different degrees of change were observable at three levels: the administrative system, the formal planning system and other territorial-focused initiatives such as territorial development programmes. Inter-municipal coordination is a particularly intriguing field of work, as Portugal was subjected to several transformations in the last few years, with varying results in terms of institutional change and continuity (Oliveira and Breda-Vázquez, 2011; Silva and Syrett, 2006; Syrett and Silva, 2001).

In a country where intermediate scales between the municipal and the national levels were remarkably weak (there are no metropolitan or regional governments in mainland Portugal), attempts to promote inter-municipal coordination represents a major challenge. Successive legislative packages devolved increased competencies to the local government but the lack of human, technical and financial resources often hampered further development (Syrett, 1995). On the other hand, although many different kinds of inter-municipal institutions were created in the last thirty years, they are generally emptied of significant competencies. Further integration on territorial policies faced resistance from local authorities in giving up their own competencies at the expense of supra-municipal entities (Oliveira and Breda-Vázquez, 2012).

This is especially evident in the case of formal planning. In spite of the existence of law provisions for Inter-municipal plans (PIOT) since the end of the 1990s these plans, which are not compulsory, remain nearly absent in Portuguese planning practices. As a consequence, old traditional top-down procedures remain, as the intermunicipal scale of planning is mainly provided by regional plans, which are promoted by agencies controlled by the national government (Oliveira and Breda-Vázquez, 2012). This situation reproduces the main characteristics of the planning system as a cumbersome, over-centralized and technocratic apparatus (Amaral and Monteiro, 2004), where attempts to change are regularly hampered by deep-rooted administrative practices.

Other instruments were more effective in introducing governance-led practices. The raise of so-called territorialized programmes was apparent in the last two decades, frequently in close association with European Union funding. Some of the most innovative experiences involving inter-municipal coordination were either incentivised by the EU or inspired in other European experiences. Nevertheless, in

the case of Portugal, they hardly assumed a prominent role in the country territorial policies, which remained deeply committed with more traditional, regulative approaches. 'Institutional isomorphism', fostered coercively by EU rules, promoted through good-practice exchanges or the activity of key actors, contributed to transform institutional landscapes, yet this process was strongly conditioned by the strategic calculus of local actors, as many of them were far more interested in funding access rather than on long-lasting local strategies (Oliveira and Breda-Vázquez, 2012).

In all these examples, a web of 'tangled' institutionalist factors is apparent, either in promoting or in hampering change. Change may be fostered by sociologic institutionalist factors such as isomorphism, or hampered by the strategic calculus of local or national actors, especially in contexts where 'veto points' proliferate. Change may be the product of historical institutionalist factors, either abrupt such as 'critical junctures' or smooth such as cumulative decentralization measures. But it can be halted, or at least mitigated, by the continuous presence of deep-rooted non-written norms.

5. Conclusions

By using different streams of institutionalist thought, the paper aimed to expose the main factors laying behind change and continuity in institutions, and their relationship with recent evolution in spatial planning and territorial policy issues. We conclude that the mix of institutionalist factors present in each context is a central factor in determining the outcome of processes such as the rescaling of administrative and planning systems or the transition from government to governance.

The wide range of 'new institutionalist' perspectives would lead us to evaluate institutionalism in planning as a 'chaotic' approach, in a striking need of deconstruction. Nonetheless, the case described in this paper illustrates how co-existence among different perspectives is not only defensible but also desirable. Multiple threads of thought do not necessarily lead to incoherence, as long as each of them remains parsimonious in its claims, and the boundaries between them are rigorously defined (Benneworth and Henry, 2004). As each theoretical perspective is endowed with a specific set of strengths and weaknesses, an integrative approach may even lead to a more enlightened description of the role of institutions in planning.

There is a need to deepen this multi-perspective approach of planning in further research, as the joint exploration of conflicting and intersecting threads of thought offers new opportunities for adding value to planning and territorial policy studies.

Paper presented at the 26th Annual AESOP Congress in Ankara, Turkey, July 2012

Abstract

Over the past decade, the concept of path dependency has begun to appear in planning literature with increasing frequency as planning scholars have sought to explain historical continuity in a variety of urban policy issues including the economic development of regions, the provision of infrastructure and transit and the organization of planning processes. However, while path dependence offers a useful theoretical framework for exploring continuity and change in urban planning and policy, it remains an under-theorized and underutilized concept in planning.

This paper uses historical institutional analysis to investigate and interpret the conceptualization, planning and implementation of the public housing redevelopment program in Chicago. The paper argues that the evolution of Chicago's public housing program between the 1950s and the 1990s left an institutional structure, in which many local actors were deeply invested, that shaped and constrained efforts to create and implement redevelopment plans. Chicago's public housing program initially proved resistant to change. While it did eventually change, this change was highly contested and the resulting plan for redeveloping Chicago's public housing continued to reflect the institutional structure and corresponding power relations under which it was created. This institutional structure filtered attempts to develop a coherent approach to applying the HOPE VI program, a federal program which funded the revitalization of public housing, in Chicago and framed the process through which actors and resources were rallied in order to implement this approach.

Drawing on interviews and a detailed history of Chicago's public housing program between 1937 and 2007, this paper attempts to further understanding of how institutional path dependency shapes plan formation and implementation and the implications of this for urban growth and change.

1. Introduction

Over the past fifteen years, the concept of path dependency has begun to appear in planning literature with increasing frequency. The reason for this growing interest appears to be a desire to explain historical continuity and the resistance to change being observed in a variety of urban phenomena ranging from the economic development of regions to the provision of infrastructure and transit to the organization of planning processes. Yet, planning scholars, while increasingly referring to plans, policies and processes as path dependent, have rarely engaged with the concept of path dependence in a systematic or deep fashion. References to path dependence are made to suggest the importance of history in shaping the outcomes of a particular case without theoretical development or empirical support with a few notable exceptions (c.f. Moulaert et al. 2007; Henderson, Bowlby and Raco 2007; Pflieger et al. 2009 and Sorenson 2010). Despite growing recognition of that path dependence offers a potentially useful theoretical framework for exploring continuity and change in urban planning and policy, it remains an under-theorized and underutilized concept in planning scholarship.

This paper is an attempt to do three things: first, to provide a brief outline of a theoretical framework of path dependence as it applies to planning processes; second, to use historical institutional analysis to investigate and interpret the conceptualization, planning and implementation of the public housing redevelopment program in Chicago; and, third, to reflect on the implications of this theoretical framework and analysis both for planning practice and for planning scholarship. Underlying these three endeavors is an attempt to explain why Chicago's public housing program, a program that was glaringly unjust and inefficient, so stubbornly resist change. Chicago's public housing program was initially considered a model to which other cities across the US should aspire. Less than 15 years after its founding, its esteem had fallen such that it was already being considered as an example of how not to undertake public housing. Despite widespread recognition of its flaws, Chicago's public housing program retained the same basic structure that had garnered such criticism for another forty years. What explains this persistence? Further, what effect did this historical path have on efforts during the 1990s to revitalize and reform Chicago's public housing?

This research initially began as an investigation of Chicago's public housing program between 1989 and 1999. This period which began with the initiation of the Mixed Income New Communities (MINCs) program and the formation of the National Commission on Severely Distressed public housing and ended with the release of the Plan for Transformation of Chicago's public housing, was chosen because it encapsulated a 'policy window' (Kingdon 1995) during which Chicago's public housing program was restructured and redeveloped after decades of inertia. This initial research focused on how a new direction for Chicago's public housing was chosen, by whom and for what ends. This research found that the eventual agreement on how to restructure

and redevelop Chicago's public housing had been produced by an (unequal) coalition of the variety of different actors noted above and that the inclusion of several unexpected actors was the result of the exercise of their ability to impede the planning process and force their inclusion (Gebhardt 2009 and 2010).

This initial 'snapshot' case study is where most planning studies would have ended. However, the results of this initial research were unsatisfying for two reasons. First, while it explained the changes that took place during the policy window and the negotiations that led to the new strategy for Chicago's public housing set forth in the Plan for Transformation, it did not explain why change of some sort had not come earlier. Every single actor involved in the process agreed that the program that existed in 1989 was broken, yet this was the same program that had existed for 30 years. Why and how had it lasted so long despite being so clearly deficient? Second, and perhaps more interestingly, the negotiations between the different actors were framed by inherited institutional constraints. Setting a new path for Chicago's public housing required nearly a decade of highly contentious battles and the alteration or elimination of many existing institutional structures. These institutions were absolutely essential for explaining why certain actors were able to force their inclusion in the planning process and why certain approaches required dramatic changes. The snapshot approach revealed that these institutional structures existed, but not where they came from or why they persisted.

The rest of this paper describes Chicago's public housing program prior to the policy window that opened in the 1990s as path dependent and examines the implications of this conclusion. The first section provides a brief summary of the concept of path dependence. The subsequent three sections describe how the path of Chicago's public housing program was first set, then maintained and finally changed. The final section examines the implications of this for planning theory and practice.

2. Theoretical Framework

The term path dependency provides a label for empirical observations and intuitions about the historical continuity of institutions and organizations (Kay 2005, 558). At its most basic, path dependence is the assertion that it is possible to identify a clear historic pattern in which some initial often historically distant event(s) change the probability of later events. As a result, some are more likely to happen than others.

Path dependence originated in economics as a means of explaining the adoption and persistence of technologies. The first to articulate this concept was David (1985). David used the example of the persistence of the QWERTY keyboard despite its inefficient design to illustrate how, once a particular technology is adopted by a large number of users it becomes increasingly difficult to challenge even if other, better

options are available and the original circumstances that prompted design no longer exist. The concept was later elaborated on by Arthur (1994) who argued that the persistence of technology could be explained by high set up costs reducing the incentive to switch and learning and coordination effects along with adaptive expectations increasing the value or expected value of an existing technology to individuals as they both learn how to use the technology more efficiently and benefit from others adoption of the same technology. In both arguments, increasing returns and positive feedback "lock-in" the original advantage of a given technology over its rivals. Douglass North (1990) used this same logic to explain the role of the constraints imposed by historic institutions on economic growth arguing that path dependence in institutions helps explain anomalous economic performance.

Path dependence has since been borrowed and adapted by scholars in other disciplines. Of particular interest for this paper is the application of path dependence to politics and policy formation. Kay (2005) suggests that path dependency is a useful and emerging conceptual tool for understanding the public policy process because it allows observers to unpack dynamic processes as they unfold over time and to better understand the historical antecedents of a particular policy. Pierson (2000, 2004) presents the most developed conceptualization of path dependency as it applies to public policy. He argues that policy outcomes are the result of historical events, both large and small. The timing and sequencing of events matter; even small events that happen early in in a sequence can have profound impacts on outcomes and once a particular course of action is initiated can become increasingly difficult to reverse. Thus, starting from relatively similar conditions, it is possible to arrive a wide range of outcomes.

Drawing on the literature in economics, Pierson (2004) emphasizes how actions in the political and policy making realms can become self-reinforcing through the positive feedback as "the relative benefits of the current activity compared with other possible options increase over time". The longer a particular path is followed the more actors invest in a particular course of action and build institutions, policies and partnerships around it and the more the relative benefit of continuing this course of action and the relative cost of switching to an alternative increases. Eventually, alternatives that may once have been feasible become unattainable (Pierson and Skocpol 2002). Thelen (1999) makes a similar argument stating that once a path is chosen and a system is in place, actors adapt their strategies to reflect and work with and within this system. This also serves to reinforce this system as the new relationships and institutional arrangements can increase the cost of exit. Over time, the amount of sunk costs as well as the number of vested interests increase can "lock-in" a particular path making changing course difficult (Thelen 1999).

In Mahoney's (2000) formulation at the outset there must be more than one competing choice available. The choice made at this point in time is consequential because it

creates a pattern that endures over time. Mahoney (2000) suggests that there may be several different mechanisms at work maintaining path dependent sequences. The first is efficiency. An institution, policy or program is reproduced because it serves a function for an overall system and the transaction costs associated with changing the original decision are prohibitive. The second is legitimacy. Here decisions that have been made are viewed as legitimate because they fit with broad institutional norms while alternatives lack this legitimacy. The final is power. In this case, elite actors with power reinforce and support a path because it suits their purposes. While only one of these mechanisms is necessary to initiate and maintain a path, all three appear to be present in the Chicago case.

While path dependency describes the persistence of particular institutions, policies and programs over time, it suggests that the old is not scrapped every time something new comes along or is proposed. Change continues as social, economic and political fluctuations put pressure on an existing path. However, this change is bounded change until something erodes or swamps the mechanisms of reproduction that generate continuity (Pierson 2000, 265). Rather than these pressures causing dramatic shifts in an existing path, new ideas and strategies are assimilated and made to fit the that path. New institutional layers are formed as the new ideas are coopted into existing structures (c.f. Mouleart et al 2007). Institutions may be changed through layering as new rules or structures are added on top of what already exists. Institutions may be reoriented to serve new purposes or reflect new power dynamics. They are not abolished altogether, but rather are changed to reflect external demands in order to survive. These new layers represent only small changes individually, but cumulatively may result in a fundamental change in an institution (Thelen 1999). As the below case suggests, the longer a policy or program remains in place, the more external pressures it will be subject to and the more institutional layers it will accumulate.

Path dependency is potentially useful for explaining continuity and persistence of institutions, policies and programs. However, this does not help explain how and when change does occur. To resolve this problem, scholars of path dependency have incorporated the concept of "critical junctures" (Collier and Collier 1991, Thelen 1999, Katznelson 2003). Critical junctures are part of a punctuated equilibrium model wherein endogenous contradictions and/or exogenous forces result in crisis points at which an existing path ceases to be sustained. At these points, path shaping takes place and alternative systems compete for dominance (Davies 2004). Drawing on Mahoney's (2000) observations about the mechanisms sustaining path dependent sequences, critical junctures represent moments at which the costs of switching to a different path are lessened or an existing path loses legitimacy or powerful supporters.

Finally, Harvey's (1989) concept of artifacts adds a useful spatial dimension to the path dependency literature. "Artifacts" (Harvey 1989, 6) are physical, social and cultural

constructs, the result of the process of creating a city, that "dominate daily practices and confine subsequent courses of action." Generally concerned with the operation of institutions or economies, path dependency typically does not explore the way a particular course of action produces urban space or the way that these physical manifestations serve to constrain future actions. Patterns in the built environment would certainly seem to match descriptions of path dependent sequences as contingent decisions that occur early in a process can constrain later events, particularly as actors make investments and decisions based on this initial pattern. Studies of national housing systems that have applied path dependency have noted that one factor that contributes to the path dependent nature of these systems is that housing is expensive, lasting and place bound (c.f. Bengtsson and Ruonavaara 2010). When looking at Chicago's public housing program, it is impossible to separate out the local policy arena, the organization and the housing itself. The politics of public housing, the structure of the CHA and the expensive, immovable public housing itself all contributed

The next three sections provide a history of Chicago's public housing program from its inception in the 1930s through to the turmoil and eventual restructuring in the 1990s. These sections apply the concept of path dependence in an effort to identify what event or events set the program on the trajectory that carried it through second half of the 20th Century. It also describes how this path persisted (and was maintained) despite considerable external pressure to change. Finally, it concludes with a discussion of how the persistence of the path over three decades and the steps taken to maintain it constrained efforts to conceive a new path for the program during the 1990s.

3. Data and Analysis

3.1. Establishing the Path

The Chicago Housing Authority (CHA) was established in 1937 by Mayor Edward Kelly. The board of the organization was originally filled with many of Chicago's most progressive reformers. The board was led by prominent African American, Robert Taylor. Elizabeth Wood, a progressive reformer herself, filled the position of the CHA's first executive secretary. The CHA was considered at the time to be a model public housing authority known for cutting-edge design and conscientious management. Despite the progressive orientation of the CHA (and at times because of it) by the time Elizabeth Wood left the organization in 1954, Chicago's public housing program was on a path that would lead it to be considered forty years later as one of the worst in the country marked by poorly constructed high-rise developments ill-suited to the needs of families located on enormous, isolated, segregated tracts and an inefficient, chaotic bureaucracy incapable of maintaining these buildings. This need not have been the path but for decisions made at the outset of the program, and, indeed, the leaders of the CHA pushed hard during these initial years for a quite different program. Yet once the path

was set, it became increasingly difficult to change producing the program that became one of the most notorious in the country. This section details the setting of the path.

The CHA was established in response to the 1937 Housing Act which authorized and funded the establishment of local public housing authorities. The CHA initially constructed housing for war workers and returning WWII veterans. These early housing developments were low rise and built in both slum and greenfield locations. In keeping with the requirements of the authorizing Act which tied public housing to slum clearance, the CHA's leadership, dominated by housing reformers, gave preference to new projects on cleared slums. While not consciously segregated, the policy in place at the time was to fill public housing projects according to "neighborhood composition" wherein the number of families admitted to a new public housing complex would mirror the composition of the surrounding neighborhood. This rule meant that, despite concerns about the progressive tendencies of the leadership of the CHA, public housing itself remained acceptable to most residents and politicians and was built in neighborhoods throughout the city (Meyerson and Banfield 1955, Hunt 2009).

The nature of Chicago's public housing program changed in 1946. In that year, the CHA began selecting tenants to fill two new temporary housing developments. Both were greenfield sites near existing, predominantly white neighborhoods. With the conclusion of WWII, demand for public housing increased substantially as returning veterans sought inexpensive housing options. To deal with this pressure as well as demands for equality from black veterans, the choice was made to pursue racial integration for these developments. The integration of the first, on the northwest side, went unnoticed. The attempt to integrate Airport Homes on the southwest side raised the ire of white residents of the adjacent neighborhood. They protested the move and attempted to intimidate the project's black families into leaving.

This event precipitated decisions that would set a path for the CHA that would persist until the late-1980s. The unrest at Airport Homes in 1946 alerted Chicago's white aldermen to the CHA's intentions to integrate new public housing. The CHA had, up until that point, been protected by a sympathetic mayor in Kelly. His ouster in 1947 exposed the CHA to a backlash from various sources. Many of the CHA's powers for slum clearance and site selection were taken away by the State legislature in 1947 and, in 1949, the Chicago City Council was afforded veto power over the selection of sites for new public housing construction (Meyerson and Banfield 1955, Hirsch 1983, Hunt 2009). If there was a single, contingent event that set Chicago's public housing program's path, this was it. It was the fight over integrating Airport Homes that resulted in greater City Council interference in the CHA. And it was this fight that resulted in decreased decision-making authority of Taylor and Wood.

Previously, Taylor and Wood, while not entirely trusted by the City's aldermen, had been allowed to operate the CHA largely free from Council control and built public housing in both black and white neighborhoods on both clearance and greenfield sites. The ultimate shape of the program had yet to be established. Had the issue of integration been raised at a later point, after Taylor and Wood had established a clear path, it is possible that the pattern of public housing sites would have been different. Further, as the following paragraphs explore, had Taylor and Wood not expended their political capital on this battle at this point in time, they would have maintained some ability to affect some of the subsequent decisions regarding the physical design of Chicago's public housing. As it was, neither survived the fight over Airport Homes with sufficient power to shape later events.

Between 1948 and 1950 a series of proposals for new public housing sites were presented by the Chicago City Council and the CHA. The proposals put forward by the City's aldermen were decidedly in favor of building large projects in the City's African American neighborhoods while avoiding nearly all white neighborhoods. In contrast, the CHA presented a series of proposals for building a large number of units on both slum clearance and greenfield sites. The majority of the CHA's original commissioners were in favor of a large public housing program that would be built both on vacant sites and on slum sites throughout the city. They also favored a program that was desegregated (Meyerson and Banfield 1955, 45). The demand for housing in Chicago was substantial at the time with nearly a half million people living in neighborhoods considered slums (Meyerson and Banfield 1955, 91). Large slum clearance projects were perceived as necessary because the scope of the slum problem in Chicago was considered so large that small renewal efforts would be overwhelmed.

The CHA lost every fight with the City Council over new public housing sites. Eventually, after arguing for several years for a broader program, the CHA was forced to accept the City Council's sites in order to be able to build at all (Hunt 2009, 91). Robert Taylor resigned in exasperation in 1950 after it became clear that Chicago's public housing program had become a vehicle for promoting redevelopment and reinforcing segregation (Hunt 2009, Meyerson and Banfield 1955, Hirsch 1983).

As Hunt (2009) argues, the City Council's blatant racism helps to explain why little or no public housing was built in predominantly white neighborhoods, but is insufficient to explain the extensive building of public housing in the City's black neighborhoods. In this, the progressive tendencies of the early leaders of the CHA also played a part as they attempted to improve the conditions of poor blacks and slum dwellers. Driven in parts by the available funds, by the amount of substandard housing in the city and by a desire to create modern neighborhoods to replace old slums, the CHA pushed for large-scale projects over a more limited, scattered site approach (Hunt 2009). The construction of large amounts of public housing in the City's predominantly black wards was also

supported by African American aldermen who sought to consolidate votes and political power in their wards (Meyerson and Banfield 1955). Yet despite the concern with slum clearance and large projects, had the CHA retained some authority over site selection and the greenfield sites that it proposed been accepted, the concentration and density of the projects built in the City's black neighborhoods would not have needed to be so high. This density proved to have disastrous consequences.

Another key characteristic of Chicago's public housing program, one that has been intensely criticized, was the predominance of high-rise buildings. The original CHA manual specifically directed the organization's architects to design only buildings with a "domestic" and "non-institutional" appearance (Meyerson and Banfield 1955, 95). In the early-1950s, the CHA experimented with high-rise buildings. The first elevator buildings, Dearborn Homes opened in 1950. Loomis Courts opened in 1951. Further complicating the situation, the CHA pursued a well-intentioned program to design and fill flats that met the needs of perspective tenants. As the majority of perspective tenants were large families, the majority of new units being built were for large families. This had the effect of concentrating large numbers of children into the new public housing.

While she originally supported experimentation with high-rise developments, Elizabeth Wood quickly identified that low-rise projects were a better form for public housing particularly for families with children (Hunt 2009, Meyerson and Banfield 1955). In 1952(!), less than two years after the first high-rise buildings had been completed in Chicago, Elizabeth Wood wrote a piece for *Architectural Forum* where she stated that the experiment with high-rises had been a mistake and argued instead for low-rise buildings more suitable for families. Experience with the first two high-rise developments made clear the flaws of this approach. Yet, by that point the path had already been set and Wood's authority was all but gone. Local politicians and civic leaders had reached a mutually satisfactory agreement over the shape of Chicago's public housing program which required high density high-rise development. This approach was further bolstered by the position of national level bureaucrats who viewed high-rise development as the most cost effective design. The cost restrictions imposed by the federal government coupled with the structure of Chicago's public housing program meant that high-rise buildings were inevitably the "best" choice. Thus, in a rather dramatic illustration of path dependency nearly 14,000 units including high-rise buildings at Harold Ickes Homes (1955), Grace Abbott Homes (1955), Henry Horner Homes (1957), Stateway Gardens (1958), Cabrini-Green (1958 and 1962), Rockwell Gardens (1961) and Robert Taylor Homes (1962), were built by the CHA using a model and designs that the leadership within the CHA had clearly identified as flawed.

Between 1948 and 1952, Elizabeth Wood and her staff became increasingly isolated from the CHA board. In a further confirmation of the chosen path of Chicago's public housing program, Wood was fired in 1954, after several years of increasing tension with

the CHA Board over design, siting and integration culminated in a scathing letter criticizing their lack of commitment to achieving social goals. After Wood's departure former General William Kean took over as Executive Director. He lifted all racial quotas imposed on CHA developments, the result of which was that black demand for public housing quickly overwhelmed white demand. Kean changed the focus of the CHA from one in which progressive social goals were paramount to one in which administrative efficiency was most important. This fit neatly within the chosen path. In 1956 Mayor Richard J. Daley appointed a close political ally, Charles Swibel, to the CHA board. This move was intended to bring the CHA more closely under the control of Chicago's political machine. Swibel assumed the chairmanship of the CHA board in 1963 which insured the Authority's quiescence.

3.2. Maintaining the Path

Political, social and economic changes at both the local and national level resulted in considerable pressure being applied to the path of Chicago's public housing program at several points in the program's history. There were multiple points at which CHA and City of Chicago decision-makers were presented with opportunities to change the trajectory of the CHA. While minor changes were made, at each point the cost of switching to a different path was judged too high. The overall path remained constant. In keeping with the observations of Pierson (2000) and Thelen (1999), new rules and institutional structures were created and fit into the existing path. These layers, while they had little immediate impact on the program, had profound implications when a policy window opened in the 1990s and attempts to shape a new path for Chicago's public housing program were begun. This section discusses the period between 1955 and 1990 and the challenges that were made to the path of Chicago's public housing program and the steps that were taken to maintain it.

Chicago's public housing program followed the basic path set out in the early-1950s without major challenge until, in 1966, a group of CHA residents filed a lawsuit against the CHA. The product of the changing social environment of the Civil Rights era, this lawsuit claimed that the CHA had engaged in racially discriminatory project siting and tenant selection procedures in violation of Title VI of the 1964 Civil Rights Act by locating all but a handful of public housing projects in predominantly African-American neighborhoods and placing African-American tenants only in the segregated projects. In 1969, a federal judge ruled on the lawsuit against the CHA in favor of the plaintiffs. Known as the Gautreaux decision after the lead plaintiff in the case, this ruling divided Cook County by census tract into "general areas" (areas with less than 30% African-American population) and "limited areas" (areas with 30% or more African-American population). For every unit of public housing built in a limited area, three units had to be built in a general area. This legal decision put pressure on the CHA to change and offered an alternative path for Chicago's public housing program. The standard practice

in Chicago of deferring to aldermen regarding development decisions in their ward essentially rendered General Areas off-limits to new public housing construction. As the Gautreaux plaintiffs and the presiding judge argued at the time, this was an opportunity for the CHA to change its practices and create a very different program (*Gautreaux v Chicago Housing Authority* 1969).

Rather than pursing an alternative path, opening additional neighborhoods to public housing and establishing a scattered site approach, the City and the CHA instead chose to halt new public housing construction altogether (Popkin et al. 2000, Wilen and Stasel 2006). Opening the City's white neighborhoods to public housing, which was by this point occupied nearly exclusively occupied by African American's, could not be done without enormous political cost. This calculation was made plain in 1971 by a request by the CHA to postpone making public sites for new public housing that had been located in white neighborhoods so that they would not become "the central issue of the upcoming campaign" (Wade 1970 quoted in Hunt 2009, 250) and the immediate and ferocious response from the City's white aldermen when this request was denied and the list was made public immediately before an election. A scattered site program would have enraged white voters, introduced black voters into white wards and drained black voters from black wards. None of these were acceptable outcomes for local politicians, black or white. The status quo worked for those in power, and they saw no need to change it.

The CHA again was pressured to change in the mid-1970s. Under Charles Swibel, CHA projects were allowed to deteriorate as a result of rampant fraud, cronyism, mismanagement and corruption. Poor engineering and lax maintenance also contributed to a precipitous decline in buildings. During Swibel's tenure, the CHA's employment rolls ballooned and maintenance of CHA properties declined significantly (Hunt 2009, Sheppard 1982). Despite ample evidence of managerial incompetence and considerable pressure from tenant groups during the 1970s, the CHA proved "immune to reform" (Hunt 2009, 214). During the 1970s, CHA residents formed the Chicago Housing Tenants Organization (CHTO) and began a campaign to force the CHA to improve conditions in Chicago's public housing. Here again, those that benefitted and drew power from the existing configuration of Chicago's public housing program used their authority to adjust institutional structures to maintain the overall trajectory of the program. The residents' campaign led to the creation of the Central Advisory Council (CAC) which would include residents from each project in a monitoring and oversight board. However, the CAC was populated with resident leaders hand-picked by the CHA and beholden to Swibel. Local Advisory Councils (LACs) were set up at each site ostensibly to provide greater tenant control over CHA projects. In practice, these were used to discourage resident activism and give the illusion of resident authority.

In addition to pressure from below, pressure was applied to the CHA from above. As the fiscal crisis of the 1970s deepened and greater emphasis was placed on the efficient operation of programs such as public housing, nine different reports were written by auditors and consultants between 1978 and 1982 outlining numerous and widespread problems with the CHA's management. As with before, little was done to actually reform the organization. The CHA as it existed benefited some powerful interests including black politicians, the Democratic machine and Swibel himself. It was happily ignored by most everyone else. In 1982 the most comprehensive and scathing review of the CHA was written by Oscar Newman on behalf of the federal government (Sheppard 1982). It outlined in excruciating detail managerial intransigence, less-than-competent senior leadership and a bloated bureaucracy that resulted in crumbling buildings and an organization that resisted any attempts at reform (Hunt 2009). The CHA ran a deficit every year and public housing buildings were not maintained.

In 1981, newly elected Mayor Jane Byrne had appointed a new executive director, Andrew Mooney, who brought credentials as an advocate of "good government". However, Swibel, a major contributor to Mayor Byrne's campaign, was allowed to continue to serve as CHA chairman. After Newman's report was released in 1982, HUD finally forced Swibel to resign his position under threat of a federal takeover of the CHA. HUD's report and the dismissal of Swibel offered another chance to change the trajectory of the CHA, but again the cost of doing this, both in political terms for the politicians that benefitted from the existing arrangement and, for the first time, in fiscal terms[1] given the enormous maintenance backlog, prevented change. Also, as with earlier actions taken to preserve the existing path of the CHA, the legacy of Swibel's tenure as chairman of the CHA and the political fight with Mayor Byrne over his resignation left lasting legacy that would affect later attempts to restructure and redevelop Chicago's public housing. The fight to preserve Swibel led to a period of distrust between HUD and the CHA. It also led to a period of regular turnover of CHA leadership. Mooney lasted only two years as director of the CHA and accomplished little. Between 1982 and 1988, the CHA had three different chairmen and five different executive directors. The regular turnover in CHA leadership resulted in the further deterioration of the housing stock and of the CHA's relationship with residents and with HUD.

The upheaval within the CHA was reflective of the changes occurring in Chicago's political landscape during the 1980s. In 1983, after one term as mayor, Mayor Byrne lost the Democratic primary to Harold Washington. While Harold Washington's election

[1] One of the common myths about Chicago's public housing program is that the buildings deteriorated because there was insufficient national government funding to maintain them. As Newman's report details, up until the early-1980s, the CHA had sufficient funds to cover maintenance costs, but corruption, incompetence and poor organization meant the money was not used effectively. Here is a case where initial political costs of switching to a different path eventually led to and were compounded by actual financial costs.

as mayor altered the Chicago political landscape making it more inclusive of disaffected minorities and neglected neighborhoods, the governing coalition he assembled ultimately did little to change the CHA. Mayor Washington remained loyal to the public housing residents who helped secure his election victory, strongly opposing tentative plans to demolish public housing that began to appear during his mayoralty (Ziemba 1987a). Nevertheless while he supported many reforms, Washington remained a Chicago politician and, thus he ultimately did little better than his predecessors in changing the culture of the CHA. The status quo continued to benefit too many powerful players to be changed. One of the Mayor's powerful supporters, Renault Robinson, was appointed chairman of the CHA. Robinson's support of Washington secured him the job and insulated him despite repeated failures and poor management (Polikoff 2006). Robinson finally resigned as chairman in early-1987 when his performance became an impediment to Mayor Washington's reelection campaign (Spielman and Golden 1987).

As with previous opportunities, the choice was made to preserve the existing path by adding another new institutional layer. The constant turnover in CHA leadership meant that the agency was not able to pursue a coherent strategy to maintain deteriorating units, reduce criminal activity, improve budgetary practices or reform bureaucratic inefficiencies. In 1987, as they had in 1982, HUD threatened to take over the CHA. The CHA's lack of progress on construction of scattered site public housing had led the Gautreaux plaintiffs to repeatedly return to the Gautreaux court to try to force the CHA to comply with the consent decree. Beginning in 1980, Polikoff requested the appointment of a receiver to implement the scattered site program. This request was denied in 1980. In 1981, the Gautreaux case was assigned to a new judge, Marvin Aspen, who repeatedly accepted the CHA's arguments that the leadership turnover was responsible for the delays and pushed for the two sides to resolve their differences outside of court and without a receiver. Finally, the 1987 revelations of financial mismanagement that forced the resignation Robinson led HUD to strongly suggest that the CHA consider hiring a private management firm. Eventually, faced with enormous maintenance and new construction obligations, a lack of funds for these programs, and hoping to stave off direct HUD, Mayor Washington chose to support a receiver for CHA's scattered site program. The costs of more drastic changes (i.e. allowing HUD to take over the CHA) were judged to be too high in political and financial terms, but also, for the first time, in terms of the number of jobs that might be lost through a major reconfiguration of the program.

In May 1987, the Habitat Company was named by Judge Aspen as receiver. As receiver, Habitat was empowered to oversee the scattered-site program including "all CHA non-elderly public housing development programs which may in the future be authorized by HUD" while the Gautreaux decision remained in effect (*Gautreaux v Pierce and Chicago Housing Authority* 1987, 2). Thus all new family public housing construction in Chicago became the responsibility of the Habitat Company while

jurisdiction over senior public housing buildings and over rehabilitation remained under CHA control. Over the next five years, the Habitat Company would do little more than the CHA to expand the supply of public housing or encourage integration. Again, decisive change was avoided through the addition of a new institutional arrangement that had little immediate impact on the overall trajectory of the program. Yet, as with earlier adjustments made to preserve the existing system, these new institutional arrangements only prolonged the inevitable critical juncture and would eventually complicate later path shaping efforts when that juncture did arrive.

3.3. Critical Juncture

The period between 1989 and 1999 appears to encapsulate a 'policy window' (Kingdon 1995) during which Chicago's public housing program was reshaped after three decades of inertia and before settling back into a new period of relative stability. As the previous section described, this was not the first time Chicago's public housing program was under pressure to change. Chicago's public housing program eventually collapsed under the weight of a combination of different pressures during this critical juncture. However, while the previous path was abandoned, the past choices, particularly those made to sustain the path in the face of previous pressures to change, narrowed the set of options that could be considered and increased the costs to certain groups of alternatives to these options. This section describes the arrival of the critical juncture and the forces that precipitated it.

Chicago's public housing had been built in areas of the City that were previously considered slums. The choice to locate public housing in these areas was a choice that satisfied both the housing reformers in charge of the CHA during its formative years that wanted to remove Chicago's slums and aldermen that preferred public housing in the least desirable sites for development, far away from the City's white wards. The design of the buildings also represented a compromise that was, at least initially, supported by both groups. However, these decisions led to maintenance problems brought on by the size and design, little interest from non-poor families in living in public housing, and little interest from politicians in fixing the problems. The decline of Chicago's public housing was self-reinforcing: growing maintenance issues confounded management and poor management led to more maintenance issues. Chicago's public housing became deteriorated concentrations of poverty and crime, an image popularized in media reports and books such as Alex Kotlowitz's *There Are No Children Here*. Eventually the deterioration and mismanagement reached a point at which the status quo could no longer be tolerated or ignored. Beginning in 1986 with a plan for redeveloping the vacant of Lakefront Homes, advanced by prominent local developer Ferd Kramer, Chicago's public housing projects faced mounting pressure for redevelopment. As interest in reorganizing and redeveloping public housing grew among local elites in the early-1990s, Chicago's public housing stock was so physically dilapidated and

symbolically reviled that it was relatively easy to argue that drastic change was necessary. Further, when the federal government mandated an assessment of the viability of all of Chicago's public housing stock in 1996, nearly 18,000 units failed, meaning that they *had* to be demolished. The decisions made during the first decades of Chicago's public housing program had a cumulative effect that, by the 1990s, meant both the literal and figurative cost of keeping Chicago's existing public housing complexes had become too high. Even Vince Lane, who had initially favored rehabilitating existing buildings into mixed-income complexes, eventually accepted redevelopment.

Second, as noted above, much of Chicago's public housing was built in areas formerly considered slums. Chicago's historic pattern of development outward from the central area meant that the oldest residential neighborhoods – the areas considered slums – were located very near the city's core. Thus, many of Chicago's public housing complexes were located in a ring around the City's central business district, the Loop. The decision to locate Chicago's public housing in these areas had the consequence that, fifty years later, these complexes were located directly in the path of the City's revitalized and growing Loop. Thus the redevelopment of public housing is consistent with the ongoing redevelopment of Chicago's core neighborhoods. The growth of the Loop was a result of the City's changing economy as well as political changes made in response to these changes. Even as Chicago continued to lose manufacturing jobs for the preceding several decades, during the 1980s the City began to add service jobs. These jobs were concentrated in the Loop, spurring a prolonged period of new office, retail and residential construction. Eventually, the demand for space in the Loop exceeded supply and development spilled over into adjacent areas. When Mayor Richard M. Daley took office in 1989, he instituted policies that continued and enhanced this pattern of development, and which appear to reflect, in part, recognition of Chicago's changing economy and, in part, a politically motivated choice. The initial investments in downtown infrastructure made immediately after Daley's election were chosen both to appease the business interests that helped him get elected and to appeal to Chicago's residents and visitors. These Loopcentric, pro-development policies proved popular with Chicago's voters and created a positive feedback loop that then reinforced these policies. In the mid-1990s this path collided with the path of Chicago's public housing. Sustaining both was considered infeasible. Suddenly the calculation of the relative costs and benefits of maintaining the trajectory of Chicago's public housing program was flipped. The costs of keeping the program now dramatically outweighed the costs of changing it. Further, public housing reorganization and redevelopment, as it has been implemented in Chicago, works because it is consistent with the Daley administration's broad, and popular, strategy that favors enhancing the city's image and tax base through civic beautification, public safety, gentrification, consumption and development. Moore (1986) argues that ideas are more likely to be brought into practice if they demonstrate consistency with established practices, and, indeed, the Daley administration's approach

to public housing redevelopment is remarkably consistent with its approach to all redevelopment.

In June 1988, after the resignation of yet another executive director, Mayor Eugene Sawyer appointed Vincent Lane as executive director of the CHA. When Lane assumed control of the CHA, approximately one sixth of all units were vacant. Years of no maintenance meant that many of these units were uninhabitable. One quarter of the elevators in the CHA's high-rise buildings were non-functional, and Lane lacked financial reserves with which to address maintenance backlogs (Flaherty 1989). Under Lane the CHA began to slowly remedy existing maintenance issues, conducting crime prevention sweeps of Chicago's projects, and lobbying HUD for flexibility to pursue income mixing; however, despite his initial position in favor of fixing public housing, he eventually became an advocate of demolition and redevelopment. Lane explained his reversal as a realization that high-rise public housing could not be saved, claiming as evidence several high profile incidents involving Chicago's high-rises. However, Mary Pattillo (2007) notes that Lane's circle of close friends and associates included several developers who were strong advocates of demolition and redevelopment and he was apparently influenced by their views. These include Alison Davis and Ferd Kramer, both of whom would later be involved in redevelopment efforts at one or more public housing site.

Changes at the national level brought about by the election of a Republican Congress in 1994 and the subsequent threat to dismantle HUD completely, created an opportunity for major reform of public housing generally and Chicago's public housing in particular. New sources of funding and greater flexibility to pursue comprehensive redevelopment of public housing was made available through the HOPE VI program. This removed or at least reduced the constraint on change presented by federal funding and regulation.

Perhaps more significant still was the election of Richard M. Daley, the son of former Mayor Richard J. Daley, as mayor of Chicago in 1989. Daley narrowly defeated the incumbent Mayor Eugene Sawyer, who was appointed after Harold Washington's death, along with three other candidates in the Democratic primary in a vote that largely split along racial lines. Daley went on to defeat Harold Washington Party candidate, 4th Ward Alderman Timothy Evans and Republican Party candidate, 10th Ward Alderman Edward Vrdolyak in the general election. Again, this vote vote was largely split based on race. Daley was elected based on his image as a competent administrator. Washington had had an acrimonious relationship with the City Council during his tenure – his first term was marked by the so called "Council Wars" in which the remnants of the Democratic political machine attempted to block all of Washington's major initiatives – and Daley appealed to voters' desire for stability and action (McCarron 1989). Daley had been elected despite drawing only about 6 percent of the black vote and could conceivably have won reelection without any black support. While he did

make overtures to Chicago's black communities, unlike previous mayors, he was not reliant on public housing residents as a major voting block (Dold and Hardy 1989). Thus, Mayor Daley, rather than attempting to shield Chicago's public housing program from another federal takeover threat, chose to embrace it instead. Unlike previous Chicago politicians, Mayor Daley had no vested interest and drew no power from Chicago's public housing program. Quite the contrary, the existing program was a major potential impediment to his source of power and popularity, the expansion of Chicago's middle class neighborhoods and Loop.

3.4. Setting a New Path

Throughout its history pre-1990, Chicago's public housing program and its powerful supporters had continued to resist comprehensive reforms. The program had repeatedly faced pressure to abandon the status quo brought on by social, economic or political changes. Instead of yielding, when faced with negative feedback that encouraged abandoning the old path and forging a new one, the CHA and the City repeatedly opted to create new institutional structures to that would neutralize the negative feedback, maintain the existing system and push any changes further into the future. In the estimation of those with the power to change the trajectory of Chicago's public housing program, the costs of changing the path to their own political power and to the city in terms of civil service jobs as well as the actual financial costs of altering the physical stock were simply too great. By the time HUD took over the CHA in 1995 minor corrections such as the appointment of the receiver had, as Hunt (2009, 257) observes, "closed off possibilities for policymakers and left only the option of drastic measures."

During the 1990s Chicago's public housing program was remade through concurrent efforts to assemble coalitions to create and implement redevelopment plans at multiple public housing sites and citywide efforts to reorganize and restructure the CHA. These efforts were shaped and constrained by the institutional structures that were inherited from the previous era. Initial attempts by first the CHA and then the CHA (under HUD control) and City to impose restructuring and redevelopment plans on the City's public housing failed because of these institutional structures. Repeatedly throughout the planning process, a group of actors attempted to move forward with redevelopment, and repeatedly these efforts were stymied by the entrance of a new actor with the power to impede implementation, power that derived from the institutions and institutional structures put in place during the preceding thirty years in order to maintain the previous path. Over the course of the coalition building process, the participants first made visible the layers of institutions and institutional structures that constrained the trajectory of the Chicago's public housing program. Each time a new layer of sedimentation that impeded agreement upon and implementation of a redevelopment plan was discovered, it had to be lifted away. The process of peeling away the institutions and institutional

structures that impeded redevelopment continued until a coalition of actors was assembled with the power to successfully proceed.

At each public housing redevelopment site throughout the city coalitions were formed, often after raucous battles. Each member of the coalition planning and implementing redevelopment brought power to resolve a specific problem or complete a specific task. Some were the result of prevailing economic and political forces acting at a national or international level. For example, developers were necessary to provide financial backing for and build the proposed developments. The CHA was necessary to secure demolition grants and oversee relocation and social services. However, the participation of many actors was necessitated by the left over institutional structures from the previous path. The Gautreaux plaintiffs' counsel was necessary to secure court approval for redevelopment. This was only necessary because the requirements of the original consent decree had not yet been met as the choice had been made to preserve the status quo rather than build integrated projects. The Habitat Co. was necessary to build new public housing units, a direct result of the choice to allow the appointment of a receiver in 1987 in order to avoid more dramatic restructuring through a HUD takeover. Residents, through their LACs and the CAC, established as a cooption mechanism to neuter resident demands during the 1970s, were also necessary participants. This, then, explained the odd makeup of the coalition that was assembled to oversee the restructuring and redevelopment of Chicago's public housing. It was a direct result of the steps taken between the 1950s and 1990s by those in power to preserve the path of Chicago's public housing program for their benefit.

Beyond the organization of the coalition, the initial decisions to pursue large-scale, high-rise developments in segregated neighborhoods also constrained the choices available during the policy window. The path of Chicago's public housing program prior to the 1990s had left projects that were no longer viable even with improved maintenance. The decline of Chicago's public housing had been self-reinforcing: growing maintenance issues confounded management and poor management led to more maintenance issues. Eventually the deterioration and mismanagement reached a point at which the status quo could no longer be tolerated or ignored, and, when interest in reorganizing and redeveloping public housing grew among local elites in the early-1990s, Chicago's public housing stock was so physically dilapidated and symbolically reviled that it was nearly impossible to argue that anything other than drastic change was necessary. Further, when the federal government mandated an assessment of the viability of all of Chicago's public housing stock in 1996, nearly 18,000 units failed, meaning that they *had* to be demolished. The decisions made during the first decades of Chicago's public housing program had a cumulative effect that, by the 1990s, both the literal and figurative cost of keeping Chicago's existing public housing complexes had become too high. Even Vince Lane, who had initially favored rehabilitating existing buildings into mixed-income complexes, eventually accepted redevelopment.

4. Conclusions

For a little more than three decades from the 1950s to the 1990s, Chicago's public housing program followed a path that to most observers was blatantly unjust and inefficient. The buildings were isolated, segregated and poorly designed and maintained and the organization was ineffective, bloated and poorly managed. Yet no steps were taken to change this by any with the authority to actually affect change. Instead, when faced with external pressure to change, steps were taken to bolster the existing program. This inertia is not surprising. Pierson (2000) has illustrated that institutions and public policies, once established, tend to be self-reinforcing by establishing patterns of relationships and behavior that are not easily altered. In the case of Chicago's public housing, local elites were deeply politically invested in the existing program. Public housing residents represented a significant and captive voting block for a group of powerful, black Aldermen. The CHA represented a significant employer of black civil servants and a landing spot for patronage hires. In addition, federal regulations governing public housing made reorganization and redevelopment nearly impossible by requiring replacement of demolished units, prohibiting mixed-financing arrangements and limiting the use of modernization funds. Finally, with the exception of Cabrini-Green, there was little incentive to reconfigure public housing into the 1980s as development in the Chicago region was occurring either in the Loop or in the suburbs. There were other costs as well. The cost in time and political capital necessary to change federal laws and rules governing public housing was simply too large, particularly when public housing had such a small and relatively powerless constituency.

For planning practice, this case offers some useful lessons. Most importantly, the history of institutions, actors and places matters in the crafting and implementation of new policies and plans. Planners and policy makers do not start with a blank slate, but begin with the accumulated sedimentation of existing policies, plans, procedures and places. Certain events, some of which may have occurred in a quite distant past, play a crucial role in creating new plans. Understanding the history and context of a plan or program, and in particular why a plan or program has persisted over a long period of time, can help planners to better understand how to change it. This can also better identify what constraints exist or what historical institutional structures need to be addressed in order for a new plan to be established and implemented. If one knows how stability is maintained, who is invested, how power is exerted, coalitions constructed and agendas set this can provide opportunities for change. This case also suggests that, if processes, even inefficient or unjust processes, tend to persist rather than change, then conflict can be good. It can produce negative feedback and reduce the value of particular courses of action to produce change. Negative feedback and conflict eventually led to window of opportunity to change. Lawsuits and protests and media campaigns, while they were resisted by those benefitting from Chicago's public housing

program for some time, eventually helped create moment of change. Finally, events around (including preceding and immediately following) a critical juncture are crucial – this suggests that planners need to have a vision of what should be put into practice.

This case also provides some useful lessons for planning scholarship. Studying the historic path of a plan or a program is useful because it allows a researcher to unpack dynamic processes as they unfold over time and to better understand the historical antecedents of a particular policy. As this case demonstrates, there may be significant temporal distance between causes and effects. Decisions made at the outset of Chicago's public housing program had enormous ramifications fifty years later. Focusing on singular events or those with short time frames may erroneously lead to conclusions and generalizations that are really idiosyncratic or contingent while missing crucial contextual and historical factors which may be causal. This is an argument in favor of longitudinal studies, of panel studies and of evolution over time rather than one-off studies. Some outcomes are the result of a sequence of events that happened over a long period of time. Finally, as with practice, it is important for planning to have a coherent theoretical and conceptual justification and vision. Policy windows may open only infrequently, and it is important for planning to have a position in order to be able to influence decision-making rather than simply observing from afar.

IDEOLOGICAL MIS-DIRECTION: IRANIAN LOW INCOME HOUSING POLICY OR SURFING PLEBIAN EMOTIONS

Elham BahmanTeymouri [1]

Abstract

This paper will explore social housing policy in Iran and attempt to illuminate the ideology underlying and facilitating these policies and the consequences that they induce. Ideology is as an essential and universal essence, it constitutes a society's social reality (Žižek 2008). Any dominant ideology produces a series of fantasies that partially shapes the way its members contextualize knowledge, the economy, society, and obviously planning (Gunder, 2010). For instance, the egalitarian creeds underlying social housing are imbedded in a fantasy promise of addressing a deficiency, such as "better life for low income groups" or "the right of people to possess housing commensurate with their needs", which also appears in constitutional laws, rules and policies of the state. Yet, this paper contends, following Gunder and Hillier (2009), that these policies and laws tend not only to, fail to achieve success, but also to often ignore and obscure other humanistic needs and democratic demands. In this vein, the attractiveness of housing and its related land policies make housing one of the most effective tool of popular domination (Laclau, 2005). Accordingly, governmental housing policy is often one of the most important tools for the manipulation of mass movements. This paper attempts to demonstrate, in an Iranian context, three main issues: first, the fact that housing policies based on the promise of egalitarian achievement can act as a hindrance to citizen rights and democratic demands. Second, housing policy can act as a political tool, which reproduces the dominant ideology, and third, as technocrats, planners facilitate the use of these populist and ideologically inducing policies.

In more democratic and modern societies, the function of planning is a complementary to the market; however, in a non-democratic, reactionary and dictatorial populist system, the role of planning changes to become the actual distributor of public goods and services; this is sometimes at odds with democratic demand. In the shadow of this egalitarian rhetoric, populist policies are used to create the mass movements of government support and to legitimize decisions that have been made. The paper will demonstrate that the consequences of these policies are that over the thirty year period of the current Iranian regime, a consolidation of capital has occurred drawing accumulation from the wealthy and middle classes to the central government. This has hindered private investment in housing and the pertinent related industries, further increasing dependency on, and support for the current regime by the masses. In this regard, the policy inherently impedes the

[1]The University of Auckland, Auckland, New Zealand – ebah488@aucklanduni.ac.nz

formation of social and economic market mechanisms to meet the needs of the populace and further reinforces dependence on, and support for the regime.

1-Introduction

This paper argues that a dominant ideology frames all of our ideals and ideas. Ideology identifies our action as planners. It discusses how ideological creeds structure society's norms, ideals, expectations, and finally, policies and planning. Based on Althusserian's understanding of ideology, ideology encompasses all aspects of our social life. It includes 'more or less all unconscious medium of habitual behaviors' (Payne & Barbera, 2010, p. 340). It can be considered in planning as well, Gunder (2010) contends that planning always has an ideological component which largely reflects the dominant ideology of the time. He emphasizes that, in the current world, this ideology is causing the evolution of capitalist market. In fact, it is not only capitalism but also every hegemonic ideology that can drive the mechanism of society and planning.

However, Yates (cited in Allmendinger & Gunder, 2005) mentioned that 'environment of policy making and the character of urban problems determine the shape of urban policy'. Based on Foucault's works (1979b, 1992, 2002, 2008), this paper argues that power and power relations determine both the environment of policy and the character of urban problems. Dominant power and hegemonic ideology are the different names for the same mechanism (Carpentier, 2011). Hegemonic ideology may be seen as having core concepts and peripheral concepts; the importance of concepts has changed over time. At times, some concepts are borrowed from other ideologies to provide the aims of power (Freeden, 2003). Therefore, power, through a hegemonic ideology in a specific space and time, identifies and codifies everything. Where are the planner and the planning in this hegemonic ideology? As Gunder (1999, 2010) stated, planners work for the desire of the Other (power). The desire of the big Other (power) appears in the form of laws, policies and planning. Actually, planning and policies provide the best tools for power according to the modern interpretation of power that is the state or bureaucratic government. Specifically, planning in less democratic mechanisms has provided better apparatuses to legitimize power or dominant ideology.

One of the oldest questions in politics is how those in power are able to maintain their rule over those they oppress. According to many political theories, there are four ways for power to reproduce itself (Hume & Hendel, 1953; Machiavelli, 1961). The first is through charismatic power, which uses rhetorical speech, promises and discourses to attract people and masses. The second is providing for people's needs; dependent people accept oppression more easily than those who are independent. The third way is through populist policies that include emotive slogans such as, "we give people whatever they want". Finally, the traditional and easiest way for power to be reproduced is through the military, the police force, and by the use of threats to the populace. As Foucault (1979a) stated, in the modern world, the punishment of the body has changed to more modern methods and mechanisms such as: policies, fines

and the use of media. Indeed, the forces of power may be using more than one of these tools at the same time.

This paper deploys a Lacanian approach to explain how housing policy, as one of power's (Other) apparatus – repressive government – is used to reproduce and sustain the dominant ideology and to oppress demands for civilization rights. This paper analyses public housing, or low-income housing policybased on Islamic egalitarian ideology and populist interpretations of it in Iran. The main concern is a particular type of public housing 'Maskan Mehr'. This recent policies have reverted to the first years of the revolution. The policies have a radical, Islamic approach, egalitarian and anti-elitism ideologies determine all policies and decisions. The paper will try to explain how these ideologies, as fantasy, encompass all reality and how planners as agents of power work to shape this fantasy for all society.

In this regard, I try to answer four questions:

- How does a dominant ideology shape and encircle policies in planning?
- What is the role of the actors, including planners, and who affected by these policies?
- What are the populist policies?
- What are the functions and consequences of these policies?

2- Dominant ideology and planning

> *Ideology... is indispensable in any society if men are to be formed, transformed and equipped to respond to the demands of their conditions of existence.* (Althusser cited in Eagleton, 2007, p. 150)

According to McLellan (1986) ideology is the most elusive and very essential contested concept in social science. As Žižek (2008) implied that the very elementary definition of ideology goes back to Marx. Orthodox Marxism believed that ruling class-interests determine and justify ideology; consequently, ideology, as a dominant ideology, integrates superstructures (law, political systems, religion). Orthodox Marxism denotes negative meanings in ideology such as misrecognition, distorted representation, false consciousness, commodity fetishism. Marx'(1946) famous quotation describes his concept of ideology: "They don't know it, but they are doing it." Therefore, ideology is merely presented as an epiphenomenal illusion to be dispelled by positive science. Later, Marxism is criticized because it conceives that the human mind spontaneously misrepresents the external objects presented to sense experience. Althusser elaborated the notion of ideology, which Marx had initiated and Gramsci had developed. However, he was greatly influenced by Lacan (Gunder, 2010). In fact, an articulation between Marxism and psychoanalysis provided a materialist account of how subjects were constituted in, and by, Ideology. In relation to this, Lacan with Althusser and Foucault made a triple alliance, the common denominator being their theoretical anti-humanism (Payne & Barbera, 2010). Namely, anti-humanism rejects autonomous subjects. Humans should not be

considered as individuals. The human as a subject is a part of a chain, the chain of society. Althusser believed that there would no ‘end of ideology’. ‘Ideology would persist, both because of the ineliminable opacity of the deep structures of any conceivable Social formation and because human beings were not the rational animals of pre-Freudian liberal humanism. (Payne & Barbera, 2010, p. 343)’.

As mentioned, oppressors cannot rule those they oppress merely by force, body punishment and the power of the police. Power cannot use police or army members to easily control a large population that unequivocally desires a change of regime. ‘Oppression can only be sustained if a substantial number of the oppressed come to hold beliefs that their oppressors’ rule are legitimate (Hume & Hendel, 1953, p. 18)’. Where does such this legitimation come from? How and from where power gains its legitimation. Althusser introduced a distinction between the repressive state apparatus (RSA) and ideological state apparatuses (ISAs). These two categories developed Gramsci's differentiation between coercion and consent. ‘Whereas the RSA operates by force, the ISAs- the family, schools, the mass media, etc. - function to reproduce existing relations of production by subjecting social classes to the dominant ideology (Payne & Barbera, 2010, p. 345)’. The fact is that, ideological state apparatuses configure our unconscious to accept the legitimation of power and the unconscious is Lacan’s most important concept in relation to ideology. We believe in dominant ideology, deeply. As Pascal stated (cited in Butler, et all, 2000, p. 118; Gunder & Hillier, 2004, p. 228), ‘if you do not believe, kneel down, act as if you believe, and belief will come by itself’, Not only do we have to, but also we spontaneously welcome the values, norms and rules of dominant ideology.

Freeden (cited in Gunder, 2010) believes that Lacanian approaches provide a new way of critic toward ideology. The core of Lacanian approach of ideology is the impossibility of escaping from ideology and of not being subjected to it. There is ‘no utopia, no solution just awareness’. We move from one ideology to another ‘perhaps we can make an ideology that does not dehumanize those who hold it’ (Gunder, 2010, p. 308). ‘Lacan described the unconscious as a discourse: the unconscious is the discourse of Other’ (Evans, 1996, p. 219). According to Lacan, the Other must first of all be considered as a locus, a locus in which discourse is constituted. Therefore, Other as a government, market interest, ruler, law-making institution or decision-making institution, takes this locus. Accordingly, planning as an apparatus of government/state (Other), plays the role of assistant for it. Pursuant to Gander (2010, p. 305) planning is a facilitator for the state to ‘normalize and internalize the dominant logic of state in the minds and bodies of citizens, so that planning is integral to governmentality and is an important ideological state apparatus’.

On the other hand, based on Lacanian psychoanalytical theory (Allmendinger & Gunder, 2005; Gunder, 2011), ideology defines and works based on ‘lack’ or ‘deficiency’. It works as a fantasy to fill this lack. As Laclau (2005) illustrated, the identification of a lack such as inequality, insecurity, etc. needs a solution. The solution frames a necessary specific ideology. ‘The ideological articulation of the solution provides an emotive and powerful political tool for the implementation and desirous materialization of public planning policy’ (Stavrakakis cited in Gunder,

2010, p. 306). Therefore, planning and policies work to provide the desire of Other to fill its lack. In fact, planners work based on desire of Other (power or hegemonic ideology). As Gunder (2003, 2011) stated, policies have been made to fill the lack of Other. The fantasy of better life that housing policies provide specifically for poor people can support an egalitarian or justice-oriented ideology for a government. According to the Žižekian interpretation of ideology 'it is a fantasy-construction' or 'illusion which structures our effective, real social relations and thereby masks some insupportable, real, impossible kernel (Žižek 2008, p. 45)'.

The main purpose behind a policy is adherence to one, or to a set of, existence ideologies through normative or prescriptive processes. These processes make central to politics the concept of ideologies. Implicitly every political or economic tendency entails an ideology. It is how society sees things. Therefore, ubiquitous ideology encompasses and identifies everything including planning policy, planners' responsibilities, their concerns and even people's expectations of planning.

Poverty is an economic problem in every society. Poor people live with the desire for a better life. They demand better houses, equality and wealth. In a society with a majority of poor, unemployed people who live in inappropriate houses, egalitarian creeds can be the best ideology to make movement amongst them. An ideological state based on egalitarian rhetoric, can easily free ride over this movement. Planning is the best apparatus to provide the fantasy of "better life for low income groups" or "the right of people to possess housing commensurate with their needs". However, planning as the ideological state apparatus takes a paradoxical position. It has to maintain deficiencies to maintain the hegemonic ideology. This mechanism will be developed in following section of this paper.

3- Political or apolitical planner: Nefarious planner

This section of the paper endeavours to define the profession of planner based on the two following concepts: firstly, the planner is a subject that works in the context of a hegemonic ideology whose profession is identified by the prevailing informal norms, values and laws. These characteristics are located in the field of Other, as Lacan said, in symbolic order. Secondly, the planner is a subject presumed to know. The planner (subject), unconsciously knows the consequences of his/her work (Žižek 2008). Specifically, he/she knows he have to accept his/her apolitical responsibility therefore, he/she masks this compulsion by being a professional. Planners know they cannot make a better life without political and radical intervention. In practice, they devise a fantasy to justify their inability. In other words, power defines an apolitical role for the professional planner- a semi engineer -to justify will to power. They know their plans cannot obliterate poverty in an ideology, which is supported by the poor. They have to mask their inability by scientific methods or diminish it to merely scientific failures; the mechanism will be explained in the next paragraphs.

Referring to the Lacanian attitude, the planner, in a hegemonic ideology, acts based on identification (Gunder & Hillier, 2004). How is this identification configured?

Based on the Lacanian notion, identity emerges through three stages: first, the mirror stage ‘this is where a child sees its image in reflection and commences to identify itself as the image in the mirror…it is a transformation that takes place in the subject when he assumes an image’. In fact, identification with images is the most important aspect of this stage. The mirror stage is followed by the imaginary stage. In this stage the identification with image continues. This image can be ‘the imaginary ‘other’’. In this stage, the subject realizes a permanent split between the self and the image. In fact, identification is never completed. On the other hand, the subject is always driven by a tragic desire for completeness and attempts to reunite with others. The third stage is the symbolic, in which the subject ‘socializes in to language, culture, informal norms and values and formal laws’ (Gunder & Hillier, 2004, p. 222). In this stage, the subject identifies with signifiers and Other.

In addition, according to Lacan, the subject is not simply equivalent to the conscious sense of agency. Consciousness is a mere illusion produced during the mirror stage. However, the subject is equivalent to the unconscious. Lacan stated that, ‘the subject is a subject only by virtue of his subjection to the field of the Other (Evans, 1996, p. 198)’. Therefore, the planner works in the field of Other or in hegemonic ideology and power. He/she must act in Other’s field and be responsible toward his/her actions. Therefore, the planner, as a subject, identifies her/himself in accordance with the law, the employer and the norms and values which the dominant ideology defines for everyone, including planners.

One of the most useful of Lacanian topic discussions is ‘Science and Truth’ (Fink, 2004, p. 855). He ‘criticized modern science (positivism) for ignoring the symbolic dimension-including; language, culture, the external identity of a signifier, informal norms, values and laws - of human existence and thus encouraging modern man to forget his subjectivity’ (Evans, 1996, p. 176). He also compared modern science to a ‘fully realized paranoia’, in the sense that its totalizing constructions resemble the architecture of a delusion’ (Evans, 1996, p. 176). Specifically, his critique points to positivism because he believed that it is a ‘deviation from true science’ (Evans, 1996, p. 176). Lacan argues that science is characterized by a particular relationship to truth. On the one hand, it illegitimately attempts to monopolize truth as its exclusive property. The modern human subject is a ‘subject of science’; a subject that has a mono rational a scientific route to knowledge; this is now a common presupposition (Fink, 2004).

Nevertheless, it is necessary to ask: What is the relationship between these Lacanian concepts and planning? Based on genealogy of planning, it emerged in the modern era with the objective of pacifying the side effects of modernism (specifically its industrial effects) and of interfering and intervening in modern urban space relations (including those of society, the economy, state and power relations, amongst others.) (Allmendinger, 2009; Foucault, 1979b; Friedmann, 1987; Lefebvre, 1991). In fact, planning was created to facilitate market relations. Planning, as a product of the modern era, has the problem of modernism including; sing instrumental rationality to overcome social problems. Based on the Lacanian discussion in regard to science, which was mentioned in previous paragraph, a scientific approach illegitimately

monopolizes truth as its exclusive property. The rational scientific management of space dominates the field of planning. On the other hand, as Foucault (2002; Foucault & Rabinow, 1984) stated, power codifies and identifies knowledge. The dominant ideology needs apolitical professionals who provide, without question, the right apparatus for the political implementation of laws, plans and decisions. Professionals should accept and enjoy their role. As Žižek (2008, p. 49) stated an ideology can hold us only 'when we do not feel any opposition between it and reality- that is, when the ideology succeeds in determining the mode of our everyday experience of reality itself'.

The everyday life experience of planning is revealed in its visual representation in structures, in cities, highways, buildings and shapes. The everyday life of planning provides a fantasy of beautiful buildings, high-rise structures, affordable houses and beautiful roads accompanied happy and satisfied people who can gain whatever they want or they need. Both the planners and citizens enjoy that fantasy. Such fantasies take the place of real demands and relations and change the motivation of planner's function. Therefore, they find themselves in a prevailing environment and in a specific frame in which they can act and work easily, enjoyably and indisputably. Planners in theory and practice generally misinterpret the symptoms. Planning deploys scientific and technocratic approaches instead of finding the underlying causes of socio-cultural problems.

4- Populism as an ideology or a policy

Populism can be defined as an ideology of political philosophy. The Cambridge dictionary (2008, p. 1100) defines populism as: 'political ideas and activities that are intended to represent ordinary people's needs and wishes'. Ernesto Laclau (2005) made a profound study of the concept of populism and its characteristics. He gave a broad explanation of populism through a genealogy of the way in which it works and how it shapes the space of policies and politics. He stated that the vagueness and indeterminacy of populism is not its weakness but it is the sign of inscribed vagueness and indeterminacy in social reality. According to Laclau's opinion, populism is the 'royal road' to understanding something about the ontological constitution of political issues and devices. Therefore, populism is 'one way of constituting the very unity of the group (Laclau, 2005, p. 73)'. However, it is not the only way of accomplishing it.

I endeavor to develop Laclau's notion populist configuration in order to apply it to the Iran case. According to Laclau, an unsatisfied demand is a precondition of populist configuration. The demand or a series of demands have been shaped based on a difference. The social logic of difference makes an internal antagonistic frontier separating the people from the power. In the next step, 'an equivalential articulation of demands makes the emergence of the people possible (Laclau, 2005, p. 74)'. Finally, the third step is a unification of these various demands. The third step can come in the form of a hero, a charismatic leader or even a popular president. The

logic of populism is interesting. ‘Equivalence does not attempt to eliminate differences. If the particularity of demands disappears, there is no ground for equivalence (Laclau, 2005, p. 79)’. In fact, the functions of difference and equivalence are related to each other. In a spiral movement, they reproduce each other and the existence of difference relies on the existence of equivalence. Therefore, populism needs that particular demand or difference to continue working. If populism has been configured based on the demand for equality and justice, it needs continuous poverty and inequality to survive.

For instance, in a society with a large mass of agrarian migrants who live in informal settlements in marginal areas of big industrial cities, living in poverty in unqualified housing; obviously, these people will demand better housing. This demand can be the starting point of a populist movement. The demand for better houses and public services establishes an equivalential relationship between masses. Every claim based on the provision of better life and housing and services can be an emotive factor in absorbing them in a new charismatic power.

Laclau implied that there are three important aspects in the construction of social and political identity. ‘The relationship between words and images, the predominance of the emotive over rational the sense of omnipotence, the suggestibility and the identification with the leaders are all too real features of collective behavior (Laclau, 2005, 39)’. Thus, words and rhetoric can help to construct a fantasy and a kind of image for the crowd. Thereupon, rhetoric has been ancillary to the classical ontology of populism. This fantasy acts as a ‘means to simplify the anxiety inducing complexity and apparent inconsistence of reality so that social reality appears as a coherent materialized, yet simplified (Gunder, 2012)’.

In fact, distinguishing the populist policies and the results of them is not difficult. Populist policies emphasize some of most important needs of people and appear to give people whatever they want. People think, that their demands will come true through the provision of images through populist devices. People find their demands in the words of their leaders. Notwithstanding populist policies succeed in providing satisfaction because they respond to some parts of the desires of the supporting group. These policies render as the movement of masses who have not experienced political movements. As a result, the people think they have proper rights to determine their taste, needs and rights. The very best example of this is the current situation in the United States of America. Many thinkers have criticized American culture because they believe it has become more populist although, superficially, it appear to be more democratic (Strinati, 2004).

In fact, differing demands, as the basic principles of a populist movement, exist in every society and thus populism can be configured in a wide political spectrum from left wing to right wing. Populism sometimes appears in the form of elitism, or, at other times, as anti-elitism or National Socialism, such as in Nazism. It tries to provide the desires and demands of the masses. As mentioned in previous sections of the paper, planning is one of the hegemonic ideology/power’s forms of apparatus. Hegemonic ideology defines and codifies planning’s responsibilities to reproduce

that ideology. Planning - including housing policy and the distribution of public services and goods – provides policies to respond to the demands of the people. Populist ideology, as a hegemonic ideology, easily codifies planning to provide the fantasy of satisfaction of demands. Undoubtedly, planning is the best apparatus to promise a better life for the masses and to respond to their demands. Therefore, Planning can be the best apparatus to assist power in maintaining itself.

5- Low-income Housing policies: fantasy or reality

Iran is a developing country; a producer of raw oil that is led by a regime whose ideology stems from the Islamic Revolution. In Iran, planning application is predicated on two processes. Firstly, there is a politico-rational process, where by the preliminary and final decisions made by government authorities and institutions even the supreme leader. This level frames all policies, rules and laws. The second process is a techno-rational one in which plans and projects are made based on supreme plans. These techno-rational processes use GIS, maps, modeling, technics and statistics to collect and analyse data. In some local action plans or projects, professionals in governmental sectors and consulting companies use the partnership of private sector to provide financial aid. They legitimate and justify the first decisions and follow the first line in their plans and projects. Obviously, power or hegemonic ideology defines and dictates all the lines and policies in the planning and, the planner, as an agent operates consistently within the supreme frame.

After oil, Iran's construction industry is one of the most important industries in the country. Housing policy has been one of the most important tools of planning. During the three most recent decades, three different policies, including those of; urban land supply; financial policies and social housing, have been applied in Iran. This paper will survey only the last one, 'public housing'. Islamic egalitarian ideology and populist interpretation of the notion of private in Islam such as 'brotherhood', 'unity', 'equality', postulated the ideology of post-revolutionary planning in Iran (Valibeigi, 1993). As has occurred in other developing countries, Iran has faced huge migrations to big cities and informal settlements. In fact, planning faces expanded urban poverty. The population of informal settlements is estimated to be about 10-12 million people living on the outskirts of cities. On the other hand, there was a baby boom in the first years of the revolution. After 30 years the 'baby boomers' have become young people who demand jobs, housing and facilities. Official statistics reveals that Iranian cities have experienced a serious growth in the population of young couples who have a high demand for affordable housing. However, many people cannot afford appropriate housing due to expanding unemployment, the high price of housing and the increasing demands for accommodation. In addition, a house is a kind of investment for an Iranian family. People have the tendency to buy and own their own homes.

Based on what it mentioned in the definition of populism, a crucial demand has been configured: the demand for housing. It was timed to coincide with the third policy

period between the years 2005 and 2009 started with the presidency of President Ahmadinejad. The main concern of this period is a certain type of public housing 'Maskan Mehr'. The policies in this period turned back to those of the first years of the revolution. Radical Islamic approaches, egalitarian and anti-elitism ideologies determined all policies and decisions. Thus, the main rhetorical ideology of the revolutionary Iranian government re-postulated most of its policies and plans, including intended equality and wealth for the poor. However, after more than thirty years, many surveys have concluded that none of those pro-poor policies have achieved their claims (Saeidi, 2001; Salehi-Isfahani, 2009). Even the many governmental surveys have revealed many failures as a result of the plans and policies. In fact, most of policies have merely transformed rural poverty to urban poverty, squeezed the middle class and reproduced the prevailing power relations; and finally, have led to the suppression of other demands in the political domain (Milani & McFaul, 2008-2009). Nonetheless, the current president of Iran started his presidency with some rhetoric promises such as arresting the corrupt previous authorities and managers, providing justice and equality. In this case, the populist leader would seek to mobilize the masses against the corrupt elite, regenerating the values and norms of first year of revolution by redistribution of wealth (Dodson & Dorraj, 2008). Many planners have unofficially criticized policy because they believe the current policy has diminished the whole of the planning system to being solely that of a housing policy, or even just a project.

Indeed, a supreme housing policy was imposed upon all of the province's organizations and companies. People, both the poor and the wealthy one rushed to specified centers of registration. Housing institutions registered 4,234,766 people. However, after about 7 years, official statistics announced that only 946,890 people have the appropriate criteria for getting public housing. Many cases of infraction and infringement have been reported to the Ministry of Housing from different cities and provinces. Therefore, a special office has been established to deal with infractions and to supervise the projects in the various cities. The enacted law in relation to public housing specified a deadline for the officials; the establishment of the office was supposed to solve housing problems for Iran up until 2013. Many of the parliamentary representatives criticized the policy because they found it expensive and to be consuming their budget; in addition it still did not solve the problems of housing. As the first step of this policy, the government considered a 53 billion USD budget for public housing. But now, because of such things as, sanctions, stagnation and inflation, the government faces a budget deficiency. Therefore, it cannot provide the necessary credit for the plan. Many professionals have stated that the government needs 140 billion USD more than its primary estimate.

Moreover, because of hasty decision-making about the policy, many projects have been started on unsuitable land and planners have faced problems in providing infrastructure. For example, for the provision of water pipes for just three projects in Tehran requires 6 billion USD. In addition, people who have registered for public housing now need more personal finance to be able to their own homes, far more than first predicted. Nonetheless, the government had to cut in its budget in the 2012 New Year because of the deficiency and consequently, the public housing policy will

receive less credit than last year. To the contrary, when a journalist asked authorities about the future of policy, officials answered: ‘Maskan Mehr is not a governmental phenomenon, it is a popular plan of which the credit and budget is provided by the people; therefore, it is not necessary any governmental credit or budget for it’.

6- Conclusion

One of the most important effects of the above-mentioned policy in Iran was the agglomeration of all the considerations and implementations in the central government. In addition, all the processes of financial transformation and transaction for housing have to pass through government institutions. Indeed, these sorts of central policies make the government sector larger and diminish the private sector. Many private, individual, and micro-companies have been bankrupted in the favour of monopolic governmental sector. Finally, the mentioned policy has diminished the urban bourgeoisie - the social class that can provide the appropriate context of democratic demands. Inversely, the policy plumps up the mass who are dependent on central power at the same time as supporting power. However, the policy never eliminates poverty and lack of the housing; the policy is merely used as an apparatus of populism to get the support of the poor.

Unfortunately, when plans fail and are relinquished, planners search for fault in agencies or computation failure, they think that it is the fault of the professionals because they have made mistakes in calculations and in the technical aspects of plans. They try keeping on with the fantasy for themselves and continue to criticize plans by finding mistakes. However, the reality is that the policy worked in the best way, because it was not supposed to solve housing problems from the start. It was supposed to reproduce the power and impede democratic demands.

Multi-Location Recovery Planning in Japan

William J. Siembieda[1], Haili Chen[2], and Norio Maki[3]

Abstract

The Great East Japan Earthquake and Tsunami of March 11, 2011 was Japan's first multi-location disaster event in modern times resulting in over 16,000 deaths, severe economic and physical damage in Iwate, Miyagi and Fukushima prefectures and the release of radioactive material from a damaged nuclear reactor. This article examines how Japan has structured its recovery planning from this multi-location event. Three themes dominate the plans: ensuring safety, rebuilding lives, and expansion of technology and natural resource based industry. After one-year, all major infrastructure systems are working, debris disposal remains a challenge, and funding has begun to address housing, land use, economic, and safety needs. A mixed model of municipal and prefecture based proposals with central ministry oversight has emerged and the creation of a central government recovery agency. A partial strategy for the nuclear accident has emerged, but challenges remain for long-term stability.

Key Words
Risk reduction, Recovery, Governance, Multi-location Disaster, Nuclear Accident, Land-Use Planning, Tsunami, Tohoku

1.O Introduction

All large-scale disaster events present complex challenges in shaping a recovery strategy. Central governments must determine what is best for the survivors, for the region as an impacted economic area, and at times for the country as a whole. Prefectures (provincial governments) need to determine how to address needs of municipalities and people living outside of city limits. Municipal governments try and restart basic services, address safety needs, and help to get people working again. The survivors struggle to address loss of family, jobs, and community ties. This occurs in the historical context of the country and socio-economic context of the impacted region (Alesch and Siembieda 2011).

The Great East Japan Earthquake and Tsunami of March 2011 (known as 3/11) was Japan's first multi-location disaster event in modern times resulting in over 16,000 deaths, 330,000 destroyed or heavily damaged houses, severe damage to 32 coastal cities in three prefectures, and a release of radioactive material from a damaged nuclear plant.1 Ninety five percent of the deaths were tsunami related, and there were no

reported deaths due to radiation exposure. Table 1 provides a listing of selected damage indicators. Its intensity on the Japanese Meteorological Agency (JMA scale of 1-7) was 7 in Kurihara and Miyagi prefectures and 6 in 8 other prefectures. The tsunami that followed the seismic event and its aftershocks occurred over 530 km of coastline with a run-up level of 10m and above, the highest one in Ayasato Bay of 40m breaks record of the Meiji Sanriku Tsunami in 1896.2 Figure 1 shows the spatial extent of the tsunami inundation, and Figure 2 shows the primary towns in Iwate, Miyagi and Fukushima prefectures damaged by the earthquake and tsunami. Within Figure 2 is the chart of casualties and destroyed and heavily damaged buildings by municipality.

TABLE 1 Selected Casualty and Damages Categories

	Iwate Prefecture	Miyagi Prefecture	Fukushima Prefecture
Death/Missing [1)]	5,989	11,250	1,989
Building Damage [1)]	24,739	222,081	83,557
Inundation Area [2)] (building Infrastructure land use %)	58 Km^2 (37%)	327 Km^2 (23%)	112 Km2 (13%)
Economy Loss [3)]	257.3 billion (JPY)	7.39 trillion (JPY)	NA
Coastal Area Capital Loss Rate [4)]	47.3%	21.1%	11.9%
Evacuee at maximum [1)]	51,553 (2011,3,15)	320,885 (2011,3,14)	131,665 (2012,3,12)
Current evacuee [5)] (inside/outside Prefecture)	42,771 1,574	127,952 8,494	98,221 8,494

1.1 The Main Questions

How then did the three levels of government move forward to develop their recovery strategy? What are the components of the strategy? How well is it working after one year? This exploration in how Japan has fashioned its recovery strategy directs itself in part to the issue of centralization and decentralization in planning (Siembieda et al., 2012). Do the efficiencies of centralized systems outweigh the tendency of decentralization to be more diverse in addressing planning issues, or do decentralized approaches provide more humanistic outcomes simply because they are diverse and reflective of cultural variation?

1.2 Content of Sections

Section 2 describes the shaping of central government policy. Section 3 examines some aspects of the voluntary sector. Section 4 summarizes salient aspects of the prefecture and municipal recovery plans. Section 5 the outcomes of the first round of central government funding to the municipalities and prefectures. Section 6 provides a conclusion and discussion in terms of future actions based on the present strategy and the RA model.

1.3 Nuclear damage

Not since Chernobyl was there a nuclear accident like this. Reactors 1 and 4 of the Tokyo Electric Power Company (TEPCO) plant the Fukushima 1 plant had accidents related to their fuel cooling systems. Reactor 1 had a meltdown and spilled contaminated water into the Pacific Ocean and dispersed radioactive materials into the surrounding area that was mostly farmland and ocean.[3] The fact that there was an earthquake and then a tsunami in this area did not come as a surprise. The Japan National Earthquake Council's 2010 Annual Report stated that there was a 99% probability of an estimated 7.5 Mw event in the next 30 years in this area (Japanese Headquarters for Earthquake Research Promotion 2010).

This accident was classified as a 7, the highest level, on the international nuclear accident scale. This led to a temporary 30-kilometer evacuation area of around the reactor. Sixty thousand people were then cut off from their houses, work and fields. The temporary evacuation zone was later reduced to 20 km and has been declared by the central government as a restricted zone for the indefinite future. After one year residents along the zones edge have been allowed to visit their homes for short periods.

The ripple effect of this nuclear accident is extensive. The Prime Minister requested that all the 54 nuclear reactors in the country be shut down and inspected. All the companies compiled the central governments request and conducted inspections. No plant has been restarted, although requests have been made to do so prior to annual

increased summer demand for power. Shutting down of all the plants has called into question the nation's overall energy policy.

The restricted zone creates particular recovery challenges for recovery for land use, resettlement, livelihood, and health. Mayors of Namie, Futaba and Okuma towns in Fukushima prefecture have proposed new creation of "temporary towns" in adjacent cities, and the major of wishes to merge his town with that of the next town (Kyodo, 2012). Because the restricted zone is likely to span at least one generation, this form of resettlement becomes a permanent population shift within the region. Requests are being made to the government to exempt the residents of Namie Town for life from paying any medical costs. Figure 7 shows the locations of these towns that are partially included in the restricted nuclear zone.

1.4 A region with multiple municipalities

This is a multiple location disaster with major impact in three prefectures (total population 5.67 million) containing over two hundred municipalities, only three have populations of more than 100,000. Prior to 3/11 the region was loosing population and faced economic challenges in many business sectors. The recovery challenge is not one of restoration of prior buildings and infrastructure, but how to address the population decline, radiation exposure, and loss of employment in many towns. Fishing, a major employer in small coastal towns has begun a slow recovery as boats are replaced and fishing areas reestablished. The development planning challenge, as recognized by the Reconstruction Design Council Report (2011) is how to bring this region forward during a period of rethinking Japan's future.

2.0 Shaping of Central Government Policy

The central government has shaped its recovery policy in three phases: the Disaster Headquarters period, (months 1-3); the Recovery Headquarters (months 4-10); and the Reconstruction Agency (month 11 onward). While a Disaster Headquarters was established in the Office of the Prime Minister on 3/11 there also was an effort to provide a broader strategy for recovery. After three months there was a report to the Prime Minister laying out seven principles that link the recovery of the region to the nations economic well being (Reconstruction Design Council 2011).[4] The report sets out the concept of "disaster reduction" as a central tenant in reconstruction planning and includes "people-oriented measures" as well as structural (hard built) measures. The local people then become part of disaster reduction process, not separate from it. This is a form of collective action to reduce vulnerability. Also called for is a "New Public Commons" where a wide range of actors could the included in the reconstruction process. This is an attempt to broaden the decision-making base for recovery, something learned from the Great Hanshin Awaji (Kobe) Earthquake experience of 1995. The Report calls for reconstruction planning to utilize a strategy of multiple defenses rather than lines of defense (the existing approach) and to place this concept into the Building Standards Act. If placed in the law it would then require local governments to make plans in such a manner.

A fundamental principle is that the main actors should the municipalities themselves. The role of the national government is to set overall policy, provide a vision, and provide financial, human resources and knowledge as needed. The national government, it is suggested, shall take prime responsibility for resolution of the nuclear accident at the TEPCO Daiichi reactor. Most of what this Report suggests has become reality, through the dual-level governance model finally put in place. This duality is not one of equal influence as the ministries set the rules by which the municipalities are required to follow. This report was given to Prime Minister Kan in month three (June) and by month nine (September) Mr. Noda (from the same party) became Prime Minister. During this time there was a Disaster Headquarters in charge of the recovery effort.

Four months after the event the Disaster Headquarters issued a “Basic Guidelines” document setting out the central government strategy to implement the Basic Act on Great East Japan Earthquake Reconstruction (Law No. 76, 2011). This strategy closely followed the Design Council Report, and also sets down economic sector objectives for Fukushima prefecture where the nuclear accident occurred. Also mentioned, but in no great detail are the issues of an ageing population, the need to rebuild with a generational focus in mind and a recognition that gender issues need attention. The Basic Guidelines forms the basis for what was to become the next phase: a new central government Reconstruction Agency (RA) that began its work February 11, 2012, eleven months after the event. The RAs primary functions are to approve the Creation of Special Economic Zones at the prefecture level (for all cities), to administer grant applications from municipalities and prefectures, to provide technical and consulting support and most important for implementation, to coordinate the actions of the various ministries through which reconstruction funds will flow. A "private-sector investment promotion special zone" in Miyagi Prefecture and a "public health, medical service and social welfare special zone" in Iwate Prefecture was approved within 10 days of application and a special external business committee activity was created to craft a regional economic expansion scheme for the region. Table 2 provides a Time Line of Main Events during the first year.

Table 2 Time Table of the Main 3/11 Events

Mar 11, 2011 14:46	Earthquake Occurred
15:14	Establishment of Headquarters for emergency disaster control
17:15	Establishment of Nuclear Emergency Response Headquarters
Mar 11	Application of Disaster Relief Act
Mar 12	Designation of Extreme Severe Disaster
Mar 12	Application of Act on Support for Livelihood Recovery of Disaster Victims
Mar 13	Designation of Specified Disaster
Mar 17	Establishment of Special Headquarters for Measures to Assist the Disaster Victims Lives
Jun 24	Enforcement of the Basic Act on Reconstruction of Great East Japan Earthquake
Jun 24	Establishment of Reconstruction Headquarters in response to Great East Japan Earthquake
Jul 25	Approval of the 2nd Supplementary Budget of FY2011 (1.9988 Trillion JPY)
Jul 29	The Basic Guidelines for Reconstruction in response to the Great East Japan Earthquake
Aug 11	Iwate Prefecture Great East Japan Earthquake and Tsunami Reconstruction Plan
Oct 19	Miyagi Prefecture Earthquake Disaster Recovery Plan
Nov 20	Approval of the 3rd Supplementary Budget of FY2011 (12.1025 Trillion JPY)
Dec 26	Enforcement of the Special Recovery Zone Act of Great East Japan Earthquake
Dec 28	Plan for Revitalization in Fukushima Prefecture
Feb 9, **2012**	Recognition of the first recovery promotion plan
Feb 2	4th Supplementary Budget
Feb 10	Establishment of Reconstruction Agency
Mar 2	Announcement of the 1st round recovery subsidy possible amount

The RA is headquartered in Tokyo with regional field office in the three prefectures. This model is different from that used in Indonesia and in New Zealand where the central government's recovery agency was located in the impacted region. The RAs general workflow structure is shown in Figure 3. Japan generally uses a toshikeikaku (top down) model more than a machizukuri (bottom-up) model of planning due to the central government being more comfortable with large infrastructure projects (Edgington 2010). It is not clear how the Consultative Body shown in this figure operates or to what extent it provides input to the process. It does however; recognize the political need for such a unit.

Figure 3 Reconstruction Agency Operations Flow

2.1 Framework for Land Use Planning

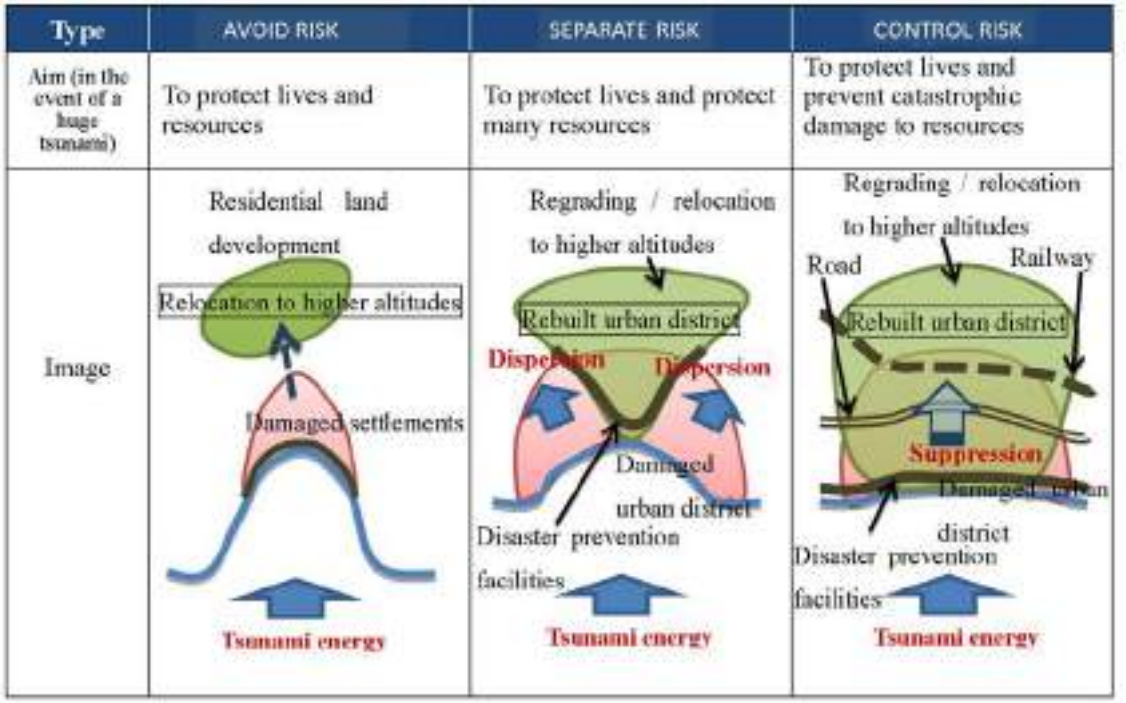
The main land use planning issues are shown in Table 3. For towns closely surrounded by steep hillside reuse of existing sites, if safe, is the preference. Relocation of critical facilities such as hospitals, government offices, and schools is needed and will require years to complete. Some cities, such as Rikuzentakata, lost all of their public buildings and require entire new visions of where to locate the new facilities and how to make them safe. Cities that experience subsidence and liquefaction need to apply both technical strategies for reuse and relocation strategies. In Fukushima the decontamination of land and buildings and the prevention of further exposure to radiation is the main land use and public safety issues. Salt intrusion on rice fields requires decontamination, and is focused mainly on parts of the Sendai plain.

Table 3 Land Supply Issues in the Tohoku Region

Land Use Issue	**Challenge**
Retention of Useable Land	Providing protection for urban uses
Sites for relocation of urban activities	Availability, location, cost, time to acquire
Subsidence and liquefaction	Technical issues and alternative uses
Decontamination	Radioactivity and salt intrusion

From an examination of the prefecture and municipal plans there three land use strategies emerge to that address safety from tsunami events. These strategies are: Avoid Risk, Separate Risk and Risk Control Through Multiple Defense. They are illustrated in Figure 4

Figure 4 Frameworks for Tsunami Defense



Source: Illustrated from "Iwate Prefecture Great East Japan Earthquake and Tsunami Reconstruction Plan Basic Reconstruction Plan"

To **Avoid Risk,** the areas of highest danger become restricted zones for residential uses and people who lived in such zones are relocated or use limited to specified non-residential activities. These areas can be used for non-residential purposes. The strategy establishes the separation of uses concept, not popular in Japan where there are few controls on building in hazard prone locations. This strategy is being considered in various municipalities and imposed to 20 km in the cities adjacent to Daiichi nuclear power station in Fukushima prefecture. To **Separate Risk,** that some land areas are restricted, while other area are elevated and still other areas serve to divert tsunami inundation in designated directions. To **Control Risk,** means multiple defenses are part of the preferred solution (e.g. sea walls, levees, elevated roadways, and elevated land areas that lessen the tsunami inundation at various locations). These strategies can be used in different locations within a municipality. For example, on the urging of community members the town government of Otsuchi in Iwate prefecture has adopted a variation of this strategy (The Daily Yomiuri 2012).

Each strategy generates its own land use requirements. For example, to **Avoid Risk** requires a relocation plan, the identification of available sites, and the determination of what infrastructure is needed for the new sites and its costs. Existing legislation under Article 39 of the Building Standards law allows a municipality to implement the **Avoid Risk** strategy. To **Separate Risk** requires determining where to elevate land areas, how

to relocate buildings on these sites and how to redirect the tsunami impacts. Where there is subsidence this also requires avoiding such areas for elevation. For the **Control Risk** strategy this means determining heights and locations of multiple defenses and what to allow in each area that lies within the different defense zones.
Related to each of these strategies is the policy on the height of sea walls or levee (dykes) defense areas. The central government supports the construction of Level 1 defenses designed to protect against 100-year events. The exact height of any sea wall or levee is determined through tsunami simulation modeling that takes into account data from the 3/11 events. The government has chosen to support a third worst historic event height as the level 1 baseline. Data on such events go back as far as the year 869 in some townships. In most area the height allowed will be increased over present levels. In Iwate prefecture this means as high as14.5-meter sea walls, and increase of nearly 8 meters in some communities (The Daily Yomiuri, 2012).

The central government practice has been to pay 50% of sea wall costs however; now with added grants possible from the Reconstruction Agency this can be raised to 100% of the cost. Level 2 defenses are those heights derived from a 1,000-year event. If the municipality with the support of the prefecture chooses a Level 2 defense, funds for this would not be forthcoming from the central government. Heights between levels 1 and 2 can also be agreed upon. The achievement of level 2 protection can also come about through applying the control risk strategy and elevating roads inland from the sea wall. This variant is proposed by Sendei City, mostly due to the extent of its low lying plain from the ocean to the central areas of the city.

3.0 Voluntary Sector Actions

Voluntary actions are broad ranging and extensive in the Tohoku region. They include continued financial support from businesses to small enterprises, organized non-profits working to improve temporary housing conditions to people spending a week helping out whomever they can. This effort reflects the national spirit of support for the people of Tohoku that is reflected in actions at all levels. Many Japanese universities have ongoing assistance projects to cities such as Kamaishi, Otsuchi and Ofunato. Two of the many efforts in place are discussed in this article.

3.1 NGO efforts

The NGO/NPO sector continues to play and important role in the recovery. NGO/NPO organizations began they efforts in the region five days after the 3/11 earthquake.
In Miyagi prefecture 26,588 volunteers were registered three after the event, and then rose to 91,549 in May 2011 (Sakamoto, 2012, 28). Taking lessons about the coordination challenges with the NGO/NPO sector from the Great Hanshin Earthquake of 1995, major coordination tasks were assigned to the Japan Platform (representing 17 NGOs) working with the local Social Welfare Councils and the Government Disaster Management Headquarters. This arrangement allowed for four party consultations to occur. Four party consultations involve the center government disaster on-site headquarters, the Self Defense Forces, the Prefecture government and the NGO/NPO coordinating representative. This level of coordination was supported by the central government and reflects part of what is called as part the new “public commons”

approach. The NGO/NPO work initially was to provide basic life support services to victims. This quickly expanded to assistance with housing recovery in terms of repairs and communications for those in temporary shelter, to consultation assistance with local government and groups in communities related to recover plans and support services such as improvements to temporary housing and making sure people were visited and cared for on a regular basis.

Prefectures have the responsibility to provide the temporary housing, but the local municipalities are charged with ongoing social service support and some maintenance. Temporary housing (total of 135,944) units is supplied by new construction, government owned units, public housing and private rental housing. It is scattered throughout the prefectures, mostly in clusters of less than 50 units. This presents a challenge communications and support challenge to smaller towns, and an opportunity for continued NGO support services.

3.2 Prefecture to prefecture cooperation and support

As part of the recovery system for the Wenchuan Earthquake of 2008, the Chinese Authority utilized a system of "twining" prefectures governments. This support function to prefecture and city governments was a positive step in rebuilding local government capacity. The Chinese Authority choose and matched (twining) the prefectures and cities. In the case of Japan the Union of Kansai Governments, a seven-member prefecture group (a local public entity created using the Local Government Authority Act for the purposes of pursuing decentralized government in Japan) decided to engage in "twining" on a prefecture-to-prefecture basis, rather than a regional basis. This initiative was voluntary and not central government directed.

The Kansai Union activities included: provision of relief supplies, provision of personnel and the acceptance of refugees. Hyogo prefecture alone houses 1,058 refugees, the largest group coming from Fukushima. This counterpart system worked well as all of the prefectures in the Tohoku region received assistance. Some prefectures such as Hyogo are now development mid and long-term assistance plans. This is in keeping with the Kansai Union's objective of strengthening a decentralize society in Japan. The assignment of the prefectures is shown in Table 4, and illustrated in Figure 5

Table 4 Japan Prefecture "Twining" Assignments

Receiving Prefectures	**Sending Prefectures**
Iwate	Osaka, Wakayama
Miyagi	Hyogo, Tottori, Tokushima
Fukushima	Shiga, Kyoto

4.0 RECOVERY PLANS – Initial Version

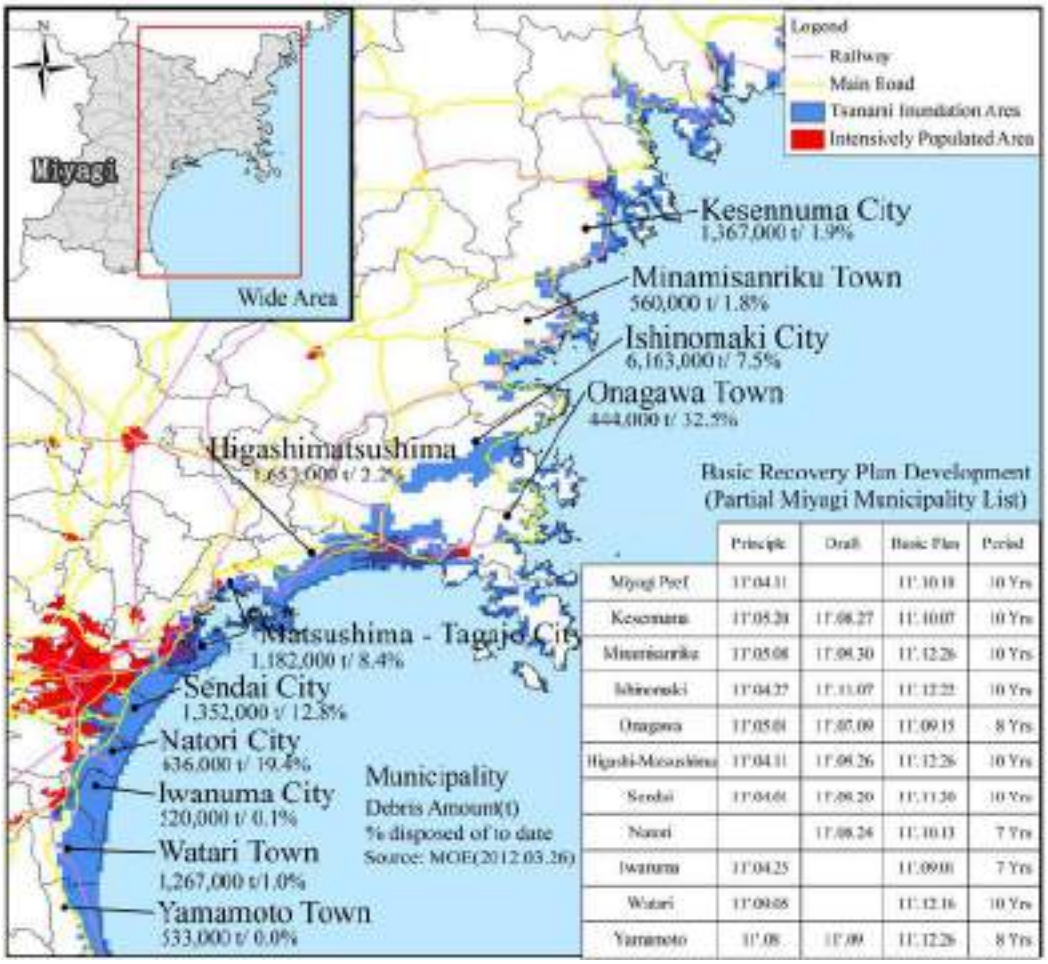
Initial recovery plans are meant as starting points, not as final products. All are subject to revision as is usually the case in large-scale disaster. They provide the basis for continued discussion on the vision for the place and people and a guideline for what to do next.

4.1 Prefectures

Miyagi Prefecture. The prefecture passed the initial recovery plan on October 18th, 2011 seven months after the earthquake and tsunami. The first work group plan meeting began three months after the event. The plan draft was presented to citizens in the north, south and southern part of the prefecture. Six hundred people participated directly and 200 written statements were received during the open public comment period. The plan time frame is 10 years is to be staged in three phases: restoration (3 years), reconstruction (4 years) and development (3 years). Figure 6 shows the prefecture, its main towns, the plan periods and the amount of debris and the % of disposal. Miyagi received assistance from 17 other prefectures, but did not have enough staff to coordinate the effort. This created a coordination challenge in terms of where to allocate staff and support services. It demonstrates the important function that coordination plays in the recovery process.

Figure 6 Miyagi Prefecture: Recovery Plans Dates and Disposal Status

Source: Compiled by H. Chen.



Fukushima Prefecture. Is basic vision reflects the unique situation of the nuclear accident at the Tokyo Electric Power Company (Tepco) Daiichi nuclear plant #1. The basic concepts for the vision are: Building a safe, secure and sustainable society free from nuclear power, revitalization that brings together everyone who loves and cares about Fukushima, and a homeland that the prefectures people can all be proud of once again. Certainly this has a strong basis in collective action. See Figure 7 for the towns within the restricted zone. This creates not only a land use distortion, but also eliminates any economic recovery for these communities and their residents. This plan lists 729 proposed projects. This is a very large number and reflects special character of the nuclear accident impact.

Figure 7 Fukushima Prefecture Plans and Debris Status

Iwate Prefecture. The prefecture assembly passed the initial recovery plan in August 11, 2011, just five months after the earthquake and tsunami. The Plan consists of three basic principles: ensuring safety, rebuilding lives, and regenerating industries, and reconstruction to return to a society in which people can safely live and work. In 2009 An Iwate Prefecture Resident Plan was developed and its objectives are incorporated into this recovery plan. The Plan envisions a 7-year period divided into thee phases 2011-2013 where foundational reconstruction is done; 2014-2016 when full-fledged reconstruction is done; and 2017-2018 is a consolidation period for further development. It will use a multi-preventative community planning that appropriately combines coastal protection facilities, community planning, and cultural measures. It expects the government to take a central role in reconstruction efforts as a national project, including nationally run initiatives. See Figure 8 for the main cities, and information on the debris status in these cities.

4.2 Municipal level plan(s)

The municipal recovery plans in the three providences were adopted between July and December 2011, or 4-9 months after the event. All cities in Iwate and Miyagi prefectures have a plan as have 9 of the 10 coastal cities in Fukushima. The plans ranged from 5 to 227 pages in length. A content analysis of the plans was conducted using basic chapter areas to list main content. The plans were consistent in stating the basic principles on which the plan is founded, the basic concepts, and framework. Stating the principles is a fundamental starting point for a Japanese plan and many principles can find support in those of the Disaster Reconstruction Council Report. Reconstruction periods of between 7-10 years are called for. Only 40 percent of the plans contain a list of program of projects to move forward. Such lists likely were being developed as project proposals (discrete actions), as this is the way in which funding is provided by the central government.

The statement of principles and concepts do establish the direction the municipalities wish to take and therefore form the basis for their strategy, and a means by which the local officials can continue a dialogue with the citizens related to the choices and options open to them (such as relocation, job expansion, where to locate public buildings and how to insure safety in the future). The majority of plans are not “road-maps” to action and fall short of what is called for in a recovery plan that can be

quickly become operational (Blakely et al. 2011, p.198). Given the short time period in which the plans were developed, and the uncertainly of the central governments position on the way assistance would be provided (beyond the emergency phase of caring for the victims and providing them temporary shelter). The variation in plan content reflects in part the context of the event for each municipality. Some communities lost municipal personnel and many lost the city halls and other public buildings. These plans are the beginning of a process that will have much iteration in the coming years as critical employment, land use and hazard safety issues are resolved (Olshansky et al., 2012). The plan tone is quite positive and reflects a belief on the nations ability to assist and their own desire for betterment.

4.3 Central government driven approach – general model

In the case of the Hanshin-Awaji earthquake (Kobe earthquake) of 1995 the central government established an Earthquake Recovery Headquarters to coordinate the efforts. There was no Reconstruction Agency but there was a Hanshin-Awaji Reconstruction Committee reporting to the prime minister on construction priorities. The committee was composed of local officials, business leaders and professional experts in city planning and reconstruction. This mechanism provided the guidance needed for central government actions. The Hashin-Awaji Reconstruction Committee took a position that all reconstruction programs are carried out by the prefecture and the municipal governments, thus keeping with a decentralization and a smaller central government policy at the time. This position meant that Kobe City government (that had special city status) and Hyogo prefecture would be in charge of the planning and implementation with the central government ministries providing support expertise and coordination according to their basic service mandates, such as major highways, etc. This policy suited the Japanese ministries that are funded sector by sector and are not experienced in working together in a coordinated manner. Also the legislation directing ministry activities is developed by sector (Transport, Marine, etc.) and makes cross-boundary decision-making difficult to accomplish.

In the Great East Japan Earthquake the prime minister transformed the disaster headquarters function into a reconstruction agency function, something that was rejected by in the Kobe earthquake and the central government also passed legislation to relieve municipalities and individuals from tax burdens. The Tohoku region did not have the municipal strength of Kobe and the vast number of cities required a more integrated tool for coordination of resources and assistance.

5.0 Initial Funding Choices

Examining where the money is spent is a strong indicator of priorities. Living support payments to survivors, relief from social insurance premiums for individual and tax relief for municipalities were but in place within six months. Nearly one year after 3/11 the first round of funding for reconstruction was awarded. It combined recovery grant funds with public funds already in ministry budgets. This reflects a model that relies on the ministries to be supportive of requests from lower government levels. This is part of the system of checks and balances within the Japanese general governance model. Table 5 lists the main project categories. Housing is the largest funding

category, with 44% of the total. This reflects the pressure to move from temporary housing to permanent housing for the large number of survivors. Relocation is the second highest category with 16.9% of the funds. This will be used for acquiring new land sites and preparing them for new construction. It implements the Separate Risk and Control Risk strategies discussed in Section 2.1.

Table 5 (a) Main Recovery Grants By Category, Round 1

Main Project	Municipality	Amount
Fishery Industry and Port Facility Development Project	21	258 (8.5%)
Disaster Prevention Collective Relocation Promotion Project (project fee for expected initial project areas, 5200 household)	12	437 (14.3%)
Disaster Prevention Collective Relocation Promotion Project (survey fee)	15	79 (2.6%)
Disaster Recovery Public Housing Development Project	32	1,356 (44.4%)
Farmland Development Project	16	52.8 (1.7%)
Urban Disaster Prevention Integrative Promotion Project (survey fee and so on)	39	30.0 (1.0%)
Urban Area Liquefaction Countermeasure Project (survey fee)	6	7.9 (0.3%)
Residential Land Sediment Disaster Countermeasure Project	12	324.7 (10.6%)
Total	59	3,053.2

Source: Reconstruction Agency (Mar 2, 2012), Amount: 100 Million JPY; percentage of whole amount

Table 5b First Round Recovery Grants Structure

Category	**Amount**	**% of Total**
Housing	1,356.0	44.4
Relocation	516.0	16.0
Disaster Prevention	362.6	11.9
Industry	310.8	10.2

6.0 Conclusion and discussion

The central government and the people of Japan are united in support of the Tohoku recovery. This is evidenced by the legislature (the Diet) approving $US 129 billion in recovery funding, the purchasing of the initial recovery bonds entirely by people within Japan, and the continued work of the volunteer section to support municipality recovery efforts at all levels. The nuclear accident by itself makes this event unique and the focus of worldwide attention. The ripple effects of the nuclear accident create special challenges in crafting a long-term recovery strategy. This strategy, out of

necessity, must be led by the central government, keeping in mind the wishes of the prefecture citizens. In each city however, the process local decision making that balances safety with efficiency is occurring, This article has not addressed in any detail the needs of those people in temporary housing, how livelihoods are to be restored or if the incentives of the special economic zones are sufficient to yield an expansion of regional employment.

As in all large disasters, the weakness of the place are quickly revealed. In this case, these include many towns with declining populations, a growing elderly population and slow economic expansion. No central strategy to address these issues has come forward to date from the prefectures or the central government. This is the real recovery challenge after the safety issues are properly addressed. The model of projects coming from the municipalities for funding must be supported by a clearer and broader regional strategy they may not come from the central government but from groups such the Union of Kansai Governments that has demonstrated it commitment to regionalism. After one year, the Tohoku region has just begun its journey to recovery, and will need at least a decade to get to where it wishes to be.

[1] In contemporary terms (the last 100 years) this event was the deadliest in Japan, with over 15,800 deaths 95% tsunami related, and over 3,200 injured. This was not the largest death toll in history for the region, that distinction going to the Meiji-Sanriku earthquake and tsunami of 1896 that has over 27,000 victims.

[2] Run up is the maximum height on land reached by the tsunami wave as it comes ashore. For example, a 40-meter run-up would reach the top floor of a ten -eleven story building at its highest point.

[3] This meltdown was caused by lack of adequate water supply to cool the nuclear fuel rods because all power to the plant was stopped due to falling power lines (weakened by soil failure) and the back-up diesel generators being destroyed by the tsunami that breached the walls of their uncovered storage area.

[4] The Reconstruction Design Council was for created by decision of the Cabinet on April 11, 2011 and on April 14th then Prime Minister Naoto Kan approved and made the request that establish a 15 member Council made up of business, academic and elected officials of national stature.

Title:

Resilience in complex adaptive systems: the relationship between planning and institutional resilience in bushfire prone regional Australia

Authors:

Dr Sophie Sturup, University of Melbourne Parkville, Victoria, Australia, ssturup@unimelb.edu.au

Dr Alan March, University of Melbourne, Parkville, Victoria, Australia, alanpm@unimelb.edu.au

Abstract:

Research on institutional resilience in complex adaptive systems such as regional towns in Australia has demonstrated that resilience in bushfire events is a product of complex interactions between capabilities held by different organisations and indeed the individual community members at different scales. However in the face of disaster (the breakdown of most or all of these capabilities) the ultimate level at which resilience will be found is in individuals. This reality suggests that measures introduced in planning must be mindful of their effect, not just on the resilience of the organisation to which they are targeted, but also on the resilience of individuals in the community. This has implications for the traditional institutional separation of disaster functions: Preparation, Response, Relief and Recovery, particularly where the professionalization of bushfire services creates increased separation between agencies and individuals in the community. This paper will present the findings of research into institutional resilience to bushfire through a case study of the Australian regional city of Bendigo during the 2009 bushfires.

Key Words:

Bushfire, Planning, Resilience, Complex adaptive systems

The Relationship Between Planning and Institutional Resilience in Bushfire Prone Regional Australia.

1. Introduction

Planning for the management of bushfire risk requires the coordination of a wide range of activities. This is because planning for management of bushfires, and individual survival in the case of bushfire disasters, requires development of a set of capabilities that run across the disaster domains of prevention, preparation, response, and recovery. These domains of action take place at different times in relation to any particular bushfire event. They are acted upon by a complex array of institutions operating at a variety of scales, from individual, local to state level, of which urban planning is only one. Because urban planning affects the spatial layout and functions of urban systems, its activities can impact many features of disaster resilience.

The functions of institutions and a given community interact in a complex adaptive system (which is, to a degree, self-organising) including a range of monetary, governmental, ecological, individual and other elements that influence resilience to threats such as bushfires. Key adaptive capacities sets identified by Norris et al are (2008) 'economic development, social capital, information and communication, and community competence' (p.127). The ways that these capabilities are built upon and modified by institutions after disasters, such as the Australian Black Saturday Bushfires of 2009, interact with the ongoing self-organisation of the complex adaptive systems of regional towns, impacting upon the overall resilience of the system. In disaster events, which are understood as the breakdown of all or most of institutional support systems (Handmer and Dovers 2007), the final expression of resilience will be by individuals acting within any remaining systems. This research examined the implication of this: that individuals' resilience in a disaster will be a product of the remaining capabilities available to them. Accordingly, planning for bushfire disasters must always seek to enhance resilience in ways that appreciate impacts that any actions may have upon complex adaptive systems. This perspective creates a new imperative for planning for bushfires and explains concerns expressed by interviewees in our research. It is argued in this paper that improvements in professional urban planning, response and communications relating to bushfire may actually reduce community resilience, resulting from mismatches between government expectations of self-reliance and community belief in improved professional abilities and disaster resistance.

This paper firstly outlines the methods of our research, and provides background on the regional city of Bendigo, which was chosen as a case study. It then sets out a discussion of the theory of resilience in complex adaptive systems, followed by contextual information regarding bushfire management in Australia, the concept of 'shared responsibility', and concerns over the professionalization of bushfire

services. We then provide an example of one set of capabilities (namely "communications") which are subject to planned changes across a variety of institutions. The example includes an exposition of the communications failures experienced by Bendigo, the nature of proposed changes in capability and the concerns expressed by interviewees about the likely impact of those changes on community and individual resilience.

2. Method

The questions examined in this paper arise from research into institutional resilience and bushfire conducted by the University of Melbourne. The research was undertaken by a multidisciplinary team from planning, social work, marketing and geography. Leveraging concepts of resilience, complex adaptive systems, and capabilities, the team developed a working theory of the nature of resilience in complex adaptive systems (see section 4). To begin to test the usefulness of the working theory, a case study was developed on the institutional response to the Australian Black Saturday 2009 bushfires in the town of Bendigo in regional Victoria, Australia. The research included reviews of changes to policy introduced since the fires and in particular in response to the Royal Commission of Inquiry conducted by the State Government of Victoria. A description of the institutions central to prevention, preparation, response and recovery of disasters in Bendigo was developed. Seventeen qualitative interviews with members of these various institutions both within Bendigo and at the state level were undertaken. Based on the key elements of resilience forming the basis of enquiry for the study (set out below), the interviews focused on institutional capabilities, how they had responded in the event of disaster, and what had occurred since. The use of a detailed case study of communications systems was used to allow deeper understanding of adaptive change in one feature of the complex adaptive system, from which conclusions could be drawn back to the theory of resilience, adaption and complex systems, rather than the entire complex adaptive system itself (Yin, 1993).

3. Background

On 7 February 2009 the State of Victoria in Australia experienced severe bushfires across much of the state. The day has become known as Black Saturday. One area affected by fire on that day was the regional city of Bendigo. Bendigo is a major regional city, part of the City of Greater Bendigo which encompasses both the urban area of the town of Bendigo and outlying towns spanning an area of approximately 3000 square kilometres. Bendigo lies approximately 150km North West of Melbourne, with an estimated population of 91,713. The fire started within the municipal boundaries about 8 km from the central business district. Before being brought under control, it came within 2km of the central business district and within three blocks of the main police station. One fatality occurred. A spot fire threatened a major hospital and an adjacent retirement home, and 61 homes and 125 sheds were damaged or destroyed.

Fire agencies and emergency services across Victoria were aware several days before the event of the forecast weather and fire conditions for the weekend of 7th February. In preparation, the Country Fire Authority had prepared a level 3 Incident Control Centre (ICC) in Bendigo which was fully staffed and linked with central command centres in Melbourne. A secondary level 2 ICC was established in Bendigo to handle any smaller incidents which might occur. At 15:11 a fire commenced at Coliban Park Road, Redesdale, a small community which was partly within the region of Greater Bendigo. The level 3 ICC in Bendigo responded to the fire by sending trucks and equipment, and commencing coordination of efforts to fight the fire at Redesdale. At 16:20 another fire commenced in the city of Bendigo itself.

4. The nature of resilience in complex adaptive systems

To consider how institutions have sought to improve disaster preparedness in Bendigo, this section sets out key concepts used in the study. The concept of resilience varies considerably between its "origin" disciplines of physics, psychology and ecology (Norris et al 2008). In ecology, resilience is said to be the amount of disturbance a system can absorb before shifting into an alternative regime (C. Holling, 1973). Under this understanding resilience is therefore improved by improving the capacity of the system to *resist* disturbance. One key method developed in human systems for improving this type of resistance to disturbance (or even avoidance of disturbance) is risk identification and mitigation (Beck 1992).

In physics, resilience is about the ability to "*bounce back*" after a serious shock. In this understanding things are resilient if they do not break when placed under pressure, nor do they change their fundamental properties (for example change to gaseous form, become permanently more brittle). In psychology, this idea of resilience has been applied to individuals, whereby an individual's resilience is a measure of their ability to maintain a stable equilibrium (Bonnano 2004). Applied to human systems this understanding leads to a concept that resilient systems are typically those which have developed, through experience, mechanisms to cope with "shocks" so they can return to normal states (B.H. Walker et al., 2006).

In a disaster, the fundamental conditions which formed and maintain the system in normal states are changed. In these circumstances "bounce back" to previous states isn't necessarily possible nor desirable. This has led to a concept that in disaster terms, systems can be considered resilient when they are capable of *adapting* (Handmer, 2007). Or put another way, systems can be considered resilient when they are capable of adapting, while maintaining their essential identity. "By resilience we mean the capacity of linked social-ecological systems to absorb recurrent disturbances such as hurricanes or floods so as to retain essential structures, processes and feedbacks" (Adger et al 2005 p. 1036).

An additional concept is that human settlements such as the regional city of Bendigo in Victoria can be understood to be *complex adaptive systems*. Complex adaptive

systems are systems that adapt and evolve while self-organising over time (Urry, 2005). They include a number of inter-related functional components: social networks, institutions and inter-related systems of economics, ecology and physical structures. The capabilities of each element and their interaction produce the self-organisation of the system. Perturbances caused by the interaction of these elements are necessary to the ongoing adaptation (or maladaptation) of these systems (Cork, 2010, p.133). The scale at which these systems interconnect, the level of connectedness and ability to adapt to different shocks will be variable (Cilliers, 2005, 257).

Taken together, the concepts set out above suggest that resilience in the context of regional communities and bushfire can be understood as a set of dynamic capabilities. These capabilities firstly allow the complex adaptive system to *resist* being effected by the bushfire, but then in the event of failure of the response capacities (disaster), would ideally allow rapid and appropriate '*bounce back*' to normal states, and where necessary, positive *adaptation* to new circumstances over time. That is, resilience is a set of capabilities built up and utilised before, during and after emergencies. It is "a process linking a set of adaptive capacities to a positive trajectory of functioning and adaptation after a disturbance" (Norris et al, 2008, p. 130). Where adaptive capacities are defined as "those with dynamic attributes, that is resources which are robust redundant and rapidly accessible" (Norris et al., 2008, p. 131). These adaptive capacities include dynamic capabilities such as management processes, organisational structures and competencies which are internal to a community (Teece & Pisano, 1994). They can be improved through longer term strategic policy in emergency management (Handmer & Dovers, 2007).

According to this framework, improving disaster resilience can be understood as a broad approach to a cycle of activity which encompasses the general contexts of planning, preventing, responding to and recovering from disasters. Disaster resilience requires a suite of capabilities across a range of organisations, institutions, communities and places, at a variety of scales to be effective, integrated with predilections for adaptive learning across scales (Gunderson et al 2008).

This understanding of resilience is depicted in simplified form in diagram 1, where resilience is shown as responses to an event in one of three ways (resistance, bounce back, or adaptation). Timeframes will differ for specific capabilities and in each of the elements. Because of the systems' complexity, capabilities within given elements may take any one of the responses, self-organising over time to form a new set of pre-event capabilities adapted to the environment developed in the intervening period. Thus resilience has to be understood as a process which is constantly developing and changing in response to a myriad of factors across the complex system.

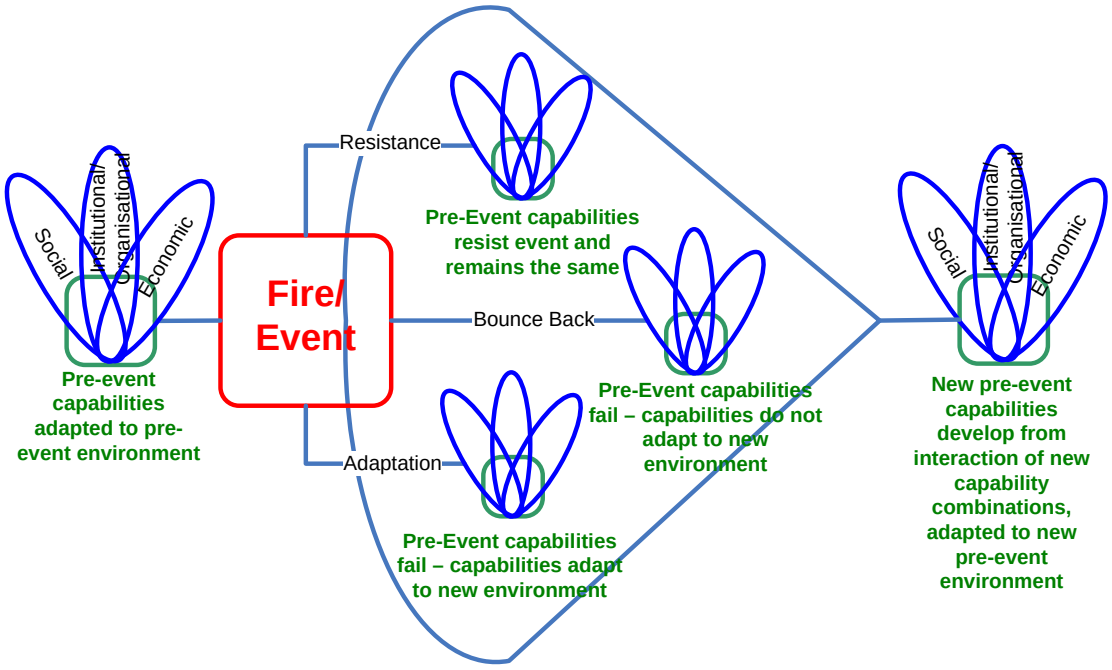

Figure 1: Resilience in Complex Adaptive Systems

Our research suggests that increased disaster resilience exists in communities and within agencies that empower the lowest possible levels to take responsibility for their own preparedness and recovery, while at the same time developing close working relationships across the community. As we will demonstrate with an example below, this means that actions to increase resilience in one area or one organisation need to be coordinated and planned so that they do not destabilise resilience in other sections of the complex system as it self-organises in response to changes.

5. The structure and professionalization of disaster services – and their separation from the community

In Victoria the key institutions involved in bushfires are organised across the activities of prevention, preparation, response and recovery as listed in table 1. Each agency is separate and has developed specialised capabilities and increasingly professionalised delivery of services. They are often multi-scalar, operating at both State and local levels. This presents challenges for the integration of service delivery and for understanding their interaction and the interaction of their capabilities within complex adaptive systems.

Table 1: List of Main Institutions involved in Victorian Bushfire by Domain of Action

Domain of action	*Institution*

Prevention of fires or reduction of intensity	*Planning System* (Bushfire Management Overlay; building codes) *Department of Sustainability and Environment* (management of forests)
Preparing for the event of fires or reduction of intensity	*Country Fire Authority* (education of community) *Private Landholders* (Clearing around houses, maintenance of private property)
Responding to fires	*Country Fire Authority* (direct fire management and containment) *State Emergency Service* (Logistics assistance, assistance with emergency centre staffing, assistance with provision of camp services for front line fire-fighters *Local Government* (Municipal evacuation centre, emergency relief, coordination of local resources – bulldozers, fuel, clearing equipment) *Police* (road blocks, assistance with coordination of evacuation centres, logistics, management of the public) *Red Cross* (registration of persons in distress)
Recovering from fires	*Department Human Services* (short term provision of emergency accommodation, longer term counselling services) *Department of Planning and Community Development* (longer term community recover, community engagement officers, economic recovery, distribution of longer term aid) *Health Services* (ambulance services, hospitalisations, dealing with injured in direct aftermath)

Professionalism, as a system of allocating specialised roles and responsibilities to experts, has traditionally been seen as a guarantee of high standards, delivering overall benefits to the public, but at the risk of distancing the public excessively (Koehn, 1994: 147; Friedson, 2001: 217). A theme that emerged in the research was that "planned" and agency based responses to bushfire risks have increasingly professionalised and institutionalised action in many ways that separate the public from bushfires, while paradoxically seeking to "share responsibility" a theme taken up in the Council of Australian Government (COAG) documentation on National Disaster resilience (Ellis et al., 2004) and reiterated increasingly after the 2009 fires, including in the Final Report of the Royal Commission of Inquiry (2009: Volume 2).

In contrast to professionalization of bushfire response is the long tradition of volunteerism in the Country Fire Authority (CFA) of Victoria. This has engaged large numbers of the public directly with preparation and response processes over a long period. The CFA's focus upon local provision of fire preparation and response, has long been intertwined with volunteerism and community engagement (Murray & White 1995). The brigade structure which still exists today, and which was originally entirely self-funded and relied entirely upon volunteers, was formed in 1926, in response to serious bushfires in Victoria, although its history goes back to the 1870s. In 1945 the CFA was formed to coordinate the brigades at the recommendation of a Royal Commission of Inquiry into the devastating 1939 bushfires. Over 1,200 brigades now exist in Victoria, only some of which are staffed by a core of 629 professional firefighters in larger regional centres supported by some 60,000 volunteers (Strachan Research, 2000; CFA: 2012).

Largely in response to the disaster of 2009, recent changes in Victorian fire risk management systems have been dramatic by comparison to previous progress, with the introduction of significantly stricter policies via urban planning and building regulations in 2011. The introduction of planning and resource management controls over time increasingly map, assess, design and seek to reduce bushfire risks through expert and centrally derived urban planning mechanisms. In summary, these controls have been oriented to improved building and construction standards, combined with urban design and forest management mechanisms that modify vegetation near to buildings and settlements. In addition attention has been given to the distance of buildings to fire sources and provision for response and escape routes.

Australian Standard 3959 establishes a scale of building performance levels against Bushfire Attack Levels (BAL), progressively requiring more resistive structures as the risk level of the environment increases. In parallel, the Wildfire Management Overlay (WMO) which was previously applied only to limited spatial areas, has been replaced with the Bushfire Management Overlay (BMO). The BMO, used in parallel with the BAL, provides for development setback distances and "asset protection zones" according to the nature and level of the bushfire threat in an area, thus combining building and planning mechanisms. The BMO and BAL "tests" must be used in all areas designated to be "Bushfire Prone" according to recent mapping which has identified most areas outside established towns and cities as being at risk. Finally, the state has committed to an extensive ongoing fuel reduction programme, requiring 5% of all land or 390000ha of bushland to be treated each year (VBRC 2009). While the long term impacts of these changes, focused upon developing *resistance*, remains unclear the following sections consider the impacts of these institutional changes upon the complex adaptive systems in which they are implemented.

6. An example of a planning measures which effect institutional resilience and individual resilience.

We have argued above that in complex adaptive systems resilience is a product of capabilities developed by and available to individuals and institutions across a range of timeframes. These capabilities develop and interact across the complex system, and thus learning in one institution, which changes the capabilities of that institution, will affect capabilities unevenly across the wider system. In some cases the improvement of capabilities in one area, may actually destabilise disaster resilience in other areas. This occurs because in the event of disaster, when normal capabilities are overwhelmed (Handmer and Dovers, 2007), the capabilities left to individuals on the ground need to be 'theirs', and cannot be sourced in a professional organisation that will 'save them'. We argue that given this reality, care needs to be taken with the context in which improvements to capabilities are made, so that they provide for generalised improvements to resilience of the system overall. To achieve this, the interconnections and context of the complex adaptive system must be properly understood.

An example allowing us to explore this theory is the development of communications capabilities since the 2009 fires. To understand the impact of changes to the information capabilities within and between response and recovery agencies on the resilience of community members, it is first important to understand the context of information failure during the fire of 2009. This example will therefore provide firstly a basic description of the communication failures during the 2009 fires. The response of the Royal Commission of Inquiry held by the Victorian government will then be examined before the data collected on agencies concerns about the impacts of changes to communication capabilities is presented.

6.1. The problem of information in the Bendigo fire of February 2009

From the beginning, fighting the fire in Bendigo was plagued by difficulties in communication. For example, there was a failure in the central emergency control centre for the State of Victoria so that telephone calls could not get through. The first report of the fire was provided by residents who drove to Eaglehawk Country Fire Authority (CFA) base to report the fire in person. The Eaglehawk pumper was en route before being paged by central command which had eventually been contacted by phone. ("Redesdale and Bendigo Fires Submissions of Counsel Assisting: Letters Patent ", 2009)

During the initial stages of fighting the fire communications with those at the fire front were limited. Communications between the ICC and central command were also limited. The Regional Emergency Control Centre was alerted to the Bendigo fire by Eaglehawk CFA, and moved to establish who would take control of incident management for the fire. At 16:45 the level 2 ICC at Adams Street in Bendigo ('Adams St') was given the Bendigo fire to manage. Adams St was unable to make radio contact with the crews on the fire ground using the CFA Regional channel, the trunking system[1], or fire ground channels. There was also very limited communication between the two ICCs. The level 3 ICC sent a number of staff to the fire front without informing Adams St that they had done so. One of those was Mr A, an experienced field controller. ("Redesdale and Bendigo Fires Submissions of Counsel Assisting: Letters Patent ", 2009).

An example of the lack of communications is the lengths Mr A[2] went to to bring about control of all aspects of the fire fighting effort. Initial incident control was undertaken by Mr B of Eaglehawk CFA who was first on scene at 16:40, established a command centre, sectorised the fire as he saw it and commenced fighting it. At about 19:15 Mr A, having driven around to find Mr B and a number of others now fighting the fire, held a meeting and from a map drawn on the bonnet of his car, re-

[1] *Trunking systems* are complex multi-channel radio system managed by a computer that allow higher numbers of simultaneous users on a given frequency.

[2] Names have been changed to protect anonymity as per human ethics requirements.

sectorised the fire and allocated command points to those present (Interview Gilmore). At 19:45 Mr A was contacted by Mr C at Adams St, who asked him to come and provide a briefing. This was done at 21:00. Consequently the Adams St ICC was largely irrelevant in fighting the fire. The crews on the ground were largely responsible for controlling the fire, with almost no communications and assistance. ("Redesdale and Bendigo Fires Submissions of Counsel Assisting: Letters Patent ", 2009)

Further evidence of difficulties were apparent in communications with the public. One issue was that on a very hot day, most people were inside their houses with curtains drawn to prevent heat entering, in the main watching cricket on television, rather than tuning into local radio stations (Morris 2009). As a result many residents who were under direct threat were unaware of the problem until the police or a neighbour knocked on their door to advise them. The police communications were overwhelmed, both at the level of contact with the public and the police radio band (Interviewee 1 Victoria Police). An initial evacuation centre was set up at Eaglehawk which was subsequently threatened by the predicted wind change. A new evacuation centre was established at Kangaroo Flat. 60 persons were relocated from relief centre at Eaglehawk to Kangaroo Flat (Morris 2009). The radio stations made mistakes concerning the location, directing people to Eaglehawk even though it had been moved due to threat from fire.

The broader community of Bendigo became aware of the fire, if through no other medium, via the amount of smoke in the vicinity. Embers and ash fell on areas of the town south and then east of the fire, up to 7km away from the actual fire (Interviewee 1 Bendigo Business Council). Many members of the community thus experienced considerable uncertainty, which given the lack of knowledge about the exact location of the fire front was not able to be ameliorated by announcements being made from the ICC (Interviewee 1 Community Sector). In fact, conflicting announcements were made. For many members of the community, this lack of information was unexpected and unacceptable.

Information required for critical forward decisions on the distribution of resources in recovery was also limited.

> “The bits we didn’t do all that well in was the initial 24 hours after. From 6 on the 8th feb until 6 on the 9th feb I reckon we were in absolute trouble. Because couldn’t get the picture right. We couldn’t work out how many people didn’t have a home. We couldn’t get the data and information to make good decisions.” (Interviewee 1 CFA).

The only element which seemed to do a reasonable job with regard to information was the sharing of information on what had happened between recovery agencies after the initial recovery period

> "With the bushfires we managed that (the distribution of welfare payments) better because agencies shared information about who exactly had been effected. We share information well. Early on we got an agreement that so long as we collected the information for this purpose we could share it " (Interviewee 1 Local Government).

6.2. Post-Disaster Response of Agencies to the issue of Information

These types of communication difficulties were repeated across the state.

> "Clearly the gathering of information was overwhelmed, there was no capacity to collect the amount of information that needed to be collected, considering what was going on. But when you think about it, it still was pretty good. We knew the regions that fires were in – not necessarily where they were" (Interviewee 2 CFA).

Unsurprisingly, the Royal Commission made many recommendations relating to communications. In summary, the recommendations involve improvements to information provided to community prior to bushfire seasons to enable them to be better prepared (recommendation 1, 2, 7 37, 44) and to provide for improvements to on the ground communications between response agencies in the event of a fire (recommendation 14, 22 and 23). These recommendations collectively provide a clear message that the community members will be informed of how best to protect their families and property in the event of fires, and that during the actual event fire response agencies will be able to communicate and accurately know where a fire is and to predict its movements.

At the same time that these recommendations concerning information were made, two other recommendations of relevance were made. Recommendation 3, essentially provides for municipal authorities to plan for the identification of and evacuation of vulnerable persons. Recommendation 5 provides for the opportunity to encourage people to evacuate where circumstances indicate that will be a safer option than staying to defend properties. Both these recommendations radically change the nature of Australia's long-standing 'leave early or stay and defend' policy. They provide a clear message to the community that in the event they are at serious risk, they will be instructed to evacuate, and that prior to this they will have had all necessary information at their disposal.

The complete wording of each of these recommendations is included in the table below.

Table 2: Recommendations of the Victorian Royal Commission into 2009 Bushfires pertaining to 'communications'

Recommendation 1: The State revise its bushfire safety policy. While adopting the national Prepare, Act, Survive, framework in Victoria, the policy should do the following:	Recommendation 7: The Commonwealth lead an initiative through the Ministerial Council for Police and Emergency Management, facilitated by Emergency Management

- Enhance the role of warnings – including providing for timely and informative advices about the predicted passage of a fire and the actions to be taken by people in areas potentially in its path
- Emphasise that all fires are different in ways that require an awareness of fire conditions, local circumstances and personal capacity
- Recognise that heightened risk on the worst days demands a different response.
- Retain those elements of the existing bushfire policy that have proved effective
- Strengthen the range of options available in the face of fire, including community refuges, bushfire shelters and evacuation
- Ensure that local solutions are tailored and known to communities through local bushfire planning.
- Improve advice on the nature of fire and hose defendablity, taking account of boarder landscape risks.

Recommendation 2: The State revise the approach to community bushfire safety education

Recommendation 3: The State establish mechanisms for helping municipal councils to undertake local planning that tailors bushfire safety options to the needs of individual communities. In doing this planning, councils should:

- urgently develop for communities at risk of bushfire local plans that contain contingency options such as evacuation and shelter
- document in municipal emergency management plans and other relevant plans facilities where vulnerable people are likely to be situated—for example, aged care facilities, hospitals, schools and child care centres
- compile and maintain a list of vulnerable residents who need tailored advice of a recommendation to evacuate and provide this list to local police and anyone else with pre-arranged responsibility for helping vulnerable residents evacuate.

Recommendation 5: The State introduce a comprehensive approach to evacuation, so that this option is planned, considered and implemented when it is likely to offer a higher level of protection than other contingency options. The approach should:

- encourage individuals—especially vulnerable people—to relocate early
- include consideration of plans for assisted evacuation of vulnerable people
- recommend 'emergency evacuation'.

Australia, to develop a national bushfire awareness campaign.

Recommendation 14: The Victorian fire agencies amend the AIIMS framework before the 2010–11 fire season in order to do the following:

- designate the Information Unit as a separate section reporting directly to the Incident Controller and require that the Information Unit contain a dedicated Public Information Officer whenever a full incident management team is required
- specify a set of functions in relation to which the Deputy Incident Controller for a level 3 incident will have oversight, which may be adjustable for a particular incident by agreement between the Incident Controller and the Deputy Incident Controller
- ensure that an individual with local knowledge is incorporated in an incident management team.

Recommendation 22: The Country Fire Authority and the Department of Sustainability and Environment standardise their operating systems and information and communications technologies with the aim of achieving greater efficiency and interoperability between agencies.

Recommendation 23: The Country Fire Authority review and improve its communications strategy as a matter of priority and develop a program for identifying and responding to black spots in radio coverage.

Recommendation 37: The State identify a central point of responsibility for and expertise in mapping bushfire risk to:

- review urgently the mapping criteria at present used by the Country Fire Authority to map the Wildfire Management Overlay, to ensure that the mapping used to determine building and planning controls is based on the best available science and takes account of all relevant aspects of bushfire risk
- map and designate Bushfire-prone Areas for the purposes of planning and building controls, in consultation with municipal councils and fire agencies
- finalise the alignment of site-assessment methods for planning and building purposes, taking into account bushfire risk to human safety as well as to property.

Recommendation 44: The Country Fire Authority produce for community guidance material on fire-resistant landscape and garden design, including a list of fire-resistant species

6.3. Analysis of likely impact of information recommendations on institutional and individual community member resilience

Taken together with the changes to the wildfire management overlay and changes to the planning provisions, the community could be forgiven for expecting that they will be protected by the State both before and during bushfires. As one senior government interviewee put it:

> What have we done? Well if you live in a bushfire area well you need to be prepared and plan to leave, but if you get caught short, first of all you will get information, you will probably get a fire truck rolling up, DSE will keep the forests safe in any case (and if it isn't then it is their fault), the CFA will tell you how to build your house. You have this place you can go to – which you will be told in plenty of time to go there – and if that doesn't happen then the police will order an evacuation and they will organise to send you somewhere else. And if you are vulnerable then DHS will have a plan to deal with you (Interviewee 2 CFA).

The conflict between this set of community beliefs and a disaster management system which is based on shared responsibility is perhaps obvious. Concerns were raised by interviewees that the recommendations and improvements to institutional capability are likely to create unrealistic expectations concerning the capacity of response agencies during disasters and the role of the community in shared responsibility.

> But the other thing is that you can't separate the emergency service from the community. So the commission has also decreased community resilience. The treatments it came up with have built an … expectation of a place to go, an expectation that information and expert advice will always be available, … . All of that is in parts of the recommendations coming out of the royal commission, which is completely contra to the COAG disaster resilience strategies for community. We (COAG) talk about communities talking to each other, taking each other on the journey, looking after each other, knowing that it is going to happen (Interviewee 2 CFA).

The specific concerns raised by interviewees were as follows. First it is considered critical for CFA functioning that front line response personnel make decisions in a timely fashion, a long standing disaster response principle. These front line people need to be able to make a decision on low levels of information.

> When you are at the sharp end, what you are relying on is having people who are able to view the situation and see a number of options, and choose one. Choose one based on the knowledge they have available to the then, and act on it (Interviewee 3 CFA).

Thus in situations of fighting bushfire it is necessary to make decisions with minimal information. This is as true for central command as it is for the front line. Indeed evidence shows that acting decisively is critical for survival at the individual level (Interviewee 3 CFA).

> Resilient organisations have people who have the experience base, or the place to go, or the processes by which they are able to make decisions

> without all of the information they would normally have. The worse a situation is, the more difficult to it is to get information (Interviewee 2 CFA).

Not only does the findings of the Royal Commission potentially destabilise individual decision making, the fact that it also sought to determine blame for individuals, based upon 'who knew what, when', further destabilises the capacity of response agencies to function.

> When you are pushed outside of normal routine operations, and I am talking about within the emergency management scenario, in the ones where the agencies have to come together, then you need to be adaptable, flexible and supported in making decisions. You only make decisions with the information that you have at that point of time, and it is challenging to do that (Interviewee 1 State Government).

Without support in making decisions, there is a risk they will not be made because information is not available, or that unreasonable levels of resources will be put to documenting the exact nature of information available on which the decision was made.

> The big issue is being able to justify your decisions after you have made them and the problem with that is that the worse the disaster gets the less information is available to you. The system of information gathering breaks down or at least provides you with less information the worse things get (Interviewee 2 CFA).

The second big issue is that the CFA now feels that it has a responsibility to provide the community with information.

> The other big change is that we are a lot more aware of our responsibility to provide public information. It is really annoying at times when you are trying to work on a fire. But we feel we have to do it. We track fires, and now we want to know what will be affected in the future, with a public message that we can get out immediately it becomes necessary… . Now we accept that we need to tell people what is going on, even if it is just where the smoke is from (Interviewee 3 CFA).

This is despite the fact that in many cases of bushfire, this information is not known during the response phase, and the fact that any system will be subject to overload and dysfunction at some point in a disaster. Given that the CFA increasingly feels it is responsible for disseminating information, combined with the technical and professional work being undertaken by various agencies to increase capabilities to give information, it would hardly be surprising if that created an expectation in the community that information will be available on which to make decisions. Indeed there is evidence from the Bendigo Community Recovery Plan that the community

does indeed expect better information in the future. Under the heading "Community Awareness/Planning for next time", they have highlighted the need for "communication and fire warning". Noting that the community was unprepared and no fire warnings were universally recognisable on Feb 7th. They felt there was a need to facilitate community preparedness and awareness of where to go and what to do in case of evacuation in any natural disaster (Victorian Bushfire and Recovery Authority 2009).

A concern with this expectation of information being available on the day, and during, a disaster is that it will also destabilise efforts at preparation and even prevention. Recently improved building codes provide for buildings to be located in areas at risk of bushfire, assuming that preventative and protection measures are carried out, especially in maintaining vegetation distance from buildings. This requires ongoing action by individual property owners in perpetuity. As individuals' expectations of information and advice increases, it is possible their attention to messages of prevention and preparation will decrease. Thus, even with an increase in the amount of messaging and awareness of the risk of bushfire, the effect on actual preparation is possibly diminished. As one CFA interviewee put it:

> The message is out there more, and the expectation that information will be better is out there. I worry about if we do a code red day, and people's expectation about what they should do and what that means. I don't think we have changed this personal responsibility issue. We know that if you can stay at home and do all those things I was talking about before within the community, looking after yourself and neighbours, stay informed and aware of what is going on around you. Then if you are told you are under particular threat you will make good decisions. I don't think we are at that point. I think that if there is a fire out there at Castlemaine or somewhere, people will be flocking in to the Neighbourhood Safer Place with carloads of stuff and pets and all that thinking that it will be open and there will be people there to feed them and stuff like that. So I think that some people will do better, but that will be offset by people doing stupid things and chewing up resources unnecessarily (Interviewee 3 CFA).

This is therefore a good example of a situation where planning for increased resilience by improving the system of communications could potentially lead to a destabilisation of resilience in the people who will need it in the event of disaster. In the final analysis we can return to Norris et al (2008) who state that 'information increases survival only if it is "correct and correctly transmitted". Closer local sources of information are more likely to be relied upon than unfamiliar distant sources' (p.140).

7. Conclusion – Avoiding Maladptation and Reduced Resilience

In this paper we presented a working theory examining the relationship between institutional actions post-disaster, and the resilience of the wider complex adaptive system affected by the changes. The study examined the case of Bendigo after the 2009 Victorian Bushfires, particularly communications breakdowns in response phases. The study shows that building the capacities of institutions active in the domains of prevention, preparation, resisting and responding bushfires can raise significant doubts as to the ongoing resilience of local communities to bushfire risks, particularly in disaster situations where "normal" processes of response are overwhelmed. The interconnected and largely self-organising response of citizens to the institutional changes in capabilities may be to increasingly rely upon formal system of communication for information about fire risks and evacuation decisions.

Further, ongoing changes to forest management and building and planning systems give the impression that existing settlements have become less risky. In fact, the effect of these actions will be realised at vastly different time scales, due to the slow rate of ongoing change allowed by development control systems in planning. In addition, the focus of planning and building controls upon improved resistance will lead to greater expectations of safety based upon underlying expert processes, aided by improved professional response abilities facilitated by better communications. This suggests that actions to increase resilience in one area or one organisation need to be coordinated and planned so to minimise destabilisation of resilience or maladptation (Adger, 2005) in other sections of the complex system that self-organise in response to changes.

This research points to methods and a need of researching how increases in state intervention and improvements to institutional capbaility can lead to decreased individual responsibility, capability and resilience. Further research is required into the nature of the complex adaptive systems which are our regional towns if improvements in capabilities are going to lead to the desired outcome.

PLANNERS' TECHNICAL EXPERTISE. CHANGING PARADIGMS AND PRACTICES IN THE ITALIAN EXPERIENCE

Bruno Zanon[1]

Abstract

Why is a planner hired? What is the specific knowledge and know-how that he/she brings into a planning process? These questions recurrently arise in planning practice owing to the rapid change taking place in disciplinary approaches and methods, the legal and administrative framework, and the ways in which actors interact. It is well known that political and technical aspects are intertwined in the planning process, and this may give planners a key role also in the definition of the goals for action. More often, however, common knowledge prevails in public decisions.

Planners have long been required to address issues no longer circumscribed to physical spatial organization and planning process management. Consequently, technical expertise has evolved from its architectural-engineering base to include socio-economic and environmental issues, as well as communication methods and participatory procedures. This evolution is still ongoing, challenging professional practices and educational programmes. This progress responds to the need for sounder methods and more effective tools with which to manage complex problems. But at the same time it produces a looser image of the planner as involved in a variety of issues, and distant from such strong professional figures as the engineer and the architect, who, in many countries, are traditionally responsible for physical planning. As a consequence, a wider – but well-defined – field of competence must be devised.

The paper focuses, after an analysis of how technical paradigms have evolved in the planning discipline in Italy, on the emerging types of expertise that are expected to form the planners' "toolbox". This requires linking the discipline's progress with that of the professional practice (controlled by the professional orders), overcoming the so-called theory/practice gap, as well as connecting the legal framework with the educational system (which still reflects traditional models). The analysis of the emerging need for planning expertise makes it possible to define some paradigmatic "planning figures" which can well represent the variety of technical expertise required.

Keywords: technical expertise, planner's profession, Italy

[1] Dipartimento di Ingegneria Civile e Ambientale, Università degli Studi di Trento, via Mesiano, 77 – 38123 Trento – Italy – bruno.zanon@unitn.it.

1. Introduction. Why is a planner hired?

Why is a planner hired? What is the specific knowledge and know-how that he/she brings into a planning process? These questions recurrently arise in planning practice owing to the rapid change taking place not only in socio-economic phenomena, but also in disciplinary approaches and methods, the legal and administrative framework, and the ways in which actors interact.

The complexity of urban government requires an extraordinary ability to understand change, to forecast future trends, to build consensus on feasible proposals, and to construct coalitions. There is also an urgent need to give efficiency and equity to the public choices taken in the concrete forms of urban space organization and land-use regulation. Accordingly, specialized/sectoral knowledge is required together with expertise in decisional and implementation process management. In short, there is an increasing need for planning, although it is an activity whose legally binding rules and formally defined disciplinary practices recurrently become obsolete, and even more so land-use plans (Alfasi et al., 2012).

It is well known that political and technical aspects are intertwined in the planning process, and this often implies that technical expertise (which should "complement democratic discourse": Alexander, 2008, p. 210) play a minor role, while common knowledge, and in many cases political rhetoric, tend to prevail in many public decisions. This is why in some countries, Italy included, planners are marginalized with respect to administrators (Mazza, 2002, p. 24).

While for some scholars the focus of planning theory has been put on ethical and political issues, so that "planning theory literature… tends to flatten down planning to politics", thus marginalizing or cancelling the role of technical knowledge (Mazza, 2002, p.17, p.12), for others the opposite is true: "much of professional rhetoric of planning" remains "resolutely attached to the reassuring claims of technical expertise". It is stressed, anyway, that there is "at least implicit recognition that moral judgements and ethical questions pervade the daily practice of planning" (Campbell and Marshall, 1998, p. 117; also: Campbell and Marshall, 2000a).

Planning is a procedure applied to a variety of contexts and decisional processes, some of which are highly specialized, while others are more loosely connected to practices organized and defended by professional orders and associations. Planners have long been required to address issues no longer circumscribed to physical spatial organization and urban planning process management. Consequently, technical expertise has evolved from its architectural-engineering bases to include socio-economic and environmental issues, as well as communication methods and participatory procedures, and the process is still ongoing, challenging professional practices and educational programmes.

This progress responds to the need for sounder methods and more effective tools with which to manage complex problems. But at the same time it produces a fragmented discipline and a looser image of the planner (Mazza, 2002). The planner, in fact, is involved in a variety of issues, and his/her status is distant from that of such strong professionals as the engineer and the architect, who in many countries are entitled to take responsibilities for spatial planning.

In general, it is expected that a planning process (or a 'plan' as a statutory document) will bring 'rationality' (in its different conceptions: Alexander, 2000) into spontaneous processes (the market, social behaviours), as well as efficiency, effectiveness and equity into public decisions, operating with a view to the 'public interest', whatever its definition (Campbell and Marshall, 2002). From this perspective, what is the expertise provided by the planner?
The paper addresses these issues with clearly borne in mind that motivations for planning must be found in the search for collective benefits, going beyond the "implementation of a set of statutory requirements". This implies that the "importance of competence should never be disregarded" (Campbell, 2010, p. 472), because the "status of planners as experts resides in their command of specialist knowledge" (Rydin, 2007, p. 53).
The paper focuses on the Italian case by analyzing the progress of technical expertise from the traditional 'urbanistica' – characterized by the integration into the figure of the architect of the diverse competencies required by recurrent professional demand – to a more complex articulation of competencies.
The research questions addressed – with specific regard to the Italian case – are the following:

- What specific technical expertise is required of the planner?
- Is planning a compact discipline or is it fragmented into a number of sectoral bodies of expertise?
- What evolution has occurred in the educational system and what is the role of the professional orders?
- What are the expert roles performed by the planner?

An additional question regards whether there is a short-circuit between the demand for and supply of qualified expertise, considering that in many cases the awareness necessary to involve an expert emerges from a structured representation of problems and feasible solutions, as well as from the availability of qualified professionals.
In the paper, some key terms are used to define the issues at stake. In particular, by 'knowledge' is meant a person's endowment of information organized by means of theories and methods (on the basis of "causal relationships": Rydin, 2007, p. 53), considering that knowledge production follows different paradigms (Alexander. 2010), but in planning it is mostly "socially constructed" (Healey, 1997), or "constructed through social processes" (Rydin, 2007, p. 52). Know-how (competence) is the ability to make use of knowledge in order to achieve the results expected. Expertise is the capacity of a person (often recognised as a professional) to make use of appropriate knowledge and know-how to analyze problems and propose solutions.

Planning theory and planning practice

The nature of planning is primarily operational. Its rationale consists in its capacity to yield results better than those expected from the unplanned course of events. Its main goal is "the development of practical outputs" (Goldstein and Carmin, 2006, p. 68) in order to provide benefits for the communities involved, and its strength

consists in the ability to furnish a strategic framework that interacts with the operational solutions (Mazza, 2002, p. 11).

These premises stress that the discipline is oriented to devising and applying operational methods and tools, and that it accompanies political actions in order to improve current conditions from a 'public interest' perspective (Alexander, 2002; Campbell & Marshall, 2002). This is a key issue which raises ethical concerns due to the application of values, so that a strong role is assigned to political representatives and – when activated – to participatory processes.

It is traditionally assumed that, in order to pursue specific goals, a government authority "can select one instrument among others" (Ponzini, 2008, p. 12), but policy tools and government instruments – planning practices included - become part of the 'government culture' and problems are often expressed in light of the consolidated technical-administrative instruments. This is the case of Italy, where the role of municipal plans has become consolidated in the public opinion (notwithstanding their unsatisfactory effectiveness), and professionals are educated and trained in order to address problems by means of the statutory planning instruments.

It is probably counter-intuitive that the prevalent operational orientation of planning and the complex technical/political relationships require a strong theoretical basis. In fact, actions must be supported by a sound knowledge of reality, an appropriate interpretation of phenomena and trends, as well as by the ability to connect diverse points of view and sectors of activity. And this implies a sound theory and interdisciplinarity. In fact, planning "has a history of drawing from many disciplines" (Goldstein and Carmin, 2006, p. 68) and this can be considered "a weakness – making it difficult for planners to know exactly what belongs to planning", while "others see it as a key strength" (Davoudi, 2010, p. 33). The risk is the fragmentation of the discipline and the coexistence of different – sometimes conflicting – theories and methods, while there is a strong need for technical knowledge meant as "a formalized knowledge that is linked to defined theoretical frameworks and leads and affects practices" (Mazza, 2002, p. 12).

Planning is characterized differently among countries, but it is generally founded on technical sectors – in particular urban design – on the one hand, and it shares methods and tools with social sciences on the other (Goldstein and Carmin, 2006, p. 67). In short, it concerns policies and practices, and its scientific bases are related to sociology, economics, environmental sciences, geography and GIS, but it also includes creativity and know-how in urban design and many other substantive fields of operation.

A key question regards the connections between methodological and operational aspects, and therefore the extent to which theory is important for practice and, on the contrary, the extent to which experience is important for innovating theory (Salet and Finka, 2010). In planning, theoretical issues are not commonly addressed by practitioners, who leave to academia the task of working on theory, developing criticisms, and formulating new proposals, while practitioners are subject to well-regulated procedures and must apply rules and respect legal constraints. These differentiated roles create the 'theory-practice gap', which regards "how theory is or is not used in planning practice" (Allmendiger, 2002-2009, p. 23) or, as Alexander (2010) put it, whether "planning theory affects practice", due to the complexity of

transferring innovative knowledge into operational practices. In this regard, it must be considered that "epistemic communities… or communities of practice… operate to construct knowledge in processes that involve scientific experts and practitioners" (Rydin, 2007, p. 53).

As said, planning is intrinsically locally connected because it is related to the politico-administrative system, the educational tradition, and the professional environment, and because it reflects a wider institutional culture. However, there are common bases and similar historical developments, together with shared current concerns. A first step in the evolution of the discipline dates back to the public interventions in the economy after the 1929 crisis, which gave a wider role to the state, enlarged the areas of regulation from the physical space of the city to other sectors, thereby requiring the development of methods and techniques for programming – temporally and spatially – the interventions and assessing the expected results. A second step can be identified in the 1960s, when planning "became firmly ensconced as a public sector activity that drew increasingly on formal social-scientific theories and rational decision-making to solve problems" (Forsyth, 2007, p. 464). In the 1950s planning split between "'town planning', which is essentially procedural, and 'urban design', which is essentially qualitative" (Alfasi and Portugali, 2007, p.166).

These are the bases on which the discipline has developed in recent decades, with growing exchange and integration across regions and countries. However, differences among countries in planning trends and practices still persist. In recent years, planners in the USA and the UK "have seen themselves as applied social scientists" (Stiftel and Mukhopadhyay, 2007, p. 565), after a struggle with Urban Design and Architecture (Anselin et al., 2011), whereas "Design approaches to planning appear to be more common in continental European schools and in schools in developing regions" (Stiftel and Mukhopadhyay, 2007, p. 565).

In the European countries planning has evolved significantly in recent years, defining a discipline not centred on design and rational-comprehensive urban planning models. In fact, European integration has produced an amalgam of intervention models which were once markedly distant. Moreover, professional planners increasingly share approaches, languages and tools (Fürst, 2009), although there are still important differences in the founding bases (national legal systems, in particular), in their denominations (Vogelij, 2008), and in the instruments and procedures adopted (Tira et al. 2011).

In Italy, the delivery of planning courses mainly at the schools of Architecture and Civil Engineering and a professional practice still dominated by such practitioners keep the discipline connected to urban design.

2. New planning demands. The Italian planning case

The Italian case is characterized by a paradox: a unique urban history but poor current urban development. This is due to the ineffectiveness of planning practices, which goes hand in hand with the weak recognition of the role of planners, in contrast to the celebration of a handful of 'archistars'. The inefficiency and the

lengthiness of planning processes reflect, on the one hand, patron-client relationships and the role of 'dark and grey networks' (Scattoni and Falco, 2011, p. 48), on the other the involvement of practitioners not specifically trained or professionally focused on planning (Scattoni and Falco, 2011, p. 48).
The Italian planning system has been defined in terms of an 'urbanism tradition' (CEC, 1997; Espon, 2007). In fact, it is based on urban design and centred on the municipal plan, although this level is nested in a hierarchy of different spatial plans, and in recent years sectoral programmes and different approaches and practices have emerged. The innovation has concerned different issues: firstly, the form of plans, then their contents, lastly the planning process.
As regards the form of plans, the following aspects should be stressed:

- a distinction between structural features and operational contents, with the former role assigned to spatial/regional plans, but also to structural municipal plans framing operational/ implementation documents (Tira and Zanon, 2011; Scattoni and Falco, 2012);
- the multiplication of spatial (regional, provincial, landscape defence) and sectoral plans;
- the activation of a variety of implementation plans by means of concerted actions (Gelli, 2011; Governa and Salone, 2005);

As regards contents, plans must deal not only with the organization of new urban zones but also the rehabilitation of already built-up areas (historical centres included), the protection of natural values, and support for economic development (Piccinato, 2010). The innovation of the planning process is closely bound up with the previously cited aspects, and it includes citizens' participation, a pivotal role of assessment procedures, and a growing weight of public-private partnerships. More generally, there is abandonment – in many cases without it being clearly stated – of the 'rational-comprehensive' model in favour of a multi-level system and an incrementalist method. And the technical competencies required must change accordingly.

3. Evolution of planning expertise

In Italy, planning is a regulated profession as far as statutory plans are concerned, while numerous other planning processes and actions do not require a chartered professional. Territorial and urban planning processes must be conducted, and in particular concluded, by an expert who is entitled to 'sign' such a plan. This implies that different figures intervene in the process, but its coordination is the duty of a chartered professional. Social scientists, geographers and experts in legal and administrative matters are therefore excluded.
With the inception of formalized urban planning procedures (in the 1930s and in particular after the approval of the urban planning law in 1942), both substantive and procedural contents started to be addressed by architects and civil engineers. Subsequent changes in the issues to be tackled and the way in which planning processes must be managed have not reduced the role of such technicians, who are well protected by their professional orders.

In the 1960s and 1970s, the shift towards regional development and the emergence of social concerns required new kinds of expertise. Regional economics and regional science began to play a role, in particular at the territorial level, while concerns about urban quality and the effectiveness of urban plans – reflected in new legal requirements – entailed a renewal of planners' expertise. The drawing up of municipal plans required more accurate forecasts as well as precise quantitative definitions of housing, social service, and green area needs. Zoning became a more structured way to provide rules. Notwithstanding the search for 'fairness' and 'transparency', the planning process remained top-down and bureaucratic.

In the 1980s the issues were, at the territorial level, landscape defence and environmental protection. At the urban level, the rehabilitation of historical heritage and, more extensively, of the built environment – including derelict land and industrial sites –- constituted the main theoretical and operational innovations. These concerns required not only assigning new tasks to local authorities but also defining new challenges for urban planning, and soliciting new technical expertise. Finally, a response to the complexity, lengthiness and ineffectiveness of usual planning was found in an incremental approach based on "a kind of informal deregulation, characterized by 'doing', with emphasis on achieving greater effectiveness through specific urban policies" (Gelli, 2001, p.190).

In the 1990s other challenges and opportunities brought about further innovations. In particular, the perspective of sustainable development and the adoption of practices such as Local Agenda 21s – together with many environmental conflicts – were characterized by the involvement and participation of citizens, interest groups and associations. And new kinds of expertise started to be required to facilitate the participation and involvement of citizens and social actors, as well as for dispute resolution.

Other changes characterized the controversial 'negotiated programming' schemes which, at different politico-administrative levels, produced "public-private agreements or pacts" formally reached among different administrations and interest groups (Gelli, 2001). This period was also characterized by the role of European Union's projects and programmes as well as by the European spatial planning culture (Governa & Saccomani, 2004). In particular, urban regeneration programmes marked an evolutionary shift "from physical renewal to urban regeneration" (Governa & Saccomani, 2004, p. 337), because they addressed spatial-architectonic aspects together with social and urban quality issues – including competitiveness goals. As regards the expertise required, the incrementalist method implies the capacity to choose the appropriate 'policy tool' (Ponzini, 2008), to assess alternatives, and to elaborate agreements among different actors. Communication, assessment and negotiation should characterize such planning processes.

Other issues at the urban level regard efficiency, quality and equity of land-use plans. And these have prompted experimentation with new planning methods and tools, in particular with 'equalization' schemes intended to balance the gains and losses due to zoning prescriptions, as well as to share the advantages of development rights between private operators and the public authority.

Planning approach	Perspective	Planning model	Key technical figure	Expertise required	Legitimacy and justification for planning
Urbanism	Aesthetic quality	Urban design	'Integral architect'	Town planning	Architecture history/ Creativity
	Functionalism	Planning techniques (infrastructure, functions allocation)	Civil engineer Infrastructure engineer	Spatial organization Infrastructure planning	Techniques
	Land-use rights assignment	Zoning	Law expert	Legal framework	Law
	Planning procedures	The plan 'as the law says'	Administrative procedures expert	Legal framework / organization management	Legal procedures
Economic / local development	Socio-economic development	Regional development plan	Economist/ social activist	Regional / local development	Effectiveness of public expenditure
	Service provision	Social planning	Sociologist	Sociology	Social quality
Concerted planning	Effectiveness Equity Feasibility	Incremental planning Land-adjustment PPP	Assessment expert Mediator	Assessment /	Consensus
	Multi-level governance	Multi-level planning	Mediator	Communication / Interaction	Agreements
Participatory planning	Citizens' involvement /participation	Communicative planning	Facilitator	Communication / Interaction	Deliberation/ Plan effectiveness /efficiency

Table 1. Planning approaches , motivations, models, and practices, planners' roles, expertise and legitimacy for planning in Italy.

The current situation is therefore characterized by a plurality of issues to be tackled by different planning processes and documents, and the need for technical expertise has increased and also diversified. The recent evolution of technical instruments from GIS to data management and communication tools (internet and social

networks) has added new requirements for planners, who must intervene in complex processes and appropriately manage such a variety of instruments.
In table 1. it is provided a synthesis of the coexisting planning approaches, motivations for action, planning models used, key technical figures involved, expertise required, and legitimacy foundations for planning (and plans as legally binding documents).

4. The educational system and the professional environment

The change in the planning practices required the innovation of professional expertise. The need for change in the educational process was well understood back in the 1970s by Giovanni Astengo, who founded the first planning school in Italy at the Faculty of Architecture in Venice (Vettoretto, 2009). The new school gathered scholars qualified in various disciplines, but recognition of the professional role of planners was slow in coming because of the consolidated role of architects and engineers and the opposition raised by their professional orders.
In recent years, as the other European countries, the Italian universities have been reformed following the 'Bologna system', and also planning courses have been re-organized (Davoudi and Ellison, 2006; Geppert and Verhage, 2008; Geppert and Cotella, 2010). Not only have courses been split into undergraduate/master levels, but greater freedom has been granted to schools, which can now propose a variety of programmes. In theory, a break in the traditionally strict connection among the school (until recently called 'Facoltà', now 'Dipartimento'), the degree course, and professional practice has been introduced. In the past, in fact, graduates from faculties of architecture, having passed a 'state examination', could enrol with the professional Order of Architects, similarly to engineers, doctors, and lawyers, all of whom were entitled to enter professional orders. Now, different disciplinary schools can offer similar degree courses, and new programmes have been introduced in response to demands that had long gone unsatisfied. This innovation has required reform of the technical professions, recognizing the differentiation of specialisations and competencies, and finally accepting new figures into the boards of engineers and architects. This new system is more open than the previous one, but it reinforces the role of chartered practitioners against others whose expertise is more loosely defined, such as urban sociologists, geographers, environment analysts, etc. In particular, innovation has concerned the activation of courses, within the schools of architecture, in landscape architecture, historical heritage preservation, urban, territorial and environmental planning. The schools of engineering, for their part, have activated courses, besides the traditional one in civil engineering, in territorial and environmental engineering and in building engineering-architecture. A number of other courses relating to territorial matters have been activated, reflecting the specific orientations of the schools. For instance, undergraduate courses in landscape are offered by the schools of agriculture, while master courses in geography and cultural heritage management have been activated in the humanities faculties, and master courses in urban sociology, tourism and environmental subjects are present in the schools of sociology and economics.

An analysis of the planning courses offered by the Italian universities prompts some considerations. A total of eight master courses have been activated (plus one by a distance university). Contents and organisation are described in similar ways, but it is difficult to determine, on the basis of the usual wording of the 'Dublin descriptors' (Knowledge and understanding, Applying knowledge and understanding, Making judgements, Communication, Learning skills: Geppert, 2010), the differences among formats and contents. In general, they reflect the international debate and in particular the requirements of the 'core curriculum' proposed by AESOP and the 'common core' elaborated by ECTP-CEU, associations which devote considerable effort to gaining recognition for the role of planners (Geppert, 2008), promoting quality education, and amalgamating educational processes across Europe.
Descriptions define planning courses offered by the Italian universities not centred on urban design, which is a central subject for the schools of architecture. The aim is to train professionals able to support public authorities in the devising and implementation of policies, plans and projects. This implies knowledge of the issues tackled and the methods, instruments and procedures involved in planning processes. The planner must be familiar with economic, social, institutional, legal and ethical issues, and as a professional must be trained to support strategic, physical and land-use planning by public authorities but also by private companies. He/she must be able to coordinate experts in the various disciplines involved in urban, territorial, landscape and environmental planning processes.
Planning is considered a methodology with which to manage complex decisions, and as a process with which to draw up strategic, spatial, urban, landscape, sectoral and land-use plans. It is described as a complex and multi-disciplinary activity requiring different types of knowledge and abilities:

- ability to understand urban and territorial change, also in a historical perspective;
- knowledge and use of planning theories, methods and techniques;
- knowledge of methods and procedures for drawing up urban, territorial, landscape and environmental plans;
- ability to define strategies for urban development, spatial organisation, landscape and environmental protection;
- capacity to coordinate inter-disciplinary experts and activities;
- ability to communicate and manage participation processes;
- ability to make use of assessment procedures.

As said, the university reform has also required reform of the professional orders, which are now differentiated between undergraduate and graduate levels. The engineers' order is organised into various sectors. The civil engineers' sector gathers graduates in civil engineering, engineering-architecture, and environment and territory engineering. All of them are qualified to take responsibility in planning processes. Also the architects' order is now composed of different sectors: one is for 'traditional' architects, who can operate in all the various fields. Other sub-divisions regard historical heritage conservationists, landscape architects, and planners (Davoudi and Ellison, 2006, p. 34).

Considering the figures on the practitioners enrolled, the success of the reform has been limited. In 2008, there were only 468 planners compared with 134,507 architects. Engineers number more than 540,000, of whom one-fifth work in the civil and environmental sectors.

5. Planning paradigms and technical expertise

The following discussion rotates around the distinction between 'urban design' and 'urban planning' and draws on the distinction between 'theory in planning' and 'theory of planning' (Faludi, 1973) in order to ascertain what 'knowledge of planning' and what 'knowledge in planning' is needed.
The professional environment and the dominant demand by local authorities are still oriented towards the traditionally strong role of physical planning. But design of the urban space is one of the tasks to be accomplished by planning, and it can be regarded as either the key tool, within the 'urbanism tradition', or one of the products to be delivered by a multifaceted decisional process. More generally, planning should support the efficiency, effectiveness and equity of public decisions. But it is also concerned with goal definition. Planning expertise therefore regards the process, on the one hand, and the multiple issues addressed on the other, as well as the ability to communicate and interact with the client and the community, appropriately managing value-laden decisions. Different theoretical approaches, methodologies and knowledge characterize the action of the professional figures involved in planning.
As far as planning approaches are concerned, a variety of models coexist owing to the fragmentation of decisional processes, but an incrementalist practice dominates, together with the trend towards differentiating between strategic/structural planning levels and operational ones. Different directions are taken by regions and cities: the drawing up of specific 'strategic plans' in parallel with consolidated urban planning, re-interpretation of the statutory plans (Balducci et al. 2011), and activation of the 'two levels' system. This model integrates a strategic approach with the definition of structural-territorial aspects – concerning non-negotiable values and long-term decisions – to frame operational decisions. Current trends are strict defence of environmental and landscape aspects at the upper level and public-led operations at the lower one (this is the policy of regions like Tuscany and Emilia-Romagna), but also neo-liberal methods giving large space to private initiatives (Milan's position). The results are not entirely satisfactory: in particular, the Tuscan policy has not attained the efficiency expected (Scattoni and Falco, 2011) and Milan's planning is criticised in terms of its transparency and effectiveness (Mazza, 2009).
Methodologies connect the planning model adopted with the type of knowledge used. In particular, together with more technical-scientific methods concerning environmental, urban and social analyses and interpretation of future trends, design-oriented methods are used to elaborate proposals, and participatory methods support interaction with the actors involved.
As far as knowledge is concerned, it must be considered that in planning the scientific paradigm can be used only partially, because knowledge "informs 'good'

practice by 'enlightening' practitioners to improve their judgment rather than equipping them with technologies for better practice" (Alexander, 2010, p. 100). Therefore, different knowledge types can be recognized (after Rydin, 2007):

- empirical, relating to specific issues (design, infrastructure, assessment, etc.);
- process coordination, relating to process management ;
- communication/interaction, relating to process management and the involvement of stakeholders and citizens;
- legal/procedural, relating to process management and definition of the statutory contents of plans;
- normative, relating to the goals and decisions taken in the public interest.

The adoption of a planning model, and the use of specific methodologies and knowledge, define different professional profiles. The New Charter of Athens 2003 (ECTP-CEU, 2003) sees the planner as a scientist, a designer and a visionary, a political advisor and mediator, an urban manager. The analysis of the Italian case confirms these roles, and enables their operational definition. The proposed description may help in making planners' profiles clearer and more visible, expressing not only 'what they do' but 'what they are', considering that the legitimacy of expertise derives not only from recognition of the usefulness of the expert's knowledge but also from the trust gained by the expert. The scheme follows in some way the "role theory" (Mayo and Johnson, n.d.), because planners not only make use of their expertise, but intervene in a social arena, thus assuming a recognized role or, better a role-set, together with the associated professional responsibilities and obligations (Campbell and Marshall, 2000a, p. 300). They make use of different types of knowledge, take part in the co-production of knowledge during the planning process (Rydin, 2007) and play diverse "parts and scripts" (Mayo and Johnson, n.d., p. 3), adapting their behaviour to the context, but also contributing to change the context itself.
In short, the following planners' profiles can be described, stressing that roles depend on the specific planning approach adopted, but in many cases this choice is rather vague and multiple roles are performed.

- The 'process manager'. The planner knows how the planning machine works, first of all in legal terms. S/he is the 'driver'. This is not a minor role, because the Italian legislation is rather complicated, and a specific ability is required in order to overcome a bureaucratic application of rules (the plan as 'what the law says') which would refrain from innovating practices. Planning requires adopting an approach which can give the planner a minor (executive) or a major (consultant, social activator) role. In particular, a strategic approach should give the planner space to help change even the urban policy agenda (Pasqui, 2011). Management also involves coordination 'of' the planning process, that is, the multiplicity of actors involved, each pursuing his/her own objectives, as well as coordination 'in' the planning process, which concerns the experts in the different sectors involved. Management also requires communicative abilities, and the capacity to face the effects of the technological innovations (GIS, web-GIS, etc.) which are changing not only the materials of statutory plans (from 'paper documents' to 'electronic plans') but their

very nature (becoming dynamic, flexible, easily accessible to everyone, and hopefully interactive).

- The 'urban designer'. This is a consolidated role for the Italian tradition. The planner is expected to be able not only to physically organize the urban space connecting different structures and resolve conflicts in the use of space, but also to add value to the city. In particular, this is why the most celebrated urban planners and 'archistars' are involved in urban projects aimed at changing the face of cities suffering from economic crisis or loss of strong functions (Frank Gehry's Guggenheim museum in Bilbao has become the paradigm in this regard). Expertise therefore oscillates from technical know-how concerning zoning, building codes and the like to more creative abilities. The emerging demands concerning sustainability, energy efficiency, environmental protection, urban security, require the innovation of consolidated knowledge, and the development of new urban models.

- The 'infrastructure engineer'. This is a traditional role, but innovation is rapid, and the consequences for the space organization of such 'sociotechnical' constructions (Graham, 2001) are important. Expertise therefore regards the specific structure and its effects, material and immaterial, direct and indirect, on space and society, on the environment and the landscape. The search for a more consistent connection between infrastructure networks and the territories involved (and local societies and economies) has been the focus of a programme of the Italian Ministry of the Infrastructure which showed the crucial importance of this topic and the sophisticated nature of the expertise required, which involves strategic thinking and local development perspectives (Fabbro and Mesolella, 2010; Janin Rivolin, 2010; Servillo, 2011; Zanon, 2011).

- The 'expert in local development'. Territory can be seen as the material basis on which to operate (as usual for economic development initiatives) or it can be considered the result of the complex relationships among the local society, the natural heritage and the historical organization of space (Balducci, 2011, p. 34, note). Competition among regions and cities has become a challenge for public policies and planning is progressively engaged in 'intercepting economic resources' and in supporting place-based economic development. 'Social capital' (Coleman, 1988; Putnam, 2000; Trigilia, 2001) and 'institutional thickness' (Amin and Thrift, 1995; Healey, 1998) are the terms supporting this bottom-up vision and the planner is expected to play the role of a social activator, and to provide expertise in EU projects and financial support (Governa and Salone, 2004; Salone, 2010).

- The 'expert in assessment'. Planning increasingly relies on assessment of alternative proposals and on the evaluation of actions as far as environmental, social, economic effects are concerned. The ineffectiveness of traditional urban planning solicits replacement of the usual methods based on a prior design and allocation of rights and the subsequent control of the compliance of actions with legally binding rules. Also the 'two-level' articulation of plans requires the establishment of assessment criteria based on clear parameters in order to ascertain whether the goals

defined by the 'structural plan' are achieved, and what the environmental and social effects are (Scattoni and Falco, 2011; Tira and Zanon, 2011). As regards equity, this regards the equal treatment of landowners but also assessment of public spending and the effectiveness of planning because the public administration must find the resources and land to build the 'public city' (Micelli, 2002). Other issues are involved in terms of urban quality, feasibility, and sustainability. Planning tends to become a 'decision machine' generating a continuous flow of analyses, proposals, social and political interactions. It therefore requires the accurate assessment of decisions, and often negotiation with the stakeholders in order to manage land adjustment or to assign bonuses. The paradigmatic experience in terms of 'equalization practices' is that of Casalecchio di Reno, close to Bologna (Pompei, 1998), while environmental aspects were first addressed in innovative manner by the plan of Reggio Emilia (Campos Venuti, 1995).

- The 'regulator'. The planner knows how the legal framework operates and how the planning process must be developed in order to gain legitimacy for the plan. And this is strictly connected to land-use and development rights assignment. This role can simply involve the application of disciplinary knowledge or legal rules, but it is expected to go beyond such bureaucratic procedures. In fact, the innovation of planning is connected to the ability to manage land-use and development rights when the public authority grants bonuses in order to obtain additional public space, greater urban quality, and energy saving.

- The 'facilitator'. Participation is a problem of democracy (in order to involve citizens) and of efficiency (preventing the 'NIMBY syndrome'). The communicative method has become an "orthodoxy", although the search for consensus can imply quite different approaches and sensitivities (Rydin, 2007, p. 54). The consequences of this approach are important. Firstly, it supports the production of "local, experiential and contextualized knowledge", allowing the "contextualization of conventional scientific knowledge" (Rydin, 2007, p. 54). Then, it implies that planners, assuming a 'deontological' perspective (Campbell and Marshall, 2002), can help define what the public interest is among a plurality of interests. Communication expertise is not consolidated in Italy, in particular among technical planners, although participatory planning schemes in Italy are not new. In the 1960s and 1970s some charismatic architects (in particular Giancarlo De Carlo) and social activists (Danilo Dolci) experimented with participatory processes and more radical experiences. During the 1970s the city was the issue for many spontaneous political groups that pursued the 'right to the city' theorized by Henri Lefebvre, but were soon institutionalized in the form of 'neighbourhood councils'. In the 1990s the Local Agenda 21 schemes led to the activation of public participation, and in the past decade the multiplication of environmental disputes has pushed towards change in decisional methods, often after harsh social conflicts, which shows that local communities want to be informed and to take an active part in decisions. Finally, the strategic/structural role of upper-level plans, and the negotiation practices of operational levels, imply active interactions with the community, on the one hand, and landowners and economic operators on the other. A specific expertise is

therefore required for the management of participatory processes in order to avoid a misuse of citizens' involvement, to make an appropriate use of non-technical knowledge (Campbell and Marshall, 2000b) and to balance the power asymmetry among actors (Fainstein, 2000, p. 451).

6. Conclusions

In conclusion, what is the specific role for the planner? Certainly, most of the types of substantive expertise cited above do not specifically regard planners or planners alone. But some of the key roles devised require the involvement of professionals with sound specific knowledge, specialized training, and openness to experimentation (Balducci et al., 2011). In recent decades, the technical expertise of planners in Italy has been enlarged to include a variety of issues, and it is difficult to understand why the planner's role(s) is (are) not yet fully recognized. Of course, the discursive contents of most of the documents produced are not as impressive as architects' plans and engineers' calculations. But most often management of the planning process is extremely difficult and requires specific competencies. Some 'planning disasters', like that of the high-speed train project in Valle di Susa (Bobbio and Dansero, 2008), testify to the need for the appropriate management of decisional processes.

	Type of knowledge				
Planners profile	Empirical/ Technical	Planning process	Communication/ Interaction	Legal/ Procedural	Normative/ Value laden
Process manager		√	√	√	
Urban designer	√	√		√	
Infrastructure engineer	√				
Expert in local development	√		√		√
Expert in assessment	√		√		√
Regulator	√		√	√	√

Table 2. Planners profiles and types of knowledge involved.

Many of the pivotal issues characterizing planning, and in particular forecasting/time management, coordination and regulation, together with communication/interaction and assessment are fields to be covered by specific expertise. One risk is that specialization tends to fragment the discipline into a number of strands which often do not communicate with each other, bringing about, together with the "flattening

down to politics", a de-professionalization of planning (Mazza, 2002, p. 12). An effort to make specific expertise more visible (the 'roles' described above), and to coordinate the different sectors, would produce more recognizable and 'marketable' professional profiles, that are experts able to master different knowledge types, as described in table 2.

Italian planning education has been innovated, and its quality is comparable with, and competitive with, that in other countries. But planning still lacks an adequate recognition in Italy. Professional architects' orders have accepted planners but still tend to enhance the role of architects. The university reform has given sounder recognition that a specific educational process is required for planners, but the reform has given rise to a variety of courses in different subjects (geography, cultural heritage, etc.), some of which are extremely weak in professional terms, while the traditional subjects (architecture, engineering) still remain strong. Moreover, more operational expertise (typical of bachelor degrees), similarly to other technical professions (architects and engineers), is not yet recognized, although some specific competencies (GIS, for instance) are not covered by the usual degree courses.

Recognition of the roles performed by planners may help in developing awareness that different planning practices are performed, each requiring specific expertise, thus giving autonomy and visibility to policies, planning actions, and, at the same time, to planners.

In conclusion, planners are hired because they can play a specific role, and often in order "to be advocates for particular interests" (Campbell and Marshall, 2000, p. 302), but in many regards they are successful when they play more roles and these change over time, because planning becomes a learning process contributing to modify the decisional environment, and possibly the balance among the power relations.

ENVIRONMENTAL ASSESSMENTS INSTRUMENTS FOR URBAN TRANSPORTATION PLANNING. FROM A REACTIVE TO A PROACTIVE APPROACH.

Julio A. Soria [1], Luis M. Valenzuela [2] Luca Bertolini[3]

Abstract

There is a growing interest regarding the development of environmental assessment instruments for application in urban transportation planning. Nevertheless, a great number of studies show that present instruments have a very low effectiveness when confronted with the complexity of the environmental consequences of urban transportation in its interaction with land use factors. Furthermore, the majority of environmental instruments are rather oriented towards monitoring plans than towards supporting decision-making.

To address these problems, this paper presents a strategy for proactive environmental instruments design ('PEID strategy') as a method for developing environmental assessment instruments for supporting decision-making in urban transportation planning. Accordingly to this strategy, environmental instruments must fulfil four key criteria: be performance-based, reference values-based, integration-oriented and decision-oriented. To illustrate and assess the worth of this strategy, an environmental assessment instrument has been developed following these criteria and applied to evaluate alternative plans for a transit corridor in the city of Granada, Spain. The paper describes this application and reflects on the advantages and disadvantages of the strategy as well as on issues for futures research.

Keywords: Environmental assessment, decision-making support, urban transportation planning,

1. Environmental assessment for urban transportation planning

The growing interest regarding the incorporation of sustainability goals into planning has a relevant milestone in 1972. In this year was celebrated by United Nations the seminal conference on 'The Human Environment' in Stockholm, Sweden. Ever since, sustainability has been incorporated into many levels of society such as education, planning, economy, etc.

In the case of planning, the transition to sustainability requests that its performance must be assessed (Ness et al, 2007). This has originated important challenges to the scientific community in providing efficient tools. As a response to these challenges, sustainability assessment has become a rapidly developing area associated with the family of impact assessment tools (Pope et al., 2004) (e.g. Environmental Impact Assessment and Strategic Environmental Assessment). In Devuyst´s words (2001, p. 9) a sustainability assessment tool is 'a tool that can help decision-makers decide what actions they should take and should not take in an attempt to make society more sustainable'. In recent years, a lot of countries have conferred to sustainability assessment, and specifically to Environmental Impact Assessment (EIA), an important and decisive role into their planning systems.

EIA is a widely used ex-ante tool to support decision-making in transport planning. It is aimed to make an overview of the environmental impacts of projects. The central goal is to reduce the potential negative effects using corrective or compensatory measures (Ness et al, 2007). It has a long tradition starting in the 1960s and a lot of countries made EIA compulsory into their planning systems. For this reason, the role of EIA has become increasingly important. In the case of EU, Council Directive 85/337/EEC was the first European Community directive to provide details on the nature and scope of environmental assessment, its use and participation rights in the process. The origins of the 1985 Directive lay in the EEC's 1973 First Environmental Action Programme, which identified the need to implement procedures to evaluate the environmental effects of certain activities at the earliest possible stage. Ever since, EIA was periodically introduced in the legislation of Member States (EC, 2009). Due to such legal requirements, nowadays there are strict guidelines for the EIA process in the EU and other countries (e.g. USA or Canada) (Cornaro et al., 2010).

Like many others cases, a reduction of negative environmental impacts in urban transportation (air pollution, energy consumption, etc.) is thought to be decisive in promoting more sustainable planning outcomes (Banister, 2005; Litman, 2009). Nevertheless, evidence show that this objective is hardly achieved in daily planning practice (Hull, 2008; Joumard and Gudmunsson, 2010). As a consequence and among other factors, the effectiveness of the EIA for evaluating urban transportation plans/interventions is contested, as strongly argued by several academics (Arce and Gullón, 2000; Browne and Ryan, 2011). Accordingly, assessment innovations seem to be needed. Many of them focus on supplementing and improving the predominant environmental assessment instrument, EIA.

This paper hypothesizes that the problem of EIA in the case of urban transportation planning could be related to its increasingly reactive use in the planning processes by practitioners. This means reacting to environmental

impacts that happen rather than avoiding them to happen. This is a consequence of, on the one hand, that many times the EIA process only includes environmental specialists, and on the other hand, that the used methods are not always the most suitable to identify ways of preventin potential impacts (Soria, 2011).

To face this, the paper identifies the need to overcome a certain number of substantive communication barriers between EIA makers and transport planners. Firstly, these barriers are linked to the types of results hoped for. EIA measures static environmental impacts, however, urban transportation is a dynamic system, with varying environmental performance in varying temporal and spatial contexts, as described by different scholars (Peyrbrune, 2000; Dobranskyte et al., 2007). Secondly, transport planners scarcely receive inputs from EIA in order to support their decisions (Soria, 2011). Therefore, tools that foster learning between different specialists are needed.

This paper presents a strategy for proactive environmental instruments design ('PEID strategy'). According to this strategy, environmental instruments must fulfil four key criteria: (i) be performance-based; (ii) reference value-based; (iii) integration-oriented and; (iv) decision-oriented. To illustrate and assess the worth of this strategy, an environmental assessment instrument (ETV-model) has been developed following these criteria and applied to evaluate alternative plans for a transit corridor in the city of Granada, Spain.

The case of Spain is illustrative of the problems previously described (Gomez-Orea, 2007). The RD 1131/1986 Law incorporated EIA into its planning system. The main consequence of that was that different Spanish governments (local, regional, etc.) have used EIA to prioritize their proposed plans and projects. However, despite the application of EIA since 80s, it is being difficult to achieve sustainable goals in the case of urban transportation (Serrano, 2009; Valenzuela et al., 2011). Authors such as Garmendia (2005) and Gomez-Orea (2007) explain that the design of more proactive environmental assessment instruments could contribute to solve that.

In the following, we will start by defining the 'PEID strategy' (section 2). Then, the Environmental Threshold Values Model ('ETV-model') will be presented (section 3). This model has been designed following the 'PEID strategy' and it has been applied on metropolitan transit corridor in Granada, Spain. The suitability of this study-case is due to institutions nowadays debating implementing a Light Rail System in the corridor. Finally, we shortly discuss on the worth and advantages of this strategy, as well as on issues for future research (section 4).

2. The 'PEID strategy'

The central goal of the 'PEID strategy' is to lead the design of proactive environmental assessment instruments. The strategy is done in two phases. The first phase is the analytical and comparative phase and the second is the decision phase (see figure 1).

The first phase (analytical and comparative) focuses on designing tools that can compare different alternatives and diagnose the advantages and disadvantages of them. The objective is to evaluate urban transportation according to its dynamic characteristics rather than valuate only its final effects. To achieve that, the 'PEID strategy' proposes to develop environmental assessment instrument fulfilling three key criteria: be performance-based, reference values-based and integration-oriented.

To be performance-based (first criterion) means changing the goals of the evaluation. While EIA measures how each alternative transforms its environment, the performance-based evaluation analyses what alternative has a better environmental functioning. The advantages are not only that the performance based evaluation could represent better the dynamic characteristics of urban transportation (Dobranskyte et al., 2007) (Ricci et al., 2010), but also, it permits the incorporation of other practitioners (non-environmentalist) into the evaluation since earlier stages. This aspect is a consequence of the fact that performance-based evaluations can calculate easier than other methods an aggregated or synthetic value (Gerike et al., 2010).

Complementary to performance-based evaluations, understanding sustainability as a normative orientation can be a useful way to make the outcomes of evaluation more understandable for the spectrum of decision-makers. This could be determining performance trends through the incorporation of reference values into the evaluation (second criterion of the 'PEID strategy'), (Nijkamp and Ouwersloot, 2004). The major problem faced in practice is that the reference values are many times fuzzy, and decision-makers may have different views on their adoption. Consensus solutions to the above could focus on designing methods based on experts´ opinion.

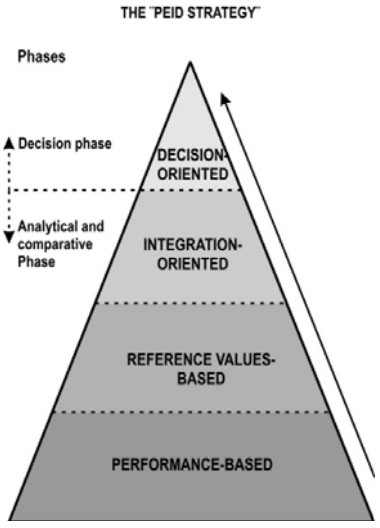

Figure 1. Key criteria of the 'PEID strategy'

The third criterion of the analytical and comparative phase is that the evaluation should be transport land use integration-oriented. In an urban transportation context, this is especially relevant in the case of the interrelationships between urban structure and transport. As studied by several authors (Priemus et al., 2001; Cervero and Kockelman, 1997; Naess, 2006; Cao et al., 2009), the empirical evidence demonstrates that there are significant influences between spatial planning and transport. Nevertheless, traditional environmental assessment approaches focus solely on transport as environment-polluting agent, obviating these interrelationships. The main advantage of an integration-oriented evaluation is to understand the environmental performance of each alternative under determined urban contexts. This would permit to generate a discussion framework between EIA-makers, urban planners and transport planners since the early phases of the planning process.

With respect to the first phase of the 'PEID strategy', each of the three described key criteria tries to adapt the environmental assessment to the specific characteristics of urban transportation. This can be especially appreciated through the idea of promoting a performance-based evaluation, as well as through the incorporation of an integrated vision between urban structure and transport. On the other hand, this phase pursues to make the environmental assessment results more understandable to non-environmentalist. The proposal of reference values and the adoption of a performance synthetic value are related to this objective. Finally, the interaction and discussion between decision-makers is one of highlighted aspects of this phase. The promotion of integrated visions between urban structure and transport into the evaluation could stimulate this.

Once the first phase of the 'PEID strategy' has been completed, the second phase focuses on implementing decision-oriented tools. The main goal is that decision-makers can know how their decisions can affect the environmental performance of urban transportation. The problem is that traditional instruments as EIA aim to identify the alternative with the lowest negative impact. Nevertheless, it is difficult to find examples where environmental assessment instruments can support to take decisions to design/modify alternatives, and thus improve by decreasing negative impacts. The growing use of sensitivity analysis in social sciences could be a good solution to develop support tools for this (Geneletti and van Duren, 2008).

3. Case-study: the ETV-model and an application in Granada, Spain

To illustrate and assess the worth of the 'PEID strategy', an environmental instrument has been developed following the four criteria established by this strategy. The instrument was labelled Model of Environmental Threshold Values (ETV-model) and applied to evaluate alternatives for a transit corridor in the city of Granada, Spain.

Since the 1970s, the metropolitan area of Granada (MAG) began to have significant urban transformations that have lasted until the present. The origin of these transformations is an intense growth in real estate development, the creations of new infrastructures, the growth of the private vehicle market, etc. (Aguilera, 2008). Parallel to this process, a huge increment of environmental problems has been experienced in the region, especially problems originated by urban transportation (e.g. congestion, air pollution, health problems…). To face these problems, local institutions are, among other policies, promoting the implementation of a Light Rail Tran (LRT) System into the most important transit corridor in MAG. The EIA is the tools used to evaluate different alternatives and practical solutions. Concretely, ETV-model will be applied on two possible alternatives: (i) Alternative S.0, based on non-implementation of LRT into the corridor; (ii) Alternative S.1, based on implementation of LRT. Figure 2 shows the location of the proposed Light Rail Train System in MAG.

Figure 2. Light Rail Train System in the Metropolitan Area of Granada.

The most representative substantive problems in the use of EIA discussed in section 1 seem to be also present into the study-case (related to types of results hoped for and the fact that transport planners are scarcely involved into EIA processes) (Soria, 2011). Hence, it could be asserted that there is a great suitability of this case-study to prove the 'PEID strategy' through the elaboration and application of the ETV-model.

Before explaining the details of ETV-model development, table 1 shows its main characteristics.

Table 1. Main characteristics of the 'ETV-model' following the criteria of the 'PEID strategy'

The 'PEID strategy'		ETV-model
Analytical and comparative phase	Performance-based	-Input to system (energy and resource consumption). -Output to system (waste emission and noise). -Integrated use of corridor (barrier effect and public space)
	Reference values	-Quality Critical Threshold (QCT). It represents an optimum value of indicators where the environmental impacts of urban transportation would be irrelevant. -Impact Critical Threshold (ICT). It represents an impact value of indicators where the environmental impacts of urban transportation would be very serious.
	Integrated orientation	-It proposes the concept of 'mobility environment' as spatial unit of integration between urban structure and mobility patterns. -The environmental evaluation of alternatives is focused on these mobility environments.
Decision phase	Support-based	-Using sensitivity analysis, the model proposes four decision support indicators for decision-makers.

As can be seen in figure 1, the ETV-model has been developed following the four key criteria proposed by the 'PEID strategy'. The methods proposed through this strategy will be detailed for each criterion below.

Performance-based:

The adoption of performance evaluations must include indicators that reflect various levels of analysis, although it is important to take their relationships into account to avoid double-counting (Litman, 2009).

Therefore, the central goal is to propose an indicators system that permits to evaluate and compare the two alternatives in the case-study. Given the characteristics of the corridor, the indicators system will cover the main negative externalities of urban transportation (figure 3): (i) An inefficient use of energy and resources; (ii) Emission of wastes and noise; (iii) Integrated use (both for staying and passing-through) of corridor.

Six indicators are proposed (see figure X): (i) Energetic efficiency (Mj/Passenger-Km); (ii) Spatial efficiency (m2 corridor/Passenger-km); (iii) PM10 Concentration (μgr/m3); (iv) Noise emission (dbA); (v) Barrier effect (BE/m); (vi) Public space liveability (m2 non-motorized/m3 motorized).

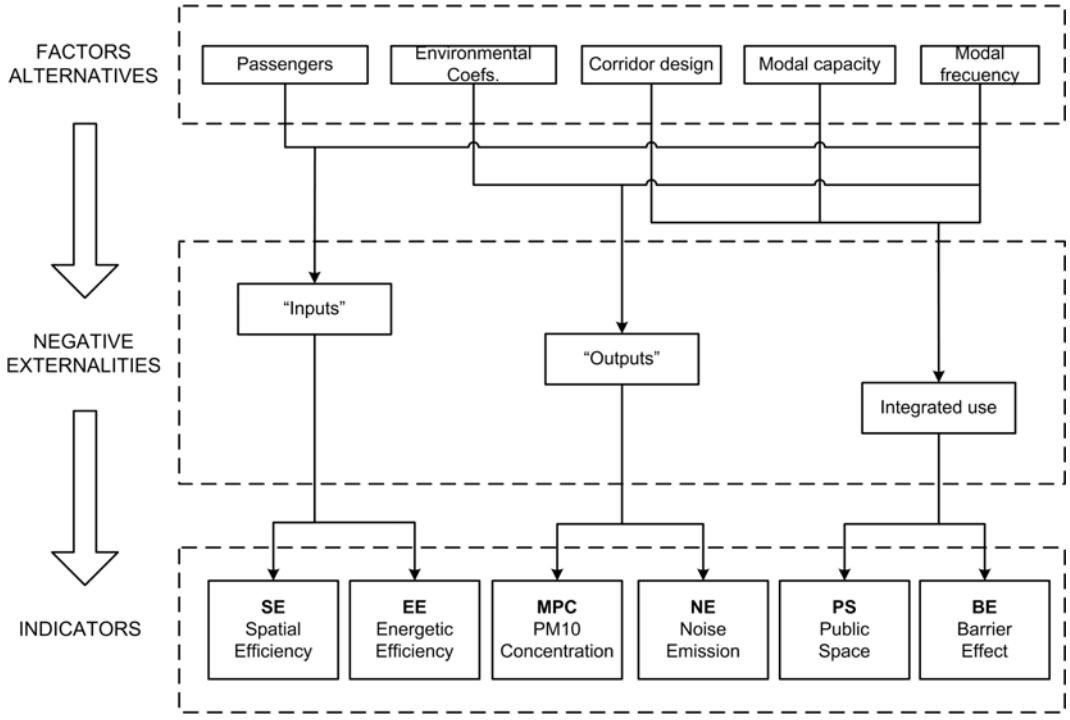

Figure 3. Performance indicators system

Following step-by-step the 'PEID strategy', an aggregated value will be obtained in order to make more understandable the results for non-environmentalists. To address this, simple additive weighting methods are used. These methods have been operationalized using a GIS system. The decision-makers directly assigned weights to each indicator by means of an expert panel. Formally, each alternative (Us) is evaluated by the following formula:

$$U_s = \sum_j w_j x_{ij}$$

Where x_{ij} is the score of each indicator, and w_j is a normalized weight, so that $\sum_j w_j = 1$.

Reference values-based:

Another important aspect of the 'PEID methodology' is to establish a decision framework taking sustainability as a normative orientation. The strategy considerers that the identification and definition of reference values could be useful to achieve this objective.

Inspired by e the 'Flag Model' (Nijkamp and Ouwersloot, 2004), the 'ETV-model' determines two threshold values for each indicator: (i) Quality critical threshold (QCT); (ii) Impact critical threshold (ICT). On the one hand, the QCT would indicate an optimum value per indicator where the environmental impact of urban transportation would be negligible. This means that this concept refers to a threshold value identifying the limits of an acceptable damage to the environment. On the other hand, the ICT would be an impact value indicator where the environmental impacts or urban transportation would be serious. This means that this concept refers to a threshold value that cannot be exceeded without causing unacceptable damage to the environment.

The adoption of two thresholds (QCT and ICT) determines three possible environmental performance ranges for urban transportation (see figure 4): (i) Optimum performance, when the indicator doesn´t exceed the QCT: (ii) Acceptable performance, when the indicator is between QCT and ICT; (iii) Negative performance, when the indicator exceeds the ICT.

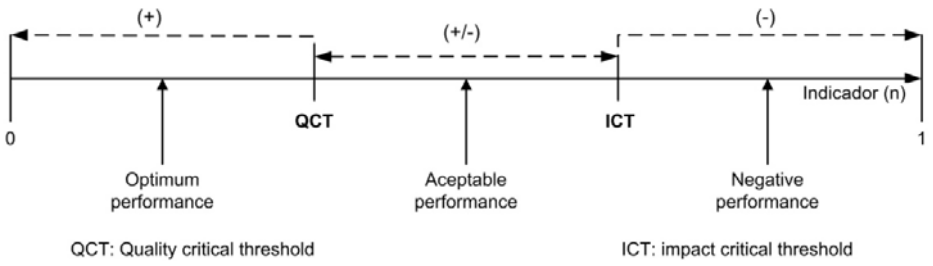

Figure 4. Reference values and performance ranges.

The existence of legislation has been the chosen criteria to determine the reference values for each indicator. Performance indicators such as energetic efficiency, PM10 concentration and Noise emission are regulated by European and national legislations. In the cases of the other three indicators (spatial efficiency, barrier effect and public space), specific thresholds have been estimated for the case-study following handbooks, guidelines, etc.

Integrated-orientation:

Due to the inextricable interrelationships between urban structure and transport, understanding the environmental performance of urban transportation under these parameters seems to be a determinant aspect. The main advantage would be to generate a common framework for discussion between decision-makers since the early planning phases.

To achieve that, the 'ETV-model' proposes to identify 'mobility environments' (inspired by Bertolini and Dijst, 2003) as operational spatial units for the assessment. The objective is that the environmental performance of each alternative can be interpreted under the contexts of these 'mobility environments'.

The ETV-model proposes a method to identify 'mobility environments'. The method includes the definition of representative indicators and mobility vectors of urban structure and transport for the study-case. The combination of indicators and vectors will be used for identifying and defining 'mobility environments'.

After applying the model, five 'mobility environments' have been defined for the corridor: (i) Proximity and local dimension; (ii) Proximity and transit distribution; (iii) Motorized transit; (iv) Metropolitan centrality; (v) Intermodal station. Figure 4 shows the location of each 'mobility environment'.

In the first mobility environment identified (proximity and local dimension), the majority of daily necessities (working, shopping, etc.) can be covered without motorized modes. This is a consequence of that the proximity component is very relevant. On the other hand, in the second 'mobility environment' identified (proximity and transit distribution) is not only very important the proximity component, but it has an important role for the motorized modes too. The rest of 'mobility environments' nominated are more associated with a motorized use of the corridor. Table 2 shows the proposed criteria to diagnosticize the environmental performance of the alternatives in each 'mobility environment'.

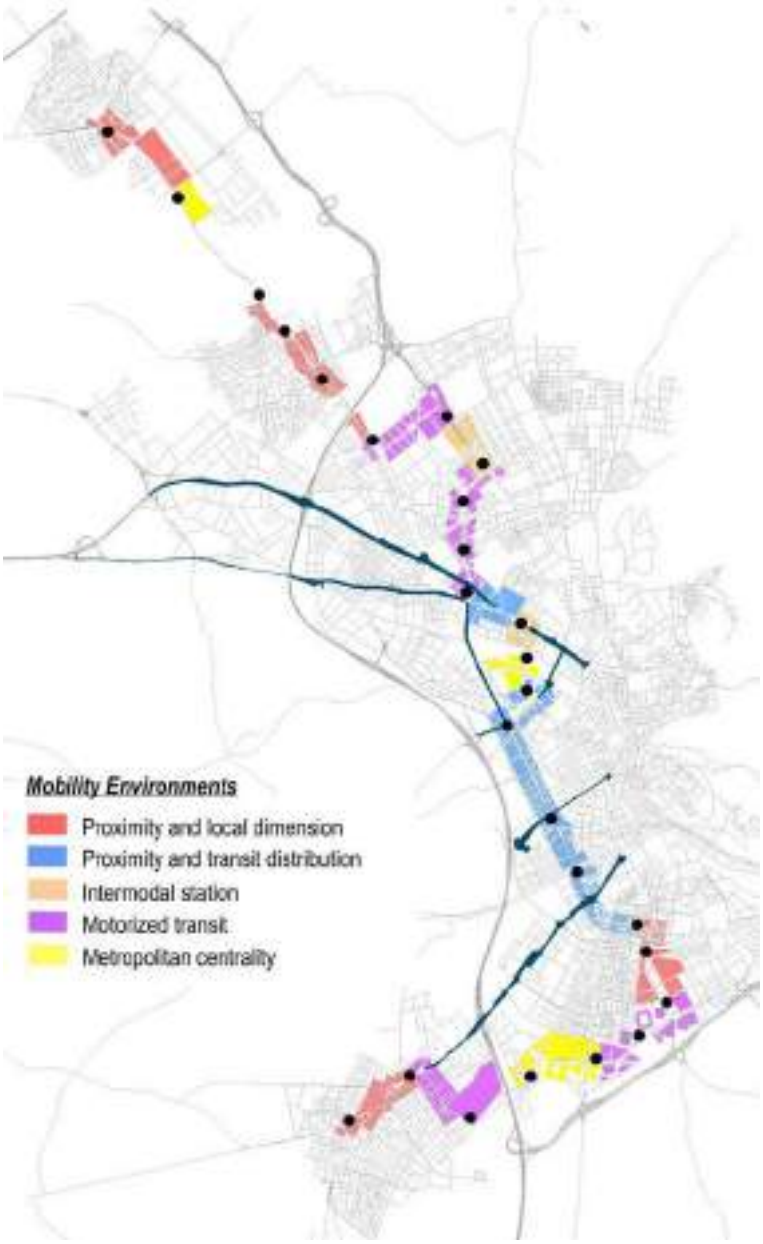

Figure 4. 'Mobility environments' in the corridor

Once applied these three sets of criteria (performance-based, reference values and integrated orientation) to the case-study, different conclusions could be underlined. Alternative S.1 (corridor with Light Rail System) seems to be more performing than Alternative S.0 (corridor without Light Rail System) when the results are valuated under the two first criteria (performance-based and reference values). Nevertheless, when these results are filtered through the specific requirements of the identified 'mobility environments', it could be asserted that Alternative S.1 is not always the most convenient according to the characteristics of each of them. Eventually, decision-makers chose Alternative S.1 for the corridor. However, the assessment indicates the need to modify this alternative in

those 'mobility environments' where its urban integration was worse (specifically this was the case in the menbility vironments 'motorized transit' and s 'metropolitan centrality'). Following the 'PEID strategy', next a module oriented towards design support was developed. This is discussed in the next section.

Table 2. Relationships between performance indicators (see Figure 3) and 'mobility environments'

'Mobility environments'	Environmental performance of corridor					
	Inputs		Outputs		Integrated use	
	EE	SE	MPC	NE	PS	BE
Proximity and local dimension	○	○	●	●	●●	●●
Proximity and transit distribution	●●	●●	●●	●●	●●	●●
Motorized transit	●●	●●	●	○	○	○
Metropolitan centrality	●●	●●	●	○	●	○
Intermodal stations	●●	●●	●●	●●	●●	●●

○ Without influence ● Important ●● Very important

Decision-oriented:

According to the 'PEID strategy', the incorporation of decision-oriented tools into environmental evaluation could be an important way to promote proactive assessment instruments. One of the main problem of EIA is that while it allows to identify the alternative with the lowest negative impact, it doesn´t say how decisions of decision-makers could affect the environmental performance of the alternatives.

The last part of the ETV-model incorporates a decision-oriented module that allows decision-makers and practioners to know how their decisions can affect the environmental performance of alternatives. In our case-study this module will be used to analyse possible design modifications on Alternative S.1 in order to solve its integration problems in some 'mobility environments'.

To address this question, the ETV-model proposes two indicators labelled 'Absorption capacity' and 'Improvement capacity'. Both indicators are based on the respective reference values estimated for each performance indicator. The

'Absorption capacity' indicates the capacity of a mobility environment to absorb a reduction in its environmental performance without overcoming its Impact Critical Threshold. On the other hand, the 'Improvement capacity' indicates the capacity of one mobility environment to increment its environmental performance reaching its Quality Critical Threshold.

The development of these indicators has its origin in the growing use of sensitivity analysis in the social sciences (Geneletti and Van Duren, 2008). Both indicators evaluate the sensitivity of environmental performance to different characteristics of alternatives such as passengers, modal capacity, modal frecuency, etc. In this way, decision-makers could know how their decision can affect to the environmental performance of corridor.

Finally, these decision indicators were applied on Alternative S.1. They were used to check what elements of this alternative could be modified to increment its performance in those mobility environments where it was less convenient. Given the expected level of passengers in these mobility environments, the results showed that reducing the number of public transport lines could be acceptable and useful for incrementing the energetic efficiency and reducing the barrier effect. These changes would situate the environmental performance of Alternative S.1 at an 'acceptable level' in all 'mobility environments'.

4. Conclusion and discussion

This paper started with describing the problems of the EIA to assess urban transportation plans/interventions. It was hypothesized that this was partly due to the existence of the merely 'reactive' use of this assessment instrument. Substantive communication barriers between EIA-makers and transport planners were identified as responsible of this situation. These barriers were related to the types of results hoped for and the fact that transport planners scarcely receive inputs from EIA that can support their decisions. Accordingly, the objective of the paper was to present a strategy for proactive environmental instruments design ('PEID strategy'). According to this strategy, environmental assessment instruments must fulfil four key criteria: be (i) performance-oriented; (ii) reference value-based; (iii) integration-oriented and; (iv) decision-oriented. To illustrate and assess the worth of this strategy, an environmental assessment instrument (ETV-model) was developed following these criteria and applied to evaluate alternatives for a transit corridor in the city of Granada, Spain.

The 'PEID strategy' was implemented in two phases. The first phase (analytical and comparative) included three of the four key criteria of the 'PEID strategy', specifically, be performance-based, reference values-based and integration-oriented. Its central goals were basically two. On the one hand, to develop assessment and diagnostic methods oriented to the dynamic characteristics of urban transportation. On the other hand, to facilitate the involvement of other practitioners and decision-makers (non-environmentalist) into the evaluation processes. To follow the three key criteria above mention seems to be

fundamental to achieve the goals of this first phase. The connection between these criteria was relevant when the ETV-model was applied in the metropolitan area of Granada. In this application, the outcomes of the model reflected in general that Alternative S.1 (corridor with Light Rail System) had less environmental negative impact than Alternative S.0 (corridor without Light Rail System), although this statement was dependent on the 'mobility environment' considered. During the application of the ETV-model the outcomes were related to dynamics characteristics of urban transportation, covering different temporal periods and including the interaction between urban transportation and urban structure. Another relevant aspect was that the outcomes of the model stimulated and facilitated the discussion between different decision-makers (environmentalist and non-environmentalist) to obtain comprehensive conclusions, being a relevant aspect of the development of more proactive environmental assessment instruments.

The second phase of the 'PEID strategy' (decision-oriented) aimed to support the practitioners in their decisions. In other words, complementing the assessment through tools that can be also useful to know how environmental performance of urban transportation can be modified by the decisions of planning practitioners. Following the fourth key criterion of the 'PEID strategy', designed a decision-oriented module was into the ETV-model. This module was completed with two indicators labelled 'Absorption capacity' and 'Improvement capacity'. These decision indicators were applied on Alternative S.1 in order to evaluate possible changes for improving its adaptation to the different 'mobility environments'. The outcomes obtained oriented decision-makers to modify the alternative with respect to the number of lines of public transport.

Following use of the 'PEID strategy' to develop proactive environmental assessment instruments, future research needs to analyse the impact of this strategy into planning practice and identifying ways of improving it. As a consequence of the results obtained in this paper, the case of Spain could be a representative context for this objective. The elaboration of sequential workshops following an 'experiential approach' (Straatemeier et al., 2010) with decision-makers and practitioners could be a useful way to analyse and improve the worth of this strategy and the impact of ETV-model in practice.

Cross-border Planning in Europe – The Case of ULYSSES

Wolfgang Jung, Benedikt Brester, Andreas Putlitz[1]
Virpi Kaisto[2], Georgios Sylaios[3], Efren Feliu[4], Carlos Tapia[5], Tobias Chilla[6], Jan-Hendrik Wolf[7], Eduardo Anselmo Castro[8]

Abstract
ULYSSES is a case study oriented project focussing on the implementation of applied research results produced under the ESPON 2006 and ESPON 2013 Programmes as a yardstick for decentralised cross-border spatial development planning. The main aim is to produce analytical results rather than realising a cross-border harmonisation of quantitative data.
ULYSSES addresses the following cross-border areas: The Upper Rhine area along the land borders between France, Germany and Switzerland; the area along the entire Spanish-French land border (Pyrenees); the area along the land border between Greece and Bulgaria; an area covering parts of the Northern Finland-Russian land border (Karelia), an area along the borders between Poland, Germany (land border) and Sweden (maritime border); the area along the land border of Spain and Portugal (Extremadura/Alentejo).

Out of these six cross-border areas under full research, three will be presented as example for a Northern Europe border area with an EU external border (Karelia), Southern Europe border area with one of the new member states of the EU (Greece-Bulgaria), and a centrally located "old" border area, having an external border, though (Upper Rhine). After giving an overview of each cross-border area, results of the factor analysis are described as basis for the results and lessons learned.

The Transnational Partnership Group of ULYSSES used a multi-scale performance and a cross-border institutional analysis in order to find out to what extent borders influence the economic performance and the social interaction of territories and to reveal if and how the economic performance and social conditions of border regions are affected by the fact that they are generally at the outskirts of their countries.

1. Introduction

Territorial cohesion is one of the main objectives of European policies, and territorial cooperation is among the key strategies to reach this objective. In this context, cross-border cooperation plays a vital role. It contributes to creating synergies and coordinating actions between different Member States' regions, featuring different governance systems and performance realities. On regional scale, cross-border cooperation is representative of the actual performance of the European territorial cohesion process. This territorial dimension of European policy is also highlighted in the document "Europe 2020: New European strategy" (2010) approved by the European Commission.

1.1 The project ULYSSES[9]

ULYSSES is an experimental and innovative project supported by 18 European border and cross-border areas (hereafter CBA) that aims at using applied research results from ESPON as a yardstick for decentralised cross-border spatial development planning. Within this overall framework, a targeted analysis including high-quality, comprehensive and **multi-thematic territorial analyses** (hereafter MTA), has been performed on six specific CBA across Europe (see Map 1, page 4):

- The Upper Rhine CBA along the land borders between France, Germany and Switzerland
- The CBA along the entire Spanish-French land border (Pyrenees)
- The CBA along the land border between Greece and Bulgaria
- A CBA covering parts of the Northern Finland-Russian land border (Euregio Karelia)
- A CBA along the borders between Poland, Germany (Euroregio Pomerania, land border) and Sweden (maritime border)
- Extremadura/Alentejo (ES/PT)

The **territorial analyses** focused on the main topics mentioned by Territorial Agenda of the European Union (EC 2007; EC 2011b), namely (i) cross-border polycentric development, (ii) patterns of urban/rural relationship, (iii) levels of accessibility and connectivity, (iv) effects of demographic change (*territorial profile*), and (v-vi) level of attainment of Lisbon/Europe 2020 and Gothenburg objectives by the CBA (*territorial performance*). In parallel, an **in-depth statistical analysis** focused on the six MTA areas was performed as well. This analysis included (i) a catching-up analysis; (ii) a principal components analysis, and; (iii) a multiple regression analysis.

Additionally, a comprehensive **cross-border institutional performance analysis** has been included as well in every MTA. This analysis captured the diversity of governance frameworks existing within each CBA by paying regard to both the *structural dimension*, i.e. the overall framework that can hardly be influenced by the partners of cross-border cooperation, as well as the *activity dimension*, i.e. the

[9] Texts and maps stemming from research projects under the ESPON Programme presented in this paper do not necessarily reflect the opinion of the ESPON Monitoring Committee.

intensity and continuity of institutionalised cross-border cooperation on the regional level.

All the abovementioned activities crystallised in a comprehensive diagnosis for each MTA area that was delivered as an annex to the Interim Report of ULYSSES. On that basis, an **integrated analysis** taking account of previous inputs was performed at a later stage of the project. From a methodological perspective, this integrated analysis adopted the form of a two-phase SWOT analysis that included (i) a *status-analysis phase* in which the findings derived from previous research tasks were organised and prioritised as main challenges and opportunities, and; (ii) an action-decision phase in which a response to each one of the challenges and opportunities identified in previous phase was proposed as a potential strategy.

Both the challenges and strategies were discussed and validated by stakeholders of the MTA areas.

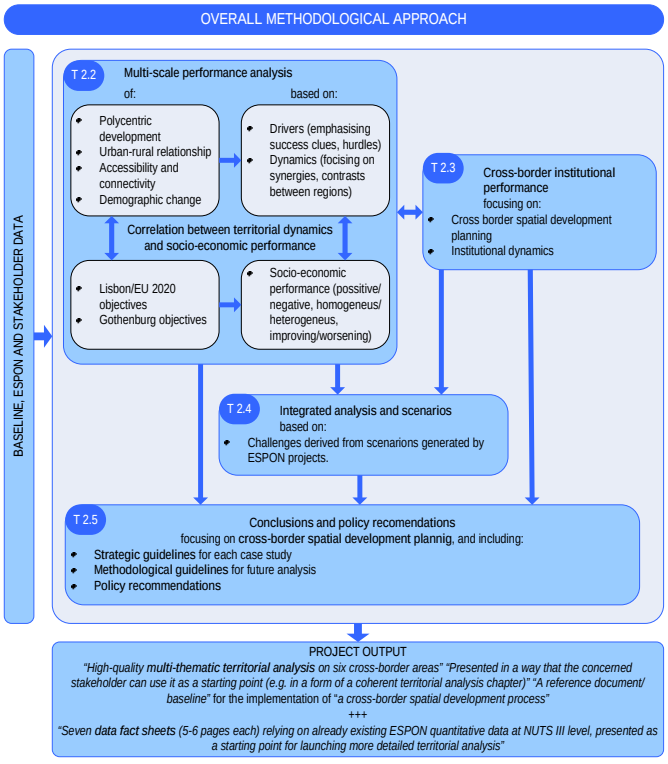

Figure 1: Methodological Approach

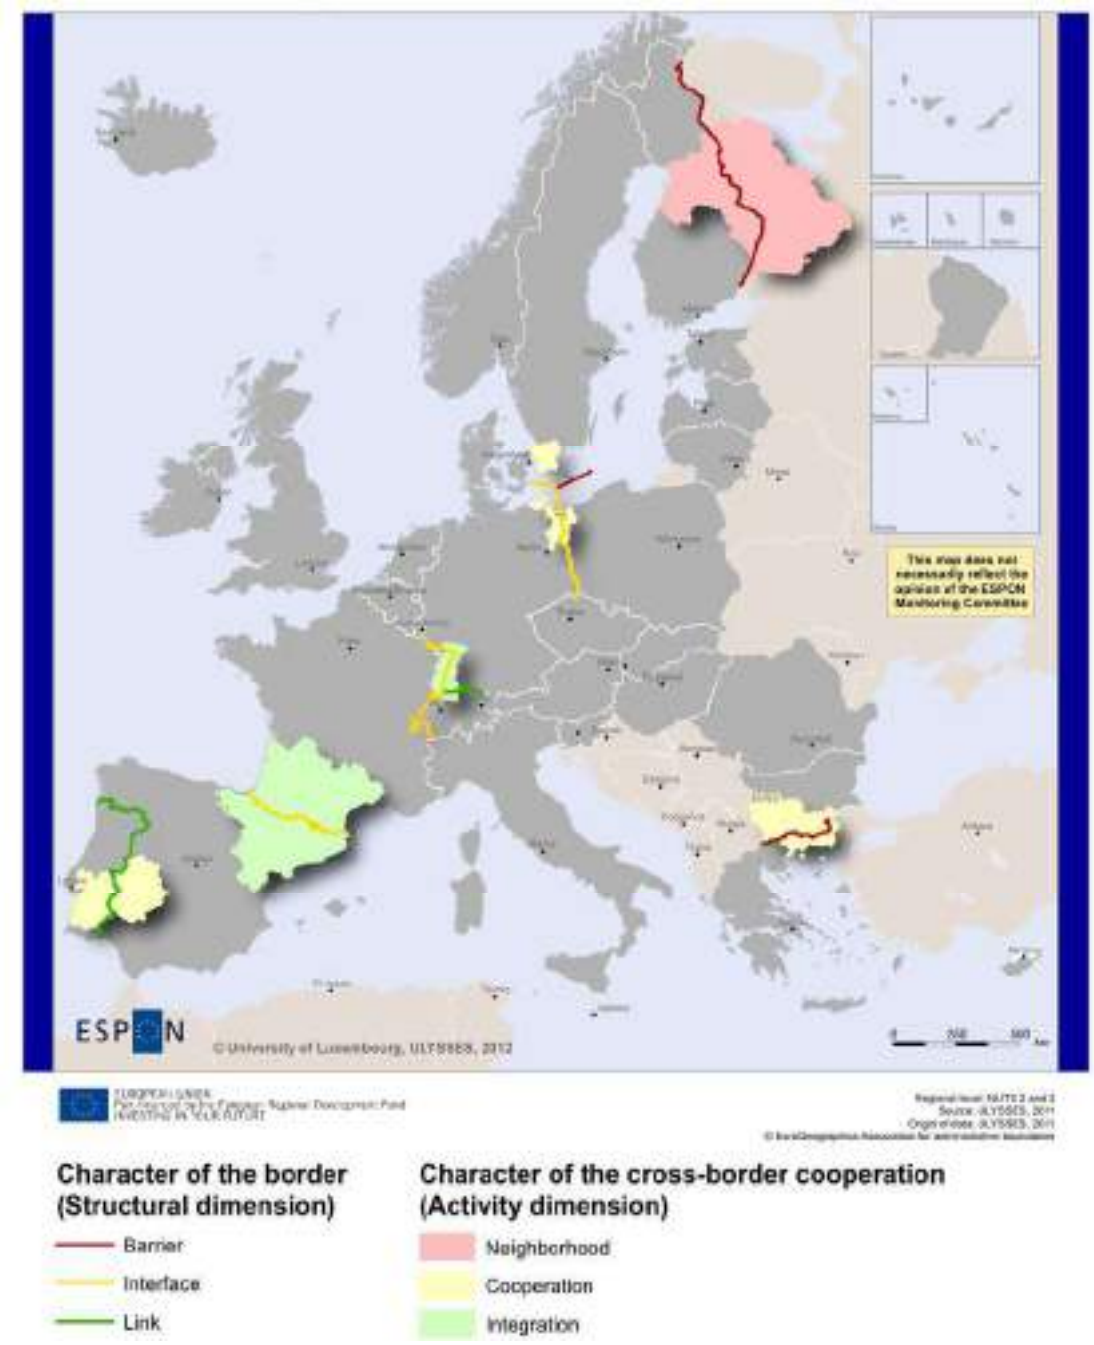
2. Key findings of the multi-thematic territorial analyses

Borders are almost synonymous with political, demographic and economic remoteness and they also behave as functional and territorial discontinuities. Consequently, economic activities do not tend to concentrate close to the national borders and public institutions normally have a limited interest in investing in these areas. However, the growing integration of European regions should therefore lead to the development of many border regions that could exploit their formerly hindered potential, as well as to an increase in population and Gross Domestic Product (hereafter GDP) growth along the borders.

The level of cooperation already achieved is shown in Map 1, p. 4, which gives also an overview of the cross-border areas under full research in the project ULYSSES.



Map 1: Structural Dimension and activity dimension of the ULYSSES regions' institutional setting

The following chapters give an overview of three out of the six cross-border areas under full research in the project ULYSSES: the centrally located Upper Rhine along the land borders between France, Germany and Switzerland, the rather remote

Euregio Karelia covering parts at the Northern Finland-Russian land border, and a Southern-Europe CBA, the land border between Greece and Bulgaria.
After giving an overview of each cross-border area, results of the factor analysis are described as basis for the results lessons learned.

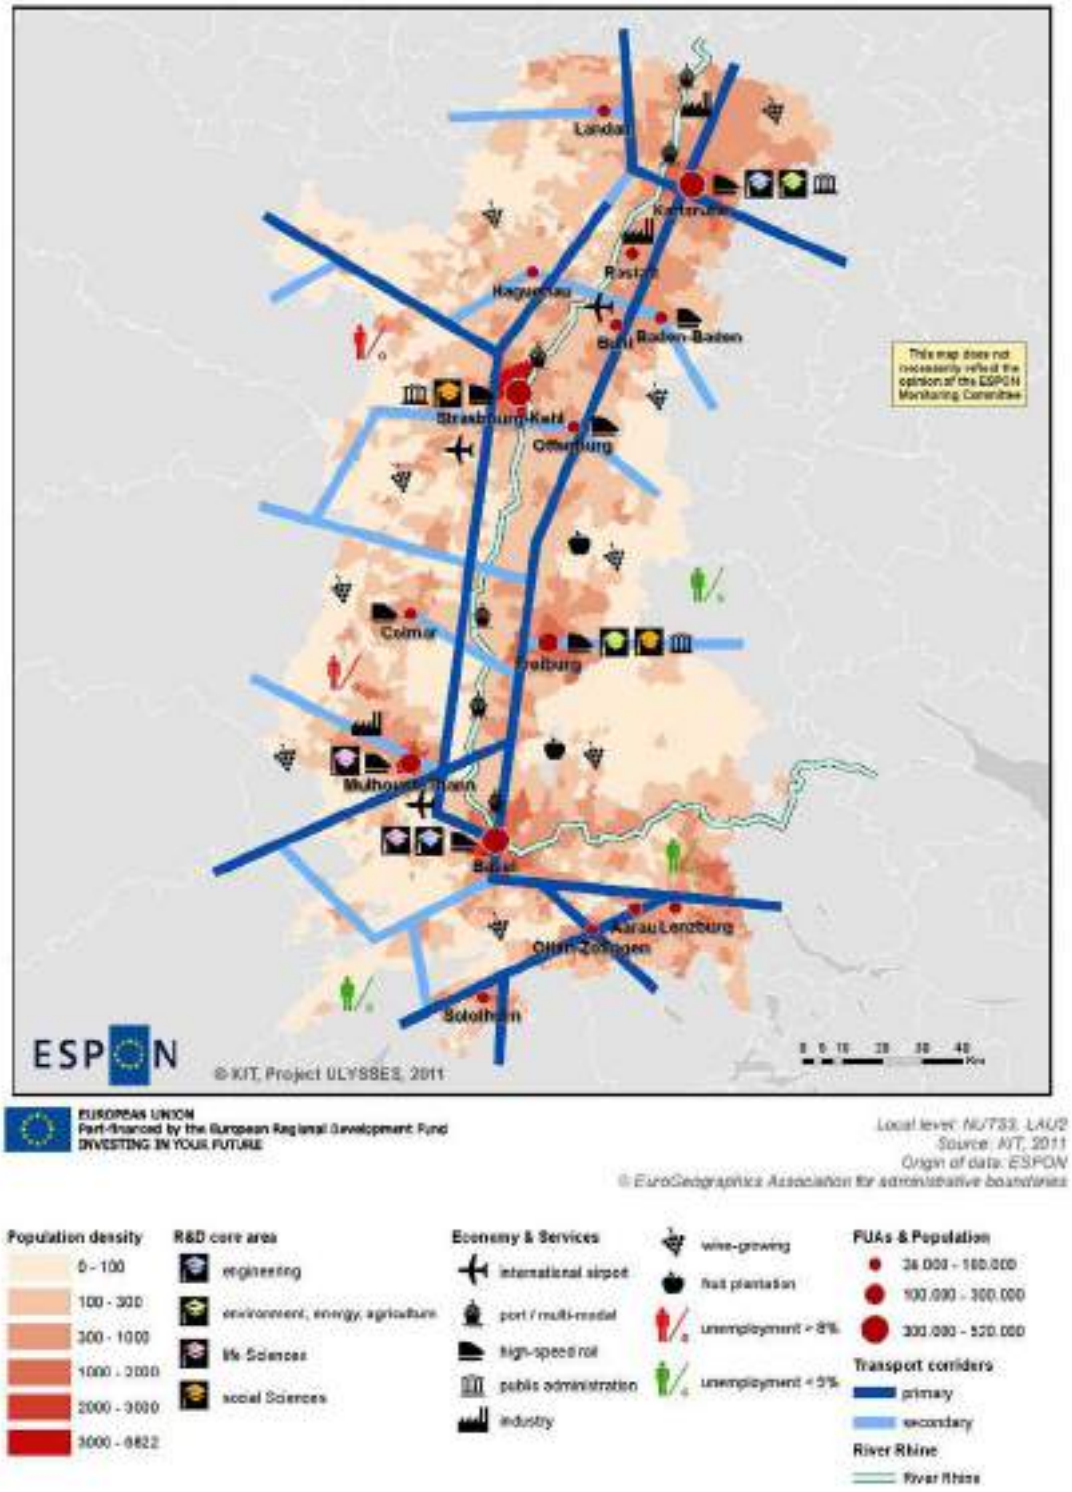
2.1 Upper Rhine

2.1.1 Overall situation

The Trinational Metropolitan Area Upper Rhine is a peripheral and at the same time central region in Europe: it is peripheral as it is located in the northern part of Switzerland, eastern part of France and south-western part of Germany with the River Rhine as its natural border between these three countries. And it is at the same time centrally located within Europe, being part of the "Blue Banana" respectively the "Pentagon". With its central position in Europe and the existence of a variety of small, medium und larger cities and conurbations, the CBA hosts a quite strong economy, administrative centres (e.g. the European Parliament), and research centres, resulting in rather low unemployment rates and high GDP respectively GVA.
There is a dense network of larger and medium sized cities in the CBA, though advantages of the development following the principle of decentralised concentration cannot not fully be exploited, as the network does not quite work in a cross border way. While the Rhine Valley is place of various land-use conflicts of environment, settlement, economy and transport, the more rural areas of the low mountain ranges suffer from losses of population and functions.
The Rhine Valley is one of the European main corridors for passenger and freight transport. There are excessive networks of road and rail, but the interconnections between those are still insufficient. The expected increases in traffic all over Europe – especially freight traffic – and new connections through the Alps like the Gotthard will put pressure on the transport networks in this important part of the North-South connection within Europe.
Also the public transport of the CBA is quite comprehensive in all national parts. The existing transport network is focused on national needs and institutions and a shared use is seldom aspired. The interconnections and qualities of service in-between are hence still an important issue of cross-border cooperation, as a real cross-border network does not exist.

Cross-border cooperation in the region has a long tradition. Even though the affiliation to national spaces is still dominant, the region disposes of a diverse and differentiated governance structure, with several cross-border institutions on different scales with different tasks coexisting complementarily. This causes a twofold situation, as stakeholders pointed out: On the hand institutional simultaneities hinder the regional ability for marketing, lobbying and strategy building, as it is often criticized. Also time consumption due to engagement in multiple institutions is an issue. On the other hand, stakeholders reminded, that institutional differentiation and redundancy provide for a plurality of arenas and levels on which cross-border cooperation can be achieved. Also, the density of regional stakeholder networks is

positively affected by this, as well as the regional governance system is less prone to stagnation due to institutional blockades or dependency on charismatic leaders.



Map 2: Territorial synthesis of the Upper Rhine CBA

2.1.2 Centrality

This factor has its highest values in central European countries, especially in the Ruhr, Belgium and Southern England, in a pattern that clearly lines out the „Blue Banana“. In the less central regions, the higher values tend to be concentrated around capitals and other major urban agglomerations. The factor centrality has high positive correlations with all the indicators expressing potential accessibility and, to a lesser extent, with the share of employment in the financial intermediation and real estate, the employment in high and medium tech manufacturing activities and with commuting to other regions. It also has a strong negative correlation with the share of employment and GVA in agriculture and fishing.

All NUTS3 units of the CBA fall into the two highest percentiles of all European NUTS3 units, expressing the high centrality of this region. The CBA Upper Rhine can be seen as part of the Blue Banana with slightly less centrality indices than the highest scores of Rhine-Ruhr or Belgium. This could also derive from excluding Switzerland as the data is missing here, which could in the analysis lower the centrality index for South-West, Germany and North-West Italy.

2.1.3 Economy

The factors regarding economic development appear to represent the proximity of NUTS3 areas to public administration centres, as the indicators positively correlated with this factor are the share of employment and the GVA in public administration, community services and activities of household and the indicators negatively correlated with this factors are the share of employment and the GVA in industry. The regions with the highest scores of this factor are majorly depressed regions in which, because of their poor economic performance, the public sector assumes an important position. It is interesting to see that most of the borders NUTS3 areas in Spain and Portugal have very high scores in this factor, as well as Karelia.

In some border areas, the involved regions seem to have higher scores in the indicator unemployment than the more centrally located regions. This is the case in Portugal, on the northern border of France and Bulgaria, Finnish Karelia or the Czech Republic where it borders Eastern Germany. The coefficients indicate that high levels of unemployment have a strong negative correlation to a high investment in R&D, demographic dynamism, central locations and high levels of immigration. As expected, the factor referring to administrative centres has a significant and positive impact.
The CBA Upper Rhine has quite low scores regarding this factor, as unemployment rates are significant lower than the national and EU averages (exceptions are DEB37 Pirmasens and FR422 Haut-Rhin). Including data from Switzerland (data is missing here) would have highlighted to good conditions for workers and employees in the CBA.

2.1.4 Research and Development

This factor represents the innovation dynamic and the scientific development of each NUTS3 area of the EU27 space. This factor appears mostly related to R&D

investment of the different sectors and, to a lesser extent, to EPO patent application and the tertiary educated active population. Mapping the spatial distribution of factor scores, it is interesting to note that, besides the capital cities, it is possible to identify specific innovation strongholds such as important university towns or high tech industries (Airbus in the Toulouse area, Volkswagen around Wolfsburg, Cambridge or the Silicon Glen). The Scandinavian countries also have a very favourable position in this factor.

The CBA shows high values of the R&D indices, all but the two French NUTS3 units above the national averages and within the highest percentiles in Europe showing the high capacity of R&D of this region within Europe and in comparison to the average. This accounts especially for the German parts of the CBA, where a common German prejudice comes true about the people of the state of Baden-Wuerttemberg being "Tueftler" (tinkerers – like Walt Disney's Gyro Gearloose) and hence having the highest amount of patents per inhabitants.

2.1.5 Demographics

This factor seems to express the demographic dynamism of NUTS3 areas, as the indicators positively correlated with this factor are the young age dependency rate, the crude rate of natural population increase and the total fertility rate. This factor depicts negative correlation to the old age dependency rate parameter. Mapping the spatial distribution of factor scores, it occurs that the regions with the lowest scores of this factor are in the Mediterranean countries, such as Portugal, Spain and Greece, as well as Germany. On the contrary, the northern parts of France, Ireland, central Great Britain, Scandinavia and Eastern Europe are the regions with the highest positive scores.

The factor analysis reflects the different natural population development especially in comparison between France and Germany with a big difference in fertility rates and hence dependency ratios. While the German parts of the CBA still grow due to migration, the natural development of the population is negative, while the French NUTS3 units still have a slight natural increase. Although the CBA has continuous immigration, scores compared to the national averages are relatively low, i.e. the EU average of all NUTS units is higher than the rates of the CBA.
Although being a border region, the indicators used show a high attractiveness of the CBA by steady immigration. Despite low fertility rates, the CBA is slow but steadily growing by immigration. This indicates a strong labour market, especially in the Swiss NUTS3 units of the CBA, with a high share of incoming commuters from France and Germany.

2.2 Karelia

2.2.1 Overall situation

Euregio Karelia is a cross-border region situated on the Finnish-Russian border area. It is formed out of three Finnish regions; North Karelia, Kainuu and Northern Ostrobothnia and the Republic of Karelia in the Russian Federation. The borderline dividing these regions is an external border of the European Union and it is approximately 700 kilometres long with only three international border crossing points between Finland and Russia. In contrast to EU internal borders, there exists no visa-free entry on the Finnish-Russian border, and the visa regulations are determined by EU-Russian visa agreement and the Schengen-regime.

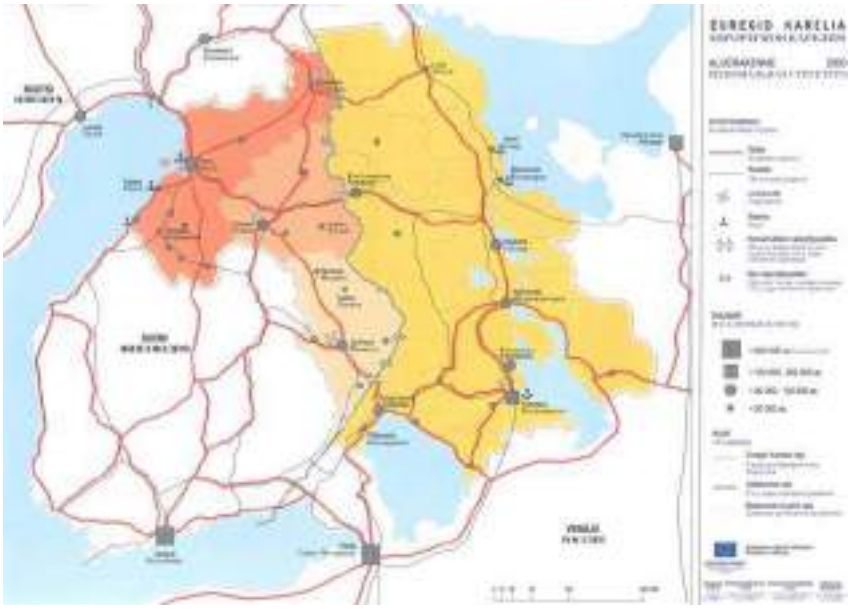
In demographic terms Euregio Karelia is struggling from negative population change. Accordingly the population density in the CBA has been declining. Net migration has not been able to compensate for decrease of population, because it has been moderate and below the national averages. Urban structure in Euregio Karelia is not dominated by one big city, but it is relatively polycentric. However, the urban structure of the CBA could be fragile, because there is a fairly small total amount of Functional Urban Areas (9) in the CBA compared to the European average. On the Russian side of Euregio Karelia there is only one FUA, which is Petrozavodsk. The FUAs are dependent on traditional manufacturing and thus very vulnerable to effects of globalisation.

Euregio Karelia is in the European context classified as a CBA with low urban influence and low human intervention. Eurostat classification considers the CBA as a predominantly rural region. The Euregio thus appears rural from the European perspective. However, the share of agricultural areas in the region's total area is significantly lower than the European average. This is partly explained by the large share of forests in the total area.

Euregio Karelia is located far from central European road and rail infrastructure and thus has low accessibility and connectivity.

All the Finnish regions of Euregio Karelia (except for Northern Ostrobothnia) have been in economic terms identified as less developed non converging regions. There are also large differences in GDP per capita between the Finnish and Russian regions of the CBA. The Finnish-Russian border has had positive effects on trade in the regions located in close proximity of the border. There is a strong variance between regions of Euregio Karelia concerning performance in research and innovation and social cohesion, Eastern Finland and the Republic of Karelia performing the weakest.

Euregio Karelia is located on the EU external border, which creates a relatively difficult structural context for cross-border governance and institutionalized spatial planning. Cross-border cooperation does take place in Euregio Karelia in a multi-faceted and increasing way. Still, the difference to internal EU cooperation is very obvious and a spatial planning or a transport policy has not been institutionalized on a cross-border level yet.



Map 3: Transport infrastructure in Euregio Karelia (2000)

2.2.2 Centrality

Euregio Karelia scores very low in the centrality factor. All the regions of the CBA are below national average and the average of all the studied countries.

When we look at the location and accessibility of Euregio Karelia from the perspective of services and transport factor, we can see that in the European context Euregio Karelia scores low in these aspects as well: Euregio Karelia is located far from central European road and rail infrastructure and thus has low accessibility and connectivity. Despite its remote location, air connections make the CBA better accessible to the European countries. Considering connectivity within the CBA, the Finnish-Russian border, being an external border of the European Union, does not allow free movement of people and goods. Cross-border traffic has been steadily increasing and the border crossing infrastructure has been developed. Thus the Finnish and Russian regions of the CBA have become better accessible to each other.

2.2.3 Economy

The factor of economic development has a high correlation with GDP per capita, share of Natura 2000 areas and soil sealed area. It is a factor, which expresses high degrees of development and urbanization. In Euregio Karelia Northern Ostrobothnia has the highest score in this factor. North Karelia and Kainuu score significantly lower than Northern Ostrobothnia and the Finnish and European average. In Europe regions with the highest scores for this factor are concentrated in Central Europe, Scandinavia and in capital cities of more marginal countries. Regarding the economic catching-up, a factor that relates GDP level and growth between 1997 and 2008 of a given region to the pattern evidenced by the leading region, Northern Ostrobothnia is again the best performing region of Euregio Karelia. The overall pattern of the border regions is to follow the national tendency.

Concerning the factor of unemployment the situation is similar to the performance of Northern Ostrobothnia being more positive. The unemployment factor correlates

with variables such as unemployment, long-term unemployment and youth unemployment. The geographical distribution of this factor's scores shows a concentration of highest values in the more depressed areas of Europe and countries with a structurally high unemployment.

2.2.4 Research and development

Total intramural R&D expenditure in Karelia in 2007 was higher in Finland than in EU countries in average. Expenditure was even higher than the Finnish average in Northern Finland while in Eastern Finland R&D expenditure was below Finnish and EU average. When looking at the sectoral R&D expenditure it is obvious that expenditure in Northern Finland and Finland in general has been greatest in the business sector. Northern Finland shows stronger performance than Eastern Finland both in the amount of EPO (European Patent Office) patent applications and the amount of persons employed in high and medium tech manufacturing activities.
In Euregio Karelia Northern Ostrobothnia is the only region performing better than national or EU average, while North Karelia and Kainuu are performing weaker in respect to this factor.

2.2.5 Demographics

The factor of demographic dynamism correlates with the young age dependency ratio, crude rate of natural population increase, total fertility rate and old age dependency rate (this last one has a negative correlation). In Euregio Karelia the regions are performing very differently in demographic terms and the only region that is performing better than the European average is Northern Ostrobothnia. In the European context, regions with the lowest scores in demographic dynamism are in the Mediterranean countries.
Concerning the factor of immigration that correlates with the indicators of population growth and net migration ratio, Northern Ostrobothnia is the only region in Euregio Karelia that is performing better than European average.

2.3 Greece-Bulgaria

2.3.1 Overall situation

The Greece – Bulgaria CBA is considered as a region distanced from the central parts of Europe, facing population reduction, over-ageing and low fertility rates. Although fertility rate gradually increases over the latest decade, its value appears significantly lower than the corresponding EU27 rate. Population distribution shows strong disparities, with higher population densities near urban conglomerates. Along the well-established transportation axes, the border seems to attract population and economic activities, affecting population density and growth patterns. On the contrary, newly opened crossings do not seem to affect settlements near the border.

Population density decreases over the latest decade, due to strong depopulation, although the CBA may still be characterized as a 'strongly rural area'. Over the last decade a gradual increase in urbanisation has occurred in the CBA, mostly shown by the sharp decrease of population employed in the primary sector and the respective

GVA produced. This urbanisation tendency of the CBA is also accompanied by a subsequent transformation of agricultural areas into artificial areas.
The accessibility and connectivity infrastructure has improved in the CBA during the latest years, especially by the construction of motorways and the expansion of airports. However, more development in the cross-border transportation infrastructure is needed to integrate CBA's economy and improve its performance.

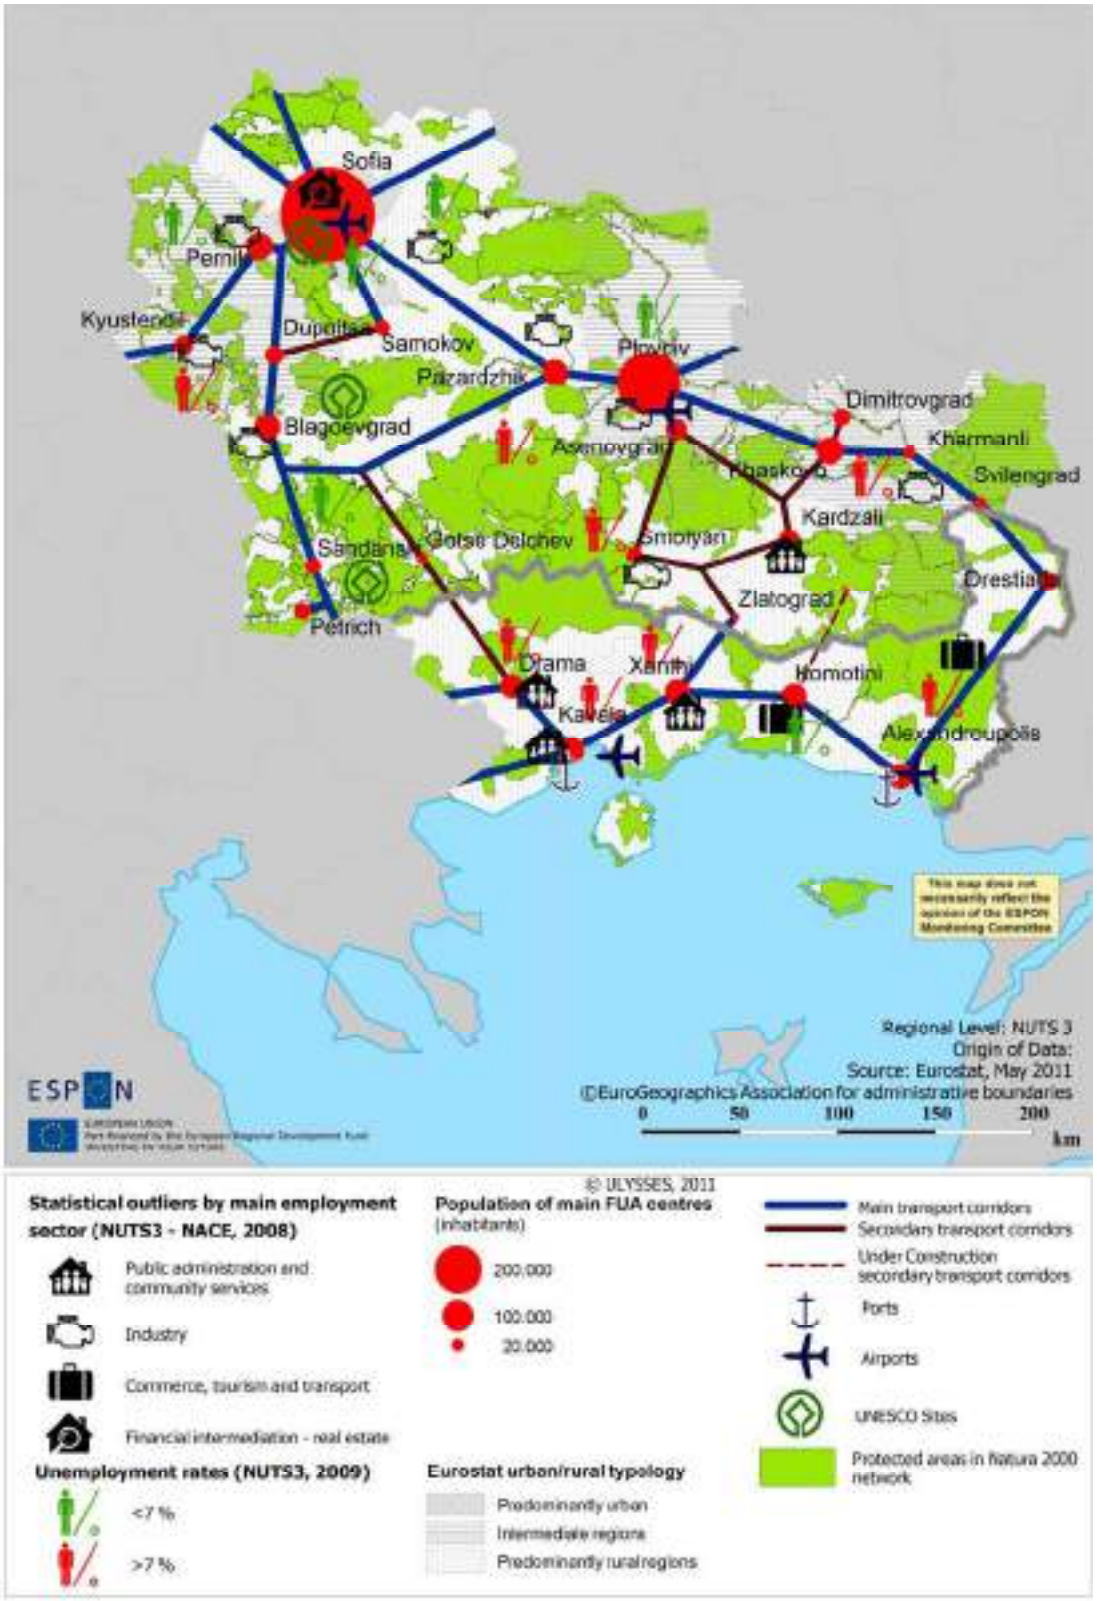
Significant disparities exist in terms of the convergence dynamism of the CBA, as the Bulgarian part exhibit a steady catching-up behaviour, while the Greek areas are characterized by a slow converging pattern. Employment in the CBA seems distributed rather evenly among all economic activities, exhibiting a marginal annual rise over the last decade. This increase seems attributed to construction, the financial and real estate sector. Trade, tourism and transport are the main economic sectors supporting local CBA's economy. The reduction in the employment in the primary sectors is apparent.

2.3.2 Centrality

The Greece – Bulgaria CBA shows very low factor scores in relation to 'centrality' in comparison to central European countries or around capitals and other major urban agglomerations of less central regions. Most NUTS3 areas score at the lowest 5th and 20th percentiles of all EU27 areas. Territorial profile analysis revealed that the lack of central CBA's location over the EU27 space is a major disadvantage: Poor economic convergence seems related to the low centrality of the region and the increased public administration sector. Central location appears a more important factor to support economic development of a region, than the R&D investments.

2.3.3 Economy

Trade, tourism and transport seem to be the main economic sectors supporting local CBA's economy, followed by subsequent reduction in construction and service sectors. The CBA underperforms in all social cohesion indices, although they showed a gradual increasing tendency up to 2008. Thereafter, a sharp decline was noted, increasing unemployment in most economic sectors.
Overall, the poor economic performance (high unemployment, especially at its southern parts, and limited economic development, showing spatial disparities due to the stronger Bulgarian convergence tendency) of the area seems related to its low centrality, the exaggerated public administration sector, the low R&D investments and the limited demographic dynamism.



Map 4: Territorial synthesis of Greece-Bulgaria CBA

2.3.4 Research and development

Bulgaria and Greece are modest innovators exhibiting a below average performance, and the three NUTS2 regions under study present similar characteristics, demonstrating low innovation performance and weak innovation potential that in terms of the number of patents fall well below the EU27 and the USA averages. The Greece – Bulgaria CBA shows relatively low factor scores in relation to 'innovation dynamism'. R&D investments and innovation orientation appear below average, having low contribution to CBA's economic growth.

2.3.5 Demographics

Over the latest decade, the total population of the CBA shows a significant decrease by approximately 4.3%, Based on this trend, the total population of the CBA in 2020 will be diminished at the level of 4,062,969 inhabitants. Excluding Sofia, the CBA's population reaches 2,9 million inhabitants in 2009, exhibiting depopulation with an annual rate of 5.0%. Xanthi (GR113) and Sofia (BG111) are the only NUTS3 areas of the CBA depicting positive population growth rates, even higher than the mean EU27 growth rate.

Net migration is responsible for the population increase in Sofia. In most of the NUTS3 unit levels of the Greece – Bulgaria CBA, population decrease is due to both, natural causes and out-migration.

2.4 Results

The territorial profile and performance analyses conducted in ULYSSES are interested in understanding how the borders function in different contexts and the impacts of the general challenges they pose. From this perspective, there are some aspects that can be highlighted from the different multi-territorial analyses of the border areas as well as from the factor and regression analysis that was performed at the EU27 countries:

- The first one is that the **differences in the CBA seem to be pretty much a consequence of their overall location and not so much of their border position**. This means that the central European CBA are performing at a similar level than other centrally located regions, while border regions in peripheral countries perform similarly as other peripheral regions.
- The second one is that **borders keep playing a major role in explaining the behaviour of the different regions**, by dividing different national realities.
- The third one is that **the border condition seems to be more relevant at the regional than at the local level**. For example, while the position of the total CBA in the national or European context is clearly relevant, the settlement patterns at the LAU 1 or 2 levels seem often to be indifferent to the border.
- A fourth one is that the **cross border commuting still tends to be low**, when compared to the commuting between regions of the same country.
- The fifth is that the **borders seem to keep functioning as a limit for the diffusion effects of development poles**. This essentially indicates that, besides the European effort in promoting territorial cohesion, the national level maintains a prime role in regional development.

From a **governance perspective**, border regions are often called 'laboratories of Europe', and this label is also confirmed by the ULYSSES project: the 'contact zones' of different national systems reveal very clearly the added value and, at the same time, the challenges of European integration. The six regions under full analysis in ULYSSES confirm the diversity of borders and border regions in Europe also from the institutional point of view: The structural and the activity dimension have very different values, and the analysis such diverse conditions lead to some general conclusions:

- **The internal EU 15 borders are, from a structural point of view, still more favourable for cross-border governance** than, for example, external EU borders or borders with transition states.
- At the same time, the structural dimension cannot be explained in a *deterministic* way, that is to say, **the degree of institutionalisation cannot be directly linked to any specific status or socio-economic arrangement**.
- **Socio-economic development alone does not determine cross-border governance**, neither.

Territorial diversity has to come along with different institutional settings, and the involved institutions have to face the respective challenges on the ground. Hence, following the principle of tailor-made strategies, **all regions have to develop their own ways in order to exploit their cross-border potential**. It became obvious though that ongoing deepening of cross-border-cooperation depends strongly on the commitment and effort of leader personalities as well as the great persistence of those efforts.

3. Conclusion/Lessons learnt for policy development

Generalising the crucial findings from the ULYSSES study we have pinpointed some general ideas that might be of relevance for European cross-border policy development:

- **Borders matter**: The evidence collected by ULYSSES project shows as (i) borders keep playing a major role in explaining the behaviour of the different regions; (ii) border effects are clearly perceivable at the national and regional levels; (iii) cross-border commuting between different regions still tends to be low, and; (iv) borders seem to keep functioning as a limit for the diffusion effects.
- **Geography matters**: Local geographic conditions impact on territorial development within cross-border areas in many ways. Indeed, borders are very diverse across Europe and may have different implications depending on the sometimes neglected geographical features that characterise such borders.
- **Regional delimitation matters**: The territorial analyses made evident as the regional statistical units available for statistical purposes across Europe, namely NUTS 2 or 3 regions, have totally different connotations depending on the area.
- **Scale matters**: Evidence have shown that (i) the geographic scale at which data is produced/collected conditions the final results of the analysis in various ways, e.g. the NUTS units are of very uneven sizes in the different Member states and in general, NUTS 3 or even 2 are too rough for analysis; (ii) many of the topics covered would require further analysis based on fine-grained data; (iii) ESPON data is a precious asset in approaching the cross-border issue at the European level, but its reference scale seems somehow inappropriate for designing local strategies.
- **Cohesion matters**: Both the multi-thematic analyses and the governance analysis show clear differences between the different parts of each border region, between the border regions and their domestic hinterland, and amongst the border regions across Europe. The goal of a balanced territorial development remains a challenge.
- **Diversity matters**: The diversity of the involved territories must not be regarded as a barrier to a successful territorial development but as an opportunity for complementary labour markets and cultural richness. The challenge is to enact place based approaches that make use of the territorial potential.
- **Territorial cooperation matters**: All ULYSSES regions have a certain experience with bi- and multi-lateral cross-border institutions. In all regions, the institutional setting shows the overarching importance of the structural funds, in particular with regard to the INTERREG programme. Moreover, the new European tool of the European Grouping for Territorial Cooperation (hereafter EGTC) is broadly tested and adopted within the ULYSSES regions.
- **Spatial development strategies matter**: ULYSSES experience proves that the knowledge basis for cross-border regions is not comparable with the ones of domestic regions, and that most regions have already formulated strategic elements for territorial development, either in form of more analytical studies

or of joint political declarations. However, we see a certain tendency that these documents are often quite abstract and not always institutionalised in a political way.

- **Knowledge matters**: Reciprocal knowledge of current territorial trends by all parties is essential in order to boost successful strategies. This calls for a joint effort for producing focused, complementary and tailor-made analyses within all the CBA.
- **Institutionalisation matters**: Cross-border strategies related to spatial planning will only be able to influence later territorial development if the key messages will be institutionalised in political way. On top of aligning agendas and priorities at regional and local levels, this would allow the CBA to have a shared strategic objective to lobby national or European authorities in support of local actions.

Paper for the 26th AESOP Congress,
Ankara, 11 - 15 July 2012

Abstract

The paper provides an overview assessment and critique of CBA as an evaluation technique to be applied in participatory processes, including communicative and collaborative planning. Broad citizen involvement requires different things from the evaluation technique than expert-oriented processes, as participants should be able to grasp what the experts are doing, make sense of the technique, and figure out how they are likely to be affected by the proposed project. Individuals who are very strongly devoted to one single value or one special kind of project effect (environmental degradation, for example) will find the economic reasoning of CBA particularly unsatisfactory. The preferences of wholeheartedly dedicated people are not likely to be properly incorporated in the CBA by standard tools, and some consequences of this are outlined. One suggested solution is to elicit non-market preferences not only from contingent valuation techniques but also from hybrid techniques involving both stated preference interviews and deliberative small-group processes. This brings analytic evaluation closer to communicative planning theory. The recently proposed 'deliberative monetary valuation' can for example make use of focus groups, citizens' juries, consensus conferences, and deliberative polls and thus allow for preferences that change throughout the planning process.

1. Introduction

Planning processes can differ widely in character, ranging from top-down strategies organized by the state at the national level, to local bottom-up empowerment efforts initiated by grass-root movements. The problems of selecting the best method/process combinations and adapting well-known analytic techniques to

participatory processes have been pondered for decades, also when it comes to the cost-benefit analysis (CBA) (Sager 1979, 1982). Since the 1970s, much progress has been made on problems that are highly relevant to the theme of the present chapter: how small-group problem solving and dialogical planning processes can form and yield preferences; distinguishing types of preferences, and the potential (and limitations) of stated preference techniques for eliciting preferences that are appropriate for collective decision-making; deliberative monetary valuation of environmental consequences.

Two very different approaches can be used in planning and decision-making. One might employ an algorithm allowing calculation of 'the best' solution, or one might discuss the matter and try to reach an agreement. Planning can be algorithmic or communicative, and the title of the paper indicates that even hybrids are possible. The purpose of this paper is to show that standard CBA employs techniques and procedures that may de-motivate lay participants, and to suggest how the drawbacks can be ameliorated by methodological simplifications and recent developments of theory and practice, such as deliberative monetary valuation. As understood here, the CBA is an economic evaluation method which is used ex ante to calculate in monetary terms the net benefit to society from an infrastructure investment, a plan or a policy (Mishan and Quah 2007). The focus here is on the philosophies and techniques for establishing the entries on the list of costs and benefits expressed in monetary metrics. The part of the evaluation dealing with consequences that are not transformed to pecuniary figures is not discussed. Participatory planning is conceived as preparation for democratic decisions by means of processes in which the citizenry as well as the stakeholders are involved and can debate the planning proposal with each other, developers, public planners and other bureaucrats.

This paper presents a critical view of CBA in participatory planning processes. Every theory and method in the social sciences can be criticized from some relevant perspective, and the CBA is no exception. It should thus be said already at the outset that knowledge of valid criticism does not imply that one should abstain from using the method. Furthermore, it is a good rule to avoid making a caricature of the method under scrutiny and not waste energy on chasing some imaginary bogyman. Criticism hits harder if it is valid even in a sympathetic interpretation of CBA.

Relevant objections to CBA as an element in participatory planning can point out theoretical, practical, and political inadequacies. There are limits to meaningful critique, however:
(1) Critique should be in line with the purpose of the analysis under scrutiny. For example, the ambition should not be for analytic method to provide final answers in a democracy, as that would make elected politicians superfluous (Saitua 2007:29). CBA should not be blamed for giving an incomplete basis for making decisions. Findings obtained from the CBA can have a legitimate role as an input into, but not as a substitute for, political deliberation.
(2) Critique should not be utopian. CBA is a tool for practical planning and decision-making in the real world, so suggestions based on assumptions of a perfect society or

reaching for unachievable ideals are of little use. For example, in the context of participatory planning processes one objection to CBA might be that one should instead ask people how well they like the project or plan (Osborne and Turner 2010). However, to yield answers comparable with the CBA, this assumes much more information among people than they actually possess. The answers would not tell us whether or not the project contributes to the economic efficiency of society.
(3) Critique should be directed towards good established practice (state of the art), not towards misconception or careless use of the method. For example, double-counting of benefits occurs time and again in evaluations by means of CBA. This happens when the same attractive consequence is hidden in several entries on the list of benefits. In assessments of road projects including the entries 'better accessibility' and 'improved transport standard', both can be valued partly because of the travellers' time savings, which would then be counted twice in a carelessly conducted analysis. Double-counting is not an inherent weakness of CBA, but the result of sloppy practice.
(4) Critique put forward in this paper does not deal with the way single variables are gauged or the way parameters are estimated. For example, the economic value of reducing CO_2 emissions by one ton, and the correct size of the social discount rate in long-term environmental projects, are both controversial. Current practice will nevertheless not be discussed here.

The next section explains a few concepts from moral philosophy. These will prove helpful in the following when responding to potential critical questions about CBA from groups of participants, and when considering what is reasonable to demand from evaluation techniques in processes with citizen involvement.

2. Philosophical background for critique of the CBA

Planning processes with broad participation are likely to include people with very different motives, values, and rules to live by. Some will see opportunities to reap advantages where others will see breach of principles or self-serving violation of values. Such conflicting positions often have philosophical counterparts. The philosophies are only sketchily outlined here, as the modest aim is to give just enough background to understand why they – consequentialism and deontology – help to explain different attitudes to the CBA.

Deontological ethics determines the value of an action (project, plan, policy) not primarily from its anticipated consequences and, for example, welfare effects. The duties one tries to do by carrying out the action are important for its moral value. A road project that interferes with a vulnerable ecosystem can be rejected regardless of economic costs and benefits by people believing that they have a duty to protect the natural environment. And a gentrification plan regarded by some as entailing an encroachment on the rights of working-class inhabitants of the regeneration district can be voted down by people feeling a duty to defend rights regardless of economic considerations. For some people, deontological ethics requires that certain rights

should be respected not only for humans, but also animals, plants, and ecosystems. Duties and rights are often treated as absolutes, while the CBA assumes that anything can be traded off. This can alienate deontologists in the planning process and lead to protest responses in the valuation process.

Consequentialism is an ethical position holding that the consequences of an action should be the ultimate basis for judgment about the rightness of that action. It is morally right to implement a project, plan, or policy if it is expected to produce an overall good net outcome – a tenet that is endorsed in the CBA. Consequentialism is usually contrasted with deontology, although the distinction may be less clear than it appears at first glance. Sen (2000) contends that anticipated violations of rights can be regarded as consequences, and thus be incorporated in a consequentialist CBA.

The consequentialist position gives room for a wide range of assessment rules, among which only rules differing along the equity dimension are mentioned here. Several evaluation approaches that emphasize equity and fairness more than economic efficiency put heavier weight on those who are worst off or stand to lose because of the proposed action (prioritarianism). For example, the Difference Principle of Rawls (1971) takes the form of making the worst-off members of the society as well off as possible. This implies a radical breach with the everybody-counts-equal principle and takes us a long way from classical utilitarianism.

Classical utilitarianism says that a proposed action is to be subjected to the following test: will it produce a greater balance of benefits over harms than any competing course of action? It is right to perform that action which will be productive of the greatest happiness of the greatest number, which will have the greatest utility (MacIntyre 1977). In calculating the greatest utility, the standard utilitarian practice is to let everybody count for one and nobody for more than one, which is also CBA procedure. CBA may be regarded as an operational definition of what is implied by basing a public policy on a utilitarian calculus. There will most often be some losers, but the plan is nevertheless recommended if there is the theoretical possibility of fully compensating the losers by costless redistribution of money – the Kaldor-Hicks criterion.

In the following, I shall assume that standard practice of CBA is in line with classical utilitarianism. Utilitarianism requires that consequentialism be combined with another pair of ideas. These are utility as a measure of value, and sum-ranking, meaning that the ranking variable is the sum of the individuals' net utilities.

3. Questions from participating groups

This section answers five pertinent questions that might hypothetically be raised by sceptical citizens involved in a planning process that makes use of CBA for providing background information to the public debate.

Why don't you just ask us?

Like other evaluation techniques, the CBA disaggregates the future impact of the project into a number of consequences and then adds up again all these costs and benefits. Maybe some aspect or byproduct of the project is lost in the way the totality is split into separate items and then put together again. As already mentioned, we do not know that a monetary assessment of the project as a whole would be equal to the sum of the entries in the CBA account.

Planners may, for example, *impute* that the local users of a new road will obtain a positive net utility from the project because of time savings, fewer accidents, reduced driving costs, etc. In principle, these users might nevertheless be opposed to the new road. The reasons may be their conviction that:

- Some politician promised in the last election campaign that the road would be postponed to protect nature
- The money would come to better use on other public tasks
- They have been let down in the planning and decision-making process
- The project is in conflict with the rights of some group
- The project is ugly or it does not fit with the image of the locality
- The project should be further examined before a decision is made
- The funding of the project should have been organized differently
- Some unpopular big shot stands to gain from the project.

The list could be expanded, but the above suffices to make the point: There will very likely be considerations extraneous to the CBA which contribute to citizens' overall assessment of projects. The CBA is not meant to give a complete picture of the viewpoints that form people's opinion. Instead, the CBA answers questions about efficient use of society's resources, which are not clarified by asking for citizens' opinion. This is not a weakness of the CBA.

We have other goals than economic efficiency. Will the CBA take them into consideration?

Academics can handle a problem in different ways. They may be able to change reality and solve the problem, or they may try to change people's conception and interpretation of reality so that the problem no longer seems to be important. Academics are sometimes modelling the problem away, making it invisible in their theoretical world. The CBA provides an example: Many people see unfair distribution of economic welfare as a real and important problem. But the more attention given to CBA as the normative basis of decision-making, the less likely we are to deal with the equity problem, as standard CBA models it away by complying with the Kaldor-Hicks criterion and thus not requiring factual compensation of losers.

Transfers between domestic accounts cancel each other out in the national summation of costs and benefits. CBA is therefore not well suited for evaluating policies which aim at redistributing economic activity between regions, such as relocating state agencies from the capital to peripheral cities. For the same reason, CBA may not be the best technique for evaluating measures improving Universal Design. The main objective in many UD projects is fairer treatment of people with reduced ability to master the transport system, for example. The wish to increase their access to a range of destinations is founded more on justice than on the anticipation of economic benefits.

CBA is, by and large, a summation of willingness to pay for good things, minus summed willingness to accept compensation for bad things. Analysis founded on preferences deduced from revealed willingness to pay raises serious worries about equity goals, given the unequal endowments among members of society. Willingness to pay is affected by ability to pay, and as we live in a market society, what we can do is constrained by what we can afford.

Equity is not the only goal to be inadequately treated by CBA. CBA cannot measure multi-dimensional aspects of project desirability, such as sustainability, issues of rights, and social values associated with respect, dignity and identity. Several environmental goals are closely connected to ethical values and are better catered for in deontological than in consequentialist analysis. Projects that are primarily aiming to affect goal variables of, for example, ecosystem management, biodiversity loss, and global climate change might not be adequately assessed by CBA.

When we state our preferences, will they be built into the CBA at the expense of market information?

CBA calculates profitability on the basis of individual preferences. This is an attractive feature in participatory planning, as it is regarded as democratic that people's input about what they like and dislike is applied in the evaluation. Nevertheless, there have been objections of at least two types. The first relates to the characteristics of individual preferences; their knowledge base, independence, stability, and consistency (Kahneman and Tversky 2000). I concentrate on the second type of objection to the use of individual preferences for making collective decisions, questioning the way preferences are elicited. Different elicitation procedures can produce dissimilar orderings of options, so individual preferences sometimes seem to provide a weak basis for imputing the prices serving as value coefficients in the CBA.

Where market prices are available, standard CBA procedure is to use them for establishing pecuniary measures of costs and benefits. When market imperfections are caused by externalities, for example, market prices should be corrected. Even with corrections, value coefficients deduced from preferences revealed through market transactions may well differ from value coefficients deduced from 'stated preferences'. Stated preferences are elicited from individuals who fill in elaborate

interview forms. The respondents state their choice between a number of hypothetical options which are designed to enable the planners to estimate the monetary value that the respondent puts on some cost or benefit component in the CBA.

There may well be a difference between the private preferences people reveal when buying goods and services in the market, and the 'laundered' preferences stated in interviews (Goodin 1985). The first reflects their selfish desires as consumers. However, when co-deciding on a public good that will serve numerous people, they might aim to act morally superior to the standard they manage to keep in day-to-day private affairs. They might want to act in a public spirit as good citizens, with an other-regarding attitude. Preferences for collective decision-making can thus differ from those that can be inferred from willingness to pay in market transactions.

Individual preferences are seldom exogenously given. They are rather formed in the planning process designed for exchange of information, debate, and consensus building. The private preferences of participants in open and inclusive planning are influenced by the social and interactive process (Niemeyer and Spash 2001). Participants must be prepared to defend their viewpoints and arguments against critique from groups with opposing interests. It is usually assumed in communicative planning and theories of deliberative democracy that ignorance, malevolence, envy, and revengefulness will form the resulting laundered preferences to a lesser extent than the initial private ones.

CBA can be used for assessing street lighting, roads, parks, sanitation systems, and water purification facilities, among many other kinds of public goods. We buy toothpaste without any need to know what others are willing to pay for the tube. However, when asked for the amount of money we will contribute to a public good, the answer depends on what others are expected to pay. Uncertainty about this affects the estimated utility of environmental conservation projects as well as man-made public goods. For example, the relative value of noise abatement compared to other aspects of a road project depends on the organization of the planning process. Psychological and economic literature on public goods experiments shows that communication between potential contributors tends to increase their willingness to pay (Meier 2006). CBA can take into account other preferences than those revealed in markets, but even stated preferences can insufficiently reflect the preference 'laundering' taking place in participatory planning processes.

Does the CBA respect that we know our own best?

Lay participants know that decision-making politicians are not bound to comply with their wishes. Against individual preferences, government can set default rules and take certain other limited actions that the government believes are in most individuals' self-interest, for example, concerning prevention of climate change or prohibition of building on ground prone to land slide or avalanche (Mandel and Gathii 2006:1054-55). Participants may still worry whether expert tools such as CBA

do justice to their opinions and preference input. We shall see that several lines of reasoning open for CBA practice that can lead to paternalism. Paternalism is defined as the interference of an individual or a collective actor with another person, against the will of the latter, and justified by claiming that the person interfered with will be better off or protected from harm. Paternalistic attitudes on the part of experts and decision-makers may de-motivate lay participants in planning processes.

It is difficult to evaluate paternalistic policies, such as prohibiting the use of segways, or making the use of cycle helmets compulsory. The reason is that a presumably significant cost element of such policies should reflect the annoyance created by restricting people's autonomy, and a credible way to value the loss of autonomy has not been developed.

Mainstream economic theory treats society as the sum of individuals, and individual preferences are added up (or in other ways aggregated) to the welfare of society. Næss (2006) advances an heterodox viewpoint when professing, on a critical realist platform, that the value of something for society is not reducible to the aggregate utility of individuals. If preferences of society – over and above the preferences of individuals – are allowed into the CBA, the possibility arises that individual preferences will be overruled, which in turn opens for paternalism. It seems difficult to defend a planning process in which citizens are first invited to actively take part, and then not trusted to know their own best. Furthermore, if the decision-makers were to determine society's preferences in the CBA, it would be difficult to separate the advisory ex ante evaluation from the actual decision. Such a mix-up, designing CBA to simulate the final answer, is an often-voiced critique of elaborate evaluation tools.

Some scholars hold that the satisfaction of people's preferences is not an adequate index of well-being because there are conceivable circumstances in which these preferences might be satisfied, even though the individuals' true interests are far from being served. Adler and Posner (2000) examine the reasons for such distorted preferences, for example, lack of information and unjust social conditions. The preferences of some participants in the planning process may have been misshapen by poverty, lack of basic education, or damaged self-respect. Adler and Posner argue that CBA can and should be modified in a way that corrects for the failings caused by inserting distorted preferences into the analysis. Disrespect for some preferences invites paternalism, however.

Distorted preferences would not disappear in practice even if people were to express volitions and inclinations in dialogical and deliberative processes rather than through market behaviour or stated preference studies. Misuse of power can distort the outcome of communicative processes as well as bias the result of analytic work. It is not obvious that more confidence should be placed in preferences drawn from a 'willingness to say', than in preferences inferred from a willingness to pay.

Standard CBA takes preferences as exogenously given, thus not distorted in the planning process. Preferences revealed in market transactions are usually taken at face value. There is more room for paternalism when using stated preference studies and adjusting them for lexicographic preferences and protest responses. Such adjustments are briefly discussed below.

We have strongly felt values that we do not want to compromise. How does the CBA deal with that?

According to mainstream economic thinking, everything can be compared and traded if the price is right. All items in the CBA account are regarded as commensurable and measured in money metrics and can therefore be summed.

Lexicographic preferences follow from absolute values or duties and are associated with deontological ethics. With such preferences, one particular consequence dealt with in the CBA is seen as overwhelmingly important, while other consequences are insignificant as long as the state of the primary goal variable is not satisfactory. In stated preference interviews it often happens that the option of protecting the environment is chosen by a significant share of the respondents no matter which attractive attributes the alternative options are supplied with. Hypothetically, the environment would be protected at any cost (Spash 2000).

Stated preference studies work best when interviewees adjust to a utilitarian mode of thinking when filling in the forms. The reaction of deontologists to methods like contingent valuation concerning environment or justice can engender protest responses resulting in missing answers, zero or infinite registered willingness to pay, or very strange observations as judged from rational choice theory (Price 2000:188). The planner may treat such preference data as unreasonable outliers, branding the respondents as irrational. Some value coefficients in the CBA may easily become biased if the planners exclude or misinterpret the answers from those who express a willingness to uncompromisingly protect the environment.

Much work has been done on the design of stated preference studies to avoid protest responses of various kinds, but the underlying difficulty is that asking people to trade their principles, even hypothetically, is seen as inappropriate and even morally disreputable to some. They are reluctant to choose between something of instrumental value and a truly moral position (Söderholm 2001:489). Ultimately, CBA risks developing into an institutional mechanism that systematically pushes the preferences of a significant group to the background; that is, the part of the citizenry believing in inviolable rights (Spash 2008). Lexicographic preferences do not necessarily receive proper treatment even in alternative decision tools, though. In referenda, for example, a majority of people with weak preferences always defeats a minority with strong preferences.

4. Demands on evaluation technique for use in participatory planning

This section deals with the following characteristics of evaluation techniques, which seem to be attractive in participatory processes. I comment on the points below in the same sequence as they are listed.

- Methodological basis reflecting democratic values
- Transparency
- Procedures to display consequences for each affected group
- Ability to deal with preference change
- Openness to values and preferences articulated by participants in the planning process

A basic premise of CBA is that of consumer sovereignty, meaning that the analysis respects individual preferences. Government decisions should reflect what the citizens want their government to do. 'The will of the people' is a problematic concept, but other things equal, the mere fact that a citizen prefers an option counts in its favour (Richardson 2000:991). In addition, every individual's willingness to pay is given equal weight in the analysis. This gives CBA the flavour of being a fair and democratic analytic tool for preparing collective decisions, even if willingness to pay depends on how the respondent is blessed by the existing income distribution. When CBA is used as informational input to a democratic decision-making process, it can be a problem that the technique is not politically neutral. If lump-sum transfers are not feasible, CBA cannot rank projects without relying on specific normative and controversial assumptions, such as indifference to marginal redistribution of income in society (Medin et al. 2001, Nyborg and Spangen 2000). Moreover, the democratic flavour is diluted by the relatively low score of CBA on some of the other points above.

An evaluation technique can advance transparency in the sense of lifting choice criteria and value trade-offs from inside the head of the planner to a text that is available to the public. Here, however, transparency concerns the ease with which participants in the planning process can unlock the black box of expert analysis and figure out what the algorithms of CBA are really doing, and how the results of the analysis are correctly interpreted. The evaluation technique should use procedures and criteria for valuation that are easily understood and accepted both by lay persons and the political decision-making bodies. The purpose of several computation routines that make CBA hard to penetrate for lay people is to transform quantified environmental consequences from physical units to monetary metrics (Nyborg 2000, Vatn and Bromley 1994). Other algorithms that may be conceived as complicated make adjustment from private to social costs, discount future costs and benefits, monetarize time savings and accidents, forecast future demand, and derive individual preferences from stated preference approaches, such as contingent valuation. Participating lay people who are unable to play any meaningful role in this work may suffer reduced motivation, spilling over on their attitude even when there is eventually some real decision-oriented content to discuss.

The evaluation technique should be general enough to consider the consequences separately for initiators of the project, groups of project users, nearby residents, and workers and others in the vicinity. It is of special importance in controversial planning that evaluation deals properly with those bearing the disadvantages of implemented projects. It would be preferable, when addressing a politically diverse public, if the CBA were flexible and able to highlight the aspects of economic valuation of particular interest to the different stakeholders and affected groups. This need must be balanced against the disadvantage of complicating the CBA by including ever more hard-to-value social and environmental variables. It speaks in favour of CBA that just in situations with many conflicting interests and thus with fragmented presentation of the consequences of the plan, the decision-makers are most likely to request an aggregate assessment: Is the plan desirable for society regarded as a whole?

Preferences are not exogenous to the planning and decision-making process of the project being analyzed, and are not likely to be stable for the time frame in question. For instance, big highway projects in Norway often have a planning period of eight years or more. People do presumably have the capacity to reformulate ends and aims in light of what emerges about the costs and benefits of proceeding with a plan, and their preferences for the various planning alternatives will change accordingly. Such reconsideration is essential to using resources wisely and effectively, but CBA takes individual preferences as given and stable and lacks procedures for incorporating revisions (Richardson 2000). There can be considerable alterations in affected groups' ranking of the planning alternatives without any changes showing up in the CBA. The analysis in effect supposes that all significant practical reasoning has already taken place, or else there would still be room for revision of preferences.

Use of information from the participatory planning process itself should be an invariable rule. It is surely the case that dialogue and deliberation in planning can be distorted by manipulation, lies, threats and other power games, and – consequently – preferences can also be distorted and deviate from the real interests of the person who holds them (Adler and Posner 2000). But the solution is not to ignore preferences articulated in planning forums and place all confidence in preferences revealed by market transactions. Firstly, this is usually infeasible, as some environmental items on the list of costs and benefits are not traded in the market. Secondly, preferences revealed by transactions can also be distorted. There is a huge industry of public relations and marketing aimed at affecting purchasing behaviour and thus preferences.

Self-reflection, response from others, and need to make one's own arguments sound reasonable to others, can make deliberators change their preferences. This is an important political reason for letting extensive deliberation processes precede final decisions, whether they are made by popular vote, legislative assembly, or government agency. Even if deliberation and dialogue do not lead all the way to consensus, the legitimacy of the final decision can be greatly improved, and thus also the willingness of the citizenry to comply with it. The recent trend among scholars is

to recommend that these political rewards be sought through deliberative monetary valuation (Niemeyer and Spash 2001, Söderholm 2001, Spash 2007, Vatn 2009). This approach is an interplay of analytic technique and social deliberation based upon values, interests, and policy options.

Several deliberation techniques have been proposed, such as focus groups, citizens' juries, consensus conferences, and deliberative polls. They have in common that lay people develop preferences about complex policy issues through informed discussion. Planners should not push hard for consensus in the valuation exercise. Conflicting views on environmental values can give useful information to decision-makers, and consensus can be repressive, particularly in communities with cultural diversity and historically excluded minorities. Deliberative monetary valuation in small groups seems to work best when:

- The important interest groups have their representatives in the deliberative valuation
- Countermeasures are taken against manipulation and domination in the small-group process
- Silent parties are encouraged to have their say
- Participants have a common set of rights and capabilities
- Communication between group members is comprehensible, factually true, sincere, and appropriate within the normative context of public planning.

Small-group deliberation faces problems of inclusiveness, representation, competence, and manipulation, so deliberative monetary valuation is no panacea. The deliberative approach can nevertheless answer some of the criticism against contingent valuation: The outcome is not limited by narrow definitions of rationality which result in exclusion of interlocutors' judgments on the suspicion that they are acting strategically, protesting, or just violating the accepted constraints of economic valuation.

5. Concluding remarks

In democracies, the final decision concerning important public plans and projects are made by elected politicians. The political decision can be influenced by the preceding process of policy analysis and planning, however. The paper at hand is about democratization of this process by demanding that analytical tools be designed to take into account the values of involved citizens and address their problems. Rather than having the many engage in the actual policy decision, this democratization asks that planners devise and actively practise ways to recruit and include citizens' views into the policy development and assessment process. More engagement with the evaluation techniques facilitates the partial return of planning and policy formulation to the constituencies (deLeon 1992). The finally enacted policy may not agree with their particular preferences, but for citizens to accede to a political judgment that they have helped formulate is presumably less alienating than

having to accede to a majority that have outvoted them without preceding deliberation.

The Kaldor-Hicks compensation test underlies the recommendations of standard CBA. In the words of Lutz (1995:190) it is 'contaminated with the inequities of the existing income distribution, as well as being blind to notions of human rights and human needs'. In order to centre policy evaluation on human dignity, he defends a three-steps procedure: It starts by testing the project in terms of its consistency with relevant rights, then appraises the project in terms of its impact on basic human needs. Only if the results of these steps are favourable is the project moved on to the third stage of assessing costs and benefits on the basis of market prices and stated preferences. This procedure is in line with the critique of CBA put forward in this paper.

Richardson (2000:1000) suggests that advocates of CBA as a normative standard face a dilemma: if democratic legislatures and elected representative councils at lower administrative levels are legitimate assemblies for setting collective ends, 'then these ends, as worked out in collective deliberation – and not individuals' preferences as revealed in the market or in contingent evaluation studies – should provide the crucial basis of evaluating alternatives'. As the party politics of local councils does not necessarily fully absorb the popular feeling and the interests of those strongly affected by a plan or project, this paper argues for a compromise: The values people hold regarding matters of collective choice can be constructed and articulated through reasoned dialogue and debate with other members of society in participatory and deliberative planning processes (Howarth and Wilson 2006). Deliberative monetary valuation is a promising set of hybrid techniques combining economic and political science knowledge to clarify participants' preferences and insert them into analytic evaluation.

9. HERITAGE, URBAN CULTURES, URBAN DESIGN

Nightscapes: from the urban design to the urban cultures

Teresa Alves[1]

KEYWORDS
Night, urban design, urban cultures, Lisbon

ABSTRACT

Research of spatial practices related to urban design tends to be concentrate on processes and events during day time; the urban design and spatial practices at night has been marginalized and underexposed in geographical studies. With this paper we pretend to discuss how the urban design could promote new opportunities of development in some areas of the cities at the night and create new forms of urban cultures. The central question is how urban design can stimulate the use of the space at night and play a determinant role on the social construction of nightscapes and new urban cultures?

We start with some examples of Lisbon where urban design has been an opportunity to develop new economic activities and to stimulate the old economy with new forms of consumption, attracting residents from other parts of the city and tourists, particularly at night. In these areas the pedestrian movements are very important and give life at street level. The night landscape is very different from the day landscape. There are two cityscapes and the nightscape is more vibrant, full of life. The old quarters, with cozy streets, and the traditional viewpoints have a key role in these dynamics.

At the same time, in Lisbon, we have some developments of night life in restrict places, like old factories or port installations, with impact on the economic developments of these areas, but with little effects on people movement in the streets. Travel with car is more important and the existence of places to park is strategic to the success. In some cases the heritage has an important role in the selection of the places and the revitalization of old urban areas.

The work of a research project about the night in Portugal (*Night: Opportunities and Innovation in the Territory* PTDC/GEO/64240/2006) demonstrate in the case of Lisbon that the night-time economy and the processes of production, reproduction and consumption have create new opportunities to some areas and have transformed the urban nights in practices and discourses, creating a new urban cultures.

1. Urban nights a lost and unexplored space-time in literature

Research of spatial practices related to urban design tends to be concentrate on processes and events during day time; the urban design and spatial practices at night has been marginalized and underexposed in social studies, in general, and in geographic studies, in special.

The night has been a neglected dimension of urban life but has already led to remarkable works such as Anne Cauquelin (1977) *La ville la nuit*, Luc Bureau (1997) *Géographie de la nuit*, Luc Gwiazdzinski *La ville 24 heures sur 24 heures* (2003) and *La nuit la dernière frontière de la ville* (2005), which contributed to a multidisciplinary approach of this space-time. Generally in the literature originating in the countries of Francophile tradition, the night is seen as a territory to discover, with a character closely related to the arts and creativity.

On the other hand in the United Kingdom scientific literature, the night economy is limited almost exclusively to trade in alcohol, sex, drugs and gambling. The regeneration of many of the cities centers, that had lost vitality with the end of the economic model based on manufacturing industry, is often based on investments that promoted the growth of economic activities related to the consumption at night (O'Connor 1997, Helms 2008). According Marion Roberts (2009) the UK planning system was constrained by a neo-liberalist insistence on land-use planning in the 1980s and early 1990s, thereby providing the institutional framework for deregulation of the numbers, capacities and types of licensed premises in town and city centers. This had a direct impact on crime level, violence and anti-social behavior. Criminologists have criticized planners for their complicity in this process, but Roberts argues that entertainment uses have been marginal to the social and ecological preoccupations of the planning.

In the literature on urban design are few references about the night and only recently appeared some works thinking about the issues of the city at night.

The works of Elizabeth McDonald and Michael Larice (2006) *The Urban Design Reader* and Matthew Carmona and Steven Tiesdell (2007) *Urban Design Reader* contain an anthological selection of classic and contemporary texts, concerning various aspects of urban design, but no one spoke about the urban night. With contributions from Howard, Le Corbusier, Lynch, Jacobs, Hiller, Koolhaas and Sorkin these works provide perhaps the most important historical material of the urban design, from the foundations of the urban design to the alternative agendas focused on lively places, strategies for reinforcing local physical identity and the creation of memorable places. These books provide essays about sprawl, density, community health, public space, everyday life, sustainability and urban resiliency. Never in any of these texts occurs a discussion or a reflection about the necessity of thinking in urban design for a city that can have life 24 over 24 hours, the need of a good urban design to support cities lived continuously, day and night. Urban design as a form of place making has become an increasingly

significant area of academic studies, of public policy and professional practice, but without consider the space time night it is not possible to implement a complete work.

The books edited by Alexander R. Cuthbert (2007) *Designing Cities: Critical Readings in Urban Design* includes essays by Manuel Castells, David Harvey, Christian Norberg-Schultz, Peter Marcuse and others. The organization of this work promotes a particular theoretical paradigm, suggesting that urban design is best viewed as a branch of spatial political economy. The material is assembled in categories with an associated guiding question for each. The categories are: theory, history, philosophy, politics, culture, gender, environment, aesthetics, typologies and pragmatics. For example the questions: philosophy - what systems of meanings informs the urban process? politics – what value systems and compromises are involved in the design of the cities?;, culture – how do society and culture give rise to urban form?. Also here the night is never a matter of discussion, even when considering the case of Las Vegas (Chaplin, 2007). The analysis of Las Vegas design urban are related to the development of urban entertainment centers, where consumption is the new production, and where "cultures industries" replace manufacturing and the tourism market are the objective. Despite everything that is described, including the series of shows that make Las Vegas a collective spectacle, is more relevant at night, the fact is that the analysis don't refer any difference in how we live day or night in Las Vegas Strip. It would be interesting to discuss why space inside casinos is designed with the absence of natural light. The objective is to make to believe that it is always night? If the city is conceived like a theme park ("safe, clean, predictable yet diverting" (Chaplin, 2007: 349)), casinos contain the greatest illusion, eternal night, which only ends when we want.

Starting from the idea that the "personality of the city's night became the detonator of its attractiveness in the context of international competition between cities" Marc Armengaude, Matthias Armengaude and Alessandra Cianchetta (2009) *Nightscapes.* show how the night redefines the framework of thought and action in the realm of the imaginary of territorial planning and the practice of urban design. The aim of the authors is to arrive at contemporary urbanism based on perceptual experience. In the first part Marc Armengaude reflect about the originality and value of the experience of nocturnal landscape for thought and creativity, the nightscape as an experience, a symbol and representation. In the second part Matthias Armengaude define infrastructures as the nocturnal landscape´s real scale and strategy. The infrastructural nature of the night because only the night as revealing the scale of the territorial network. In the third part Alessandra Cianchetta presents some examples of nocturnal architecture and landscape: urban lighting projects, architectures in the night and temporary nocturnal cities. To these authors space, scales, speeds and time are dimensions with different magnitudes on day or at the night. At night the city is still very soft, vulnerable, most spaces are not planned to be used. We need to invest, plan, imagine, relocate, revitalizing or simply leave sleep. As an

element ephemeral night calls of different interventions of the day, more light, playful and dreamy.

2. Methodology

The main sources of information were surveys to 1) people in public spaces of the most important areas of night life in Lisbon, and 2) people, in general, in several areas of the country and 3) 25% of municipalities of Portugal (from the research project *Night: Opportunities and Innovation in the Territory* - PTDC/GEO/64240/2006). We surveyed people to see how they perceived the places where they stay at the night. We surveyed municipalities to understand the role of local power on planning the territory at the night.

Another main source of information is the direct observation. Many hours walking and watching how people use the streets, plazas and the best view points of the city. Many hours filming and photographing them, analysing films, photos and data, and quantifying what we observe about people using public spaces in order to specify principles for good pratices.

Secondary information sources were consulted, including academic, professional and the popular press. Websites were also explored. The late night economy in Lisbon was examined by interviews with police, council and employees in the late night economy.

3. Urban nights a lost and unexplored space-time in planning

In Portugal almost all of the municipalities don't have figures in planning related to the night. A survey to the local planning authorities in Portugal, found no planning actions related to land use dedicated specifically to the period of the night (source: surveys to municipalities - *Night: Opportunities and Innovation in the Territory* PTDC/GEO/64240/2006).

Some decisions can occurs when some conflicts happens, like the hour of close the nights activities or restrictions on the location of economic activities that produce noise at night. In some cases there is a ghettoization policy of economic or cultural activities with a higher incidence during the night, removing them from residential areas, and locating them in more peripheral areas. Sometimes in areas whose economic activities have declined, as former industrial or storage sites.

Even in the field of public lighting only in very specific cases there have been light-plans for restricted areas. The first action in lighting planning has occurred for over 20 years and has covered the historic center of a city classified by UNESCO World Heritage (Évora). Process of this dimension was not repeated in other cities. The normal is the development of projects for small areas.

1. Planning related to the space-time night by type of municipality

	Rural Areas	Middle Towns	Metroplitan áreas
Noise	-	X	XX
Electronic surveilance	-	-	X
Lighting	-	X	XX
Nighlife	X	XX	XXX
Land use	-	-	X
Activities night schedules	-	-	X

Source: Surveys to municipalities 2008-2010 from the project *Night: Opportunities and Innovation in the Territory* (PTDC/GEO/64240/2006)

In recent years the municipalities of the largest cities (Lisbon and Oporto) decided to install electronic surveillance in areas with more leisure at night. Although still very few municipalities reveal concerns about issues related to space-time night, these are more evident in areas with higher population density or metropolitan areas (Table 1).

In the same survey all municipalities have said that make annual investments in cultural activities, entertainment and leisure with particular importance of which occur at night. In some cases they are regular activities in municipal facilities such as theaters, in others there is a concentration of activities in the summer or at the time of the annual municipal festivities. The support for the nightlife often occurs by the incentives to local associations that produce annual traditional festivals. A survey of residents in different regions of Portugal show that regardless of age, education level, type of work or place of residence all people surveyed said they go out at night for leisure at least several times a year (Table 2). The frequency with which people go out at night for leisure increases with the level of urbanization.

2. **Reasons to go out at night by type of local of residence**

Work	10	19	28	12
Family	15	31	35	22
Leisure	100	100	100	100
Shopping	5	56	87	25

Source: Surveys to persons 2008-2011 from the project *Night: Opportunities and Innovation in the Territory* (PTDC/GEO/64240/2006)

In the document that founded the National Policy Planning (Programa Nacional da Política de Ordenamento do Território - www.territorioportugal.pt/pnpot/) there is no single reference to the space-time night. The National Policy Planning is the instrument of territorial development of a strategic nature that sets out the main options of relevance to the organization of the national territory, constitutes the reference framework to consider the elaboration of other instruments of territorial management.

The night, though, has still remained an unknown space-time, a kind of unexplored territory, where politicians and scientists have made little investment. The blackout and the dark appear frequently associates to the absence of life, the time in suspended, when nothing can be done. But the social changes and techniques of the last decades had taken significant alterations in the way as we live the night. The activities that we associated with the day are each time more present in the night. The night already does not correspond to a suspension of the time. The number of people who study, work or play in public places at night continues to grow.

4. Urban design, opportunities of development and the social construction of nightscapes

With this paper we want discuss how the urban design could promote new development opportunities in some cities areas at night and create new forms of urban cultures. The central question is how urban design can stimulate the use of the space at night and play a determinant role on the social construction of nightscapes and new urban cultures?

The work of a research project about the night in Portugal (*Night: Opportunities and Innovation in the Territory* PTDC/GEO/64240/2006) demonstrate in the case of Lisbon that the night-time economy and the production processes, reproduction and consumption have create new opportunities to some areas and have transform the urban nights in practices and discourses, creating a new urban cultures. The urban design of this areas are or not a crucial role in this process?

In Lisbon the areas with more life at the night are filled with persons who come from outside the municipality. The aging process of resident population of Lisbon is very intense. In 2011 the resident population aged 65 and over reached 25% in Lisbon (the national average was 19%). The resident population aged between 15 and 24 years did not amount to 9% of the total (the national average was 11%). So Lisbon by night welcomes people that during the day don’t have place in the town, because they don’t have conditions to work or to live there.

According to a survey[2] conducted in several locations (Fig. 1) of the night in Lisbon the majority of the respondents resided outside the city of Lisbon (Table 3). However this was the place of work or study for 57% of the respondents and the municipality first chosen for the night leisure (75%). The fact that over 40% of respondents are studying in higher education justifies the relevance of Lisbon as place of study. The municipality of Lisbon concentrated almost all institutions of higher education in the Metropolitan Area of Lisbon.

3. Lisbon night: places of residence, work, study and leisure

%	Lisbon	Others in MAL	Others out MAL
Municipalities of residence	27,3	62,1	10,6
Municipalities of workplace or study	56,6	36,4	7,1
1st municipality for leisure at night	74,6	23,3	2,0

Source: Surveys to persons 2010 from the project *Night: Opportunities and Innovation in the Territory* (PTDC/GEO/64240/2006)

When asked about the reasons for the choice of the places to go out at the night we find the main reason was “a very lively night” (72% of the responses) immediately followed by a “high probability of finding friends” (68% of the responses). Safety or proximity to the place of residence had no significance (less than 12% of the responses).

The level of lively of the night depends of several aspects, but the most frequently mentioned were being freely in public, drinking, smoking, walking or talking (78%). The existence of bars and clubs is important but not decisive (39%). The existence of restaurants is even less relevant (32%). The existence of specialized commerce that keeps open late is not a factor of attraction for these respondents (15%). The proximity of spaces such as theaters and art galleries also has no significant impact on the decision to choose this or that place at night (10%). But the existence of certain indoor concerts was very relevant to the presence of these persons (57%). The conditions for "stay" in public spaces are the most important aspects for the choice of places to go out at night.

And what are these conditions: streets with low traffic or completely closed to traffic; streets where are ease and secure walking; good accessibility by public transport or in parking facilities; spaces integrated into traditional neighborhoods where the housing function continues to be relevant and where some more traditional outlets sell at reduced prices, drinks and food until hours later; the existence of pubs or

[2] Survey of 180 randomly chosen people in different places of the night in Lisbon: Bairro Alto; Santos; Santa Catarina and S. Pedro de Alcântara.

restaurants, but also clothing, personal services with hours that extend into the night and give to these neighborhoods the air of spaces with life.

Main lines of pedestrian circulation
Others places and directions of the night

The physical characteristics of the spaces can improve the success of the night life. Bairro Alto (Fig. 1) is the case with more longevity and success on the night of Lisbon. It is a traditional neighborhood in the old city center. The resident population is elderly, but has been rejuvenated with the rental homes to foreign students and the development of luxury real estate projects. Bairro Alto has narrow streets with significant slope in some cases. The undulating shape and the more or less straight perpendicular paths contribute to a sense of territorial control that helps to circulate in the busiest nights. In the interviews are often referred

expressions like "we can see the confusion and cut to other way" or "when BA is full, we can always go out and avoid confusion". The narrow streets closed to non-residents traffic, become welcoming to visitors. From Thursday to Saturday thousands of visitors arrive to this area at the night.

Bica (Fig. 1) was an extension of Bairro Alto, but in this moment have a specific life with the presence of lot artists. This area is focused on one of the steepest streets in Lisbon. In this street during the day is one of the traditional lifts, but at the evening is filled with people run way from the excesses of the Bairro Alto. The excitement of the night results from the combination of bars that have opened recently and old associations and local communities. Once again the absence of traffic, the integration into traditional neighborhoods and the renovation with new functions (bars, restaurants and art galleries) are very important to the dynamics of the night life in this area.

The success of spaces like the gardens and viewpoints of Santa Catarina or S. Pedro de Alcântara (fig. 1) is due to the fact that they are close to Bairro Alto. They are large public gardens, with facilities such as cafes and street furniture like tables and places for people stay seated. In general they are the places where the night ends. After Friday or Saturday nights, the cleaning services of the municipality collect hundreds of empty bottles in these spaces.

The Cais do Sodré (Fig 1) near the Tagus River keeps more marginal activities particularly related to the practice of street prostitution. Because of this the commercial prices are lower than in other areas around. What has been stimulating to the location of successful activities that integrate, renew and create new dynamics in the area. Thus we find the theater company Casa Conveniente (House Convenient http://casaconveniente.pt/), Music Box one of the most innovative music place in Lisbon (http://www.musicboxlisboa.com/), and new spaces of a bar which share the street with the old activities.

The success of these night areas can be related to an urban design sensitive to human needs: cozy streets are comfortable even in the winter; physical format make the space functional; a strong relationship between art, culture and leisure; an economic dynamics associated to the food and drink; ease access to transportation systems. The fact of local resident use the space creates more sociable places. The presence of historical and traditional elements, the human scale development or the design of built environment may not determine human behavior but can have powerful, positive influences on human beings (Armengaude, Armengaude and Cianchetta, 2009).

The bibliography of other cases (Helms, 2008; Roberts, 2009; Talbot, 2007) show very negative positions and criticize how badly the built environment fits human needs ugly, impersonal, dirty, dangerous, dysfunctional, race and gender segregate areas dominate many cities nights today. On the contrary the spaces of the night in Lisbon are felt by thousands of users as spaces that belong to them. Despite

the poor hygiene, some conflicts due to noise and disrespect, problems with excessive drinking, that can disturb the peace of the residents and visitors, the night of Lisbon can be classified as peaceful. [In the survey in Lisbon night sites we asked how often have watched situations of disrespect. The dominant response has been not frequent, less than 10% of times.] The older residents have the presence of visitors as something that does not disturb their lives and have become accustomed to their presence. In some cases, may even be to ensure more revenue with the renewal of commercial space and the extension of the traditional trading hours.

The pedestrian friendly streets, the permanence of historic buildings, the presence of residents in public space and the revitalizing economy create spaces that tell to "outsiders" they are welcome and they fell as at home. Urban design has been an opportunity to develop new economic activities and to stimulate the old economy with news forms of consumption, attracting residents from other parts of the city and tourists, particularly at night. In these areas the pedestrian movements are very important and give life at the level of the street. The landscape of nights is very different from the landscape of days. There are two cityscapes and the nightscape is more vibrant, full of life. The old quarters, with cozy streets, and the traditional viewpoints has had a key role in these dynamics.

4. The nightscapes and new urban cultures

The culture of the night in Lisbon in the old neighborhoods of the city center is closely linked to life in public space, walking between the different locations, close but also distant. The night usually starts in the Luis de Camões Square in Chiado (fig.1). The proximity to public transport is very important. This plaza serves as the gateway to the Bairro Alto, is the place of reunion to start the night.

Walk through the streets of the Bairro Alto is a ritual. Rather than stopping at a bar is important to move and find more friends. Access to food and drink is not exclusive of modern spaces, the traditional commerce has adapted to the night life time and ambulant vendors provide goods at lower prices. With the economic crisis there are many who eat and drink at home before leaving, or purchase goods and bring them.

The race and gender segregation is more present inside restaurants and pubs. There are bars and restaurants with more clients from some community, but that does not make the public space more segregated for those who do not belong to these groups. When we ask on the survey if there are spaces from specifics communities in Bairro Alto the answers is always: yes. When we asked if this creates limitations to the movements the answer is always: no.

Noise, litter, graffiti, fly-posting, alcohol, drugs and drug dealing are problems present in Bairro Alto, but they don´t have sufficient importance to create an anti-social behavior. When confusion begins, for disrespect or simply because there are too many people, the tendency is to go out and search a place more calm like S.

Pedro de Alcântara and Santa Catarina. When economic activities close at 2 am or 3 am (Friday and Saturday), people move to other places or try the discos and bares near the river, either in the direction of Santos, Alcântara, Docas de Santo Amaro or Santa Apolónia (Fig. 1).

Outside the old districts in the city center night life in Lisbon comes in a strip along the banks of the Tagus River where the activities take advantage of the availability of space and because they are outside the constraints of the residential areas. The closing times are later and larger parking facilities are more accessible. In some cases there are located in new buildings, but others take advantage of old storage facilities linked to port activities. The night life is more important inside, but some spaces are developed in plane air or with view to the river.

Braço de Prata and Lx Factory are two of the most relevant places of the cultural live in Lisbon with a significant innovation in the night activities. These two spaces have in common: the fact of occupied former factories, become localized at points where accessibility is very dependent on private transport and a strong association between arts, culture and entertainment.

Braço de Prata exists because the financial crisis has failed the development of Renzo Piano project for the area. Braço de Prata is one of the main centers of cultural life in Lisbon, presenting every day performances, conferences, forums and debates, cinema, art fairs or expositions. A bookshop and a restaurant create some dynamic all the day, but the night is the most important moment (http://bracodeprata.net/).

In the case of Lx Factory the space was originally abandoned (http://www.lxfactory.com). The company that own the buildings is waiting for the council´s decision about the zoning plan of Alcântara area and decide to go ahead with the Lx factory project. Attracted by rents of 6 to 12 euros per square metre, about 80 companies (design, architecture, restaurants, advertising, mode, arts, performance, music, technologies, marketing, communication, leisure...) have occupied almost all the available space.

One of the main attractions of Lx Factory is a bookstore - Ler Devagar (Read Slowly) - with more than one hundred and fifty thousand books, is installed in the room of an old rotary that have printed the main newspapers in Portugal. It was considered one of the most beautiful bookstores in the world. With a permanent cultural program and a small space to eat and drink is a great mark of Lisbon nights (www.lerdevagar.com).

In the weekend we can see in Lx Factory parties with thousands people into the vast empty space in the main building of the old factory. Other innovation in Lx Factory is the Open Day event, with live music, film, food, art fairs, expositions and DJ until late. In the Open Day event visitors can enter in all the spaces and know what is happening there. From the start the occupation of Lx Factory was provisional, but that’s a part of the project, the main asset of this project is the ability to use creativity

to produce spaces suited to activities with low levels of investment taking advantage of the environment.

These projects have stimulated the development of new economic activities and renovation of older ones in areas where they are located. The developments of night life have impact on developments of these areas but with little effects on people movement in the streets. Travel with car is more important and the existence of places to park is strategic to the success.

The industrial heritage has an important role in the selection of the places and the revitalization of old urban areas. These places are very important to the development of tourism and cultural events in Lisbon night. Particularly in a context of resident population reduction in the city centre the development of these leisure clusters creates conditions to attract both people and new economic and cultural activities.

When we asked about what persons associated to the night, the answers more frequent are: bohemian, party, fun, mystery, dream, freedom, creativity, rest and sleep (more than 60% of the answers). Almost no one associated the night to responsibilities, work or study (less than 10%). Drinking, drugs, violence and insecurity are associated to the night for who don´t have frequently night life. On the survey to people in the night street of Lisbon these items have less than 20% of the answers with association to the night.

5. Conclusions

In the dynamic of Lisbon nightlife we found a very strong tendency to use public spaces as living spaces, meeting, socializing, shared by residents and nonresidents. The law which prevents smoke indoor stimulated the development of outdoor terraces. Also traditional close spaces like restaurants and bars tend to open themselves occupying spaces in the street for their clients.

In the neighborhoods of the historic center with narrow streets and no traffic make the stay in public spaces safe and cozy. The thousands of visitors who circulate in the Bairro Alto, Bica and Cais do Sodre feel safe and are not felt by residents as threats. Despite the trash, noise and confusion in some places there are always "islands" of peace that are used as alternatives.

On the banks of the Tagus the night spaces are design to live the life inside. But this inside is relative, the development of the spaces take advantage of the quality of the climate, mild all the year, and the quality of the landscape, and have generous areas at open air. Here more than the urban design is the natural characteristics and the proximity of the river that contribute to the quality of night life. The music program could have some influence on the attraction of clients, but the quality of the places could be sufficient.

Other important aspect of the night life in Lisbon is the strong association between arts, culture and entertainment. Live music is present in many spaces of the night. Cultural events like art exhibitions, concerts and street entertainment are also very common.

The nightscapes in Lisbon is associated to the possibility of chose, be free, be alive, with friends in the street. The urban design can stimulate the life in the streets with news forms of consumption, attracting residents from other parts of the city and tourists. The old quarters, with cozy streets, and the traditional viewpoints has had a key role in these dynamics.

Revitalization Strategies in Iranian Historical City Cores
The Case of Shiraz

Azadeh Arjomand Kermani[1], Eric Luiten[2]

Abstract

The issue of cultural heritage preservation is more challenging in developing countries than in other parts of the world. In societies eager for progress, the modern European cities are regarded as the most desirable reference for a high quality urban environment. Urban settlement transformation in the developing world was very slow before the industrial revolution but old urban fabrics experienced a significant structural transformation with commercial, economical, social and cultural changes.

During the last fifty years, Iran has had numerous experiences in various scales and subjects of urban design in the context of historical city parts, ranging from urban renewal projects to urban regeneration and rehabilitation projects. Most of these have not been actually successful, and unfortunately no lessons have been learned from those failures.
The mutual strategic aim in all projects was to reach out into more interesting communities that inhabit the old urban area; these communities can help the whole city to provide better facilities for more residents. This goal would only be achieved by creating a new balance between conservation and development. Urban design strategies that illustrate these specific principles and methods should be developed.

This paper attempts to identify major approaches to revitalize Iranian historic cores. It focuses on ways to revitalize traditional structures, patterns and values in the process of regeneration of Shiraz; one of the most historical cities in Iran. It starts with a brief discussion on the history of large-scale interventions in Shiraz and its key stages of transformation. Rehabilitation projects of *Sang-e Siah* and *Shah Cheragh*, two major historic neighborhoods in the city center of Shiraz are described and analyzed. The main successful results and policies in these two projects are defined and shortcomings and possible solutions are discussed in the last section.

1. Introduction

[1] Delft University of Technology, Delft, The Netherlands - A.Arjomandkermani@tudelft.nl
[2] Delft University of Technology, Delft, The Netherlands - E.A.J.Luiten@tudelft.nl

The modernization movement in Iran started with Qajar king's travel (Naser-ed-Din Shah) to Europe in the 1870's, but it was during the Reza Shah period (1921-41) that the idea got momentum. The European influences that had been filtering into Iran since the 16th century finally gained ascendancy and the country underwent a phase of intense westernization.

Reza Shah's urban modernization led to changes not only in cultural patterns of urban life and the economic structure of the country, but also in spatial organization. He attempted to modernize major cities by driving a network of long straight roads through the heart of the urban fabric. Construction of urban highways and boulevards intensified the urban circulation system from the 1950's during the Second Pahlavi era as a sign of modernization (H.Bahrainy – 2007). Wide streets with free access to traffic and different parts of the city became an apt place for shops and commercial spaces following the preference of both shopkeepers and consumers. This has caused maintenance and exploitation problems for the old Bazaar structure.

The result was a radical heterogeneity in major historical cities because old city cores had been generated by different social and environmental circumstances and were not capable of accommodating the requirements of a modernized society. Large areas of most old urban centers are becoming desolate wastelands of empty stores and buildings which are hostile to a vital society. Regeneration of these urban areas will help the whole city to function better.

2. Shiraz formation and transformation

Shiraz, the sixth largest city in Iran after Tehran, Mashhad, Isfahan, Tabriz and Karaj is the center of Fars province in southern Iran. The city is located 895 km south of Tehran and 100 km north of the Persian Gulf.

2.1 Shiraz transformation before *Safavid* period

The earliest reference to the city, as *Tiraziš*, is on *Elamite* clay tablets dated to 2000 BC found in the south western corner of Shiraz city (Cameron 1948). According to some Iranian mythological traditions, it was originally erected by *Tahmuras Diveband*, and afterward fell to ruins (Conder 1827).

Figure 1. Shiraz; Physical structure of the city in 12th century A.D

Although the foundation of Shiraz was before the Islamic period, the city became the provincial capital only in 693 A.D, after the Arab armies

conquered *Estakhar*, the nearby Sassanian capital. As *Estakhar* fell into decline, Shiraz grew in importance under the Arabs and several local dynasties.
The *Buyids* (945-1055) made it their capital. Although Shiraz was spared destruction during the *Mongol* invasion, the town was devastated in turn by *Timur* (1387 and 1393), by great floods in 1630 and 1668, by the Afghan invaders in 1724, and by earthquakes which partially destroyed the city in 1789,1814, 1824 and 1853 (Lockhart 1939; Clarke 1963; Wilber 1975).

2.2 Shiraz transformation until 1925

During the *Safavid* period (1502-1722), security and prosperity returned to Iranian cities and was maintained for about two centuries. The Governor-general of Fars put great effort in beautifying Shiraz. He copied Shah *Abbas*'s famous *Chahar-Bagh* at Isfahan" (Lockhart 1939; Arberry 1960) and constructed a magnificent palace in the great square.

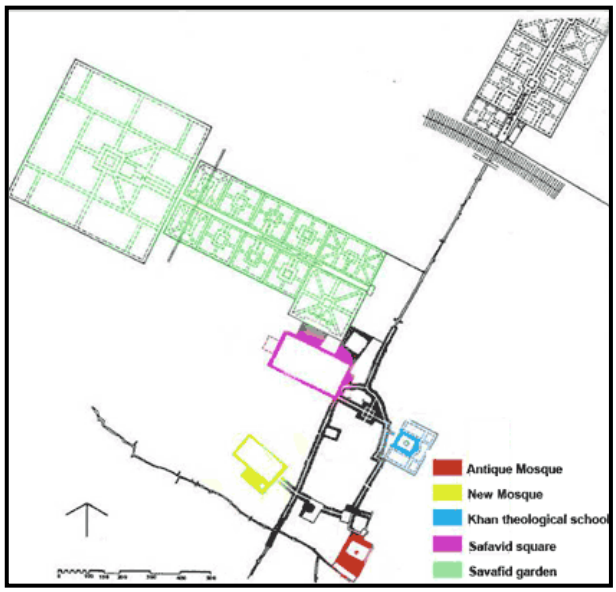

Figure 2. Shiraz; Physical structure of the city in 16th century A.D

Shiraz was initially circular in shape, however the regular pattern of the city soon changed to an organic structure like other Iranian cities, comprising the main elements of such cities. The form of the city stabilized in the 15th century and its shape from that time until the 20th century exhibited a fair representative of a typical traditional city before modernization (Karimi 1998). Shiraz's decline started with the Afghan raids in the early 18th century, several earthquakes, and an internal uprising. In the middle of the eighteenth century, the city again came back to life and splendor "under the benevolent attention of a regent-ruler, *Karim Khan Zand*" (Wilber 1975; Boyle 1978). Twenty-seven constructions in Shiraz, of which sixteen remain today, are attributed to *Karim Khan Zand* (Scarce 1991).

Although the prosperity of Shiraz was seriously interrupted by the decline of the *Zand* dynasty (1794) and Tehran took the place of Shiraz as the Capital from this period, Shiraz remained one of the most important provincial cities during the *Qajar* period.
The map of the city in this period shows that the old district is clearly the most integrated place in the city, which coincides with the geographical centre of the city as well. The city consisted of eleven distinct quarters (*mahallas*), inhabited by separate communities with powerful social cohesion.

2.4 Shiraz transformation after 1925

The metamorphosis of Shiraz into a modern city began with the attempts of Reza Khan (1925-1941), the founder of the Pahlavi dynasty (1925-1979). After the first period of modernization the growth and development of Shiraz became radically different from its traditional pattern. A regular pattern of modem networks was superimposed on the historic core as the common pattern of expansion, and the organic shape of the traditional area has been trapped inside the enclosed and segmented historic core.

Apart from the influences of many political and economic changes since World War II, the intensified forces of modernization and industrialization transformed the city in the late 1960s and the 1970s. The old core turned into a very small part of the sprawling city, suffering from decay and lack of maintenance. Social, political, and economic changes during the post-revolutionary period, particularly during the first two decades after the revolution (1979-1997), also affected the fate of the old core. This was particularly executed through the direct interventions of the state and a constant desire toward unbridled development and modernization despite the apparently traditional nature of the government.

Figure 3. Expansion of Shiraz during 1960, the historic core gradually became a minor part of the sprawling city and lost its physical, social, and economic significance.
Source: Shiraz municipality

Master planning in Iran started in the 1960s. Before this era the act of road building was on the agenda in different cities, but these acts did not follow any predetermined plans. The decisions were rather casually prepared depending on the time and location. The need for master plans started to emerge when cities grew enormously, and when the country was introduced to the achievement of Western planning methods. These master plans had three important components: road network, land use, and building density or heights. Through the control of these three elements, the master plans attempted to achieve their initial goals.

After the first program of road building in Shiraz, the first comprehensive plan was produced by Tehran University, department of architecture in 1966. The plan produced

by these planners was very radical. A rectangular grid of roads designed for cars has been superimposed on the older grid without the slightest regard to the historic evolution and older patterns of growth. The usable land area for different urban factors increased from 22 sq. kilometers in 1962 to around 80 sq. kilometers in 1992.

In reality the comprehensive plan was not fully implemented. Only some of the major streets proposed by this plan were built. New streets created by this plan together with the ones created before were enough to influence the whole integrity of the city. The second master plan was prepared by *Naghshe-Jahan-Pars* Consultants about two decades ago.

The autocratic control of the decision-making, policy formulation, planning and design exercises by the central government and its agencies, together with access to financial resources made the instrument of authority a determining factor in the implementation of large-scale redevelopment oriented programs. All these schemes involved the modernization of the pre-existing urban structure of the historic center by means of cutting wide and straight avenues through its densely built-up quarters. However, since 1997, several political and administrative reforms at national, provincial and local level changed this situation and provided a basis for the emergence of a new series of regeneration and conservation activities in this area.

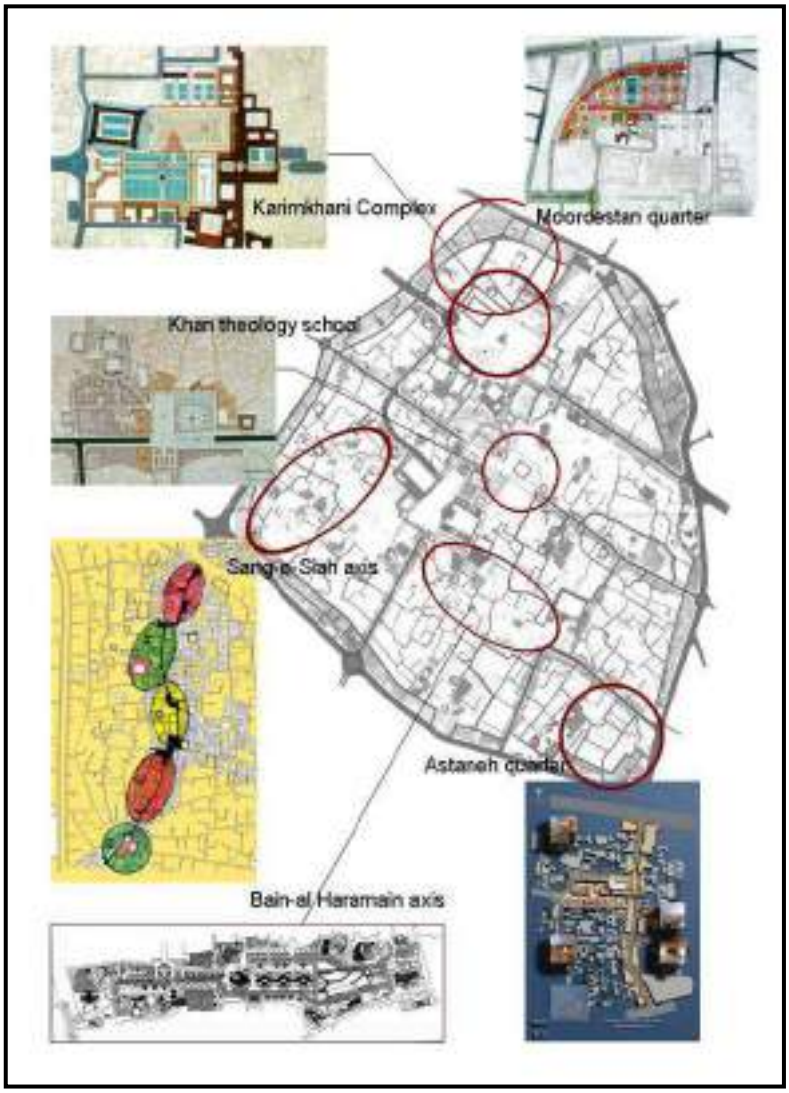

Figure 4. The Comprehensive Plan for the historic core of Shiraz. (Naqsh-e-Jahan-Pars 1998)

According to the above discussion, four key periods are identified during which the historic core was under pressure from various waves of renewal and redevelopment including: *Zand* dynasty [1750-94], Modernization under Reza Khan [1920-41], the period of city sprawl in the late 1960s-1970s, and the first two decades after Islamic

Revolution of 1979, the so-called post-revolutionary period (1979-1997).

3. Case studies

During the past decades, the historic city centre has suffered from depopulation, extensive deterioration, several legal impediments and official obstacles, lack of investment, high crime rates, social fragmentation, poverty, deprivation and inefficient urban management. However, since 1997, several political and administrative reforms have changed this situation and provided a basis for the emergence of a new series of regeneration and conservation activities in this area. In this section two major projects that have been designed for the old city of Shiraz are discussed.

3.1 Sang-e Siah project

The study area is located at the heart of an urban block on the west side of the historic core which encompasses the old quarters of *Darb-e Masjed*, *Armenian Sar-e Bagh*; as well as the main parts of Shah Square, *Sar Dezak*, and the Jewish quarters. The names of the neighborhoods are still used as general geographical locations, but the corporate structure of individual quarters no longer exists.

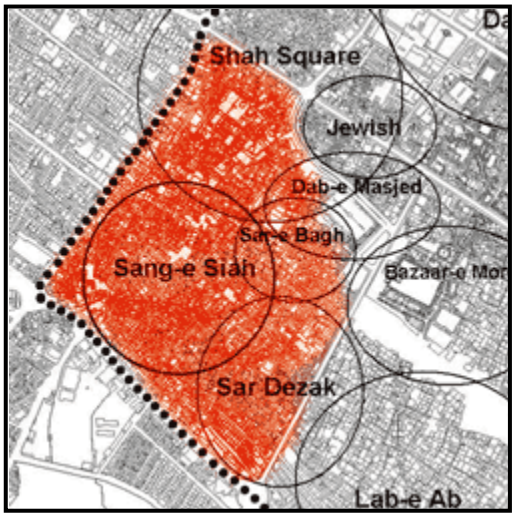

Figure 5. The boundary of the urban block, which contains historical quarters

3.1.1 Site analysis

The imposed avenues of the 1920s and 30s disintegrated the social and spatial networks of the old quarters and formed a series of large urban blocks which contain parts of historic quarters. This block covers approximately 70.4 hectares and contains over 2476 residential units, with 15435 inhabitants (18.74 percent of the historic core area) (Naqsh-e-Jahan-Pars 1998; Pardaraz 2003). Residential area is the dominant use (62%). The second most dominant use is access network with 19%. Most commercial uses are located along new streets on the border of the urban block. There are also four local commercial centers, literally *bazarcheh*, in the proximity of the historic neighborhood centers which mainly provide the daily or regular needs of the residents of their immediate neighborhoods. The area contains more than 26 religious centers including mosques, local shrines, and theological schools.

Although the spatial dimension of the area has changed to some extent, it still largely retains its traditional layout. There are fourteen monuments listed by the Cultural Heritage Organization, as well as more than hundred unlisted but architecturally

significant buildings (mainly historic residential houses) that determine the quality of this urban context.

The dominant route for pedestrians is "*Sang-e Siah*" axis, the north to south spine, from *Bibi Dokhtaran* tomb to the *Taj-al Din Gharib* mausoleum near the old *Kazeroun* Gate. Although Shiraz is not a pilgrimage centre like Mashhad, mosques and shrines dominate the skyline of the historic core, and are the most noteworthy features of the urban landscape (Clarke 1963). A close examination of the area shows that the major monuments are in close proximity to each other and form five distinctive clusters. They are located along *Sang-e Siah* axis, the main spine of the area.

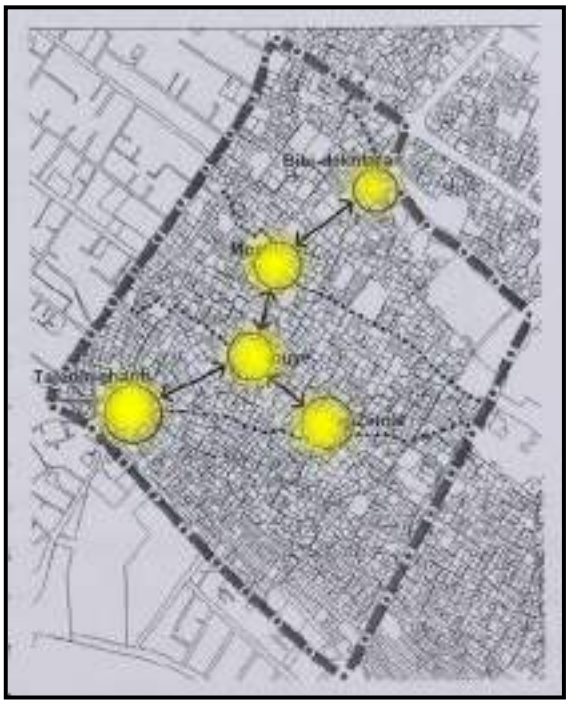

Figure 6. The monuments clustering along the *Sang-e Siah* axis define a heritage corridor which plays a vital role in this area.

3.1.2 Design analysis

The origin of the *Sang-e Siah* Project lies in 1999 when the Council for Historic District approved a proposal presented by the local representative to share the implementing responsibilities of a regeneration program for the eastern part of the historic core, called *Sang-e Siah (Izadi 2008)*. From the beginning, the basis of the project was to be a partnership among the different agencies involved each with responsibility for conservation and regeneration at their respective levels. The *Sang-e Siah* regeneration project has been planned and designed in order to reverse the dramatic conditions in the area.

The manifesto prepared by the Council for Historic District justified protection of the historic environment. It was a guidance note which emphasized the importance of the historic area and its elements. The manifesto (called *maram-nameh*) marked a major step forward in official attitudes towards the historic environment. This manifesto reflected anxiety about the increasingly rapid loss of parts of the historic environment. Nevertheless, it authorized small scale development of ruined buildings and vacant lands into required functions and services for the neighborhoods (Izadi 2008).

At the preliminary stage of the program, the main focus was on restoration of individual buildings and public open space. However, regarding the critical situation of the area, it needed to be complemented and supported by other modes of interventions, such as adaptive re-use, careful urban renewal and even substitution of elements which were no longer viable or needed to be replaced by the new functions.

Historic houses and monuments have been rehabilitated in an effort to revitalize the existing architectural heritage and make them accessible to the local community as well as visitors. The adaptive re-use of restored buildings is considered from the beginning in order to keep the building alive, provide meaning to the physical intervention, make local communities 'own' the building and generate income for future operation and maintenance (UDRO 2001). The program is specifically aimed at attracting investment in the historic urban centers by promoting the re-use of key buildings as a means of encouraging sustainable regeneration of these neighborhoods.

There was an emphasis on a gradual process of physical rehabilitation and economic improvement. The new policy declared that facilitating the gradual rehabilitation of existing residential units through the creation of necessary conditions including the improvement of infrastructures, development of required services and functions, and upgrading of public open spaces.

As can be seen from figure 7, there are five zones identified by the strategic plan including pilgrim and tourist zone (*Bibi-dokhtaran*), local commercial and service zones (*Moshir* and *Haj-zeinal*), cultural zone (*Sibuyeh*) and commercial zone (*Kazeroon Gate*). These five prioritized zones were introduced by the strategic plan, each forming a focus for rehabilitation, upgrading and conservation.

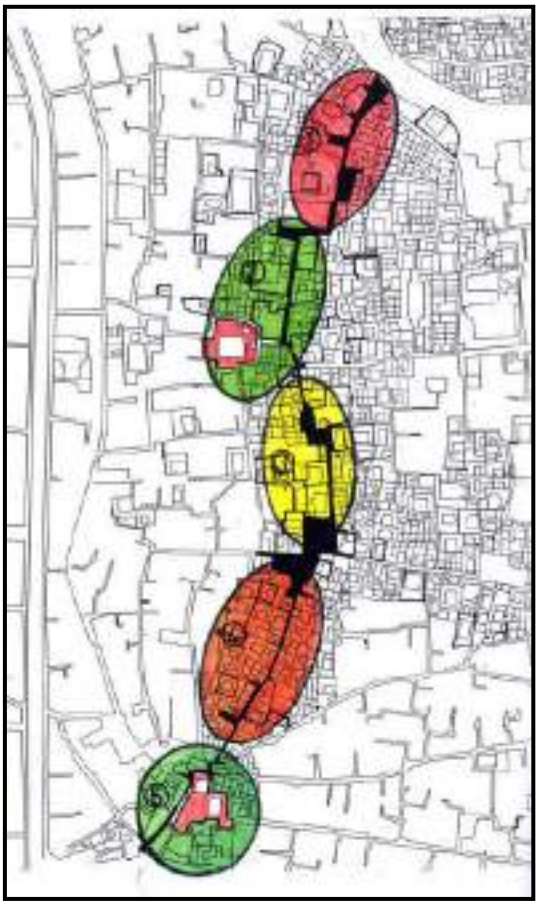

Figure 7. Five zones identified by the strategic plan including pilgrim and tourist zone (*Bibi-dokhtaran*), local commercial and service zones (*Moshir* and *Haj-zeinal*), cultural zone (*Sibuyeh*), and commercial zone (*Kazeroon* Gate). These five prioritized zones were introduced by the strategic plan, each forming a focus for rehabilitation, upgrading and conservation.

With recent social and cultural changes, historic buildings have been subject to extensive changes, alteration and in some cases a considerable amount of damage. The historic houses which were in danger of destruction has been rehabilitated, upgraded and converted in to a local library and cultural centre. These structures are seen not only as monuments and historic building to be preserved, but also as potential focal points that can attract tourists and stimulate the inhabitants to continue or start new activities. In this project, the infrastructure improved, the main access resurfaced, and building facades

were rehabilitated with the traditional patterns particularly those which are located around the newly constructed plaza.

3.2 Shah Cheragh Project

The second case study is located at a very central part of the historic core which encompasses the old quarters of *Bazaar-e Morgh*, *Balakaft*; as well as some parts of *Darb-e Masjed, Eshagh Beig*, and the Jewish quarters. This area is significant for the important monuments that it houses such as *Shah-e-Cheragh*, New Mosque (*Masjed-e-No*), *Hakim* theological school, Antique Mosque (*Masjed-e-Atigh*), *and Seyed Alaeddin Hossein* shrine.

3.2.1 Site analysis

The project area covers approximately 61.2 hectares and contains over 1000 residential unit, with 6000 inhabitants (7.23 percent of the historic core area) (Naghsh-e-Jahan-Pars 1998; Pardaraz 2003). Residential is the dominant use (31.1%). Apart from access network, shrines and religious activities are the second most dominant use with 14.8% in total. There are also short parts of the local bazaar which mainly provide regular needs of pilgrims.

In 1995, imitating Tehran municipality in its *Navab* project, the mayor of Shiraz introduced a comprehensive redevelopment scheme joining two religious complexes, *Seyed Alaeddin Hossein* and *Shah-e Cheragh* called *Bein-al-Haramain*. Between 1995 and 1996, Shiraz municipality demolished 4.95 hectares of the historic core to create a new axis between those two religious centers. Much of the urban fabric was demolished without any consideration for the local culture and architectural heritage in this area. The guiding principle was the construction of a broad, straight street (450 meter long and 110 meter wide) which would allow the circulation of traffic right through the historic urban fabric. It was an ambitious plan which not only failed to provide income for the municipality, but also wasted the resources of the municipality.

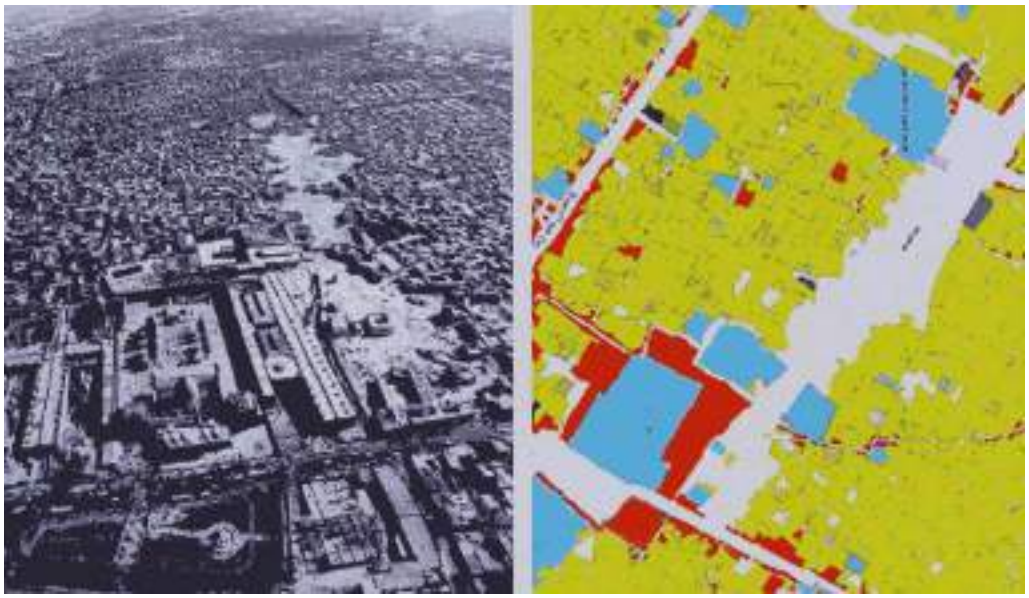

Figure 8. Comprehensive redevelopment scheme of *Bein-al Haramain*, Shiraz, 1995- 96
Source: Iran Surveying Organization (left photo), 1996, Pardaraz Consultant, 2003 (right map)

The comprehensive redevelopment scheme for *Bein-al Haramain* was not an isolated case which was superimposed on the historic urban fabric during this period. The pressure on the *Shah-e Cheragh* Shrine and *Sayyed Alaeddin* complex generated by a mass pilgrimage, which require facilities and new spaces, persuaded their administrators to seek an extension scheme in order to provide wider open spaces around the shrines, the enlargement of old structure and preparing modern facilities.

The financial abilities of these institutions, which were supported by the religious authority particularly after the revolution, enabled these agencies to manage large scale redevelopment projects. The integration of the shrine with associated functions and surrounding buildings was the prime objective of these redevelopment schemes. However, in practice, the main factors of change were the increasing demand for vehicular access and improving circulation, combined with large scale commercial development. These redevelopment schemes transformed the vast area of the historic urban fabric around these pilgrimage centers.

Although the spatial structure of the area has changed to some extent, it still contains valuable monuments and spaces. There are more than 30 monuments listed by the Cultural Heritage Organization, as well as more unlisted but architecturally significant buildings. Although the area of these historic buildings is less than 8% of the whole area, the traditional design of the district is distinctive.

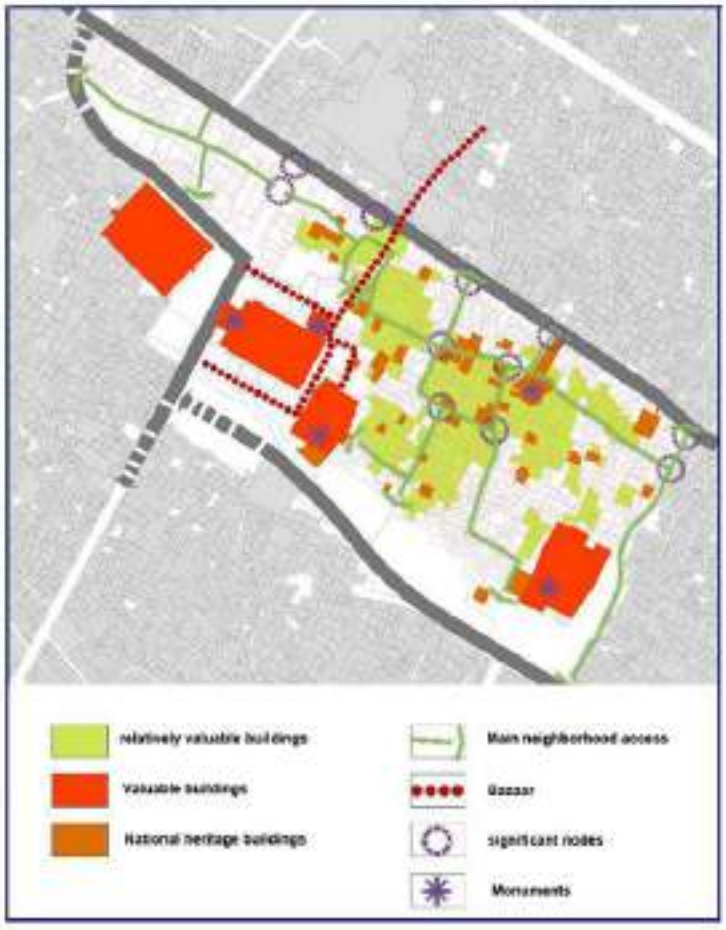

Figure 9. The existing fabric and its valuable and historical buildings in the area
Source: Bavand consultant report, 2010

3.2.2 Design analysis

Revitalization and development project of *Shah-e Cheragh* was designed to compensate the insufficiencies and shortages of religious buildings and their pilgrims and also residents and employees of the area.
The main aims of intervention in this district as mentioned in the report are: the major aim of intervention in this district as mentioned in the report is spatial restructuring of *Shah-e Cheragh* complex with respect to history and religious spaces and monuments in order to equip it into the top tourist pilgrimage destination in the country and region. To achieve this, providing sufficient space for future development of shrines and religious monuments is essential. A central and significant position for the shrine has been defined, the peripheral range around them organized and improved and tourist facilities for hundreds of thousands of annual pilgrims to the shrine has been provided. Solving traffic problems of pedestrian and vehicle traffic and creating proper space for inhabitants and pilgrims to move, stop and rest along transport networks is the other aim of this project.

In order to achieve mentioned aims, some strategies were declared. Green and public transport has been prioritized. Courtyards around shrines and their connection to pedestrian routes were organized. Multi land use spaces along these pedestrian routes were located and appropriate urban furniture in proposed areas were designed for rest and recreation. District development was restructured with participation of private and public investors according to valuable patterns based on sustainable development and urban environment quality.

By considering other functional areas for residents and also the fact that the designed area is a combination of various old neighborhoods which has been separated by later built street, six major routes have been designed to define the main structure of the area. These routes link shrines, pilgrimage facilities, and cultural activities and make corridors for visitors and residents full of experiences and life. They also lead tourist from other neighborhoods and bazaar towards the shrines and cultural centers in the area (figure 17).

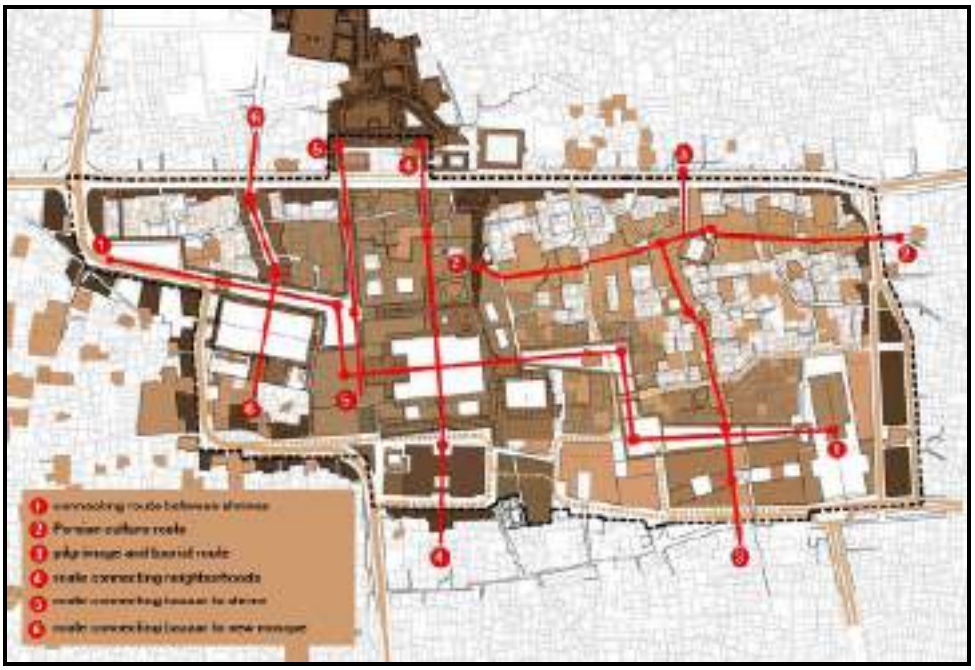

Figure 10. The final urban design of the area focuses on six main axes which connect a number of monuments and buildings and link the area to the rest of the old city (Source: *Bavand* consultant report, 2010).

4. Discussion and Conclusion

The preceding section has identified the features of two different projects in Shiraz city center and explored the driving forces behind them. Although both projects have been driven by a desire to revitalize the historic core and the concerns for the quality of the urban environment, each has followed a different approach, policy and strategy in addressing the issues.

Large-scale interventions in the historic urban fabric have always been associated with the autocratic powers, whether central or local, secular or religious, and traditionalist or modernist. In these projects, a new revitalization program has been formulated based on the lessons learned from previous experiences, which were mostly run by the central government.

There was a shift in attitude and the development of initiatives, in which the local authorities were encouraged to form partnerships and compete for regeneration funds. *Shah Cheragh* project has not been implemented yet but the project for revitalization of *Sang-e Siah* quarter is a prime example of this new approach. Some successful strategies and approaches are as below:

1. Small scale redevelopment of ruined buildings into a centre of local retail units has proved to be the catalyst for the general revival of the area.

2. The new role of the central government influenced by the decentralization policy which the state redistributed the authority, responsibility and financial resources at provincial and local level

3. The strategic and efficient role of the local leadership in building networks of communication and trust among the different actors

4. Careful replacement of new buildings on vacant or broken-down land used to enhance the prestige and importance of monuments and historic buildings Sang- e Siah project is notable for reinforcing and stimulating a gradual process of the historic environment revitalization.

Intervention strategy of this program gave priority to facilitate the gradual rehabilitation of existing residential units, avoiding large scale intervention and focusing on structure and infrastructure of the area. Although the implementing phases of *Shah Cheragh* project are already underway, a gradual strategic plan is neglected, maybe because of the autocratic religious power with enough resources and money. This will cause a comprehensive development in shrine complexes, which may damage the residential area. Concentrating on infrastructure and public space improvement and focusing on cultural activities can be seen as the engine of rehabilitation.
Description and analysis of these two projects introduce some useful approaches towards livable Iranian historical city cores. Despite a number of creative strategies utilized by the local authorities, economic deprivation of inhabitants in the historic core and high rate of mobility of residents prevent public participation in these areas. With description and analysis of more interventions in Iranian historical urban areas, strategies in historical city cores should be introduced and evaluated. Singular successful patterns and strategies should be brought together to build up a framework of strategies of urban design in context of historical Iranian city cores.

BUSINESS NETWORK AND LOCATIONAL MAP OF FASHION AS A CREATIVE INDUSTRY IN IZMIR

Onur Mengi [1], Koray Velibeyoğlu [2]

Abstract

In today's globally competitive environment, the shift towards to the production of culture and creativity, and the presence of a class driving the new knowledge and creative economy becomes essential to the city development. Many scholars have underlined competitiveness as a result of globalization (Begg, 1999; Uzun, 2003; Hall, 2000; Landry, 2003; Kunzmann, 2004). Cities competitive advantages now derive from creativity and innovation based on a blend of their social, economic, political, cultural and environmental assets. For the social assets, a high concentration of the so-called 'creative class' and for the economic assets, tourism, fashion, visual arts, radio/television, publishing firms, toys/entertainment, sports, architecture, design, film/video, advertising, events, television, film, computer games and cultural institutions the so-called 'creative industries' together help to cluster culture, creativity and development.

The city of Izmir illustrates an instance of such intent of clustering the industry around the production and consumption of fashion and textile. This research intends to analyze its business network and locations in the city to understand the ways in how fashion industry are situated in complex webs of economic activity network and agglomeration trends and locational dynamics. The methodology will cover literature review and open-ended interviews. The data is processed in two phases; creating a preliminary chart after the collection of initial data that illustrates certain components and functions, and developing a more detailed locational map indicating the findings from additional interviews.

The overall aim here is to draw current picture of the fashion industry in Izmir. The findings will present a network analysis and map that illustrate locational agglomerations of the industry, and how they cooperate with other interrelated sectors. The paper will also briefly cover the problems and suggestions for the current fashion industry in the city.

1. Introduction

The 1980s were characterized by the cities competing internationally, nationally and at regional levels within the globalization phenomena. Many scholars (Landry, 1995; Begg, 1999; Uzun, 2003) have underlined the rise of new economy which can be named ‘creative’ over the past 20 years. According to this economy, there is a competition between cities through urban restructuring in order to promote themselves for attraction of international attention and gain profit from various investments. For the last mid century, as Gospodini (2007) reported, we have witnessed three shifts of evolving production systems and their influence on urban restructuring and landscape. During the 1950s and 1960s, urban restructuring was based on industrial development and the growth of size and height of the city centers was substantial. Between the 1970s and 1980s when the post-fordist mode of production became visible, new service sectors including management, marketing and engineering consulting, commercial and industrial real estate were emerged. Consequently, urban area became a part of greater global networks. However, through the 1990s, new specialized services, information technology, innovation and design, cultural production and creativity have led a major change in the spatial and social structure of cities. Since then, cities have been shifted and expanded, consequently evolved to a new spatial as well as social organization. This spatial and social organization has been mainly shaped by the concepts of creative class and the creative industries.

The new type of spatial and social organization in a competitive environment has led the emergence of the creative cities and the rise of the creative class with the aim of promoting specific values, attracting international investment and showing up on the global scene as being ‘creative’. In previous researches, it has been found that the economic viability of a place depends on its ability to attract creative people and render a creative class, and these people prefer places which are innovative, diverse and tolerant. In addition to that, locational, cultural and political preferences of the creative class greatly differ from those of scientists, engineers, managers and lawyers. It is assumed that the group of creative people in a city prefers to be in certain urban spaces which reflect their particular interests and wants (Florida, 2002; Kim and Short, 1999). Then, how does this affect the industry and its spatial organization and locational dynamics?

Particularly, fashion industry has been chosen from the given creative industries for this study. Regarding, the case study looks at the city of Izmir, since its future development is also planned around the production and consumption of fashion and textile. Then, how does fashion industry operate now in Izmir province? This qualitative research aims at drawing its business network and locational organization as well as bringing out the problems and suggestions. The data for business network is processed using components involved in the network and considering some actors with their major and minor roles, and their connections in creating such business network. Second, the data for its locational characteristics are visualized.

This paper consists of the following sections; the second section begins with discussing how creativity is defined in general and why we talk about creativity in relation to cities. Then, it carries on with defining and understanding the concept of the creative class and the creative industries, and their more recent interpretations in the related literature. The third section portrays a case study giving general description of fashion industry in Izmir, and then goes into the details for its organization specific to the city and, problems and suggestions accordingly with the literature review and results of the interviews. This will also include the business network chart and the current picture-locational map for the fashion industry in Izmir province. In the last section, implications for the city regarding its organizational and spatial configurations within such business environment are presented.

2. The Creative Class and the Creative Industries

The shift towards the production of culture and creative products and the presence of a class leading the new knowledge and creative economy associates with the emergence of the creative city and the concepts of 'creative class' and 'creative industries. This section aims to elaborate the definitions for these concepts. Before start, the general meaning of creativity will be discussed, especially in relation to cities.

2.1 Creativity and the City

Landry and Bianchini (1995) claims that much of the literature makes use of the etymological base of creativity, seeing it as about bringing something into existence, generating, inventing, dealing imaginatively with problems. Creativity is not solely about something new, but also involves opening ourselves out to the ideas, influences and resources that are all around us. In addition, Kunzmann (2006) defines creativity as originality, capability to develop new projects, procedures or approaches, visionary power, willingness and readiness to experiment and to take risks, mental and cognitive flexibility and multi-dimensional thinking. Moreover, Higgins and Morgan (2000) employ the meaning of creativity as an ability to relate or combine knowledge in a new way which is of some practical use or adds value. Why do we to talk about creativity in relation to cities then?

Despite the fact that old industries have faded away as the industries of the 21th century initiated the applications of new knowledge to products, processes and services, the case is not only for our century, but also throughout the history. For instance, as Hall (1998) stated, cities have tied together their technological, organizational, productive, intellectual and cultural innovations for many years. Also Charles Landry refers to history that creativity has always been significant contributor for cities that it is needed to work as markets, trading and production centers, with the entrepreneurs, artists, intellectuals, students, administrators and power-brokers. Besides, his work together with Bianchini (1995) states that "whereas the dominant industries of the nineteenth and twentieth century's depended on materials and industry, science and technology, the industries the twenty first century will depend increasingly on the generation of knowledge through creativity and

innovation" (Landry & Bianchini, 1995: pp.2). On the other hand, for Higgins and Morgan (2000), creativity in relation city and its planning, is not an end in itself, rather a means which can lead to development. Creativity in relation to the urban context is an integrated process including social, economic, political, cultural and environmental assets that together cover every aspect of urban living. In this respect, Florida (2002) suggests that the economic success of a city is determined by the attraction of the 'creative class'. Florida (2005) has found that the creativity is the most important commodity in our economy, and thus the economic health of a place depends on its ability to attract creative people and render a creative class. In his interpretation, the creativity can be achieved in a city where the presence of the creative class is highest.

2.2 The Creative Class

The notions of creative talent and creative class that lead urban economic development have been studied by Richard Florida. Florida (2002) claims that the urban economy of the 21st century is driven by the location choices of creative people who prefer appealing place that is rich in cultural diversity. He emphasizes a social structure comprising new systems for technological creativity, innovation and entrepreneurship, and new models for producing goods and services. Florida (2002) suggests that the heterogeneity in cosmopolitan cities is the spine of creativity and innovations He defines the creative class as those who creates new ideas, new technology, and new creative content.

According to him, the workers who invent and create new products, who apply knowledge, who invent brands and designs associated with new life styles and commodities are integral part of the creative cities. These creative workers are called the creative class. This class is not necessarily highly educated but considerably engaged in creative, innovative jobs. The creative class does not only include writers, designers, musicians, painters and artists, but also scientists, managers and people in computer, engineering, education, healthcare, legal and financial occupations (Florida, 2002, pp.328-329). Florida asserts that "creative people power urban and regional economic growth, and these people prefer places that are innovative, diverse and tolerant" (Florida, 2005, pp.34). What Kim and Short (1999) have found from their empirical research on the impact of creative artists on urban growth, is that the locational, cultural and political preferences of artists, a key component of Florida's creative class, differ greatly from those of scientists, engineers, managers and lawyers.

Cities are now in search for the presence of arts, creativity and culture and they intend to provide a diverse and tolerant urban environment in order to attract the creative class and to foster the certain-mainly creative- industries for their future spatial and economic developments. Again in the literature, industries indicating creative essence are increasingly highlighted as an important contributor to the degree as much as they contain creative class.

2.3 The Creative Industries

The creative industries encompass a broader range of activities that indicates knowledge and information, and all the cultural or artistic production. These activities in different industry categories are largely based on the capabilities of creative workers, a substantial realization of artistic or creative endeavors. The value of output in the creative industries depends on the creative production means of individuals and the sort of organizations that they are associated.

The original conception of creative industries was developed by the Department of Culture, Media and Sport in the United Kingdom in the late 1990s. The department describes the creative industries as "those industries which have their origin in individual creativity, skill and talent and which have a potential for wealth and job creation through the generation and exploitation of intellectual property" (DCMS, 2001, pp.4). This contains twelve creative sectors in their 2006 documentation; Advertising, Architecture, Arts and antique markets, Crafts, Design (Communication Design), Designer Fashion, Film, video and photography, Software, Computer Games and Electronic Publishing, Music and the Visual and Performing Arts, Publishing, Television and Radio. As stated previous sections, these industries provide a basis for being creative and innovative as one of the powerful competitive advantages in the globalizing world to race with other cities and even countries, especially since many urban places now appears the same (Landry, 2003).

The contribution of creative works and creative industries is considerable to cities and countries (Hall, 2000). Kunzmann (2004) intends to prove that through some statistical facts of the UK's particular creative economic development for the last decade. Through art, culture and innovation, the creative industries do not only support the economic development, but also provide a social base for intellectual capital and creativity via employing the creative workers. This base is realized through agglomerations of small businesses, self-employing and artist-hiring employers in media, advertising and arts and entertainment industries. On the other hand, Evans et al. (2006) state the importance of creative industries for place quality, creative thinking, and construction of urban identity, and they are one of indicator of the creative city formula (Durmaz et al., 2008). Such cities are driven by strong innovation, knowledge and culture-indicated activities as well as by the creative class and art organizations. The creative industries render a positive image for cities and bring livability and quality to urban life.

Scott (2000) has conducted a research on Los Angeles and Paris and mainly found out that that creative industries flourish where three conditions are met: first, multiple interdependency and agglomerations of competitive firms; second, regional policy enterprises that attract and retain these industries and consider their locational preferences; and, last, the industries should reflect and capitalize their status and distinction of their urban locations (Scott, 2000).

3. Case Study: Fashion Industry and the City of Izmir

No doubt that the creative industries appear as an important component of post-industrial creative economy and a considerable incubator for urban development. Despite a growing attention on creative sectors for policy makers, practitioners and academics for the last decades and their awareness in this fact, some localities are still unconvinced of the importance of supporting growth of any of these sectors. Nevertheless, an increasing number of governments have recognized the significance of creative industries and started to develop specific goals to encourage them.

Izmir province, located on the west coast of country by the Aegean Sea and according to the Turkish Statistical Institute census record for 2010 with population of 3.9 million recently, has been familiar with the term creative industries. Throughout the past years, the city of Izmir fell behind in the global inter-urban competition and began to lose its appeal among the other Mediterranean cities. Consequently, Izmir Metropolitan Municipality collaborating with the representative from different sectors and universities determined to gain its previous reputation and envisioned a creativity-based development to overcome this deficit. To this end, the city of Izmir is now in the progress of constructing a new path for its future progress. Various design industries and their related key actors appear in the center of such path. Latest improvements in this regard came into sight as a design forum. Izmir Design Forum that organized collaboration with the Izmir Metropolitan Municipality in 2011 brought creative sectors and their representatives for the future goals of the city on the way to being creative. This aspiration brings the fashion sector in attention.

An examination of the Izmir fashion industry reveals some path dependent development so far. Hence, the following sub-sections will present some very limited literature and the interviews conducted as a pilot study to investigate how fashion industry operates now in Izmir.

3.1 Fashion and Textile Review

Since globalization brings inter-urban competition and advances in technology today, fashion design with its supporting components has become a sector that draws new and more investments and an industry that grows rapidly (MUSIAD, 2009). Similar to a research conducted by Antwerp Management School (2011) in Flanders-Brussels which presents creative industries, in general, operate within supporting creative components, facilitators and peripheral organizations, and actors from other sectors, Enlil et al. (2011) categorizes the fashion design industry mainly consisting of three areas; main activities, related activities and cooperated activities. The main activities cover clothing design, preparation of collections and seeking advice for textile companies. Second, the textile and ready-to-wear industries and retailing are considered as related activities. Third, for the cooperated activities, design education, graphic design, fashion photography, hairstyling-cosmetics, modeling and magazine publications, and accessory and perfume design are considerably supportive for the fashion industry. On the other hand, the relationship between the fashion design, and

the textile and ready-to-wear manufacture has been vital since growing global competition obliges textile and ready-to-wear sectors concentrate on design than ever before. The textile sector now encompasses 28% the country's industrial employment (Enlil et al, 2011).

Specific to Izmir, textile sector covers 9,8% of the total employment in Turkey (IZKA, 2010). Textile industry is the third most demanded sector with 732.012.937 USD export share (8,85% of the total export in the district, % 6,13 of the total export in the country) and has the second largest employment range in Izmir (IZKA, 2009; IZKA 2010). According to IZKA (2009) research report prepared for Izmir province, there are 12.603 people employed in the textile sector in Konak (6,32% of the total employment in the district) 10.443 people in Bornova (8,8%), 1.657 people in Karsiyaka (3,49%), 4,160 people in Cigli (10,60%), 7.458 people in Gaziemir (23,05%) 638 people in Torbali (2,21%) and 2,384 people in Buca (8,44%) by the year 2008. For the recent years, there has been a growth around the city center in terms of clustering textile sector. Despite the accumulation of the textile in Cigli has decreased, it has raised up in Buca, Gaziemir, Konak and Bornova (Figure 1).

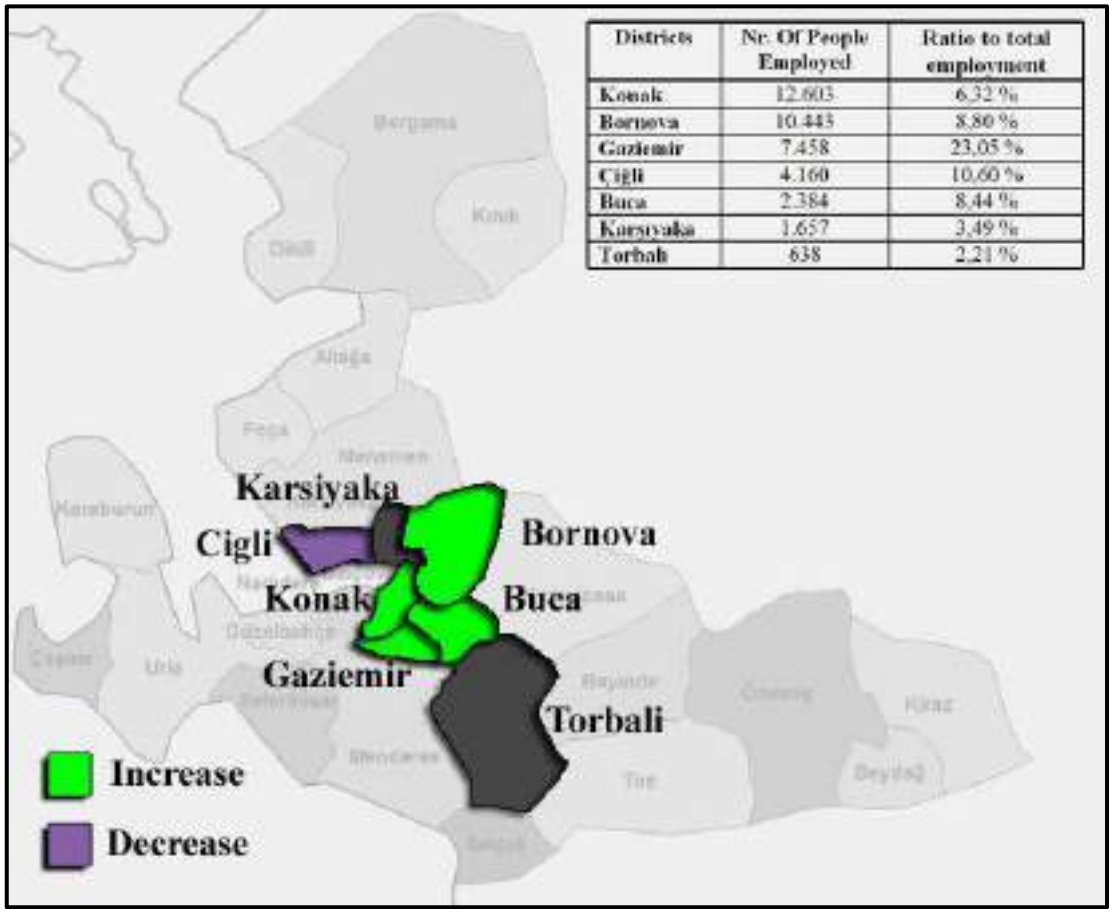

Figure 1. Izmir Province Textile Sector-Intense Districts Employment in 2008 and Accumulation Change between 2004-2008
(Adapted by the author, Source: IZKA 2010)

Particularly in Izmir, the fashion sector is mainly based on manufacturing, textile outsourcing and wedding industry and that one hand provides a greater flexibility in the overall production network, lower investment, and a chance to switch production according to varying market conditions, but on the other, stays very limited and weak in terms of appearing in the international fashion network, attracting global investment and branding the city. For the wedding industry products, Izmir leads the Turkish market (IZKA, 2010). According to IZKA research report (2010), this sector has been found sufficient in terms of its production capacity, human resources, financial resources and information and knowledge web. Yet, it is unsatisfactory for international trade and marketing. It is also insufficient regarding fashion design implications on their products range. However, recently Izmir has started to more focus on these weaknesses. There has been a rise in number of national and international fashion events. Fashion Weeks and Weddings Fairs have been organized for few years. IF Wedding Fair has been held for six years and every year almost 1000 fashion firms participate to be seen internationally (IZKA, 2010). This event brings designers, models, agencies, photographers, celebrities, fashion magazines, retail buyers, stylists, venture capitalists, media and advertisers together. Fashion fairs make known and attach importance to the production networks of fashion industry. Also Izmir University of Economics and Dokuz Eylul University with their Fashion Design Departments located in Izmir and some private design programs courage that process. Their ties with the fashion practice are considerably strong.

3.2 Interviews

The design of this research is based on the open-ended interviews through snowball sampling with the information-rich academic members of the Fashion Design Department in Izmir University of Economics. Snowball sampling method (Atkinson and Flint, 2001; Biernacki and Waldorf, 1982) has been conducted to identify key players in the field, product, manufacturing processes, and other interrelated actors and sectors, since the department academic members are considerably involved in the fashion design practice of the city. Snowball has applied here to use one contact to help us recruit another contact, who in touch with someone else. However, the research content for this study has been kept limited to the academic members. Other key player and interrelated actor contacts discovered in this research, namely a set of potential contacts, will be interviewed in the further studies (Table.1). The Fashion Design Department has been regarded as a primary source to us to know the sector, especially the key players, creative workers, organizations and associations as well as their locations.

In addition to that, many of those members we have interviewed took roles as representatives in Izmir Design Forum 2011, where architecture, fashion, communication and industrial design, film and photography, the visual and performing arts, as well as publishing sectors came together for the future goals of the city with respect to the creative industries including particularly the fashion industry.

Table 1. Snowball Sampling Stages

The interviews also cover some hints from the outcomes of the forum. The preliminary results gained from the interviews have been grouped as the following statements;

Problems

- Izmir has a potential, consciousness and demand, despite, still it is not a competitive city
- Fashion industry wants to be visible within the city
- Wedding as a sub-industry carries a considerable importance yet it is neither well-organized nor well-formulated in terms of its regulation
- The clusters and the organization of stages for the value chain in fashion industry is limited and old-fashioned
- Izmir lacks of "identity" (for ex. Florence is known as men's wear capital and Bologna is labeled as shoe design quarter)

- There is no art direction and a lack of people with in-depth knowledge in art and design involve in the production of fashion in Izmir.
- There is a lack of agency dealing with the fashion industry's relation with the other sectors
- What we call fashion in Izmir is based on outsourcing. After having learnt the process and designs from the leading producers, companies and firms start to develop its own brands yet they do not employ any fashion designers or styling and photography experts for business.

Suggestions

- Fashion industry is more than textile and manufacturing, that should be empowered and re-envisioned in Izmir
- Fashion industry should work with the production companies/agencies that offer locating, planning, transportation, crew, models, digital equipments, styling and photography production
- Besides agencies, fashion shows, fairs, retailing and media should be involved in fashion production and consumption
- Production, retailing and education with sectoral power should be brought together
- Wedding industry should be supported, improved and promoted
- There should be a supply platform to meet demands of the fashion design potential in Izmir
- There is a need for a commission to manage and organize the industry and its supply
- Fashion sector should be interactive with the supporting sectors and cooperated activities namely with other creative industries
- Creative workers, fashion designers should be encouraged to work in Izmir, not in Istanbul

Apart from the current state of the industry in Izmir, preliminary literature review on fashion and textile in Izmir, and interviews based on experiences in the industry and Izmir Design Forum have eventually enabled us to draw the business network and locations of the industry.

3.3 Business Network and Locational Map

The fashion design sector offers a value chain including various steps of creation, production, distribution, to consumption steps (Table 2). In a highly competitive market, many other outsourcing countries threat the textile sector in Turkey so that there has been a shift towards more design based creative production and improving the quality of what is produced (Table 3).

Table 2. A Typical Fashion Industry Value Chain

Stages	Planning & Development of Collection	Design & Prototyping of Models	Production, Design, Planning and Monitoring	Manufacture & Assembly	Marketing	Distribution and Logistics	Point-of-sale Marketing	Sales
Steps	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**

Thus, the textile and ready-to-wear manufacturing processes are now highly involved in the fashion design. This is also expected for Izmir according to the interviews. Eventually these sectors will start to chase global trends, promote cultural aspects and to develop brands besides a mere production and manufacturing. That will enable the fashion design sector take a crucial role in the process.

Table 3. New Type of Production Structure in Fashion (Source: MUSIAD, 2008)

Stages	**Old Type**	**New Type**
Production	Mass Production and Bigger Capacity	Customized, Faster
Design	Outsourcing	Still Outsourcing but advanced with some contributions and Own Designs
Marketing	Passive Marketing	Active Marketing
Branding	Outsourced Products	Own Brands

Specific to Izmir, there are basically five non-governmental organizations in Izmir (NGO) namely Aegean Region Chamber of Industry, Aegean Exporters' Unions, Aegean Clothing Manufacturers' Association, Association of Aegean Leather and Leather Products, Izmir Chamber of Commerce and Izmir Development Agency. There is no other professional association of which covers managing the fashion design, textile and manufacturing. This absence is one of the reported inadequacies with the industry. However, Izmir fashion industry together with textile sector illustrates a different picture (Figure 2). According to the Aegean Region Chamber of Industry data, for the Aegean Region where Izmir is located, there are 904 textile firms and 45113 workers registered in the Aegean Region Chamber of Industry. In recent years, Izmir has become synonymous with fashion, increased profits and opportunities for apparel manufactures focusing exclusively on wedding dress design, accessory and outsourcing for ready-to-wear.

Additionally, the fashion industry operates with different components; fashion photography, modeling agencies, fashion designers, retailing (boutiques and franchise), accessory (mainly zip and footwear), ready-to-wear, manufacturers (factories), magazine and media.

Figure 2. Izmir Current Fashion Industry Network

Many of the previous researches on the subject discussed the power of specialized industry built-ups in specific localities and clusters since the signifiers of new economy are found in fashion precincts that generally clustered in cheap inner-city rental space. Though having such a network including main activities (ex. clothing design, wedding industry), related activities (ex. textile and ready-to-wear) and cooperated activities (ex. events and fashion education) of the fashion industry, there are hardly formed a complete "fashion district" in Izmir. Spatially, Izmir has rather wedding based firms and clusters, as well as outsourcing and manufacturing based organized zones (Figure 3). The Chamber of Industry claims that the fashion together with textile manufacturers appears as the most important industry in the Aegean Region. In terms of clustering in certain locations of Izmir, there are 28 firms in AOSB Industrial Zone and 42 firms in ESBAS Free Zone according to the records of the Izmir Development Agency (Source: http://www.izmirkumelenme.org/).

In a locational analysis of the sector in Izmir province, Cankaya (Mimar Kemalettin Street) and Kemeralti Bazaar are places to the low profile and generally copied design fashion industry, and also excessively wedding dress. Comparatively, Alsancak spatially serves for higher profile boutiques and fashion design stores which are yet clustered. Alsancak is also a place to the trade chambers and associations as well as some fashion-related sectors' (supporting activities) agencies.

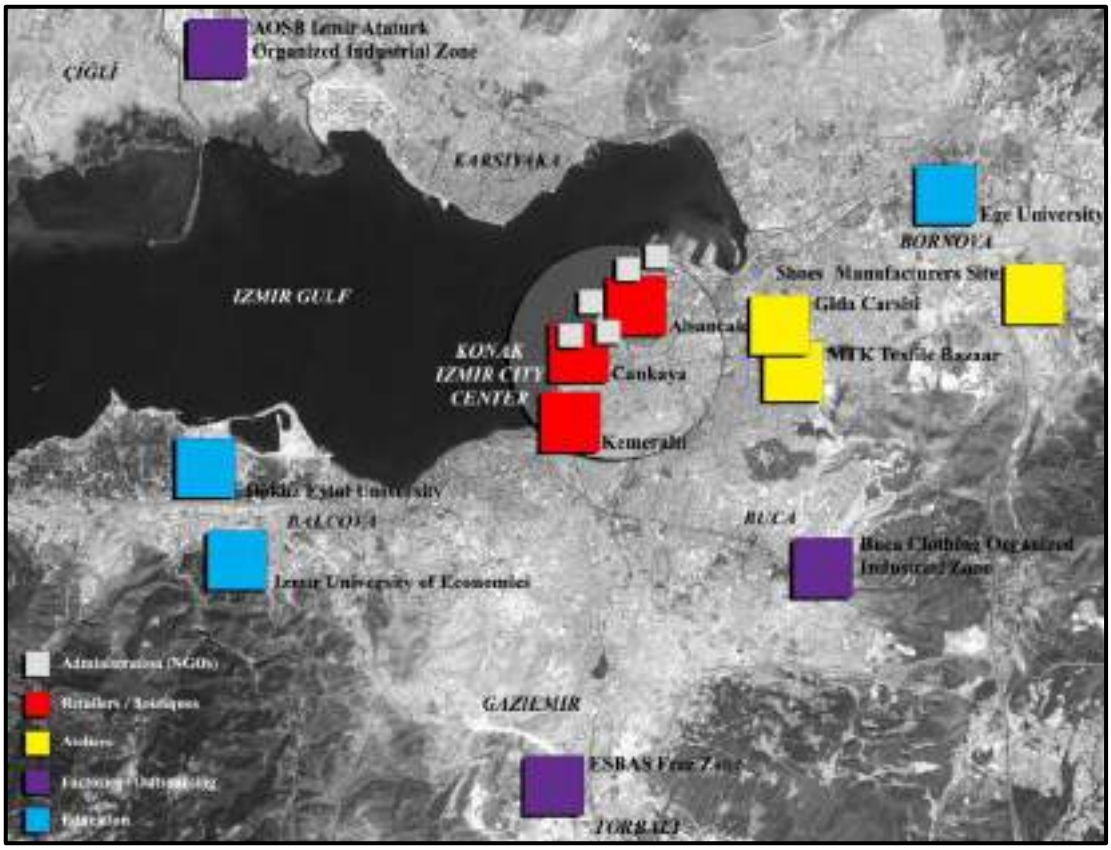

Figure 3. Location of Fashion Industry in Izmir Province
(Drawing by the author on the image from Google Earth)

Throughout the peripheries of the city, there are some manufacturing-based industrial sites; namely MTK Textile Bazaar, Shoes Manufacturers Site, ESBAS Free Zone, AOSB Izmir Ataturk Organized Industrial Zone, and Buca Clothing Organized Industrial Zone. For the education aspect, Balc”ova on the west axis of the city is where Izmir University of Economics and Dokuz Eylul University fashion design departments are stand out. Furthermore, Ege University the department of Textile Engineering is located on the east axis.

4. Implications for Izmir Fashion Industry and Its Future Development

Many governments in the world now see the creative industries as principal drivers of their future development and economic success. As globalization has diffused, the fashion industry has been identified increasingly as leverage in order to create economic and cultural values for the city. Regarding, in Izmir, some creative industries, particularly fashion, have been tried to be harnessed to governmental aspirations to appear on the global scene, at least to compete with other cities outside the region and reinvent the city as a fashion capital. Fashion as a creative industry is now closely associated with the production of consumption spaces, the development of urban characteristics and uniqueness, as well as city branding.

The present study is a pilot research and illustrates very preliminary findings. Looking at the picture, Izmir's current "fashion related" business operates through export-led, outsourcing manufacturing and textile. For the network evaluation, the fashion industry operates through a complex yet very weak and unconnected pattern of networking including following components; fashion photography, modeling agencies, fashion designers, retailing (boutiques and franchise), accessory (mainly zip and footwear), ready-to-wear, manufacturers (factories), magazine and media. For the locational evaluation, certain points in the centre of the city and the peripheries especially industrial zones and free zones appear as major spots, but none of these acts as serving pieces of the whole fashion industry. Rather, they are mainly divided into ready-to-wear, accessory and wedding industry concentrations. Despite its potential to serve as a creative industry to city where creative class can both live and work, the fashion design industry is still not well-planned or organized in Izmir province. Just for few years, national and international fashion events have started to be held, and there has been attempts to shift towards more design based creative production and improvement of the fashion industry. This shift should be extended to an opportunity to retain creative class, interact with other relevant creative sectors, and to learn about the latest trend as well as develop national and international connections as a creative city.

Organizational

The industry is governed by the Aegean Region Chamber of Industry, Aegean Exporters' Unions, Aegean Clothing Manufacturers' Association, Association of Aegean Leather and Leather Products, Izmir Chamber of Commerce and Izmir Development Agency. With respect to the interviews, fashion industry in terms of its clusters and the organization of stages for the value chain is limited and old-fashioned in Izmir. There is not a strong identity for the industry. However, there are some signs of the three components of the fashion industry; main activities (ex. clothing design, wedding industry), related activities (ex. textile and ready-to-wear) and cooperated activities (ex. events and fashion education). The workers in the sector are hardly called creative class who design and develop new products, use knowledge and skills to invent brands and new life styles. While companies and firms develop their own brands they do not entail and employ any knowledgeable fashion designers or stylist collaborating with photographers and magazines. There are problems with managing and organizing the whole fashion industry and its supply since a leading commission is absent. In addition to that, there is also a steering agency problem that dealing with industry's relation to the related sectors.

However, the findings from the interviews show that the fashion industry is more than textile and manufacturing, should be empowered and re-envisioned in Izmir. Thus, the production companies that offer locating, planning, transportation, crew, models, digital equipments, styling and photography production should be involved in the process. In other words, fashion industry is expected to collaborate with the other creative industries. As well as, fashion designers should be encouraged to take role in the fashion industry in Izmir. Also, fashion shows, fairs, retailing, media, education and education should be brought together. Specifically, wedding industry

carries a considerable importance to the city's creative potential. Last but not the least, except the recent efforts in Izmir Design Forum, our research has illustrated that Izmir lacks of a comprehensive public policy, a team work or a full-bodied robust network for the improvement of fashion as a creative industry. Considering the creative industries and creative city concepts, the focus is to be on creative workers as individuals and independent workers, besides, team working, networking, and cooperation should be promoted. These are known as integral to the clustering of particular types of creative sectors in specific geographical locations.

Spatial

For business characteristics and locations, certain points in the centre of the city and peripheries especially industrial zones and free zones stand out. According to this analysis, Cankaya (Mimar Kemalettin Street) and Kemeralti Bazaar are the areas in where mainly wedding industry and the copied design fashion, Industrial Zones in where textile and manufacturing as well as accessory production are concentrated. Most of the textile and manufacturing companies reduce their production costs by locating in the organized industry zones and free zones. Also, some, but not clustered, boutiques and fashion design stores and administrative chambers and associations are located in the prestigious spots in Alsancak.

All in all, the fashion design in Izmir has seen promising as an industry that can do more than manufacturing and outsourcing. Our findings have illustrated that firm clusters, inter-firm networks and linkages, and relationships with the supporting creative activities and consumers have been reported as inadequate and unorganized. Such findings, we believe, are significant, and appear as reasons not to create and develop clusters, and most importantly not to compete with Istanbul as well as other fashion design-led city developments around the world. Clusters are seen to be vital for innovation, productivity growth, comparative advantage and international competitiveness. They also become important since that fashion designers and the creative workers in the network want to be in physical proximity to each other as well as to textile retailers and other relevant actors in order to construct strong, face-to-face relationships. More generally, our work has brought some important clues into the determinants of successful business network of fashion industry in the city. What has become apparent is that the fashion industry is not well-clustered, creative workers are not present. However, fashion design would actually enable regional development in the form of clusters and incubators via identity building. In addition to that, this development would indicate young and marginalized groups, namely latent creative workers dealing with innovative and creative work.

This research can be furthered with the investigation of key player and interrelated actor contacts discovered in this research, namely a set of potential contacts acting in the network of Izmir fashion industry and their spatial expectations from the city. Such in-depth research would generate substantial awareness and foster collaboration with a range of creative workers that can later influence the city's future precinct development policy. Eventually, this merges a base for urban planning and design in

imagining and creating new spaces such as creative cities, clusters, and globally and socially connected cities, regions or neighborhoods.

EVENT-LED REGENERATION: SUSTAINABLE DEVELOPMENT AND STAKEHOLDER DECISION-MAKING IN LONDON 2012 OLYMPIC GAMES

Ozlem Edizel[1]

Abstract

Appealing to politicians and other interests, the hosting of mega-events as a competitive city strategy is a controversial topic since there are several environmental, social, economic and urban risks involved. Nonetheless, there is a widespread trend towards the use of mega-events to promote a city, stimulate the local economy and regenerate rundown post-industrial areas and communities. City governments thus develop event-based strategies in order to increase city attractiveness and (re)position themselves in the regional and world city hierarchy. However, a set of questions arise about how to regulate pro-growth strategies within sustainable urban development imperatives. The success of mega-event led regeneration lies in a more inclusive approach which considers the cultural values of the 'local'. In practice however, many cities bidding for mega-events do not adopt or consider this approach and limit their efforts to the event site, external visitors and to short term branding exercise. By the nature of competitive bidding, most aspiring cities are of course unsuccessful (and some re-bid again and again). This study examines the contradictions between sustainable development and competitive city agendas through a study of mega-event led regeneration and explore the changing landscape and communities resulting from mega-event led regeneration. Regeneration in the Lower Lea Valley where the London 2012 Olympic Games will be staged is analysed as a case study area.

Research methods include document analysis, semi-structured interviews with the stakeholders in the planning and organization of London 2012 and observations. The primary research analysis provides a sound base from which the planning of more sustainable major events can be undertaken in the future and the evaluation of their impact more fully measured across a wider stakeholder community.

1. Introduction

In many respects, regeneration has become a major element and driver of urban policy since the late 1970s. In a broader sense, urban regeneration is considered as a dynamic process of physical, social, environmental and economic transition. It is a normative process where policy makers and others agree on what an urban area should look like, how it should 'perform' and the practical process whereby visions for these places come into action (Raco & Tunney 2010).

The aim and emphasis of urban regeneration projects has changed in different periods. From the 1980s, there has been a shift in urban governance system from a managerial to an entrepreneurial structure which means that urban governance has started to adopt

[1] Cities Institute, London Metropolitan University, London, UK - o.edizel@londonmet.ac.uk

entrepreneurial strategies such as new ways to foster and encourage local development and employment growth; instead of the managerial practices of earlier decades which focused on the local provision of services, facilities and benefits to urban populations (Harvey 1989, p.3) . Therefore, boosterist policies as the main feature of urban entrepreneurialism have started to gain more attention from city and central governments as a result of globalisation and the imperative for place competitiveness. Peck (2005) suggests that regeneration projects have an important role in urban development since policy-makers develop various strategies in order to increase city attractiveness, (re)position their cities in the regional and world city hierarchy and also, provide new gentrified work, leisure and housing for the 'professional managerial'(B. Ehrenreich & J. Ehrenreich 1979) and the more recently identified 'creative' class (Florida 2005). Cities have consequently started to expand their marketing policies (Ward 1998) to create and change their image to attract more tourists, businesses, inward investment and service industry workers.

On the other hand, sustainable development principles and sustainable community planning and aspirations have become core components of urban regeneration policies since the beginning of the 2000s. Since UNCED (1992), more than 2,000 local governments have implemented Local Agenda 21 (LA21) Plans indicating that the sustainability agenda has started to be taken seriously at the local level because at local level it is easier for governments to integrate economic, social and environmental professions so as to facilitate sustainable policy developments (Newman & Kenworthy 1999). It is now obvious that sustainable development is not only an environmental concern, but it also has economic, social and governance (and cultural) dimensions (Dalal-Clayton & Bass 2002; Hershgal 2008).

In the UK, the holistic approach to regeneration inferred by the term 'sustainable' fits in the 'agendas of inclusiveness, multiagency partnerships, and the shift from government to governance' (Jones & Watkins 1996, p.1416). Deindustrialisation has left considerable vacant, derelict, brownfield and waterfront areas where there are numerous development challenges and opportunities (DCLG 2008). However, in the 1970-80s, powerful, localist quango agencies applied 'fast-track' initiatives to make sure that property-led regeneration projects were delivered in designated sites with minimum local opposition and involvement (Cochrane 2007; Raco & Tunney 2010). Without this local democratic planning process, Urban Development Corporations (UDCs) were able to focus on converting these spaces into highly visible regeneration areas (Raco & Tunney 2010). By the early 2000s, the tension between sustainability and development is highlighted in national and international documents and policies. During the International Conference on Financing for Development in 2002, world leaders agreed to mobilise and increase the effective use of financial resources and achieve economic conditions for poverty reduction and sustained economic growth. Also, Tony Blair suggested that 'development, growth, and prosperity need not and should not be in conflict with sustainability' in Securing for the Future Report (DEFRA 2005). The report suggests that it is important to maintain a more competitive economy, to compete internationally and also, build a sustainable community which is possible by improving the knowledge and skills base of everyone.

In order to strike a balance between competitiveness polices and sustainable development, stakeholder partnership and community involvement are considered to be the two main components of sustainable urban regeneration. Among different types of urban

regeneration models such as property-led, retail-led, housing-led and design-led regeneration; event-led regeneration has had a greater economic, tourism, physical and socio-cultural impact and meaning (e.g. self image, identity) for host cities when compared to their relatively short duration (Ritchie 1984). According to Harvey (1989), when some events are used as a tool for urban regeneration, they give the host city the opportunity to produce a new and entrepreneurial image, internally and to external audiences. In this frame, mega-events being normally one-off, high profile festivals, sports competitions or trade fairs held for a limited time in which the built environment has global and symbolic significance and attract national and international interest - investors, media, tourists (Getz 1997; Ritchie 1984; Roche 2000) have distinctively bigger impact on urban regeneration and related governance policies.

In the context of mega-event based regeneration, Getz (2009, p.65) suggests that multiple stakeholder perspectives are essential when analysing the outcomes of such events and all stakeholders have to be in consensus in order to deliver sustainable events. In order to understand how event policies are realised, it is important to know how different actors are involved and interact (Hall & Rusher 2004). Accordingly, a set of questions arise about how to regulate pro-growth strategies within sustainable urban development imperatives. Sustainable events are arguably the ones that can fulfil crucial social, cultural, economic and environmental roles that people value (Getz 2009). However, an important deficiency has emerged - as cities try to adapt the same strategies for their social, environmental and economic regeneration, irrespective of each city and region's cultural assets, architectural capital, political organizational and economic structure. This study examines the contradictions between sustainable development and competitive city agendas through a study of mega-event led regeneration and explore the changing landscape and communities resulting from mega-event led regeneration. Stakeholder decision-making structure in the regeneration of the Lower Lea Valley where the London 2012 Olympic Games will be staged is analysed as a case study area.

2. Conceptual Framework

Broader research methodology adopts an integrative approach in which built environment, social structure and stakeholder organizations are studied together. In order analyse sustainable development in any regeneration project, it is important to understand the relation of these three components with each other. The research uses multiple theoretical perspectives, sources of data and methodologies to analyse cases. Changes in built environment, social structure and stakeholder organization are analysed in connection with each other, not as single units. Each aspect is evaluated accordingly with the changes in others to understand the complex structure of the regeneration in the area in a holistic way. While analysing the relation between organisation structure and community, participation between two bodies is considered as the main element. Inclusion of local and cultural values on the changes in the built environment and the extent local communities are involved in regeneration decisions are one of the sustainable development factors in a regeneration project. Finally, the effect of stakeholder decision-making strategies on built environment and different regeneration policies are analysed through stakeholder interviews and document analysis which is the focus of this paper. (See the Figure 1).

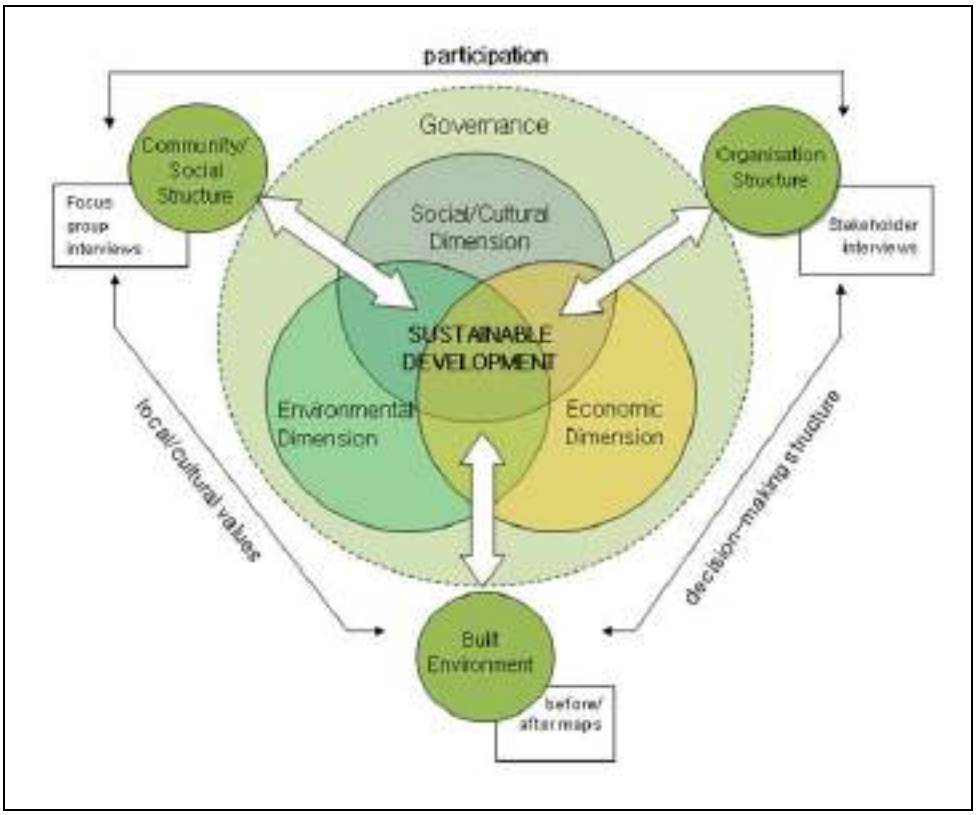

Figure 1. Conceptual Framework (Work-in-progress)

3. Case Study: London 2012 Regeneration Games

The Olympic Park is located within the Lower Lea Valley, in the Boroughs of Newham, Hackney, Tower Hamlets and Waltham Forest. It is situated around the River Lea, bordered by the A12 in the north and Stratford High Street in the south (See Figure 2). The Park is primarily situated on contaminated and derelict land. Much of the land is fragmented and divided by waterways, sewers, overhead pylons, roads and rail lines.

The area is also home to some of the most deprived communities in the country. According to the English Indices of Deprivation 2010, three of the Host Boroughs still contain the sixth, seventh and the fourteenth most deprived wards in the country respectively Hackney, Tower Hamlets and Newham[2]. East London also experiences significant levels of unemployment roughly twice the English average: with Hackney 16.4 per cent, Newham 13.5 per cent, and Tower Hamlets at 11.8 per cent[3]. The area has one of the highest levels of black and ethnic minority populations in the capital.

From 2012, the area will be providing valuable resources to local communities and visitors. The Olympic Village will accommodate 17,000 athletes and officials during the Games. After

[2] http://www.communities.gov.uk/documents/statistics/pdf/1871208.pdf

[3] London Divided Income inequality and poverty in the capital, 2002: static.london.gov.uk/mayor/economy/docs/london_divided_all.rtf

the Games, it will leave the legacy of around 2.800 new homes, parks, and community facilities which will form the first phase of a far wider regeneration and development of the whole Olympic Park. Five new neighbourhoods will be established around the Park, each with its own distinct character which will involve up to 11,000 new homes where 35% will be affordable and 40% will be family homes[4]. This regeneration will be supported by new schools, infrastructure, roads, transport, and community and health facilities in the local area.

Figure 2. London 2012 Olympic Park Map in year 2012

4. Methodology

Semi-structured interviews are conducted with the decision-making stakeholders of London 2012 Olympic Games as a research methodology. Interview questions are directed towards understanding plans undertaken to develop the mega-event strategy, the response to the mega-event led regeneration, reasons behind decisions made, expectations from regeneration, relationships with other stakeholders and opinions about public participation. Before deciding on the interview questions and questionnaires, research indicators are determined and related

[4] London Legacy Development Corporation: http://www.londonlegacy.co.uk/the-park/homes/

questions are decided to reach the information about the indicators. Determined indicators are as follows: changes in organization structure led by mega-event, organization structure of the mega-event, leadership, representativeness, conflict resolution, success factors, legacy and lessons learned, changing community structure, mega-event as a catalyst for social, economic and physical regeneration and public participation. Interview questions are also considered in relation to the Meta-Evaluation of the Impacts and Legacy of the London 2012 Olympic Games and Paralympic Games study and necessary adjustments applied.

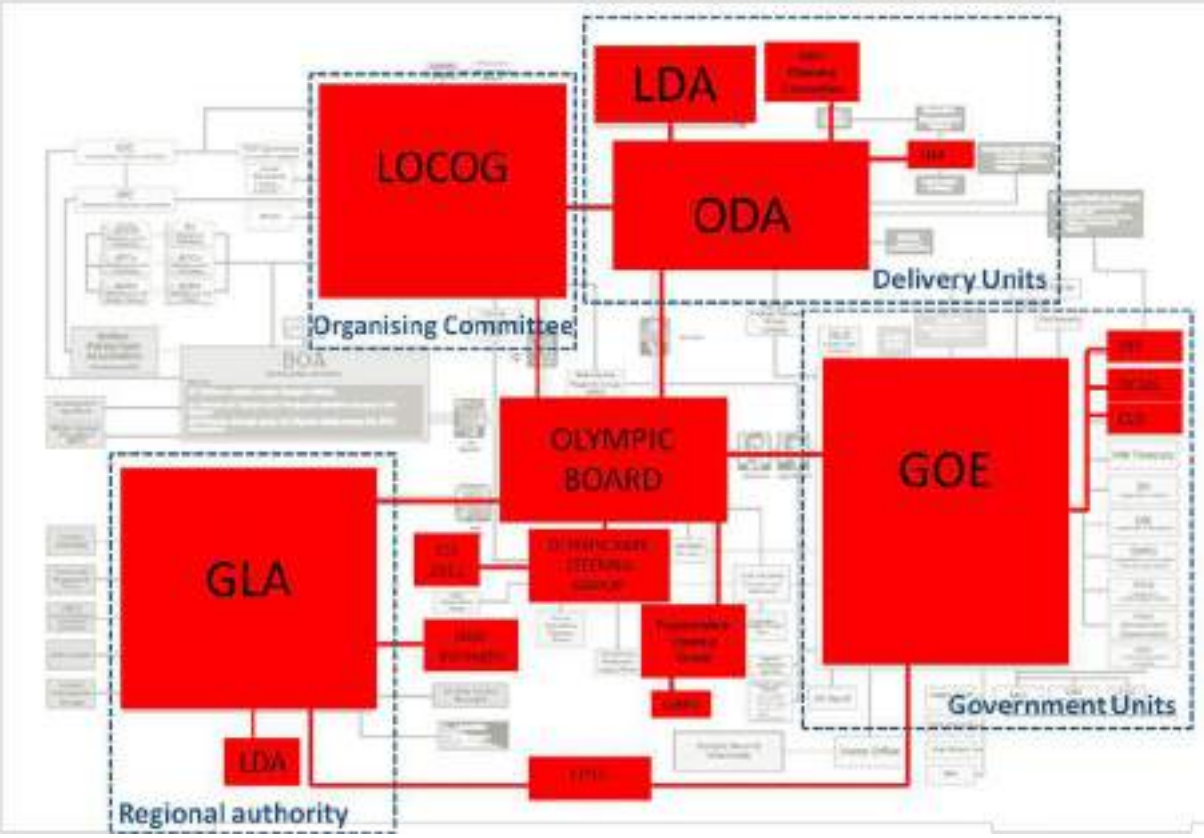

Figure 3. Regeneration Decision-making Structure of London 2012 Olympic Games

Investigation of the stakeholder interviews including deciding on the contact database and questionnaire design started in May 2010. A contact database is being created of the case study organisations, intermediaries and key informants (See Figure 3). Before starting interviews, a letter is emailed to the central regeneration and mega-event contacts. The letter indicates the intention to conduct further research in the area and ask support for the research (including access to key people, policy and other non-public documents, e.g. 'grey' material). The contacts are telephoned/e-mailed and agreed contacts participate in the study. 24 interviews have been conducted with 20 institutions. Additionally, 10 informative meetings have been held with university members doing research about London 2012 Games, research institutes and community relations staff. These meetings helped to figure out different perspectives and reach a broader scale documents and reports in this area.

5. Preliminary Results

The overall vision of the London 2012 Olympic & Paralympic Games is "to host an inspirational, safe and inclusive Olympic and Paralympic Games and leave a sustainable legacy for London and the UK" (CSL2012, 2010). The six resulting strategic objectives are:

- To make the UK a world-class sports nation: elite success, mass participation and school sport.
- To transform the heart of East London.
- To inspire a new generation of young people to take part in local volunteering, cultural and physical activity.
- To make the Olympic Park a blueprint for sustainable living.
- To demonstrate that the UK is a creative, inclusive and welcoming place to live in, to visit and for business.
- To develop the opportunities and choices for disabled people.

Regarding the vision and objectives, it is clear that leaving a sustainable regeneration legacy in the East London is one of the most crucial targets of the London 2012 Olympic Games. In terms of social and economic regeneration, hosting the London 012 Games helped to raise aspirations, offered training, apprenticeship and volunteering opportunities for local people. Moreover, it is expected to have employment opportunities in the area before and after the Games. Chief Planner in London Borough of Hackney thinks Media Centre is the biggest piece of land that potentially can generate employment in the borough. It is expected that the area around Media Centre will turn into a high-tech hub and create employment for locals. Hackney representative says “it is an amazing capacity and with the government decision of Hackney, being the heart of the high-tech digital companies focusing and clustering in the borough, that potentially targeting one end of in Hackney other end in Shoreditch”. Similarly, Councillor in London Borough of Newham highlights the importance of job creation and education in the borough with following words: “For us employment is very, it is crucial. You can have a flat but if you’ve got no job, it’s no good. That’s the first thing. The second thing is improving education in the Borough, driving up standards in education”. Income levels, employment, educational achievement, housing and health may be regarded as major signifiers of a community’s well-being. Targets in these areas may be achieved in a variety of ways and take place over a timescale that extends several years beyond 2012 and the Games themselves.

In terms of organisation structure, sustainable regeneration covers the schemes of inclusiveness, multiagency partnerships, and the shift from government to governance. GLA interviewee supports this by saying “delivering the Games is a multi stakeholder proposition, it has to be, and we’ve found that obviously there’s a number of challenges, different organisations have different organisational priorities and, and managing some of that it has been basically a lot of effort”. As different actors from a range of fields were involved in the Olympic Board, “heterarchy” which can be defined as ruling through diversity (Jessop 1997) was sustained at some point however; knowledge transfer was not completely achieved. LDA interviewee thinks that the park will be better than before but will not have the integrated model that was planned in the beginning because of the deficiencies in organization structure

saying “So you’ll end up with a special park, you’ll end up with great housing around you, but what you won’t have the integrated model that you wanted in the first place”.
Moreover, several stakeholders agree that the responsible body of the Games should have been a transparent, public sector institution which is accountable to tax payers. GLA interviewee says “I would say that I think it would have worked better if there was one delivery organisation, so if LOCOG, the role, the functions of LOCOG and the functions of LDA could have been brought together in one organisation, that’s public sector organisation and therefore publically accountable”.

6. Conclusion

It is hoped that the findings and primary research analysis will also provide a sound base from which the planning of more sustainable major (‘mega’) events can be undertaken in the future and the evaluation of their impact more fully measured across a wider stakeholder community. This may go some way towards what Getz proposes as a model of sustainable events (2009) and for which this study will contribute empirical evidence and conclusions which may be further developed in subsequent research.

CRIME MAPPING IN URBAN AREAS: CASE STUDY CITY OF PATRAS

Sofia Vagiota[1]

Abstract

The work describes the development of a Geographical Information System designed to analyze and study the spatial distribution of violent acts and events (property crimes) that took place at the city of Patras (Greece) during the years 2007 – 2010. The final geodatabase is composed of 5400 records (occurrences) categorized in 50 distint fields (variables) Crimes of violence are an old and rather common category of crime. Property crime is a category of crime including, among other, burglary, robbery, theft, motor vehicle theft etc. (Spinelli, 1985); it includes only the seizure of money or property, and does not involve force or threat against a victim. The main objective of the described GIS is to contribute to the study, research and analysis of criminal incidents parameters in conjunction with the parameters of the urban environment – which is the receptor space of such events – in order to design and identify strategic orientations and create safer urban areas. Generally speaking, people have legitimate and obvious right to be and feel safe in their homes, neighborhoods or the city center, and generally in the broad environment where they live. Cities are places where people meet, where social life is more intense and complex, where culture is produced, where economic development together with technical and scientific changes are more evident. People are increasingly sensitive to the perception of social risks, including risks related to crime and victimization (AGIS, 2006-2007). As it turns out, it is interesting to clarify how theory and practical analysis can help to apply their knowledge to design and prove that although the socioeconomic characteristics of the residents exert a strong influence on crime rate, the physical characteristics of the urban layout can exert a counteracting influence. Particularly the work documents the theoretical background of crime mapping and crime analysis process and presents all steps of logical and physical design of the GIS and its implementation: organization and verification of the crime report data, identification and encoding of variables, design and implementation of the databases structure, normalization as well as the spatial dependence process of data georeference. Finally, it presents the early conclusions of the research, regarding the spatial distribution and inventory of events accompanied by visual examples.

1. Introduction

The focus of strategic urban planning issues in deterring crime events has not been adequately studied. There are not only actions to improve the built space preventing and reducing the likelihood of generation of criminal incidents and antisocial behavior but also the principles and objectives of public and / or private space (Cohen, LE & Felson, M., 1979). The spatial structure of city's infrastructures (roads, open spaces, etc.) requires special attention in order to prevent such types of actions (Nes A. Van, 2005a). According to international literature (Shu, 2000; Keith, 1999) it is indicated that under certain circumstances, urban planning parameters such as building factor, the number of floors in a building, the distance from the city center, the width of the sidewalk, land use, the area of building blocks, the age of buildings, population density, the territoriality etc. are important elements which contribute to the "safe" image of a city. The design process of the Greek cities, and the legislation framework, do not correlate such relationships and parameters. The focus and the only approach are from the point of view of forensics (Deladetsimas, 2009).

The objective is to study the relationship of the spatial distribution of criminal actions with the spatial and planning parameters of the urban environment in which these acts are committed. The main research question is whether it is possible for the urban planning to take into account factors that can prevent the commission of criminal incidents or hostile / antisocial behaviors. The research focuses on the contribution of criminal analysis results in the improvement of urban planning.

Geography has a major influence on crime. Combining geographic data with police report data and then displaying the information on a map is an effective way to analyze where, how and why crime occurs. Computerized crime maps became more common with the introduction of desktop computing and software programs called Geographic Information Systems (GIS). Analysts map where crime occurs, combine the resulting visual display with other geographic data (such as location of schools, parks and industrial complexes), analyze and investigate the causes of crime, and develop responses. Recent advances in statistical analysis make it possible to add more geographic and social dimensions to the analysis (AGIS, 2006-2007).

2. Space and Crime

The creation of urban environments that are defensible against crime has been a focal point of criminological discourse from as far back as the 1960s, when sociologists discovered that certain places, like people, possess a higher risk of being victimized than others. Although much attention in criminology has rested on sociological explanations of the concentration of crime at place – such as social disorganization and control theories – many researchers have subsequently changed focus, looking to the built environment rather than the sociological context for causal explanations of crime (e.g. Jacobs, 1961; Newman, 1972; Jeffrey, 1999). With this principle, the crime–design perception offers an exclusive point of view, because it emphasizes the fact that the built environment is more easily manipulated than the sociological con-

text, making it a potentially more fruitful angle from which to tackle crime prevention at place (Reynald & Elffers, 2009).

The early studies on crime and the urban image of the city were developed in The Chicago School in 1920 (Shu, 2000). As a key question had been claimed, whether crime as a phenomenon, can be identified in areas within the city of Chicago and associated with the 'type' of residents. For that purpose, there was a data collection focused on victims, such as the gender, the residence and age and the type of criminal act. Hence, applying this information in city maps and taking into account the population and the crime rates in each region, the research concludes that higher ratios are located on the outskirts of the city and especially in areas in transition. Terence Morris (1957), Brantingham & Brantingham (1975), Hope (1988), and Gilling (1997) emphasize that in the correlation of space and crime, the place of crime is not connected with the offender's residence (Shu, 2000).

One of the most remarkable theories focused especially on how urban space can affect the kind of criminal acts was in the book 'The Death and Life of Great American Cities' of Jane Jacobs (1962). Jacobs supports the idea that the relationship between space and crime depends on the city's function and all parts of a city are not safe in the same way. However the citizens and the visitors of an area can play a key role in the feeling of safety. In this direction, the author states the following conditions in order a city to be safe: mix of land use, small building blocks, coexistence of old and new buildings and finally should be enough density of residences and visitors. The appearance of Oscar Newman's '*Defensible Space'* in 1972 signaled the establishment of a new criminological subdiscipline that has come to be called by many "Crime Prevention Through Environmental Design" or CPTED. All 'Defensible Space' programs have a common purpose: they restructure the physical layout of communities in order to allow residents to control the areas around their houses. This includes the streets and grounds outside their buildings and the lobbies and corridors within them and it depends on resident involvement to reduce crime and remove the presence of criminals. Also, it has the ability to bring people of different incomes and race together in a mutually beneficial union. The key word in Newman's concept is territoriality.

In what follows in 1989, Hillier and his research team address the controversy about the relationship between crime and spatial design. There are two divergent views: the one which advocates open and permeable environments in which strangers as well as inhabitants pan through spaces and the second based on the model of defensible space in single mix which advocates closed and impermeable environments. Research by Simon, Shu (2000) and other crime–space studies carried out by the Space Syntax Laboratory have some striking results – they found no correlation between crime and density, only a poor correlation between affluence and crime, but a very strong correlation between layout type and all kinds of crime, with traditional street patterns, the best, and the most 'modern' hierarchical layouts, the worst. The approach offers some simple design guidance: join buildings together, avoid any kind of secondary access, make sure that all public spaces are continuously 'constituted'

by dwelling entrances and maximize the intervisibility of these entrances by a linear rather than a broken up layout.

The dual relationship of crime and urban planning keeps an important role in predicting crime in urban areas. Crime prevention through environmental design (CPTED) began as a theoretical effort in order to demonstrate the relationship between the urban environment and crime and also to prevent crime through urban interventions (Crowe, 1991). The theory of CPTED belongs to the criminologist Ray Jeffery, after the publication of his book in 1971. The aim is to prevent crimes through a design which will also influence positively human behavior and will leave no room for committing crimes while it reduces the chances. People living in areas where CPTED strategies are followed should feel a sense of security, and potential criminals consider this area as a particularly dangerous place to commit a crime. The main issue of Crime Analysis is the prevention of criminality. Generally speaking, the design of urban spaces prevents or allows the commission of a crime (Keith 1999).

3. Urban Planning Strategies

A complex range of factors contribute to insecurity in the city. Economic conditions and social problems are generally considered as the main causes, but safety is also affected by the physical environment. It depends also on the way in which cities are planned, designed and built; the way in which people identify them with the environment which they live in, and the way in which urban spaces are looked after and managed. The layout and organization of urban spaces influence their level of security: they can contribute to making them safer, but they can also contribute to making them more dangerous. A good or bad layout can contribute to making a city more or less safe. Urban planning deals with the distribution and physical organization of activities and population in urban spaces; it can contribute to prevent phenomena of insecurity in our cities because there is a link between crime and the structure of urban spaces (AGIS 2006-2007).

To commit a residential burglary the offender must first navigate public space in order to gain access to private space and then negotiate entrance to the proper. The crucial question that must be answered is which particular part of public space gives the easiest access to the private space from the viewpoint of the offender. This question determines which kind of spatial information is relevant and needs to be extracted from the crime records in order to map each burglary case to its exact location and link it to the part of public space responsible (Shu, 2000). In fact, accessibility, density, mix of uses, integration, pedestrian and vehicle network, number of floors and vitality are key issues for crime prevention through urban planning. Crime prevention criteria should therefore be considered from the early stages of decision making, at the scale of planning; strategic plans, master plans, local plans and urban regeneration programs as well as infrastructure projects all affect in their specific way urban safety. The research focus on the following urban parameters:

- Social and Physical structures: the city is a living organism, where inter-relationships are the essence of urban life. It has been shaped over time by a self-regulating process. Any intervention affects the existing equilibrium and therefore the insertion of a new part requires careful evaluation in order to avoid rejection. New projects (regenerating an existing urban district or developing a new area) should become part of the whole urban structure. Social inclusion and social cohesion are goals to be strongly pursued for preventing isolation and social exclusion that lead to insecurity or at least are favorable grounds for crime. Indeed, social and economic characteristics of residents are strong predictors of crime (AGIS, 2006-2007).
- Accessibility: good accessibility and a capillary road network are essential to foster flows of movement which produce vitality, natural surveillance and therefore increase safety. To guarantee continuity of movements it is thus important to avoid fractures in the road and pedestrian networks. Lack of accessibility can also contribute to social segregation, and can create enclaves or isolated areas concentrating social problems.
- Vitality: traditional zoning practice tends to separate land-uses (residential, business, commercial, industrial, institutional). This creates districts with streets and public spaces which are not used some times of the day or days of the week, curtailing natural surveillance. Areas with "mixed use" avoid this drawback and therefore should be preferred to single function zoning, wherever possible. Activities add vitality to streets and public spaces, and provide an efficient "eye on the street". They are therefore one of the most powerful tools for creating spontaneous surveillance. Moreover, vitality is also important for social inclusion and cohesion, and thus for the potential reduction of crime.
- Providing mixed status: a safe city is a mixed and open city, with districts where different social groups live together. Providing diversified housing units on the same site attracts different economic groups and persons of different ages, with different habits, schedules and patterns of movements. This helps to create neighborhoods with good vitality which improves safety. In many cities, offices are concentrated in business districts which – being unpopulated at night – may become dangerous places that have no natural surveillance and are difficult to control even employing private police. Natural surveillance is lacking also in residential areas where housing density is too low to generate vitality and flows.
- Visibility: visibility allows people to see their way (and thus avoid dangerous situations) as well as to be seen as they use public spaces, thus making spontaneous surveillance possible. Natural surveillance is defined as the capacity of physical design to provide surveillance opportunities for residents and their agents (Newman, 1972). Indeed, windows and doors that are designed to face each other along a street have a better visibility of the private and public space around residences. The increased sense of security results in a more frequent use of space by residents, which in turn increases surveillance and improves the desire to defend that space (Reynald & Elffers, 2009).
- Number of floors: in residential buildings, the height of the ground floor should be such as to allow switching from residential to commercial use or vice versa. This allows replacing activities which close down with dwellings, and avoid the

sense of abandonment and the lack of surveillance generated by empty ground floors.

- Territoriality: the degree of safety of a place – public or private – depends considerably on the sense of belonging of the users and their identification with the place, because people respect and protect the places they feel as theirs (Newman, 1972). The appearance of residential space creates an image of the area that symbolizes the lifestyle of inhabitants. When the image of an area is a negative one (isolated, dilapidated and neglected) it becomes negatively differentiated from surrounding areas, making it vulnerable to criminal activity. If, from its outward appearance, an area appears to be well maintained, Newman suggests that a message is communicated to offenders that an area is well cared for and controlled by residents, and this serves as a symbolic deterrent to potential offenders.
- Attractiveness: an attractive place, instills respect, enhances the sense of belonging and civil responsibility of the users and inhibits misbehaviors. Besides, the *broken windows theory* which is a criminological theory of the norm setting and signaling effect of urban disorder and vandalism on additional crime and antisocial behavior, states that monitoring and maintaining urban environments in a well-ordered condition may stop further vandalism and escalation into more serious crime.
- Pedestrian network: walks shall be provided for safe convenient direct access to each unit and for safe pedestrian circulation throughout a development between facilities and locations where major need for pedestrian access can be anticipated. Walks shall be located so that they are easily surveyed from the interior of units.

Crime and fear of crime can affect the way a city works as well the attractiveness and functioning of some urban areas. When people feel threatened, they alter their lifestyle and consequently the way they use the city on a daily basis. Many do not go out in the evening, do not use public transport in the slack hours, avoid underground car parks, do not use public spaces (parks, squares etc.) and shut themselves in armored flats or gated communities. Local crime problems also make business activities and life in public spaces decline. Therefore, safety affects economic development. A complex range of factors contribute to insecurity in the city. Economic conditions and social problems are generally considered as the main causes, but safety is also affected by the physical environment.

4. Crime Mapping & GIS Analysis

During the past 20 years, many scholars have introduced definitions of Crime Analysis. Although definitions of crime analysis differ in specifics, they share several common components: all agree that crime analysis supports the mission of the police agency, utilizes systematic methods and information, and provides information to a wide range of audiences (Boba, 2009). The following definition of crime analysis could be the best description of its meaning: *"Crime analysis is the systematic study of crime in order to solve problems related with socio-demographic, spatial and temporal factors and focus to the crime and disorder reduction, crime prevention and evaluation".*

Crime analysis is the systematic examination of crime and disorder problems. It is not haphazard or anecdotal; rather, it involves the application of social science data collection procedures, analytical methods and statistical techniques. More specifically, crime analysis employs both qualitative and quantitative data and methods. The qualitative methods, specific to crime analysis, include field research (such as the observation of characteristics of locations) and content analysis (such as examining police recording reports). Quantitative data and methods deal with statistical analysis of numerical or categorical data. The spatial nature of crime is crucial to understanding the nature of the phenomenon. Crime Mapping is the process of using GIS technology to conduct Spatial Analysis of criminal incidents.

Crime mapping serves three main functions within crime analysis (Boba, 2009):

- It facilitates visual and statistical analyses of the spatial nature of crime and other types of events.
- It allows analysts to link crime data with geographic variables and location.
- It provides maps that support the visualisation process.

Based on the previous, a typical schema for a feasible crime analysis process includes: data collection, data collation, analysis, dissemination of results and feedback from users of the information.

Collection: The crime analysis process begins with observations (data). Data is drafted from various sources including, in most cases, outside crime analysts. Crime analysts examine data observed and collected by others, such as police officers, call-for-service dispatches, community service officers and geographers (Crowe, 1991). The police agencies, officers or civilian employees insert crime reports and other data into a computer system (not always as in our case). These data usually include longhand reports and have no specific form. However, the manner in which data are stored and the amount of data stored are important in crime analysis. Data must be kept in a digital format and to be collected for a significant amount of time to be useful for crime analysis. In general, the crime analysis data collection process requires the following:

a. The data must be collected accurately and consistently.
b. Only data appropriate for crime analysis should be compiled.
c. The data must be collected in a timely manner
d. The data must be stored for an adequate amount of time to allow effective analysis.
e. The data must be accessible in digital raw form to be queried and downloaded.

Collation: The main sources of the crime analysis data are from police sources. These data are not often coded or under any type of quality control. Data collation entails a number of different tasks, but it generally takes three forms:

a. Cleaning: the process of correcting mistakes and inconsistencies in the data.
b. Geocoding: the process of locating the crime analysis data and therefore to be enriched with spatial data and characteristics.

c. Creating new variables: the process of recoding or computing new variables from existing variables for more effective analysis.

Analysis: Analysis takes place after data collection and collation, including the use of many different statistical and visualization techniques. The crime analysis process in not a linear process. Very often the crime analyst is aware of problems related to data until the analysis begins. When this occurs, the analyst must often return to the collection and collation steps in order to improve or change the way data is collected, stored or collated. This practice is called data modification subcycle. Therefore the crime analysis process has to move from collection to collation and to analysis and vice versa. These tree steps are the most important and time-consuming and define the quality of the next steps.

Dissemination: Once the data analysis is completed, the crime analyst needs to disseminate the results to various types of audiences. In fact, tables, graphs, diagrams, and thematic maps are easily understood. However, the presentation should be tailored to the knowledge of the particular audience and the presentation of the results should convey only the most necessary information. In more specific terms, much of the work of crime analysis takes place behind the scenes and the presentation of results need not include all the information and all the work has been done.

Feedback: The researcher has to benefit from the dissemination process and to enrich the analysis results by receiving feedback and transform it to new information. This step improves the whole process. Analysts must receive feedback about the quality and the nature of the analyzed data in order to reach to a better decision making.

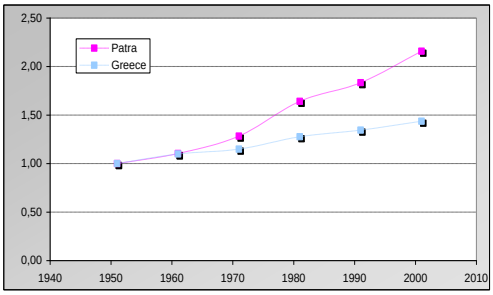
To sum up, the crime analysis process is not linear. It is cyclical since in every step there are improvements and feedback. Analysts spend a lot of time in the modification of their data. However, the process is constantly evolving by improved policies such as technologies, databases, training and examples of effective analysis. The research of space and crime can be achieved by creating a complete, appropriate and flexible methodological framework. This would define the main axis that will make easier the problem's solution by providing a logical interpretation, a prioritization of targets and a development of new data and information.

5. The Database for the city of Patras

The present chapter refers to the development of GIS and the relevant thematic database. The case study is the city of Patras (Greece), third urban complex in Greece and one of the oldest, having a continuous history of 4.000 years. The modern history of city is characterized by a rapid and continuous development and transformation, concerning its structure, function and physiognomy. It presents all the characteristics of a developing urban center as it concerns to the organization of its urban structure and socio-economic activities. Patras has a population of approx. 203,000 inhabitants (2001), and the evolution of its population, is shown in the following table and graph compared to the population of the country (Table 1).

Table 1. Population evolution in Patras and Greece

YEAR	PATRA	GREECE	PATRA	GREECE
(real population)				
1951	94.192	7.632.801	1,00	1,00
1961	103.985	8.388.553	1,10	1,10
1971	120.847	8.768.641	1,28	1,15
1981	154.596	9.740.417	1,64	1,28
1991	172.763	10.259.900	1,83	1,34
2001	203.273	10.964.020	2,16	1,44



At the beginning of 2008, the Central Police Department of Patras, offered to the university Laboratory all census forms of criminality acts (1614 reports) - for year 2007 – however, not including those who do not safeguard the privacy of the individual (data referred especially the so-called "Crime of the road"). These data have a great volume and do not exhibit any standardization in coding.

Therefore there was an obvious and time-consuming appropriate treatment in relation to their standardization and more specific the focus was to identify variables' encoding and credible digital conversion into a database. Along the way, the database was tested with respect to data reliability and normalization rules. After the final database tests, all the records were georeferenced using the digital cartographic structure (digital map) of Patras – which includes building blocks, buildings, roads, etc - by the Greek Statistical Authority (2001) as it is the only reliable digital map with such information. We have to mention that more updated maps are not yet available as there are only preliminary results from 2011 population and building national census. The final database contains 50 distinct fields describing the inventory data sheets. That georeferenced data was the source material for a pilot approach which used to control the process efficiency. Then the police passed to the laboratory the inventory records of violent acts for the years 2008, 2009 and 2010. These records- more than 5.400- are on hard copy and currently they are being rendered in an electronic database. In this sense, the initial results presented below (Figure 1), refer to the pilot data of 2007 (1624 cases). The characteristics of a crime are distinguished into three categories: a) modus operandi, b) persons involved in the crime and c) vehicles involved in the crime.

Modus operandi (MO): a Latin term meaning literally "method of procedure" refers to the method of crime, which is the key elements of the crime incident itself (Boba, 2009).

What: the nature of crime (e.g. burglary, robbery etc.).

How: the way the crime was carried out (varies by type of crime). Characteristics include but are not limited to the following: a) point of entrance, b) method of entrance, c) suspect's actions, d) method of escape etc.

Where: Where the crime was committed. Characteristics include but are not limited to the following: a) address, b) location, c) area, etc.

When: when the crime was committed. Characteristics include the following: a) exact time, b) first date and time, c) last date and time.

Persons involved in crime: the information about a person involved in a crime typically includes a description of the victim and the criminal. These data refer to the name/address/date of birth and gender.
Vehicle involved in crime: this category of information concerns the involved vehicles. This kind of data is important because vehicles often serve key roles in the commission of crimes. Some of the characteristics include the color and the type of vehicle (car, truck, motorcycle, etc).

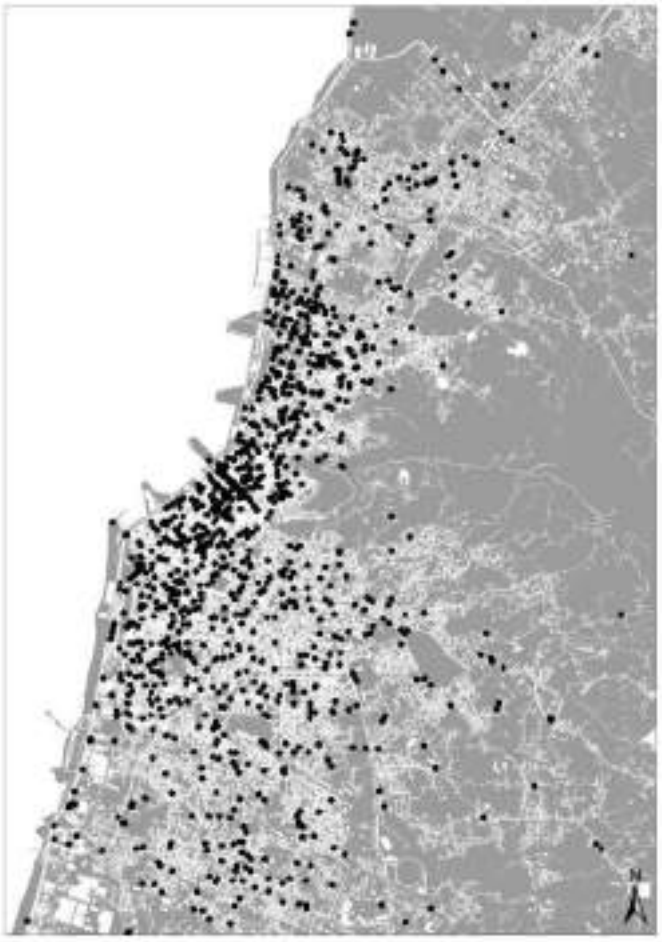


Figure 1. Spatial distribution of crime events

Based on the available information, the implementation of the previous modus operandi renders the database structure for the city of Patras, as presented in Table 2 below.

Table 2. Database variables

modus operandi (MO)	**NAME**	**TYPE**	**DESCRIPTION**
	XID	Integer	The serial number of every criminal record
	YEAR	numeric	The year of the committed crime (2007, 2008, 2009, 2010)
WHAT	XTHEME	text	The theme of the committed crime (α = attempt, δ = burglary, κ= theft, λ = robbery)
	XTYPE	text	The type of the commited crime (building, citizen, state property, vehicle)
HOW	XENTRANCE	text	Point of entrance (door, window, unknown, balcony, etc)
	XLEVEL	text	Level of entrance (1^{st} floor, 2^{nd} floor, etc)
	XATTACKED	text	Object of offence (against person, against property)
	PRESEN	text	Situation of victim (presence, absence)
WHERE	PLACE	text	The name of the city (Patras)
	ADRESS	text	The exact address (example Ag.Nikolaou Street)
	XNUMBER	text	The precise number of the address (1, 56 ,102, etc)
	LUSE	text	The type of location (commercial, public space, residential, street)
WHEN	STARTDATE	date	Precise start date xx/xx/2007 etc
	ENDDATE	date	Precise end date xx/xx/2007 etc
	MONTH	text	Month of the incident (February, March etc)
	EPOXH	text	The incident's season (α = spring, κ = summer, φ =autumn, χ = winter)
	STARTTIME	date	Precise start time (example 11:45, 12:50)
	ENDTIME	date	Precise end time (example 13:45, 17:50)
	FOUND	text	Criminal's arrest outcome: arrested or

CRIMINAL			not (yes, no)
	CGENDER	text	Criminal's gender (α = male, θ = female)
	CYEAR	numeric	Criminal's year of birth (example 1965 etc)
	CAGE	numeric	Criminal's age (example 18, 20, 52 etc)
VICTIM	VGENDER	text	Victim's gender (α = male, θ = female)
	VYEAR	numeric	Victim's year of birth (example 1975 etc)
	VAGE	numeric	Victim's age (example 22, 30, 42 etc)
VEHICLE	COLOR	text	The color of the vehicle (black, red, blue etc)
	VTYPE	text	The type of the vehicle (car, motorcycle, truck, bus)
PROPERTY	AOBJECT1	text	The type of the stolen object (passport, documents, clothes etc)
	VALUE1	numeric	The value of the stolen object (100, 20, 1000 etc –in euro)

As it was mentioned earlier, the database records are georeferenced based on their address with visual confirmation on a map. Therefore, an independent digital cartographic structure with point topology was created, compatible with the digital base map in accordance with the current Greek reference geodetic system (EGSA '87). The GIS software used is ArcGIS of ESRI. As the research is in progress, there is a growing literature research simultaneously ongoing with the collection and input of new data. In this framework, the paper presents initial results and, obviously, there is a potential of changes or rejections in the future. The results in the following tables and figures present a first statistical description of selected variables from the database and the spatial distribution of positions of the violent acts in the city of Patras (pilot data of 2007) in cooperation to initial experimental applications for calculating density distribution (Kernel density) for different instants of time. As these are some initial results, there are no comments so that they cannot be considered as main positions of the research. The main aim is to give an indicative impression of the spatial database's potentials with regard to the upcoming data of the years 2008, 2009 and 2010.

Table 4. Theme of crime

Attempt	89	5,5%
Burglary	642	39,8%
Theft	847	52,5%
Robbery	36	2,2%
Total	1614	100,0%

Table 3. Type of crime

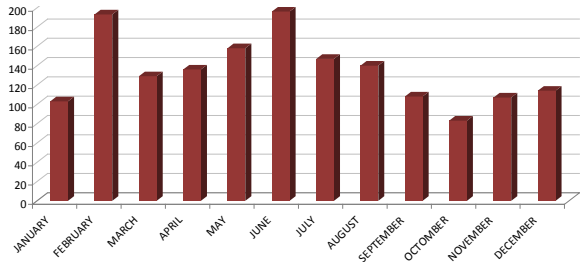

Figure 4. Monthly distribution of crime

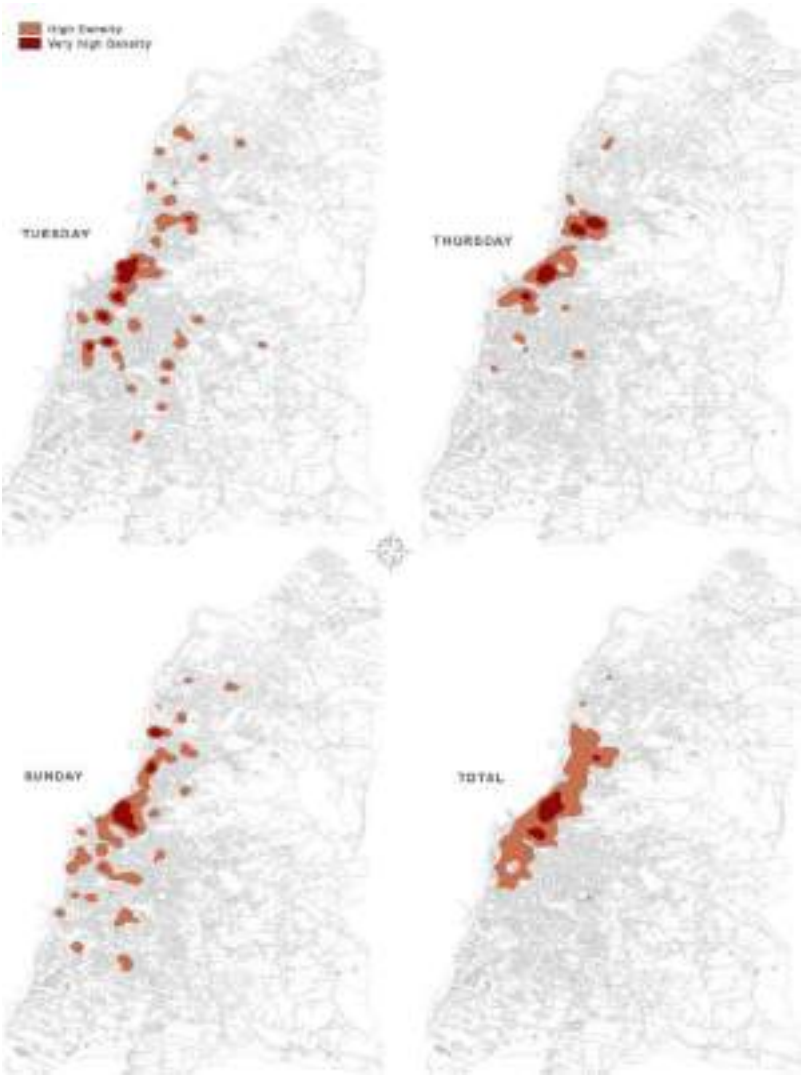

Figure 5. Spatial densities

On Tuesdays the minimum of average events is occurring and on Thursdays the maximum. They are only the top two classes from Kernel densities.

6. Future research

The future research will focus in the effort to integrate and incorporate the results of the study of space and crime in the process of urban planning. On a broader level, it seems that violent acts are the product of social and environmental factors (Nes van A., 2005b).

Unfortunately, there are still hidden analytic dangers lurking just below the surface, especially at the larger scales of analysis. First and most obviously, there is always an extremely uneven distribution of crime opportunity in cities because cities have uneven distributions of people and activity with more people, cars, activities in some areas than others, and, above all, far more people and activity, and therefore crime

opportunities, in the central areas than elsewhere (Shu, 2000). So if we do a simplistic analysis, we will always find the highest rates of crime in the city centers, because this is where there is by far the highest concentrations of crime opportunity are, and this might be taken – mistakenly, as we will see - to reinforce the idea that people are a source of danger. However, nearly all of this is property crime against commercial premises, and this can -by definition- only happen where commercial premises are located, and commercial property crime rates are often well above those for dwellings (land use).

Crime rates must clearly then always be correlated to opportunity, and comparison shall be made with variables of same spatial nature – for example city centers to city centers, not city centers to residential areas. This applies not only to the number of premises offering crime opportunity. This inherent difficulty in spatial analysis is exacerbated by the spatial distribution of social and economic factors. A third difficulty is the correlation between the crime and spatial mechanisms: pickpockets are helped by crowded streets; muggers need victims one at a time, burglars need secluded access to dwellings and so on. Again Alford's work shows that different crimes have different distributions, and also different distributions by night and day, but all are powerfully related to space. An overly aggregated analysis might well have missed the genuinely spatial influences on crime distributions that articulates so good.

Finally, a fourth difficulty arises from the familiar search for 'crime hot spots'. The identification of these can of course be very useful for the police in deciding where to deploy their resources, but from the point of view of identifying spatial influences on crime, they tend to be misleading because most hot spots turn out to have social explanations. So, even if it is shown that the crime rate in an area is higher than in another, or even that more criminals come from one area than another, it still isn't known whether the high rate has been produced by the area itself or by the social process that put its population there. In principle, it ought to be possible to resolve this statistically by using multivariate analysis to isolate the influence of different factors (Scott, Ken & McLaren, 2000). In technical terms, more effort to control the layout variables needs to be made.

Eventually, the applied part of the research is in progress and in the near future, according to the methodological design of the research, it will focus on the methodological integration of investigation's findings of literature and how these are specified in accordance with the requirements of the collected and organized in a GIS spatial database. Moreover, there is a growing literature research simultaneously ongoing with the collection and input of new data. Hence, the theoretical phase will identify the models of spatial analysis to determine the contribution of urban parameters in the process of spatial distribution of crime incidents. The objective of crime mapping is to offer some directions about how to deal with such kind of urban transformations. A crime map sets out to show us something we cannot otherwise see. Its goal is predictive, to identify patterns and anticipate future criminal acts by collating information about the time, place, and frequency of past crimes, not only to see, but to foresee (Aurora, 2009).

GREEN INFRASTRUCTURE RESILIENCE PLANNING FOR CLIMATE CHANGE: STORMWATER BMPS AND SOCIAL VULNERABILITY FOR CLIMATE-INDUCED FLOODING RISK ASSESSMENT FRAMEWORK

Chingwen Cheng[1]

Abstract

Climate change and urbanization affect hydrological cycle and lead to more frequent and intense human-influenced climate-induced floods that subsequently have significant environmental, economic, social, and cultural impacts on the society. Under increasing urbanization trends worldwide, more people are likely to be exposed to flooding hazards that threaten their livelihood; particularly for those who are socially vulnerable with low coping capacity. Green infrastructure, including both structural and non-structural stormwater best management practices, has been widely accepted in polices for stormwater management and an emerging strategy for climate change adaptation in spatial planning. There is a need in planning for integrating risk assessment and using green infrastructure as an adaptive planning strategy for resilience planning. The goal of this research is to provide a resilience planning framework to unpack risk assessment methodology and a tool for investigating the role of green infrastructure for climate change adaptation using the Charles River watershed in the Boston Metropolitan Area as a case study.

The overarching research questions are: (1) to what degree does the climate change become sensitive to long-term flooding hazards? (2) what are the key indicators for evaluating urban resilience and social vulnerability to long-term climate-induced flooding risks in the Boston Metropolitan Area? (3) to what degree can green infrastructure mitigate long-term climate-induced flooding risks of the Boston Metropolitan Area? (4) what is the role of green infrastructure in integrating social vulnerability and climate-induced flooding risks for climate change adaptation in landscape and urban planning?

Risk assessment is synthesized and spatially correlated through hazard, exposure and vulnerability studies. The long-term flooding hazard is defined by the probability of daily flow rate higher than the bankfull discharge. Exposure refers to the population who live in the flooding hazard zones. Vulnerability is reflected upon social-economic indicators related to flooding hazards coping capacity. Hydrological modeling for stream flow is conducted using the Soil and Water Assessment Tool

[1] Department of Landscape Architecture and Regional Planning, University of Massachusetts Amherst, USA – chingwen@larp.umass.edu

(SWAT). In addition, six green infrastructure land cover patterns varying in development density with a combination of various stormwater BMPs (porous paving, bioswales, and green roofs) based on the concept of transect planning are identified for Hydrologic Response Units (HRU) in SWAT. Climate change sensitivity approach through combinations of temperature and precipitation scenarios (+1, +2, +3, +4 ºC with an increment of 10% daily precipitations) are used to assess climate-induced long-term flooding hazards and mitigation threshold capacity from stormwater BMPs.

The expected results will demonstrate the effectiveness of applying a full range of probable stormwater BMPs in rural to urban transect planning for reducing climate-induced long-term flooding risks. The limitation of structural BMPs indicates that non-structural BMPs and comprehensive land use and watershed management policies for green infrastructure planning is needed for climate change adaptation. More over, an integrated hydrological risk assessment including social vulnerability is essential for resilience planning. Finally, this paper proposed a comprehensive green infrastructure resilience planning framework and methodologies that can be applied in practice to cope with climate change and enhance resilience in the Boston Metropolitan Area and other urbanized watersheds.

1. Introduction

"*Man takes a calculated risk when he builds his towns, cities, and other installations on the floodplain of a river. He, thus, is responsible for flood damages, if not for the floods that cause them.*" (Savini and Kammerer, 1961, pp.1591-A)

Not only is man responsible for the human-induced floods as a result of urbanization but also for the environment and the society that man created for socially vulnerable groups to be more susceptible to flooding hazards. Our built environment is multifaceted that involves limited natural resources and diverse cultures under local, regional, and global political and socio-economic context. The complexity between natural and human systems is intertwined and intangible. The world population grows exponentially since industrial revolution changed the face of civilization. The consequence of urbanization development has caused significant and irreversible environmental, economic, social, and cultural impacts that are not sustainable for our future generations (Bruntland 1987). One of the pressing issues is the climate change, which is a result of green house gas emission largely derived from urbanization and anthropogenic changes to the atmosphere (Karl, Melillo, and Peterson, 2009; IPCC, 2007).

Climate change and urbanization affect hydrological cycle and lead to more frequent and intense human-influenced climate-induced floods that subsequently have significant environmental, economic, social, and cultural impacts on the society. One of the major impacts from urbanization is the increased impervious land cover that alters hydrological cycles resulting in excessive runoff, lack of infiltration, and insufficient aquifer recharge (Booth and Jackson, 1997; Brabec, Schulte, and

Richards, 2002). Consequently, human-induced flooding at various scales is a problem in urbanized areas. Under climate change impacts, climate-induced flooding as a result of increased intensity and duration of storm events are likely to affect the New England region (Rock et al., 2001). Compounded by population growth in urbanized areas, more people are likely to be exposed to climate-induced disasters. The under-served population would be particularly more vulnerable due to a lack of available resources for risk mitigation, preparedness, response, and recovery (Hardoy and Pandiella, 2009; Bartlett, 2008; Douglas et al., 2008; Maantay and Maroko, 2009). Hardest hit are often the socially vulnerable groups, such as the elderly, those of low socio-economic status, and minority communities. Finally, top-down regulatory planning over past decades tends to dismiss local knowledge that traditionally passes down to generations in coping with Nature. The alteration and eroding of local culture therefore increases community's vulnerability to climate change (Umemoto and Suryanata, 2006).

1.1 Green Infrastructure and Stormwater BMPs

Green infrastructure, including both structural and non-structural stormwater best management practices (BMPs), has been widely accepted as alternative stormwater management for restoring or enhancing ecological services. In lieu of grey infrastructure, green infrastructure is defined by the United States Environmental Protection Agency (EPA) as a system that "uses natural systems – or engineered systems that mimic natural processes – to enhance overall environmental quality and provide utility services." Applying what ecosystem services can provide to achieve the same functions that are designed to serve urban infrastructure purposes; green infrastructure incorporates alternative BMPs to better improve environmental quality. The enhanced ecological functions consequently help to increase resilience of ecosystems to absorb environmental impacts from climate change.

Structural BMPs emphasize ecological engineering design such as bioswales or rain gardens, porous pavements, and green roofs. Non-structural BMPs emphasize policy and regulations that help to alleviate the root of the problem – urbanization – and engage the public (Urbonas, 1994). Non-structural BMPs include a wide range of strategies, including but not limited to land use planning, natural resources management, streams and wetlands restoration (Ellis and Marsalek, 1996), and smart growth. Recent research suggests that the integrated structural and non-structural approach in green infrastructure plays an important role as an adaptive planning strategy for mitigating flooding risks and serves as a climate change adaptation strategy in spatial planning (Gill et al., 2007).

1.2 Planning for Climate Change

Planners have been given the challenge for decades in resolving conflicts between environmental protection, economic development, and social equity for sustainability (Campbell, 1996). Under the climate change impacts with increased risks to human-influenced and climate-induced natural disasters, planners have a greater mission in

planning for resilience and facilitating resources distribution to achieve multiple mutual benefits for the environment, economy, equity, as well as diverse cultures.

Planning for resilience in enhancing capacity of adaptability to climate change impacts is a top national priority in cities (Godschalk, 2003; Beatley, 2009) and a top agenda in the world climate change summit. Planning strategies in the new urban world require robustness and adaptability with multiple objectives in order to be resilient to climate change variations and uncertainty (Ahern, 2011). The theory and application of resilience in planning application remain an open discussion in that what a resilient urban form is like (Hamin and Gurran, 2009), how the governance structure can be more resilient (Lynch, 2008), or in what planning process can achieve resilience (Hebbert, 2009; Lessard, 1998). This research is intended to fill the gap of resilience research in green infrastructure planning.

1.3 Research Goals

The goal of this research is to provide a resilience planning framework to unpack risk assessment methodology and a tool for investigating the role of green infrastructure for climate change adaptation using the Charles River watershed in the Boston Metropolitan Area as a case study. The overarching research questions are: (1) to what degree does the climate change become sensitive to long-term flooding hazards? (2) what are the key indicators for evaluating urban resilience and social vulnerability to long-term climate-induced flooding risks in the Boston Metropolitan Area? (3) to what degree can green infrastructure mitigate long-term climate-induced flooding risks of the Boston Metropolitan Area? (4) what is the role of green infrastructure in integrating social vulnerability and climate-induced flooding risks for climate change adaptation in landscape and urban planning? This paper will address those questions from theoretical and methodological framework and provide implications of using the green infrastructure planning framework into practices for climate change planning.

2. Theoretical Framework

2.1 Resilience Theory

Resilience is defined as a capacity in a system to absorb shocks from disturbances that change the system's ability to return to the state of the same structure and functions (Holling, 1973; Walker and Salt, 2006). Resilience thinking can be applied to society as a "capacity to anticipate, prepare for, respond to, and recover from significant threats with minimum damage to social well-being, the economy, and the environment" (NRC, 2010). It provides system thinking in dealing with complex issues such as climate change in the coupled natural and human systems (Liu et al., 2007). The resilience framework should be robust rather searching for optimal control in the social-ecological systems and this framework is intended to inform adaptive planning (Anderies, Walker, and Kinzig, 2006).

2.2 Vulnerability Theory

Vulnerability is a sign for the erosion in the elements of social-ecological resilience (Adger, 2006). When communities have insufficient coping capacity for the shocks and disturbances in the coupled natural and human systems, they are more vulnerable to the adverse effects of uncertainty and extreme variation which climate change has promised. Vulnerability for climate change is closely associated with social resources in terms of an individual as well collective adaptive capacity to mitigate, prepare for, respond to, and recover from environmental hazards (Birkmann, 2006). Under the context of complexity in politics and economics in the urbanization process, a "risk society" is often created with socially vulnerable groups who are more susceptible to environmental hazards (Colten, 2006; Blaikie, 1994).

Social vulnerability is therefore intertwined with environmental, economic, social, and cultural dimensions. Environmental vulnerability refers to the physical environment that is susceptible to natural or manmade hazards. For example, the low land and floodplain areas are prone to flooding hazards or the built environment with massive impervious areas increasing the risk of flash floods. Economic vulnerability is intertwined with the economic systems at global, national, regional, local, and individual levels. Depends on the scale of vulnerability assessment, the economic vulnerability can be specified at appropriate scale. For example, poverty is the key indicator for economic vulnerability and its measurement is often to be gross domestic product (GDP) at the global or national scale and median household income at the regional or local scale. Social equity vulnerability refers to whether the society created inequitable environment in which the policies and resources distribution are limited for marginal groups of society thus making those people who tend to get more exposure to hazards and are susceptible to damage and causality caused by disasters. Socially vulnerable groups include low income, disabled, women, children, aged groups, minorities, and immigrants (Pelling, 1997; Laukkonen et al., 2009). Cultural vulnerability is the inverse of cultural sustainability that aims to preserve tangible or intangible cultural heritage. It is related to individual as well as collective attitudes and behaviors toward actions in climate change mitigation and adaption to achieve the culture sustainability. All vulnerability factors among four dimensions are interrelated and have impacts and feedbacks on one another.

3. Green Infrastructure Resilience Planning Framework

Climate change and urbanization have impacts on hydrological cycle, land cover change, and people's livelihood. Landscape and urban planning is essential for an integration of coupled natural and human systems to reduce environmental hazards and social vulnerability while in the mean time achieve climate change mitigation and adaptation. Risk assessment encompasses three components: hazards, exposure, and vulnerability. Hazards are spatially defined in the physical environment; exposure refers to population who are located in the hazard zones. Social vulnerability indicates coping capability of a community to mitigate, respond to,

recover from, and adapt to the exposed hazards (Birkmann, 2006; De Wrachien, Mambretti, and Sole, 2008). When exposure is highly spatially correlated with social vulnerability, it implies an equity issue in which people who have least resources to cope with disasters live in the highest environmental hazard areas. This research focuses on climate-induced long-term flooding risk assessment.

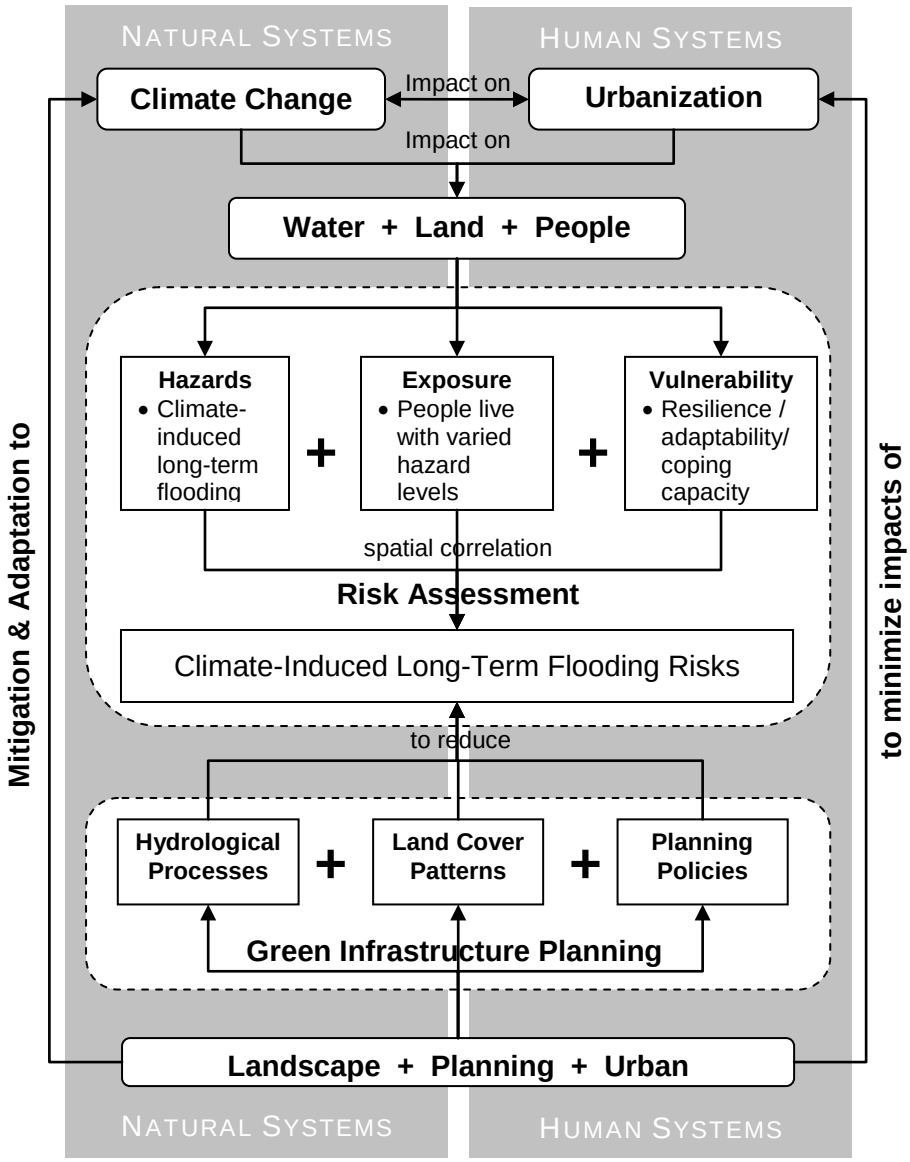

Figure 1. Green infrastructure resilience planning framework integrating climate-induced flooding risk assessment for climate change adaptation in the coupled natural and human systems

A comprehensive green infrastructure planning addresses hydrological processes, land cover patterns, and planning policies for reducing climate-induced long-term flooding risks. Effective integration of structural and non-structural BMPs can reduce impervious land cover and restore hydrological function in urbanized areas for stormwater management and long-term flooding hazards mitigation. Planning

policies influence the location and implementation of green infrastructure practices that are closely linked to land cover patterns and hydrological processes. Finally, green infrastructure has multiple benefits that can subsequently mitigate urbanization and climate change impacts such as reducing carbon emissions, minimizing impervious surfaces, reducing urban heat island effects, and improving environmental quality (Figure 1).

4. Methodologies

4.1 Study Area

The study area includes 24 municipalities in the 770 square kilometers of the Charles River watershed. As population growth continues in urbanized areas under current development patterns, more impacts from urbanization and interactions with climate change will impose more potential risks for society. Aside from the potential climate-induced sea level rise impacts on the coastal communities, this study focuses on inland climate-induced long-term flooding risks. Charles River watershed has over 3 millions population and is the most populated watershed in the Boston Metropolitan Area, including the City of Boston. Charles River watershed encompasses the most environmental justice populations defined by the Massachusetts Office of Geographic Information, including neighborhoods with high minority, non-English speaking, low-income, and foreign-born populations.

4.2 Risk Assessment

Risk assessment is highly spatially correlated in the coupled natural and human systems through a comprehensive synthesis of three major analyses: hazards, exposure and vulnerability. Long-term flooding hazard is defined as a probability of daily stream flow higher than the bankfull discharge:

$$P(Q > Q_{bankfull}) = \frac{days\ when\ Q > Q_{bankfull}}{365}$$

Stream flow can be simulated through hydrological models. Soil and Water Assessment Tool (SWAT) is a long term hydrological model that operates on a daily time step (Arnold et al., 1998). Key elements used to simulate hydrological balance in a subbasin level include digital elevation model (DEM), temperature, precipitation, land use, soil, and slopes. The hazards index will be built upon 20 years of data from 1992 to 2011, in addition to 2-year warm up period 1990-1991. Assuming the maximum long-term flooding hazard reaches the probability of stream flow surpasses bankfull discharge everyday in the raining season; the long-term flooding hazard index can be scaled from 0 to 1 for each subbasin in the watershed. Climate-induced long-term flooding hazards are calculated through climate sensitivity study using a combination of incremental temperature (+1, +2, +3, and +4 ºC in daily temperature) and precipitation (an increment of 10% in daily precipitation) change until the long-term flooding hazard index reaches 1. The climate sensitivity study reflects a range of probable climate change scenarios at the local scale.

Exposure index is illustrated by the ratio of percentage population of total in the US census 2010 at the unit of block groups in GIS. Based upon hazard index in each subbasin, population at the census block groups can be spatially overlaid to determine the total affected population in the watershed as well as affected population in each subbasin. Exposure index can then be calculated based on the ratio of affected population in each census block groups over the total affected population in the watershed.

Social Vulnerability Index is built upon a US nation-wide study conducted by Cutter (Cutter, Boruff, and Shirley, 2003). Key social-economic indicators related to the Boston Metropolitan Area will be identified to reflect regional characters for climate-induced long-term flooding risks. Vulnerability index will then be constructed at a scale from 0 to 1 based on key indicators in each unit of the census block group.

4.3 Stormwater BMPs Assessment

Structural stormwater BMPs for mitigating climate-induced long-term flooding risks are assessed through land cover patterns change on the hydrological processes under the assumption that on-site stormwater management can help to mitigate a range of long-term flooding hazards under climate scenarios. Three commonly used stormwater BMPs are tested: bioswales or raingardens, porous paving, and green roofs. Six stormwater modeling typologies (SMT) are developed based on the concept of rural-urban transect planning (Dunay and Talen, 2002) as hydrologic response unit inputs for SWAT hydrological modeling. Land cover patterns vary in close association with development density that is largely defined by six land use categories: forest, rural residential density or agriculture, low density residential, medium density residential, high density residential and other intensely built areas such as commercial, industrial, transportation, and institutional land uses. Each type of development patterns implies different potential for stormwater BMPs applications. For example, bioswales or raingardens can be applied at a greater scale in the low density than those in the high density residential areas. In addition, porous paving and green roofs are more likely to be implemented in the high density and intensely built areas than those in the rural and low density residential areas. As a result, six stormwater modeling typologies with a full range of probable stormwater BMPs are developed. Then determine parameters in the SWAT model to reflect the stormwater BMPs in each stormwater modeling typology for completing the risk assessment described above.

4.4 GIS Spatial Analyses

Risk assessment and stormwater BMPs assessment designed in this research are highly spatially correlated and rely heavily on GIS spatial analyses. The expected results will indicate the low, medium, and high risks levels for long-term flooding under low, moderate, and high climate change scenarios. In addition, socially vulnerable index can be spatially correlated with exposure index to examine to what extent the vulnerable populations are also spatially distributed in the high hazard

zones. Moreover, the stormwater BMPs assessment will indicate a range of threshold capacity under various climate change scenarios. Finally, risk assessment at the census block group level in the watershed scale can reflect the variance of sensitivity and vulnerability to climate change scenarios between municipalities and between upstream and downstream communities.

5. Conclusions

Planning essentially is a science of resolving people's problems over time addressing long-term sustainability. As climate change emerges as a top global as well as local agenda, its impact on the coupled natural and human systems needs to be addressed in resilience planning. This paper explores the link between climate change, risk assessment, and green infrastructure planning through the lens of climate-induced long-term flooding risks, social vulnerability, and stormwater BMPs. Climate Change is likely to impose long-term hydrological impacts on the urbanized watershed. As a result, more people, particularly socially vulnerable groups, will be exposed to climate-induced long-term flooding hazards. Structural stormwater BMPs have threshold capacity and are not sufficient in mitigating climate-induced flooding risks. Therefore, it is critical for green infrastructure planning to incorporate risk management and non-structural BMPs across watershed scale for climate change adaptation. The proposed comprehensive green infrastructure resilience planning framework and methodologies can be applied in practice to cope with climate change and enhance resilience in the Boston Metropolitan Area and other urbanized watersheds.

Some Determinants of Growth in Off-Java Lagging Regions Since Decentralization

Jennifer Day and Peter Ellis

ABSTRACT

This study explores some determinants of sub-national growth in Indonesia, and focuses particularly on off-Java manufacturing outcomes since the country's "Big Bang." Since 2001, Indonesia has been undergoing administrative, fiscal and governance decentralization. Often referred to as the "Big Bang," provincial and local (district) governments began to assume control over many policies. District governments – with varying levels of capacity – coordinate local service delivery such as health programs and local roads, in addition to elections of local and national representatives. In 2006, transfers to sub-national governments increased again. Indonesia's provinces and districts now spend a record 37 percent of total public funds, which is higher than the OECD average.

One of the main inquiries in this study is whether urbanization or localization effects are more significant for development in off-Java lagging districts, sine the Big Bang. Our analysis excludes districts on Java completely. Java is the most-populated island in the Indonesian archipelago, and also generates the most economic activity.

Our intent is to examine the impacts of urbanization (urban growth and population concentration), localization (concentration of like businesses), government investment in infrastructure, population, human capita, and other relevant factors, on economic growth in the manufacturing sectors, since economic decentralization began in 2001. To this end, we develop two sets of econometric models to examine panel data for Indonesian administrative districts (*kabupaten* and *kota*) for the seven years between 2001 and 2007. We choose three outcome variables and estimate separate equations for each of them: number of manufacturing establishments in a district, number of manufacturing jobs in a district, and total manufacturing value-added *per capita.* We define a "lagging" district as one with less than the median *per capita* income for overall Gross Regional Domestic Product (GRDP).

We analyze off-Java urban and rural areas separately. We estimate the general overall effect of a given variable, and also the differential effect for lagging districts using interaction terms. This set of interaction terms was introduced because we found disappointing levels of significance on most growth variables when the differential effects of lagging regions were not accounted for. In general, the outcomes for leading and lagging regions are so different that their combination can skew the findings.

Our findings indicate that lagging districts in both urban and rural areas respond much better to localization than to urbanization. This presents two issues for consideration. First, the more immediate gains to the industrial sectors are to be gained from the concentration of industry. Second, Indonesia is failing – at least with regards to the manufacturing sectors – to leverage its urbanization for economic growth. We also find that, in both urban and rural districts, the presence of state- and local-government-owned enterprise boosts economic outcomes, but government participation in industry suppresses growth in urban districts. As we said above, this makes a strong case that government-led industrial growth can provide a core set of firms and value-added in lagging regions, but future policy programs should focus on growing the private sector.

INTRODUCTION

This study explores some determinants of sub-national growth in Indonesia, and focuses particularly on off-Java manufacturing outcomes since the country's "Big Bang." Since 2001, Indonesia has been undergoing administrative, fiscal and governance decentralization. Often referred to as the "Big Bang," provincial and local (district) governments began to assume control over many policies. District governments – with varying levels of capacity – coordinate local service delivery such as health programs and local roads, in addition to elections of local and national representatives. In 2006, transfers to sub-national governments increased again. Indonesia's provinces and districts now spend a record 37 percent of total public funds, which is higher than the OECD average (Adams, Fengler et al. 2007).

The bulk of studies that address the spatial issues of the New Economic Geography (Krugman 1991a; Krugman 1991b; Krugman 2007) focus on countries as the unit of analysis. While this type of study is useful, they cannot address critical questions such as how to handle the particular issues of lagging sub-national regions. With more than 17,000 islands and vast regional disparities in incomes, health, accessibility, infrastructure, ethnicity, literacy, governance, and levels of urbanization, Indonesia provides an enough internal variation to study sub-national growth outcomes while also providing a stable over-arching political and cultural context.

One of the main inquiries in this study is whether urbanization or localization effects are more significant for development in off-Java lagging districts. Our analysis excludes districts on Java completely. We already know that on-Java districts are richer, with higher Gross Regional Domestic Products (GRDP) *per capita* than all but a few districts in the outlying Islands (Vidyattama, Hill et al. 2009). Economic activity in Indonesia is concentrated on Java, and on Java, it is even more concentrated in the Jakarta Metropolitan Region (JMR). In 2004, Java contributed 61, 66, and 67 percent of the country's total GDP, non-mining GDP, and household expenditure, respectively. In 1975, no province held more than a 20-percent share in the manufacturing economy. By 2004, seven provinces and three on Java, has shares greater than 20 percent – with West Java holding 43 percent. The only significant case of "deindustrialization" since the mid-1980s in Indonesia has occurred in Jakarta, where the manufacturing has declined as factories migrate to outlying districts of the JMR (Vidyattama, Hill et al. 2009). We know that firms are much more likely to locate on Java than anywhere else in Indonesia, to take advantage of agglomeration economies (Deichmann, Kaiser et al. 2005).

What we know less about, are the factors that induce growth in off-Java regions. Any analyses of growth in Indonesia that include Java – even if they don't focus on Java specifically – are essentially using Java's attributes as a baseline. Using Java as a baseline is appropriate in some contexts – for instance, when studying firm location choice, since firms will locate where conditions are most favorable. The problem with this approach is that the (relatively) overpowering growth and productivity on Java can mask albeit smaller effects that could be instructive on other islands. Our study attempts to fill this knowledge gap.

With a GDP of about $3,039 nominal USD *per capita* in 2010 (WB 2010), Indonesia still has some way to go before it reaches the roughly-$10,000 threshold, after which Brulhardt and Sbergami (Brülhart and Sbergami 2009) conclude that agglomeration provides few benefits in terms of economic output. Thus, Indonesia is well-positioned to take advantage of agglomeration economies, though it has historically failed to do so (Ellis, Dowall et al. 2011).

The remainder of this paper provides a brief review of the background literature, a summary of our approach to the analysis (including data, indicators, and modeling), findings, conclusions and recommendations.

BACKGROUND

Studies on economic growth in Indonesia are relatively sparse, especially since the Big Bang administrative decentralization that began in 1999. McCulloch and Sjahrir (McCulloch and Sjahrir 2008) examine value-added growth and convergence in all sectors (not just manufacturing), and including Java, and conclude that poorer districts tend to grow faster than better-off districts, and that nearness to a growing district is associated with growth. They find no evidence of spatial divergence in growth after 2001. They do not differentiate between urban and rural districts. They also rely solely on GRDP as an outcome variable, which even they admit is very noisy.

In Indonesia, most studies focus on the country as a whole (McCulloch and Sjahrir 2008) (Deichmann, Kaiser et al. 2005) or on Java only (Henderson, Kuncoro et al. 1996; Kuncoro and Dowling 2004; Kuncoro and Dowling XXXX????). Few studies examine off-Java effects specifically. In a national study, Deichmann and Kaiser (2005) conclude that road-infrastructure improvements would do little to draw manufacturing to outlying, lagging districts in East Kalimantan and South Sulawesi provinces in Eastern Indonesia. Although they address the issue of regional disparity in firm location, their approach is cross-sectional, only for 2001. Our study examines change over time in Indonesia's post-Decentralization period, beginning in 2001.

Numerous studies have commented on various legacy factors that can lend advantage to certain regions within a country. Natural advantages – endowments that make regions attractive for investment by firms – can include legacy investment such as roads and power (Ellison and Glaeser 1999). Production externalities, on the other hand, result from attributes of the local economy that provide efficiencies for a firm's production process, interactions with its market, suppliers, and pools of qualified labor. This study attempts to differentiate effects of natural advantage and local externalities.

Local externalities can include the institutional and regulatory climate (Peck 1992; Amin 1999). McCulloch and Sjahrir (2008) note, although do not have the data to study, the potential influence of institutional factors such as strong local leaders, on growth in Indonesia. As they note, forthcoming data on local parliaments and leaders are available only after 2004, so our analysis leaves out leadership variables. However, our analysis attempts to capture the effects of institutional legacy on growth in the manufacturing sectors. Other studies in the enormous literature on political and institutional policies that affect growth, have concluded that pre-Bang national policies in Indonesia favored Jakarta, resulting in better economic outcomes there (Henderson and Kuncoro 1996; Kaiser 1999). In a cross-country study, Davis and Henderson (Davis and Henderson 2003) argue that investment in both inter-regional infrastructure and fiscal decentralization promote growth of population and economic activity away from primate cities and into lagging hinterland cities. Our study pays particular attention to the issue of government involvement in manufacturing activity.

Beginning with Krugman's seminal work on the New Economic Geography (Krugman 1991a; Krugman 1991b; Krugman 2007) numerous theorists have argued that transaction costs affecting trade can be reduced by lessening distances – a concept that is operationalized in the World Development Report 2009 (Lin, Gill et al. 2009) as "economic distance." Our analysis also pays particular attention to the issue of economic distance in the formulation of critical indicators of urbanization and localization.

APPROACH

Our intent is to examine the impacts of urbanization, localization, government investment in infrastructure, population, human capita, and other relevant factors, on economic outcomes in the manufacturing sectors. To this end, we choose three outcome variables and estimate separate equations for each of them: number of manufacturing establishments in a district, number of manufacturing jobs in a district, and total manufacturing value-added *per capita.* We note that value-added is measured per resident in the district, not per worker. This was

done because we wish to measure the size of the industry, not its per-worker productivity. We define a "lagging" district as one with less than the median *per capita* income for overall Gross Regional Domestic Product (GRDP). We take the median of GRDP for urban districts, and a separate median for rural districts.

We analyze off-Java urban and rural areas separately. We estimate the general overall effect of a given variable, and also the differential effect for lagging[1] districts using interaction terms. Like McCulloch *et al* (McCulloch and Sjahrir 2008), we found disappointing levels of significance on most growth variables when the differential effects of lagging regions were not accounted for. In general, the outcomes for leading and lagging regions are so different that their combination can skew the findings. Noting that wealthier districts will be slower-growing while lagging districts play catch-up, we decided to isolate the effects of growth on lagging districts.

For each of these spatial designations (urban and rural), we develop two sets of models:

1) *Cross-Area Panel Growth Regression (CAPGR)*. These models are a variation of the cross-country panel growth regressions initially developed by Barro and Sala-i-Martin (1991a) and subsequently used extensively in analysis of economic growth, e.g., (Hausmann, Klinger et al. 2008). This model regresses GDP per-capita growth over a period of time against the logarithm of initial GDP per capita and other explanatory factors:

$$g_{it} = \gamma + \alpha \log(y_{i,t-1}) + X_{it}\,B + X_{it}(L)\,B + \varepsilon_i$$

where
γ is a constant
g_t is the nominal growth of GDP per capita over the time period
y_{t-1} is the initial level of GDP per capita
X is a matrix of relevant district characteristics
B is a vector of coefficients to be estimated
L is a dummy variable denoting a lagging district
ε_i is an idiosyncratic error term.

A note regarding equilibrium is in order. The CAPGR and fixed-effects models were chosen because they most-closely match the effects that we wish to observe. We recognize, however, that the CAPGR models were developed as long-run growth models, and that one limitation of our application of these models here is that it is difficult to conclude the long-term effects of policy changes from them, since they do not reflect long-run equilibrium (Acemoglu 2010), i.e., changes in supply and demand of various factors as a long-term result of policy changes. We present the findings here, mindful that system equilibrium adjustments could affect the outcomes we report.

2) *Fixed Effects Panel Model*. A fixed effects model was used to examine the impacts of change in the independent variables over the analysis periods, on growth over that time period. Unlike the cross-area panel growth models, which examine the effects of initial conditions on growth, the fixed-effects model examines growth as a function of change. Both models have advantages: since the effects of some processes (e.g., infrastructure investment) often need a longer time horizon for their effects to manifest, the CAPGR models are useful. However, CAPGR models cannot help us to understand the outcomes of change. For those

[1] Lagging districts are defined as those below the median GRDP *per capita* in a given year. Urban lagging regions are those below the median GRDP *per capita* for urban regions; rural lagging regions are those with GRDP *per capita* below the median for rural regions.

effects that are more immediately apparent (e.g., EXPY), the fixed effects model can perform this function. In tandem, the models tell a more complete story. The fixed-effects model has the additional advantage of controlling for time-invariant unobserved variables, which helps with the potential specification bias that we identified with the CAPGR models. A Hausman test was used before the regression was run, to determine whether the fixed or random effects model was appropriate. A fixed-effects model was run as follows:

$y_{it} = \gamma + X_{it}\beta_1 + Z_i\beta_2 + L*Z_i\beta_3 + \alpha_i + \varepsilon_{it}$,
where
y_{it} is the nominal GDP per capita for a given year t in district i
X_{it} is a vector of time-varying regressors
Z_i is a vector of time-invariant regressors
L indicates a lagging interaction term
α_i is an unobserved effect for individual districts
ε_{it} is an error term.

One advantage to the fixed-effects approach is that it controls for the effects of unobserved and time-invariant, location-specific effects. These could include natural advantages – endowments that make regions attractive to firms like legacy investment such as roads and power (Ellison and Glaeser 1999), protracted religious and ethnic conflicts that have been running through the analysis period (as in Aceh and Maluku). We use heteroskedasticity-robust and clustered standard errors (clustered by urban agglomeration[2] for metropolitan areas and by Island Region[3] for rural areas).

One advantage of focusing on lagging districts is that we can ignore some of the problems with endogeneity in the lagging interaction terms in the fixed-effects models. Many of the factors that are related to growth – education and human capital, population growth, capacity for innovation – are endogenous to the system. That is, we would expect (for example) higher levels of GRDP to lead to better education outcomes, in addition to the reciprocal relationship. If endogeneity is not corrected for (generally using some sort of instrumental variables technique), then bias is introduced into the models. When there are multiple endogenous relationships, suitable instruments become a problem, as is the case in this study.

Our approach assumes that most of the endogenous effects, e.g., increased median years of schooling as a result of economic growth, occur in the leading districts. Our findings imply that this is true – that is, the effects in the general case and on the lagging terms are often opposite each other in the direction of the effect. When the effect on lagging districts is isolated, as we will show below, we see effects consistent with the hypothesis that the endogenous effects are concentrated in leading districts.

We focus on the 2001 to 2006 time period for the analysis, because we are interested specifically in determinants of growth in the post-decentralization period. We recognize that 2004 provides an interesting break-point in this type of study, as Indonesia's national Gross

---

[2] Urban agglomerations are metropolitan regions, and were defined using Uchida and Nelson (2008) framework for identifying metropolitan agglomerations, with modifications to make the framework more suitable for Indonesia. In general, the process works as follows: an urban core region is identified using GOI-defined *kota* as the core. Then, surrounding non-*kota* districts are added to the agglomeration if they meet certain proximity and density standards. We refer the reader to Ellis *et al* (2011) for a detailed explanation of this process.

[3] The Government of Indonesia (GOI) has designated seven Island Regions: Java-Bali, Sumatera, Sulawesi, Papua, Kalimantan, Nusa Tenggara, and Maluku.

Domestic Product (GDP) returned to pre-Asian Economic Crisis levels in 2004. However, we felt that the 2004-2006 analysis period was too short to provide interesting insights on growth. We save the post-recovery analysis for a time when sufficient data are available.

Both models include metrics designed to capture the effects of the following factors on economic outcomes:

i. Population
ii. Human capital
iii. Composition of the economy
iv. Development expenditure
v. Innovative capacity
vi. Capital
vii. Urbanization and localization economies

Data were drawn largely from surveys conducted and compiled by Indonesia's Central Bureau of Statistics (BPS). In general, we draw on surveys which provide representative samples for each district, and which are conducted annually. Our outcome variables (value-added, firms, workers) come from the Manufacturing Survey of Medium and Large Firms (also known in Indonesian as the *Survei Industri*, or SI). The National Socio-Economic Survey (Susenas) is conducted annually by BPS, and has been a nationally-representative sample since 1993. For our study, Susenas provides population figures. The Regional Finance Information System (SIKD) provides data on public investment in infrastructure development.

Human capital is proxied using median years of education in the district, from Susenas. Given Indonesia's relatively recent (1999) and continuing transition to centralized to local governance, and the variation of different regions in levels of reliance on state-owned industries, we follow Fan and Scott (2003) in including the level of government intervention in the economy, and include proportions of the local manufacturing economy that are generated by nationally-owned, local government-owned, foreign-owned, and private Indonesian-owned enterprise. As another measure of economic composition, we use EXPY. EXPY is a measure developed by Hausman *et al* (2007) as an indicator of the sophistication of a country's export basket – i.e., whether a country is producing goods that are on the "upscale" end of the product spectrum. The core idea behind the EXPY computation is that, if all other factors are held constant, "an economy is better off producing goods that richer countries export." Hausmann's results show that high EXPY values – that is, countries whose exports are more upscale – are associated with high levels of economic growth. We apply Hausmann *et al* (2007) framework to a sub-national data, to develop an indicator of the competitiveness of Indonesia's sub-national (district) economies. EXPY values are computed from ISIC Revision 2 manufacturing data at the four-digit level. We direct the reader to Appendix A of Ellis *et al* (Ellis, Dowall et al. 2011) for a detailed discussion of the EXPY computations.

Many studies on growth in Indonesia and throughout Asia have noted the importance of infrastructure in economic growth (Deichmann, Kaiser et al. 2005; Vidyattama, Hill et al. 2009). SIKD data on public works development (as opposed to maintenance and operations) expenditure by local governments, was used as an indicator for infrastructure investment. Electricity reliability was proxied using SI measurements showing the proportion of manufacturing energy that firms self-generate (as opposed to buying it from PLN, Indonesia's state-owned electricity company)[4]. As an approximation for capital, we use the proportion of

[4] *Perusahaan Listrik Negara*

manufacturing value-added that is dedicated to the servicing of loans, also from SI. We note that more-precise measures of capital were not available for all study years.

In addition to using BPS-prepared statistics, we compute several spatial indicators using GIS. Urbanization and localization economies are approximated using gravity indices that represent their position relative to major population centers and sector-specific industrial concentrations. We believe this approach is an improvement over previous indicators for urbanization economies, which have considered only population or distance, but not both. For instance, Fan and Scott (2003) use population of largest city in the province in a provincial-level study of agglomeration in China. Deichmann and Kaiser (Deichmann, Kaiser et al. 2005) use road density and travel time measure access to markets and population centers. McCulloch and Sjahrir (2008) use a weighted average of GRDP growth in neighboring districts. Our analysis takes this further, employing a gravity index that considers distance and weight. Unlike these simpler measures, a gravity index provides a measure of the proximity of a place to regional attractions, weighted by the distance that must be traversed to reach those attractions. Thus, it reflects "economic distance" (Lin, Gill et al. 2009), and unlike measures that reflect accessibility to one urban concentration, the gravity index also captures the effects of smaller urban agglomerations that may be in close proximity but not adjacent. The general formula for a gravity index is as follows:

$$GI_i = \Sigma_j \frac{[ATTRACTION_j]}{e^{\gamma(ED)ij}}$$

where
i denotes a spatial area (in our case, a district)
j denotes an attraction (in our case, metropolitan and economic centers)
GI_i is the gravity index for a given district
$ATTRACTION_i$ = denotes the attractive force of a population or economic center
γ is a analyst-defined decay coefficient, which we assume to be one
ED_{ij} is a measure of economic distance, e.g., time or physical distance between origin i and destination j (in our analysis, travel time)

Higher gravity indices denote higher levels of accessibility to the attracting areas. We use this principle to develop two sets of gravity indices:

1) Market gravity to proxy urbanization economies (ATTRACTION = population)
2) Sector economic gravity to proxy localization economies (ATTRACTION = sector value-added).

Following but modifying the procedure set forth by Hausmann *et al* (Hausmann, Hwang et al. 2007), we compute EXPY, an index reflecting the sophistication of the manufacturing basket for a district. This is done using the Industrial Statistics (see Annex XX for a detailed discussion of EXPY). Finally, using a gravity model, we compute measures of spatial accessibility to population centers, and to manufacturing hubs by sector. These gravity indices provide a measure of the proximity of a place to regional attractions, weighted by the distance that must be traversed to reach those attractions.

One complexity arising from comparisons of data over time is the large number of new districts that have been created as a result of decentralization. At the time of decentralization in 1999, there were 292 districts and five additional districts comprising Jakarta. As of 2009, there were 497 districts, including six making up Jakarta. Fortunately, districts were largely formed by splitting an existing district into two or more new districts, so it was fairly easy to collapse the data to pre-Bang spatial units. We follow McCulloch and Sjahrir (2008) in collapsing the data to the 292 pre-Big Bang districts, so that they can be compared over time. All monetary values are in 2000 constant Indonesian Rupiah (IDR).

Noting the potential influence of spatial autocorrelation, Moran's I test was run to determine whether spatial autocorrelation was present in the outcome variables. Spatial autocorrelation is a problem in regression techniques that assume independence of observations, such as OLS. We ran Moran's I test on both overall *per capita* value-added and value-added for the sectors examined in Section 6, using districts as the spatial unit of analysis. For overall GRDP *per capita*, the test reveals very weak but statistically significant spatial autocorrelation for all analysis base years. Given the weakness of the association, we assume that spatial autocorrelation will cause few problems in the analysis. For the sectors, spatial autocorrelation is again statistically significant in all years, and has larger effects, with Moran Indices of between 0.1 and 0.12 (Moran's Index varies from -1 to 1, with -1 and 1 representing perfect correlation, and zero representing no correlation). We conclude that these levels of spatial autocorrelation are unlikely to heavily bias our results.

FINDINGS

Final model specifications were chosen from a number of candidate specifications. For the general-effect variables (i.e., terms that are not interaction variables, hereafter referred to as the "overall effect") variables were allowed to remain in the final models if they were of theoretical import, regardless of significance levels. For the interaction terms, given the small sample size, variables were allowed to remain in the models if they were approaching significance, i.e., standard errors less than 0.2, and the lagging term produced an effect with the opposite magnitude as the overall term. Tables XX and XX present the final models. Note that p-values are not presented in this table, but asterisks on the coefficient indicate the level of significance. Variables with significances between 0.1 and 0.2 are presented in ***bold italics.*** This section presents the findings.

Multicollinearity

Pearson correlations between population gravity and manufacturing gravity ranged from 50 percent overall to 58 percent for 2006. These high correlations would be expect to inflate standard errors, as the two metrics would partly measure the same underlying effect. However, for lagging districts, the correlations were much lower: 15 percent for all years (2001 to 2006) combined and 14 percent for 2006. This makes us reasonably confident that multicollinearity does not pose a threat to the viability of our findings.

In rural regions, correlation between population gravity and manufacturing gravity was much lower – ranging from 8 percent overall to 11 percent in 2006. Thus, we can be reasonably assured that they are not measuring the same underlying effect.

Findings – Urban Regions

Urbanization and Localization Effects

In general, larger populations are associated with higher levels of manufacturing value-added. The fixed-effects models indicate a positive association between population and manufacturing value-added: an increase in population of one million persons is associated with around 9,000 Rupiah increase in manufacturing value-added per capita (note that this is not value-added per worker, but that the metric is indexed to the entire population of the district, so the effect is large). We note the potential bias due to endogeneity; however, the bias on this variable should be downwards – that is, the additional population that would be attracted to high value-added regions would tend to pull down the average value-added per person. Thus, our estimate may be a conservative one, but we can reasonably conclude that the effect is positive, though we do not speculate on the causality of the relationship here.

For the panel growth models, the coefficient on population for lagging districts provides a counterweight to the general population effect, in the equation for manufacturing value-added. Endogeneity is not a concern for this model, as it models growth against a set of initial conditions (i.e., conditions in the district or metropolitan area in 2001, at the beginning

of the analysis period). Although there is a significant and negative effect for lagging regions, this effect does not counterbalance the positive association between population and value-added. We note that the effects on interaction terms should be interpreted as the sum of the coefficients for the overall indicator and the lagging interaction term. Thus, the effect of a population increase of one percent on value-added in lagging regions would be: 3,224.75 – 2116.15 = 1,108.60 Rupiah. This is still a significant positive effect, though less than for leading regions.

With regards to localization, districts with high levels of accessibility to manufacturing centers demonstrate higher levels of value-added and more firms (Models 1 and 2), but slower growth (Models 4 and 6). This is expected, as districts with larger economies tend to grow more slowly. Model 1 indicates that lagging districts with higher levels of accessibility also have net positive levels of value-added growth (a one-percent increase in accessibility has a net effect of 2,076.93 – 1,908.80 = 168.13 Rupiah *per capita* for lagging districts).

Interestingly, better levels of accessibility in lagging districts' is associated with higher growth in job numbers in manufacturing (Model 6). Lagging districts have a net positive effect on this variable of (-1,481.38 + 1,863.39 = 382.01 jobs over the 2001-06 analysis period). Although this effect does not hold for value-added or firm numbers, we read it as a positive sign that increased accessibility in lagging districts can improve growth outcomes and help lagging districts narrow the gap with leading districts.

Effects of Economic Composition

In lagging districts, higher levels of central-government participation in the manufacturing economy are associated with increased levels of value-added and more firms (Models 1 and 2). At first glance, this suggests that increased state-owned enterprise (SOE) activity has positive impacts for productivity and job growth in lagging places. However, Panel Models 5 and 6 paint a more-complicated picture. In lagging districts, increased SOE participation is associated with slower firm and job *growth* in lagging regions over the analysis period. We suspect that the legacy of SOEs in lagging regions is still strong and positive in that they provide firms and productivity to districts that would otherwise have little economic activity. However, their apparent inability to generate growth in lagging regions is worrisome.

The story with local-government participation in manufacturing is similar. For firms (Model 2), lagging districts with higher concentrations of local-government-held manufacturing, show small but net positive effects (the net effect in Model 2 is 0.0.08 – 0.07 = 0.01), even though the impact in lagging districts is lower. In lagging districts, though, firm growth slows as local governments produce more of the value-added (Model 5).

Together, these findings suggest that government-led industrial growth can provide a core set of firms and value-added in lagging regions. However, their presence seems to have the effect of suppressing growth relative to private-sector activity (the suppressed term in this group of variables is the percent of manufacturing value-added generated by privately-held, Indonesian-owned manufacturing firms). There is no urgency for central and local governments to abandon existing industrial programs, then, but future policy programs should focus on growing the private sector.

The other industrial variable, EXPY, suggests that lagging regions with more-sophisticated economies have higher levels of value-added and more firms than lagging regions with lower EXPY levels Models 1 and 2). Model 4 suggests that higher EXPY levels raise value-added growth in general (this includes lagging regions), but that higher EXPY can have a suppressant effect on jobs in lagging districts. This is not surprising, given that more-upscale industries tend to be less labor-intensive.

Human Capital

The variable we chose to proxy for human capital reflects the median years of schooling for adults over the age of 25. The effects of education are significant only in the jobs equations – Models 3 and 6 – and have sign and magnitude splits between the overall terms and the interaction terms. Increased levels of average education suppress the number of jobs (Model 3) and job growth (Model 6) for the overall variable. This is expected, as districts with higher levels of education cannot benefit as much from marginal education gains. However, the lagged term indicates significant gains to job numbers (Model 3) and job growth (Model 6) as education levels rise in lagging districts. We conclude that industry – particularly low- to

medium-skilled, labor-intensive manufacturing – can benefit greatly from marginal increases in the education levels of the labor pool.

Energy

As a proxy for the quality of infrastructure, we use the percent of manufacturing energy in a district that is self-generated by the firm – that is, not purchased from PLN or other off-site electricity providers. We also included variables reflecting road extensiveness and connectivity in previous iterations of these models, but they were highly correlated with the energy reliability variable and show no significant values. Thus, they were left out of the final specifications.

The expected sign on this variable was negative, as districts with less-reliable energy sources should be less likely to attract and retain firms. The jobs models show negative signs on the job numbers (Model 3) and job growth (Model 6) for lagging districts. In Model 6, the coefficient on overall job growth is positive. This likely reflects high growth outcomes in extractive industries in isolated districts, which would require self-power generation. In lagging districts, however, the effect on job growth is significant and negative – indicating that lagging districts have better growth outcomes when their PLN-supplied energy supply is reliable.

Development Expenditure

Local government expenditure on infrastructure development is a complicated issue in Indonesia. Districts with larger tax revenues will spend more on infrastructure, so we expect to see some positive association between infrastructure spending and economic outcomes. At the same time, high-spending regions with slower growth will likely still spend large amounts on infrastructure improvements, though their economic growth may not reflect this investment to the same degree. Also, transfers from the central government allow lagging regions to increase spending on infrastructure. Our analysis isolates the effect of infrastructure spending on lagging regions, allowing for comment on the relationship between expenditure and manufacturing outcomes in the worst-performing districts.

Models 2 and 3 suggest an inverse relationship between infrastructure spending and both firm and job numbers for the general (non-interaction) term. This is likely because firm-rich and job-rich districts have a legacy of infrastructure and do not need to spend more on new projects (they may spend more on maintenance, but our metric captures only spending on new infrastructure). We do not speculate on the causal relationship here, as there are likely positive effects in both directions, i.e., the effect of expenditure on economic outcomes, and vice versa. The net effects on the lagging districts also have a net negative effect.

The interesting relationship here is the lagging interaction term in Model 4. In lagging districts, a one percent increase in infrastructure spending in 2001, has a negative net effect (-4,250.34 + 3,043.47 = -1,206.87 Rupiah of value-added *per capita* for each one percent increase in infrastructure expenditure). This means that, even in lagging districts where the suppressant effect of high-income, slow-growing districts is removed, lagging districts lack the ability to generate positive returns to infrastructure spending. This is problematic and an issue worthy of further study.

Capital

Capital is a problematic issue for Indonesia's local governments. In both the overall case and in lagging regions, higher levels of capital is associated with more sluggish job markets (Model 3), though lagging regions do mitigate this effect somewhat. The negative net effects seen here could be the effect of capital-intensive industries with minimal labor needs (e.g., mining).

Even more disturbing is the effect seen in Model 4, which suggests that higher levels of capital generated stronger growth in value-added over the 2001-06 analysis period. However, for lagging regions, this trend is reversed. Lagging districts have a net negative coefficient (68,908.82 – 101,843.56 = -32,934.64 for each additional percent of value-added that is dedicated to loan servicing). This suggests that – even for those manufacturing firms that can secure credit – increased capital investment does not yield productive returns. This is a fundamental problem that should be addressed in future research.

Findings – Rural Regions

Urbanization and Localization Effects

For rural regions, we use an index of market gravity in the place of the size of the population agglomeration. We do this guided by the hypothesis that access to urban agglomerations will be more important to rural district development than the population of the individual district. Once manufacturing gravity is controlled, there are no significant overall (non-interaction) effects in any of the models for the market gravity index. This implies that, once we have accounted for manufacturing gravity and other relevant controls, the effect of nearness to population centers is not important. In Models 1 and 2, there is a differential effect on the lagging variables, suggesting that lagging rural districts with higher levels of accessibility to population centers have lower value-added and fewer firms compared with those further away from population centers. This is an unexpected result. Likely, the negative sign in Model 1 reflects population pressures, as high-accessibility rural districts that border metropolitan areas are often settlement areas for economic migrants to metropolitan areas.

Localization effects are larger and generally have more significance than urbanization effects. Models 1 and 3 suggest a stronger presence in value-added and jobs for districts with better access to manufacturing centers, and the lagging term in Model 1 suggests a net positive return to accessibility (150.74 – 140.03 = 10.71, so we expect an increase of 10.71 Rupiah *per capita* for each one percent increase in manufacturing accessibility). Furthermore, Models 5 and 6 indicate that lagging districts have net positive returns to accessibility in firm and job growth (a growth of 11.16 firms and a net growth of -1,018.29 + 1,171.12 = 152.83 jobs per one-percent increase in accessibility over the 2001 to 2006 analysis period).

We draw two important conclusions from these findings. First, urbanization effects are less important in growing Indonesia's manufacturing economy than localization effects for lagging rural districts. Second, accessibility to manufacturing concentrations is important for lagging districts seeking to increase their presence in the manufacturing economy. The gravity-based metric used here reflects both the magnitude of economic activity and distance to that activity. Although not much can be done about a district's geographic location, decreasing its the economic distance (Lin, Gill et al. 2009) to manufacturing hubs can have positive effects on growth. Connectivity policies and infrastructure development, then, can help to bring economic growth to lagging communities. Our infrastructure and development findings (discussed below) provide some further support for this assertion.

Effects of Economic Composition

The variables reflecting the extent of participation by central and local government, and local and foreign companies, in the manufacturing economy, are largely insignificant. Model 1 shows an effect approaching significance, which suggests that higher levels of value-added produced by central-government firms is correlated with lower manufacturing value-added *per capita*. In addition, the lagging term suggests that central government participation can have a net positive effect in lagging districts. This concurs with the findings for lagging urban regions above. For the overall variable, local government participation appears to have a positive effect on firms (Model 2) and jobs (Model 3). A higher presence of foreign-owned firms is correlated with fewer workers, which is likely because foreign firms tend to be

involved in extractive industries, which are less labor-intensive than other manufacturing activities.

EXPY is a perplexing indicator in all of the models where it is significant. Models 1 and 2 suggest that districts with higher levels of EXPY generate less value-added and have fewer firms. The net effects for lagging districts are also negative, though somewhat less in magnitude than the overall scenario. Furthermore, Models 5 and 6 indicate that higher levels of upscaleness in 2001 were associated with slower growth in firms and jobs over the 2001 to 2006 analysis period. We expected the effect to be just the opposite in both sets of models – that increased upscaleness in the economy would yield higher returns, particularly in lagging regions, and lagging districts with more-upscale economies would grow faster. Our evidence suggests that Indonesian districts do not capitalize on innovative capacity to make further gains in growth and development. We think this is a serious problem: innovation is key to economic development. Exploring this issue further is beyond the scope of our study, but worthy of future inquiry.

Human Capital

Median years of schooling has positive returns for the overall variables, and positive net returns for the lagging variables, in the fixed-effects equations for *per capita* value-added and firms. That is, even though the coefficients on both variables are negative, the net effect in Model 1 is 341.65 – 283.63 = 58.02 Rupiah *per capita* of value-added for each additional year of schooling. The net effect in Model 2 is 17.20 – 10.34 = 6.86 additional firms for each additional year of education.

In the growth models, only the effect on firms is significant. An additional year of schooling for the median adult is associated with a positive differential firm growth. This suggests that better-educated populations help to attract manufacturing firms, and that investments in human capital can help lagging regions close the gap with leading regions.

Energy

None of the lagging terms on our proxy for energy reliability produced significant effects, but where significant, the coefficients for the overall effects produced the expected results. Models 2 and 6 suggest that districts in which firms self-produce more of their energy, have fewer firms and grow jobs more slowly than districts with lower levels of firm-produced energy. This is an argument for investment in reliable power.

Development Expenditure

Spending on capital projects appears to be associated with positive effects in all districts regardless of leading or lagging status, for value-added and firms in Models 1 and 2. Model 3 provides evidence that development expenditure in lagging districts can have a positive effect on manufacturing jobs in these districts.

Capital

Most of our models did not produce significant coefficients. The exception in Model 6, the growth model with job growth as its dependent variable. The negative coefficient on the overall variable indicates a negative correlation between loan capital and growth. As with other variables, this is more likely the effect of larger amounts of capital being concentrated in already-leading, slower-growing districts. We are more interested in the lagging term, which suggests that capital applied to lagging regions more than makes up for the negative overall effect. In lagging regions, the net return to loan capital is -23,275.08 + 26,530.90 = 3,255.82 Rupiah for each additional one percent of value-added dedicated to loan servicing. Though we cannot comment here on the overall average benefit for all districts, we can conclude that lagging districts where capital is more available to firms, have better growth outcomes.

DISCUSSION

Table 3 summarizes the effects for the variables considered. A plus sign indicates that an increase in the independent variable is associated with a positive effect in the dependent variable. One plus or minus character indicates a count of the three indicators (value-added *per* capita, firms, and jobs) that showed an effect in that direction, i.e., two plus signs means that two of the three dependent variables showed a significant and positive effect in the models. A negative sign indicates an inverse relationship. The cells are left blank if no effect was observed. Where the lagging term was excluded from the model, overall (non-interacted) effects are counted as affecting lagging districts (because they affect all districts).

Table 3. Summary of Effect Strengths

Table 3 provides some insight into the kinds of policy interventions that could help improve the outcomes of lagging districts. Lagging districts in both urban and rural areas respond much better to localization than to urbanization. This presents two issues for consideration. First, the more immediate gains to the industrial sectors are to be gained from the concentration of industry. Second, Indonesia is failing – at least with regards to the manufacturing sectors – to leverage its urbanization for economic growth. If Brulhardt and Sbergami (2009) are correct in concluding that urbanization within countries boosts GDP growth up to around 10,000 USD per capita (Indonesia's GDP *per capita* was $3,039 nominal USD *per capita* in 2010 (WB 2010), then Indonesia can capitalize on it urban areas – perhaps in manufacturing, and perhaps in other sectors.

In both urban and rural districts, the presence of state- and local-government-owned enterprise boosts economic outcomes, but government participation in industry suppresses growth in urban districts. As we said above, this makes a strong case that government-led industrial growth can provide a core set of firms and value-added in lagging regions, but future policy programs should focus on growing the private sector.

The other obvious areas of intervention are in education, power, infrastructure, and capital. A better-educated population consistently produces better economic outcomes in this analysis (all four model sets), indicating that lagging regions with a better-educated public are both better off and grow faster than their counterparts with lower education levels. The variable reflecting energy reliability, percent of energy that is generated by the firm, shows negative signs across all four sets of models, indicating that higher levels of self-generated power are associated with negative economic outcomes in the manufacturing sectors.

There is some evidence that increased expenditure on infrastructure is associated with positive effects in lagging rural districts. This encouraging result is somewhat diminished by the reverse finding in urban areas: increased infrastructure expenditure is associated with diminished outcomes in the fixed-effects models, and slower growth in the CAPGR models. Although this may simply reflect the long way that some lagging urban districts have to go to begin producing net returns on infrastructure investment, the positive effect in lagging rural regions – which would presumably be even more behind in infrastructure development than the urban districts – suggest that some other forces may be at work that are hindering urban districts from developing net positive return on infrastructure investment. This topic is worthy of significant future study.

Finally, our findings provide some evidence that the injection of capital can improve the outcomes for lagging rural districts. For the same reasons as with infrastructure expenditure, the findings for urban regions are worrying. If rural districts can realize positive growth returns with the infusion of capital, then it stands to reason that urban areas can do the same. This suggests that there are different challenges faced by Indonesia's urban and rural districts. Identifying these challenges and suggesting strategies for surmounting them, should be addressed in future research.

The practice of multicultural planning in American and Canadian cities

Abstract

There is a disconnect between academic discourse about urban planning's neglect of cultural diversity and the robust embedding of ethnic cultures in the landscape of North American cities. We assess how planning practice is responding to cultural diversity through culturally sensitive policies adopted by municipalities in selected metropolitan areas in the United States and Canada. Using an index of multicultural policies as the basis of a questionnaire, we surveyed local planning departments in major immigrant-rich metropolitan areas in the United States and Canada. The survey, though limited in scope, yielded revealing findings on planning practice. Planning departments, led by market initiatives and community demands, are accommodating cultural diversity on a case-by-case basis, particularly in large and medium-sized cities. Canadian cities have gone farther in adopting multicultural polices, but American cities are not far behind. Practice is outpacing theory, which is largely occupied with advocating greater sensitivity to cultural differences and emphasizing measures to involve ethnic minorities. We find that planning processes are already responsive to ethnic minorities, but challenges lie in reconciling competing objectives in land use, development, and the provision of community services. This article not only illustrates the state of multicultural planning, but also points to a strategy of reasonable accommodation of cultural diversity.

Key words: multicultural planning, culturally sensitive policies, cultural diversity and urban planning, pluralistic planning.

Research support: The authors wish to acknowledge the help from three Research Assistants, Alfiya Kakal, Nisha Shirali and Amanda Chen, in administering the survey and analyzing the data collected. The survey was partially supported by funds from the Dean, Faculty of Community Services at Ryerson University.

Mohammad Abdul Qadeer AICP, FCIP (mq35@hotmail.com) is professor emeritus at the School of Urban and Regional Planning, Queen's University, Canada. His article on pluralistic planning for multicultural cities (JAPA 97) was the 1998 Honorable Mention for Best Article. He has published numerous articles and book chapters on multicultural planning and ethnic enclaves, many co-authored with Sandeep Agrawal.

Sandeep Kumar Agrawal AICP, MCIP (sagrawal@ryerson.ca) is a professor of urban planning and management at Ryerson University, Canada, and director of the Master's program in the School of Urban and Regional Planning. He studies the transformative impact of immigration, ethnicity, and religion on urban landscapes and its effects on urban planning practice and policies.

The practice of multicultural planning in American and Canadian cities

Introduction

Ethno- racial diversity of urban populations in cities of the US and Canada has reached levels beyond the point of minorities being dotted among white majorities of European origins. Increasingly, these cities and even states are turning into majority- minority areas, where whites are less than 50% of the population and minorities are made up of many groups, from native born Blacks, aboriginals, as well as the second generation and immigrant Latinos, Asians, South Asians, Africans etc. William Frey, a demographer at the Brookings Institute, concludes from an analysis of the US 2010 census data that of the 50 largest cities, 32 are now majority non-white and among those cities are not only in New York, Los Angles but also in small southern cities such as Austin and Charlotte (Frey2011). Moreover, the minorities are not largely concentrated in central cities but they have a proportionate share of population in suburbs, namely 35% of suburban residents in 100 metropolitan areas are non-white minorities equal to their share in the total population. Canadian cities are also heading towards majority-minority status. Markham and Brampton were already majority immigrant (mostly non-white) cities, Mississauga and Toronto city were at the cusp of majority-minority by the 2006 census as were Richmond and Surrey in the Vancouver metropolitan region. They would have turned into majority immigrant cities by now.

This demographic transformation of the North American cities is realigning the urban economic organization, social structure, ethnic and race relations as well as politics and power. Today's city is a new city on the old foundations. This transformation necessitates

rethinking of both planning theory and the practice. Of course, both the academe and profession are responding to this challenge though somewhat at variance from each other. Under the rubric of multicultural planning or planning for diversity, a substantial volume of literature has emerged critiquing the practice and exhorting planners about equity and responsiveness towards ethno-cultural minorities, particularly asking for the accommodation of their cultural differences, implying that the current practice is deficient on this score. (Sandercock 2003, Burayidi 2000, Pastieau and Wallace 2003, Qadeer 1997,2009, Milroy and Wallace 2004, Reeves 2005, Viswanathan 2009).

Practicing planners write sparingly about their approaches and experiences. Yet they point to the thriving ethnic enclaves and business districts, malls and mosques, fairs and parades, involvement of immigrants and minorities in public policy discussions including the provisions of translation and interpretation services, and the most striking evidence of the inclusiveness of today's cities lies in the parade of ethnic restaurants, music festivals and cultural shows and other manifestations of the multicultural civic life. Professional planners imply that the vibrant multiculturalism of cities is a testimony to their responsiveness to ethno-racial groups' needs[1]. Particularly, urban planning can be credited to have evolved through its responsiveness to immigrants needs (Vitiello, 2009).

The divergence between the discourse of planning theory and urban planning practice regarding the state of responsiveness to the interests of ethno-racial minorities has inspired this article. It attempts to answer empirically the question: how has urban planning as an institutionalized practice responded to the growing ethno-cultural diversity

of North American cities? In order to answer this question, we will briefly review the planning theory (in fact a series of opinions and propositions) and examine what guidance it provides to urban planners. This review combined with empirical evidence will cast light on the relationship between the theory and the practice of urban planning on the one hand, and point out the scope and limits of accommodating ethno-cultural differences in the shared spaces of cities, on the other.

Cultural diversity and equality as the goals of multicultural planning

The discourse about the incorporation of ethno-cultural differences in urban planning processes and policies is rooted in two values: diversity and equality (Reeves 2005, Sandercock 2003). Diversity is the variation of forms in a social, biological or economic system or organization. In our context it is about the recognition of cultural differences and racial identities among people both as individuals and groups. Class, race and ethnicity have been the historical markers of social differences, but recently gender, ability (disability), age and, in some instances, lifestyles have come to be the bases of defining differences in people's needs, identities, and entitlements. Our focus is primarily on ethnic-cultural diversity, which includes both racial and cultural markers, and its bearing on urban planning policies and processes.

Equality is the right or entitlement to equal access and fair treatment in the public sphere, regardless of race, ethnicity, gender, etc. The Canadian Charter of Rights and Freedoms states clearly: "Every individual is equal before law and has the right to the equal protection and equal benefit of the law without discrimination based on race, national or

ethnic origins, color, religion, sex, age or mental or physical ability" (Constitution Act 1982). The Fourteenth Amendment of the U.S. constitution (1868) and U.S. *Civil Rights Act* (1964) as well as many court rulings confer similar rights. Both countries have enacted human rights legislation as signatories to the Universal Charter of Human and Minority Rights. These laws firmly lay down equality as a goal of public policies. Equity, frequently used as a synonym of equality, is the realization of the right of equality and the results obtained there from. One talks of equity when referring to the policies and programmes through which the principle of equality is implemented. It is essentially the result of equal treatment with recognition of differences. Recognition of diversity would be an empty slogan without equity in the provision of public policies, programs, and services and equal access to the planning decision-making processes. This is how diversity comes to be combined with equality as the basis of urban planning's responsiveness to ethnic differences or in other words multicultural planning.

Academic discourse on diversity and urban planning

Paul Davidoff's seminal article, "Advocacy and pluralism in planning" (1965) was the first to recommend addressing diversity of communities and interests through planning, instead of conceiving singular plans in the name of unitary public interest. It laid open the path to the recognition of the divergent goals and needs of Blacks, the poor, and ethnic minorities.

The rise of feminist theories and their influence on planning thought combined with the emergence of large Hispanic, Asian, and Eastern European ethnic communities from the

post-1965 wave of immigration, have extended the definition of diversity to include ethnics, immigrants, women, and gays among the objects of pluralism in planning (Burayidi 2000, Qadeer 1997, Sandercock and Forsyth 1992, Spain 1992, Thomas and Krishnarayan 1994).

The academic discourse largely revolves around two themes: 1) the biases in the dominant paradigms and 2) the advocacy for including the perspectives of women, Blacks and ethno-cultural minorities in planning theory and practice. Leonie Sandercock speaks for many theorists in pointing out "some of the glaring absence in mainstream account of planning history" (Sandercock 2003:45). The excluded interests and perspectives (such as ethno-racial minorities and women) point to the "relationship of planning to power and the power of the system of thought" (Sandercock 2003:45).

Generally, planning theorists are critical of the planning approaches, methods, and practices applied in culturally diverse cities, which would include most North American cities now. Their criticism is built on four sets of propositions.

1. Urban planning is embedded in Anglo-European cultures and elevates their perspectives into universal values, sweeping away cultural differences. Yet culture matters, as Burayidi says, including the cultures of minorities (Burayidi 2000:2). The built environment is culturally inscribed and the planning system is the agency for imprinting it (Thomas 2008). This proposition is sometimes extended to add institutionalized racism and discrimination as other forms of white euro-centredness.

2. The modernist bias of planning theories, emphasizing scientific reason, technical rationality, and what historians call "the Enlightenment tradition," predispose urban planning to ignore diversity of traditions, customs, and cultural values. The rise of citizen participation and community-based modes of planning are counterpoised as the post-modernist answers to the modernist biases of planning processes, as are qualitative methods, discourse analysis and story telling are elevated to be the methods of information gathering (Burayidi 2000, Pestieau and Wallace 2003, Reeves 2005, Sandercock 2003).
3. Cultural differences should not only be recognized, but also expressed in planning policies and programs. Milroy and Wallace maintain that "Ethno- racial diversity is not a separate environmental condition that must be processed through the planning framework. It is the framework and planning sits in it (Milroy and Wallace 2004:4) A vision of multicultural planning should guide practice, in which the goals and values of different communities are fully taken into account. This argument is couched in abstract terms such as, "the right to difference and the right to city…recognizing the legitimacy and specific needs of minority or subaltern cultures… to participate as equal in public affairs" (Sandercock 2003:103).
4. From the above critiques are constructed visions of new planning paradigms that emphasize expansive goals for the profession and prescribe community organizer's virtues, roles and skills for planners. The discourse shifts to their personal qualities and organizational cultures, calling for "new modes of thought and new practices … (shifting away) from outmoded assumptions embedded in the culture of Western planning" (Sandercock 2004: 140). Leonie Sandercock offers a planning imagination

based on four key qualities: i) political- to be alert to the politics of who gets what from their proposals, ii) audacious- daring to break rules, iii) creative – both in the form of offering visionary leadership and in the ability to mobilize creativity of residents, iv) therapeutic- to bring people together for working through their differences. It involves dialogue and negotiations across the gulf of cultural differences (Sandercock 2004 : 134-139). Patsy Healy observes that planners are under pressure not only "to absorb new sensitivities and demands in their thought worlds and practices, but (also) to transform their own cultures" (Healy 2003: 245). Leela Viswanathan demands from planners postmodernist and postcolonial imagination which brings "to the fore ideas about identity and citizenship as associated with colonization, immigration and naturalization…. with conceptions of justice, in particular, the struggles of recognition and redistribution" (Viswanathan 2009: 169).

From these propositions, planning theorists have constructed vigorous critiques of planning practice that form a part of ongoing arguments about procedural planning theory and the processes of decision- making in planning. Even suggestions for making planning systems more responsive to diversity are largely conceived in terms of increasing the participation of minorities in planning processes and powers. In fact, the theorists often use the term planning without any adjectives, such as urban, which define the institutional parameters of the practice. They conceive of planning as a societal planning or some form of generalized community planning. They rarely engage with the substance of urban planning, namely with strategies, policies, programs, and proposals for land use

and development, housing, services, environment, economic development, and transportation in cities and metropolitan regions. Even in terms of the planning process, the arguments of advocates of multicultural planning are dated. The involvement of citizens is now a legislatively mandated part of the planning processes and minorities are not unrepresented. The practice of planning has long been communicative and collaborative (Healey 1997, Innis 1998).

So how does one square the vibrant multiculturalism of New York, Los Angeles, Chicago, Toronto, or Vancouver with critiques suggesting that the interests and needs of ethnic communities have been neglected in the planning practice? What of the thriving Chinatowns, Barrios, India Bazaars, and other ethnic commercial areas and malls, the expanding ethnic economies, the national and religious parades and festivals, the multilingual street signs, and the range of religious institutions in the cities of the US and Canada and slow but steady advance of minority representations in local and regional authorities?[2] There is an obvious disconnect between the theory and what can be seen, heard, or even smelled in our cities.

This is not to suggest that minorities' interests are fully reflected in urban planning outcomes or there are no structural biases against communities of colour, the poor, and the disadvantaged.[3] Members of ethnic groups, like everybody else, are frustrated by the cumbersome, costly, and time-consuming planning processes. Paradoxically, these complaints are themselves partly the result of the extensive participatory requirements of the planning processes, as practicing planners often point out.

Planning theory presents a static view of planning institutions, as well as of the cultures of urban communities. However, both are evolving. Planning institutions are shaped by national and regional legislative and political systems and embedded in the social values and ideologies of societies. They change with socio-political systems. The American planning system has been restructured by the Civil Rights movement of the 1960s and subsequent national and state legislation and court cases. Equal opportunity laws and fair housing provisions, employment equity and requirements for the equitable distribution of public services have had visible effect. Since 1980s, the conservatives' ideologies are realigning urban planning institutions. Similarly Canadian planning institutions are subject to the country's multiculturalism policy (1971), the Charter of Rights and Freedoms (1982), and the *Multiculturalism Act* (1988), as well as other equity and cultural rights provisions Planning practices operate within the framework of these values and laws. It cannot be discriminatory without being challenged in courts and undermined in the political arena.

Similarly ethno-racial cultures are not static and are continually affected by technology, economy, and interactions with society as a whole and with each other. Processes of fusion, hybridization, and differentiation keep transforming all cultures. The fluidity and dynamism of ethnic cultures has to be acknowledged in assessing urban planning's response to cultural differences. It is a mistake to regard ethno-racial cultures as fixed and always at variance with the dominant values. When minorities are becoming majorities, new challenges of inter-minority relations and mutual recognition are arising.

Finally, an assessment of urban planning's responsiveness to diversity has to take into account competing demands on planners and the multiple objectives of planning policies and programs. Urban planners are answerable to city and regional elected leaders, higher levels of governments, legislative bodies, and diverse local communities. Also they have to make trade-offs among goals of common good such as sustainability, affordability, cost-effectiveness, public health, job creation, fair housing, the reduction of car dependency with the accommodation for cultural differences .

Obviously, diversity cannot be pursued single-mindedly without regard to other goals of urban development. Howell Baum has summed up planners' challenge in accommodating cultural differences in the title of his article, "Culture matters – but it shouldn't matter too much" (Baum 2000). We would rephrase this as Culture matters, but it should dovetail into the common interests and goals of a community as a whole. Accommodating cultural differences should be conceived as a two-way process in which responsiveness to culture is accompanied by the incorporation of common interests in community cultures.

Although planning theory is primarily focused on modes of planning, but there is a growing body of case studies that describe the workings of the planning systems around issues of land uses, housing and community services. They range from development of multicultural places of worship, ethnic malls, neighbourhood and housing (e.g. monster home controversies) policies, programming of community services and, special use permits (Preston and Lo 2009, Poirier, Germain and Billett 2006, Harwood 2005). These

case studies are as much the evidence of the demands and controversies arising from cultural differences as they are the examples of the balancing acts of the planning practice to work through divergent interests, albeit by muddling through.

Two sides of multiculturalism and urban planning

A culture is made up of a web of norms, values, beliefs, and attitudes that serves as a map for the ways of life of a group.[4] The term 'culture' applied to ethnic communities and religious, or lifestyle groups, forming part but not the whole of a society, is of limited scope. It is essentially a (sub) culture embedded in the mosaic making up a national or societal culture. This multiculturalism is evident in the lived reality of the social life in the United States as much as it is an official creed in Canada.[5]

Multiculturalism is a two-sided coin. One side stands for the private domain of family, domestic, and community institutions of distinct beliefs and behaviours in which (sub) cultures operate. The other is the public domain of laws, economy, citizenship, education, technology, official language(s), and environment in which common values, norms, symbols, and even everyday etiquette (such as using subways) reign (Rex 1996). Cultural diversity is complemented by shared but evolving common ground. The construction and reconstruction of common ground, incorporating the interests of minority (sub) cultures, is a necessary part of an inclusive society.

Urban planning plays both sides of multiculturalism. It is expected to meet the culturally defined needs of diverse groups and reconcile them with the common ground of space,

environment, and provision of services and facilities (Qadeer 2009). A city itself is a form of common ground ruled by public interests and collective goods. Here the health, welfare, and satisfaction of some are indivisible from the well-being of others. The expression of cultural differences in the private domain goes hand-in-hand with their reconciliation with the norms, standards, and values of the public domain. Fulfilling these two demands is the challenge of urban planning practice.

Accommodating cultural differences in urban planning

In urban areas, the cultures of ethnic and lifestyle communities are expressed in their preferences for housing, neighbourhoods, jobs, and services. They are also represented in strivings for a fair share of power and participation in civic decision-making. What brings this about is the strategy of reasonable accommodation of cultural needs, often practiced as cultural differences come into clash with the embedded values in planning norms and policies. As proposals to develop synagogues, mosques and Mandirs uncover the tilt towards churches in the planning and zoning polices, the policies and standards are appropriately revised to accommodate these new places of worship (Germain 2009, Agrawal 2009, Hequet 2010)

The strategy of reasonable accommodation has not been formally defined in planning, but it is implicit in planning practice and now increasingly referred in planning reports. . It is based on long practiced legal and public policy doctrines. A demand may be accommodated if it does not cause undue hardship, unreasonable cost, the disruption of an organization or institution's operations, infringement on other people's rights, or the

undermining of security or public order (Bouchard and Taylor 2008:19). Reasonable accommodation is not an uncontested concept. Its critique comes from both the right and left perspectives. For the commentators of the right it is a question of the limits of accommodation and reasonableness. For the left, it is the primacy of the rights of minorities that define both the scope of reasonableness and the extent of accommodation. Arguments range around specific practices; is face veil of Muslim women in public places a right to practice religion freely or stepping outside the boundaries of reasonableness from the perspective of national values of secularism? As the idea of reasonable accommodation has been injected in Quebec's political discourse, it is there that much of debate about it is presently raging (Nieguth and Lacssagne 2009).

Reasonable accommodation has long been the guiding principle in the legislations of occupational health and safety, disability management and educational administration. In practice it is a pragmatic and balanced approach to accommodate differences while maintaining institutional integrity. In urban planning, reasonable accommodation means that the cultural needs of a community should be balanced against common interests of a city as a whole and the criteria of fairness and equity for others. Leonie Sandercock acknowledges common good and maintains that it "must be generated not by transcending or ignoring cultural and other differences (the liberal position) but through their interplay in a dialogical, agnostic political life" (Sandercock 2003:104). Urban planners have the challenge of tacking between the two currents, common good and cultural differences. Paul Davidoff's model of advocacy planning also envisages interest-driven community plans as means of generating value – explicit alternatives to be

debated in the public arena allowing for trade-offs among divergent groups and interests (Davidoff 1965).

Framing planning practice

We may reiterate that our focus is on the institutionalized urban planning. The term "reasonable accommodation" suggests that the urban planning practice should include policy measures to respond to cultural diversity within the parameters of common good and equity for others. These measures encompass the full range of activities that constitute urban planning, namely from procedures to ensure the representation and participation of ethnic communities in planning processes to policies for the provision of culturally sensitive housing, neighbourhood and land use plans, and community services for members of ethnic minorities and immigrants. This is how the needs of multiple (sub) cultures can be accommodated, while advancing area-wide objectives in equitable ways. Using the range of substantive activities that fall in the jurisdiction of urban planning as the basis, we have drawn on the policy index from Qadeer (2009) as the yardstick for measuring the responsiveness of planning departments, see Figure 1[6]. It captures a range of initiatives conceivable in North American urban planning practice and serves as the tool of our survey of culturally responsive planning practices in major metropolitan areas of the United States and Canada. It can also be used as a guide for multicultural planning.

Figure 1 about here

The survey

We followed an empirical approach to assess how urban planning departments respond to cultural diversity. In 2009 we mailed or e-mailed a questionnaire to municipal planning departments of central cities, suburbs and exurban jurisdictions of (selected) metropolitan regions in the United States and Canada. The regions selected for the survey are the first and second tier gateway areas, known in the literature for their diversity. The survey did not include regional or metropolitan municipalities of these Census Metropolitan Areas or Regions. Included in this survey were the municipal planning departments of the component municipalities of Los Angeles, San Francisco, New York, Chicago, and Houston metropolitan areas in the United States and Vancouver, Calgary, Edmonton, Toronto, and Montreal metropolitan regions in Canada. All in all, 109 large and small municipalities were contacted by e-mail and followed up in many cases by a second or third wave of questionnaires and calls to the offices of directors of planning. We addressed the questionnaire to the directors or persons in charge of planning in all municipalities asking that it be filled by a managerial level professional fully knowledgeable about the jurisdiction's policies. A total of 42 completed questionnaires were received from 23 U.S. and 19 Canadian municipalities, a return of 38.5%.

It is not a statistically random but a purposive sample. We wanted to measure how some high-immigrant areas are responding to cultural diversity in planning practice. The aim is to get some practitioners' perspectives on what they are doing to accommodate ethno-cultural differences. It is not to generalize for all North American cities .The questionnaire was based on the index of policies shown in Figure 1. Questions were designed to assess the incidence of these policies in municipalities. The questionnaire

also included open-ended questions eliciting comments and elaborations and asked for information such as the percentage of immigrant population in the particular city and some indicator of the economic base.[7] The answers to these open-ended questions have been used to triangulate, confirm and explain the responses to the closed questions and to get some descriptive accounts of measures taken.

The practice of culturally sensitive planning

The responses show a clear pattern in which large cities (those with populations of more than 500,000) have adopted a substantial majority of the 19 policies listed in the index. The mean number of policies adopted is 15.4 (out of a maximum of 19) for Canadian and 12.6 for the American large cities of the sample. Figure 2 shows the distribution of policies adopted by large, medium-sized, and small cities differentiated by the country. These sampled places are within metropolitan regions; "small" usually means an exurban municipality.

Two trends stand out from Figure 2. First, the Canadian policy of multiculturalism is reflected in the higher values of the mean number of adopted policies by large and medium-sized cities, with small municipalities lagging behind. Second, large American cities, though lagging their Canadian counterparts overall, were also following most of the listed policies. American medium-sized and small cities were almost at the same level in terms of adopted policies. All in all, the incidence of culturally sensitive planning policies is related to the size of the municipality and the country in which it is located.

Statistical tests of the significance of these relationships show that U.S./Canadian differences of mean values are significant (0.05 level) for large and medium-sized cities, but not for the small cities.[8]

These observations suggest that the planning practice is fairly responsive in initiating multicultural policies in these cities. We are not witnessing here a striking lag in the initiation of multicultural measures. These responses are not a proof of the outcomes of these measures. For outcomes we have looked at the generalized state of the North American cities regarding their accommodation of diversity.

Figure 2 about here.

The 19 listed policies have been grouped in three clusters. Policies number 1 to 5 relate to factors such as the use of minority language(s), representation and inclusion of ethnic groups in decision-making, and routinely using ethnic variables in analysis. The other two policy clusters are land use and development polices (numbers 6 to 11 and 14 of the index) and policies relating to community services to meet ethnic needs (policies 12, 13, and 15 to 19). Figure 3 provides a cross-tabulation of the incidence of 19 policies according to the size of city and the country. Figure 4 is extracted from Figure 3. It shows the weighted average (standardized mean) of the incidence of policies in the three clusters.[9]

Figure 3 about here

Figure 4 about here

Before getting into specific policies, we want to paint an overall picture by looking at Figure 4 first. The patterns noted above are confirmed by this table. Large and medium-sized Canadian cities use a larger number of policies on average than American cities in all three clusters. Small cities show the reverse pattern.

In terms of the incidence of policies in the three clusters, the differences among them are notable. In all sampled cities, land use and development policies have the lowest level of use. By and large, planning process policies have the highest average values, followed by the policy cluster of community services. Small Canadian cities vary slightly from this pattern in that community services scored relatively high on the mean values.

What this all means is that the sampled cities, specifically the large and medium-sized ones, were following most of the policies that promote the inclusion of the interests and voices of ethnic groups in planning decision-making. This finding goes against the academics' insistence on the neglect of ethnic interests in the planning process. Policies for accommodating cultural diversity in providing community services are the second most common practice among the sampled cities. Land use and development policies have the lowest use of the three clusters. Yet it does not mean that little is being done to accommodate cultural diversity in this area. This will be discussed later.

To probe these patterns further, we examine the incidence of policies individually as shown in Figure 3. None of the 42 cities had adopted any citywide policies for the development of "ethnic neighbourhoods, places of worship, and other cultural

institutions" (policy 7). Such developments, being plentiful, have occurred through market processes and under the rubric of zoning and site plan regulations. The creation of such neighbourhoods and institutions has been worked out on a case-by-case basis rather than by any overarching policies of culturally specific development. The next least-used policy is the deliberate development of ethnic business enclaves or malls, such as Asian malls. In responding to questions on how these commercial developments have come about and what role the city played, only six cities, Chicago in the U.S. and Toronto, Montreal, Edmonton, Saskatoon, and Richmond in Canada, indicated that they either designated such developments as special districts or had special commercial policies for them. The other 35 indicated that these developments had occurred within the scope of overall policies with some case-by-case adjustments.

The most frequently used policies are numbers 14, 18, and 11 with frequencies of 30, 30, and 27, respectively, out of 42 (Figure 3). These are policies intended to protect ethnic heritage, including the heritage of indigenous people, promote ethnic art, culture, fairs and parades, signage and street names. Planning departments have varying roles in relation to these policies; some fall directly in their jurisdiction, while for others their role is advisory. For example, in the matter of signage, Montreal must conform to the Province of Quebec's official language laws, which give primacy to French for public signage. San Jose in California, under the rubric of its Strong Neighborhood Initiative (SNI), gives wide leeway to local communities to set cultural or ethnic identity as a priority goal. Certainly, most ethnically diverse cities have streets and squares named by the ethnic identity of an area, such as Greek Village, Little Italy, or Chinatown. Toronto

had 310 street closures in 2002 for parades and community events. Its Caribana parade of Caribbean dance and music annually draws about a million spectators every year. Responsiveness to cultural diversity is also manifest in community events and initiatives.

Figure 3 supports the observations derived from Figure 2. Policies for cultural accommodation in community services generally show a wide range of usage, ranging widely from 12 to 30 cities out of 42; paralleled by policies for accommodating diversity in planning processes, falling in the range of 19 or 24 cities for each policy. The incidence of land use planning and development policies brings up the rear, in the range of 0 to 19 cities, with 27 being an outlier. The differences by the size of city and the Canadian/U.S. divide are also confirmed by these findings.

We also probed some other relationships, most of which turned out to be weak. A brief summary of those probes is shown in Figure 5.

Figure 5 about here

We attempted to see whether the proportion of immigrants in the population of a city affects the number of multicultural policies it adopts. We were interested to determine whether the percentage of immigrant is an intervening variable in the relationship between city size or US/Canada location and the number of policies.

The correlation coefficients for the percentage of immigrants relative to the number of policies of cities differentiated by sizes and countries, for six samples controlling for the

city size and the country were calculated (Figure 5). The results show that the percentage of immigrants as an independent variable has either no or very little effect on the number of policies adopted. Certainly the large and medium-sized cities of both countries have low correlation coefficients and are not significantly affected in the adoption of policies by the percentage of immigrants.[10] Small cities are the only ones with a significant correlation between the two variables. It may be that once a certain threshold of immigrant population is reached in case of medium and large cities, variations in the percentage of immigrant population make little difference. Whereas, for small cities falling below that threshold, this variable has some effect. Overall, this analysis suggests that the percentage of immigrants is at best a weak intervening variable, largely applicable to small places.

At this point, we turn to the interpretations of these findings for the broader question of the responsiveness of planning practice to cultural diversity.

Interpretive discussion

What do the findings of the survey mean for the broader discussion of multicultural planning and responsiveness to cultural diversity? We believe they are relevant to the three areas of planning practice.

1. Representation in the planning process

The planning process, by and large, is well attuned to the needs and interests of ethnic minorities. As our survey indicates, this is particularly true of large and medium-sized cities in both Canada and the United States, where ethnic diversity is a structural

condition. Ethnic minorities are drawn into the citizen participatory processes of decision-making, which are now deeply entrenched legally and institutionally in urban planning. Over the years, innovative approaches continue to be forged to involve minorities and other communities of interest more closely in planning processes. From translation and interpretation services, kitchen meetings, public hearings, task forces, community mobilization, and web dialogues to mediation and negotiation among conflicting interests, a host of techniques are employed to involve minorities and other communities.

Examples of the use of innovative techniques for involving citizens, particularly minorities and immigrants, are a staple of planning reports and practitioners' journals such as *Planning* and *Plan Canada*. Vancouver, for example, has a protocol for providing translation and interpretation services. New York's mayor Michael Bloomberg issued an executive order in 2008 for all agencies to provide language help to people who spoke little or no English.[11] Similar practices are followed by most of the large and medium-sized cities we surveyed. Yet it takes resources to employ translators and interpreters. Even then such services can only be provided for major linguistic groups, e.g. Chinese, Korean, Latino etc. but not for all groups which number could run into hundred or more. The point is that citizen involvement is a necessary condition for urban planning exercises and minorities are often actively involved, with support from planners within the scope of resources.

The empowerment of minorities through representation in city councils, planning boards, or planning departments is not, however, coming about in parallel with the increasing number of immigrant ethnics. Breaking into the power structure is largely a political process and not a planning exercise. Minority representation in these bodies is increasing in Los Angeles, New York, Toronto, and Vancouver as the composition of the population changes and ethnic minorities collectively become the majority. The conflict of interests between whites and non-whites or native-born versus immigrants may give way to interethnic political competition and cultural clashes among Latinos, Blacks, Chinese, South Asians, and other groups.[12]

Planning theorists have not moved beyond the narratives of the 1970s and are not taking into account rapidly changing reality. Planning processes are including minorities and responding to cultural diversity to a large degree in cities where the needs are pressing and the infrastructure of participation has developed.[13] The locus of culturally responsive planning lies in substantive issues of land use, development policies, and equity in the provision of services and opportunities. These are the arenas of resource allocation in which competing interests vie with one another and limitations of resources have major influence. The post 2008 era of budgetary deficits is already affecting the overall planning activity in these substantive matters. Ethnic communities' needs are bound to be affected.

2. Equitable cities and reasonable accommodation

We have found a paradox of multicultural practices in land use and urban development, the core area of urban planning. Our survey shows a low incidence of citywide policies for the siting and development of ethnic places of worship, cultural institutions, commercial areas, enclaves, or other spatial manifestations of multiculturalism. Canadian cities such as Toronto, Edmonton, and Richmond have more frequently instituted such policies compared with the U.S. cities in our sample. Yet such developments are plentiful in both countries and are thriving and vibrant assets in many cities. Policies or no policies, cultural diversity has been incorporated in the spatial organizations of North American cities.[14] Relatively low incidence of land use policies in our survey may be a reflection of the land use decision being site specific and thus accommodated through community negotiation processes incrementally and not through city wide general policies and standards.

Cultural accommodation has apparently come about by market and community initiatives on an incremental basis, case by case, through site-specific planning approvals. At the macro level, multicultural planning practice has languished, but at the micro level, it has flourished. Ethnic minorities have created a lively community life in North American cities. This does not mean that their situation is free from problems, including intimations of discrimination. Yet these institutions and identities continue to be incorporated in urban structures.

This is by no means an argument for not bothering with city-wide multicultural policies. The need for comprehensive planning is pressing. The major issues of integrating ethnic

enclaves, commercial areas, and institutions in the urban fabric and reconciling cultural interests with the overarching goals of sustainability, compact urban form, equitable development, good design, economic growth, and fair housing remain to be addressed. A comprehensive set of policies defining the criteria and performance standards of reasonable accommodation have to be forged to allow for mediation among competing cultural and civic goals. It is necessary to establish both the scope and limits of cultural accommodation. The bases of reasonable accommodation have to be explicitly defined in comprehensive planning goals and policies. As a start, sustaining cultural diversity should be among the goals of comprehensive plans and a legal basis for minor variations and rezoning in land use planning, within the scope of public interest, health, and welfare.

3. Restructuring community services and carving a common ground

The differences in access to housing, jobs, good-quality schools, recreation, sports and arts facilities, and cultural services arise both from inequalities of income and of political and social resources on the one hand and cultural and linguistic barriers on the other. Community services are meant to be equitably distributed. Yet ethnic communities and new immigrants regularly confront barriers of cultural predispositions and linguistic inadequacies in getting access to services, in addition to economic and political handicaps. The culturally sensitive mode of delivery of these services is meant to overcome the former biases.[15]

Pertinent to multicultural planning are two values: equality of need satisfaction and uniformity in the provision of services. Practitioners say they cannot play “favourites”

and produce one type of service for one group and another for others. Yet in many services, assumptions about needs are based on historical norms. Feminist scholars have bared many such cultural biases, even in the definitions of a family or household, and pointed out the resulting inequities. Similar cultural biases of what constitutes "need" in recreation, sports, arts, or culture have been found in the provision of such services for multicultural cities.

A city of diverse ethnicities, whose cultural and recreational policies focused only on symphony orchestra and museums, or on baseball diamonds and hockey rinks, is not accommodating the needs of communities, who enjoy Bollywood songs, Latin rhythms or play cricket or bocce. Even the policies regulating funeral services have built-in biases towards Christian rituals to the disadvantage of Hindus, Muslims, and others (Agrawal and Hathiyani 2007). These examples illustrate how cultural assumptions about the form of services affect people's satisfaction. The thrust of multicultural polices in the provision of community services is to uncover such hidden biases and find common ground to equalize outcomes and make pluralistic provisions.

Such changes are happening incrementally both in the market sphere and in the public arena. Wherever ethnic populations have increased in medium-sized and large cities, the pressures of demand have realigned community service policies. Ethnic art and culture are flourishing with the support of cities. Libraries have expanded their multilingual holdings. Ethnic business improvement services are part of many cities' economic

development strategies. In the Toronto area, municipalities have incorporated cricket fields and bocce courts in their park plans.[16] New York and Los Angeles have built cricket pitches. All in all, responsiveness to ethnic diversity can be seen in the provision of services but it is reactive rather than proactive.

Conclusions

Culturally sensitive planning in North America is a work in progress. It is vigorous in large and medium-sized cities within metropolitan regions, where ethnic communities are expanding with immigration, and emerging in small, exurban municipalities. Under the umbrella of national multiculturalism, Canadian cities are more responsive to cultural diversity than the U.S. cities. Yet the Civil Rights movement and lived multiculturalism of the U.S. have resulted in parallel developments in large American cities. New York, Planning institutions, energized by market initiatives, are responding to the demands of diverse communities, more in some places than others. Practice is outpacing theory, which is largely occupied with advocating sensitivity to cultural differences and involvement of minorities.

Our empirical survey of planning practices, albeit of a limited scope, suggests that planning decision-making processes by and large include ethnic interests. The issues that exercise planners relate to balancing ethnic demands against general interests and common objectives, as well as balancing the demands of competing communities. The greatest challenges lie in land use and urban development policies and the provision of community services, where ethnic communities' demands are most concretely expressed.

How do we sustain pluralism in planning policies while maintaining equality of outcomes, without compromising overarching goals such as sustainability, smart growth, fair housing, or job creation? Put differently, how do we construct a common ground that reflects diverse interests, but advances general health, welfare, and environmental sustainability? The complexity of balancing diversity, equality, and public interest is the challenge of planning practice. The strategy of "reasonable accommodation" appears to be the key to multicultural planning. The policy index used in this study has turned out to be a good instrument of measuring multicultural planning practice. It also offers a framework for institutionalizing reasonable accommodation.

Multicultural planning is not a new type of planning. It is not going to be a new idiom of planning. It is largely the strategy of embedding, within the existing planning system, explicit modes of reasonable accommodation of cultural diversity and constructing a common ground of objectives, criteria, and standards that balance pluralistic interests. Obviously much more work needs to be done to flesh out this strategy. At present, reasonable accommodation is happening incrementally. It has to be made more explicit and anticipatory.

[1] These opinions are expressed in planning conferences and in personal interviews. Though there is some evidence in print also see Qadeer 2009. In the magazine Planning, a planning director is quoted as saying, "the whole idea of customer service is based on respecting differences in the population and acknowledging them as positive thing" (Knack 1997). This is a common theme among planners.

[2] For example, a Google search revealed lists of about 100 mosques and 70 temples in the Toronto area; New York has 75 mosques and 30 temples and Gurdwaras; and Los Angeles has 59 mosques testifying to religious diversity of these cities. In each of these cities, new places of worship are being built every year. They would not have come about without accommodation within the urban planning policies.

[3] There is no evidence of pervasive dissatisfaction with the planning systems among ethnic minorities. Public meeting in planning have heated arguments, sometime along ethnic lines, but there is little sense of permanent deprivation among various ethnic communities, except among poor Blacks and immigrants. For example in the Toronto area, every single mosque seriously proposed has been eventually approved, although many were opposed in community meetings, sometime after appeals to the provincial planning board.

[4] There are innumerable definitions of the term "culture." We have taken the most common elements referred in these definitions. For reference, see the entry on culture in Abercrombie, Hill, and Turner 2000.

[5] Canada has officially adopted multiculturalism as a national policy and social identity. It is described in the metaphor of a social "mosaic" in contrast to the long-held view of the United States as a "melting pot." Yet, the lived reality of the United States is different. It is an amalgam of cultures with a stronger sense of national identity. That the United States is also a multicultural society is now widely accepted among sociologists and other observers of the American social life. Nathan Glazer, the dean of American assimilation studies, observes, "Multiculturalism must be accommodated whether in schools, in the work places and in public ceremonies" (Glazer 2004:72). Others have described New York, Los Angles as multicultural cities (Davis 2001, Foner 2007, Waldinger and Bozorgmehr 1996).

[6] Policy index for measuring multicultural policies is increasingly used as a tool of evaluating the effectiveness of multiculturalism. See Soroka, Johnston and Banting 2007.
[7] The questionnaire was pre-tested by a graduate student as part of his master's research work and was reviewed for consistency and clarity (Newman 2008). The survey followed the ethical protocols of survey research (e.g. promising confidentiality) and methodological criteria for validity by framing questions in objective terms and cross checking results with those of the fore mentioned study and other information.

[8] Two sample T-tests were used to compare the probability of mean values of Canadian and the U.S. cities by size for significance. The null hypotheses were rejected at the .05 level for the large and medium-sized cities but not for small cities.

[9] The weighting of means was done to standardize the size of three clusters, as two clusters include 7 policies each and one has only 5, namely, the planning process cluster.

[10] It may be that after a certain threshold level of ethnic population, there is enough diversity of interests to sustain multicultural polices. Any further variations in the percentage of immigrants may have little effect.

[11] The language help was found to be inadequate two years later.

[12] Illustrative examples of inter-ethnic clashes of values include Orthodox Jews' and Caribbean Blacks' differences in Crown Heights, Brooklyn; the conflict between Blacks and Koreans over businesses in poor areas of Los Angeles; and disagreement between Chinese and Muslims over the building of a mosque in Markham, Ontario. (See Lee 2002, Henke and Irish 2004)

[13] The infrastructure of participation includes staff resources for interpretation and translation and negotiations, community organizations and NGOs that advocate ethnic communities' interests, and the ethics of negotiation. This does not mean that there are no dissatisfactions with processes of participation. Minorities are also subject to NIMBYism and a failure to fulfill goals may be described as evidence of discrimination.

[14] A recent and striking example of site-specific accommodation of an ethno-religious institution is the Lower Manhattan Community Board's approval of a 13-storey Islamic centre near the iconic symbol of the current American war on terrorism, Ground Zero of the World Trade Centre. The proposal aroused strong emotions in view of the symbolic value of the site, yet in the end, with the support of Mayor Bloomberg, the Board in a vote of 29 to 1 approved the development of the centre in May 2010. The controversy continues to rages in the media, led by neo-conservative politicians.

[15] For example, if housing code requires that no more than two persons occupy a bedroom, then members of ethnic minorities who live in large, multigenerational families may be effectively barred from rental housing.

[16] In the Toronto area, schools offer equipment and facilities for cricket. There are scores of cricket teams and many tournaments. The city of Toronto has built a cricket field in Thorncliffe Park.

POLICY AND INSTITUTIONAL REFORM OF INDONESIAN PLANNING SYSTEM: NEXUS TO METROPOLITAN AND LOCAL PLANNING EFFECTIVENESS

Mahesti Okitasari [1], Tetsuo Kidokoro [2]

Abstract

Started in 1999, Indonesia has embarked on a program of fiscal, administrative and political decentralization in the same time. With spatial planning no longer a main policy field for the central government, decentralization had shifted the country to the most decentralized side in term of planning governance and policy. Following the decentralization program, within the span of 10 years, Indonesian planning system undergoes rapid changes with issuance of new planning policies range from plan making to land use control, thus forcing all level of governments to adapt in the new system. In the same time, decentralization movement with its devolution of power transforms the relationship between central and local governments. However, only little known about how these changes affects the planning effectiveness in regional and local level.

The concern of this paper is to examine the implication of policy and institutional changes to the Indonesian tiered planning system while reviewing the cogency of planning institutions in region-wide comprehensive plan and municipal master plan toward rural-urban development. What it offered is an understanding about the process and effect of alteration power of the metropolitan region planning compare with the pre-decentralized time. As a case study, depth identification of land use changes and correspondent instruments in Surabaya peri-urban area was done to understand the consequences of the transformations in local land use planning and its effectiveness. Assuming decentralized planning shall be able to give positive feedbacks to the local planning system and land development process with a significant decreasing number of land use change deviation that did not comply with the plan, the study discuss alternative ways of understanding why decentralization in Indonesian planning system still has long way to go to achieve its stated aims in terms of promoting good governance.

Keywords: decentralization, planning policy, land use, peri-urban.

1. Introduction

The study of decentralization has important policy implication for planning system as it related to many aspects of planning namely urban growth management, environmental conservation and property taxation. Decentralization gives local government power to regulate its planning within the general guidelines set by higher authorities. However, the transfer of power to local governments is nothing less than controversial. Precedent research claimed that decentralization will increase both efficiency and equity in the public sector because it allows customization of public services to local preferences, promotes scrutiny by citizens of government expenditures, and encourages innovation through inter-jurisdictional competition (Oates, 1972, 2006; Tiebout, 1956) while also raised problems due to lack of administrative capacity, potential corruption and the risk of raising elite (McLure, 1999; Sewell, 1996).

The importance and duality of the argument on decentralization provided the rationale for a number of studies to review decentralization in both developed and developing countries and to explore areas of consensus and disagreement among scholars on the opportunities and risk of decentralization. The evidence presented shows that results on the link between decentralization and effectiveness are vary significantly across cases (Ingram and Hong, 2007). Furthermore, the connections between decentralization and local policies appraise how decentralization is related to jurisdiction size, local environmental policy and urban economic development strategy (Fischel, 2007; Oates and Portney, 2001; Wallace, 2007).

Started in 1999, Indonesia has embarked on a program of fiscal, administrative and political decentralization (Law 22/1999 and Law 25/1999). With spatial planning is no longer a main policy field for the central government, decentralization had shifted the country to the most decentralized side in term of planning governance and policy. Following the decentralization program, within the span of 10 years, Indonesian planning system has been undergone rapid changes with issuance of new planning policies range from plan making to land use control, forcing all level of governments to adapt in the new system. In the same time, decentralization movement with its change of power transforms the relationship between central and local governments. The local government, including Provincial and Local (Regencies and Municipalities), will have a greater role in several important functions. Hence, the reform could potentially change the pattern of urban and regional development (Firman, 2003) and governance towards a pattern of spatial segregation and a fragmentation of regional development (Firman, 2009). However, only little known about how these changes affects the planning effectiveness in regional and local level. Thus, this study tried to raise questions: How does decentralization shape local governance? What are the implications of decentralization towards the policy and institutional changes?

The aim of this study is to examine the implication of policy and institutional changes to the Indonesian tiered planning system while reviewing the cogency of

planning institutions in region-wide comprehensive plan and municipal master plan toward rural-urban development. What it offered is an understanding about the process and effect of alteration power of the metropolitan region planning compare with the pre-decentralized time. The focus is on the particular case of land use change and the possible local government effectiveness on local level within the metropolitan region.

In the reminder of this paper, the relationship between the plans and the actual land use change in timely manner will be analyzed to identify the inconsistency of urban planning and urban area development will be addressed through the comparison between the planned areas as mentioned in the master plan and actual built up area, planned and actual land use structure, to highlight the difference between before and after the decentralization law was enacted. To compare the effectiveness, the disparity of building permit application and the number of incompliant land use change to draw the elasticity of local planning implementation. This elasticity is estimated using data assembled for the period from 1999 to 2009.

2. Decentralization and change of power in Indonesian governance

After experienced a nation wide reformation movement in mid 1998, the Indonesian National Assembly issued Law 22/1999 and 25/1999, regarding administration and fiscal decentralization in Indonesia. From local and regional planning point of view, both laws state clearly that the local government and local communities through local representative councils should have greater discretion in deciding what is best for the urban and regional development in their areas. However, after a decade, it remains a debate what kind of actual decentralization taken place in Indonesian governance and up to which extend the change of power from central to local government occurred.

Theoretically, decentralization leads to more power designated for local government to control its planning (Stiglizt, 1999), both preparation and implementation. It assumed that people will solve problems better at the local level, if they were allowed and can be considered an institutional arrangement that brings about participation and local decision making. Another scholar defined decentralization as transferring functions and responsibilities to lower levels of government or as leaving tasks to the market (Helmsing, 2000). Thus legislation is very important in the case of decentralization. It prescribes a planning procedure and specifies the level where the responsibilities are put, where central government has to delegate certain functions and responsibilities to lower levels of government.

While reviewing the type of decentralization and the transfer of power took place in other developed and developing countries, there are three common types acknowledged (ADB, 2008). The first is being deconcentration or the transfer of responsibility from central agencies and ministries to their regional or field units where some discretion is allowed but they are subordinate to the central authority. Second type is delegation described as moving functions from central government to semi-autonomous public authorities and corporations granted the authority of

planning and implementation. The last is devolution defined as transfer of decision-making power and authority to local governments which have the power and resources to perform relatively independently from central agency intervention. The exact meaning of Indonesian decentralization cannot be fitted into a single type aforementioned above but can be pointed between deconcentration and devolution. The essence of Indonesia's decentralisation policy reform is a shift of several government functions, responsibilities, and tasks which previously located in the central to local government (Firman, 2003). It is not intended to weaken the role of central government under the principle of as much as autonomy as possible and as much as central power as necessary (Koswara, 2000)

Before the law concerning regional autonomy and fiscal decentralisation in 1999, involvement of central government at local and regional level is very strong and at some extend there is competition within local agencies to prepare the plans due to own preference interests. After the decentralization act was enacted, all central government agencies previously located in its subordinate level were merged into its correspondent department under the authority of provincial and local government. Local and regional government planning office (Local and Provincial Development Planning Board) became the main agency responsible for planning as illustrated in Figure 1.

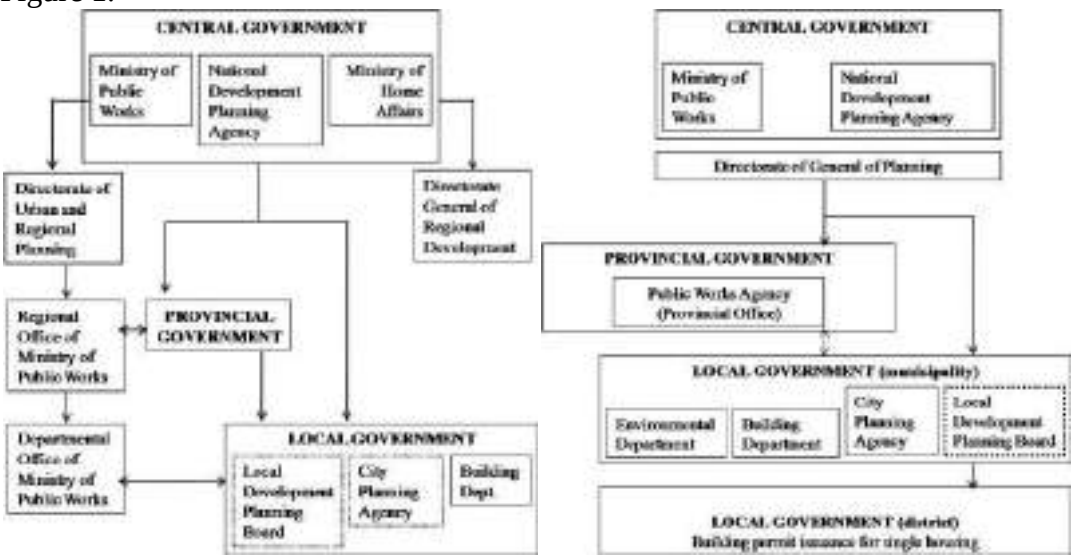

Figure 1. Indonesian Planning Administration before and after the decentralization.

According to the newest Law on Regional Administration (32/2004) amended Law 22/1999 that further defined the transfer of responsibility, decision-making and authority from central to local government, spatial planning is no longer a main policy field for the central government. It encouraged most of policy fields to be transferred to the provincial and local level with exception of foreign policy, defense, security, judicial, monetary and fiscal, and religion. At present, the process of transforming governance ideology experiencing in Indonesia already has been taken place for more than ten years but as many would agree that this kind of process result

only can be recognized in long run. When the new planning law was enacted in 2007 to replace the old one in 1992 it shifted some responsibility from master plan to district plan and introducing several new set of development control, a question was raised regarding this shift whether the new system will give more benefit to more sustainable urban development or will contribute to more negative impacts.

After the issuance of the Presidential Decree regarding spatial planning implementation, the making of regulation and management of urban planning especially those related to land use in Indonesia became even more inconsistent and confusing. Planning law still accommodate the role of central government in all planning policy aspects characterized in rigid hierarchical plan making, land cultivation, land cultivation control (Hudalah and Woltjer, 2007). While planning system still shows centralized direction, the gap caused by the centralization has been reduced since all the coordination was concentrated on the local government level but the existence of intergovernmental conflicts between local-provincial and local-central became more evident, as well as the movement of the planning practice towards informal, discretionary approach due to strong influence of private sector (Hudalah et al, 2009). Nonetheless, the central government should focus on the broad planning policy framework and cede the planning implementation such as urban land development to the local authorities. Moreover, the current Regional Administration Law in 2004 validates the decentralization principle in the spatial planning act. The importance of local citizen aspirations is applied later in spatial planning, carried out by government by involving community participation and conducted at least through a public consultation through a forum created by local authority. This means the decentralization has improved citizen participation in spatial planning from the level of informing to the level of consultation.

3. Institutional context of metropolitan and local planning system

Post issuance of the Spatial Planning Law (26/2007), metropolitan planning in Indonesia is becoming more and more complex, not less, with the changes in its planning policy. Under the same law (update from Law 24/1992) metropolitan planning policy was put into more rigid position and interconnected with other planning levels while before only as a mere acknowledgement. Subsequence to Law 26/2007, Government Regulation 26/2008 on national spatial planning specified the definition of metropolitan areas according to Indonesian context. Metropolitan is defined as an urban area covered a minimum one million inhabitants which consist of single city or urban core with its surrounding area functionally linked to each other and connected to integrated infrastructure system. Metropolitan is included in National Strategic Area, an area with a priority spatial planning due to national importance, if qualified as National Core Centre *(Pusat Kegiatan Nasional/PKN).* PKN is an urban area functioned to serve activities in international, national or several provinces level (economically). The boundary of metropolitan included in National Strategic Area is decided by Central Government through each Government Regulation in Metropolitan Spatial Planning. Boundary is based on administrative

boundary but not always according to municipality/regency boundary but can be down to district boundary.

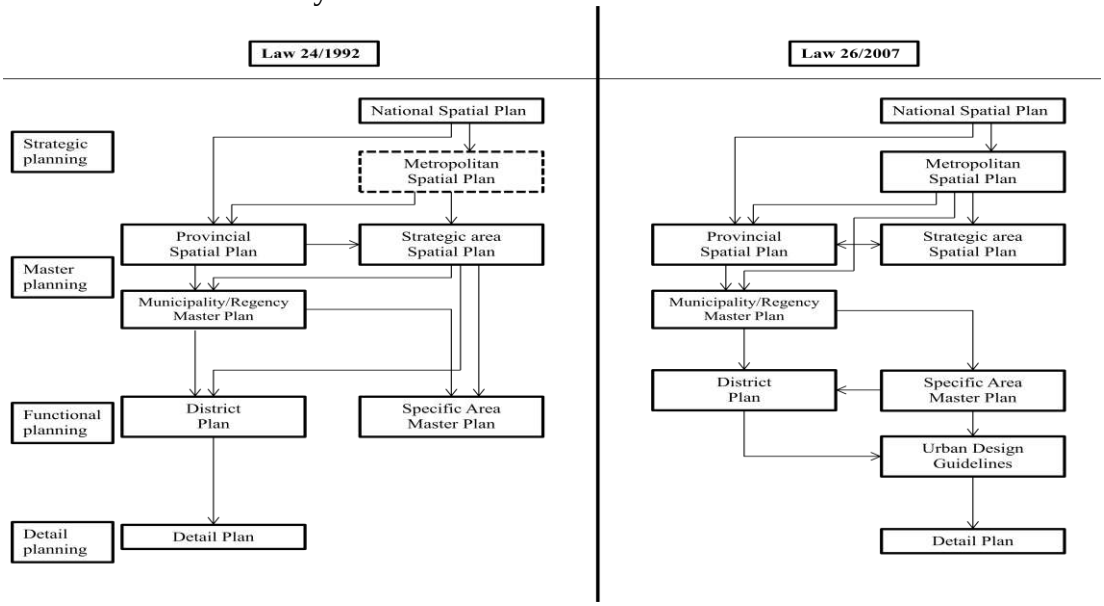

Figure 2. Indonesian Spatial Planning System before and after the decentralization.

According to the spatial planning law, metropolitan area is defined as a national strategic area and is put on the spatial plan hierarchy (same planning level as island-wide and national border area planning) and under the responsibility of central government. The spatial law also regulated the scope of planning and coordinating agency for each level of planning including metropolitan spatial plan and introduced zoning system attached to spatial plan as a planning control measurement. Zoning system shall be based on its correspondence spatial plan and refer to higher level of plan. In local level, zoning regulation was made based on detail plan and then translated into urban design guidelines. Before zoning regulation was implemented, development control on local level was done through technical plan. Since there is no fixed administration government body for metropolitan area, spatial planning documents are prepared by central government (Ministry of Public Works, Directorate General of Spatial Planning). In some cases there are development plans (transportation, settlements) but in general there is no specific long-term and medium term development plans for metropolitan area. Before 2007, some of metropolitan spatial plans were prepared by provincial government which different with strategic program prepared by central government.

As for 2008, central government has acknowledged 7 metropolitan areas categorized as the National Strategic Area in Indonesia. The first and most populated metropolitan is Jakarta the capital, served as home for 26.6 million inhabitants as per 2010, followed by Gerbangkertasusila, a metropolitan area enclosed Surabaya, the second biggest city of the country. 4 out of 7 metropolitan located in Java island, making the island as the most populated and conurbated region in Indonesia. Those four metropolitan areas spread from east to west, creating a continuous urban

corridor. Jakarta Metropolitan Area was the first declared as metropolitan area in early 1970s, translated into a regional plan created in 1975 by the Ministry of Public Works making JMA as the first metropolitan region planned by the central government. On the other hand, Gerbangkertasusila was originally planned by the regional government around the same time when JMA was introduced, making the metropolitan approach can be seen as more a bottom-up planning. Its first spatial plan was created in 1980s as a joint works of provincial and central agency. Among 7 metropolitan areas, the government initiating the planning varies among central and regional level government. At some metropolitan area, spatial plans were made by provincial government, but after the implementation of Law 26/2007 and Government Regulation 26/2008 regarding national spatial planning, it should be done by central government through Ministry of Public Works. Assessing these issues raised question whether this movement shift back the metropolitan planning to the top down planning and from decentralized to centralized planning approach.

Table 1. Metropolitan area planning in Indonesia.

Metropolitan area	Year started	Pop.	Spatial and Development Planning
JMA	1969-central	26.6	Regional Plan (1975 - MoPW) Development Plan (1980s - MoPW) Structure Plan (1985 - MoPW) Development Plan (2005 - MoPW) Jabodetabekpunjur Spatial Plan (2008 - MoPW)
GKS	1970s	9.1	Spatial Plan (1980-MoPW - Prov. Public Works Agency) Spatial Plan GKS+ (2007 - Prov. Public Works Agency) Spatial Plan (2010 - JICA, PDPA)
BMA	1980s-central	7.0	Spatial Framework Plan (1984 – MoPW) Urban Development Plan (1993 – PDPA) Under Provincial Master Plan (2001 - PDPA) Spatial Structure Plan (2005 - MoPW)
SMA	1984	5.9	Spatial Plan (1984 – PDPA) Spatial Plan (1988 – MoPW)
Mebidang	1985-provincial 2011-central	4.5	Spatial Plan (1985 – MoPW) Spatial Plan (1996 – PDPA)
Mamminasata	2003-provincial 2008-central	2.5	Spatial Plan (2001 – PDPA) Mid-Term Development Plan (2005 - PDPA)
Sarbagita	2008-central	2.2	Spatial Plan (2008 - MoPW)

Note: MoPW: Ministry of Public Works; PDPA: Provincial Development Planning Agency; BMA: Bandung Metropolitan Area; SMA: Semarang Metropolitan Area; Mebidang is metropolitan area surrounding Medan; Mamminasata is metropolitan surrounding Makassar and Sarbagita is metropolitan region enclosed Denpasar.
Statistics are from 2010 (in million inhabitants).

The influence of central government in planning extended through planning preparation, implementation as well as conflict resolution. Any spatial planning issue and dispute regarding spatial planning are handled through discussion in the central level, handled by the National Planning Coordination Board. The outputs resulted from the discussion are in the form of policy recommendation. Moreover, provincial

government has no control over local spatial planning issues handling process and only acts as facilitator for planning taking places in two or more municipalities/regencies under its jurisdiction. During technical substance consultation local government can challenge development substance from central, provincial government and vice versa as long as it is not violating zoning system. Conflicts between local and provincial government usually occurred during process of obtaining governor recommendation.

After 2009, metropolitan region coordinating scheme is conducted in provincial level in lieu with Local Planning Coordination Board (Ministry of Home Affairs Decree 50/2009) Nonetheless, the regional coordinating agency has remained left with no commanding power upon local governments to impose the metropolitan planning in their local planning. Each municipality and regency has statutory power for planning implementation but none at metropolitan level. Since coordinating between governments related to regional administration law, the agency is regulated under Ministry of Home Affairs, instead of under Ministry of Public Works which in charge of preparing the metropolitan spatial plan, making a scheme of multi departmental stakeholders maintaining the responsibility of metropolitan planning together with other ministerial agency such as transportation, environment, etc. Furthermore, central government also retained the responsibility for coordinating all planning level. This contradictive stipulation appeared due to the position of the metropolitan region as a national strategic area (according the spatial planning law), making central government to become a more prominent figure in coordinating its planning even though it supposed to be the responsibility of provincial government. Due to its importance toward national development, most of the discussions regarding metropolitan planning are conducted under the platform prepared by the National Development Planning Board and attended by correlated ministries and departments. Thus the spatial planning law marked the change of coordinating board of metropolitan area from regional level to more centralistic coordination.

In contrast with centralized direction of metropolitan coordinating system, local level planning actually demonstrated decentralization practice in Indonesian planning through change of distribution of the tasks between the different government institutions and coordinating institutions, including planning implementation. According to the responsibility shift from central to the local government, the decentralization law takes effects on the planning adoption and approval process in local and provincial level. Despite that the plans continue requiring to be adopted by law but the institutions involved no longer spread in every level from central to provincial to local level. Under the new system, the Master Plan prepared by the local goverment (Municipal and Regency) will need to get recommendation from the Governor before presented to central government approval. The appointed institution to coordinate in the central level is the Planning Coordination Board which is under the Ministry of Public Works. The Master Plan also no longer need adoption and approval from the Provincial level. The same manner applied for the Detail and Technical Plan, which only need local adoption before it is ready to be implemented.

The change of the adoption and approval check list for all plans is shown in the following table.

Table 2. Plan adoption and approval, before and after the decentralization.

BEFORE					
Type of Urban Plans	LOCAL	PROVINCIAL			CENTRAL
	Local Adoption	Governor Recommendation	Provincial Adoption	Governor Approval	MHA Approval
Master Plan	Yes	Yes	Yes	Yes	Yes
Specific Plan	Yes	Yes	Yes	some cases	Yes
Detail Plan	Yes	Yes	Yes	some cases	Yes
Technical Plan	Yes	-	-	-	-
AFTER					
Type of Urban Plans	LOCAL	PROVINCIAL			CENTRAL
	Local Adoption	Governor Recommendation	Provincial Adoption	Governor Approval	MoPW Approval
Master Plan	Yes	Yes	-	-	Yes
Specific Plan	Yes	-	-	-	-
Detail Plan	Yes	-	-	-	-
Urban Design Guidelines	Yes	-	-	-	-

Note: MHA is Ministry of Home Affairs; MoPW is Ministry of Public Works.

4. The background of the study area and the rising of local planning power

Surabaya is the second biggest city in Indonesia. Surabaya and its surrounding adjacent regencies and municipalities formed the metropolitan area of Gerbangkertasusila, an abbreviation of Gresik, Bangkalan, Mojokerto, Surabaya, Sidoarjo and Lamongan which are the municipalities and regencies formed the metropolitan region. Gerbangkertasusila is the second prominent metropolitan area after Jakarta Metropolitan Area. According to the regional development concept by the Ministry of Public works, the city of Surabaya is situated as the primary central core covering the whole region of East Java Province and the primary economic core for East Indonesia Region. The total population as per 2010 is 2.7 million inhabitants, occupied an area for about 333 sq km. However, as one of the most important city in Indonesia, Surabaya was considered lack in planning as unfortunately the city has no master plan until 1978. Due to lack of planning and its control measurement, in the fringes of Surabaya, during 1990-1995, sizeable areas of agricultural land had been converted into residential and commercial areas (Firman, 2000). The first master plan clearly sought to segregate industry from the settlement as industrial land use areas were planned to be concentrated in several places with most of them developed in the peri-urban area.

In case of Surabaya, the local government agencies that responsible for planning are: (1) Local Development Planning Board; (2) City Planning Agency, and (3) Building

Department (Public Works). However, before the passing of two pieces of decentralization legislation, Law 22/1999 and Law 25/1999, in practice, most decisions affecting Surabaya were made at the provincial if not the national level, while municipal government functioned simply as the bureaucratic institution. This quasi-centralized power was taken advantaged by the developers where the development permits process to control local land uses so as to accommodate the developer needs. Although the government considers this regulation as a form of bottom-up planning in regional development, local priorities were inevitably lost in the process of developing the national program. In terms of participation by the local stakeholders, there was a wide gap between what the regulation prescribed and what happened on the field.

For the first time since decentralization law was enacted, the master plan issued after the decentralization law, Master Plan 2003-2013, identified the consistency level of hierarchical planning in local level. It identified both consistency and inconsistency between master plan and detail plan, master plan and technical plan, and between detail plan and technical plan. Total area with inconsistent development reached 2.879,59 Ha (see Table 3). This identification shows that somehow even though it is clearly mentioned in the spatial planning act that district plan should follow the master plan but the reality shows differences.

Table 3. Identification of inconsistency between Master Plan 1995-2005 and District Plans.

Land use allocation		Area (Ha)
Detail Plan	Master Plan	
Residential	Open Green Space	203.06
Residential	Mixed use	810.06
Residential	Public Facilities/Service	52.00
Residential	Commercial	171.70
Residential	Industry	63.50
Industry	Port	184.82
Open Green Space	Industry	14.00
Open Green Space	Public Facilities/Service	221.00
Embankment/Conservation	Mixed use	289.00
Embankment/Conservation	Residential	535.70
Commercial	Residential	57.70

Mixed use	Commercial	10.00
Industry	Commercial	18.70
Industry	Mixed use	13.00
Mixed use	Industry	88.10
Total Area (Ha)		2879.59

Source: Surabaya Master Plan 2003-2013.

In the local context, the passing of Spatial Planning Law in 2007 made municipal authorities responsible for designating land uses and approving new development, and effectively recognized the municipality as the main planning entity. Greater

authority was given to the lower levels of government, thus weakening the central government's control over provinces and municipalities. The zoning system is officially introduced in the new spatial planning act. In addition to the long-established permit system, the new law required the government to prepare zoning regulation supported by environmental and building codes as key instruments for controlling land development. Following the renewal of master plan in nationwide, central government declared the minimum requirement for open green space land use allocation as mentioned in the Spatial Planning Law, however, Surabaya already tried to increase their greenery since Master Plan 2003-2013 which gave means local government put attention to the importance of this greeneries to the urban environment.

Table 4. Total area allocated for conservation area in Surabaya Master Plan 1978-2009.

Year	Total Area (Ha)
1978	7434.89
1984	5979.01
1991	2494.41
1996	2489.93
2003	4035.46
2007	4745.69
2009	7026.00

Source: compiled from Surabaya Master Plan 1978, 1984, 1991, 1996, 2003, 2007 and 2009.

5. Inconsistency between plan and reality: Planning effectiveness and development control

It is identified that large scale of deviation from the master plan happened in the peri-urban of Surabaya. It followed the development pattern of the built up area but occurred in places with close proximity to wide open space. In 1990s, the development that did not comply with the plan took place in the outskirts of the city, preferably in the borders close with neighboring regencies. This pattern continued in 2000s but the development no longer in large scale development but merely small scale and scattered developments.

The number of development that did not follow the master plan is reduced after the master plan was updated. However some developments that already occurred which found to be in accordance with master plan of 2003 becomes in disagreement with the new master plan 2007, especially those took place in the open green space and conservation area. This happened because the local government changed the delineation for the open green space and conservation area since based on the Spatial Planning Law 26/2007 the total area of those two land uses should be increased into at least 20% of the total urban land area.

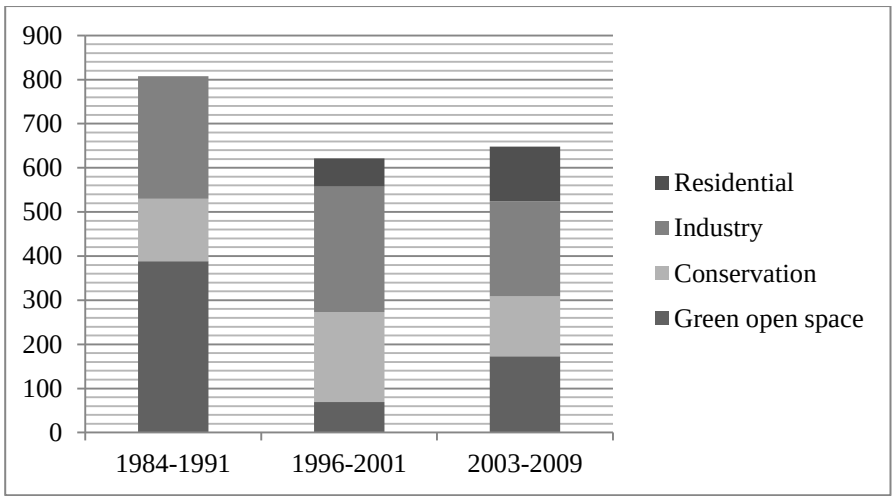

Figure 3. Proportions of the source of land being deviated.

In each period, development of residential, industrial, public facilities and service did not comply with the plans. During 1984-1991, residential development was the highest cause for deviation from master plans. The residential use constantly took place on land intended for industrial land use and vice versa. Surabaya is a regional core city with high urbanization rate from neighboring regencies. Thus, land for residential is always in high demands, especially for cheap settlements. The number of workers and the need for settlements near with working places may the reason this deviation.

Table 5. Total area of Residential land use change that did not comply with the plan.

Year	Land being converted based on Master Plan (Ha)		
	Conservation	Open Green Space	Industrial
1984-1991	141.71	388.03	277.54
1996-2001	146.82	47.19	251.31
2003-2009	121.87	140.66	189.26
2007-2009	3.50	79.20	149.33

Furthermore, what does the record say about the functions of local authorities before and after the decentralization planning was applied? And what general conclusions can we draw from the record? In Indonesia, according to building permit status, urban development could be classified as four types: planned with permit, planned without permit, informal with permit and informal without permit. Table 6 shows the total number of permit issued in Surabaya. 1996 record shows the highest number of permit issuance in one year. The following years from 1991-2001 showed the declining trend. However, in 2002, one year after the promulgation of Presidential Decree 10/2001 regarding decentralization in Land Affairs, the number of permit issued increased again.

Table 6. Number of permit issued in Surabaya 1996-2008.

	Year								
	1996	1997	1998	1999	2000	2001	2002	2003	2004
No. of permit	12490	10700	9963	9964	7537	6042	9543	9007	7090
	2005	2006	2007	2008					
No. of permit	6446	5469	4486	5181					

Source: Building Department, Surabaya Municipal Government.

In Indonesia, in prior to be able to build residential clusters, developers should acquire location permit, issued by National Land Agency (before decentralization) or local government (after decentralization). Figure 4 show the comparison of built-up formal residential and location permit to check the coherence within the two of them.

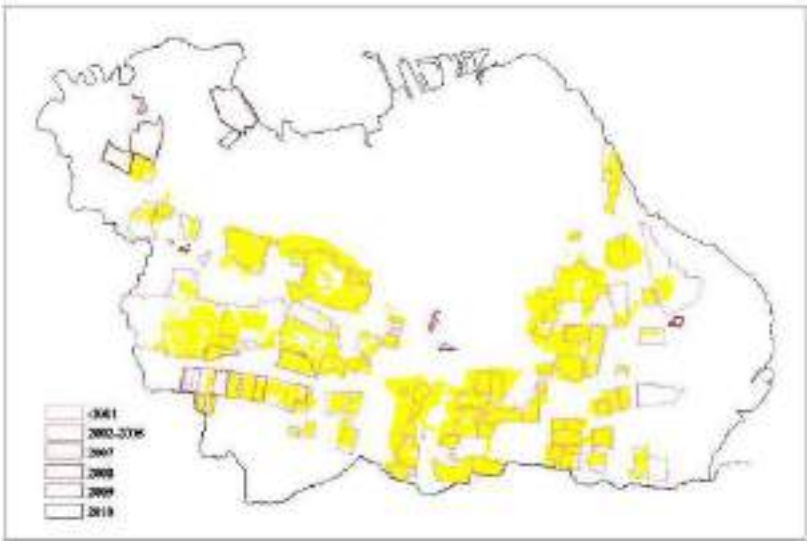

Figure 4. Comparison of number of formal residential based on location permit in Surabaya 2001-2010.

As can be seen from Figure 4, the development of formal residential is in accordance with the location permit issuance which means no developer builds without the permit. Most of large scale residential development occurred before 2001. The period after 2001 characterized with smaller scale residential projects.

6. Concluding remarks

Decentralization is clearly a complex process, and the various reform efforts intended to create an appropriate intergovernmental system and to empower local citizen will require time to take root interact and produce broader improvements in governance. The findings that can be drawn from this study are as follows:

1. *Decentralization has little influence towards metropolitan planning since it show no further effectiveness differences*
   After the decentralization the local governments have greater discretion in deciding what is best for the urban and regional development in their areas. However, planning system still shows centralized direction especially in

metropolitan planning thus creating intergovernmental conflicts. Planning law also still accommodate the role of central government in all planning policy aspects.

2. *Metropolitan planning remains less effective before and after the decentralization*
   The absence of authoritative coordinating board makes difficult to implement the plan. However since the setting up of another hierarchical governmental structure at a supra-local level may not fit into the Indonesian decentralization principles which valued the decentralized power of local government, metropolitan governance through inter local government collaboration in the near future is more likely become possible preferred action rather than setting up new metropolitan government entities.
3. *Decentralization give positive feedback to planning system but unable to restrain from development pressure yet.*
   Aside from those legal transfer of administration and planning arrangement, from the analysis it was found that there is increasing total area allocated for conservation and open green space in Master Plan after decentralization planning was applied. The number of encroachment of residential and industrial land development on the open green space and conservation as deviation from master plan is also reduced.
4. *Master plans and the subsequent land use plans were not effective in both controlling the urban expansion and managing land use change.*
   In Surabaya case, the deviations of built up area between the plan and actual development were wide enough to demonstrate the drawbacks in local planning systems. It is found that there is inconsistency between planning and reality. Master plans changes rapidly and have tendency to follow the current development as shown in the analysis result.
5. *The pattern of land use change basically did not change much after decentralization but it is getting better.*
   Regarding green space, there is change in land use allocation before and after 1999 decentralization. Total area allocated for conservation increase significantly after local government has been given more power to arrange their master plan. Overall, development which did not comply with the plan reduced compare to during centralized planning system.

Sustainable urban development requires efficient urban development planning. As affected by the decentralization and power transition, planning in transitional cities has faced unprecedented challenges. After decentralization reform in late 1990s, Indonesian cities had to develop in a climate of great uncertainty not previously experienced while problems emerged in the rapid urbanization process challenged the planning system. In this research, the overspread unplanned land use change reflects the weak land use control, cheap land, while attracted illegal activity around unclear planning.

Continuing the administrative institutions reforms shall be highly encouraged in Indonesia. Over centralized had been proofed as a major cause of delay, inefficiency and increasing the likelihood of noncompliance. The main objective is to avoid

bureaucratic delays and lengthy approval processes. An efficiency audit should be established to set performance standards for regulating agencies, monitor performance against these standards, and develop incentives and penalties for meeting or not meeting the standards. In the other hand, transparency in planning control is very much needed. During the centralized system, any planning decision made in arbitrary and even when decentralized system required more transparency however there is still no mechanism in reviewing planning through an independent system. Therefore, independent organization outside the government system is needed; such as independent planning inspector (in USA case), planning commission (in Japan case), or local council (European case).

Regarding deviation from master plan, further legal status of urban planning and efficient planning control are recommended. The prosperity of unplanned land use change reflects that rules regulating the land uses had not been taken seriously by land users and land administrators. There is no supervision mechanism to regulate the government activities in changing the master plan. Furthermore, currently there are no efficient and effective instruments for monitoring the unplanned land development. GIS and remote sensing technology should provide an efficient and economical measure to monitor the unplanned and illegal land use change. Not only gives evidence of the unplanned land use change, it provides information about the distribution characteristics of those lands. The adoption of those techniques can lead to a more operative and efficient planning control system.

Sustainable development, planning integration and spatial plans in Greece: from the institutional framework to planning practice

Ass. Prof. Athena Yiannakou[1], Dr. Anastasia Tasopoulou[2]
[1]*Associate Professor, Dep. of Spatial Planning and Development (AUTH), adgianna@plandevel.auth.gr*
[2] *Urban and Regional Planner, Adjunct Faculty Member P.D. 407/80, Dep. of Spatial Planning and Development (AUTH)*

Abstract
The notion of sustainability constitutes a core aspect of spatial planning, while planning for sustainable development has become a crucial component of all planning systems during the last two decades. In Greece, by the end of the 1990s a couple of important new Laws were issued which, on the one hand, formed an explicit hierarchy of plans from the national to the local level and, on the other, clearly adopted the notion and principles of sustainable development in all spatial levels: firstly the Urban Planning Law "Sustainable Urban Development of Cities and Towns" (Law 2508/1997) and, secondly, the Regional Planning Law "Spatial Planning and Sustainable Development" (Law 2742/99). These changes echoed an effort to keep pace with the wider Europeanization of planning policies, but also an inherent ambition that the system could smoothly move towards achieving the goals of sustainable development and planning integration at various spatial levels. The approval of the two Laws, which covered spatial development at the urban, regional and national level, apparently completed the institutional framework of the contemporary planning system in Greece. However, the relations and synergies between the various spatial levels as well as the substantial adoption and implementation of sustainability principles remain a question, which should be examined empirically in relation to the actual planning practice.

The paper discusses the way the planning system in Greece is structured after the above institutional reforms and highlights those aspects that indicate a transition from the central approach in planning to a more hierarchical and integrative approach, which at the same time incorporates notions and principles of sustainable spatial development. Drawn from empirical research on spatial planning practice in the region of Central Macedonia during the last decade, the paper argues that although the system attempted in many respects to be hierarchical with an integrative perspective, in the end planning practice is still oriented to accommodate new land for development, undermining objectives such as sustainable spatial development and spatial integration of planning. The research illustrates the considerable gaps between framework and outcome, an established feature of the Greek planning system, reflecting the longstanding deficiencies of the planning tradition in Greece.

Key words: Greek planning system, sustainable development, spatial planning, planning practice, planning integration

1. Sustainability and spatial planning systems

It is a common argument that for the last 20 years the idea of sustainability has provided a large part of the agenda of spatial planning and even its much needed "vision" (Davoudi 2000). Sustainable development has been increasingly adopted since the 1990s as a dominant policy goal in all international, national and local official policies and the public discourse in general (Rydin 2011). At the same time not only has the purpose of spatial planning become

the delivery of sustainability in a community and in a globalized urban context, but spatial planning is also considered a critical tool to manage globally driven development processes and global environmental changes in order to reach a long-term sustainable management of urban development. Moreover, the improvement of spatial planning as a tool for addressing both social and environmental externalities in urban economy has become a goal for many officially stated national and international policies (Andrikopoulou et al. 2007).

Sustainability as a vision of spatial planning brought back to the agenda the role of spatial planning as mediator and equalizer between the three corners of the "economy, environment and equity" triangle or even better between the tensions generated by three conflicts "property, resource and development" (Campbell 2003). However, planning in practice and its institutions gave emphasis primarily on the environmental aspect and more specifically on how urban growth can be managed in a sustainable manner taking into consideration the resource availability and the environmental impacts and promoting further the integration of environmental aspects into urban planning. Although there are still open questions as to what the substantive content of a sustainable spatial planning is (Naess 2000), issues such as urban form, sustainable transport, re-use of abandoned urban sites, more efficient use of sites that can be built or creation of more effective mechanisms in order to involve citizens in the planning process have gained a central position in spatial planning (Haughton and Hunter 1994, Naess 2000). In the 2000s in particular, as the issue of mitigation and adaptation to climate change has brought more and more at the top of the agenda the target of reducing emissions of greenhouse gases, regulating urban growth, and particularly urban sprawl, mobility patterns and their economic, social, environmental implications have become the core interest of spatial planning (Davoudi et al. 2009).

Achieving sustainable management of urban growth within the sustainability framework was the subject matter of the reforms of the planning systems that took place by the end of the 1990s or in the 2000s in many European countries, as did the whole system of planning and control to cover these dimensions. By and large these adaptations of formal national arrangements for planning to address common challenges of sustainability along with global competition, to which they were unsuited, provide even a measure of convergence between the European planning systems (Nadin and Stead 2008). These reforms apparently had two common features, the shift to strategic planning and the integration of sustainability into the proactive and regulatory dimensions of spatial planning.

In France, for example, the latest Law of 2000 on Urban Solidarity and Renewal reformed all basic plans, moving its emphasis from land management to planning coherence, and included instruments giving special attention to the coherence between urban planning, housing, commercial equipment and transport policies (Booth 2003). Sustainability was introduced as a key planning criterion both at the metropolitan and local level of planning. Among the main aspects of this legislation was the desire to make planning proactive and strategic, with special emphasis on the sustainability of development (Booth 2003). In England, the 2004 Planning and Compulsory Purchase Act, which was considered the most important review of this country's system in the last 25-30 years (Nadin 2007), seeks both politically and institutionally to promote changes that enable the planning system to become more transparent, flexible, predictable, efficient and targeted to results (the latter being the substance of sustainability policies) and to examine, in the context of globalization, how planning policy and processes can create economic development and prosperity along with the objectives of sustainable development. In the Nordic countries, where planning remains focused on managing ubran growth (Böhme 2003), policies of sustainable development have

entered the planning agenda in a very dynamic and persuasive way, although not always within a wider planning reform. In the Mediterranean countries there was a growing interest in spatial visions (Giannakourou 2005) within which sustainability was adopted as central strategy. Thus the discourse about sustainable development left no aside almost all planning systems including the Greek system which explicitly incorporated the notion of sustainablity by the end of 1990s, a time of important institutional changes, both at the local and the national level, which strengthened the interest in spatial planning (Coccossis et al. 2005).

Promoting sustainable urban development, which is a long term goal, involves two important institutional levels of spatial planning: the local, addressed in the planning system mainly by the development of land-use plans (or local development frameworks of the more recent English planning system) and the national or regional level which function as a higher level of coordination and policy guidance in the planning system. Besides, this higher level of coordination is necessary at regional, national or international scale in order to resolve the 'prisoner's dilemma' facing individual local communities in relation to global and national environmental problems whereas such planning is necessary to avoid the dispositions made to shift problems of one area to another within a region, a country or the globe (Naess 2001).

In the following sections we first examine the way the planning system in Greece is structured after the institutional reform of the second half of the 1990s and how it incorporates notions and principles of sustainable spatial development. Then, drawn from empirical research on spatial planning practice in the region of Central Macedonia during the last decade, the paper discusses how this guidance was specified in practice and more particularly by the General Development Plans.

2. Changes in the planning system in Greece: structuring a hierarchical system and incorporating the notion of sustainability

The Greek spatial planning system, as in fact the Greek decision making system, is traditionally highly centralised, thus classified in the past among the Napoleonic systems, whereas the EU Compendium of spatial planning systems and policies classified Greece to the 'urbanism' tradition, which had an architectural flavour and a strong concern in building control, with regulation being undertaken through rigid zoning and codes (EC, 1997). The multiplicity of laws and regulations, the lack of implicitly stated policy priorities and the lack of public approval of planning are some of the important characteristics of this tradition, characteristics that lead to ineffective control of development in particularly in the outskirts of all cities and towns. It has been long pointed out that the Greek system is a model of centralised and regulatory planning style, where important gaps exist between established plans and the reality (Giannakourou 1998).

In the second half of the 1990s, a period of high economic growth rates, spatial development and policy in Greece went through a phase of change, with two notable features: in the field of spatial development, the relatively high growth rates of all bigger and smaller cities were accompanied by very high rates of suburbanization and urban sprawl, rates that were intensified in the 2000s to such extent that they transformed the traditional compact model of the Greek cities (Yiannakou 2012). In the field of spatial policy, European policies were widely adopted in the public discourse becoming particularly influential and having a direct impact on the planning institutional framework. Giannakourou (1998: 8) at that time indicated three main trends of this last impact: a) the emphasis on strategic spatial planning, as a result

of the country's participation in the then on-going process for spatial co-operation in Europe and the European awareness for spatial planning issues, b) the introduction of the notion and principles of sustainable development into the Greek spatial planning approach and c) the introduction of the subsidiarity principle and of the partnership approach into the domestic spatial planning process, putting into question the centralised character of the Greek spatial planning policy and system.

In this period two important Planning Laws were issued, which on the one hand, formed an explicit hierarchy of plans from the national to the local level and, on the other, clearly adopted the notion and principles of sustainable development in all spatial levels. First of all, Law 2508/97 "Sustainable Urban Development of Cities and Towns" adopted, as its name suggests, the notion of sustainability into the institutional framework of urban planning and constituted the statutory basis to link urban planning to the principles of sustainable development. The purpose of the Law 2508/97 is the specification of the principles, preconditions, procedures and patterns of urban planning for the sustainable urban development of towns and cities. Among the main objectives that are stated in this Law are land use control in the areas surrounding all cities and towns, protection of the environment, prevention of unauthorized development and specification of criteria for development in a way that further land for development is very wisely released, improvement of the environment in the depressed areas, protection, enhancement and upgrade of city centres, etc. At the time of its enactment this new Law was widely welcome as it included principles and directions for the sustainable future development of cities and towns as well as for the improvement of the built environment, which affect "the qualitative options of every urban plan" (Aravantinos, 1997: 216).

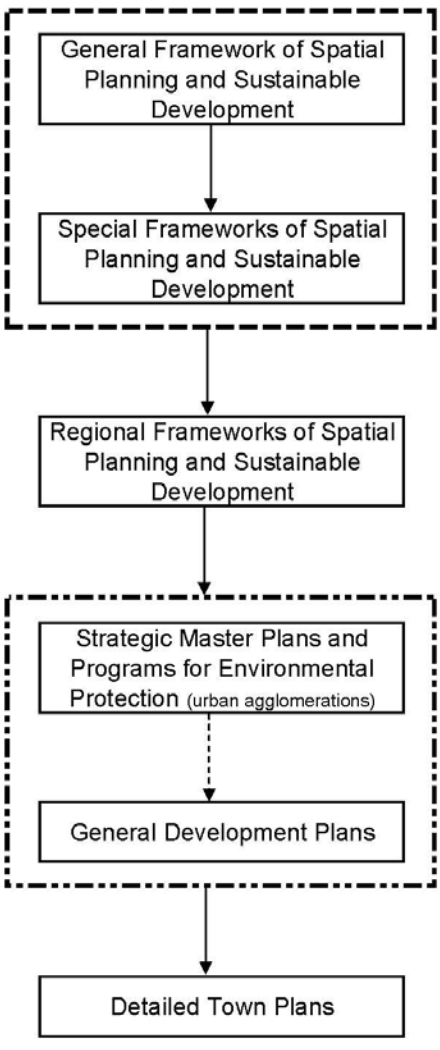
According to Law 2508/97, and following the previous Law 1337/83 with certain adaptations, urban planning is completed through the elaboration of two levels of plans: the first level which can be described as "strategic" includes a) the Master Plan and Program of Environmental Protection (Ritmistiko Sxedio) which covers the metropolitan areas and big urban agglomerations and b) the General Development Plan (*Geniko Poleodomiko Sxedio*, GPS), which is elaborated at the level of each municipality. The second level includes the detailed town plans (*Poleodomiki Meleti*) and their detailed Implementation Plan (*Praxis Efarmogis*). One of the basic statutory elements of this Law is the fact that the Master Plan and the GPS need to coincide with the principles and directions of higher level spatial planning. During the 2000s most municipalities elaborated new GPSs or revised the old GPSs along the lines of Law 2508/97, most of which have been enacted in the second half of the 2000s.

Secondly, Law 2742/99 "Spatial Planning and Sustainable Development", which was introduced two years later, initiated the notion of sustainable development - again as its' name suggests - at the level of regional and national spatial planning, a level of planning essentially enacted for the first time in the Greek planning system. The main purpose of this Law was to provide the fundamental principles and the enactment of contemporary agents, procedures and instruments of spatial planning practice, that promote sustainable balanced development, entrench production and social coherence, ensure environmental protection at the level of national territory and its different areas and strengthen the position of the country in the international and European context.

Focusing on the instruments of spatial planning at the regional and national level, Law 2742/99 enacted the elaboration of the so-called Spatial "Frameworks" apparently adopting a

more strategic and coordinative nature of these plans. At the national level, the Law introduced the General Framework of Spatial Planning and Sustainable Development (General FSPSD) and the Special Frameworks of Spatial Planning and Sustainable Development (Special FSPSD). The General FSPSD assesses the factors that affect long-term spatial development and structure of the national territory, evaluates the spatial impacts of international, European and national policies and defines the main priorities and strategic directions for the integrated spatial development and sustainable organization of the national territory. The first General FSPSD was enacted nine years later, in 2008. The Special FSPSDs specify and supplement the directions of the General FSPSD that concern the development and organisation of the national territory, especially regarding a) the spatial structure of specific of national importance production sectors, b) the spatial structure of technical, social and administrative networks and facilities of international magnitude and c) special areas characterised by strong environmental interest of crucial environmental, economic and social problems. Up to now, three Special FSPSDs were issued, all of them by the end of the 2000s: the Special FSPSD for Renewable Energy Resources (2008), the SFSPSD for Tourism (2009) and the SFSPSD for Industry (2009).

At the regional level, Law 2742/99 introduced the Regional Frameworks of Spatial Planning and Sustainable Development (Regional FSPSD). The Regional FSPSDs assess the position, role and intra-regional functions of the Region concerned, as well as the factors that affect its development and spatial structure, evaluate the spatial impacts of European, national and regional policies and define the main priorities and strategic options for the integrated and sustainable development of the regional territory. The Regional FSPSDs should harmonize with the directions of the General FSPSD and the Special FSPSDs and specify and supplement their options. All 12 Regional FSPSDs of the country's Regions (the Region of Attica was not included) were elaborated and enacted during the first half of the 2000s, in other words before the enactment of the national Spatial Frameworks. Currently these Regional FSPSDs are revised so as to harmonize with the national level of spatial planning.



Similarly at the municipal level, as mentioned above, all GPSs should harmonize with the national and regional Spatial Frameworks, while it is clearly stated that the already approved GPSs (on the basis of the previous legislation) ought to be modified in order to harmonize with the directions of these Spatial Frameworks. Thus, both Laws seek to assure the synergy between national, regional and local spatial planning and to achieve the goals of sustainable development and planning integration at various spatial levels. On the whole, the enactment of the two Laws, of the Spatial Frameworks and the new GPSs by the end of the 1990s shows a transition to a systematic and formal hierarchy of plans, from the national to the local level, that aim to coordinate the various sectoral activities of the public sector. Figure 1 shows this hierarchy among the various plans at the various spatial levels.

Figure 1. Hierarchy of spatial plans in the Greek planning system

Focusing further on the sustainability goal, the General FSPSD states that it aims at forming a spatial pattern of development, in the context of sustainability principles that will be the outcome of a synthetic and balanced consideration of those parameters that promote the protection and enhancement of the natural and cultural environment and strengthen social and economic cohesion and competitiveness. In this context, apart from the emphasis on the enhancement of natural and cultural resources as well as on the protection of the biodiversity, the General FSPSD adopts a model of balanced – polycentric development of the country accompanied by the restriction of excessive urban growth, through the improvement of the countryside's attractiveness and the strengthening of complementarity and balance among urban centers and rural areas. The General FSPSD includes a specific provision in which it adopts the principle of compact city and suggests that it should be promoted in all levels of spatial planning. Thus, it states clearly that all new development should be justified and substantiated on the basis of what is called "objective needs" (demographic, residential and production).

The three Special FSPSDs aim primarily to achieve a more rational spatial allocation of the activities concerned, formulating policies, general regulations and criteria for the location of

these activities, again in the context of the sustainability goal. More specifically, the Special FSPSD for Renewable Energy Resources defines location criteria which will allow, on the one hand, the creation of sustainable installations of renewable energy resources and, on the other, their harmonious incorporation into the natural and built environment corresponding to the goals set by the relevant European and national policies. It is worth noting here that this Spatial Framework provides a concrete context to the authorities responsible for the planning permissions of these activities and the interested enterprises, in order to orientate their businesses to appropriate - from a spatial aspect - areas without allowing the GPS to alter these regulations. The Special FSPSD for Tourism considers the protection and enhancement of the environment a precondition for the survival and strengthening of the competitiveness of the tourism industry. It aims at creating the conditions for the promotion of sustainable and balanced development of tourism in the country, according to the physical, cultural, economic and social specificities of every area, for the qualitative environmental upgrade of tourism activity, and for the provision of the necessary directions towards the lower levels of spatial planning in order to promote tourism development within the framework of sustainable, balanced, compact and integrated management of spatial development. Moreover, it seems to promote the control of dispersed tourism activities in certain areas, such as the agricultural land and islands with massive tourism activity. The Special FSPSD for Industry states that its objective is the transformation of the spatial structure of industrial activity towards sustainable development namely protection of the environment, social equity and cohesion and economic prosperity. For this purpose, it includes specific goals to strengthen the competitiveness of industry as well as its greater economic and spatial role, though the promotion of a more rational spatial pattern. Among these goals is the promotion of a radical transformation of the current dispersed and scattered model of industrial location and the incorporation of the environmental dimension into the spatial structure of industrial activity, especially by making the location of industrial plants within planned sites compulsory and by suggesting that these sites are more preferable to be planned in areas already developed with such activities and not in open land.

Taking one Regional FSPSD as an example, that of the Central Macedonia Region, its main objective is the promotion of sustainable, balanced and continuous development of the Region based on its natural, economic and social particularities. Among others, the RFSPSD proposes a spatial development pattern for the Region, which has as its core a balanced and polycentric network of urban centres, which can function complementary to the urban agglomeration of Thessaloniki, to the adoption of the principles of compact city and limitation of urban sprawl, the wise use of natural resources etc.

On the whole, the above planning framework clearly adopted sustainability as the core objective of spatial planning which is pursued through a hierarchy of guideline Spatial Frameworks and plans at the national and regional level and more specific development plans at the metropolitan and the local (municipal) level. Although this reform was not accompanied by a hierarchical decision-making system this hierarchy of plans apparently assures that sustainability is a principle regulating planning at all levels.

3. Sustainability and planning integration in the planning practice

In order to examine how planning integration, formed by the two planning Laws and the hierarchical guidance of the Spatial Frameworks, contributed to more sustainable policies adopted by the hierarchically lower spatial plans, we focused our investigation on the way the

GPSs that were elaborated and approved during the 2000s treated basic principles related to sustainable development. As previously stated, the GPS is the proactive as well as the regulatory level of planning which by law specifies the regional and national spatial planning guidance at the municipal level, regarding land use planning and development guidelines and regulations.

By law the GPSs aim at defining the main spatial planning goals of a municipality's territory, forming the basic implementation instrument of the Frameworks of Spatial Planning and Sustainable Development, especially of the Regional ones. In this context, they specify the capacity and the needs for housing development, according to the principles of sustainable development, local needs and land use suitability, and determine the Areas of Special Protection that are not intended to be developed, the planning zones for production activities, the land use and development control zones around the cities and towns and the general land use and planning rules of the existing and proposed residential areas, defining also the areas inside the inner city parts that require regeneration interventions.

Taking into consideration the nature of the GPS on one hand and the guidelines of spatial planning laws and frameworks on the other, and based on recent research conducted by the authors, the examination focuses on three issues: a) the management of urban sprawl and the proposals for new residential areas, b) the management of dispersed industrial location and the specification of planning zones for industrial and entrepreneurial activities and c) the adoption of regeneration tools in the inner city areas.

First of all, it should be highlighted that in both Laws and in almost all Frameworks the notion of "compact city" constitutes an almost axiomatic principle of the proposed development pattern, stating at the same time some general goals regarding the limitation and the control of dispersed development (the so-called "out-of-the-town-plan" development) in the outskirts of the cities and towns. This principle though, apparently in accordance with the traditional urban model of the Greek city, was incorporated into the Greek planning framework in a period where unplanned - and in many cases unauthorized - urban development all over the outskirts of the bigger as well as of the smaller towns and the tourist areas was very extensive, thus drastically transforming the traditional compact city model (Figure 2, Yiannakou 2012).

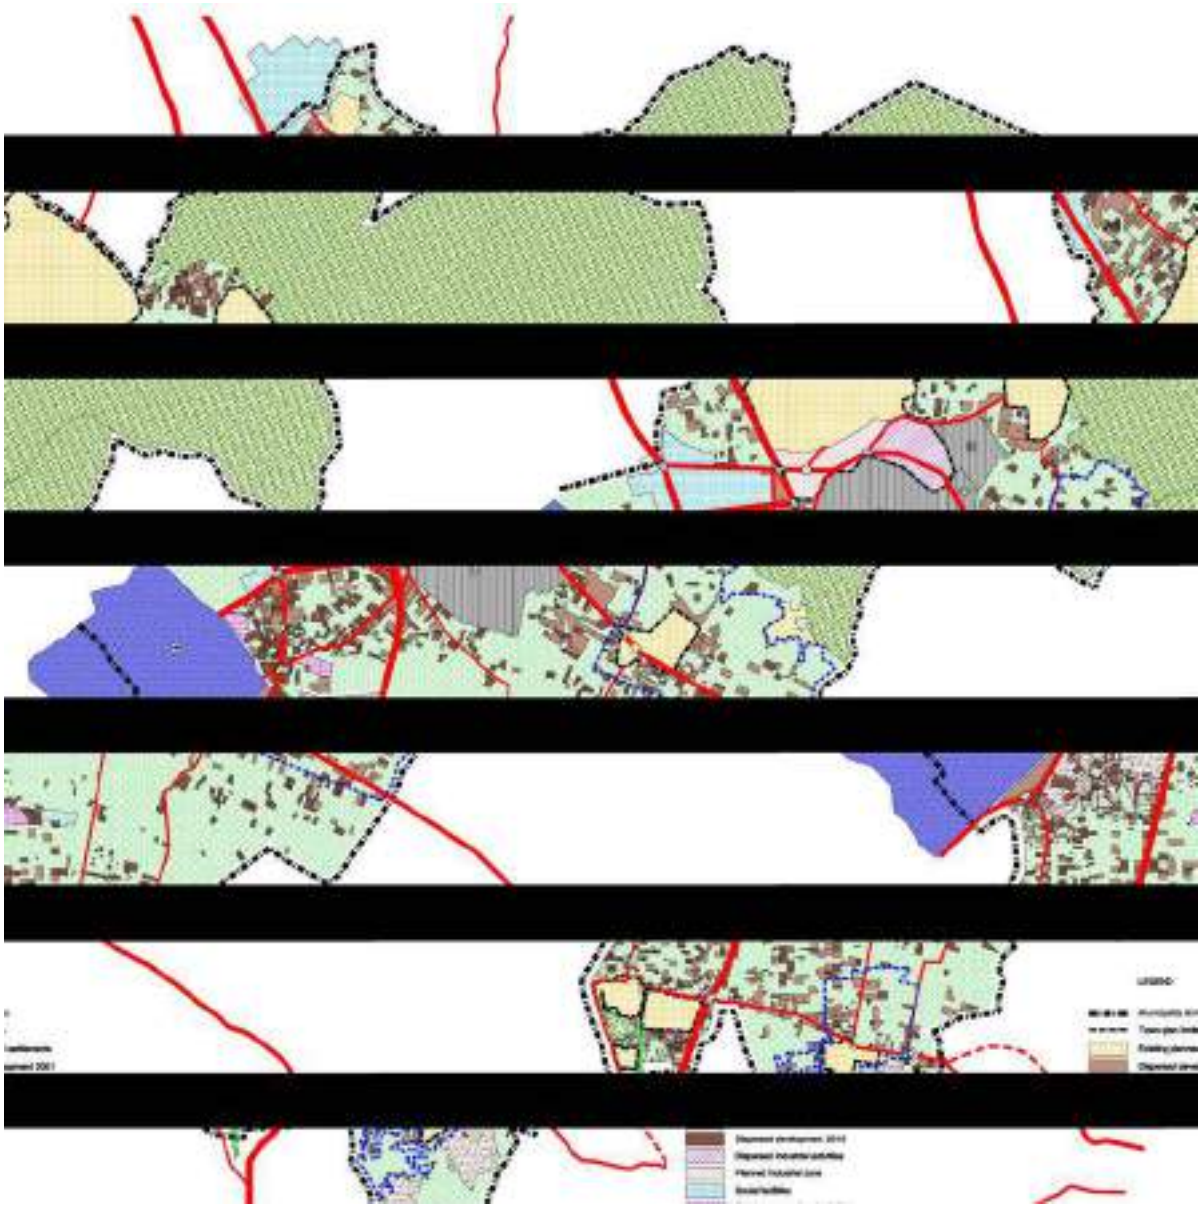


Figure 2. Dispersed development in part of the southern suburban Greater Thessaloniki Area and proposed new residential areas (Source: Yiannakou 2012)

Based on Law 2508/97 as well as its specification by a Ministerial Guidance regarding the planning and design standards that was issued in 2004, two guidelines were directly related to the goal of sustainable urban development: a) "the pursuit of the largest possible economy in new extensions of the town plan" - in other words the new areas for residential development - should be released and planned with the biggest cautiousness and b) the provision of adequate residential densities, which according to the above Ministerial Guidance should not be less than 100 inh/Ha (and not more than 400 inh/Ha), although the selection of lowest densities in soft residential and tourism areas and highest densities in large cities is not forbidden. A research conducted by Tasopoulou (2011) in 30 approved GPSs in the Region of Central

Macedonia in Northern Greece[1] showed that the new residential areas proposed by all these GPSs corresponded to more than 40% of the existing residential areas. It should be reminded here that this was not the first time that massive elaboration of GPSs took place in Greece. The first package of GPSs was elaborated between the mid 1980s and mid 1990s and by these plans a proposal was placed for 31% of extra land to be released for residential development, a size that had already been characterized as big enough (Economou, 2009). Only in the suburban area of the Greater Thessaloniki Area (GTA) approximately 5,700 Ha have been approved or are about to be approved for planning new residential areas in the 2000s by the newly enacted GPSs. For comparative reasons it should be noted that the residential area within the limits of the town plan in the compact part of the city inhabited by the 85% of the GTA's population covers an area of 5,500 Ha.

In the examined GPSs the approved plot ratios were so low that resulted in very low residential densities, inappropriate for achieving a sustainable urban planning pattern, according to the national guidelines (Tasopoulou 2011). This low-density model was selected as it was the only way to provide a reasoning of the proposed extensive new residential areas, although even in this case the anticipated housing need was far beyond any realistic future forecasts. It is worth noting at this point that the selection of low plot ratios and consequently models of development of low densities was a practice accepted and adopted by the statutory authorities in charge of the approval of these plans as a counterbalance to the mayors' pressures for as extended as possible town-plan expansions.

Regarding the management of the location of industrial and other productive activities, first it should be pointed out that in most cases it is located at the perimeter of cities and towns, usually following a linear pattern around major road axes. This location is either concentrated in certain areas or dispersed. The Special FSPSD for Industry explicitly seeks a more rational organisation of productive activities, through their aggregation into planned zones, thus avoiding their dispersed location (Evaggelidou et al. 2009). Apart from this emphasis on planned industrial zones, the Special FSPSD explicitly favours the mix of uses of the secondary and tertiary sector, even providing in some cases the possibility of coexistence of housing, naturally with certain prerequisites. An in-debt analysis conducted by the authors on GPSs currently under elaboration and after the enactment of the National Spatial Frameworks (Yiannakou and Tasopoulou forthcoming) found that in general they incorporate the guidelines of the Special FSPSD for these planned industrial zones in existing concentrations, avoiding the use of new land and promoting the mix of land uses. However, it seems that they are not fully following the Framework's provisions for restraining the dispersed industrial location and development.

This research also records some important problems that relate to the difficulties in specifying the guidelines of the National Frameworks which arise in the planning practice of the lower level plans such as the GPS. For example, the Special FSPSD for Industry includes some very useful and innovative tools for industrial organisation and development, such as the so-called "eco-zones" which nevertheless raise many questions regarding their actual application at the level of development planning. This is due to the absence of more specific guidelines, arrangements and prerequisites which the central administration should issue for the application of such tools into planning practice. Moreover, the proposed mix of uses seems to

[1] It should be noted here that most GPSs examined by this research (based on the Law 2808/97) were elaborated before the enactment of the national level Frameworks (i.e. the General and the Special FSPSD), and so the only higher-level Framework that was active at that time was the Regional FSPSD.

contribute to the solving problems that usually derive from the planning rigidity to separate the secondary from the tertiary sector uses. A second important issue is the fact that the Special FSPSD anticipates that the necessary studies and the necessary infrastructure for the creation of an industrial planning zone should be undertaken by a special agent (a municipal authority could also play this role). This kind of special planning agents (anticipated long ago in other planning instruments as well) have never before been put into practice in the Greek spatial planning practice and is always seen with suspicion by the municipal and central administration authorities involved. A third finding was the fact that even the public authorities in charge of the enactment of the GPSs hesitated to adopt these new planning tools since there was no additional guidance regarding the way these tools and mechanisms can be efficiently adopted by and implemented in the lower levels of planning. Thus, the way and even the option of using these tools and mechanisms was left to the personal believes, knowledge and perceptions of each planning consultant and/or each local administration or executive authority. Additionally, in most GPSs, dispersed development of activities is still anticipated in the areas outside the plan limits, based mainly on the already established land-uses but also affected by local interests.

Finally, one of the novelties for which Law 2508/97 was widely accepted was the fact that it included several tools for the deprived inner city areas, all under a general provision regarding urban renewal which is the nearest notion of the Greek planning system to that of regeneration, however with strong urban design flavor. The renewal of an area was defined as the directions, measures, interventions and processes of urban, social, economic and special architectural character that aim mainly at the improvement of the quality of life and the built environment, and the protection and enhancement of the cultural, historical, morphological and aesthetic elements of the specific area. According to the Law, areas that appear to have problems of degradation can be defined as “renewal zones”. Although the GPSs are the statutory plans to determine these renewal zones, it was found that in practice very few such areas have been defined in the GPSs that were approved in the Region of Central Macedonia during the 2000s (Tasopoulou, 2011). This tool has not been utilized, because of the hesitation of the public authorities (and especially the regional administration) to allow the designation of such zones. Andrikopoulou et al. (2007) argue that this deficiency is a result, on one hand, of the additional legislative requirements needed and, on the other and more substantial one, of the inherent problems of urban policy in Greece. Besides, according to the same authors, a basic feature of the Greek planning system is the great deficiencies regarding its proactive character, since there was almost no activation of other basic planning tools too that were included in the previous legislative and planning framework (the one that was initiated in the mid ‘80s).

4. Concluding remarks

Moving from a public discourse and even a legislative framework to planning practice is a difficult path, in the same way as it remains generally a difficult path to move from the theory of a very attractive notion to specific and effective strategies that make it a feasible mode of development. Most planning systems are practically at the development stage as far as the harmonization of spatial planning policies and regulations to sustainability objectives is concerned.

The reform of the Greek planning system with the introduction in the 1990s of the two Planning Laws regarding sustainable urban development and sustainable spatial planning at the national and regional level, followed in the 2000s by the enactment of the Regional Frameworks, the new GPS and by the end of 2000s the General and the Special Frameworks led, for the first time, to the formulation of a formally hierarchical spatial planning system from the national to the local level. Within this context, sustainability is adopted as a fundamental notion and the core objective of spatial planning at all levels. However, this adoption came into force in the light of no substantial understanding and assimilation of its dimensions regarding planning in practice. This planning integration concerned only the spatial instruments and not the decision-making itself, which remains centralized. In this context, it seems that the central government's role was restrained to the promotion of planning legislation without any effort to clarify and specify the directions set by the upper level frameworks and guidelines, thus leaving - as it is usually the planning practice in Greece - many of its aspects to legal interpretations which in no way function as proactive planning policies. Despite this specific planning integration, the spatial planning system does not show yet an institutional maturity including governing and learning processes that would allow for specifications and adaptations, for searching and peering into the preconditions for sustainable development in the context of the Greek urban development and for incorporating them into specific planning practices and strategies.

The principle of sustainability was introduced as a policy goal in Greece at a time of high rates of urban growth and in particular intense suburbanization and dispersed development in the outskirts of the cities and towns. The experience gained from the planning practice through the elaboration of GPSs in the Region of Central Macedonia not only shows that these development pressures along with the local communities' aspirations for further official release of land for development had a negative impact on the actual application of the sustainability principles, with planning failing to deal with sprawl dynamics in a sustainable manner and applying concepts such as that of the "compact city" (Delladetsimas 2012), but above all, it shows how strongly spatial planning is enmeshed to the development process, to specific ideologies and to a wider social model (Nadin and Stead 2008). In Greece, the new planning framework was put into force at a period of a building boom where explicit unsustainable policy and planning practices on behalf of the local and central authorities, the developers, the landowners, the professionals and the households were not simply the norm but the "life-style, building and planning" culture (Yiannakou 2012). The current crisis in the country and the deeper reasons that determined it is a new set, which should lead to a reassessment of this socio-cultural approach.

THE EU STRATEGY FOR THE DANUBE REGION – THE EMERGENCE OF SOFT SPACES AND THE ROLE OF ACTORS

Franziska Sielker[1]

Abstract

Since 2009 the appearance of macro-regional strategies has stimulated discussion regarding new concepts of territorial cooperation in the EU where functional linkages become more and more important. The emergence of soft spaces linking fuzzy functional geometries with different stakeholders is one of the most significant discussed phenomena. Driven by the current interest in macro-regional strategies this paper examines whether they can build an appropriate framework for the facilitation of transnational soft spaces. In order to analyze whether the concept of soft spaces is applicable, the governance structure and the role of the different stakeholder groups in the strategy are analyzed through the example of the newest strategy, the EU Danube Region Strategy. As clear definitions for the different stakeholders in the strategy are missing, the paper summarizes a set of tasks for each committee in order to understand the role of the different stakeholder groups and estimate the potentials for the development of transnational soft spaces. Building on the analysis of interviews the potential added-value, challenges and the expectations of stakeholders towards the EU Danube Region Strategy are examined, in particular with respect to relational geographies.

This paper shows that the Danube region, initiated by Nation States and thus following mainly a political logic, shows important characteristics of the concept of soft spaces. It argues that the governance-structure is fuzzy in a vertical, horizontal and geographical dimension and thus offers possibilities to foster soft spaces.

1. Introduction and theoretical background: macro-regional strategies and soft spaces

After the development of the first EU macro-regional strategy for the Baltic Sea Region similar initiatives evolved quickly, leading to the adoption of the EU Strategy for the Danube Region (EUSDR) in June 2011. The development of further macro-regions is currently under discussion. Macro-regional strategies build “an integrated framework” (Samecki, 2009) for transnational cooperation contributing to territorial cohesion. The macro-regional concept aims at integrating different sectors, levels and politics in one strategy through an overall coordination - tailored for functional

1 TU Dortmund University, Dortmund, Germany; franziska.sielker@udo.edu

regions. Hence, forming a strategic roof, they link regional policies as a project focused approach with sectoral policies. According to the European Commission (EC) macro-regions are defined as "an area including territory from a number of different countries or regions associated with one or more common features or challenges" (Samecki, 2009).

The appearance of macro-regional strategies has stimulated discussions regarding new concepts of territorial cooperation in the EU. As a result of ongoing globalization and Europeanization, functional linkages become more and more important, hence leading to new conceptualizations of territory based on functional approaches. Macro-regional strategies constitute an adaptation process and shape spatial development as well as the creation of networks. In the light of the rescaling debate, macro-regional strategies operate as a new framework for cooperation in the multi-level governance system of the EU (Schymik, 2011).

The emergence of 'soft spaces' at the regional level is one of the most significant contemporarily discussed phenomena in the recent planning debate. The shift from government to governance entails a new understanding of states, away from 'hard containers' towards actors in networks. The underlying processes are as well ongoing globalization, Europeanization and rescaling processes. Simultaneously, discussions on relational geographies and 'spaces of flow' aim at developing new conceptualizations of territory following functional linkages. In the course of these debates Allmendinger and Haughton (2009) argue that planners using the legal set of boundaries need to operate within 'soft spaces' across different ranges of geographies, scales and networks. Soft spaces describe "multiple spaces of governance alongside other devices for policy integration" (Haughton et al., 2010, pp. 23-24). They follow a flexible approach with respect to stakeholder participation, time frame as well as territorial delineation and they result from existing networks and functional cooperations. Soft spaces are informal and have fuzzy horizontal (across sector policies), vertical (across different levels of governance) and geographical (across different boundaries) dimensions (Dühr, 2011, p. 26). Stead (2011) and Faludi (2010, pp. 167–168) consider that with macro-regions as a new layer of intervention an example for soft spaces has occurred at the EU level. Thus, macro-regional strategies offer a chance for stakeholders of administrative units as well as for issue-bound stakeholders pursuing sectoral aims in order to cooperate loosely within their priority areas.

It remains open if the emergence of transnational soft spaces at a European scale might be facilitated in future due to the soft framework of macro-regions. Emphasizing the importance of different stakeholder groups, this paper discusses the appearance of soft spaces through actor-networks within the framework of macro-regional strategies. Against the background of the rescaling debate it is to be analyzed whether macro-regional strategies, initiated by nation states and thus following mainly a political logic, can build an appropriate framework for governance within fuzzy functional geometries. For this reason, part of this work is to examine whether the concept of soft spaces can be applied to further explain

processes on the macro-regional level. Compared to the Baltic Sea Region there is less experience in cooperation within the Danube region as there are fewer and younger transnational structures and initiatives. Hence, the governance structure developed throughout the macro-regional cooperation may give a new strategic roof that leads to new incentives linking political and functional processes. Moreover, the cooperation between old and new member states with membership aspirants and non-member states makes the Danube region an interesting case. Therefore, the example of the Danube region enables to analyze the potential to strengthen functional linkages via a flexible, macro-regional metagovernance-level in an area with less cooperation experience. All in all, the focus of the paper is to analyze whether macro-regional strategies foster the development of transnational soft spaces at the European scale based on the case study of the Danube region.

The paper is structured as follows: for setting the stage, first the Danube region and the EUSDR are introduced. Then, the governance structure of the EUSDR is worked out and the tasks of the different stakeholders within this organizational set-up are examined. Drawing on the analysis of interviews with representatives of all relevant stakeholder groups in the EUSDR, the potential added value and challenges for a successful implementation as well as the resulting expectations towards the EUSDR are presented thereafter. Building on these results, it is finally discussed whether the concept of soft spaces is applicable to the macro-regional level. The concluding remarks include opinions whether due to their governance structure macro-regional strategies foster transnational soft spaces.

2. Setting the stage: The Case of the EU Strategy for the Danube Region

The Danube macro-region

The macro-region Danube “is a functional area defined by its river basin” (CEC, 2010). Geographically it concerns primarily but not exclusively fourteen countries: “Germany (Baden-Württemberg and Bavaria), Austria, the Slovak Republic, the Czech Republic, Hungary, Slovenia, Romania and Bulgaria within the EU, and Croatia, Serbia, Bosnia and Herzegovina, Montenegro, the Republic of Moldova and Ukraine (the regions along the Danube) outside” (CEC, 2010) A map of the macro-region is shown in Figure 1. The region encompasses one fifth of the European territory, thereby constituting an important economic area within Europe (CEC, 2010). Cooperation in the Danube region has to face different challenges due to the diversity and history of the region. During its colorful history the Danube countries were involved in various conflicts and wars coming along with changes in power. After the World War II the region was separated by the iron curtain. Since the political change of 1989, a transformation and convergence towards Europe started over (Weigl, 2010). The Danube itself is still of relevance as a border river along its way (Deimel, 2010). The Danube region is characterized by high social and cultural diversity influencing the cooperation possibilities and the behavior of the stakeholders. Regarding the economic diversity the Danube region contains some of the richest and of the poorest countries of the EU (EUROSTAT, 2011). The natural

environment includes mountains such as the Alpes or Carpathians as well as low lands such as the Danube delta as well as huge diversity in flora and fauna. The whole Danube basin contains more than 800,000km^2 (Zuser, 2010). The EUSDR shall support new opportunities in order to address common challenges in this region and lead to a sustainable development.

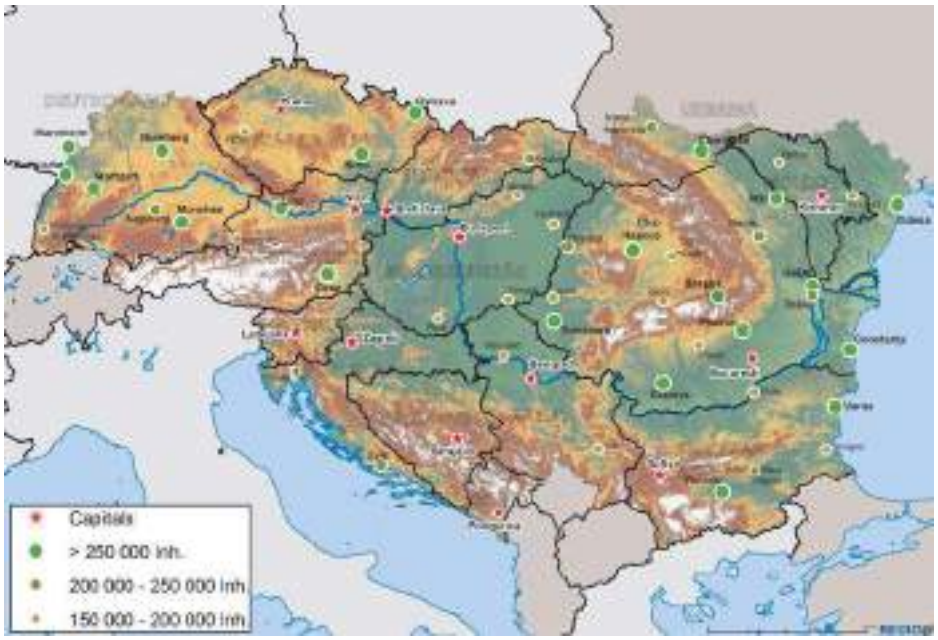

Figure 1. Geographical coverage of the Danube Region (EEAS, 2012)

Content and structure

The EUSDR consists of the Strategy document and an accompanying Action Plan. These documents are the result of an extensive consultation process coordinated by the European Commission (EC). From the idea by the end of 2008 until the Communication document of the EC in December 2010, the EC played the leading role in organizing, coordinating and drafting the document. The strategic document presents the overall goals as well as the challenges and opportunities of the region. Thematically the EUSDR is structured in four pillars with eleven priority areas (PA) (CEC, 2010; Figure 2). PA 1 is separated in PA 1a and PA 1b.

Figure 2. Set-up of EUSDR (own illustration based on Simoner, 2011)

For each PA possible aims and main issues are presented. The Action Plan provides more detailed information on the main problems within each PA and the respective actions. Furthermore, illustrative projects supporting the actions are listed (CEC, 2010a). In total the Action Plan comprises 129 actions and names 123 project examples (Figure 2). The EUSDR aims at addressing the main challenges of the mobility of the TEN-T Corridor Danube River, energy supply and production, environmental pollution, risk prevention, socio-economic disparities, security and organized crime.

3. Analysis of the EUSDR with respect to the governance structure

3.1 Methodology

The aim of this paper is to analyse the EUSDR and to reflect on this basis whether the macro-regional strategy fosters transnational soft spaces and whether this concept is applicable to the macro-regional level. As soft spaces are determined by a flexible approach in a horizontal, vertical and geographical dimension, the underlying governance structure and the participating stakeholder groups are of interest in the analysis. The development of the governance structure, the tasks of the different committees and the analysis of the involvement of the different stakeholder as well as their logics are results of an extensive analysis of 27 interviews, one written questionnaire and of primary literature, policy documents as well as presentations. The interviewees were chosen with respect to three criteria in order to include all relevant opinions. The first criterion was to include representatives from each committee of the governance structure. Secondly, interviewees from each level and from different logics were chosen. Thirdly, stakeholders of countries with different EU status were involved. In order to figure out whether macro-regional strategy might lead to transnational soft spaces, the governance structure itself as well as the participation of the different stakeholder groups during the development of the strategy were analyzed. Moreover, the potential added-value, the challenges and the expectations from the viewpoint of the different stakeholders on the EUSDR were studied and related to their institutional logic.

Governance structure of the EUSDR

The governance structure of the EUSDR is under development and may also change during the process. In particular during the first phases each committee had to find its place in the governance system. No detailed description was given top-down which as well led to a different understanding in the different PAs. There still remains uncertainty on the exact tasks and understanding of the roles of the different committees. Thus, during the conduction of the interviews it turned out to be of huge interest by all stakeholders how these different committees interact and who does

what. Building on the analysis of the interviews and existing policy documents this paper presents a first attempt to summarize a common current understanding of each stakeholder and their interactions.

The governance structure of the EUSDR can be described in three parts. First the political level (dark gray) can be identified, being responsible for the overall strategic decisions of the EUSDR. This level consists of the European Council, European Commission represented by the Directorate General Regional Policy (DG Regio) and the High Level Group (HLG) for macro-regional strategies. The fourth committee is composed of the Priority Area Coordinators (PACs) and the National Contact Points (NCPs) (Figure 3, Table 1).

The second level is the strategic level (light gray) which includes the political level and the three committees of the PACs, the annual Stakeholder Conference and the Steering Groups (SGs). These are on the linking position between the political level and the operational level (light green), but they still have an important role in the strategic decision-making and the overall development of the strategy. The annual Stakeholder Conference plays an indirect role whereas the PACs and the SGs represent the strategic decision-making level in each Priority Area (Figure 3, Table 2).

The third level, marked in light green, is the operational level responsible for the implementation of the strategy. All elements marked in dark green exist for each PA, thus, 12 times. In addition to the Stakeholder Conference, the PACs and the SGs, this level comprises consultants, Observers, different Working Groups and the Projects (including preparatory and pilot projects) (Figure 3). The implementation of the strategy is further supported by the INTERact Labgroup, the interregional group “Danube” of the Committee of the Regions as well as by other transnational cooperations and institutions of the Danube region. The implementation of the strategy builds on financing resources by Nation States and the EU (e. g., ERDF Funds and Cohesion Fund) and their project funding (Figure 3, Table 3).

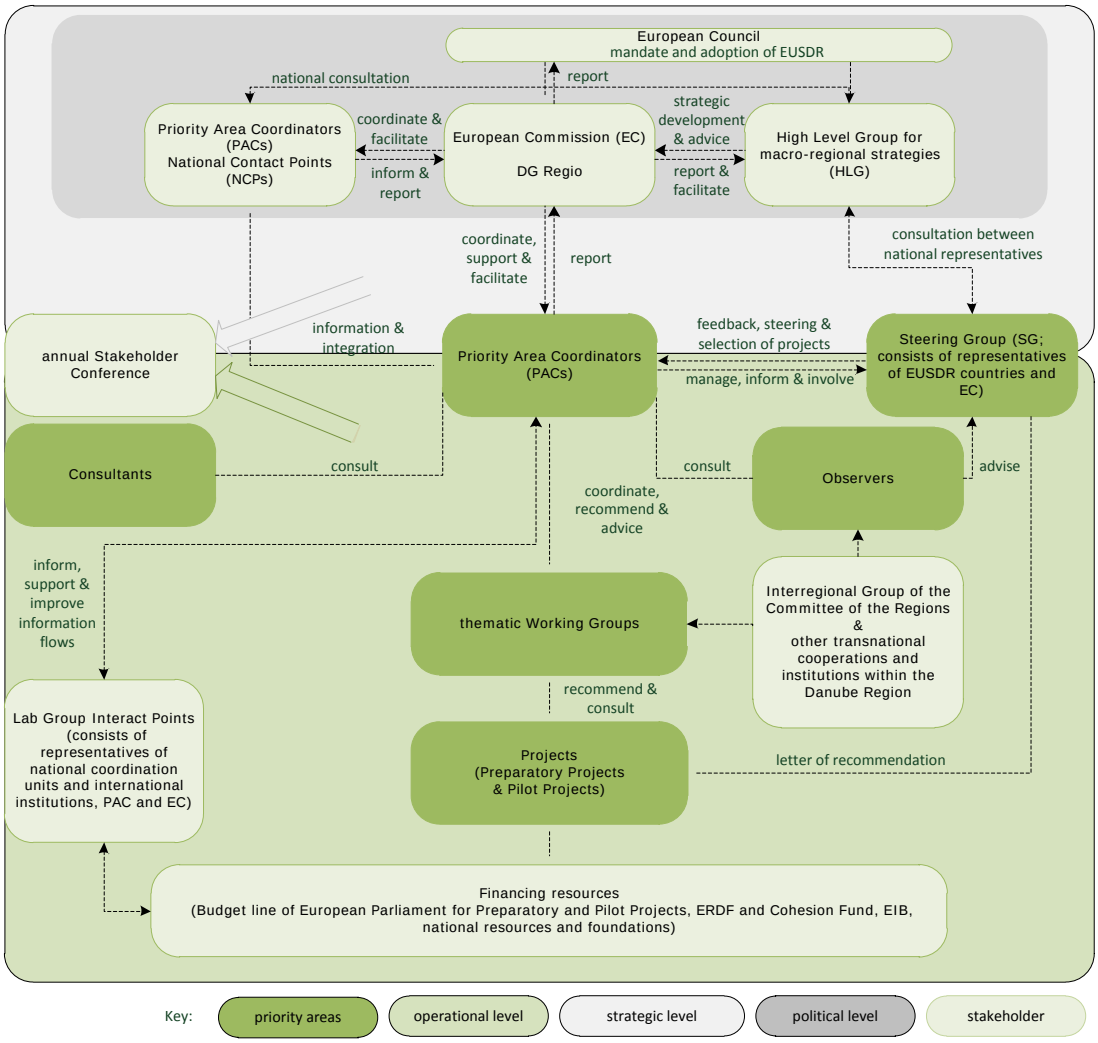

Figure 3. Governance structure of the EUSDR (own illustration on the basis of Simoner and Vorderwinkler 2011, p. 2; Schmitt, 2011)

The role and tasks of the crucial committees within the governance structure of the EUSDR can be shortly described as follows. A detailed description of the tasks of each group is given in the Tables 1 to 3.

The European Council is responsible for mandating to the EC and adopting the strategy. The ECs main task is the overall coordination, facilitation and evaluation of the strategy. During the development of the EUSDR the HLG approves the decision of the European Council. The newly constituted HLG for macro-regional advises the EC and member states and decides upon the future strategic directions. The NCPs are responsible in their national context for coordinating the official national position and implementation activities (Table 1).

Table 1. Tasks of stakeholders of political level in the EUSDR

European Council	· mandate and invite the EC to present an EU strategy · endorsed the EUSDR and call on actors to implement the strategy
European Commission (EC), mainly represented by DG Regio	· coordinate consultation and take into account other relevant policies and EU programmes · draft and review EUSDR and Action Plan · consult Member States via the HLG and NCPs · evaluate and report on progress to member states and European Council · facilitate implementation as well as decision-making and support SGs and PACs · review concept of macro-regional strategies
High Level Group (HLG)	· advise EC and Member States and make strategic decisions on future political direction and feedback evaluation of EUSDR
National Contact Points (NCPs)	· coordinate and formulate national positions and non-paper · ensure and coordinate implementation of EUSDR in home countries · inform and consult national institutions and all relevant stakeholder · report to EC on progress and implementation activities within home countries · support SGs and PACs and other stakeholders during implementation · inform on EUSDR and promote actions taken, communicate results · coordinate and ensure integration of EUSDR in national policies

(own summary based on analysis of interviews and INTERact Point Turku, 2011)

The annual Stakeholder conference is the forum for information exchange between all stakeholders. Furthermore it builds a monitoring system for the implementation steps within the year and gives the opportunity for the committees to meet and outline further strategic steps based on the presented results. The PACs are responsible for the overall management of one PA and coordinate and organize activities. They maintain the dialogue with other PAs and feedback the development of the EUSDR to the EC together with the NCPs. Having in mind the coordinating task of the implementation activities, the PACs are as well responsible for the integration of the different PAs specifically within its pillar. The Steering Groups are responsible for the strategic decisions within one PA and include representatives of each country. These ensure the implementation of the PA in the home countries (Table 2).

Table 2. Tasks of stakeholders of strategic level in the EUSDR

annual Stakeholder Conference	· forum for all stakeholders and information exchange · presentation of results and networking between all stakeholders and PAs · meeting of different committees and strategic development of strategy
Priority Area Coordinators (PACs)	· responsible for overall management of PA: coordinate and organize activities · link different stakeholders and committees in PA · propose updates of Action Plan and targets · manage SG, ensure contact and prepare project selection · report to EC on progress in PA twice a year · ensure vivid contact with each country and the policy level · maintain dialogue with projects and financing resources · facilitate alignment of funding, policies and instruments · ensure integration and communication with other PAs · ensure communication of PA and make actions taken visible · advise HLG together with NCPs in overall strategic development of strategy
Steering Groups (SGs)	· responsible for project selection and identification · promote and encourage implementation in home country · integrate strategy in policies and with different sectors · integrate, inform and contact all relevant stakeholders in home countries · integrate different sectors and different levels · seek for funding opportunities and impulse new initiatives · ensure implementation in respective field of interest in countries · decide on targets for PA and feedback PACs · prepare implementation and ensure proper circumstances in home countries · (in some countries) report to the NCPs or HLG · communicate and enhance visibility of the strategy · support transnational networking
(own summary based on analysis of interviews and INTERact Point Turku, 2011)	

The operational level is complemented by all other stakeholders involved in the implementation of the EUSDR. The Observers have an important role in advising the SG content-wise and thereby represent the functional approach of the projects. Consultants support some PACs. The Working Groups are temporarily constituted committees on expert level that support the project selection of the PAs. The projects represent the implementation activities of the EUSDR. In addition, the Labgroup supports the PACs in finding solutions for their management and builds a forum for enhancing the alignment (Table 3).

Table 3. Tasks of stakeholders of operational level in the EUSDR

Observers	· advise the Steering Group content-wise and ensure quality of projects
Consultants (of PACs)	· support organization and management of PA
Working Groups (WGs)	· responsible for content related support of PA and advise SG on expert level · prepare project selection, support PA with preparation and coordination of implementation activities, and detail Action Plan · integration of different PAs and facilitate contact with other PAs
Projects	· networking and implementation of targets of EUSDR · communicate EUSDR and ensure visibility · overcome challenges and use opportunities of the region · link the functional approach of concrete actions with targets of the EUSDR
Labgroup	· support PACs in particular concerning project identification · seek and propose operative solutions to identified issues · propose common approaches for PACs and programmes concerned · improve information flows and awareness-raising in projects and programmes and discuss possible ways to exploit synergies · support alignment of funding and integrative approach · constitute a committee for stakeholders outside and inside EUSDR

(own summary based on analysis of interviews and INTERact Point Turku, 2011 and INTERact Point Vienna, 2011)

Within the governance structure of the EUSDR the different committees have their tasks as described in Tables 1 to 3. The group of PACs with NCPs, the EC and the HLG are responsible for overall decisions for the strategic development. The EC plays an important role in linking these two committees and the European Council. The EC coordinates the political decision-making level and ensures the contact of this level with the different Priority Areas and the operational level in general. The PACs are presented in the center of Figure 3 as they are on the linking position between all stakeholders. Thus, the PACs collect a huge amount of knowledge which is beneficial for all stakeholders. The PACs work closely in particular with the SG, the EC, WGs and Observers. Moreover, they link these stakeholders. The SG ensures the implementation within the home countries and works closely together with NCPs, PACs and observer. This committee is the most important committee within each PA for proposing common initiatives of the different countries and ensuring the political commitment of the countries within each PA. Furthermore, the SG is the responsible committee for the agreement and coordination between the countries in

the implementation phase. The representatives within the SGs link national stakeholders to the EUSDR. Thus, the SG links politics and administrative challenges for the implementation. The interaction of the Observers with other committees of the governance structure is different in each PA.

From the initial idea to the implementation of the EUSDR and the stakeholder participation

Knowing the governance structure of the EUSDR and for analyzing the fostering of soft spaces within this framework, an overview of the development of the EUSDR and the involved stakeholder groups is of interest. The initial idea for a macro-regional strategy for the Danube region came up by the end of 2008. The initiative was driven forward in particular by Austria, Rumania and Baden-Wuerttemberg. The European Council endorsed the strategy in June 2011. In the time between the initiative and the adoption of the strategy three phases can be distinguished. The first one includes the period from the first idea to the mandate of the ER to the EC. Within this phase exclusively political stakeholders were involved. With the official decision approving a macro-regional strategy in the Danube region, the first two levels of the governance structure were developed along with decisions on the content, targets and the overall strategic direction (Figure 4). The second phase started in June 2009 and lasted till December 2010. It includes the consultation process and the drafting of the EUSDR. The European Parliament got involved defining tasks and giving indications on the content. The participating countries appointed NCPs that organized the consultation within the countries being responsible for the thematic direction of the strategy. Thus, e. g. ministries, NGOs or private stakeholders were included in the process in the countries. Through the consultation of the EC the administrative, civil and private logic got increasingly involved (Figure 4).

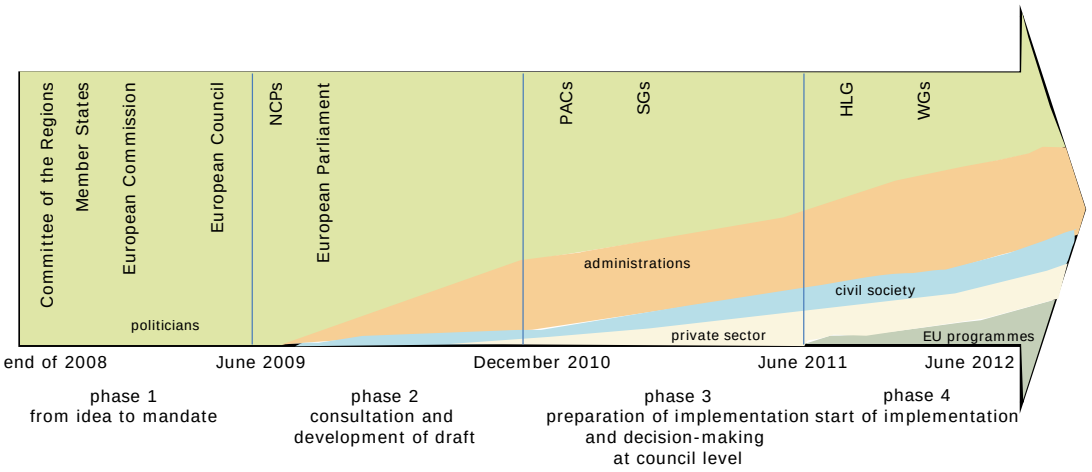

Figure 4. Different stakeholder groups during the development of the EUSDR and its governance structure (own illustration)

All in all, during the first two phases the first level of the governance structure was developed and came into action. In the implementation phase the NCPs as part of the governance structure will work in a committee with the PACs together.

The third phase embraces the time period from December 2010 till June 2011. After the drafting of the strategy document, the EC and the NCPs decided to appoint a tandem of PACs for the PAs. While the final decision on the selection of the managing countries of the PAs was in hand of the EC, the countries themselves appointed the PACs. After the PACs had started their work, the constitution of the SGs began immediately. With these stakeholders coming into charge for the preparation of the implementation, the administrative logic became more important. As Observers serve directly the SGs the private sector and the civil society became more and more influential on the decision-making. By end of this phase, also the Labgroup took up its work. It contains different logics, but most importantly includes the logic of EU programmes. With the endorsement of the strategy by the European Council the EUSDR entered officially into the implementation phase by the beginning of July 2011. The fourth phase comprises the implementation which is in a testing phase until the first annual Stakeholder Conference. In the meantime, a HLG constituted for macro-regional strategies took over from the general HLG. In order to start further detailing the Action Plan and to select projects for recommendation each PA formed Working Groups. The PACs started to communicate with the existing EU programmes and to provide letters of recommendation according to the selections of the SG. Thus, the integration of programmes and projects with their logics has started to gain more importance.

4. Analysis of stakeholders' opinions and expectations

Apart from the governance structure and the participating stakeholders soft spaces are invoked by stakeholders' behavior. The attitude towards the strategy depends therefore to a high extent on their expectations and the potential added-values of the cooperation and the challenges they see for a successful implementation. Hence, the participating stakeholder groups and their logics in the process are examined. Thereafter, a short analysis of the stakeholder opinions with respect to the added-values and the challenges is given before summarizing their expectations.

Involvement of different logics and key stakeholders for a successful implementation

Whereas in the first phase the political logic has dominated the process, gradually other logics got increasingly involved. However, mainly the political logic and the administrative logic (partly following as well a political approach, e. g., in ministries), are dominant in the process (Figure 3). It remains open whether others will gain more importance in the implementation. It can be assumed that they will. However, the direct influence on results and strategic lines will remain limited. In particular within the SGs, which as well have a decisive role, the different logics are coming together. Also, the WGs and projects include different logics. The network

formed through this process may lead to strong or weak ties between the different logics and committees depending on the interaction of the different stakeholders.

Within the governance structure of the EUSDR the stakeholders themselves and external observers assess that a successful implementation of the strategy depends highly on the PACs and their engagement. In particular stakeholders of the political and strategic level see the responsibility for a vivid implementation of the different PAs lying in the hands of the PACs. All stakeholders, in particular those of the operational level, attribute the responsibility for a successful implementation to the Nation States and their political commitment. Generally they are considered being key stakeholders as their commitment is estimated crucial for a long-lasting cooperation and support of implementation activities. The operational level concludes in accordance that without a formal mandate the PACs need to rely on strong support by NCPs and SGs. The role of the EC is evaluated more ambivalently. All stakeholders know and also accept that they have a coordinating and facilitating role. However, most of the stakeholders expect top-down orders for the different committees for enabling an efficient cooperation of the 14 countries. It should be noted that interviews were conducted in the orientation phase of the stakeholders, so this wish might as well diminish later on.

Added-values and challenges for the macro-regional cooperation

The aim to work in an integrated framework in a region with common features in order to integrate sectors, levels and politics is welcomed warmly by all stakeholder groups. The EUSDR triggered a huge dynamic. Generally a lot of interest in this new cooperation form could be observed. Knowing the governance structure, observing the first implementation steps and taking into account challenges of former cooperations within the Danube region, the stakeholders consider challenges for the EUSDR and award added-value. Thus, it is of interest what the main challenges and estimated potentials are. Further it is interesting to analyze what expectations the stakeholders have for the EUSDR due to the potentials and challenges. Thereafter, analyzing these results it is reflected whether the stakeholders consider functional regions to be fostered by the macro-regional approach.

Generally the different stakeholders are widely in agreement with respect to potential added-values of the EUSDR. Regarding the challenges the different stakeholder groups point attention to different ones. It can be observed that the political logic at this point of implementation considers more potential and does not see crucial challenges. On the contrary, the administrative stakeholders and the private sector do agree upon the EUSDR facing many challenges.

The added-values awarded to the EUSDR are the networking via this cooperation itself, the political commitment and the functional approach of the strategy. Furthermore, all stakeholder groups underline the attempt to cooperate between countries of different EU status with this conflictual history and diversity among the countries. Moreover, the agreement on common targets and priorities is considered

being of added-value for the region. The constitution of a region built on common challenges raises hopes for the development of a common identity.

Due to the orientation phase of the strategy the stakeholders mentioned in total more challenges for the cooperation. Compared to the added-values these include practical challenges for cooperation within this framework. The political stakeholders themselves consider it as a challenge that the EUSDR will have concrete influence on national politics. While the three No's of the EC (no new funds, no new legislation and no new institutions for the macro-regions) are not considered an overall challenge, the implementation of the strategy via a letter of recommendation is estimated not to be effective. Thus, many question what the concrete implementation activities are. The administrative stakeholders and the private sector emphasize the challenge of insufficient political commitment, additional administrative and financial effort as well as limited time resources. The integration of different sectors and levels as a challenge is pointed out as well. However, the most important challenge outlaid by the different stakeholder groups refers to challenges of cooperation between these different countries and the need to build up trust as well as to establish regular contact among them.

Stakeholders' expectations

The EUSDR and the first implementation steps aroused many expectations of stakeholders. In order to be considered successful the strategy is about to meet these. The analysis of the mentioned expectations by the interviewees shows clearly that the overall expectation of all stakeholders is the development of long-lasting cooperation networks and an enlargement of the individual network. The added-value of a strategic cooperation relying on existing networks coincides with this overall expectation. Moreover, the history and insufficient political support for the political involvement in these functional networks of the PAs is considered a crucial challenge for this expectation. The EUSDR raises hopes that the existing differences in the countries that have hindered the network building can be overcome under the framework of the strategy. More expectations for the EUSDR are that there will be new impulses and incentives, a high self-commitment by the different stakeholders and a long-lasting level of cooperation between the Nation States and the EC. Furthermore, the stakeholders expect the EUSDR to become a platform for agreements on policies and formulation of common targets and actions as well as a first step to harmonize standards in different sectors. The EUSDR is expected to be a first step into the direction of an integration of the different sectors and the preparation of future common policies. Through the strategy stakeholders expect existing initiatives and cooperations to be stimulated and old projects to become more prominent. The strengthening of the functional linkages is expected to possibly result from this cooperation and the political support.

5. Discussion: The EUSDR as a soft framework for transnational soft spaces?

From these results on the expectations towards the EUSDR it can be concluded that the overall expectations concern an improvement of networking and the political reconcilement of the countries in the Danube region. The direct advantages for functional regions are estimated to be a long-term added-value indirectly evolving from stronger political ties. However, a more efficient functional cooperation to overcome common challenges remains the overall goal. This paper aims at showing whether this long-term goal may be achieved with the macro-regional strategy as an appropriate framework. Do the governance structure and its actor-networks facilitate the emergence of transnational soft spaces at a European scale? Does the EUSDR as a new metagovernance-level offer possibilities for new incentives that strengthen and link political and functional processes as well as networks via a fuzzy approach?

First it is to be examined whether the concept of soft spaces can be applied to explain processes on the macro-regional level. The EUSDR, in particular during the first preparation phase, can be considered as a mainly political process. Thus, the external boundaries are administrative building a political space. The Danube Region can rather not be considered as one soft space. As soft spaces are multiple spaces of governance alongside other devices for policy integration, this framework and the macro-region Danube can be considered as such other devices for policy integration. As soft spaces are shaped fuzzy across different ranges of geographies, scales and networks within the Danube region the Priority Areas and their set-up in the governance-structure can be considered fuzzy in these senses. The governance-structure enables the PAs to operate at different levels depending on the radius the stakeholders involved use. The networks involved are changing depending on the subject currently on the top in the PAs. This means e.g., that the Working Groups and the involved projects are temporarily and change over time. Hence, the networks in the strategy are flexible and result from existing networks. Different committees, e. g., the SGs include administrative units as well as issue-bound stakeholders pursuing sectoral aims. These are all characteristics of soft spaces. If the EUSDR follows a flexible approach concerning the outer boundaries is not obvious yet. However, within the PAs and the Danube region the activities are geographically fuzzy. The concept of soft spaces may thus explain the processes on the macro-regional level. Furthermore, the overall goal and the necessity to cooperate in order to overcome common functional challenges suggest itself for applying the concept. Macro-regions may be considered as a new layer of intervention at the European level as in particular the SGs, being responsible for strategic decisions, lay out the route to take. Nevertheless, macro-regional level does not have formal competencies neither do the different committees.

All in all the governance structure may facilitate the emergence of transnational soft spaces as the different stakeholder groups are interacting with each other and thus learn about the needs of the others. Generally the governance structure offers possibilities for fuzziness to meet functional linkages as stakeholders from different levels, geographies and sectors are involved. The whole governance structure may serve as metagovernance-level for the PAs and the relational geographies in them. The different committees may as well come up with new incentives and give

impulses to the region depending on the main challenges: future political commitment and assignment of competencies, the cooperation between the different countries in the strategy and the upcoming implementation activities.

6. Conclusion

Analyzing the governance structure of the EUSDR as well as the expectations and added-values of this cooperation, the process can still be considered to be mainly a political one and thus the EUSDR also being a political cooperation. Nevertheless, the EUSDR enables through the PAs a vertical, horizontal and sectoral integration. The EUSDR offers an official metagovernance system while still leaving room for fuzziness. The Danube macro-region may strengthen functional linkages in particular in this area with little cooperation experience. Also, the EUSDR as a metagovernance-level can consolidate networks while building on existing ones. The PAs show key aspects of characteristics that transnational soft spaces would have. Concluding, macro-regional strategies and their governance structure can lead to a new macro-regional governance with the potential to favour functional linkages and thus foster soft spaces. The overall expectation of networking can be satisfied in the EUSDR. These potentials are not yet fully recognized and exploited. The author therefore underlines the importance of the PAs. How and in which way the PAs can foster soft spaces will be subject to further research and publications.

CURRENT CHALLENGES OF MANAGING URBAN HERITAGE IN TURKEY

Müge Akkar Ercan[1], Melih Ersoy[2], Bahar Gedikli[3], Güliz Bilgin Altınöz[4], Cana Bilsel[5]

Abstract

Turkey acquires a remarkable wealth of historic and cultural heritage. Yet, changing economic, political, legal and social conditions often turn this legacy into a liability. Since the mid-1980s, along with the neo-liberal policies, the widening of market mechanism and a competitive real-estate market were followed by the rapid privatization of public lands and other assets, the expansion of local governments' jurisdictions, and the growing presence of global capital especially in big cities. Together with the neo-liberal urbanism, heritage has been recognized more and more as a physical asset with its economic and symbolic contributions to the cities' competitiveness within the global market. This understanding of heritage has not only commodified and commercialized it, but it has also been undermined its social and cultural significance and values. In Turkey, heritage, like in many other countries, has become a city-marketing and branding instrument and a catalyst for urban regeneration schemes. Likewise, the rapid urbanization in Turkish cities has also acted as a growing threat against the historic and cultural heritage. This paper aims to underline and discuss a variety of current challenges and threats on the conservation of cultural and historic heritage in Turkey. It will examine these challenges and threats regarding political, legal, financial, economic and social dimensions, as well as the new planning priorities.

1. Introduction

Turkey acquires a remarkable wealth of historic and cultural heritage, but changing economic, political, legal and social conditions often turn this legacy into a liability. Since the mid-1980s, along with the neo-liberal policies, the widening of market mechanism and a competitive real-estate market were followed by the privatization of public lands and other assets, the expansion of local governments' jurisdictions, and the growing presence of global capital especially in big cities. Together with the neo-liberal urbanism, heritage has been recognized more and more as a physical asset with its economic and symbolic contributions to the cities' competitiveness within the global market. This understanding of heritage has not only commodified

and commercialized it, but it has also been undermined its social and cultural values. In Turkey, heritage, like in many other countries, has become a city-marketing and branding instrument and a catalyst for urban regeneration schemes. Likewise, the rapid urbanization in Turkish cities has also acted as a growing threat against the historic and cultural heritage.

This paper aims to underline and discuss a variety of current challenges and threats on the conservation of cultural and historic heritage in Turkey. It summarizes the evolving legal, institutional and financial background of urban conservation from the mid-19th century to the 1980s. Second, it focuses on the changes in the legal, institutional, organizational and financial dimension of heritage conservation over the last 30 years, and third, it examines the current planning system on historic heritage sites. Within these three sections, the paper seeks to underline the challenges and threats against the historic heritage sites regarding political, legal, financial, economic and social dimensions, as well as the new planning priorities.

2. Evolving legal, institutional, organizational and financial background of urban conservation from the mid-19th century to the 1980s

The early conservation policies started to be shaped in the second half of the 19th century due to the demands of European archaeologists to undertake excavations within the territory of Ottoman Empire. A series of legislations - *The Ancient Monument Regulations (AMR) of 1869, the AMR of 1874, the AMR of 1884, the AMR of 1906,* and *Conservation Regulations of Monuments of 1912*- were subsequently enacted to establish the legal and institutional frameworks for the protection of historic monuments and artifacts, particularly those that were discovered throughout these excavations and to found an imperial museum in order to exhibit these discovered historic artifacts (Table 1). The central government was the sole authority responsible for the conservation of historic monuments and artifacts. While the Ministry of Foundations (*Nezaret-i Evkaf-ı Hümayun*) was the major authority for the preservation and regular maintenance of historic artifacts owned by the Foundations, Conservation Committee of Ancient Artifacts (*Muhafaza-i Asarı Atika Encümeni*) was the agency responsible for the implementation of conservation laws. The urban conservation approach of this period was based on the idea of preserving historic assets individually. The major historic artifacts to be preserved were seen as the historic artifacts of state and foundations, such as castles, city walls, palaces, theatres, bridges, churches, monasteries, synagogues, rather than urban fabrics and neighborhoods with historic and cultural characteristics.

After the foundation of Turkish Republic, all the legal and institutional organization of the state was renewed to create a secular nation-state. The Directorate of Turkish Ancient Artifacts (*Türk Asarı Atikası Müdürlüğü*) was established in 1920 within the organization of the Ministry of Education (MoE) to be responsible for all issues of museums and archaeological excavations. A year later, it was renamed the Directorate of Culture (*Hars Müdürlüğü*). This was followed by the establishment of the Directorate General for Foundations (*Evkaf Umum Müdürlüğü*) responsible for

the regular maintenance of historic buildings belonged to the foundations in 1935, the establishment of Conservation Commission of Monument (*Anıtları Koruma Komisyonu*) in 1933 to document the historic heritage of the country and the establishment of the Directorate General for Ancient Artifacts and Museums (*Eski Eserler ve Müzeler Umum Müdürlüğü*) in 1944. During the period of 1920 and 1950, the central government was the only authority responsible for the conservation of the majority of historic heritage, while municipalities were only responsible for the conservation and regular maintenance of castles, towers and graveyards. State-funds for conservation of historic heritage were very limited. The total budget of the Parliament, MoE, Directorate General for Foundations and the Ministry of Public Works that were allocated for the conservation of historic heritage was only 0.12 % of the total national budget (Madran and Özgönül, 2005). There was no subsidy to help support the restoration costs of private individuals / agencies, although they were legally obliged to restore or carry out the regular maintenance of historic properties (Madran and Özgönül, 2005).

The conservation policy of the early years of the Republic was more or less the same with the Ottoman era (Table 1). Although preserving historic artifacts individually were the dominant conservation approach of this period, the *Municipality Law of 1930* enforced municipalities to prepare development plans of cities and to be responsible for the conservation of historic monumental artifacts. Likewise, the *Building and Road Law of 1933* claims that "monuments within the boundaries of these plans (*urban development plans*) were to be 'marked' and a ten-meter strip of open space was to be designated around them" (Şahin Güçhan and Kurul, 2009, p. 27, *italics added*). Despite the responsibilities given to municipalities in the field of conservation by the *Municipality Law of 1930* and the *Building and Roads Law of 1933*, their power, experience and financial resources were too limited to take necessary actions for the restoration and regular maintenance of historic artifacts in cities. Besides, the implementation of the development plans through the *Building and Roads Law of 1933* to build 'modern' Turkish cities led to the severe destruction of historic fabrics of cities, especially those in Istanbul throughout the 1950s (Şahin Güçhan and Kurul, 2009, p. 27).

The *High Council for the Historic Real Estates, Artifacts and Monuments* (HCHRAM) *(Gayrimenkul Eski Eserler ve Anıtlar Yüksek Kurulu)* that was founded in 1951 was seminal in the field of urban conservation. The High Council was the absolutely autonomous agency which was primarily responsible for determining the principles on the restoration, maintenance and management of historic heritage and monitoring and auditing of the implementation of the conservation projects according these principles. One of the major contributions of the High Council was their attempt to introduce the understanding of conserving historic urban areas, rather than individual historic artifacts or monuments (Şahin Güçhan and Kurul, 2009, p. 28). Despite the establishment of the High Council, historic heritage conservation continued to be seen primarily as the major responsibility of the central government agencies between the 1950s and 1980s. As a part of this centralized state

organization, local departments of the *Directorate General for Ancient Artifacts and Museums* were established in cities.

The period of 1950-1980 was also characterized by the enactment of the first conservation law, namely *The 1973 Law of Historic Artifacts No. 1710*. The law introduced the understanding of conserving 'areas' rather than 'individual artifacts', defined 'conservation sites' as 'historic', 'archaeological' and 'natural', expanded the responsibilities and power of the HCHRAM, and introduced the technical and financial supports from the state to private individuals for the restoration of their historic properties. In the 1970s, following the designation of archaeological and historic conservation sites in cities, the development plan decisions for these sites became ineffective and this revealed the need for preparing 'conservation plans' for the designated areas within two years (Şahin Güçhan and Kurul, 2009, p. 29). The notion of 'conservation plans' which emerged in these years became a subject of discussion among planners, conservationists and experts in the field (Şahin Güçhan and Kurul, 2009, p. 29). Despite this progress, the legal requirements for conservation sites were mostly seen as obstacles against urban development by municipalities and private property owners (Şahin Güçhan and Kurul, 2009, p. 29). Also, municipalities were inadequate in preparing conservation plans and conserving historic areas of cities due to their limited power, funding and experts in the field of conservation. Beside such hindrances, moving out of wealthy dwellers of historic neighborhoods to newly developed modern apartments and their replacement with the poor migrants or citizens as the tenants or new owners also led to the deterioration of these historic quarters of cities and their continuous decline in the 1960s and 1970s.

The legal, institutional and financial framework of conservation has significantly evolved since the 1980s. The Law No. 2893 of 1983 and the enactment of subsequent legislations that have made amendments on this law (*The Law No. 3386 of 1987, The Law No. 5226 of 2004, The Law No. 5571 of 2006, The Law No. 5728 of 2008, The Law No. 5835 of 2099 and The Decree Law No. 648)* provided the legal bases for urban conservation. The next section discusses the changes in the conservation field since the 1980s to today.

3. The conservation policies between the 1980s and 2010s

The neo-liberal policies came to the political agenda in Turkey following the 1980 military coup. Since the early-1980s, the policies seeking to establish a free market economy have gone hand in hand with the privatization, deregulation and liberalization policies. Since the 1980s to today, a number of legislations which came into effect have provided two parallel planning systems for historic sites in Turkey (Table 1). The Law No. 2863 (The Conservation Law of Cultural and Natural Assets) of 1983, and the legislations and regulations which have come into force to make some amendments on this law have brought about a planning procedure with a 'conservation' emphasis. That is to say, the Law No. 2863 replaced the concept of 'historic artifacts' with the concepts of 'cultural assets' and 'natural assets' into the

conservation planning in Turkey. Besides being historic, it underlined the importance of having qualitative merits (such as their architectural, economic or social qualities which represented the historic period in which they were built) of historic buildings, monuments or sites to be designated and listed as cultural assets. It also emphasized the importance of conserving the historic sites within an urban context, instead of conserving historic buildings or monuments individually. The Law No. 2863 was also a pioneering legislation in terms of introducing the concept of 'conservation-led development plans' as a new type of plan specific to conservation areas. Although the planning approach behind this law is not based on an integrated conservation approach, it is still important with its decentralization and localization policies by empowering local authorities to prepare approve and implement conservation-led development plans. The Law also brought a two-tier control mechanism for the planning procedures and actions taken for conservation sites: '*Higher Conservation Council of Cultural and Natural Assets*' (HCCCNA) that was set up within the organization of the Ministry of Culture and Tourism and '*Regional Conservation Councils*' (RCCs) that were established locally for the designated conservation sites with listed buildings and monuments.

The most important legislation, which complemented the Law No. 2863, is the Law No. 5226 (The Law of Conserving Cultural and Natural Assets) enacted in 2004. The law broadened the content of 'conservation-led development plans', making extensive studies on conservation sites compulsory, prior to plan preparation (Dinçer, 2009a). These studies were to regard conservation sites not only their archaeological, historic, natural, architectural and demographic dimensions, but also their cultural, social and economic dimensions (Dinçer, 2009a). The expected outcomes of such studies, therefore, were to be conservation plans integrating multi-dimensional problems of localities; that is to say, plans addressing not only the problems of conservation of physical environments, but also responding to the needs of communities living and working and providing collaborative planning models, financial, organization and management models for the planning process (Dinçer, 2009a). The law also introduced new financial devices for private owners (10% of the total property taxes allocated to be used for the conservation of historic heritage sites), as well as the new concepts, such as 'management area' and 'management plan' into the conservation agenda of the country (Dinçer, 2009b). It also introduced a new planning tool, transfer of development rights, into the Turkish planning legislative system. Additionally, it became compulsory to establish new specialist offices called 'Conservation, Implementation and Control Bureau (KUDEB)', employing experts in the areas of art history, architecture, city planning, archaeology and engineering sciences, were to be responsible for managing and controlling the implementation of conservation-led development plans (Dinçer, 2009b). The law suggests the identification of the 'action areas' and 'priorities' as the major requirements of the conservation-led development plans. It also emphasizes on the importance of the participation of all the stakeholders in the planning process. By suggesting a participatory management plan for conservation sites, a new financial resource and organization models, planning phases, determining the actors

responsible for the implementation of the plans, the law introduced a sustainable conservation approach to Turkish conservation policy agenda.

Parallel to this conservation-led planning procedure, a series of legislations (especially the Law No. 5393 and the Law No. 5366) were enacted to create alternative planning procedures for conservation sites to be designated either as 'urban transformation and development sites (UTDS)' or as 'urban renewal sites (URS)'. The Law No. 5393 (The Municipality Law) of 2005 defined the conditions for local authorities to designate UTDS. The article No. 73 of the Law claims that municipalities are authorized to designate UTDS on the deteriorated urban areas through municipal council decisions. The article empowers municipalities to implement 'urban transformation and development projects (UTDP)' (rather than development or conservation plans) to redevelop deteriorated urban areas, or to restore historic and cultural fabrics of a city, or to take precautions against earthquake. The Law has also given local authorities a wide range of powers to implement these projects, such as to identify the monetary values of properties on the designated UTDS and to redistribute the raising urban rents to property owners based on these values. Yet, contrary to the general planning principle of hierarchical integrity of different levels of plans, it has not enforced local authorities to integrate UTDPs with the upper-scale development plans or to prepare projects with a comprehensive planning approach. Consequently, it has opened up the way of making piecemeal and area-based projects, independent from the vision or upper-scale development plans of the city or region. For the UTDS, the Law has primarily promoted a physical and economic regeneration. Although the Law claims that mutual agreement between property owners and municipalities are compulsory to clear out and knock down the buildings and to expropriate private properties within the UTDS, it has provided a legal basis for the displacement of the poor communities living in such areas. According to the law, municipalities are required to provide new properties in the URDS only for the title holders who have had the privileged legal rights because of the amnesty laws. For the title holders other than these privileged ones, municipalities have the authority to offer alternative housing solutions in exchange to their properties in URDS, such as selling houses or lands on urban lands outside these project sites or by selling houses developed by TOKI. The law however has not had any regulation for tenants living in UTDS. Thus, local inhabitants (both property owners and tenants) who are provided such housing solutions by the UTDPs will be deprived of their homes and their rights to live in their neighborhoods and localities. The Law No. 5393 has not only provided a legal basis to violate the property rights of private owners, but it has also opened up the project implementations with a strong emphasis on physical and economic regeneration by displacing local poor dwellers and replacing with the potential wealthy incomers.

From 2005 onwards, the new legal arrangements emphasized the exchange value rather than the use value of the conservation areas. The Law No. 5366 (The Conservation Law of Deteriorated Immovable Historic and Cultural Assets by Renewal and their Utilization), which was enacted in 2005, enabled local authorities to undertake 'urban renewal projects (URPs)' which can bypass legislation on urban

planning and conservation within designated ‘urban renewal sites (URS)’. It has enabled the Council of Ministers to designate URS, while giving local authorities a great deal of planning and implementation powers on these sites by making them responsible for preparing ‘urban renewal projects (URPs)’ outside the conventional planning system without looking for any reference to vision or strategy plans of cities. Thus, it has also given local authorities the power of preparing piecemeal and area-based projects on conservation sites. Only architectural preliminary draft projects and implementation projects would be sufficient to initiate an URP in a designated historic site. The renewal of the historic environment has been the major motivation of the law that has not included any article about social and economic dimensions of designated URSs. Thus, the law has mainly envisaged and promoted a physical renewal approach for historic sites rather than an integrated and comprehensive conservation and regeneration approach. Behind this physical renewal approach that will be put into action as quick as possible through URPs, it is possible to note the intention to reveal primarily economic exchange value of historic heritage sites, rather than their cultural and historic values. Against all possible interventions from the existing regional conservation councils of a conservation site where URS are designated, the law has given the local authorities to establish regional conservation councils for the smooth operation of URPs. On the other hand, the law has failed in providing financial support to private owners to repair their houses. Yet, aiming to accelerate the renewal process, it has eased the process of expropriation and bureaucratic issues at the expense of jeopardizing individual property rights. In case private owners were not able to afford the restoration costs of their properties, or they did not accept the agreement conditions put forth by the local authority, the law enabled local authorities to expropriate the historic buildings and even to sell them to the third parties. In this sense, it has brought about not only a high risk of violation of property rights for the owners of historic buildings, but also the rise of gentrification (Dinçer, 2009a). Finally, according to the law, local authorities are only required to inform the interested parties about the URPs when necessary, rather than facilitating effective participation of all the actual stakeholders of such projects.

The Decree Law No. 648 which was enacted in 2011 to establish the Ministry of Environment and Urbanization has made significant changes in the Law No. 2863. The article No. 42 which enforced local authorities to prepare conservation-led development plans within two years following the designation of conservation sites was changed by the Decree Law and this time period was extended to three years. According to the law, when necessary, this time period can be extended as longer as possible by the RCCs. This amendment creates the possibility of not only turning the temporary conservation and use conditions during the transition period (the period when the plans are prepared) into permanent ones, but also the possibility of taking some actions in designated conservation sites without conservation-led development plans. The Decree has also narrowed down the jurisdiction of RCCs. For the issues that cannot be resolved at local levels, the Decree has given the authority of resolving these problems to HCCCNA which are to be made up of professionals and experts appointed by the Ministry of

Culture and Tourism. The Decree Law also changed all the members of RCCs and appointed new ones. Thus, by removing the autonomy of RCCs, it has shown the government's intention towards the centralization of planning power on such sites. The Decree has also limited the opportunities for NGOs and professional chambers to participate to the RCCs' meetings. All in all, the recent legislations have represented a radical move away from the decentralization which has evolved until the mid-2000s, and they therefore have brought forward the centralization of control power on conservation sites in cities.

4. Current challenges of planning conservation sites

Heritage conservation, first and foremost, requires a carefully constructed legal framework that clarifies responsibilities of public authorities, rights of private owners, types of plans in heritages and control mechanisms. There are currently two levels of development plans in Turkey which create significant conflicts and challenges against effective heritage conservation: 'Environmental plans' (*çevre düzeni planları*) which are the upper-scale strategy and vision plans at the regional or provincial scales, and 'development plans' (*imar planları*) which focus on the city level development strategies and planning actions.

Regarding the upper level spatial plans, the authorities responsible for preparing general spatial plans are the Ministry of Environment and Urbanization, Provincial Special Administrations and/or Greater Municipalities. They are prepared at the scales of 1/100 000, 1/50 000 and 1/25 000 depending on the size of the settlement. While the Ministry is responsible for the preparation of 'strategic spatial plans' and 'environmental plans'; provincial special administrations and greater municipalities are in charge of preparing 'provincial environmental plans' (*il çevre düzeni planı*) (Ersoy, 2011).

Theoretically speaking, the plans at these scales are ***structure plans*** where general strategic lines for spatial development are indicated. Nevertheless, the distinctions between the mentioned plan types are not clarified in the legislation. The Urban Development Law defines 'environmental plan' as "the plan that determines housing, industry, agriculture, tourism, transportation, etc with respect to national and regional planning decisions". As one can note, this definition does not include any statement on the conservation of cultural and natural heritage. Moreover, the law on the provincial environmental plan only defines the responsible authorities for the preparation of this plan, and does not describe ***what a provincial environmental plan is*** and ***what it should contain***. Regarding heritage conservation, 1) the multiplicity of responsible institutions with contradicting jurisdictions, 2) more than one plan type with similar aims, and 3) negligence of the conservation dimension in upper level planning lead to contradictions and inefficiencies in practice. Unlike other territories, heritage sites (cultural or natural) are places for which even further authorities are responsible and further laws are employed, contributing to the inefficiencies of conservation efforts. (Ersoy, 2011)

As far as local territorial development plans are concerned, municipalities are responsible for preparing settlement plans in accordance with the upper level plans. Settlement plans can also be accepted as strategic land-use plans that guide the preparation of the implementation plans (at the scale of 1/1000). How it is differentiated from the above group lies in its language: 1/5000 plan displays land-uses with proper forms, densities and coordinates.

As far as urban heritage sites are concerned, there are three more plan/project types, namely *conservation-led development plans, urban transformation and development projects (UTDP)* and *urban renewal projects (URP)* generally prepared at the scales of 1/5000 and 1/1000. The very name of the conservation plan in the Turkish context implies the urban development aspect in these areas together with their conservation. The Law No. 5226 defines the conservation-led development plan as the one "...prepared to improve the socio-economic conditions of households and shopkeepers; to create employment and surplus; to define conservation principles, conditions for use and limitations for construction; to show open space system, pedestrian and vehicle circulation, densities, financial aspects; to include a participatory land management model, with respect to the archaeological, historical, natural, architectural, demographical, cultural, socio-economic, ownership and building data". The Laws No. 5393 and No. 5366 however enable municipalities to prepare, approve and implement UTDPs or URPs on the designated historic conservation sites with no reference to either upper-scale plans or conservation-led development plans. The lack of hierarchical integration between these plans and projects is another factor for the inefficiencies and ineffectiveness of conservation efforts.

European Urban Charter necessitates a carefully constructed legal framework for an effective conservation strategy. In the Turkish context, the legislation defines numerous plan types that directly or indirectly related to heritage sites together with multiple authorities. An inner city urban heritage is under the jurisdiction of the Ministry of Environment and Urbanization, Ministry of Culture and Tourism, the relevant municipality; and is bound to many territorial laws and regulations. If the heritage site is a coastal one, the contradictions become even more serious since the number of authorities and laws increase.

The impracticalities caused by this situation can only be overcome through a careful revision of legislation: Under the leadership of public sector, one single upper level strategic spatial plan (the scale would be central to the settlement's particular conditions) and one single strategic conservation plan should be prepared (which should be followed by the detailed implementation plan) through the collaboration of relevant stakeholders. The three intervention types mentioned above (1) no-go areas, 2) sensitive areas, and 3) opportunity areas) should be carefully defined in these two plans. Principles for planning and design, and conservation strategies in these areas should be clarified together with the duties of relevant stakeholders. Otherwise they would not have the power to guide the implementation plans and lead to conflicting situations in practice.

5. Conclusions

The legal, institutional and organizational structure of urban conservation which was evolved over the last century has created a very complicated, patchy and messy system which includes conflicts between the legislations, agencies and jurisdictions of authorities. Especially the legislative and institutional arrangements which have come into effect over the last 30 years have not only increased the number of state agencies with planning and control powers on historic heritage sites, but they also have exacerbated the conflicting jurisdictions among these authorized public agencies at both central and local governments' levels. There is no collaborative and cooperative organization among these agencies, neither is there working attitude between them. This inevitably leads to the development of contradictory policy decisions on conservation sites.

Unfortunately there is no integrated and comprehensive strategy for the conservation of historic and cultural heritage at the national level, either. This also causes the development of piecemeal decisions on the historic heritage sites, depending on the level of knowledge and awareness of political authority in power towards cultural and historic heritage conservation. At local level, despite the legal regulations which set up new specialist offices (KUDEB) within local authorities' organizations, professionals and experts employed by municipalities with insufficient knowledge and experience in urban conservation still put further obstacles against the conservation efforts of heritage sites. Likewise, at local levels, with their diminishing autonomy, RCCs have become to be operated under the control of central government. Especially those that are set up for the designated renewal areas have been turned into the councils which approve the market-driven and profit-oriented URPs of the municipalities. The participation of NGOs to the planning process of conservation sites through the recent legislations has been limited, as well. Inadequate financial resources, grant and funding programs from public and private sectors for the conservation and regular maintenance of historic heritage is another field of challenge against the conservation of historic heritage. Despite the new state-funds and grants, and tax exemptions, high cost of restoration and conservation projects is still one of the major challenges for private property owners of historic buildings and local authorities. Rather than expecting property owners of historic properties and local authorities to pay the cost of conservation of historic and cultural heritage, all society should contribute to finance conservation projects. This requires the invention of new financial models and means for urban conservation.

Any attempt for the conservation of urban heritage is multi-faceted: Many practical cases all around the world prove that conservation is not simply a question of defining the boundaries of a historically significant area. Nor can it be limited to the restoration/rehabilitation of the historical beings within a defined area. Conservation of cultural heritage –ranging from archaeological beings to the 20th-century modern architectural/urban settings—is a rather complicated field with its physical, social, economic, environmental and political dimensions. When the heritage area under

concern is a living urban environment, it becomes even more complicated, since the area to be intervened is an integral part of the contemporary urban life. People live, work, go to school, use public spaces and have their leisure activities there. An integrated and sustainable conservation approach that reconciles the conservation and regeneration policies with community policies is indispensable in Turkey.

The legislative regulations which have come into effect over the last three decades brought about two parallel planning processes for historic sites, one of which has developed on the integrated and sustainable conservation planning approaches. This conservation-led planning system seeks to focus on the multi-dimensional aspects of conservation sites, while introducing the collaborative and participatory planning into the conservation planning, underlining the need for financial, organizational and management models for the planning process of conservation sites. It introduces the concepts of 'management area' and 'management plan' for conservation sites, suggests the identification of the 'action areas' and 'priorities' of the conservation-led development plans, and puts local community and stakeholders participation at the forefront of the conservation planning process.

The other planning system has been developed on either an 'urban renewal model or an 'urban transformation and development' model. Along with the neo-liberal policies which have increasingly promoted historic heritage sites as means of capital accumulation and instruments of maximizing urban rents, both models have put solely a strong emphasis on the economic exchange value of historic heritage rather than its cultural and heritage values. Within this understanding of urban conservation, historic heritage sites have not only been recognized as the assets to be protected for future generation, but as the spaces to be 'transformed and developed' or 'renewed' for their short-term economic benefits. This understanding has not only been significantly threatening historic sites in cities, but it has also resulted in planning actions conflicting with the public interests, as well as the interests of local communities of such historic sites.

The property-led transformation and renewal model shaped by this planning system has brought about a physical and economic renewal and transformation while undermining historic, cultural, social, environmental and ecological aspects of renewal and transformation. In recently launched urban renewal projects (such as Tarlabaşı, Sulukule), it is possible to trace the deliberate intention to protect the historic atmosphere of such sites, although the major motivation behind these projects unfortunately has not been a sensitive conservation of historic and cultural values that these places have possessed. In some projects, the facades of historic buildings were kept while the rest of the buildings were knocked down and were rebuilt to be used for residential, office or tourism purposes. In some projects, all historic buildings were torn down and their replicas were reconstructed (such as Tarlabaşı URP). This newly proliferating approach in Turkey has not only led to de-contextualize the historic sites by stripping off their historic, cultural, political and social values and contexts they have been embedded, it has also turned them into

mere ‘commodities’ to be sold and bought in property markets and ‘commercialized entities’. It is currently crucial to realize that cultural and historic heritage is not a renewable resource. To conserve and protect them for the present and future generations are one of the major challenges of not only the government agencies but also all members of the society.

The planning system based on ‘urban renewal’ or ‘urban transformation and development’ models brought about piecemeal and area-based project planning which has replaced integrated and comprehensive conservation approach to historic sites. This planning system, based on ‘project development’, has resulted in a new and flexible planning model to be easily developed, redeveloped or revised according to the demands and needs of private sectors and capitals. The legislations on ‘urban renewal’ or ‘urban transformation and development’ have not only provided the legal basis for the violation of the property rights of private owners, but they have also empowered local authorities and TOKI to restructure historic conservation sites in physical, economical and social terms. In this sense, the displacement of local communities living in these areas and their replacement with prosperous social groups are generally the inevitable and expected outcomes of these legislations. The relocation of poor vulnerable communities from their localities without addressing their problems and needs does not only strengthen gentrification, social segregation and exclusion in Turkish cities, but also raises significant concerns on how sustainable urban conservation and regeneration can be achieved in such historic heritage sites. Therefore, one of the major challenges for the local government appears to find ways of carrying out a sensitive historic conservation and sustainable community developments for the long-term success of these historic quarters of Turkish cities (such as, maintaining civil peace, raising standards in education, offering alternative affordable housing opportunities for poor dwellers, ensuring cooperative working between health and social services, providing permanent employment opportunities and improving environmental quality).

Period of time	*Legislations related to conservation*	*Institutional structure*	*Conservation authorities and responsibilities*	*Finance for conservation*	*Conservation approach (attitudes towards conservation)*
1980 - 2012	▪ *The 1982 Constitution* ▪ *The Law No. 2863 (The Conservation Law of Cultural and Natural Assets) of 1983* ▪ *The laws which have made amendments on the Law No. 2863:* *The Law No. 3386 of 1987* *The Law No. 5226 of 2004* *The Law No. 5571 of 2006* *The Law No. 5728 of 2008* *The Law No. 5835 of 2099* *The Decree Law No. 648 of 2011* ▪ *The Law no. 5216 (The Metropolitan Municipality Law) of 2004* ▪ *The Law No. 5391 (The Provincial Administration Law) of 2004* ▪ *The Law No. 5393 (The Municipality Law) of 2005* ▪ *The Law No 5366 (The Conservation Law of Deteriorated Immovable Historic and Cultural Assets by Renewal and their Utilization) of 2005*	▪ The abolishment of *High Council for the Historic Real-Estates, Artifacts and Monuments* and its replacement with *Higher Conservation Council of Cultural and Natural Assets and Regional Conservation Councils* within the organization of the Ministry of Culture and Tourism ▪ *The Directorate General for Ancient Artifacts and Museums* within the organization of the Prime Ministry between 1972 and 1989 was replaced by the *Directorate General of Scheduled Monuments and Museums and the Directorate General of Cultural and Natural Artifacts* under the Ministry of Culture in 1989 ▪ Increasing number of state agencies with the planning control on historic heritage sites (TOKI, Privatization Authority, Ministry of Culture and Tourism, Ministry of Urban Development and Settlements, Directorate General of State Railway, etc.) ▪ Establishment of the Ministry of Environment and Urbanism by replacing the Ministry of Urban Development and Settlement	▪ Decentralization of power on conservation from the central government agencies to local authorities throughout the 1980s and 2000s ▪ Increasing jurisdictions of local governments on conservation planning, as well as the planning of UTDS and URS ▪ Beside the decentralization policies, some intentions towards the centralization of planning power on conservation sites, UTDS and URS throughout the 2000s by increasing jurisdiction of TOKI, Privatization Authority, Ministry of Culture and Tourism, Ministry of Environment and Urbanism ▪ Increasing central government control on the Higher Conservation Council of Cultural and Natural Assets and Regional Conservation Councils by the Decree Law No. 648 of 2011	▪ New funding by the Law No. 5226 - 10% of total property tax allocated only for the conservation of historic environments in cities ▪ New credit options of TOKI for private property owners with low interest rates ▪ Trade-offs ▪ Grants provided by the Ministry of Culture and Tourism ▪ Tax exemptions for private property owners of historic listed buildings ▪ Despite the new funding means for conservation projects, they are still inadequate	▪ Introduction of *'conservation-led development planning'* which has become the compulsory duty of local governments ▪ Increasing awareness towards historic and cultural heritage among society ▪ Rising importance of historic areas in cities because of their economic exchange value rather than their heritage values ▪ Two parallel planning systems being in effect on conservation sites: a *conservation-led planning* procedure (under the control of the Laws No. 2863 and 5226) developed on the integrated and sustainable conservation planning approaches and the *planning procedures for urban transformation and development sites and urban renewal sites* under the Laws No. 5393 and 5366) ▪ Centralized control on urban conservation sites (by the Decree Law No. 648)

DEMOCRATIC ASSESSMENT OF COLLABORATIVE PLANNING PRACTICES

Moozhan Shakeri[1], Johannes Flacke[2], Jeroen Verplanke[3]

Abstract

Over the past decades, collaborative planning as the communicative and interactive nature of planning practices has been increasingly emphasized (Forester, 1989, Friedmann, 1973, Healy, 1992, Innes, 1996). Nevertheless the evaluation of collaborative planning practice is not elaborated extensively yet (Laurian and Shaw, 2009). Some efforts have been spent on devising comprehensive practical assessment frameworks (Frame et al., 2004, Innes and Booher, 1999, Margerum, 2002b, Moote et al., 1997), but they all ignore specific democratic values essential for any collaborative practice as part of urban democracy (Agger and Loefgren (2008).

Agger and Loefgren (2008) tried to fill this gap by suggesting a conceptual structure called "Democratic Assessment Framework". To be applicable in practice, the framework however lacks well-defined criteria. This study therefore aims at defining a comprehensive set of criteria for a framework that enables planners to assess to what extent different phases of collaboration (input, process and outcome) meet democratic norms. The defined criteria were used to evaluate different cases and types of collaboration (decision-making and consultation). The result reveals that with the criteria the framework gives a good overview of the success or failure of the practice and its reasons. As a complementary aspect, defining a set of qualitative explanatory criteria can further explain output of evaluation process by explaining the context in which the practice is happening.

1. Introduction

Collaborative planning was introduced during 1980s in response to failures of technocratic planning which was predicated on independent experts and scientific analysis. Relying on critical theory of Jürgen Habermas, this new approach was built on the idea of public involvement in planning. The fundamental assumption was that stakeholders with different preferences can come up with shared goal and principles through unconstrained discussion (Pellizzoni, 2003). In practice this approach seeks to bring together major stakeholders to address controversial issues (Margerum, 2002b) in order to come up with more innovative solutions.

2 Faculty ITC, University of Twente, Enschede, The Netherlands, Flacke@itc.nl
3 Faculty ITC, University of Twente, Enschede, The Netherlands, Verplanke@itc.nl

Despite considerable attention given to public participation in planning practice and research, the field of collaborative planning evaluation is still behind. Published evaluations of participation are limited and they mostly rely on few case studies (Laurian and Shaw, 2009). Planning professionals and academics lack definitions and criteria of success in participation as well as methods to assess participatory processes. Hence for devising any assessment framework it is important to explore ideals of urban democracy in theory and practice.

2. Urban Democracy in Theory

In urban planning context understanding and explaining the democratic character of urban transformation processes and the power relations that lie in such processes continue to challenge planning theorists and practitioners. Two dominant theoretical frames are commonly used to explain and understand democracy in urban governance processes: communicative planning theory and Mouffe's radical agonistic pluralism which are both predicated on deliberative democracy notion (Bond, 2011).

The term communicative planning is used to refer to a broad and varied range of concepts including collaborative, deliberative and argumentative planning. This concept was introduced in 1960s and later was developed by many planners such as Patsy Healy, Judith Innes and others. Habermas theory of communicative action became basis for many of these works. In communicative approach it is assumed that the most democratic way of decision-making in planning practices is consensus oriented debate between all the relevant stakeholders (Bond, 2011).

Reaching such consensus require a communicatively rational process and appropriate tools and techniques. Focusing on reaching consensus will also influence the process and tools used in the practice. It will overemphasize the importance of key communicative events in planning, such as public meetings and consequently fails to capture the importance of non-communicative processes and action (Friedmann, 1973). It is believed that Habermas's efforts to achieve more rationality and democracy draw attention away from critical attention to relations of power (Flyvbjerg, 2002).

An alternative approach to urban democracy is the agonistic theory. According to Hillier (2003) in planning practices, making a decision requires accommodating for some values against others. In this sense consensus cannot exists without control and exclusion of some ideas. So instead of trying to omit differences in conceptions and values of participants in communicative theory, agonistic approach tries to values them as driver for reaching better decisions (Flyvbjerg, 1998, Flyvbjerg, 2002, Gunder, 2003, Hillier, 2003).

The Foucauldian approach criticizes existing planning tools and processes, suggesting the need for a power-sensitised understanding of the nature of knowledge, rationality, spatiality, and inclusivity in planning theory. According to this approach effective communicative planning comprises an impossible set of tasks for the planner to successfully achieve within the real world (Flyvbjerg, 1998, Gunder, 2003, Hillier, 2002). Hence as Forester (1989) express the planner responsibility is to "work toward the correction of needless distortions, some systematic and some not, that disable, mystify, distract and mislead others".

Adopting an agonistic approach to urban democracy and Dahl's theory of democracy (Dahl, 2009), the main standpoints in this study is considering the ideal practice of collaboration as a process which does not seek complete consensus, instead it should be able to unmasked power relations and as an outcome it should give all participants the better insight of how existing power relations are. On the other hand, the process should be supported by urban or general laws as part of its accountability and effectiveness.

3. Urban Democracy in Practice

Communicative theory was introduced to the planning domain in 1966 with the work of Godschalk and Mill (1966). They believed that "meaningful and effective planning must be based on a two way communication flow between the public and the planning agency" (South Manchester Regeneration Team, 2010). Although the terminologies have been changed during decades, "planning as collaborative process" is still the main element of planning domain (Margerum, 2002a) and over the past several decades, it has been increasingly emphasized as communicative and interactive nature of planning practice (Forester, 1989, Friedmann, 1973, Healey, 1992, Innes, 1996). Adopting different approaches to urban democracy, planners have designed different tools and processes for engaging all affected parties in urban projects. These processes vary greatly in their aim, approach, tools and responsibilities and roles of those involved in the process. Therefore for developing any framework for assessing these practices, understanding the different components of these practices is essential.

To better practically reach theoretical ideals of participatory approaches, different guidelines and principles have been developed in governance and planning fields. Although there are some differences in suggested guidelines, there exists a huge overlap between concerns of different practices. Specific characteristics of context, such as social, political and cultural backgrounds, can partially explain these differences. Therefore in reviewing and analysing different guidelines it's important to have in mind how context can influence details of principles and guidelines.

Although in some cases there exist some guidelines for monitoring and preparation of the process of participation, most of the guidelines and principles are focused on the appropriateness of the process of collaboration itself. This can be considered as

one of the main limitation of existing guidelines for collaborative practices. For the purpose of this study it is necessary to classify different guidelines and principles based on each phase and step of collaboration. Therefore it adopts the three step structure proposed by Gunton (2010) being input, process and outcome.

4. Urban Democracy Assessment

Some efforts have been made to develop frameworks for assessing small scale urban democracy as public participation. According to Gunton (2010) evaluation of collaborative practices is so challenging due to great number of "confounding variables" and absence of consensus on the variable to be used.

Innes and Booher (1999) devised their framework for evaluation based on three sources being the results of theirs and others' research and practice in consensus building, the emerging ideas of complexity science and the concept of communicative rationality. Based on complexity perspective which suggests that a high quality consensus building process in an uncertain and changing society should be self-organizing and evolving, good at gathering information from the environment, and effective at making connections among participants (Innes and Booher, 1999). Using this concept they conclude that consensus building should help a community to learn and be creative. They discuss that for the framework to be practical it needs a set of criteria for process and outcome of collaborative practice.

Margerum (2002b) studied existing frameworks for consensus building in land use planning practices. According to him the important factor influencing the effectiveness of collaborative planning is the quality of the process. Reviewing existing frameworks he has used following indicators as suitable indicators for evaluation of participatory land use planning practices: "Include the full range of stakeholders", "Include public participation and involvement", "Support and facilitate the process", "Establish a common problem definition or shared task", "Organize the proves in terms of ground rules, agendas, etc.", "Engage participants, jointly search information, and invent new options", and "Reach agreement through consensus".

Considering all the discussed frameworks Frame et al. (2004) introduced one of the most comprehensive frameworks and criteria for evaluating collaborative practices. The framework consists of 14 process criteria, which define desirable features of process design and 11 outcome criteria, which define desirable outcome objectives. For using this framework in different cases he had done a comprehensive survey of participants in the collaborative planning process and a review of all relevant planning documents (Frame et al., 2004).

Although most of the criteria which are defined in these frameworks are helpful for using in any context, there are some limitations in nature of criteria and applying the framework to practice. In most of the evaluation studies done in urban planning or

environmental planning field, the main focus is on process and outcome of collaboration. Although they have mentioned some criteria for pre-negotiation phase most of the time, they have overlooked the importance of considering all three collaboration phases. On the other hand the defined criteria are not as specific as they should be for being used in practice. So there is a need for more comprehensive framework which covers all collaboration phases and provides well-defined criteria.

5. The Democratic Assessment Framework

Considering collaborative planning as part of urban democracy and comparing main components of frameworks for assessing democratic nature of governance and collaborative practices, one can conclude that the existing frameworks used in planning context, have not considered certain democratic components (Agger and Löfgren, 2008). Although there is a huge overlap between existing frameworks in planning context and democratic governance, there is a need for reconsidering components of evaluation frameworks. Agger and Lofgren (2008) have come up with five criteria for developing their framework. These criteria are: "access, public deliberation, democratic adaptiveness, accountability, the development of democratic identities (political identity)". Agger and Lofgren give some guiding questions which reflect the main points to be discussed in each norm in each phase. The output of their study can be considered as conceptual basis for a comprehensive assessment framework for collaborative practices.

To be used practically for assessing collaborative practices, this conceptual framework needs to be elaborated. All the broad concepts which are introduced in this framework need to be investigated in more details in a way that they can be related to real practices of collaboration. Then it would be possible to reflect these concepts in a number of criteria by which different aspects of collaborative practices can be evaluated. For defining the criteria, concepts and evaluation methods can be used from many different fields such as large scale urban governance, urban democracy and also ideals of collaborative planning practices.

5.1 How to Make a Practical Democratic Assessment Framework

Three main sources are used to define criteria: Literature on collaborative planning and its ideals, existing principles and guidelines for effective participatory practices and existing frameworks for evaluation of large scale governance and collaborative planning. So in the first phase of this study, extensive literature review was done to define all the possible appropriate criteria related to democratic nature of collaborative planning. Then criteria were categorized based on the suggested structure of democratic assessment framework. In order to make criteria more understandable and measurable, a set of sub-criteria were suggested for each criterion. The summary of the defined criteria is shown in table 1.

Table 1: Democratic Assessment Framework Criteria

	INPUT	PROCESS	OUTCOME
ACCESS	• Information on project • Information on stakeholders • Appropriateness of channels • Citizen's right to the city	• Information on project • Quality of provided data • Appropriateness of chosen tools for participation	• Accessibility of outcome • Fair distribution of costs and benefits
POLITICAL IDENTITY	• Existence of social institutes in city	• Contribution to empowerment of different social groups in the process	• Contribution to empowerment of different social groups
PUBLIC DELIBERATION	• Inclusive targeting of stakeholders	• Inclusiveness of the process • Equal chances and resources for all stakeholders	• Public monitoring of outcome of the project • Compatibility of final plan with agreed outcomes
ADAPTIVENESS	• Flexibility of project alternatives	• Flexibility of process and the chosen tool	• Flexibility of plans for implementation
ACCOUNTABILITY	• Public trust in urban authorities	• Transparency of process and chosen tool	• Ownership of produced maps and data • Sustainability of participatory practices

Due to the complexity of collaborative practices and importance of specific characteristics of context in which collaboration is happening, it is impossible to evaluate different practices using single type of data and criteria. Hence an embedded type of integration of quantitative and qualitative data is adopted. Furthermore this approach will reduce possible bias of an evaluator in the assessment framework. This way, using the same criteria, two different evaluators can come up with the same results.

In this framework evaluating criteria will be in a form of checklist in which existence or non-existence of certain democratic qualities of collaborative practices will be evaluated (see annex 1). After defining all the possible criteria and sub-criteria, the maximum score a project can achieve in each criterion will be defined based on measurement of its sub-criteria. Beside this binary measurement there are also some quantitative criteria which directly are measured (such as number of people who attend the practice out of maximum number of possible attendants) and the result is combined in the score of criterion. To be able to better describe outcome of this checklist, certain qualities of context have been studied qualitatively. Also to be able to judge on existence or non-existence of certain criteria in the practice qualitative analysis have been performed. Using different tools such as content analysis, document review and interviews with real and potential participants of collaborative

practice, existence and non-existence of democratic values are evaluated. For qualitative analysis direct observation, interview and document analysis have been performed.

The final score of the project in each phase is presented by a radar chart including five points which represent five democratic norms in each phase. Since the number of criteria is not equal in different norms, scores are standardized to enable the user to compare performance of the project in different norms in the final radar chart. The criteria in each phase are defined in a way that there is no correlation between different norms within a single phase. But based on existing literature it is assumed that a combination of two norms in a phase may affect other norms in following phases.

6. Case studies

This framework was applied to three case studies. Case selection was based on aim, scale, tool and specific context of each project. All cases are similar in their scale as they are all plans for neighbourhood. The other important factor in case selection was whether the project is completed or not. Since the framework contains the outcome phase, the chosen project should be already completed and have approved or implemented plans. Two cases were chosen in England and one case in the Netherlands.

Chorlton Local Action Plan: City of Manchester has a long history of practicing collaborative planning. In Manchester Partnership's Community Engagement Strategy for 2011-15 typologies of different participation practices have been defined. From different typologies two most commonly used in urban planning context have been chosen for this study. Developing action plans for different neighborhoods (in this study Chorlton neighborhood) is part of consulting type of participation. Chorlton District Centre is one of the strongest and most distinctive district centres in Manchester. Therefore a plan was developed for its centre. Along with the plan public consultation was carried out for 3 months and its findings was used for refining the plan. In this program gathered feedback on the strengths, challenges and draft key principles in order to form a foundation for the District Centre Action Plan. Survey results were obtained from 1,003 completed questionnaires and targeted focus group feedback (South Manchester Regeneration Team, 2010).

'U Decide Events': Apart from regular participatory practices for preparing urban plans, the city of Manchester is experiencing another type of public engagement which is called 'Participatory Budgeting'. According to the developed toolkit (Manchester City Council, 2009) for carrying out such project, Participatory Budgeting (PB) is a "mechanism of community engagement to devolve power or influence of public budgets to the community at a local level." In Manchester council has some grants (CASH grant) dedicated to each neighbourhood. So Manchester

Councillors, Ward Co-ordinators, and Support Officers have been encouraged to use these money to engage residents and community groups to discuss and vote on spending priorities. This has been done through holding "U Decide" Events. Among practiced participatory budgeting, Chorlton and Whalley Range neighbourhood were the most successful ones (Manchester City Council, 2011, Manchester City Council, 2010).

Roombeek Redevelopment Plan: With its 154,000 inhabitants, Enschede is one of the most important cities in the east of the Netherlands (Gideon Consult bv., 2008). "In 2000, a major explosion in a fireworks storage depot destroyed the entire urban district of Roombeek in the city. More than 900 people were injured, well over 1,500 citizens were displaced because their homes were destroyed, and more than 200 companies were forced to relocate" (Denters and Klok, 2009). Weeks after the disaster intensive participation was initiated among all groups concerned: young people, older people, tenants, home owners, migrants, entrepreneurs, building corporations and schools. Simple question were asked from the residents: 'what do you want to keep – or bring back – from the former neighbourhood or district, what must be different, and what is important?' In the end, more than 3,000 wishes, suggestions and ideas were received (Gideon Consult bv., 2008).

7. Results

Adding all the criteria and sub-criteria scores in each norm and phase, the overall performance of projects is evaluated. The maximum possible scores are also calculated by adding maximum possible scores of each criterion in different phases and norms.

Chorlton Action Plan: As it is shown in radar charts (figure 1), in the input phase this project meets democratic values quite well except for accountability. This is mostly because of the unsuccessful participatory practices that have previously happened in this neighbourhood. The project though has not fulfilled ideals of democratic process of collaboration. Avoiding conflicts is the main cause of such low score. In the outcome phase, although in the public deliberation and political identity norms, project has scored low, the overall outcome of the negotiation phase and the project is as democratic as the input phase.

Although different stakeholders had a quite well access to information about the project and they were invited to participate (high score in public deliberation), the actual participation in the process (public deliberation score in process phase) is not high. One of the factors that explain this low score is the lack of trust among public in urban local authorities which is reflected in the very low score of accountability norm in the input phase. On the other hand high score of political identity in input phase shows that there are a lot of opportunities for collaborative practices but with low amount of actual participation in the process and low accountability score in the input phase, the project was not successful in using this potential or to enhance it.

'U Decide' Events: Since these events directly engaging public in decision making process, they seemed to be more democratic than previous practices. The results shows that 'U Decide' event were not successful in meeting democratic values in the input phase (figure 2). Inability of the project in identifying stakeholders, strict timing and plan for participation and number of previous unsuccessful participatory project lead to low score of these practices in input phase.

Despite insufficient stakeholder analysis, due to good publicity and high potential of participation (reflected in high political identity in input phase) in both wards, many people actually participate (high score in public deliberation) and that leads to more collaboration between different community groups in the process (high score of political identity in process phase).The design of the event in which decision making process happened once without any chance of modification, leads to 0 score in adaptiveness in process phase. In both prior and during the process, people have quite well access to all the necessary information for decision making. This can be one of the reasons that the actual participation is relatively higher than what it was planned. Compared to the Chorlton Action Plan case, these projects were more successful in enhancing political identity of the community.

The outcome of these practices highly meets democratic ideals of collaborative practices. The type of the practices which is decision making by public and the scale of the decisions allow people to be more involved in outcome of the project and it increases accountability of the outcomes. Since in most of the chosen projects public are responsible for implementation, people get more informed about different social events and consequently get more involved in them.

Roombeek Redevelopment: This case is considered as one of the successful participatory practices in the Netherlands and Europe in many studies. The specific context of this case was so influential in success of this project. The post disaster situation and the urgent need for the redevelopment plan and compensating people's loss were factors which enforce authorities to involve people in the planning and decision making process from very early stages. The stakeholders were mostly former residents of the neighbourhood. So certain group of people with specific aim gathered together and planned for future of their neighbourhood. This can explain high public deliberation in process phase, adaptiveness of the input and high accountability in outcome phase.

The chosen method for informing people which was sending personal invitations for former residents leads to high public deliberation in the process phase (figure 3). Also due to high sensibility of the issue for city authorities and national authorities, full access to necessary information was given to all possible stakeholders prior and during the process. Also the planning of participatory process was so flexible because public were free to choose their desired way of participation but when the process was planned, during the process the methods and meeting was not so flexible

due to limited time for deciding on the final plan. That is why the adaptiveness in the process phase is low.

With high access to information, high accountability of the process and the fact that people were free to express their ideas, the outcomes are highly accountable. Also the process has helped the residents to strengthen their community activities. Although this practice is special in many aspects it can be considered as a successful practice in meeting democratic values.

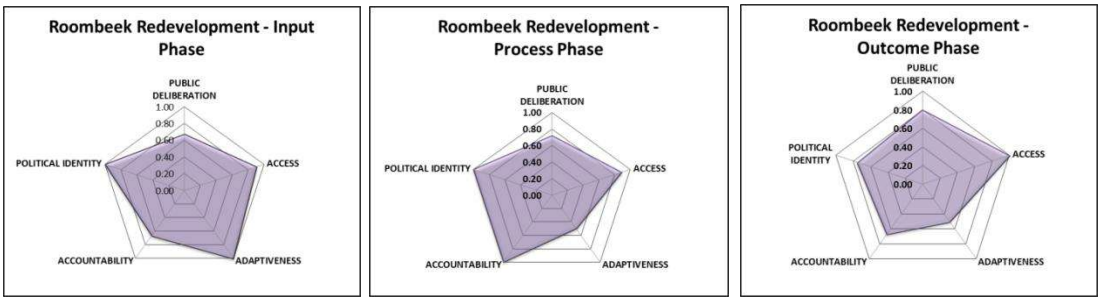

Figure 3: Radar Charts for Roombeek Redevelopment Assessment

8. Is a Democratic Assessment Framework Useful?

Applying the democratic assessment framework in different cases reveals that compared to other existing evaluation tools, this framework can more comprehensibly evaluate the democratic nature of collaboration practices. Its structure with five norms and considering three phases enables the user to define which particular deficiency in input, process and outcome, has led to success or

failure of the practice in meeting democratic values. The overall output of this framework which is radar charts and detail score of the projects in different criteria, gives an overview of democratic nature of the practice and how they have changed during the phases. These outputs can be used as a starting point for defining processes and reasons behind success or failure of collaborative practices.

Although the output of this framework gives an overview of the processes, it cannot explain reasons behind it. With help of some explanatory criteria, the outcome of democratic assessment framework can be used for explaining reasons of success or failure of any collaborative practice. Democratic assessment framework evaluates a single practice. The scores of the project in any of the norms are explainable within the limits of the defined criteria and sub-criteria. On the other hand, the output of the framework for different practices and the reasons of their success or failure won't be comparable unless explanatory criteria are investigated. These criteria focus on the context in which the practice is happening and can for instance include:

- *Motivation for public to participate:* in any context, each individual can have his/her own reasons to participate in the process. In cases like Roombeek in which the situation after the disaster has led to collaborative planning practice, due to direct impact of the plan on people's life and the high importance of the issue, people are more eager to participate or even it can be said that they need to participate. So they have more motivation compared to regular collaborative practices for modifying neighbourhood plans like the Chorlton Action Plan case. So high score of public deliberation in the process phase can directly be related to this criterion.

- *Dominance of certain political/social/ethnic group*: in some cases dominance of certain groups limits existence or activity of community associations. These dominant groups can also influence number of participants in the process and the outcomes of negotiation and implementation phase. In some cases this criterion needs more attention. It can be the case that many active NGOs or associations are present in the context but all of them have same political or social view so although political identity will score high it is not comparable to the case which has different groups being active in several fields and in favour of different social, political or ethnic groups. Low public deliberation in process phase, low political identity in input phase, accountability of input and outcomes and unfairness of outcomes of negotiation can be all related to this criterion.

The outcomes of the democratic assessment framework can also be used in designing new processes and tools for participatory practices. The results of applying the framework in different cases show that some correlations can be found between norms of different phases. The structure of the framework and nature of the norms provided enable the user to explain the process between input, process and outcome phases. Investigating common co-relations which exist in all participatory cases, and determining how these relations influence the success of practice in each phase, can

be useful in designing new processes and tools. Although to be able to find these co-relations the framework should be applied to several cases, general assumptions can be made as follows.

It is assumed that if in the input phase people do not have enough information about the project or not all the stakeholders are invited in the first phase, public deliberation in process phase won't score high. Also it is assumed that if public deliberation and political identity in the process phase is high, accountability will also increase in the outcome phase. Many other assumptions exist in collaborative guidelines and many evaluation frameworks are developed based on them but not all of these assumptions are proven. By applying this framework to different cases, validity of these assumptions can be evaluated.

Beside benefits of democratic assessment framework, there are some challenges in applying the framework in practice. Availability and accessibility of detail information about the process of participation is a crucial factor in successful application of the framework in different cases. Since the framework includes outcome phase, the participation process has happened at least some months or years before the assessment. In most cases the actual participants of the process are not accessible or some of them do not remember the details which are necessary in assessing the process phase. In the case of 'U Decide' events where evaluation forms were filled by participants immediately after the process, the evaluation is more precise than the other cases. Therefore for further assessment, it is better if after the process, based on defined criteria, an evaluation will be performed.

The other challenge is that unequal number of criteria and sub-criteria for different norms and phases make the framework sensitive to some qualities of participatory practice. Some norms such as access and public deliberation and specifically process phase have been studied and discussed more comprehensively. So properties of them are known to planners and more sub-criteria and criteria can be defined for them. Other fields such as accountability of planning practices have not been investigated as thoroughly. Therefore small variations in these norms can change the overall credits of the project. On the other hand a high number of criteria and sub-criteria will make the framework too complex to be used in practice and it will demand more data and information which may not always be available. Striking a balance between the complexity of the framework and its comprehensiveness will therefore be a decisive factor for the efficiency of the framework in practice.

9. Towards an Enhanced Democratic Assessment Framework

This study attempts to examine how the given conceptual structure of democratic assessment framework would be useful in devising new assessment frameworks for collaborative planning practices. The outcome of this study showed that this structure equips planners with opportunities for further exploring the democratic nature of collaborative practices.

Different aspects of this framework can however be improved by further studies. From a conceptual point of view it is essential to determine which notion of democracy would better suit collaborative planning in an urban context. There are few studies about how urban democracy is defined within broader notions of democracy. This issue itself can be a subject of further studies since it would change nature of criteria in the framework. This would also influence scoring of projects. In this study 'rule of law' was considered as a component of democracy which can assure sustainability and accountability of any democratic practice. This was reflected in the framework by defining criteria concerning the existence of certain urban laws and regulations. But these criteria had a weight of 0.5 compare to other criteria. Adopting different notions of democracy would therefore change these components.

Besides the conceptual grounding of the framework, the main challenge in devising a framework is to define how the different criteria will be evaluated. This can be considered as one of the main aspects of any assessment framework which is greatly affecting the efficiency of the framework in practice. If the evaluation is completely quantitative, it would be unable to capture and evaluate the many democratic aspects of collaborative practice. If it is completely qualitative, due to the large number of criteria, collecting the necessary data would be too time-consuming. For qualitative assessment it is also important to have access to those who were present in the process which is in many cases impossible. The framework therefore should use a mixed method approach to evaluate each criterion.

Annex 1: Democratic Assessment Checklist

Access

Input

- **Availability of information about the project for all stakeholders** **5 Credits**
  - ☐ Availability of information about purpose of the project and participation
  - ☐ Availability of information about the exact location of project
  - ☐ Availability of information about responsible authorities
  - ☐ Availability of information about the bigger context in which the project is being planned
  - ☐ Availability of information about the participation process (number of meetings, deadline of the project, location, time, etc.)
- **Availability of information about other stakeholders** **2 Credits**
  - ☐ Availability of information about all other involved stakeholders
  - ☐ Availability of information about the role and responsibility of each stakeholder
- **Clear ground knowledge about rights to the city** **1 Credit**
  - ☐ Availability of information about the legal rights of the citizens to the city
  - ☐ Availability of information about land administration laws
- **Appropriateness of channels for informing participants** **3 Credits**
  - ☐ Affordability of accessing information for all stakeholders
  - ☐ Time limits: how long before the process the information were provided? Is the provided time enough for stakeholders to collect enough information that they need?
  - ☐ Clarity of information provided before the process (clarity of maps showing location of project, explanation of technical terms, etc.)

Process

- **Availability of information about the project and participants** **6 Credits**
  - ☐ Awareness of participants of goals and benefits of each stakeholder in the project
  - ☐ Availability of information about the costs of each alternative
  - ☐ Availability of information about benefits of each alternative for different stakeholders
  - ☐ Availability of information on short term and long term effects of each alternative on their daily life and business
  - ☐ Availability of information about other possible locations for implementing the project
  - ☐ Access to plans and maps of larger context of the plan (surrounding neighborhoods and important city-wide projects)
- **Quality of provided data** **5 Credits**
  - ☐ Availability of different version of data/reports for different stakeholders
  - ☐ Availability of explanations for technical terms and expressions or reading maps and plans
  - ☐ Level of accuracy and amount of information given (how detailed were the maps for determining spatial effects of the project on each participant property)
  - ☐ Equality in amount of information for different stakeholders: (Is it the case that amount of detail provided for different stakeholders benefit them greatly in decision making?)
  - ☐ Comprehensiveness of data provided: do they contain all the necessary information for proper decision making?
- **Appropriateness of chosen tools for participation** **6 Credits**
  - ☐ Possibility of giving feedbacks on previous discussions
  - ☐ Possibility of getting to know other stakeholder's feedbacks on the project
  - ☐ Accessibility of updated information about the participation process during the process
  - ☐ Accessibility of channels for getting more information about the project

- ☐ Affordability of the process and method for different stakeholders
- ☐ Compatibility of the chosen tool with resources of the target context

Outcome

- ➢ **Accessibility of outcomes of negotiation and agreed plans for all stakeholders** **3 Credits**
  - ☐ Accessibility of outcomes of the participation practice to all stakeholders involved in the process
  - ☐ Accessibility of final plan for all involved stakeholders
  - ☐ Accessibility of the final plan for public
- ➢ **Fair distribution of costs and benefits** **2 Credits**
  - ☐ Fairness of outcome of final plan: (Does the final plan favor specific groups of participants?)
  - ☐ Fairness of outcomes of the discussions: (Are they biased to favor ideas of specific stakeholders?)

PUBLIC DELIBERATION

Input

- ➢ **Inclusive targeting of stakeholders** **3 Credits**
  - ☐ Presence of local knowledge/ their representatives in designing phase of the process
  - ☐ Existence of a clear stakeholder analysis and proper recognition of stakeholders before the start of the process
  - ☐ Existence of plans to approach different groups of stakeholders differently in participation process

Process

- ➢ **Inclusiveness of the process** **2 Credits**
  - ☐ Presence of different social/economic/cultural groups in the participatory process
  - ☐ Existence of a proper incentive for public participation
- ➢ **Equal chances and resources for all stakeholders** **5 Credits**
  - ☐ Equal chance for each stakeholder to express their point of view (opposition and approval groups)
  - ☐ Equal resources for all stakeholders to make others aware of their point of view (existence of appropriate media for doing so)
  - ☐ Handling conflicts: Success of the project in dealing with conflicts
  - ☐ Equal opportunity of changing properties of the plan and giving new alternatives for different stakeholders
  - ☐ Neutral influence of mediators (organizers) on emergence of or change in dominant ideas

Outcome

- ➢ **Public monitoring of outcome of the project** **3 Credits**
  - ☐ Existence of Clear ground rule for involving public in implementation phases for monitoring the progress
  - ☐ Existence of channels for communicating output of different phases of implementation with public: (like website, specific organization or a department in urban governance)
  - ☐ Possibility of monitoring and giving feedbacks on output of participation process which will be used in preparing final plan
- ➢ **Compatibility of final plan with outcome of participatory practice** **2 Credits**
  - ☐ Compatibility of outcome of participatory practice with final plan
  - ☐ Occurrence of modification in pre-defined alternatives

ADAPTIVENESS

Input

➢ **Flexibility of project alternatives and participation process design** **3 Credits**

- ☐ Non-Existence of pre-defined alternatives for the plan
- ☐ Extent of possible changes in the alternatives based on plans in larger context
- ☐ Non-existence of any political mandate for implementation of specific alternative or planning specific participatory process

Process

➢ **Flexibility of process and the chosen tools** **4 Credits**

- ☐ Possibility of modifying process and tool during the process, based on feedbacks
- ☐ Time limits: Enough given time to participants to evaluate the alternatives and make possible changes
- ☐ Possibility of getting data and operating analysis for new suggested alternatives for the project (whether the tool allows instant analysis of data for new alternatives or there is a need for another session)
- ☐ Existence of alternative tools (availability of alternative tool in case the chosen tool is not comprehensive for specific stakeholders)

Outcome

➢ **Flexibility of plans for implementation** **2 Credits**

- ☐ Existence of different agreed alternatives for implementation in case of facing problem in implementation of the most agreed alternative
- ☐ Existence of clear ground rule for determining responsible authority/organization for deciding on changes in the plan in case of facing unpredictable barrier in implementation
- ☐ Existence of clear ground rule for dealing with oppositions and negative feedbacks during or after implementation

ACCOUNTABILITY

Input

➢ **Level of public trust in authorities** **3 Credits**

- ☐ Existence of previous successful participatory practices in recent years
- ☐ Regular meetings of local authorities/representatives with residents
- ☐ Existence of specific known channels/plan for participatory practices in context

Process

➢ **Transparency of the process and the chosen tool** **3 Credits**

- ☐ Clarity of the logic behind analysis for all stakeholders (are stakeholders aware of the logic of analysis for defining alternatives and effects of each alternative)
- ☐ Awareness of participants of when and how other stakeholders will participate in the process
- ☐ Accessibility of updated information about the feedbacks and changes in the process during the process

Outcome

➢ **Ownership of produced maps and data** **1 Credit**

- ☐ Existence of clear ground rules for determining who will be the owner of output of participatory practice
- ☐ Existence of any urban law or regulation which legitimizes decisions taken in participatory sessions

➢ **Sustainability of participatory practices** **2 Credits**

- ☐ Low risk of dramatic changes in participatory practices by modifications in planning system
- ☐ Increase in trust of the people in participatory practices after this practice

ACCOUNTABILITY

Input

- **Existence of social institutes in the city** **3 Credits**
  - ☐ Existence of different NGOs and social institutes with different domain focus
  - ☐ Existence of active NGOs besides governmental organizations/groups
  - ☐ Clear role of public representatives in structure of urban governance organizations

Process

- **Contribution to empowerment of different social groups** **2 Credits**
  - ☐ Contribution of the process to unifying or separating different social, economic or cultural groups during the process (regarding the design of the process and chosen tool)
  - ☐ Does the design of the process allows emergence of strong dominant opposition or approval group during the process

Outcome

- **Contribution to empowerment of different social groups** **2 Credits**
  - ☐ Increase in number of members of different community groups
  - ☐ Increase in number of organized social events after the practice
- **Addressing needs of specific social groups or institute in final plan** **2 Credits**
  - ☐ Addressing specific needs of different economic groups of the community
  - ☐ Addressing specific needs of a desired target group of the project (would it be different ethnic groups, elderly or children)

GENDER AND MOBILITY - EVERYDAY MOBILITY DURING CHANGING GENDER RELATIONS

Mechtild Stiewe [1], Juliane Krause [2]

Abstract

Mobility is embedded in the existing gender relations of our society, whereby both the biological sex and social gender are significant. Taking the gender perspective into consideration in mobility research means broaching this aspect through data collection and data analysis and evaluation. A broadened gender concept has been developed in connection with mobility studies and has been relied upon for analysing the designs of the major German mobility surveys. It has been possible to ascertain that although gender aspects such as looking after, caring for and accompanying children and dependents have been included, they have been hitherto accorded only little consideration in the analyses and publications. Against this background, the data on "Mobilität in Deutschland" [Mobility in Germany] (MID 2008) are analysed and evaluated in line with gender mainstreaming.

1. Outline of the problem

Mobility and transport behaviour are embedded in the existing social structures and gender relations of our society. Commuting to work, going shopping, and accompanying children or older people determine our daily activities. There are always men and women, children and old people, persons with reduced mobility, people from a migrant background who cover such distances, i.e. people with a biological sex and a social gender.

Taking the gender perspective into consideration in mobility research means discussing gender relations (through specific data collection and data analysis and evaluation), whilst carrying out an exchange of views and focusing on different living situations, lifestyles and strategies for coping with everyday life, which are no longer tied exclusively to biological sex or traditional gender roles.

Mobility surveys (observations or interviews) are carried out in traffic planning to gauge transport behaviour, whereby in addition to individual mobility behaviour, determinants and subjective reasons of the behaviour are examined. Mobility and transport surveys yield socio-demographic information about people and households as well as the way they travel (e.g. whether they have a driving licence or a car, travelling purpose, and mode of transport used).

Mobility surveys in the form of household interviews in municipalities and regions are often geared to what is known as Kontiv® design (household forms, individual forms, road protocols). Although the biological sex is broached as a

[2] plan&rat – Büro für kommunale Planung und Beratung, 21 Humboldstr., 38106 Braunschweig, Germany krause@plan-und-rat@t-online.de

matter of course in all major studies as well as in municipal mobility surveys, as are gender aspects (e.g. looking after, caring for and accompanying children and dependents), these aspects have hitherto been given only insufficient consideration in analyses, evaluations and publications.
Criteria for gender-sensitive mobility surveys must consequently be developed as well as suggestions on how to modify and supplement the traditional survey designs and how to develop their evaluation and interpretation; the ultimately aim being to contribute to greater gender fairness in mobility research.
A successful implementation of gender mainstreaming in the transport sector is a quality feature of planning and policy and indispensable for the development of more concrete approaches, particularly at a time of ever greater differentiation of household structures and lifestyles.

2. Concepts and indicators with gender aspects

2.1 Gender

Gender means not looking at "women" or "men" stereotypically, but considering people in terms of their difference and diversity (Table 1). No one is only male or only female, but we live in a world which is decisively shaped by the attribution of gender roles. Through the use of the concept "gender," the sexes and their relations are brought more into the foreground, the social differences or roles are described, and social differences or roles that men and women have in our society depending on their social situation or their role are described.

Table 1. The concept of gender

The term gender...
… refers to the economic, social and cultural attributes and opportunities associated with being male or female. In nearly all societies men and women differ in respect to their activities, access to and control of resources, and participation in decision-making processes. The definition of gender – what it means to be male or female – varies between cultures and changes over time.
(Source: EU Guide on Gender Mainstreaming 2005 / EQUAL Programme)

2.2 Gender Mainstreaming – definitions

Gender Mainstreaming is aimed at gender equality and entails that due account of the gender issue is taken from the outset in all plans and decisions, regulations or laws that could have a different effect on men and women, since there is no gender-neutral reality.
The gender perspective implies that men and women, but also children/young people, persons with reduced mobility, the elderly, people with a migrant background have different living conditions and opportunities in society. They all develop specific interests and needs owing to specific gender, social, or ethnic and cultural socialisation and different living situations. They are affected differently by social processes and their repercussions.

Thus broadened, the concept of gender includes the aforementioned gender groups, whereby differentiation would still be made each time in accordance with sex and age. The broadened concept of gender comprises also the physical environment structures, i.e. the concept of **settlement structure.** The living conditions of the population vary depending not only on the regional context but also on sex, i.e. the situation of men and women differs between core cities, surrounding districts, rural areas and/or the countryside (varying availability of public transport, different types and proximity of infrastructure and facilities, remoteness of locations of everyday life).

2.3 Indicators with reference to gender[3]

Indicators indicate something. The starting point for developing indicators is expressly or implicitly the definition of an objective, towards which reality is supposed to veer. Consequently, the development of indicator systems is not unbiased.
Transport or mobility is (still) not an issue in the case of indicator systems with a gender reference in an international context, but the first steps have been taken in the national context, whereby the gender index and the federal equality atlas are significant.
The United Nations Development Programme (UNDP) publishes a report on human development every year in which the Human Development Index (**HDI**), is calculated and, since 1995, the Gender-related Development Index (**GDI)**[4] as well. At the national level, the numerous indicator systems relating to "sustainability" should be mentioned first and foremost. These are intended to help guide the necessary processes towards sustainable development on the basis of the Agenda 21.
The **national sustainability strategy** "Prospects for Germany: Our strategy for sustainable development" presents 21 indicator subjects (as per the 2008 progress report). These indicators fall under four areas. Under quality of life, the indicator subject "mobility" with the sustainability postulate "secure mobility – preserve the environment" is however presented only through indicators such as goods or passenger transport intensity or the share of rail transport in freight forwarding.
The **Gender Index**[5] is an instrument that is supposed to indicate and present equal but also unequal opportunities between the sexes and to make them comparable between the regions. It is the first nationwide measuring instrument for the regional comparison of equal treatment of men and women. The relative deviations of the values for men and women are calculated for 19 indicators for education, employment and participation. The Gender Index is the average value of these 19 relative gender differences.[6] Based on the spatial information system, the continuous spatial planning observation of the Federal Institute for Research on Building, Urban Affairs and Spatial Development (known by the German initials BBSR), the regional living conditions of men and women in these three areas (education, employment and participation) were compiled and assessed in the Gender Index for the first time in a comprehensive, systematic and exhaustive manner nationwide. The aim is to make the complex circumstances of gender equality visible and in so doing to illustrate the central

---

3 For more details, cf. KRAUSE, 2011.

4 Its significance is based on the same variables as for the HDI. The Gender Empowerment Measure (GEM) stands for the strengthening of the role of women and the promotion of participation in the political and social decision-making processes.

5 www.gender-index.de

6 This formula for calculating the Gender Index is based on the Swedish Jäm Index (also known as the Gender Equality Index). Statistical tests support the Gender Index as a suitable measuring instrument of regional equal treatment of men and women.

fields of activity for more equality of opportunity in the different regions (cf. www.gender-index.de). Mobility and transport have not been an issue (hitherto) however.
The atlas of equal treatment of men and women in Germany (**Equality Atlas)** is an initial localisation of the equality situation per federal state in Germany on the basis of 30 indicators. Of interest for the research topic is the category of the living environment with two indicators: "older people in single-persons households" and "life expectancy." Both indicators show clear, specific gender differences (BMFSFJ, 2009).
The regular consideration of key figures from the mobility area – such as consideration of the purpose of mobility or the attainability of different objectives from the gender perspective – could help to demonstrate equal opportunity or gender differences based on social conditions, attitudes and habits. The regular surveys of the population's mobility behaviour provide a good data basis.

3. Nationwide surveys on the mobility behaviour of the German population

The three nationwide surveys on the mobility behaviour of the population in Germany are "Mobilität in Deutschland" (MID) [Mobility in Germany], "Mobilität in Städten" (SrV) [Mobility in the Cities] and the "Deutsche Mobilitätspanel" (MOP) [German Mobility Panel]. These surveys also serve as empirical (calibration) bases for traffic models and thus for the overall urban or regional traffic plans.
"Mobilität in Deutschland" (MID) [Mobility in Germany] is the nationwide survey[7] on mobility behaviour. Activities outside the home and the mobility of all persons living in the household among selected samples of households were gauged on a reference date by means of a standardised questionnaire. The first nationwide comprehensive survey of the population's mobility behaviour was carried out in 1976 under the Continuous Survey on Mobility Behaviour (known by the German acronym KONTIV), which has been repeated, with a similar design each time, in 1982 and 1989. In 2002, the study was conducted as a nationwide project for the first time under the name of Mobilität in Deutschland (MiD) [Mobility in Germany]. In connection with MiD 2008, a survey was conducted over 12 months in 25,000 households with 62,000 people. Other municipalities were involved as more regions were included. The types of settlement of the Federal Office for Building and Regional Planning (known by the German initial BBR) are taken into consideration for the analysis and evaluation (cf. MEYER/ MILBERT et al., 2007). Unlike MiD 2002, the nationality (reference to migrant background) is no longer asked in Mid2008.
The "**System repräsentativer Verkehrsbefragungen" (SrV)** [Representative Survey System] collects data on the everyday mobility of people on the basis of household surveys in cities. The SrV was developed at the Technical University of Dresden (TU Dresden) for gathering data on urban passenger transport in the German Democratic Republic. The first such household survey was conducted in 1972. Pursuant to the SrV, data for midweek days (Tuesday to Thursday) were collected. The SrV results are analysed and evaluated for the participating city (random sample of at least 1,000 people per city) and abstracted for various city sizes. The principals are the municipalities, states and transport companies. The scope of the SrV 2008 study covered 76 cities, municipalities and administrative districts on the territory of the Federal Republic of Germany.

---

[7] In household surveys on mobility behaviour, the activities outside the home and the mobility of all persons living in the household among selected samples of households are generally gauged on a reference date by means of a standardised questionnaire. As a general rule, data and information are collected on mobility behaviour during work days and Sundays. The survey unit is the household, i.e. the survey documents are sent to the household address for all household members. The unit of investigation is the individual person.

The "**Deutsche Mobilitätspanel" (MOP)** [German Mobility Panel] is a longitudinal study on mobility behaviour conducted as a panel. The persons from the same household are questioned once a year about their mobility behaviour over a total of three years. The participants (all members of the household aged 10 and over) are asked each time in autumn to keep a travel diary for one week. The random sample consists of about 1,500 people (750 households) every year, two thirds of whom are "repeat participants" in the survey, and the other third is recruited newly for the panel.
Explicit "gender questions" have scarcely been broached in the mobility research up to now. There is of course a series of studies, which show time and again, that men and women move differently outside of the home (use of mode of transport, purpose of the trip, etc.). Thus, such indicators as vehicle availability, driving licence possession, choice of means of transport, and purpose of the trip are analysed and evaluated from a specific gender perspective and often also by age group. A differentiation between sex and gender has hardly been made hitherto.
The nationwide "Mobilität in Deutschland" (MID) [Mobility in Germany] will be examined closely in the context of this study.

4. Gender aspects in mobility in Germany – Basis for a gender balanced analysis and evaluation

Participation in society is a precondition to equal opportunities, irrespective of a person's sex. This is determined essentially by mobility opportunities as well, whereby easy access to the places of residence, work, care, education and cultural institutions is important. That the mobility of men and women differs can be seen in all phases of life. Only a differentiated analysis of mobility behaviour from a gender perspective can provide a realistic picture of the societal, social and spatial conditions for mobility (cf. STIEWE/ KELP-SIEKMANN, 2010).

The formation of reference groups (known as gender groups, e.g. older people, people living alone, persons with reduced mobility, people in family households, people with a migrant background) is based on the premise that the mobility and transport behaviour of these groups is "homogeneous" owing to certain attendant conditions and similar needs. The concept of reference groups was derived from the designations of phase of life (MiD), lifestyle/mobility style and household types (MiD), traffic sociological groups (SrV) as well as studies on the mobility behaviour of behaviourally homogenous groups, or on the living situation or the mobility behaviour of women. Common criteria for the formation of such groups are occupational activity (position in the work force), position in the occupation, sex, age, vehicle availability, and the presence of children in the household (cf. HOLZ-RAU, 1990).
Significant indicators for the formation of reference groups from the gender perspective and in reference to mobility behaviour were developed on the basis of a comprehensive literature research (Figure 1). The central factors for determining the mobility behaviour of gender groups turned out to be the social situation (single, single parent, partner), occupational activity and the presence of children in the household (care, accompanying mobility). Other significant factors are age, sex, phase of life, household type, economic status, vehicle availability and region type.[8]

[8] This structural typing by the BBSR breaks Germany down into three region types and nine district types, according to population density as well as the central function of the core cities of the regions (MEYER/ MILBERT et al., 2007).

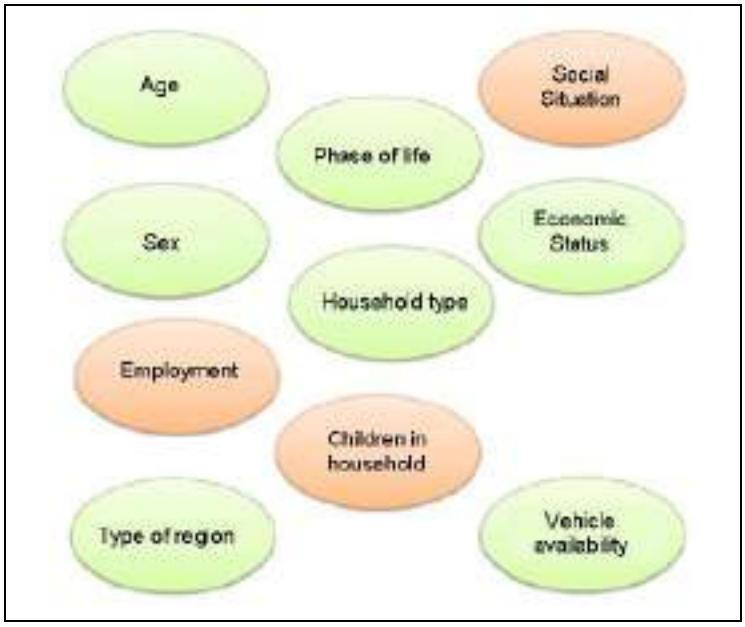

Figure 1. Indicators for the formation of the reference groups

The following reference groups with gender reference ensue: Children and young people, people with a migrant background, persons with reduced mobility and people in specific situations of life.
In what follows, the mobility behaviour of the reference group "people in specific situations of life" will be analysed from MID 2008 data as a first step:

- Single parents (1 adult and at least 1 child under 18)
- Single-person households (people aged up to 64)
- Family households (2 adults and at least 1 child under 18)
- Elderly people (aged 65 and over)

The observations are each time differentiated by gender.
The group of people living alone is, as expected, characterised by a very high percentage of women (88%); the average age is 42.2. More than one fourth (26%) of the households in this group has no car.
The group of elderly people stands out with 55% women, which is explained by the higher life expectancy of women. Almost a quarter of this group too has no car.
Only 2.4% of family households have no car; 38% of the households have a car, and 50% have a vehicle. At 40.00 years of age, people from family households have the lowest average age among the reference groups. Apart from the group of elderly people aged 65 and over, the group of people living alone has the highest average age (46.6). An examination of the age group shows that 58% of men living alone are concentrated in the 30 to 59 age bracket, while a relatively balanced distribution among all age groups can be observed for women. The number of households without a vehicle among people living alone is 29%.

5. Differences in mobility behaviour – Some results from the "Mobilität in Deutschland" [Mobility in Germany] survey

With regard to the differences in living situation in terms of gender, ethnic group, origin and socialisation, there is a perceptible tendency towards harmonisation in many areas. However, women are as before at a structural disadvantage in many social areas, in particular as regards income, working conditions or assets. In addition, irrespective of their occupational activity, they are sill responsible for the most part of household tasks such as bringing up the children, caring for dependents, housekeeping, etc. They need to move about more in order to carry out these tasks and consequently their mobility is different from that of men. Women go about more often on foot or by public transport.

Statistics show that mothers, for instance make 4.3 trips per day, compared to the overall average of only 3.4 trips per day in Germany (MiD 2008). An increase in occupational activity by women – especially mothers – does not however lead to equality between the sexes, but in doubling the workload for women whilst conditions tend to remain pretty much the same for men. On the other hand, there are no significant differences up to the age of 30 – if only gender is taken into account, irrespective of the living situation.

Some selected results of the analysis and evaluations of the MiD are discussed below (all persons aged 18 and over are taken into consideration).

5.1 Driving licence possession

A key precondition to mobility is a driving licence (Figure 2). Overall, 93% of men and 83% of women have a driving licence. The number of people with a driving licence has continued to grow in recent years. If the growing number of driving licences is considered specifically in terms of age groups, however, a slightly declining trend is perceptible among young adults: 87% of women and 85% of men have a driving licence, making this the only age group in which the number of women with a driving licence is higher than that of men. Women in all age groups are catching up in driving licence possession; however only 49% of women aged over 74 have a driving licence.

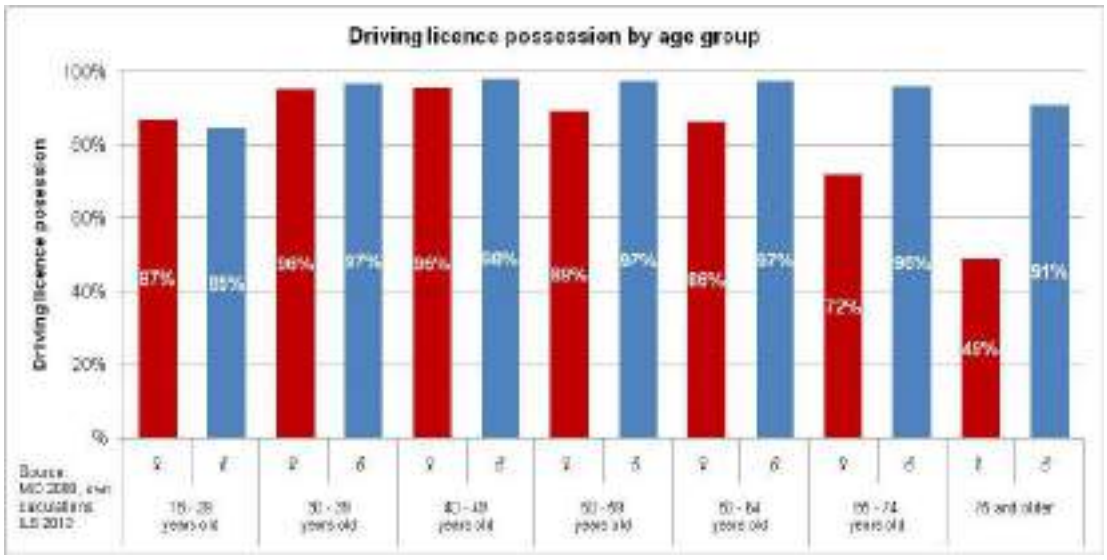

Figure 2: Driving licence possession by age group

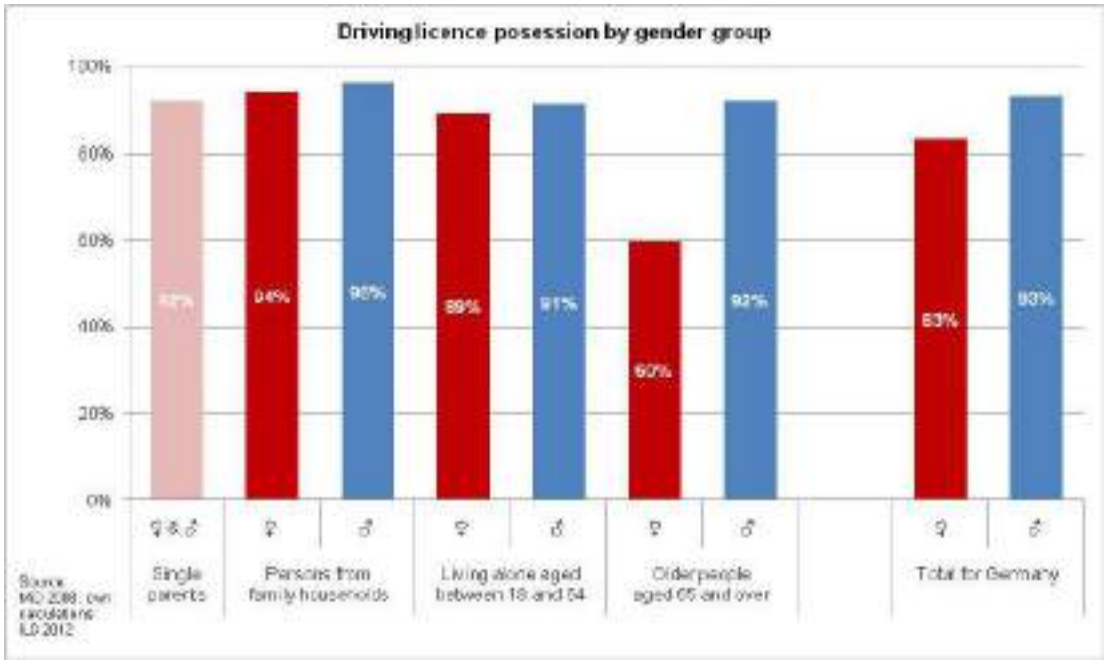

Figure 3: Driving licence possession by gender group[9]

Differences in driving licence possession are clearly evident depending on the living situation (Figure 3). Family households have the highest level of driving licence

9 There were (seven) overlapping cases between the group of elderly people and single parents as well as between elderly people and people from family households (210 cases). The cases concerned were assigned to the group of elderly people.

possession (men and women alike). Similarly, 92% of single parents[10] (88% women) have a driving licence (above average, therefore).

5.2 Vehicle availability

Apart from a driving licence, a decisive factor for mobility behaviour is the availability of a vehicle (Figures 4 & 5). Young women have a driving licence more often than men in the same age group, but they have less often a vehicle available. Overall, 83% of the men but only 72% of the women indicate that they can have a vehicle at their disposal at all times. That possession of a driving licence is not necessarily accompanied by vehicle availability can be seen in the group of young adults in particular. Across all age groups, men tend to have a vehicle at their disposal more than women. If women can avail themselves of a car, they are often not the owners of the "available vehicle." This is explained by the fact that the owner of the vehicle (especially of the first vehicle) is often the man. It can be assumed that women will have to forego the use of the vehicle more often, if there are more people than vehicles available in the household.

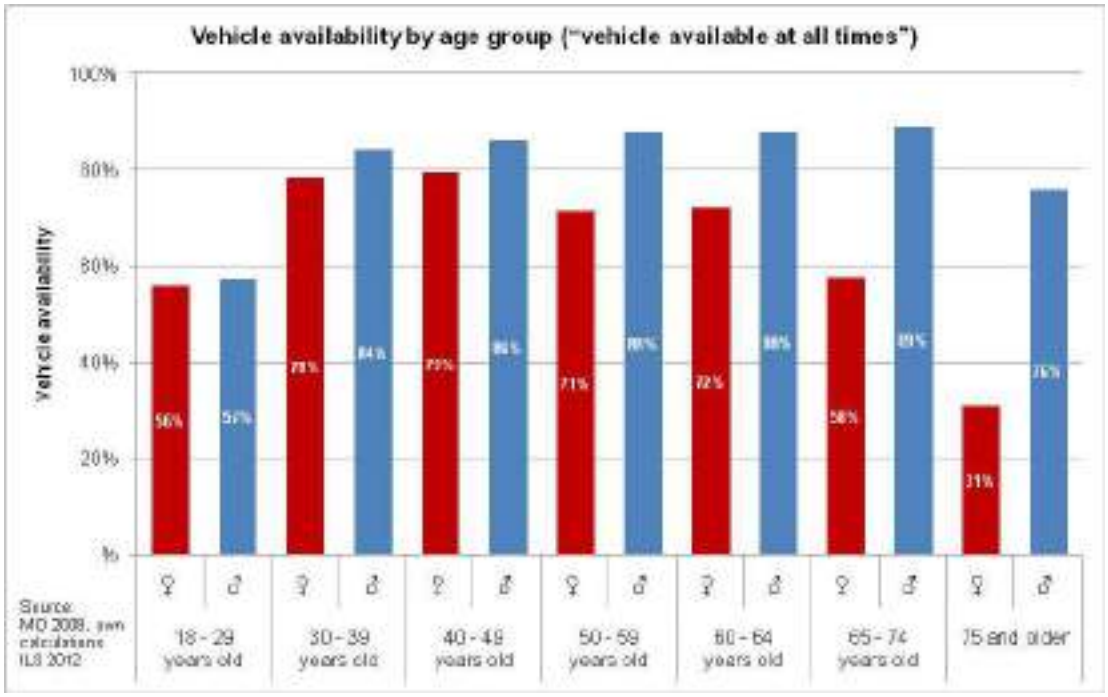

Figure 4: Vehicle availability by age group

[10] Since the proportion of men among single parents is only 12% (54 of the respondents), no gender-differentiated presentation was provided.

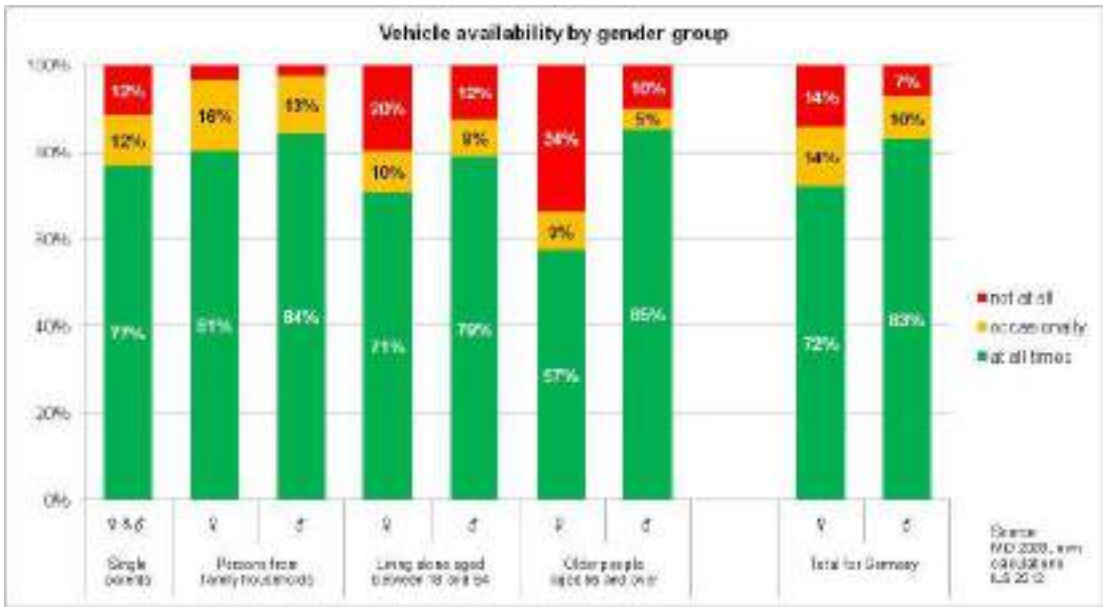

Figure 5: Vehicle availability by gender group

If income is considered in the equation, then more than half of low-income households do not own a vehicle nor can avail themselves of one. These are mostly pensioner households or households without children. Single parents constitute an exception, because in spite of their low income, they often do have a vehicle at their disposal, so as to be able to meet their multiple mobility needs and pressures. It becomes evident, therefore, that unlimited access to a vehicle is not the rule, and that there are clear cut differences depending on age and the respective living situation.

5.3 Use of means of transport

Women get about on foot decidedly more than men; this can be seen in all age groups as well as in all the different living situations (Figure 6). There is scarcely any difference between the sexes perceptible when it comes to use of public transport. Only older women clearly use public transport more often than men, which can be attributed to the fact that fewer of them have a driving licence. Most trips with the vehicle are undertaken by men from family households. It can be said overall, that the car is the means of transport used most often up to old age, and that men tend to get about by car more often than women. The use of the car is in large measure also determined by vehicle availability. If a vehicle is available, it will be used.

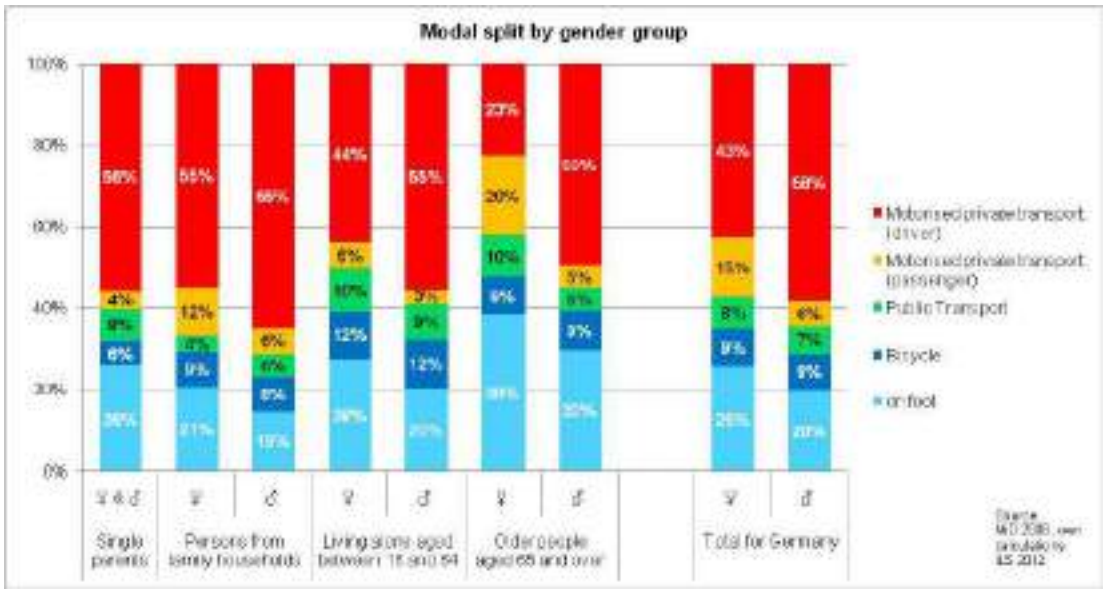

Figure 6: Modal Split by gender group

5.4 Mobility purposes

Clear differences between the sexes and in respect of the living situation can be gauged when considering the mobility purposes, where age plays a decisive role as well (Figure 7). Thus, the proportion of accompanying trips by single parents and women from family households (18% or 20%) is clearly higher than in the other groups. The number of shopping trips by women from family households (23%) is also higher than that by men (15%). At the same time, the proportion of commuting to and from work and business trips by women is clearly smaller than by men of the same group. This points to a traditional division of labour, in spite of the increasing occupational activity among women. Mobility for leisure time activities has the smallest share in the group of women from households, with 28% of all trips.

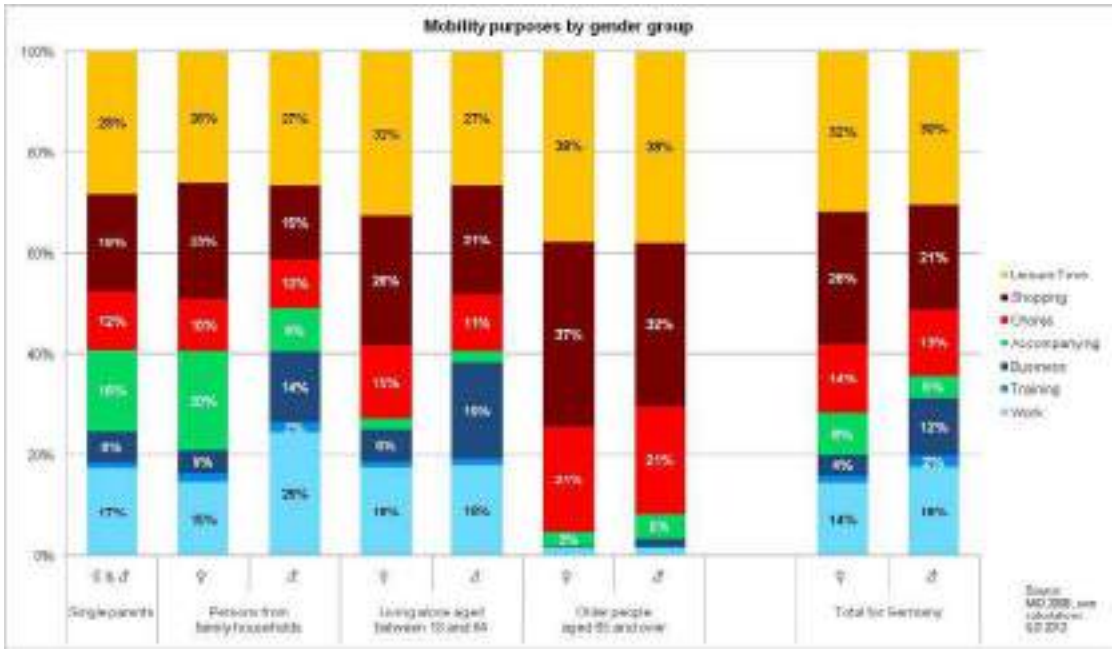

Figure 7: Mobility purposes by gender group

5.4.1 Accompanying trips

Accompanying trips (accompanying as the main mobility purpose) are trips where a person accompanies other people. The main purpose is not one's own objective, but the accompaniment – and thus the objective – of the person who is accompanied. An altogether typical accompanying trip by mothers is taking children to the kindergarten. A typical accompanying trip by children, on the other hand, is accompanying their mothers when they do the shopping. The main mobility purpose of younger children in particular is in large measure to accompany adults.
Single parents and women from family households tend particularly to accompany other persons, accounting for 16.1% or 19.9% of all trips. For younger people, people living alone and elderly people, accompanying as a "main mobility purpose" plays only a subordinate role. This does not mean, however, that they are always alone on the road, but that they have the same "objective" together with others.

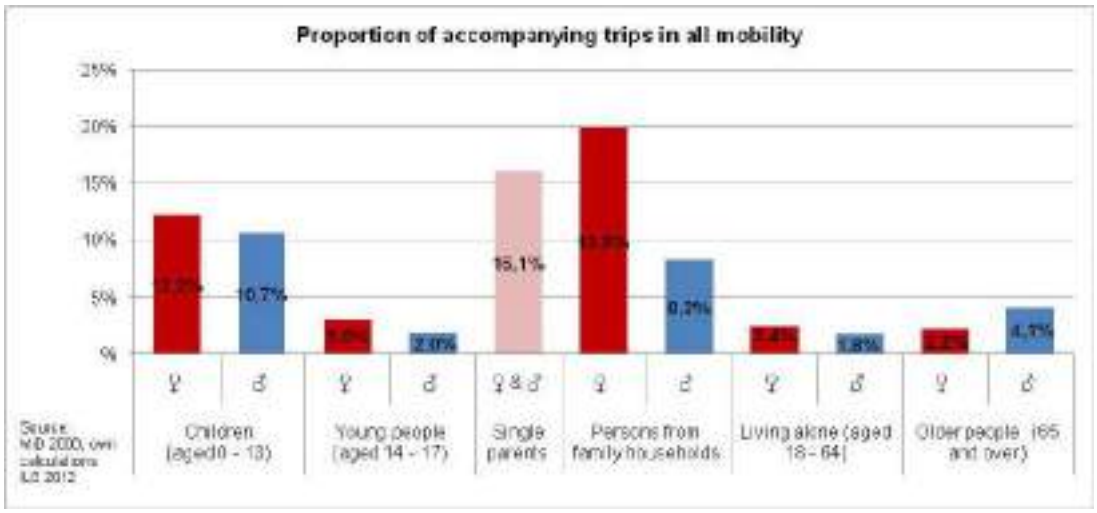

Figure 8: Proportion of accompanying trips in all mobility

5.4.2 Commuting to and from work

When considering the use of the main means of transport for commuting to and from work, the car turns out to be the most widely used means for the groups. It turns out, however, that women use the car, including the work vehicle, less than men. Apart from the elderly people – only a small segment of whom are still working—women living alone use the car the least. They cover nearly 40% of such commuting with environmentally friendly means of transport, compared with only 24% for men from family households.

Figure 9: Main means of transport for commuting to and from work by gender group

5.5 Proportion of trips, travel times and distances

Clear differences come to the fore among the reference groups in the central mobility parameters “mobile on reference day,” proportion of trips, daily travel time and distance covered (Figure 9). The number of daily trips between men and women scarcely differs, but clear differences do emerge depending on the living situation. Thus, single parents account for the largest number of trips per day (4.2), whereas older women account for only 2.6 trips. 95.5% of single parents were en route on the reference day, and account for the longest travel time with about 100 minutes per day. The average distance covered (10 km) is clearly shorter than that covered by men from family households (16 km per trip). The daily routine of single parents, but also of women from family households is characterised by a variety of trips for care and accompanying purposes, often made on foot, and considerably time consuming. Elderly women have the lowest mobility rate: 20% of them were not at all on the road on the reference day; they make 2.6 trips per day of average, and are en route for ca. 64 minutes, while they make a large portion of such trips on foot.

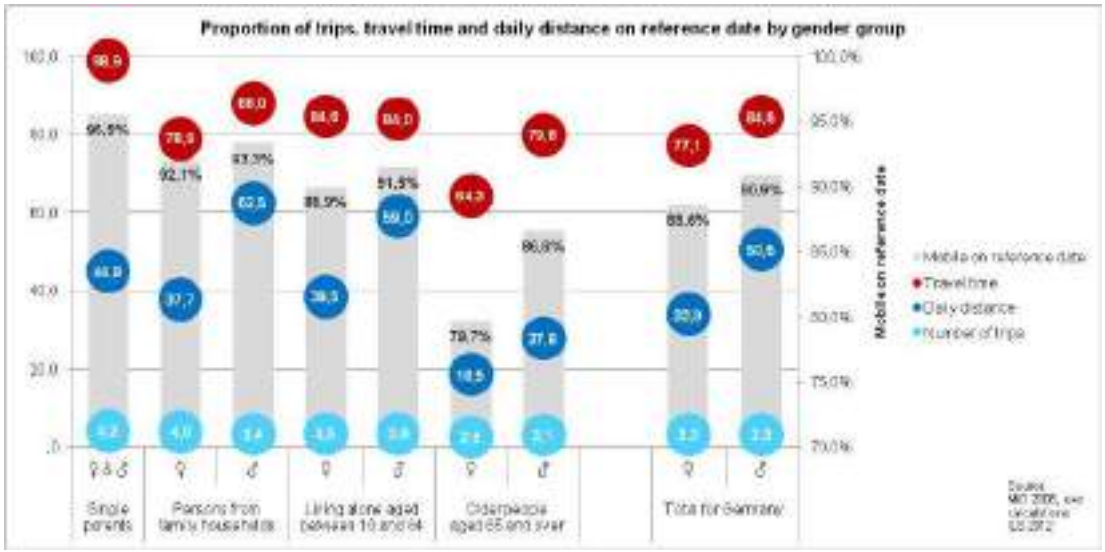

Figure 10: Proportion of trips, travel time, daily distance on reference date as well as number of mobile persons by gender group

6. Conclusion

The analysis of the design of major mobility surveys has shown that whereas gender aspects have been duly included in various surveys, they have hitherto been broached only to a limited extent in evaluations and publications.

Analyses and evaluations of the available data show that there are differences in the mobility premises and behaviour between the sexes.

More measures are therefore needed to restore equality between the sexes, whereby a key precondition is to make the status quo visible and to analyse and evaluate the available survey data in terms of gender mainstreaming.

Gender equality cannot be achieved without taking migration aspects into account. With gender mainstreaming the focus is turned to these structural differences, but at the same time the different needs, interests and requirements of men and women are sharpened within the groups (depending on the living situation). The social position, age, but also ethnic background come into focus. This requires that corresponding data be collected as well. For instance, there has been little knowledge (and hardly any data) available hitherto about the mobility behaviour of people with a migrant background. The current ILS research project entitled "Mobility of people with a migrant background and social discrimination through unequal mobility opportunities" can provide the first leads.
Even though the federal government, the states and municipalities in Germany are required to implement gender mainstreaming and thus gender monitoring, there are few gender indicators on the mobility front and data analysed in terms of gender mainstreaming.
Nationwide surveys such as "Mobilität in Deutschland" (MiD) [Mobility in Germany], "System repräsentativer Verkehrsbefragungen" (SrV) [Representative Mobility Survey System] and "Deutsche Mobilitätspanel" (MOP) [German Mobility Panel], but also mobility surveys conducted at the municipal or district level, already offer a sound data basis differentiated according to gender for gender monitoring, which can also be used for planning purposes.

REGULATORY MEASURES TO REDUCE LOCAL RISKS AND VULNERABILITIES IN PLANNING DECISIONS

Pınar Ertan[1]

Abstract

During the past decade, tools and frameworks for global disaster risk management have shifted the priorities from emergency management to pre-disaster risk management, which demand new tasks from urban planning. Safety and resilience at local, national and global levels became a shared accountability which brings in a prominent role to the planning discipline in reducing local seismic vulnerabilities via defining a local mitigation strategy. The international frameworks of pre-disaster approach bearing proactive strategies could not be easily and conveniently internalized and improved by the developing countries.

Local seismic attributes as primary indicators for urban risk management highlighted that the requirement of constituting a common language of mitigation should be clustered at the local level and linked to the international framework at the upper scale. The urgent requirement of a local mitigation strategy, which is self-organized and less dependent on current politics could provide a safety ground for urban risk management extended to the national level.

In the local context, the so-called Disasters Law, the Development Law and Act on Regeneration of Disaster Prone Areas do not provide the necessary concern and means for safety in urban planning and have no aspiration to devise appropriate tools for mitigation. The role of city planners', who could mainstream a holistic approach and facilitate community participation in decision-making processes, is hardly apparent in legislation. The constraints and possibilities in urban mitigation planning methodology provides a new area of progress which defines new objectives and roles for planning as risk mitigation and the planner as an actor accountable to utilize local, national and global capacities in mitigation. In mitigation planning, the legitimacy of the planning method and the planner is neither challengeable nor coercive but should be developed over a new ethics for the affected communities and local initiatives. The emergent requirement of building local capacity to be integrated with the national mitigation strategy is examined through the case of disaster mitigation plan Fatih district in Istanbul.

The local capacities, vulnerabilities, and the ‘risk sectors’ in the district, the regulatory measures to develop a mitigation plan, the obstacles to be integrated into the current policy structure and international frameworks will be explored via empirical data of the Fatih District. This reasons challenging the utilization of local capacity in mitigation including technical, organizational and political failures and defects are to be taken into account to build up new connections to the global framework through spatial and non-spatial terms of risk reduction.

1. Introduction

1.1 The Definitions of Risk

Risk is a peculiar and intermediary state between security and destruction where the perception of threatening risks determines thought and action (Adam, Beck, Van Loon, 2000).

For many years, evaluating risk as "destruction", promoted actuarial methods of rationalist approach, has reduced risk in to the probability of loss through accepting a certain level of loss at the beginning (Adam, Beck, Van Loon, 2000). Post-disaster approach prevailing relief and rehabilitation was the product for this claim failed by the last decade. Social dimensions of risk embedded in natural disasters and socio-technical capacity to adopt in to a new system shock was ignored and tragic consequences was faced in worldwide 1999 events. Risks as complexities both alter and interact community and create different levels in 'the willingness to accept risk' related to the difference in between dangers and risks (Luhmann, 1993). Whether dangers are externalities that are uncontrollable, initial definitions in rationalist approach refer to risks are controllable by decision making but in urban systems, risks and dangers evolve in to each other creating a level of uncertainty The uncertainty refers to relative levels of perception, ignorance or speculations in communities. Today even security might have connotations in other forms of risk as 'socially constructed phenomenon' (Beck, 1999). The dynamic structure of risks grown out of unintended consequences in transnational or global scales, hypothetical assumptions and irreversible interventions built up a wide gray area to search new ethical ground for reducing risks. Mitigation is an initial step to that, 'precaution through prevention' (Beck, 2006) rather than compensating risks; was a new strategy adopted to reduce risks at all levels for everyone. Further, how to build mitigative capacities is still a legitimate question for communities to call for new technologies of deciphering urban risks and developing new socio-technical capacities for prevention culture (UNISDR, 2005).

Moving from industrial society to information society, cities on the edge of transforming, growing or contracting as a result of deindustrialization had a major effect on change in population trends and urbanization. Urban risks and vulnerabilities pooled in cities through accelerated geographical concentration of population and productive capacities in limited areas (Balamir, 2009) which are rather pervasive in developing countries. ‘The modern approach to foresee and control the future consequences of human action’ was shifted to mitigate risks which were ‘unintended consequences of radicalized modernization’ (Beck, 1999). Modern risks or man-made hybrids are situated in a combination of natural hazards and urban risks constituting natural disasters which were aggregated in a way that the impacts of externalities: natural hazards and internal factors of urban system: urban risks are became uncertain to be separated distinctly. The uncertainty at first level is related to the inadequacy of socio-technical capacities which construct the ability to discriminate between externalities and internal factors to build proactive capacities.

At second level, uncertainty stands with a territorial ambiguity as a result of time and space compression and distantiation create the potential of contagious risks. In other words mystery hides in the problem: Do we know urban systems adequately to diagnose risk generating factors and emergencies to build consciousness and capacity?

1.2 Conflicting Perspectives in Risk Reduction

Under the shadow of seismic risks and other natural hazards, Turkey is inadequate in diagnosing uncertainty or building capacity and got far behind to integrate in to international framework. Failure causes are wide range drawbacks on legal, institutional and political processes that Turkey has been faced up. On contrary, the more emphasis given to institutional or legal failures confronting the development of a national mitigation act, the more it becomes hard to enlighten the major flaw to constitute local mitigation strategy while international framework mainstreams the ways of developing a mitigation strategy drawing away from post-disaster paradigm since 1990s.

For developing countries, difficulties to cope with global framework and internalize general principles are quite clear. As social aspects of risk and social differences in local communities are primary factors differentiating the measures in mitigation capacity. As well as, local seismic attributes are primary indicators of natural disasters reveal the significance of starting from a local strategy then built up on it. Global platform for risk reduction and mitigation mentoring to affected countries offer homogeneous principles and actions that could not be easily internalized by developing countries. A bottom-up strategy with a multi-disciplinary framework is required to cling to global framework. Developing incremental and case by case strategy through local praxis; global framework would be rich in risk definitions, emergency scenarios, mitigative measures improving the terminology on global risk sectors as an alternative way to adapt in to emergence.

International platforms under UN determined the primary roles in building an epistemological and theoretical framework parallel to post-disaster approach of emergency management and relief. The turning point for adopting pre-disaster strategy of risk reduction and mitigation has started since 1990 when UN declared that natural events were global threats and a new body: International Decade for Natural Disaster Reduction-IDNDR should be assigned. The worldwide 1999 earthquakes also claimed that the former paradigm could not go any longer and a new approach for risk reduction must be held. Later on, the Yokohoma Strategy (1994) and the Kobe Conference (2005) constructed a common language for developing prevention culture through prioritizing risk reduction, integrating risk reduction in to national, sectoral plans and defining participatory methods as an apparatus for learning programs and capacity building. The transformation period from reactive to proactive state had changed global initiative of identifying risk in quantitative loss scenarios in to a broader concept: 'risk as a socially constructed phenomenon' also shaping society (Beck, 1999).

Brand new paradigm of international community also changed the political function. As 'manufactured uncertainty', risks ‘become a major force of political mobilization’ (Beck, 1999) through the promise of security for future's unintended consequences while clouding present political goals and objectives. The more of a technical capacity building risk reduction is changed in to a matter of governance and policy making to provide sustainable development and optimal risk distribution as a primary challenge to risks emerging not only in particular regions but also in sub-regions or trans-regions (UNISDR, 2005). In order to reduce uncertainty of risks, international framework puts forward disaster preparedness in social, spatial and technical dimensions at local and national levels. Encouraging coordination and dialogue in pre-disaster and post-disaster views, is the primary objective through capacity building in terms of political and legislative frameworks, risk assessment, emergency management, educative and knowledge-sharing networks. Especially risk assessment is underlined as pre-condition for mitigation to be incorporated in to urban planning, mainstreaming sustainable development. Adapting into risk environments, requires both technical and administrative capacities but beyond this international community revealing itself through the notion of risk society (Balamir, 2009).

1.3 Mitigation Planning As Necessity

New task introducing a new ethical ground for planner, would be mediating participatory processes, 'relations of definitions' (Beck, 1999) and mitigation planning. Risks solely taken by the decision maker become danger for affected communities who are incapable of deciding or controlling the situation (Luhmann, 1993). Participatory processes are critical to eliminate the representation problem of affected communities as entitled parties have the primary right to participate to decision making processes through mutual accountability and responsibility. 'Delocalized, incalculable and non-compensable' (Beck, 1999) entities, risks are burdens of all human beings as the prior condition for survival. Risks threat everyone equally but definitions of risks may not. In Beck's risk society (1999); 'relations of definitions' refers to power of defining risks in accordance with hidden agendas that could easily change the dimensions of perceiving risk collectively through making some risks visible while making others disappear. Through participation and transparent knowledge sharing processes in hazard identification and risk assessment; planner could provide an ethical ground for risk prevention without any semantic change implies governing classes to depict risk in accordance with their private political interests. Developing democratic, power-free decisions and institutions for mitigation was an updated objective for epistemological communities, governments and planner as an mediator for coordinating all public and private actors at all levels.

Mitigation planning is the efficacious apparatus for planner to mediate national and local levels of participation and technical coordination of hazard identification and risk assessment. Urban mitigation planning is consisted of the main components hazard identification, spatial risk assessment and planning socio-economic and

spatial terms for risk reduction. Identification of hazards delivered by experts such as earth scientists identifying local seismic attributes including active faults, liquefaction,...etc. and then planners transform the data in to development plans to determine the types and levels of risks in underdeveloped and developed lands and decide the conditions for new development areas (Balamir, 2009). In fact risk assessment; evaluating, estimating and prioritizing risks according to vulnerabilities, potential life and material losses covered through scenarios is an available tool for planner to activate actors, coordinate resources and reduce uncertainty in future. Eventhough the know how was ready to be implemented for mitigation, existing administrative and technical capacities at city level may became obsolete and inert to cope with dynamic risk society.

City level is a center and a medium to collect, coordinate, share risk knowledge from lesser administrative units to national organizations. Planner developing her/his adequacy to mediate socio-technical capacities and administrative capacities at all levels through providing accessibility to local communities in developing prevention culture. Participatory processes mainstream community building and raising risk consciousness are essential to construct collective perception of risk that is known, expected and prevented through local community to society. Mitigation Planning is not a paper work but an adaptive behavior for today to minimize future's uncertainty. International community or local communities may have different definitions of risk and different objectives as conservation or sustainable development but "survival of the fittest" hast both partial and global meanings not depended to political power relations but scientific and social adequacy for adaptation which should be accessible to all socio-economic classes under 'involuntary enlightenment' (Beck, 2006).

Planner's role shifting from predictor to mediator is also an adaptive behavior to share responsibility and accountability for unintended consequences for all levels of society. From a realist perspective, planner's adequacy to intervene risks is context-dependent as it is primarily restricted to national legislative measures which may present capabilities and incapabilities in professional praxis. The absence of a compatible legislation and executive institutions for mitigation precisely paralyzes planner to play any role in the face of uncertainty. In Turkey, the dichotomy of international discourse and national discourse on risk reduction is grounded in this kind of paralyzing effect and clearly observed recently. Pre-disaster approach prevailing mitigation is incrementally blocked through political and legislative drawbacks. Planner is armless as her/his functional capacity is eliminated through political constraints for prevention of risks.

1.4 Turkey's View: Drawbacks and Constraints on Mitigation

Urban vulnerabilities engendered by seismicity and flooding hazards in Turkey are historically inherited from location and clustered in buildings. People were settled where water and fertile land was available and trends of urbanization developed according to former risk generating conditions. High population, unauthorized building stock and reinforced concrete technology speeding up the growth of cities

without applying professional engineering services and provision, created unintended consequences and transformed cities in to urban risk pools. A parallel with developing construction practice, risk prevention strategy developed around building stock as retrofitting and post-disaster approach as relief and emergency management formulating the prevention of losses after disasters happened (Balamir, 2009). To make matters worse, natural disasters were perceived as fatalistic externalities and life losses are accepted as the minimum level of risk by certain parts of society.

Turkey is exposed to seismic activity as located on Eurasian Geological Plate including North Anatolian Fault from east-west ax, East Anatolian Fault and Western Graben Complex at the Aegean Sea. Recent major earthquakes happened in between 1903-1999; at Adapazarı, Gölcük, Yalova and Bolu-Düzce; more than 100.000 people died, 150.000 people injured and 420.000 buildings were suffered significant damage (AFAD, 2009). Last major earthquake was happened at Van in 2011 with a magnitude of 7,2 in which tragic consequences and disaster management failures are observed as most of the lower class population has been still living in aid tents or containers and exposed to secondary hazards such as tent fires and lost their lives. Notwithstanding relief and disaster management failures, another conflict in resource management was declared as Compulsory Earthquake Insurance Fund necessary to reconstruct buildings after disaster was spent for road construction, social security expenditure and government debts, formerly by national government (Alp, 2011). It is crystal clear that there is an underestimation of risk and organizational ignorance in variable circumstances which produces intolerable unintended consequences, secondary risks and system faults that are even duplicating and worsening disaster impacts.

In Turkey, the definition of risk and risk perception is shaped under the general apprehension; "Earthquakes don't kill people, buildings do." Mitigative measures are applied through retrofitting of buildings and building codes could only be revised in 2007 as Earthquake Design Code. Risk knowledge produced by civil engineers and geologists and risk assessment concentrated on failures in building stock. Shortly, city level risks were reduced in to building stock risks. However cities as urban risk pools and complex systems, involve variant conflicts related to land use planning, scarcity of land and green areas, high population concentration, inadequate infrastructure and so on which could not be handled solely through retrofitting and building stock oriented approaches.

1999 events triggered a new structuring under Earthquake Board of the Prime Ministry; Disaster Affairs referring to Disasters Law (7269) established to develop disaster resistant buildings and monitor seismic activities; Development Law (3194) includes decisions related to disaster risk reduction and development such as Regulations on Construction in Natural Disaster-prone Areas but merely focused on post-disaster activities. As an encouraging step, Disaster Affairs provided that developing multi-hazard maps by local governments and assigned responsibilities for municipalities but regional or sectoral plans for mitigation is still off the agenda. National strategy for mitigation was about to be developed in 1989 when

International Decade for Disaster Reduction was declared. National Committee established under the Ministry of Public Works and Settlement to develop national action plan for risk reduction (Ertan, 2009). National Plan assigned to State Planning Organization (DPT), partially applied and implementation was interrupted by shift in the political wind alluding the problem of non institutionalization of mitigation which should be above politics in practice. National Earthquake Council (2000) and Earthquake Information Council (2009) under Disaster Affairs were two distinct models indicate different conflicts. National Earthquake Council (UDK) was established by the purpose of scientific mentoring and formed of multi-disciplinary members from academia but unfortunately abolished in 2007 for the basis of being functionless. Earthquake Information Council (DDK) involves the representatives of related ministries, research institutes and a minority of five academic member selected by the Prime Minister. In institutional arena, the ground of the action for legitimation is shifted from academia to central government. Denying, transparent participatory process of defining our own risk may rise another danger of comprising powerful actors who 'maximize risks for others and minimize risks for themselves' (Beck, 2006). Risk definitions should be represented via broader sectors and participation of independent actors such as academia and NGOs. As Beck asserts that 'even the most restrained and moderate objectivist account of risk implications involves a hidden politics, ethics and morality' (Beck, 2006) but at least defined political interests could be eluded from ethical ground for mitigation. National Mitigation Act and Mitigation Fund should be established to provide a necessity area to steer lesser administrative units and develop a holistic approach.

An obtrusive drawback for mitigation in terms of legislative framework was Act on Regeneration of Disaster Prone Areas which was actually a secondary disaster in case of local communities who have no legal support to object or counteract to compulsory regeneration activities. Urban regeneration is implemented as a mitigative action to redesign disaster prone areas. The process composed of reconstruction and construction of reserve areas for new settlements through expropriation by Housing Development Administration (TOKİ) under the Prime Ministry by transferring all the rights of planning and design. Local communities' counterclaims could get a stay of execution by the court and entitled parties indebted to government, were as if penalized with hard payment conditions. Not depending on any other legislation, Act on Regeneration of Disaster Prone Areas presupposes the denial of significant acts on military areas, sea fronts, historical and conservation areas, fields and olive orchards Local communities should own the rights of protest and bargain in large scale urban decisions such as regeneration. Otherwise, monopolistic tendencies and center-local tensions generate social risks and parallel hegemonic spaces impeding policy learning stages and the diffusion of prevention culture for all levels of society.

Mitigation is a new borne area for Turkey captured by post-disaster strategies, engineering concepts and risks on building stock. Despite the post-disaster approaches as reconstruction, rehabilitation and relocating of settlements at city level, risk reveals in more complicated and socially constructed versions such as

dangerous land use in social facilities located on the top floor of gas or LPG stations or historical districts on landslide areas. A comprehensive approach to combine post-disaster and pre-disaster stage is necessary in both fundamental law and legislative framework. A risk definition coping to social vulnerabilities such as lower socio-economic classes have to be considered in legislation. Mitigation both implemented to former legislations and compelled to be exclusively structured as a legislation should be developed and internalized by all actors at all levels in the form of shared responsibilities and accountabilities. The broader feasibility of mitigation allows discarding of short and long-term conflicts and costs that emerge in post-disaster period while providing more space for planner to play his/her role. For the sake of political dependencies and institutional inadequacies, Turkey is maladjusted to new policy on risk reduction that claims to protect natural resources, communities and cultural values. Post-disaster view as relief-based institutions and experts, symbolize a narrow paradigm that oversimplifies urban risks and invites more vulnerabilities and losses in future. As a powerful tool and a technical capacity, mitigation planning integrating hazard identification and risk assessment should be sustained and improved by local governments like a primary step to provide resilience for stratified urban risks evolving at city and duplicating the impacts of natural disasters as it was happened in Istanbul.

2. Analysis

2.1 Istanbul Fatih District As An Urban Risk Pool

Istanbul, an urban risk pool of geographical, historical, structural, infrastructural and social constraints evolved through the historical development. Fatih District at the Historical Peninsula, at the center of the Metropolitan Area harbors all the conflicts originated from its central layout and functional relations. The Historical Peninsula or Old City separated by city walls is situated at Çatalca Peninsula including the entire area; Haliç, Beyoğlu and the Bosphorus at east, the Marmara Sea, three other districts at west (Zeytinburnu, Eyüp, Bayrampaşa), laid upon the west boundary with Bulgaria (Ertan, 2009). Through the history hosting to Greek, Roman civilizations and Ottoman Empire, the district preserves the significance as a center of culture and business. Small industry and wholesales functions contradict and endanger historical structures. Therefore Fatih District is a contextual priority including various challenging attributes for planners and an inclusive prototype for containing all the general problems and constraints that Istanbul is still facing with.

Figure 1. Fatih District and The Historical Peninsula (Google Maps 2012).

The Historical Peninsula is defined as 1st Degree Earthquake Zone (Ministry of Public Works and Settlement, Disaster Affairs Earthquake Zone Map) and Fatih District is evaluated in first ten hazardous settlements.

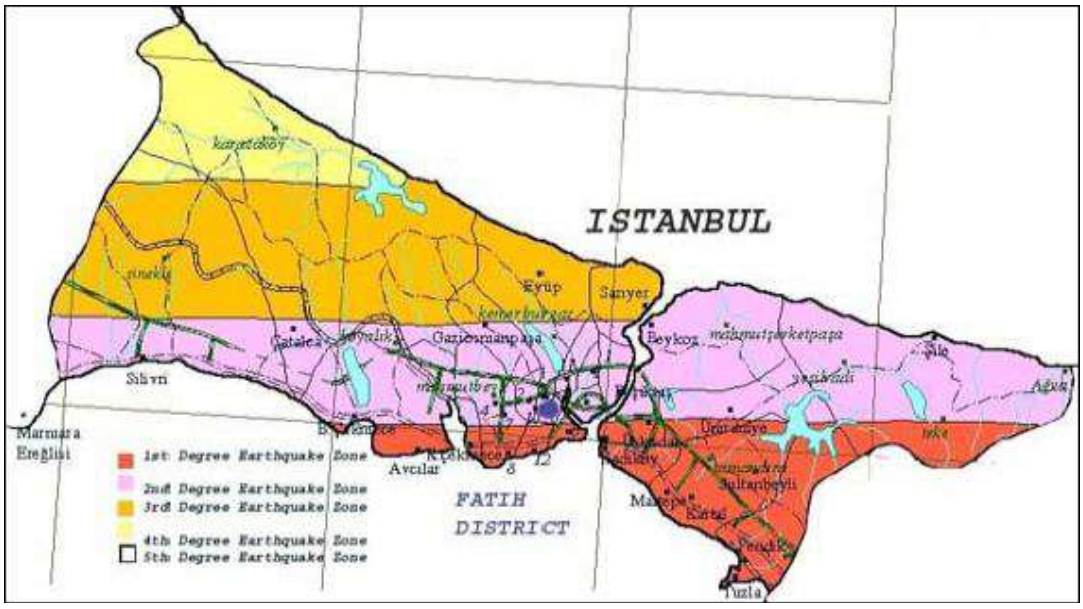

Figure 2. Seismic Zones In Marmara Region (AFAD, 2012).

2.2 A Method for Identifying Local Seismic Attributes

Natural hazards in the district are inherited from the interaction of terrain shape and hazardous geological formations to form various seismic attributes. The first step of

mitigation planning for the district is hazard identification to define, classify, represent and synthesize natural hazards to determine local seismic attributes.

Table 1. The Determination of Local Seismic Attributes in Multi-Hazard Map

[1]Available Data on Potential Natural Hazards	[2]Spatial Categorization of Hazard Areas			[3]Local Seismic Attributes
Seismicity	TERRAIN HAZARDS	LOCAL GEOLOGICAL ATTRIBUTES	HYDROLOGIC HAZARDS	**Multi-Hazard Zoning**
Landslide	Slope	Seismic Geological Formations	Watercourses	2 Hazard Combinations **(axb)**
Earthquake Faults	Liquefaction	Variations in High Peak Ground Acceleration-PGA	Water basin	3 Hazard Combinations **(axbxc)**
Liquefaction	Landslide		Tsunami	4 Hazard Combinations **(axbxcxd)**
	Artificial Fills			5 Hazard Combinations **(axbxcxdxe)**
	Alluvial Grounds			

Potential hazards are determined as distinct hazard potentials such as seismicity, landslide, liquefaction and earthquake faults with 150 m impact area. Natural hazards are categorized under three subtitles. Terrain Hazards are formed out of terrain character with high slope (20-38%) on coastal areas and lower in the mid like a great calix. (90 m to 10 m of altitude) Landslide areas on sharp slopes and soft ground attributed in liquefaction areas and alluvial grounds are the areas with high seismicity just as infill areas (>20% slope) concentrated at coastal parts (Ertan, 2009).

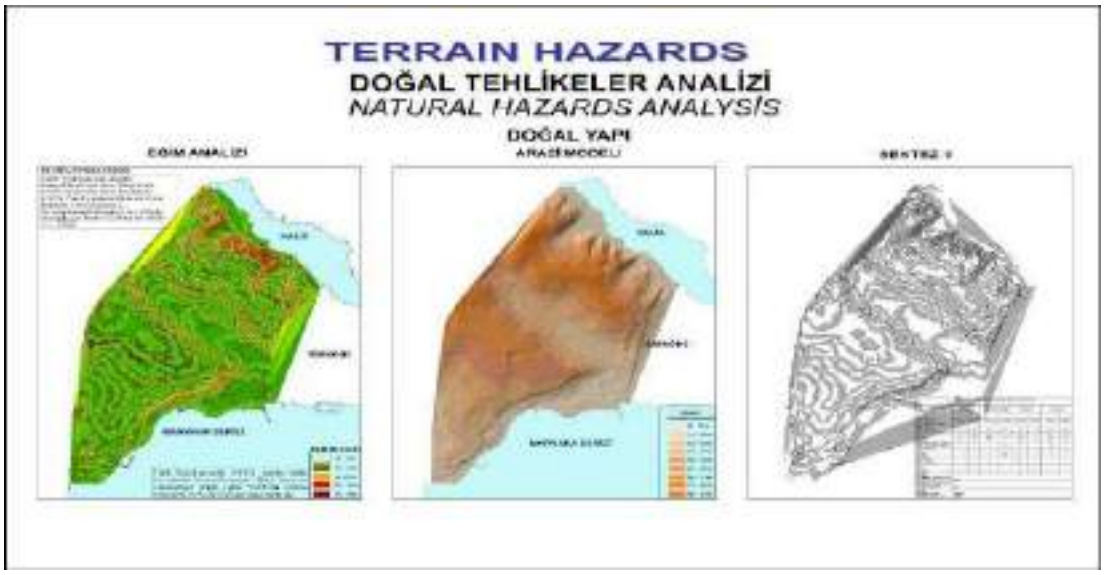

Figure 3. Natural Hazards: Slope Analysis and Terrain Model (Ertan, 2009).

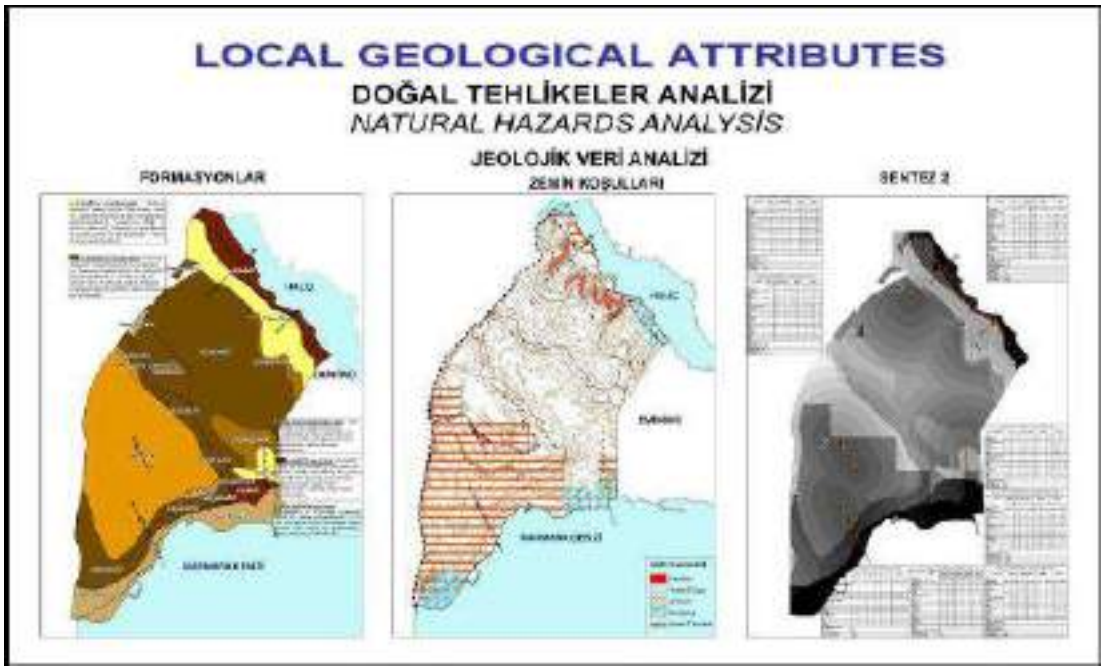

Figure 4. Local Geological Attributes: Geologic Formations and Geologic Data Analysis (Ertan, 2009).

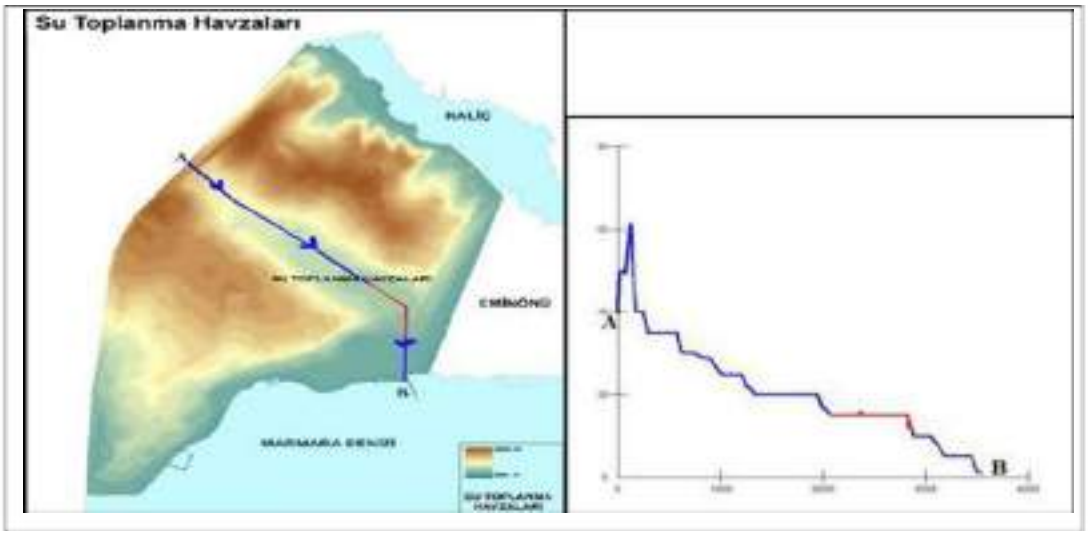

Figure 5. Hydrologic Attributes: Water Basin Model and the Profile of Water Flow (Ertan, 2009).

Local Geological Attributes include fine grained geological formations hazardous for construction and high PGA areas (Peak Ground Acceleration-PGA), seismically active areas with a high value of earthquake acceleration on the ground. In third place, Hydrologic Attributes referring to water basin form of the terrain morphology, tsunami area and old watercourse areas located in the mid of the district laid under the busy street ax holding infrastructure problems and flood hazard.

After natural hazards are examined distinctly, local seismic attributes are determined in accordance with their interactions to each other. Through the areal superimposition of natural hazards in ARCGIS 9.0 program, it is observed that natural hazards form combinations in 2,3,4,5 groups (Table.1) which determined the first level of priority and a ground map for further analyses. In order to evaluate hazards comprehensively and model a form of relationship, hazard combinations are observed and a multi-hazard map showing the most hazardous areas with 5 combinations to lesser are projected in Figure. 5 from dark red to light. In order to select most hazardous combinations a qualitative observation is required as two hazard combinations such as landslide and earthquake fault could generate more powerful impact in terms of their interaction.

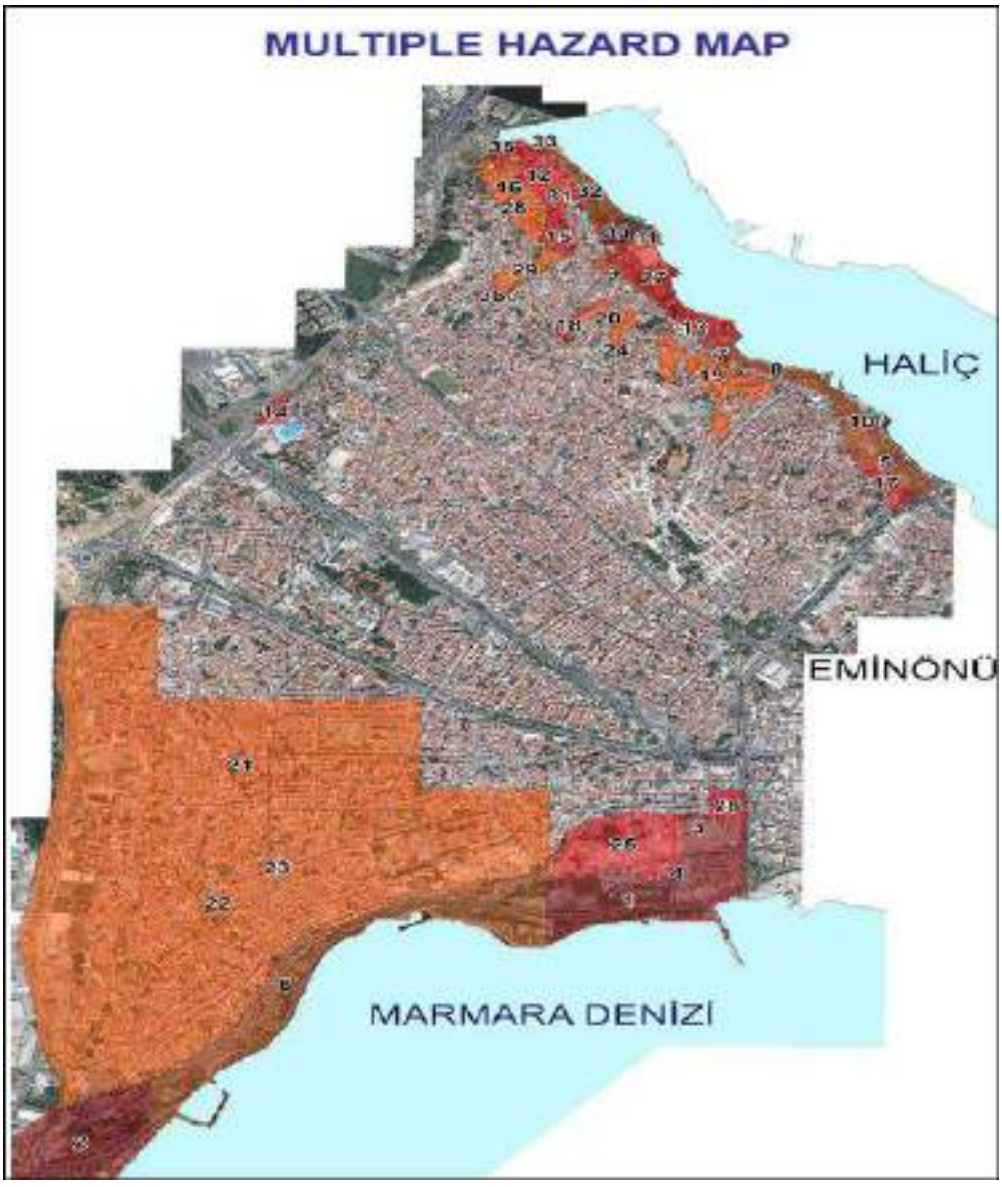

Figure 6. Multi-Hazard Map (Ertan, 2009).

The correlation in between multi-hazard areas and total built area is checked for evaluating total hazard potential of the district. Fortunately, it is observed that natural hazard combinations decrease as total built area (ha) decreases. (Figure. 7)

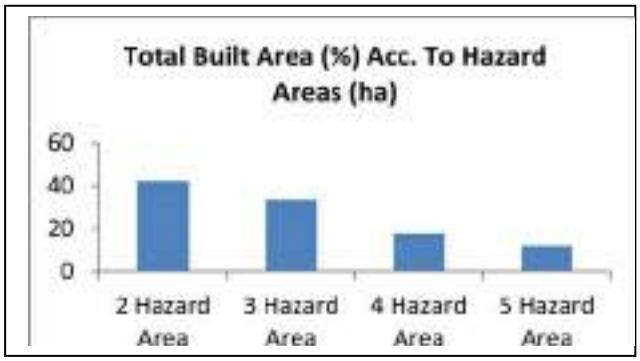

Figure 7 Multi-Hazard Map

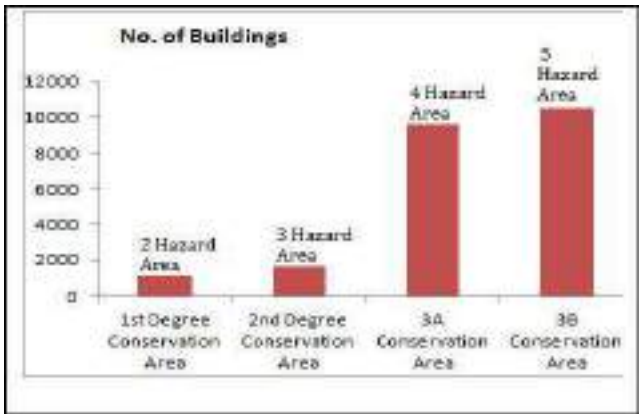

Figure.8 Multi-Hazard Map

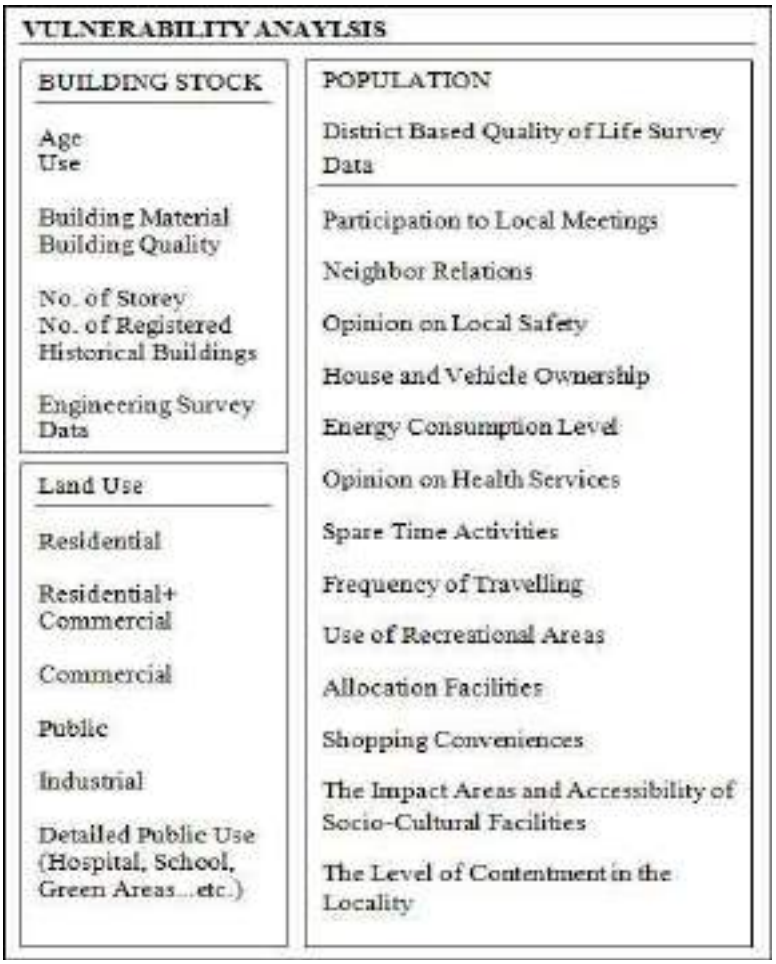
It is observed that there is no relational increase in between degrees of conservation areas, hazard areas (ha) and no. of buildings. Hazard combinations decrease as total no. of buildings per conservation area decrease. (Figure.8) After qualitative observation and determining the physical/natural constraints for planner a second constraint is needed to be analyzed: Conservation Areas. By the areal superimposition of Multi-Hazard Map and Conservation Areas the level of allowance to physical intervention and a path for planner is revealed. (Table.4)

Second step involves Vulnerability Analysis bringing out socio-economic input to diagnose social dimensions of local seismic attributes. The socio-economic input embodies building stock, land use and district-based quality of life survey data. In view of physical and legislative constraints social constraints for planner are observed and deciphered. Buildings stock in case of age, material, quality, no. of storey, no. of registered historical buildings, engineering survey data is considered for risks, vulnerabilities and local-historical attributes of site.

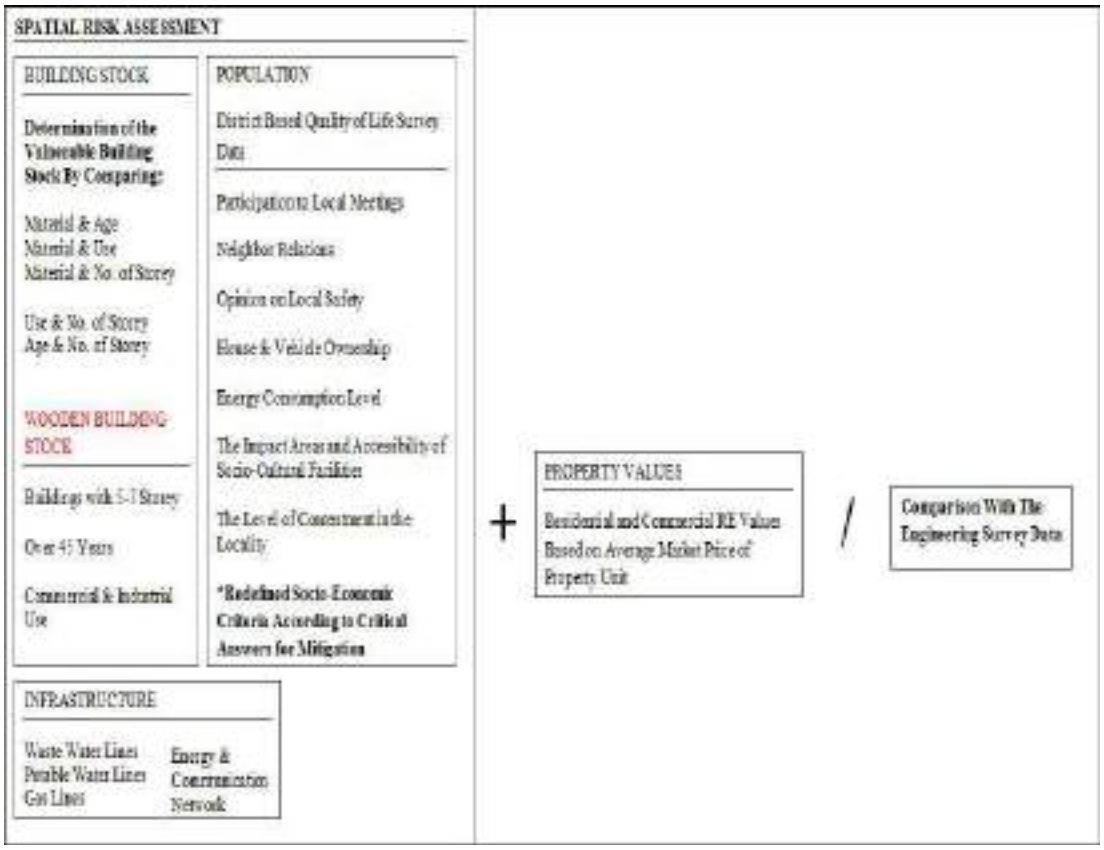
Table 2. Vulnerability Analysis



Land use is checked out to catch connections between risk sectors to residential, residential + commercial, commercial, public, industrial uses and green areas. A detailed public use survey to determine the capacities of emergency centers and public-private use ratio is carried out distinctly. As a significant input, district-based quality of life survey depicts local population to measure vulnerabilities and evaluate the medium for community building.

Spatial Risk Assessment is the third step introducing economic aspects of hazards forming risks which concentrate intensely or distinctly over the district. (Table.3)

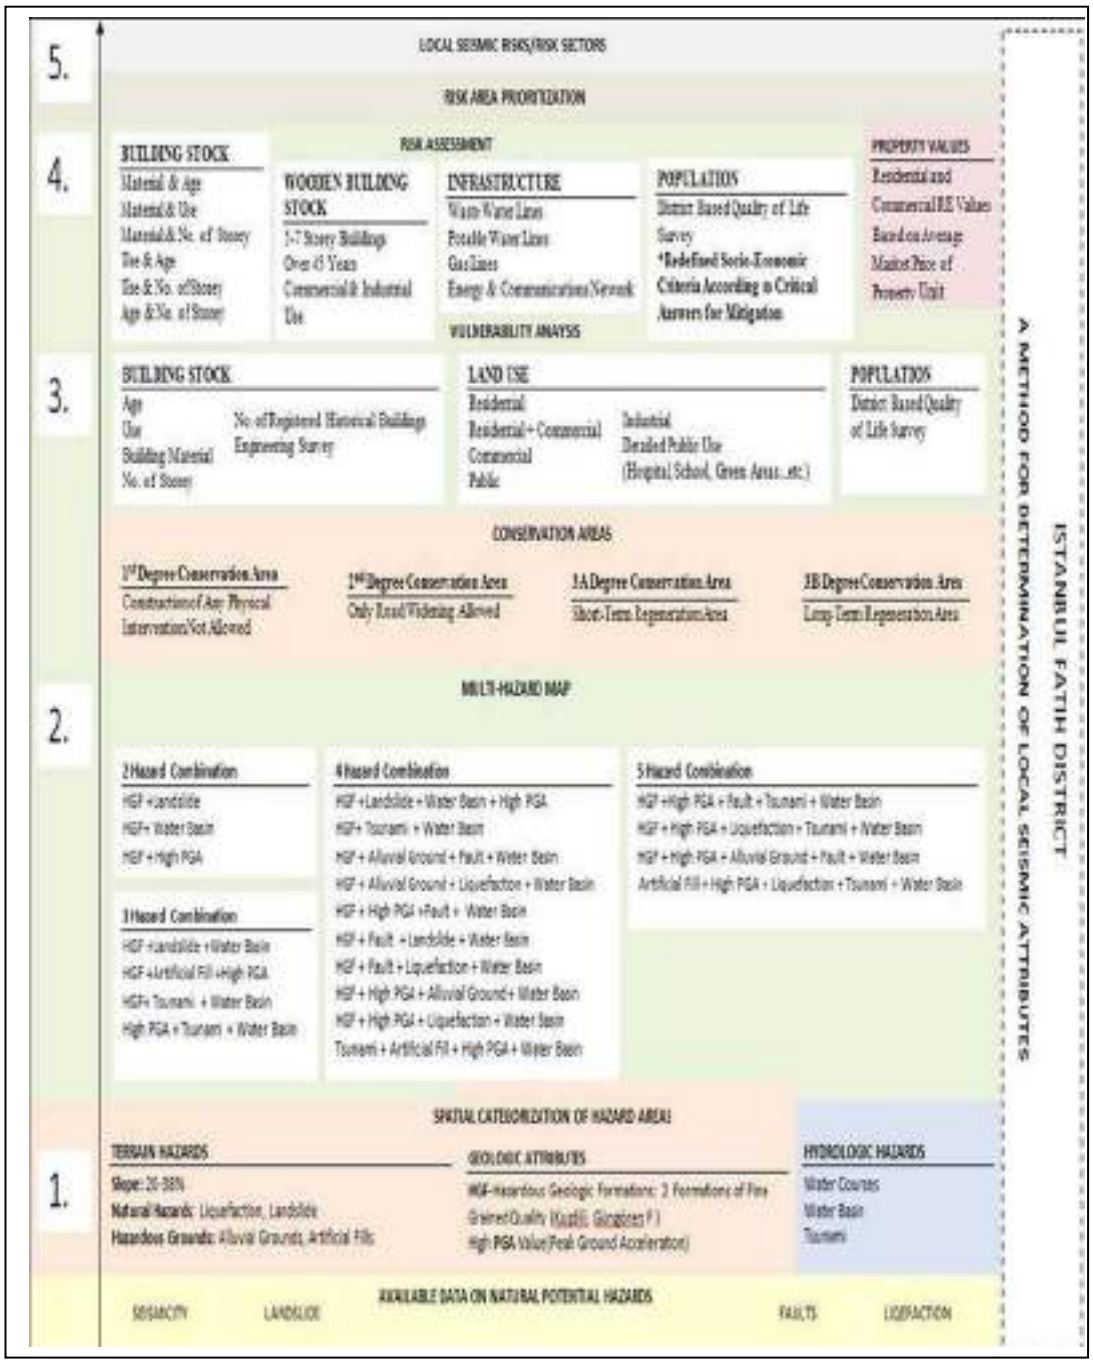
Table 3. Spatial Risk Assessment



Property values projecting residential and commercial real estate values based on average market price per unit of property are integrated to previous vulnerability analysis including building stock, land use and social survey. In order to emphasize local attributes and carry out a dynamic process, criteria for risk assessment was redefined from the marginal or extreme values of the vulnerability analysis which marks risk generating factors as wooden building stock or high level of energy consumption in high risk zones.

In building stock, it was observed that wooden building stock should be examined distinctly; even it is less in amount, hazardous to generate secondary disasters as fires which was general in district's history. Another fine difference is marked as risk-weighted answers achieved from district-based quality of life survey in which yes or no concentration is high at some social survey criteria relatively to others. Therefore, participation to local meetings, neighborhood relations, house and vehicle ownership, energy consumption, accessibility of socio-cultural facilities in impact areas and the level of contentment in the locality are separately examined through spatial risk assessment. Infrastructure as a vulnerable resource and a physical factor to generate secondary disasters such as explosions; gas lines, waste water lines, potable water lines, energy and communication networks are covered in scope of risk assessment.

Table 4. A Method for Determination of Local Seismic Attributes.



Risk Area Prioritization is the last step for determining prior areas for mitigation planning. Combining pre-disaster and post disaster priorities and eliminating short-term impacts of disasters, physical constraints to be eluded in view of emergency management are determined. Emergency measures of local administration are spatially tested for vulnerabilities in road network, availability of designated emergency facilities, temporary accommodation availabilities, emergency storage

requirements and hospital capacities and approximate schools. The capacity adequacy for hospitals and emergency centers designated by metropolitan municipality, temporary accommodation for evacuated communities, road networks for evacuation, school-hospital proximity and earthquake faults-hospitals proximity are the basic criteria proposed for emergency management as a completing step to mitigation planning.

3. Results

According to the findings, Fatih District is exposed to various socio-physical risks and natural hazards likely bear secondary disasters and contagious risks. The emphasis on local seismic areas reveals the way of interaction of hazards are specific to locality. Multi-risk areas determined as a result of multi-level election include common hazardous attributes and risk sectors.

3.1 Old Urban Texture

When multi-hazard zones are monitored, hazardous combinations located at old urban texture are the initial conflict, calls for complementary legislative approach. 1st Degree Conservation Areas contain both 150 m impact area of seismic faults, historical listed buildings and mixed uses as high percentage of health services, education facilities, auto parks, commercial use, manufacturing industry, public use. Old city texture with wooden buildings are the primary problem in case of building stock. Wooden buildings above 45 years/3-5 storey, wooden buildings with industrial and commercial uses, wooden buildings with hazardous uses at periphery and proximate gas lines constitute secondary disaster potential as fires and explosions during disaster. Through narrow road network for 2-3 m, there was a problem of accessibility in emergencies. On contrary, allowance to retrofitting and construction in those areas could invite exploitation of historical and cultural assets. It is required to be ensured by a special Act on Restoration of Historical Buildings and Cultural Assets at Disaster Prone Areas and national fund on mitigation for historical assets.

3.2 Geologic Macroform Risks

Hazardous ground types constitute the basis of local seismic risks. Building stock and green areas located on infill areas, landslide areas, liquefaction areas and hazardous geologic formation with high PGA concentrated on coastal areas and include public use and recreational facilities. Mitigative measures as national early warning systems connecting to global networks, development restriction, height restriction and floor reductions should be implemented to prevent doubling impacts of multi-hazards.

3.3 Building Stock

Building stock vulnerable to seismicity other than wooden buildings are aged (older than 45 years) (Figure.9) and high storey (5-7 storey) buildings (concrete/concrete-masonry/masonry) clustered in 3rd Degree Conservation Areas that allow regeneration. 37% of total stock are adjacent at corner increasing the vulnerability of the area during seismic shocks. Allowance for urban regeneration could be tempting for developing new opportunities by local governments but urban regeneration for the purpose of mitigation is a delicate implementation of participatory processes. public buildings and emergency facilities Demolition of weak buildings, reconstruction, retrofitting and urban regeneration methods should be decided mutually and transparently through dynamic negotiations rather than decisive top down processes.

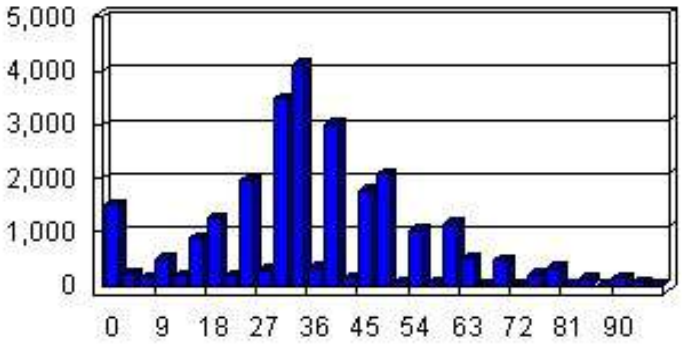


Figure 9. Age of Buildings and No. of Buildings

3.4 Social Inaccessibility

The socio-economic structure is rather depressive as 59% of the local community discard neighborhood relations, 73% discontent with the environment, 66,7% afraid to go after dark and most of the individuals are illiterate. Fatih District is preferred for cheap rents 200-400 TL and real estate values 1000-3000 TL (per unit price) District Disaster Volunteer (MAG) (Ertan, 2009) for disaster management and local community associations as FEBAYDER (Fener Balat Ayvansaray Protection of Tenants' and Property Owners' Rights and Social Collaboration Association) as a counter movement for urban regeneration projects. Social platform for mitigation gathering all small associations could be an innovative step for building community. Social development projects, revenue generating activities for unemployed individuals and women might help for social organization and collaboration. The design of participatory processes should depend upon confidence building between local government and local communities through negotiation and mutual correspondence. Further, socio-cultural programmes increasing the sense of belonging of the neighborhood, educative programmes and training programmes for public officials, trainers and local communities to build awareness, emergency preparedness and collective action for risk reduction.

4. Conclusions

For many years, risk analyses are reduced in to actuarial methods, statistical analyses, high-tech innovations in civil engineering supported by global and local economic programs. Risks and impacts have been evaluated through harm and loss analyses led to oversimplification (Denney, 2009). Social aspects of risks ignored in risk reduction praxis and changing paradigm from relief based post-disaster approach to mitigation determine an obligation for national communities to make their own definitions of risk. Socially determined or distorted risk constructed by information processes, institutional structures, social group behavior and individual responses produce risk consequences which reproduce other risks like a ripple effect. Social amplifications of risk changes the definition of risk through interacting cultural groups to interpret and validate signals, behavioral intentions to tolerate or take actions against risk, engaging in groups or individual actions to accept, ignore, tolerate or change the risk. Therefore it is impossible to define risks solely through engineering data or land use hazards that contain hidden meanings and complex networks of a social medium. Changing definitions of risk also changes the dimension of risk perception (Kasperson R.,Kasperson J., 2005).

In Turkey, the main reason of not internalizing international framework for mitigation is that dimension, reducing risk in to building level rather than city level. Building as a spatial economic vulnerability manufactured risk as an asset exchanged to avoid. Legislative framework also copes to the definition via partial implications of mitigation merely focused on post-disaster strategy in Development Law and Disasters Law. Recently updated, Act on the Regeneration of Disaster Prone Areas define risk as opportunity for redevelopment, creating power actors but increasing social amplifications of risk and social exclusion. Mitigation reveals a new ethical and technical area for policy learning and praxis that are above politics.

Mitigation plan for each risk sector enables to develop horizontal relations organized from locality to global framework on floods, earthquakes and many other natural disasters to develop common risk definitions and parallel mitigative measures. Hazard identification and risk assessment methods projecting multi-hazard maps and distinct hazard maps are essential to evaluate potential damages of hazard as well as their interaction. The collaboration of local governments to according to different risk sectors should be implemented, shared and systematized in to actions by all responsible and accountable actors as NGOs local civil movements, media and stakeholders from public and private sectors. Organizational fear of responsibility in local and national levels should be eliminated through micro-level social learning programmes of community building which successfully integrated to academic education mainstreaming all levels of mitigation plan.

The role of planner and epistemic community are prior to construct a new paradigm for the implementation of mitigative capacity. The dismissal of social amplifications of risk should be provided by developing socio-technical capacities to perceive all dimensions of risk and a broader perspective by the participation of all accountable

stakeholders. Involuntary enlightenment is a new pace for everyone to realize that risk reduction is not a zero-sum game and if not then it would be not the system but us that create new risks : The significant problems we have cannot be solved at the same level of thinking with which we created them. (Einstein)

THE NEOLIBERALISATION OF STRATEGIC SPATIAL PLANNING

Kristian Olesen[1]

Abstract
Despite the fact that strategic spatial planning practices recently have taken 'a neoliberal turn' in many European countries, 'neoliberalism' and 'neoliberalisation' are rarely used as analytical concepts in planning theory. This paper seeks to fill in part of this gap by examining the relationship between neoliberalism and strategic spatial planning. This is done through an analysis how the key theoretical ideas underpinning strategic spatial planning might be appropriated by neoliberal political agendas in planning practice. In conclusion, the paper argues that neoliberalism and neoliberalisation are helpful analytical concepts to examine and understand contemporary transformations of spatial planning discourses and practices, and that planning theory by adopting such analytical concepts can play an important role in assisting critical empirical studies of how spatial planning practices are being transformed under neoliberalism.

1. Introduction

In the planning literature, significant attention has been paid to the renewed interest in strategic spatial planning spreading across Europe from the beginning of the 1990s[i] and across the UK from the beginning of the 2000s[ii]. So far this 'revival of strategic spatial planning' (Albrechts, 2004; Healey et al., 1997; Salet and Faludi, 2000) has been treated as rather unproblematic in the planning literature, celebrated amongst planning scholars as a welcome opportunity to recover the lost ground of the planning scepticism in the 1980s. Strategic spatial planning has been seen as a new way of transforming planning practices, effectively breaking away from the neoliberal project-led planning approaches in the 1980s, and the mid-20th century welfare state planning based on land use regulation (Albrechts, 2004). This perspective still dominates the strategic spatial planning literature, despite increasing discussion of neoliberalism as a hegemonic discourse in urban policy-making and spatial planning in the more critical-minded literature.[iii] The core argument in this literature is that the fields of urban policy-making and spatial planning are today underpinned by a more pragmatic version of 'roll-out' neoliberalism, in which the state plays an active role in supporting market logics by putting policy objectives of economic growth and competitiveness in the centre of spatial policies.

In the planning literature, neoliberalism has often been associated with large-scale urban development projects (Swyngedouw et al., 2002). However, more recently it has been argued that neoliberalism penetrates planning practices in many different

[1] Department of Development and Planning, Aalborg University - kristian@plan.aau.dk

aspects of planning (Tasan-Kok and Baeten, 2012), including strategic spatial planning practices (Allmendinger, 2011; Allmendinger and Haughton, 2012; Cerreta et al., 2010, Haughton et al., 2010). Empirical research from many European countries suggests that strategic spatial planning across Europe has recently taken 'a neoliberal turn',[iv] as it has been noticed how "the ideal of strategic planning could easily be used to favour the most aggressive neoliberal models of urban and regional development" (Cerreta et al., 2010, p.x). This has led to an increasing awareness that strategic spatial planning practices are unable to resist the hegemonic discourse of neoliberalism. Instead, strategic spatial planning practices seem increasingly to be guided by neoliberal political agendas, reinforcing a post-political condition in which neoliberalism as a hegemonic discourse within spatial planning remains largely unquestioned (Allmendinger and Haughton, 2012).

In fact, strategic spatial planning practices seem to provide a smokescreen for neoliberal transformations of spatial planning in different ways (Cerreta et al., 2010, Haughton et al., 2010). This process of 'neoliberalisation of strategic spatial planning' can be understood as "the ongoing project to install market logics and competitive discipline as hegemonic assumptions" (Purcell, 2009, p.140) in planning processes. Tasan-Kok and Baeten (2012) has argued that concepts such as 'neoliberalism' and 'neoliberalisation' have generally been overlooked in planning theory and planning research, despite getting increasing attention in other social sciences. In the planning literature, there are very few empirical studies, which critically analyse how planning systems, spatial logics, and strategic spatial planning practices are changing and being transformed under neoliberalism over time in particular settings, and what the implications of such transformations are. This paper contributes to fill in part of this gap by analysing the relationship between neoliberalism and strategic spatial planning. The aim is to offer some theoretical insights and initial building blocks on which such future empirical analyses of contemporary neoliberal transformations of spatial planning practices may build.

In this paper, I firstly attempt to draw out the relationship between neoliberalism and the revival of strategic spatial planning in the beginning of the 1990s. I argue that a particular model of 'roll-out' neoliberalism played an important role in paving the ground for reviving and (re)legitimising strategic spatial planning practices in Western Europe at the time. Secondly, I seek to demonstrate how some of the key theoretical ideas underpinning strategic spatial planning, that is communicative planning, relational geography, and soft spaces, might be appropriated in planning practice to support neoliberalism as a hegemonic discourse in spatial planning. Finally, I argue that neoliberalism and neoliberalisation are helpful analytical concepts to examine and understand contemporary transformations of spatial planning discourses and practices, and that planning theory by adopting such analytical concepts can play an important role in assisting critical empirical studies of how spatial planning practices are being transformed under neoliberalism.

2. Neoliberalism and the Revival of Strategic Spatial Planning

Until recently, critique of neoliberalism in urban policy-making (and spatial planning) was a topic reserved to critical geographers writing predominantly from a Marxist or neo-Marxist perspective (Castree, 2006). More recently, 'roll-out' neoliberalism has been associated with the state spatial project of reviving strategic spatial planning in Western Europe, predominantly in the UK under the New Labour era (Allmendinger, 2011; Allmendinger and Haughton, 2009b, 2010; Haughton et al., 2010). Yet also in other European countries like Germany, Denmark, and Belgium 'a neoliberal turn' in spatial planning has recently been reported (Murray and Neil, 2011; Olesen and Richardson, 2012 forthcoming, 2013 forthcoming; Van den Broeck, 2008).

In this section, I first outline the main characteristics of neoliberalism, drawing out two different models of neoliberalism: 'roll-back' neoliberalism and 'roll-out' neoliberalism. Second, I attempt to draw out the relationship between the less visible model of 'roll-out' neoliberalism and the revival of strategic spatial planning in Europe in the 1990s.

2.1 Two Models of Neoliberalism

The basic assumption behind neoliberalism is that "society functions better under a market logic than any other logic, especially a state-directed one" (Purcell, 2009, p.141). In many ways, neoliberalism attempts to reintroduce Adam Smith's concept of 'the invisible hand' from the 1750s, as a metaphor of how the market is more efficient in allocating resources than the state. In the context of globalisation, neoliberalism has more recently been presented as the only way to promote economic growth and competitiveness. Here, neoliberalism should not only be understood as a set of policies, but as a political ideology promoting the argument that there is simply no alternative to the market in allocating resources effectively (Peck and Tickell, 2002; Purcell, 2009). Alongside this legitimising argument of no other alternatives, neoliberalism has since the 1980s developed into a dominant 'common-sense' discourse, in which market competition, including creation of a business friendly environment, has become a necessary (and at times the only) value in decision-making (Purcell, 2009). Peck and Tickell (2002) refer to this development as the normalisation of a 'growth-first' approach to urban development.

The more recent literature on neoliberalism distinguishes between neoliberal ideology in its pure theoretical form, and what is referred to as 'actually existing neoliberalism' (Brenner and Theodore, 2002), which tends to have a more pragmatic form in practice. Peck and Tickell (2002) divide the 'actually existing neoliberalism' into two different models. The first model of neoliberalism, which is closer to neoliberalism in its pure ideological form, is often associated with the elections of Margaret Thatcher in the UK and Ronald Reagan in the US in the 1980s. In the context of economic recession and increasing globalisation, neoliberal state policies were introduced, which sought to promote market logics and competition in the

public sector, whilst reducing the role of the state to a minimum. This more well-known model of neoliberalism is often labelled 'roll-back' neoliberalism (Peck and Tickell, 2002) or *laissez-faire* (let-do) neoliberalism (Purcell, 2009).

During the 1990s, a different model of neoliberalism emerged, which is much further apart from the neoliberal ideology and therefore potentially less visible in practice. This model is described as 'roll-out' neoliberalism (Peck and Tickell, 2002) or *aides-faire* (help-do) neoliberalism (Purcell, 2009). In this model, the state plays a much more active role in facilitating the accumulation of capital. The state is actively intervening in the market by among other things generating public investments into infrastructure and urban development projects in order to support market logics and competition. This softer form of neoliberalism has also been associated centre-left governments such the former New Labour government in the UK (Allmendinger, 2011, Haughton et al., 2010; Peck and Tickell, 2002). It is this latter model of neoliberalism, which in many ways helped to pave the way for the 'revival of strategic spatial planning' in Europe in the beginning of the 1990s.

2.2 The Revival of Strategic Spatial Planning

In the mid-20th century, spatial planning was mainly concerned with growth management through preparation of structure plans. It was widely recognised that a strategic approach to land use planning was needed to manage the rapid population growth and urbanisation processes characterising Europe at the time (Healey et al., 1997). In this period of spatial Keynesianism (Brenner 2004), spatial planning played an important role in correcting market failures by distributing growth and economic development evenly across state territories, providing services for a reasonable quality of life. In the 1980s, this core idea of planning came under pressure in the increasingly neoliberal political climate. Here, policies of 'roll-back' neoliberalism resulted in an increasing disbelief in planning, which was largely regarded as restricting economic growth and competitiveness. This was in particular the case in the UK, but also in many other European countries the state's role in planning was reduced, whilst planning tasks increasingly were left to the private sector, or various forms of quasi-public or public-private organisations. Planning was increasingly directed towards the market and became more project-oriented, focusing primarily on large-scale urban development and infrastructure projects (Allmendinger, 2011; Healey et al., 1997).

Whilst this new understanding of the core idea of planning as facilitator of economic growth and competitiveness first resulted in a disbelief in planning and a 'roll-back' of the nation state in the 1980s, these ideas were later put in the centre of the new strategic spatial planning emerging in the 1990s. Here, strategic spatial planning was increasingly seen as an activity for positioning cities and city-regions in the European competitive landscape or within a global market (Albrechts et al., 2003: Healey et al., 1997), promoting what Brenner (2004) refer to as the neoliberal competitive state. Rather than focusing on expanding the welfare state by promoting

equal development across the state territory, public investments were generated into major cities and urban regions, promoting a new set of spatial logics centred on major cities and urban regions as key sites for economic activity. We might thus understand the new strategic spatial planning practices emerging from the beginning of the 1990s as an attempt to transform the core idea of planning to fit the increasingly neoliberal political climate.

In the planning literature, the new strategic spatial planning has been articulated as a substantially different activity than traditional land use planning and neoliberal project planning (Albrechts, 2004, 2006; Healey, 2007; Healey et al., 1997). Planning scholars have seen the renewed interest in strategic spatial planning as an opportunity to transform planning practices and rebrand planning after a decade of considerable planning scepticism. This means that strategic spatial planning remains a rather elusive concept, defined just as much by what it is not, as by what it is (Haughton et al., 2010). Friedmann (2004) notes how it is difficult to find a clear-cut definition of strategic spatial planning in the planning literature. Instead, the understanding(s) of strategic spatial planning seem to remain somewhat implicit among planning theorists (Needham, 2000), deeply rooted in different European planning cultures. This is perhaps not surprising as 'spatial planning' was invented as a Euro-English term in process of preparing the *'European Spatial Development Perspective'* (ESDP) (CSD, 1999), as an attempt to capture the essence of various European planning traditions such as the French *aménagement du territoire*, the Dutch *ruimtelijke ordening* and the German *raumordnung* (CEC, 1997). Strategic spatial planning might thus mean different things in different contexts and planning cultures. On one hand, strategic spatial planning has been used as an umbrella term to describe a range of different planning activities taking place across Europe since the beginning of the 1990s at scales above the local governance level. On the other hand, it has been used within planning theory and by planning communities to promote a new set of normative ideas about what constitutes 'good planning' (Haughton et al., 2010).

These elusive characteristics make strategic spatial planning rather vulnerable to neoliberalisation. In the next section, I discuss how the key theoretical ideas underpinning strategic spatial planning might be appropriated by neoliberalism in planning practice.

3. The Neoliberalisation of Strategic Spatial Planning Practices

The new strategic spatial planning practices emerging in Western Europe from the beginning of the 1990s have been the subject of considerable interest in the planning literature. In academia, planning scholars have sought to elaborate and refine the concept of strategic spatial planning by adding a normative theoretical dimension to the concept in order to guide future planning practices. In this section, I attempt to demonstrate how the key theoretical ideas underpinning strategic spatial planning expose strategic spatial planning practices to neoliberal political agendas, which seek

to maintain the status quo and reinforce existing power structures. The key theoretical ideas that I discuss in this section are communicative planning, relational geography, and soft spaces.

3.1 Communicative Planning as a legitimising tool for neoliberal discourses?

Alongside the revival of strategic spatial planning in planning practice in the beginning of the 1990s, planning theory seemed to be taking a communicative turn (Healey, 1992) in which communicative planning was presented as a new paradigm within planning theory (Innes, 1995). Communicative planning ideas had a significant influence on the theorisations of strategic spatial planning, which was conceptualised as collaborative social mobilisation exercises aiming at transforming policy discourses and planning practices (Albrechts, 2004; Healey, 1997, 2007).

Here, a spatial strategy is said to have a transformative potential, if the core ideas behind the strategy are able to mobilise support and gain recognition, as they travel from arena to arena across an increasingly fragmented governance landscape (Healey, 2007). Such a strategy, it is argued, needs to be both selective by prioritising some issues over others, and synthetic in integrating diverse issues under the shelter of a single frame (Albrechts, 2004; Healey, 2007). To be successful, a spatial strategy requires the prospect of win-win situations in which all actors involved gain something from participating in the process, and develop a shared recognition of that handling particular issues is beyond the capacities of the single actor (Albrechts, 2001). Empirical research by Albrechts (2001) and Olesen and Richardson (2012, forthcoming) suggests that such win-win situations are more likely to be designed within certain policy fields, such as transport (including investments in transport infrastructure).

This expectation or requirement of win-win situations or ‘consensus’ in collaborative spatial strategy-making processes has recently been highlighted as highly problematic in the planning literature (Hillier, 2003; Purcell, 2009; Pløger, 2004), as it seeks to remove disagreements, conflicts, and political ideology from planning processes. As all participants in collaborative planning processes will serve their self-interest, and indeed are expected to do so (Innes, 2004; Innes and Booher, 2010), win-win situations will per definition not fundamentally transform existing power structures, but rather contribute to reinscribe these in the particular planning process (Harris, 2002; Purcell, 2009). A focus on designing win-win situations will therefore contribute to maintaining the status quo rather than supporting social mobilisation around issues of conflict. In fact, communicative planning practices might (unintentionally) legitimise a reinforcement of the status quo, including neoliberalism as a hegemonic discourse, as outputs from collaborative and consensus building processes are generally considered more inclusive, fair, and democratic (Purcell, 2009).

Here, Mouffe's (1999, 2000) theory of agonism is helpful, as it helps us to understand how a focus on win-win situations and consensus building suppresses conflicts and politics and depoliticises strategic spatial planning processes. This post-political planning condition has been furthered by a neoliberal discourses promoting the idea that win-win(-win) situations such as sustainable development can be designed and achieved through spatial planning practices (Allmendinger and Haughton, 2012; Swyngedouw, 2010). In the UK and possibly in many other European countries, we see a planning system and spatial planning practices emerging, which

> "gives the superficial appearances of engagement and legitimacy, whilst focusing on delivering growth expedited through some carefully choreographed processes for participation which minimise the potential for those with conflicting views to be given a meaningful hearing." (Allmendinger and Haughton, 2012, p.90)

3.2 Relational Geography as a Medium for Depoliticisation?

As part of the theorisation of strategic spatial planning, there has been an increasing concern with bringing the ideas of relational geography into the field of planning (Davoudi and Strange, 2009; Graham and Healey, 1999; Healey, 2004, 2006, 2007). The new relational conceptions of space and place set out to break with the Euclidean and absolute view of space, which dominated spatial plans in the mid-20th century (Davoudi and Strange, 2009; Healey, 2007). Instead, a relational understanding of spatiality draws into attention the multiple webs of relations or 'spaces of flows' (Castells, 1996) that intersect or transect urban areas, and opens up for multiple ways of understanding or getting to know an urban area (Healey, 2007).

The ideas of relational geography have played a dominant role in European spatial planning discourses since the beginning of the 1990s. Here, a new spatial vocabulary of networks, webs, flows, nodes, and hubs has been introduced as new, more up-to-date organising principles (Davoudi and Strange, 2009; Healey, 2006). One of the ways, in which planning practice has tried to see the world through webs, flows and networks, has been through what Davoudi and Strange (2009) refer to as 'fuzzy maps'. Rather than relying on Euclidean geometric accuracy, these 'fuzzy maps' depict the planned territory as fluid with fuzzy boundaries (Davoudi and Strange, 2009).

Whilst, the use of fuzzy spatial representations can be understood as attempts to appropriate the ideas of relational geography in planning practice, they also seem to fulfil other (and perhaps more important) roles. First, fuzzy spatial representations seem to play an important role in distancing spatial planning from its regulatory characteristics normally associated with Euclidean geography, thereby supporting the discourse of a new core idea of spatial planning.

Second, fuzzy spatial representations can be understood as the result of attempts to broker agreement or build consensus in strategic spatial planning processes. The planning literature stresses how spatial representations are highly political sensitive constructs, as they more clearly depict the potential 'winners' and 'losers' of a given spatial policy (Dühr, 2007; Jensen and Richardson, 2003; Zonneveld, 2000). The 'fuzziness' of a spatial representation, or the absence (or presence) of a spatial representation in a spatial strategy, might therefore reflect the extent of consensus among actors in the process (Jensen and Richardson, 2003). Faludi and Waterhout (2002) and Zonneveld (2000) have for example illustrated how the spatial politics in the ESDP process remained highly contested and prevented the European member states from agreeing on a policy map depicting the future European territory.

In cases where fuzzy spatial representations are prepared, their abstract characteristics might provide convenient temporary spaces for consensus. Here, the suggestive nature of fuzzy maps might play an important role in avoiding controversial or politically sensitive issues, such as distribution of future urban development (Davoudi and Strange, 2009; Olesen and Richardson, 2011). The representational vagueness of fuzzy spatial representations becomes then an effective means for camouflaging or blurring the spatial politics of strategy-making. In this way, relational geography and in particular the use of fuzzy spatial representations in planning practice might act as a medium for depoliticisation.

3.3 Soft Spaces as vehicles for neoliberal transformation of spatial planning

More recently, strategic spatial planning has been associated with the new 'soft spaces with fuzzy boundaries' emerging in-between formal scales of planning in the UK (Allmendinger and Haughton, 2007, 2009a, 2009b, 2010; Haughton et al., 2010) and beyond (Olesen, 2013 forthcoming). These new soft spaces can be understood as a mix of i) new spatial imaginations promoting new informal planning spaces located outside the formal planning system and formal scales of planning, and ii) new networked forms of governance seeking to work outside the rigidities of statutory planning.

Although, the strategic spatial planning literature does not refer explicitly to soft spaces, these spaces seem to share similarities with what Healey (2007) refers to as a restless search for policy integration and joined-up government at the scale of urban regions. According to Healey (2007), strategic planning efforts have at times to move away from formal planning arenas in order to destabilise existing policy discourses and practices, and this is what soft spaces seem to do. This search for new opportunities for strategic thinking and breaking away from pre-existing working patterns by working outside formal planning arenas is what seems to characterise soft spaces.

However, contrary to Healey's (2007) understanding of informal strategic spatial planning, the new soft spaces emerging in the UK seem to have an explicit neoliberal

agenda. In the UK, the emergence of soft spaces has been associated with transformations of spatial planning under the former New Labour government. Here, the soft spaces are characterised by New Labour's pragmatic view on spatial planning, focusing on 'what works in practice' in terms of implementation and policy delivery (Allmendinger, 2011; Allmendinger and Haughton, 2009b). They reflect attempts to short-circuit formal planning requirements and move beyond the rigidities of statutory planning in order to facilitate development. Furthermore, the soft spaces seem to be defined in ways that deliberately are fluid and fuzzy, so they easily can be amended and shaped to reflect different interests and challenges (Haughton et al., 2010). This flexibility manifested itself in the transformation of the soft spaces' rationale in UK in aftermaths of the global credit crunch, where, the soft spaces were transformed from functional spaces for policy integration and coordination to vehicles for policy delivery and growth Allmendinger (2011).

In this way, we might understand soft spaces as a reaction against statutory planning, which is perceived as incompatible with neoliberal political agendas of promoting economic development. Olesen (2013, forthcoming) has for example demonstrated how spatial strategy-making in soft spaces in Denmark was used to unsettle a particular Danish approach to strategic spatial planning rooted in a rational comprehensive planning and social-welfarist perspective, by calling for more flexible and solution-oriented forms of strategic spatial planning. Often soft spaces seem to promote certain agendas and certain ways of thinking about strategic spatial planning, which reflect a neoliberal understanding of society. In this sense, we might think of soft spaces as vehicles for promoting a particular neoliberal version of strategic spatial planning.

4. Conclusions and Future Challenges for Planning Theory

The concept of strategic spatial planning has played an important role in breaking the planning impasse of the 1980s by adjusting the core idea of planning to fit the increasingly neoliberal political environment. Throughout the 1990s and 2000s, strategic spatial planning has been promoted as a substantially different practice than traditional land use planning (Albrechts, 2004), paving the ground for a new set of planning practices primarily concerned with positioning cities and city regions in a European competitive landscape (Albrechts et al., 2003; Healey et al., 1997). Within these strategic spatial planning practices, economic growth and international competitiveness have evolved into common-sense policy objectives, reinforcing neoliberalism as a hegemonic discourse within spatial planning. In this way, the revival of strategic spatial planning was partly supported and partly legitimised by the emergence of 'roll-out' neoliberalism as the dominant political-economic agenda in Europe from the beginning of the 1990s.

Furthermore, empirical evidence of spatial planning practices seems to confirm the thesis that strategic spatial planning has recently taken a neoliberal turn in many European countries. This paper has sought to illuminate how this neoliberalisation

of strategic spatial planning are taking place in planning practice, by drawing attention to the emerging contradictions within the key theoretical ideas underpinning strategic spatial planning, when these are examined in the context of neoliberalism as a hegemonic discourse in spatial planning. The paper has demonstrated how the theoretical ideas of communicative planning, relational geography, and soft spaces might be appropriated by neoliberal political agendas in planning practice, supporting the contemporary neoliberalisation of strategic spatial planning.

The theorisations of strategic spatial planning have been criticised for being too naïve (Bengs, 2005) and too theoretical (Newmann, 2008), thought too far from the current realities of the socio-political contexts in which strategic spatial planning takes place. At the moment, we seem to know very little about how neoliberalism affects spatial planning practices, and what the potential consequences of the contemporary neoliberalisation of strategic spatial planning might be. What seems to be missing in contemporary theorisations of strategic spatial planning is a critical understanding of how the hegemonic discourse of neoliberalism shapes strategic spatial planning practices. Building up such an understanding is crucial if we are to move beyond the 'more of the same' thinking that Albrechts (2010) recently has criticised.

Here, I see a value in bringing analytical concepts such as neoliberalism and neoliberalisation into planning theory and planning research. By incorporating these analytical concepts, planning theory has a stronger foundation for assisting critical empirical studies of how strategic spatial planning practices are being transformed under neoliberalism. At the moment, there is only limited work which seeks to conceptualise the relationship between strategic spatial planning and neoliberalism, and only limited empirical research, which critically analyses how strategic spatial planning ideas might be appropriated by neoliberal political agendas in planning practice. In an environment without a strong theoretical critical mass and sufficient theoretical insight, critical studies of strategic spatial planning practices might have limited resonance in planning practice, and powerful actors and policy agendas will continue to shape and transform planning practices unchallenged. There is a need to build up a strong theoretical and empirical foundation on which such critiques can build. I believe that this is an appropriate and important role for planning theory and planning research in the future, and at least one way for planning scholars to influence and hopefully improve planning practices.

PARTICIPATORY PLANNING OF SOCIAL AND SPATIAL ORGANIZATION IN AGRARIAN REFORM POLICY IN BRAZIL: AN ASSESSMENT OF THE IMPLEMENTATION CHALLENGES

Leandro F. F. Meyer [1], Francy Mary Costa[2] Cléria Figueiredo[2] Marcelo José Braga[3]

Abstract

The social endeavors for Agrarian Reform in Brazil have a history of at least sixty years. Throughout this time, distinct political regimes, increased land concentration, disordered urbanization and the development of a dynamic agribusiness sector inserted in global economy led to both the aggravation of social conflicts over land in Northern and Southern Brazil as well as new inquiries on the features necessary for an efficient Agrarian Reform Plan in our country.

As embodied in the second National Plan of Agrarian Reform (II PNRA), the current assessment admits that corrective measures should encompass not only land issues (regulations, expropriations and settlements), but also marketing infrastructure, social support and targeted technical assistance and credit. The II PNRA cooperates with the efforts to reconstruct the National Policy of Technical Assistance and Rural Extension (PNATER), reoriented to strengthen general family farming. A renovated National Program of Technical Assistance and Rural Extension in the Agrarian Reform and Family Farming (PRONATER) reflects this perspective and calls for a participatory governance system anchored in a complex institutional structure, connecting governmental and non-governmental organizations in multiple levels.

Focused on the agrarian reform projects in the Brazilian Amazon, this work discusses on the philosophical and methodological perspectives drawn in the II PNRA. Framing our account mostly along the theoretical scaffolding provided by the Bloomington School of Institutional Analysis, we analyze the multiple challenges facing the organization and the maintenance of the institutional structure designed to facilitate participatory planning and governance of collective resources in highly complex socio-ecological systems wherein socioeconomic asymmetries, cultural diversity and poor social capital and education promote political and ideological disputes that jeopardize safeguarding global commons.

1. Introduction

As a direct intervention on the access to one of the most important factors of production – land – agrarian reform has always been a sensitive issue wherever the matter is raised. Due to its strong relations with sources of wealth and power, land expropriation and redistribution was ahead most revolutionary processes, as those in Russia, Mexico, China, Cuba, Vietnam, Nicaragua and Portugal.

In Brazil, the social endeavors for agrarian reform have a history of at least sixty years. By the fifties, the theme was adopted as a common language and focus, joining different forms of conflicts present in Brazilian rural areas (Medeiros, 2003). In the early sixties, agrarian reform became one of the main themes on the public debate concerning the definition of a national project of socioeconomic development.

Embedded in an international geopolitical environment marked by the Cold War and the dissemination of communist ideologies among rural areas, the revolutionary facet of the agrarian reform project in Brazil was aborted by the military breakdown that overthrew President João Goulart, in March 31, 1964. With a discourse that sought to harmonize ideas of social justice with agricultural productivity, the military regime subsumed the issue of the agrarian reform under the Land Act (Law 4.504) of November 30 of the same year.

Throughout the authoritarian period, which lasted 21 years (1964 – 1985), the Land Act was primarily an instrument of agricultural policy, designed to foster the advancement of capitalism in rural areas and the industrialization of the country. Increased land concentration and significant rural exodus led to the aggravation of social problems and conflicts over land in both Northern and Southern Brazil.

Pushed by growing social organization, the first National Plan of Agrarian Reform (I PNRA), predicted in the Land Act, was created about twenty-five years later, during the government of President José Sarney (1985-1990). Despite ambitious goals, the I PNRA progressed timidly along the decade, counting the governments of Fernando Collor (1990-1992) and Itamar Franco (1992-1995).

Throughout this period, major changes in the technical and economic basis of the Brazilian agriculture led to new concepts of the requirements for an effective agrarian reform in Brazil. The leading views about the issue in both Fernando Henrique Cardoso (1995-2003) and Luis Inácio Lula da Silva (2003-2011) administrations admitted that the PNRA should be renewed and extended beyond land distribution programs to encompass marketing infrastructure (roads, warehouses), social support (education and health in rural areas) and targeted technical assistance and credit.

This work discusses our views on the implementation challenges faced by the second National Plan of Agrarian Reform (II PNRA), launched in November, 2003. While we mention results from literature occupied in evaluating the agrarian reform

movement all around the country over time, our focus rests on our own recent experiences with limited reformed areas in the eastern Amazon.

The framework developed by the Bloomington School of Institutional Analysis, whose outline we present in the following section, provides us orientation. Next, we expand our view on the II PNRA as State Policy embedded in a polycentric political system (Polanyi, 1952; V. Ostrom, 1972) open to social control. Then, we address the substantive discussion on the challenges perceived in the implementation of participatory planning in agrarian reform projects, and how unsatisfactory results may jeopardize safeguarding natural resources that function as global commons. The final session concludes the work with a short reference to the role of values systems and moral choices of the individuals occupied in the social and spatial organization in the agrarian reform.

2. An outline on the IAD framework

The conceptual scaffoldings supplied by the Institutional Analysis and Development (IAD) framework went through a series of transformations since the *Governing the Commons* (E. Ostrom, 1990). Figure 1 is one of the latest attempts to portray the structure of complex governance problems involving integrated social-ecological systems (SESs). It represents a response to the challenge presented to SES scholars, in search for a proper language "to map and explore the institutional, praxeological and normative complexity of polycentric systems of human governance" (Aligica; Boettke, 2009, p. 29).

The map starts from the prior recognition that many variables affect the patterns of interactions and outcomes in those systems. It was conceived to help SES scholars "to examine the nested attributes of a resource system and the resource units generated by that system that jointly affect the incentives of users within a set of rules crafted by local, distal, or nested governance systems to affect interactions and outcomes over time" (E. Ostrom, 2007).

Figure 1 shows only the most abstract level of analysis of a generic SESs. To investigate real problems in focal SESs, scholars are required to "unpack" each one of the compound units shown in the figure in as much tiers as necessary to reach the relevant data for the particular question under study. Table 1 presents a first list of second tier variables in each category. The variables marked with an asterisk (*) are thought to affect self-organization (E. Ostrom, 2009).

Based on extensive empirical research, Ostrom and her associates on many fronts suggest that self-organization is facilitated when the resource is sufficiently small (RS3) to be monitored (GS8) and to generate reliable information (knowledge) about its general condition (U7) at reasonable costs. The likelihood of successful self-organization also depends on both the productivity of the system (RS5) and the predictability of its dynamics. The productivity of deteriorated systems should allow for feasible improvements at reasonable time schedule. These conditions are better

fulfilled when the system has clear boundaries (RS2) and the resource units are set within them (RU1). They also interact with the technology (U9) used both to harvest and recover the resource units.

The technology at the reach of users that are too distinct in their economic resources (U2) also affects the likelihood of successful self-organization. The ability to craft locally sustainable collective-choice rules is generally improved when economic asymmetries are limited and do not lead to large differences in the harvesting levels of diverse users (I1).

The economic value of the resource units (RU4) also interacts with user attributes to determine their dependence on resource (U8). According to E. Ostrom (1999), self-organization is more likely to occur when users depend on the resource for a major portion of their livelihood or other variables of importance to them. In agreement with Olson (1965) contribution, self-organization proved to be facilitated when the number of users (U1) is not too large and leadership is present (U5). In connection with property right systems and collective-choice rules, informal norms and social capital (Coleman, 1988; Putnam, 2000) also contribute to self-organization.

E. Ostrom (1999) suggests that successful governance systems addressing the core problem of how to restrict the appropriation from a common-pool resource (GS4) allocate benefits proportional to the required inputs (GS6) and are crafted to take local conditions into account. Since rule infringement (I4) is hardly ever eradicated,

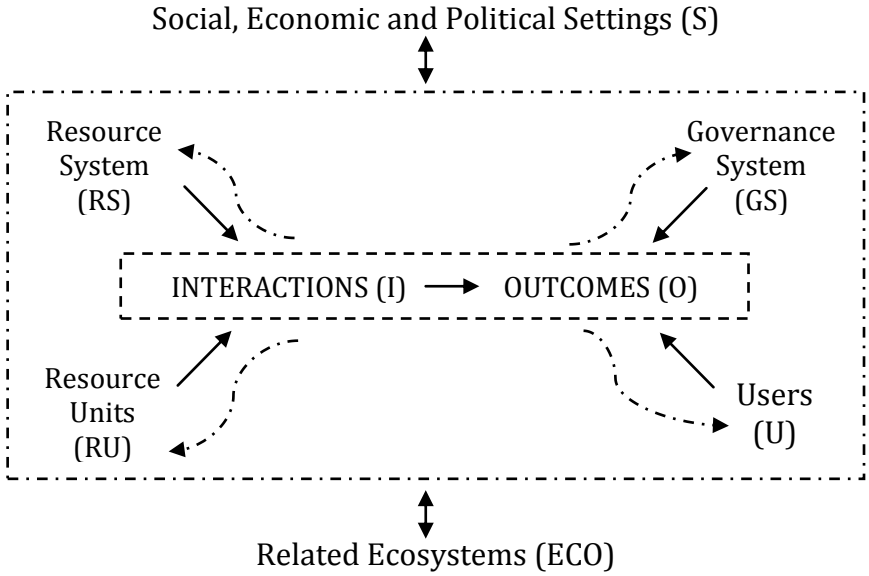

Figure 1: A multitier framework for analyzing interactions and outcomes in a linked social-ecological system (straight arrows refer to direct causal links; curved arrows refer to feedbacks)

Source: Adapted from Ostrom (2007).

sanctioning mechanisms (GS8) classified according to the seriousness and context of the offence seem to work better to reinforce the appropriation rule than disproportionate punishment.

When collective-choice rules are designed, participation emerges as a key principle underpinning the social capacity to sustain both the governance and the resource systems. E. Ostrom (1999) suggests that most individuals affected by the resource regime should participate in making and modifying their rules (I3, I7). Also, successful social agreements usually rely on monitors selected by the community of users, either individuals accountable to users or the users themselves.

Source: Adapted from Ostrom (2007:15183)

Finally, since the authority of users to devise appropriation rules over economic resources of global interest is set by larger governance and political systems (S4), their rights to organize and formulate their own rules have to be minimally legitimated by official governmental agencies (GS1). The access to rapid, low-cost, local arenas to resolve conflict among users or between users and officials is likewise referred to as an important requirement for successful self-organization (E. Ostrom, 1999).

With this broad framework in sight, we can better approach, first, the complex institutional structure drawn in the II PNRA, and then the implementation challenges brought about by different sorts of structural limitations and conjunctures.

3. The II PNRA: a polycentric political system open to social control

In November 2003, the second National Plan of Agrarian Reform (II PNRA) was launched as a comprehensive endeavour resting on an amplified conception of agrarian reform – which considers it as a State policy, open to social control and designed to foster the sustainable development of rural areas and overcome poverty and inequalities.

Hosted in the Ministry of Agrarian Development (MDA) and managed by the National Institute of Colonization and Agrarian Reform (INCRA), the implementation of the II PNRA requires strong institutional cooperation of various ministries and federal agencies, plus the committed involvement of state and local governments. Resting on a *territorial approach*, the Plan integrates different policies, plans and programs aimed at boosting the economy and the social and cultural life of the areas wherein land reform projects concentrate.

The achievement of the PNRA objectives depends largely on the efforts to reconstruct the Brazilian System of Technical Assistance and Rural Extension (SIBRATER), reoriented by the National Policy of Technical Assistance and Rural Extension (PNATER), to strengthen and empower family farming.

Based on an apt criticism of the model of technology transfer adopted in the seventies, the PNATER definitely calls for participatory planning of social and spatial organizations both in the agrarian reform settlements and the surrounding areas (as targeted territories).

4. Participatory planning in agrarian reform settlements in eastern Amazon: reflecting on our experience with the IAD framework

In this section, we organize our reflections regarding a series of implementation hindrances experienced in our work with agrarian reform projects in the eastern Amazon.

4.1 Social, economic and political settings (S)

Following the 2003 democratic elections, which brought Luis Inácio Lula da Silva to the Presidency for the first time, the political scenario was marked by popular fervor and unhampered expectations regarding historical social demands, such as the agrarian reform.

Tempered by the violent repressions happened in Corumbiara (RO), 1995, and Eldorado dos Carajás (PA), 1996, the social movements intensified occupations of target properties, believed to be potentially expropriated. The media coverage of these deeds broadcasted the issue nationally and overseas, pressing for action.

Also, based on data on economic and democratic trends, and the expectations associated to social programs of income distribution, the II PNRA document (MDA, 2004) predicted increasing demand for food and other agricultural products, and highlighted the positive impacts that the agrarian reform plan should have on food supply, employment, migrations and urban problems, inequalities and social exclusion in Brazilian society.

In many aspects, the socioeconomic and political settings outlined in the II PNRA remain applicable today. Yet, the new President, Dilma Rousseff, refuses to commit her administration with quantitative goals for agrarian reform. With a discourse that prioritizes the quality of existing settlements, the number of new families settled during the first year of her administration (22.021, according to data from INCRA) is the lowest in sixteen years (including the first years of both Cardoso's and Lula's administrations). These numbers have deeply dissatisfied the social movements, which are pressing the government.

Notwithstanding, Rousseff's focus on qualifying the existing settlements encounters support in the broad Brazilian society and is in line with the principles stated in the II PNRA. To achieve this goal, Rousseff carried out an administrative restructuration of the National Institute of Colonization and Agrarian Reform (INCRA), which included the change of its president[4]. Also, the nomination of the new Minister of the Agrarian Development Ministry (MDA), Gilberto Vargas, was welcomed by the social movements.

On the other hand, a recent decree announcing the curtailment of R$ 36 billion in the Union budget for 2012 compromised the MDA/INCRA ability to implement the necessary measures, tumbling directly their capacity to finance rural extension services and education programs in agrarian reform.

[4] INCRA current president is Celso Lisboa de Lacerda, who substituted Rolf Hackbart.

4.2 Resource systems (SR), resource units (U) and related ecosystems (ECO)

As a countrywide plan, the II PNRA encompasses a variety of integrated social-ecological systems (SESs) with different degrees of complexity and histories of use, involving different sorts of resources. Even within the geographic area under the jurisdiction of INCRA regional superintendency in Belém (SR-01/PA), the diversity of situations concerning only the physical aspects of different agrarian reform settlements poses a significant challenge to INCRA staff in charge of evaluating the ability of technical assistance suppliers to provide appropriate services in different circumstances.

The formal processes for creating new agrarian reform projects require the clear demarcation of settlement boundaries and detailed inventories of existing physical resources (both natural and human-construed facilities). This should facilitate the social organization demanded to carry out further planning activities. However, regarding the periurban settlements we have been working with, both the system productivity and the suitability of the area for organic agriculture, which is incentivized, are possibly impaired due to prior history of land use.

Located in a region considered of high biological importance and a priority for corrective measures (MMA, 2007), these settlements are marked by large changes in the primary forest cover and many social and environmental problems. The alternatives to cope with these limitations should emerge from detailed studies accomplished in partnership with the settlers, carried out by multidisciplinary teams, using participatory planning methodologies (CONAMA, 2006). Yet, the very application of participatory planning is hindered by limitations related to the governance systems and the attribute of users themselves.

4.3 Governance systems (GS)

In Section 3, we suggested that the success of the II PNRA depends on the ability to make a complex polycentric governance system work. We shall now develop this idea by exploring selected relationships, linked more directly with our field work.

Besides the Ministry of Agrarian Development (MDA), where the II PNRA was elaborated, five other Ministries are mentioned in the document (MDA, 2004, p. 16) due to their important role in the support of the Plan: the Ministry of Social Development (MDS), Ministry of Environment (MMA), Ministry of Health (MS), Ministry of Education (MEC) and Ministry of Culture (MinC). Several Programs with both complementary and overlapping purposes are developed in these Ministries and are carried out by complex bureaucratic structures that further fragment authority and accountability.

The territorial development model adopted in the II PNRA, for example, is carried out by the MDS (Ministry of Social Development). The model encompasses five categories of territories, including one that targets areas of landless encampments and

agrarian reform pre-settlements. The target territories work as priority areas to where programs developed by different Ministries converge.

Family farmers located within the so-called Territories of Citizenship, including agrarian reform beneficiaries, are entitled to benefit from the Food Acquisition Program (PAA). The PAA allows local government services, such as popular restaurants and public schools, to acquire food from those farmers, free from bidding, at regional market prices. The PAA is implemented in five modalities in cooperation with the National Supply Company (Conab), state and local governments. It is coordinated by a Management Committee chaired by the MDS and composed by other five Ministries: Ministry of Agrarian Development (MDA), Ministry of Agriculture, Livestock and Supply (MAPA), Ministry of Planning, Budget and Management (Mpog), Ministry of Finance (MF) and Ministry of Education (MEC). Social control over the PAA is provided by the National Council of Food and Nutritional Security (Consea).

The PAA in the Territories of Citizenship relate to the National Policy of Technical Assistance and Rural Extension (PNATER), which focuses on family farming and defends an *agroecological transition* in the production technology. The provision of Technical Assistance and Rural Extension (ATER) services also relies on the cooperation of multiple actors with overlapping jurisdictions that often create duplication of services or functions. Under the guidelines established in the PNATER, the Brazilian ATER System (SIBRATER) aims to organize the ATER services in a decentralized fashion, covering a number of committees, councils and other representative entities, gathering government and non-government organizations in multiple levels.

The SIBRATER social management structure includes a National Committee of Technical Assistance and Rural Extension and a National Council for Sustainable Rural Development (CONDRAF). Besides, there are also the State Councils for Sustainable Rural Development (CEDRS) and their Boards of Technical Assistance and Rural Extension (Bords of ATER) and a number of so-called “social webs” of ATER, formed by government and non-government suppliers of ATER services.

Similarly, in order to cope with the environmental issues legitimately and comply with the principles and standards laid down in the Federal Constitution, the National System of Environment (SISAMA) brings environmental organizations and institutions of the Union, States and Municipalities together with civil society. At least eight collegiate bodies with overlapping compositions and tasks interact with the structure of the Ministry of Environment (MMA): a National Chamber of Environmental Compensation (CFCA), two National Councils (CONAMA – National Council of Environment, and the CNRH – National Council of Water Resources), a special Council for Genetic Resources Management (CGEN), three National Commissions (CONABIO – Biodiversity, CONAFOR – Rain Forest, and CONACER – Savannah), and a special Commission for the Management of Public Forests (CGFLOP).

The National Council of Environment (CONAMA) issued a resolution (RN 387/2006) defining the requirements for environmental licensing in agrarian reform projects. Among other studies to be produced in different phases and circumstances of the licensing process, the Settlement Development Plan (PDA) stands as a key instrument to devise the social and the spatial organization of the projects "in strict compliance with the diversity of cases" (CONAMA, 2006). The PDAs call for detailed information highlighting the particular physiographic, social, economic, cultural and environmental aspects of settlements. They must work as basic instrument to formulate technical projects and all activities to be planned and executed in settlement areas, and as reference in monitoring and sanctioning these actions.

In agreement with the guidelines established in the National Policy of ATER (PNATER), CONAMA Resolution 387 explicitly requires that the PDAs be accomplished by multidisciplinary teams together with the settled people, using participatory planning and action research methodologies (CONAMA, 2006).

Although soundly articulated and compelling, the apparently ordered relationships comprising the governance systems under the II PNRA face a series of practical obstacles that impact the interactions of the agents and their outcomes (see Figure 1).

A great hindrance facing the implementation of II PNRA is the patently disordered definition of property rights. While the legal framework allows for unambiguous designation of "who have rights to have rights on land" (Benatti, 2011, p. 203), serious flaws in the Brazilian real estate registration contribute to what can be qualified as true "property chaos". Particularly in the Northern region, the situation reveals a "large discrepancy between the lands that are formally registered and what is actually on the ground" (Silva, 2011, p. 188). As an example of an extreme case, in the Municipality of Moju (PA), the total area registered in the notary offices is almost *twelve times* (!) bigger than the Municipality area itself (Treccani, 2012). In the State of Pará, the registered area is more than four times bigger than the total area of the state (ibid). Efforts for land title regularization, especially in the Amazon areas, face uncertainties even regarding the property rights of different public sectors. Federal, State and local governments dispute the property right on supposedly inhabited land, which is, in fact, irregularly occupied.

The described "land chaos" complicates the obtainment of land for agrarian reform settlements. Yet, when the land is obtained via expropriation, typically, the property is occupied for a long time by landless people led by social movements, particularly the MST (Landless Worker Movement). In one that we dealt with, people dwelled in the area for five years, before the formal creation of the settlement project. When the settlement was formally established, in November 2009, the people there had already implemented their own social and spatial organization in absentia of any planning. In addition to the problems relating to the definition of legal reservation areas, this sort of spatial organization also produced resource asymmetries, since some people

occupied areas previously cultivated with economic species – especially Paricá (*Phyllachora schizolobiicola*) and Guinea's Palma (*Elaeis guineensis*) – while others settled in uncultivated or degraded areas.

Apart from these challenges, Caporal (2005) mentions four groups of problems hindering the apt implementation of the PNATER, with negative impacts on the participatory planning of the social and spatial organizations in agrarian reform projects. He considers that the public ATER service institutions are still unprepared to supply and evaluate the results from actions intended for promoting the agroecologic transition recommended in the Policy. He extends this criticism toward most non-government ATER suppliers, and suggests that the development of the said social web of ATER services is stalled due to the competition for limited public funds. The author blames, at least in part, the education system for this situation. He suggests that the professional formation in most rural universities is still tied to the "green revolution" technology transference model, resting on didactic methods that are adequate neither to the attitudinal nor to the cognitive requirements requested by the new PNATER.

The agrarian reform governance system is also hindered by lacking operational performance of the public entities responsible for the policy at different levels. These problems negatively affect credit authorization, provision of infrastructure, recruiting and funding the ATER services, monitoring and sanctioning the performance of the ATER suppliers. Operational failures are often linked to structural deficiencies, including insufficient human resources.

4.4 Users (U) and interactions (I)

The broadened conception of agrarian reform drawn in the II PNRA entails a similarly extended target public. Amounting to about 50 million people, according to the document (MDA, 2004), this public also includes small family farmers, people living in traditional rural and riverside communities, those affected by dams and other major infrastructure works, the non-indigenous inhabitants of indigenous areas, rural female workers and rural youth, and other segments of a population linked to agricultural activities living in rural counties.

To some extent, the existing modalities of land access contribute to reduce the heterogeneity of beneficiaries, especially in ethnic settlements (indigenous and afro-descendents). The said agroecological forms of land access favors symmetry in the level of user dependence on resource, technology and harvesting. Among the traditional forms of land access, land title regularization presumably favors knowledge of SES.

On the other hand, the dilemmas associated with the attributes and interactions of users are increasingly important for beneficiaries of expropriated land. As previously mentioned, land expropriation processes are typically forced by occupations of rural properties led by social movements. Socioeconomic and cultural heterogeneity of the

people living in camps and occupied areas increases as these movements recruit all kinds of people on the outskirts of cities to strengthen the pressure groups and draw public attention.

Considering the settlements we have been working with, which are located in the vicinities of the metropolitan area of Belém, social organization is troubled by unequal dependence on common resources and mutual aid. On one hand, this disproportion results from unplanned forms of spatial organization that occur even prior to the settlement formal constitution, as said before. On the other hand, the proximity of urban centers opens alternative income sources for those settlers less inclined to farming work. This situation greatly complicates the participatory planning, since conflicts among users or between users and officials from INCRA often end up in either threats or effective aggressions.

The political struggle to expropriate land owned by political figures and multinational companies also leads this class of settlers to disagreements as soon as their primary motive to work together is achieved. At this point, different social movements and organizations start disputing ascendency upon split groups clustered around competing leaderships. In one of our focal settlements, nine associations with no overlapping members were instituted after the settlement was formalized, with 370 families. The occasion clearly reveals a dispute to control the distribution of the supporting funds. In cases like his, while the development of subgroups helps both information charging and deliberation processes (Ostrom, 2002), it may not reveal or favor the development of shared norms.

4.5 Outcomes (O)

The philosophical foundation and guidelines of both the II PNRA and the new PNATER call for profound changes in the conventional evaluation criteria used to measure the performance of the Policy.

Sparovek (2003) highlights the need to move beyond the usual information about number of settled families and total amount of the reformed area. The evaluation of *land reordering efficacy* should take into account the number of families actually living in the settlements, relatively to its total capacity, the numbers of abandoned and agglutinated parcels, plus the relations between the areas in Legal Reserve (RL), areas in Permanent Protection (APP), and areas that are not being used with the total area of the settlements (Sparovek, 2003).

To these indicators, the evaluation of the II PNRA performance should add a series of qualitative information. Sparovek's (ibid) estimation of the qualitative aspects of agrarian reform performance included three compound indicators. The first (living quality) characterizes the basic infrastructure (housing, electricity, roads, water supply), family access to health, education and transportation services in settlements, after government intervention. The second (social organization) refers to the relations between settlements and the external community (e.g. commercialization)

and the internal social organization (participation in associations and cooperatives, collective use of common areas). The third (operational efficiency) basically measures the liberation of predicted supporting funds and the provision of basic infrastructure.

The main instruments to enhance these qualitative dimensions are qualified ATER services and INCRA operational efficiency, including the monitoring and auditing of the contracted ATER service suppliers. New challenges emerge at this point given INCRA structural limitations to assess the effective quality of the participatory methods and the empowerment achieved through them in the field. Furthermore, the quality of INCRA (SR-01) monitoring activities is undermined by the weakness of the internal controls.

5. Conclusions

The Brazilian government official endorsement to action research and participatory planning as recommended methodologies to foster the sustainable development of rural territories has a profound philosophical significance, in terms of political superstructure (worldview). It stands as a paradigm shift when compared to the authoritarian planning-and-executing style that prevailed throughout the military period (1964 – 1985).

Concurrently, after the neoliberal policy that prevailed from 1990 to 2003, the II PNRA and the accompanying efforts to reconstruct the Brazilian System of Technical Assistance and Rural Extension (SIBRATER) reveal that the State resumed its leadership in socioeconomic development in a direction that counters the one guided by purely economic concerns and marked forces.

Rising above the conventional state *versus* market dichotomy, polycentric governance systems emerge as an adaptive rule order with potential for balancing the government exercise of command, while preventing it from becoming authoritarian and corrupt. In pursuing this performance – and central to the very existence of democratic societies – *participation* and *social control* become key elements. As Aligica and Boettke (2009) indicate, discussion on polycentricity is not only related to "legitimacy", distribution of "power" and multiplicity of "decision centers," entrenched in a general system of "rules," but also a discussion about fundamental political values, leadership and formation of political coalitions.

However, the *authentic* participation required to engage in political activity to generate public-goods and sustain the polycentric order is difficult to achieve, since it hinges on *moral conscience*, rather than pure self-interest (Meyer, 2010). Consistent with regular classroom practice, observations produced both in the laboratory (Ostrom; Gardner; Walker, 1994; Meyer, 2010) and in recent experiences in the field suggest that no institutional engineering shall ever work as substitute for genuine interest and willingness to cooperate. Concepts of authority, justice and motivations framing the choices of the individuals and their expectations regarding

the behavior of others encompass cognitive structures and stage-like changing processes that cannot be altered by social reinforcement (Maslow, 1954; Graves, 1970; Kohlberg, 1981; Selman, 1980; Heiner, 1983; Habermas, 1990; Wilber, 2000).

Hence, an important aspect in the discussion of the principles that support polycentric orders is neglected if the role of cognition, value systems and moral choices is not properly considered. Failing that, the multiple deeds leading to the selection of political leaderships and the formation of political coalitions, wherein the entire governance system relies, are prone to degenerate in disgusting battles for power and undeserved prestige, relying on the offer of personal advantages. This sort of collapse of the principles of public interest that should guide the participatory planning of social and spatial organization in agrarian reform settlements jeopardizes not only the safeguarding of environmental resources that function as global commos but also the very spirit of democratic governance and social control drawn in the Brazilian II PNRA.

HUMAN RISK AND THE CONSERVATION OF URBAN HERITAGE. AN INTEGRATED APPROACH FOR SUSTAINABLE ENHANCEMENT AND FRUITION

Heleni Porfyriou[1], Marichela Sepe [2]

Abstract

Planning and conservation policies in many European historic cities are fragmented and short sighted as they result mainly interested to the short term economic advantages of tourism. Similarly, the enhancement of the cultural heritage has direct consequences on the conservation of artefacts, in as much as it increases fruition, which implies a greater risk of decay due to the greater numbers of visitors and their interaction with the artefacts and the environment in which they are located. The so called "human risk" still nowadays is not comprehensively studied and one can observe a lack of methodological approaches capable to monitor the state of conservation of urban historic sites while in the meantime the increased mass tourist pressure in these sites alters their characteristics and inherent values.
Starting from these premises, the aim of this paper is to propose an integrated methodology, still lacking from relative literature, dealing with monitoring urban conservation in relation to tourist impact and place identity. The methodology elaborated and experimented uses two complementary approaches. The first one consists in monitoring the impact of mass tourism with respect to tangible and intangible transformations, such as uses, buildings' state of conservation and urban quality of historic sites. The second approach refers to a dynamic urban analysis and design which consists in the application of the PlaceMaker method and software devoted to both the detection of elements which constitute the contemporary identity of the places and identification of appropriate project interventions. Furthermore, suitable recommendation for sustainable enhancement and fruition of historical places will be proposed.

1. Introduction

The negative impact of mass tourism on the conservation of urban heritage and the impoverishment of central places from their traditional civic values is

[1] CNR- Institute for the Conservation and Enhancement of Cultural Heritage, helpor1@yahoo.it
[2] CNR- Institute for Service Industry Research, marisepe@unina.it

apparently evident and had already been noted in European and International Reports (Council of Europe 2000; ICOMOS 2002; ICCROM 2005; Drdàcky and Drdàcky 2006). The historic centres of many European cities (Brussels, Prague, Barcelona, Rome, Venice, etc.) are besieged by masses of tourists and are being depleted (of their traditional civic values) and degraded (growing occupation of public property, disproportionate increase of commercial activities, filth, bad smells, overcrowding). Moreover, the authorities in charge of preserving these monumental sites often authorise restoration work with dubious results; while, planning and conservation policies in many European historic cities continue to be fragmented and short sighted as they result mainly interested to the short term economic advantages of tourism. Similarly, the enhancement of the cultural heritage has direct consequences on the conservation of artefacts, in as much as it increases fruition, which implies a greater risk of decay due to the greater numbers of visitors and their interaction with the artefacts and the environment in which they are located. The so called "human risk" still nowadays is not comprehensively studied and one can observe a lack of methodological approaches capable to monitor the state of conservation of urban historic sites while in the meantime the increased mass tourist pressure in these sites alters their characteristics and inherent values (Boissevain 1996; Frers, Meier 2007; Gunn 2002; Haldrup, Larsen, Urry, 2004; Urry 1995).

Starting from these premises the initial aim of our research was to identify criteria and define a method for monitoring mass tourist impact in historic centres with respect to their conservation in physical and functional terms as well as regarding their inherent intangible values. The methodology elaborated and experimented comprised two complementary approaches. The first one was a monitoring survey consisting in a systematic collection and planimetric representation of data. Based on survey forms -- similar to the one produced by pioneers of urban conservation, such as Donald Insall for Chester in 1966-1968 – our study documented the transformations historic cores were undergoing in relation to three major aspects: buildings' uses and state of conservation; urban spaces' uses and state of conservation; place identity and traditional intangible values. Our methodology was confronted with recent research on the subject (such as for example the European 6FP project "Picture") and two major fields of experimentation were undertaken: one, regarding small historic centres of great value but relatively abandoned and not attracting mass tourism and the other regarding the historic cores of major cities under constant tourist pressure. The respective case studies were Asolo (situated in North east Italy) and Rome, whose results were presented in the ISUF conference in Guangzhou (Porfyriou 2009) and in Recife-Brazil (Porfyriou-Sepe 2011). Within this context was also elaborated and financed by the European Commission (Culture Programme 2008-2010) the project "Preserving places. Managing mass tourism, urban conservation and quality of life in historic centres" which under the co-ordination of Heleni Porfyriou (CNR-ICVBC) promoted a more broad comparison, on these issues, among six European countries (Porfyriou 2010).

The second methodology elaborated was a dynamic urban analysis and design approach based on the PlaceMaker method and software, which identifies the cultural resources and the identity of places – introducing also visitors' participation through questionnaires -- and consequently projects interventions for their conservation (Appleyard 1981; Hague, Jenkins, 2005; Lynch 1960; Massey, Jess, 1995; Sepe 2009). The PlaceMaker method gathers, processes and reconstructs the data deriving from nominal, perceptual, graphic, photographic and video surveys, and compares these data with those provided by an analysis of expectations, traditional cartography and the two questionnaires administered to local inhabitants and users. The method has been experimented in urban sites of historical relevance all over the world, including the Ramblas in Barcelona, the Oxford street in London, the Kitano-cho area in Kobe and the South Broadway Theatre district in Los Angeles.

In this paper, the case study of the Trevi-Pantheon itinerary, situated in the historic centre of Rome, will exemplify our integrated methodological approach and its results.

2. The history of the case study area

The case study area has a very long history going back to the Roman empire when Pantheon was built by Marcus Agrippa as a temple in the first century BC while later in the 7th century it was consecrated as a church. Also Hadrian's temple, situated along the itinerary has being built by a roman emperor in 145 AD, and transformed later in the 17th century by the famous architect Carlo Fontana into Dogana di terra. Only the Trevi fountain is of a more recent origin. In fact it had been completed in 1762 giving to the small square in front of it a fascinating and originally scenic image. Both Pantheon square and the one in front of Hadrian's temple have been used through centuries as market and civic places where commerce and public manifestations were held. The urban form of this old part of the city had not been changed as the Nolli map of 1748 shows when compared with the Pio-Gregorian urban cadastre of Rome of 1820s. In these squares community life has taken place, through the centuries, consecrating them as places of cultural, artistic and historical importance and as places of collective identity and civic pride, where the sense of belonging grows and takes root. In 1991 the municipality of Rome announced a competition for the "re-qualification" of this central part of the city . The aim was to close it to vehicular traffic and create a pedestrian itinerary (Fig.1) connecting Pantheon square with Trevi Fountain -- that is two of the most famous and visited monumental sites of the eternal city! Furthermore, another experimental project was proposed for the same area: the pedestrian itinerary had to be specially equipped for blind people (with pavement, infrastructures, and appropriate signs). The direct beneficiaries of these interventions should have been, according to the municipality's aims and declarations, the citizens of Rome, whose life should have been improved by less cars (due to more pedestrian streets), cleaner air, better streets and infrastructures.

These conditions should also have had a positive effect on the conservation of this monumental part of the city (Ufficio per la Città Storica 2002).

Fig. 1: The Pantheon –Trevi itinerary in the historic centre of Rome, Italy

The project was supported by the special funds of the 2000 Jubilee and had finished on time. Since then, in the last 10 years, the numbers of tourist had grown at an exponential level in Rome (and in Italy more in general). More than 30 million people per year are calculated to visit Rome (on the basis of hotel presences); which means that on a daily basis 100.000 tourists are present in the historic centre. The Pantheon square and Trevi fountain are probably together with the Coliseum and the Vatican area the major attractions of the city. Connecting Trevi to Pantheon with a pedestrian street (initially specially designed for blind people) implied creating a privileged itinerary especially attractive to tourist groups and flows; who in fact immediately adopted as the only real-direct connection between these two monumental spots of the city. It's amazing that nobody in the municipality's offices (where this project was conceived) seems to have thought of it and nobody either considered to monitor its effects, which have been devastating for the area, as our research has shown.

The aim of our experimentation at this point was threefold:

1) to monitor tangible and intangible transformations related to the increased tourist presence;

2) to evaluated the effects of increased tourists' flows on the monuments' both material and historical connotations;

3) to develop techniques for mitigation and control of tourist impact and risks having as a final aim the development of recommendations for a sustainable enhancement and fruition.

3. An integrated methodology for monitoring tourist impact

As it has already been mentioned the methodology elaborated for monitoring the Pantheon – Trevi area utilised two complementary approaches: one static, the other dynamic. The first approach consisted on three interrelated surveys mapping changes and transformations with respect to: the uses and functions of the buildings along the itinerary; the state of conservation of their facades and the urban quality of places. In other words a systematic collection of data along the itinerary was undertaken for each building in two forms created on purpose (Porfyriou, 2010a).

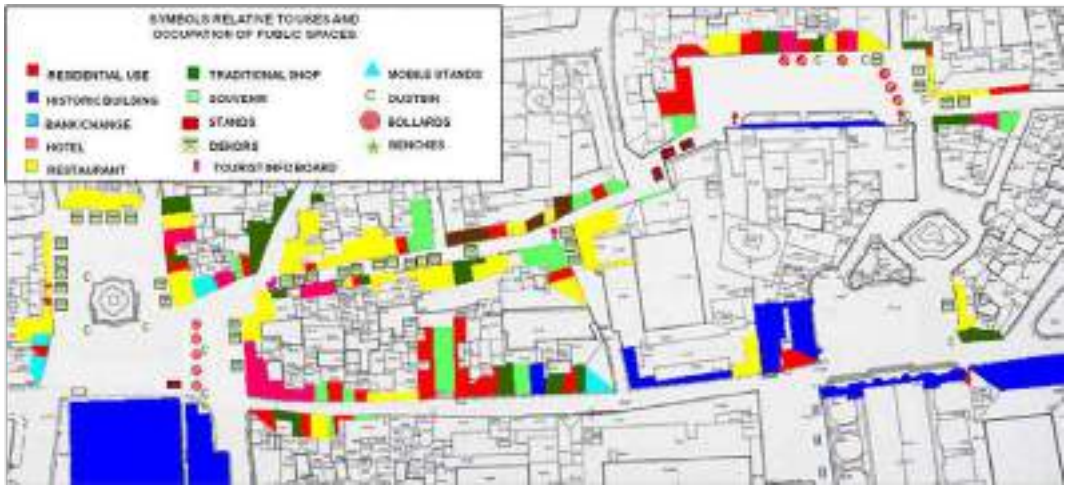

Fig. 2: Planimentric representation of uses and occupation of public space, along part of the Pantheon – Trevi itinerary

The first one documented the uses and the occupation of public space directly related to the building's pertinence. The second one documented the state of conservation of the building's street façade, particularly in relation to the various changes of uses the ground floors were undergoing. This documentation has then been utilised in order to create three thematic maps representing the: i) the uses and functions to which are destined all buildings along the itinerary; ii) the occupation of public space, both legal and illegal along the street (Fig. 2); iii) the state of conservation of the facades of the buildings along the itinerary. Finally a contextual representation of buildings' state of conservation in relation to their functions and to the use of public space of their pertinence summarised all three thematic maps (Fig. 3).

Fig.3: Contextual representation of buildings' state of conservation in relation to their functions and to the use of public space of their pertinence

The second approach implemented, that is the dynamic urban analysis and design consists in the application of the PlaceMaker; that is a method supported by a software (Sepe, 2010a) which comprises eight phases, five of analysis and three of design (Sepe, 2007).

With respect to the analysis phases, the first one is anticipatory, namely an analysis of expectations which introduces the core surveying methodology of PlaceMaker with the aim to describe, using any type of instrument or tool of expression, all information or ideas relative to the area in question, known prior to the first inspection of the site. Then follows the second one which comprises five surveys: namely the *denominative* - consisting in the collection of data regarding constructed elements, natural elements, transportation mode, people -, the *perceptive* - consisting in a survey carried out on perceptions related to smell, sound, taste, touch and visual sensations, and on the global perception, focusing on the localization, type, amount and quality -, the *graphical* - consisting in sketching the places according to a visual-perceptive standpoint -, and the *photographic* and *video* survey of the whole study area, taking care to record facts rather than an interpretation of the places. The third phase involves the analysis of traditional cartography of the selected sites. The fourth phase is a survey related to the questionnaire administered to visitors of the area in order to gain an idea of the place as perceived by those who are not involved in the study and are not

specialists in related fields, but only perceive the site as users, at various levels, such as inhabitants, passer-by, tourist. Then, the last phase of analysis is that of assembling the collected information. In this phase, we test the maps produced, the congruence of the various collected data, and choose the useful elements to construct the final map of analysis. We then have three design phases. The first one is devoted to surveying identity resources in the study area, through three distinct measures: the identification of the identity potential, the identity problems and the identity quality. In this phase the identity resources available for the project are represented as a sort of map of intents, the first step for the construction of the complex map for the identity project in question. The second one is a survey of the identity resources now addressing the users of places, locals, passers-by and tourists, to whom a questionnaire designed to elicit information emerged from the previous phase is administered. Finally, the overlay of data collected during the previous phases is represented in a complex project map, that identifies also the project proposals. This map is the last step in the design process, where the information contained in the complex map of analysis, after being filtered and transformed into resources, gives rise to proposals for the construction and enhancement of a sustainable place identity.

The PlaceMaker method is supported by its software (Sepe, 2006b, 2010a) elaborated on purpose in order to relate appropriately and communicate easily all the information collected during the different kind of surveys (Fig. 5c). With the PlaceMaker software it is possible to represent and interpret the places in an area through interactive dynamics and by creating multimedia maps (Ayeni et al., 2004; Graziano, 1999; Marinelli, 1999). Places are represented by inserting symbols and elements into maps connected to multimedia schedules that can be continuously updated. The prime users of this tool are: urban planners, administrators and citizens.

The main characteristics of the software are: flexibility, facility and rapidity of use, strong graphical impact, and indexing of the results. Its flexibility makes it possible to store, manage, modify and update in a particular format the data required to create the multimedia schedule, connected to the symbols placed on the maps. The database contains all information collected in the different phases of the PlaceMaker method as well as those related to the state of conservation of buildings and monuments in relation to their functions and to the use of public space of their pertinence -- that is the information collected from the first static monitoring survey of the proposed integrated methodology. With respect to the indexing of the results, the symbols created to construct the complex maps can be connected to a database and translated by PlaceMaker into numerical indices in order to allow the calculation of data useful for the study of the sustainability of the places in question, such as liveability, well-being, etc.. Furthermore, the map can be adapted to local changes by updating both multimedia database and symbols.

3. The outcome of our survey regarding tangible and intangible transformations

The data of our case study -- collected in the above mentioned maps -- was analysed and evaluated in relation to the original situation of the area, before the realization of the re-qualification intervention by the Municipality. In synthesis the results of our monitoring reveal that human risk and the impact of mass tourism on the state of conservation of buildings is relatively low, while totally absent is the impact on urban morphology, as revealed by a comparison between historic cartography and today's urban form. The urban form of this antique part of the city has not in fact changed at all, during the last 200 years, as one can see when comparing the Nolli map of 1748 or the Pio-Gregorian cadastral map of 1820 (Fig.4) with a contemporary Google map. Significant, on the contrary, is the impact of mass tourism on the quality of life in the area and on the quality of these places, considered as symbols of collective identity; in other words on the related to the area intangible values.

Fig. 4: The Pio-Gregorian urban cadastre of Rome (1820s) is superimposed to the Nolli plan (1748) and compared with the city plan of the area today

More specifically the outcome of our survey shows that: commercial activities, specially restaurants and bars, have been extremely increased; often substituting previous commercial activities related to residential needs, such as shops for fruits and vegetables, bakeries etc, or other neighbourhood services. While most souvenir or commercial shops don't sale anymore local products but instead products of a global market. Furthermore the commercial activities related to restaurants, bars, gift shops, souvenirs etc., gradually increased their occupation of public space (both in legal and illegal terms) with tables, umbrellas, stands, benches, dustbins, fences, flower vases, etc (see Fig. 2). The increased presence of tourists attracted also other itinerary activities, such as street actors and street sellers, taxi and carriage parking, gladiators, police cars, etc, all of them occupying in a savage way the public space. We also observed that tourist masses increased in an exponential way along this street; thus destroying the new

pavement put by the municipality, when it re-qualified the area. The urban decay of all spaces along the itinerary is quite evident, both in material terms (graffiti, occupation of public space, bad pavement, congestion), social (expulsion of residence and related functions) and civic terms (civic activities have less space to be expressed as they have to share it with mass tourist presence). The street has changed in fact from a residential to a tourist one: overcrowding, filth, unqualified occupation of public space, disproportionate increase of commercial activities.

In reference to the effects of increased tourists' flows on the monuments' both material and historical connotations we identified two major approaches. Through the analysis of the state of conservation of the facades of the buildings along the street (see Fig.3) one observes numerous interventions of maintenance and of external bettering of the facades, often realised by commercial activities occupying the ground flour of historic buildings of minor architectural prestige, which give a fresh colour to the façade of the new activity they open; a plaster, often of slightly different colour with regard to the original building colour, thus resulting to a patchwork which contributes negatively (instead of bettering) the appearance of the whole area. In parallel, important historic buildings get restored. These interventions often related to buildings bought by tertiary or commercial activities, such as hotels or banks, which want to add prestige to their investment, at times look exaggerated in their restoration or pose questions regarding the city's colour plan or relative conservation regulations (as for example in the case of the building in Piazza del Pantheon which turned from ochre to light blue after its recent restoration). The question of a city's colour plan as a method for contributing to urban conservation and to a city's visual integrity is a characteristically Italian approach. The debate was in fact initiated in the 1980s in Rome by Paolo Marconi and others in reference to issues of authenticity (Muratore 2010). It was later developed, influencing European debate, involving diagnostic methodologies, such as stratigraphic analysis and colorimetry, with the aim to define a scientific approach (Conference Proceedings 1990). However, although colour plans are integrated in Italian conservation legislation, their application remains an issue, as the Trevi –Pantheon case study reveals.

In brief, the outcome of our investigation sounds an alarm on three major aspects: i) enhancement policies (or re-qualification ones) devoid of a comprehensive vision and lacking impact monitoring may produce negative results and may become counterproductive, as the case of Trevi –Pantheon has shown; ii) conservation policies are more effective if not restricted to the restoration of a single building or monument, but to the historic centre in its integrity, comprising both tangible and intangible heritage; iii) human risk or in other words mass tourism has a negative impact on the vitality of a place, on its quality of life and on the identity of places stratified through centuries - in other words it conditions the "city of people" more than the "city of stones".

4. Mitigation techniques and recommendations for a sustainable enhancement

Among the techniques for mitigation and control of tourist impact, that our case study had posed as its third aim, we identified the following interventions which are derived from the “complex map of analysis” (Fig. 5a-b) and exemplified in the “complex map of project” (Fig.6).

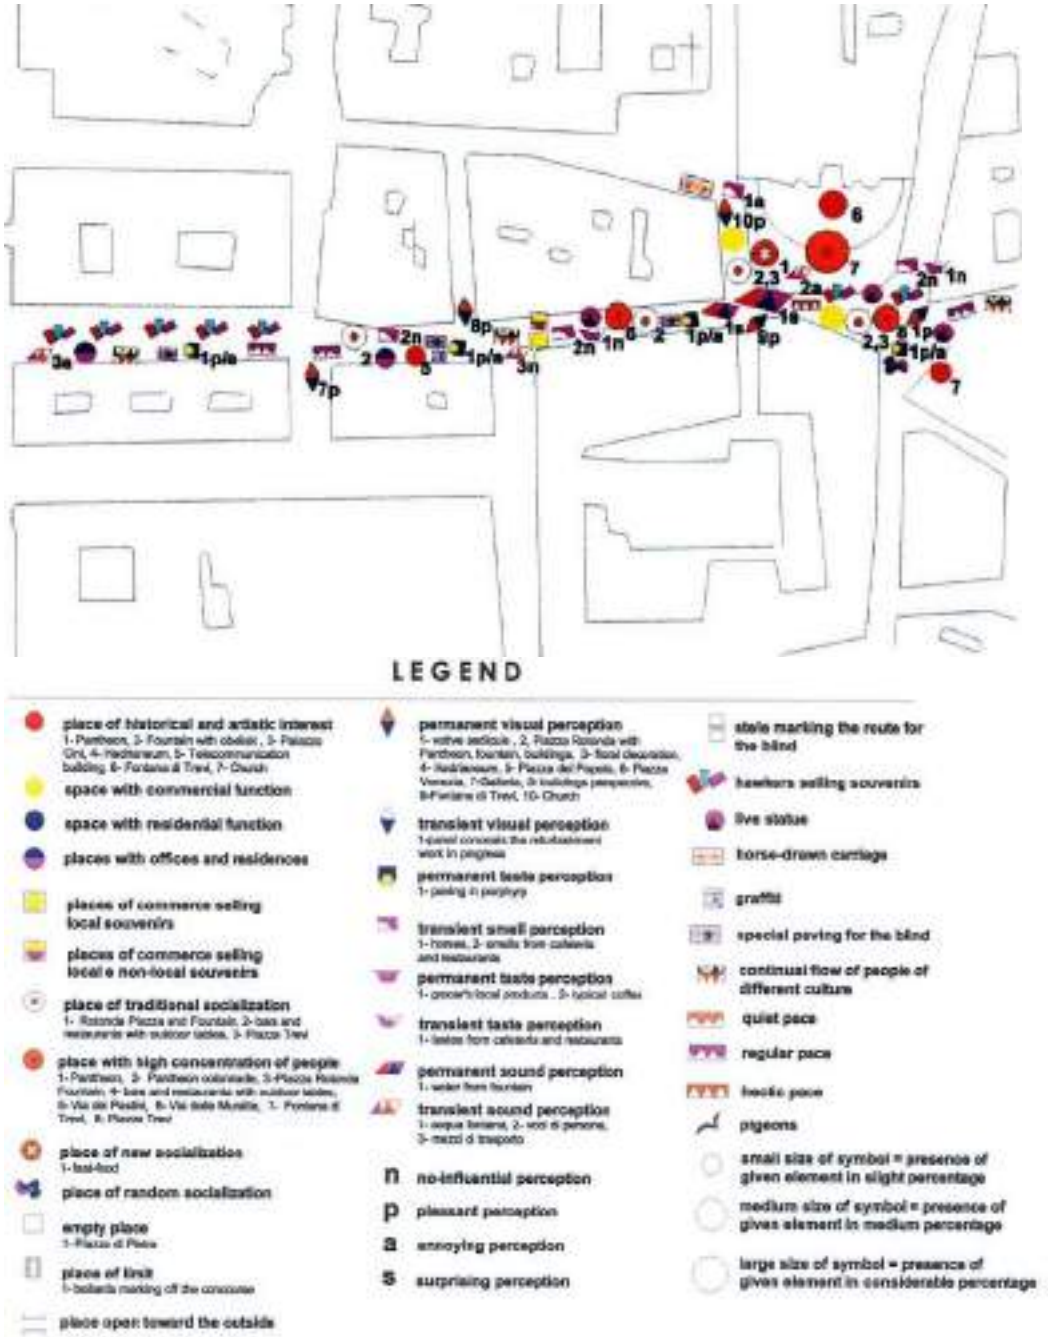

Fig. 5a-b: Detail and legend of the complex map of Trevi-Pantheon

Fig. 5c: PlaceMaker software

The first one regards restoring traditional activities, such as handicraft, or other local products, including high-quality goods, thus rescuing vanishing skills and eventually reducing the commercially undifferentiated global goods present in tourists' streets, which contribute to feelings of displacement. Similarly, the design of a coordinated project for shop signs and windows, particularly for the streets which connect major squares may ensure a greater balance in the composition of spaces and organisation of the various activities, eventually discouraging the creation of additional fast food shops and outlets. The second intervention envisaged aims to create alternative routes between the monumental squares of the Pantheon and the Trevi fountain, thus reducing tourist pressure on the pedestrian street introduced by the municipality. This solution may well prove both educational and sustainable: it would attract visitors' attention to buildings, churches, architectural features, religious icons inserted in facades, and other cultural and historical aspects which pass unobserved in a hasty visit under the pressure of mass tourism.

Other interventions identified consist in giving identity to what is transitory by: creating lightweight multifunctional structures to be introduced at the focal points of monuments and street commerce, variable in extension and dimension, opening and closing, where artistes, hawkers, living statues and others can create their own fluid spaces within a dynamic, light grid which nonetheless constitutes a framework. This form of urban décor can be equipped for various functions including multimedia. Similarly, by virtualizing the graffiti or visitor's path with multimedia guides alternative and attractive solutions can be introduced which may distribute in more thoughtful way tourist pressure and related activities (Sepe, 2010b).

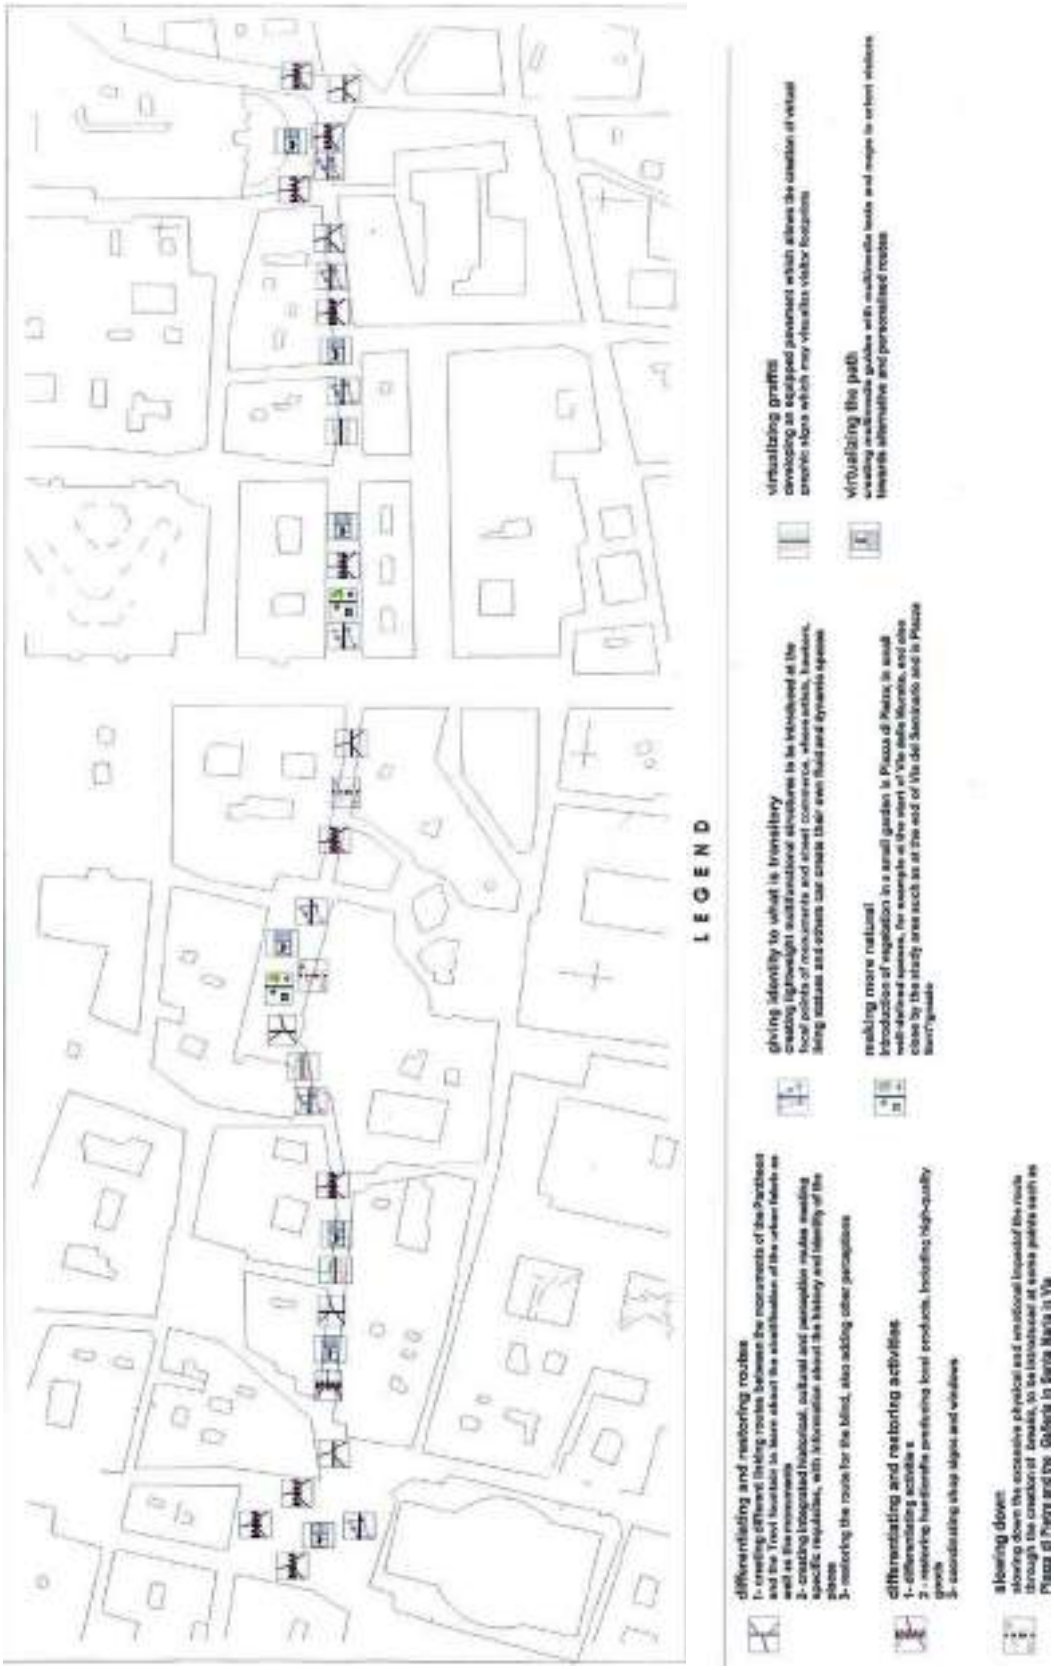

Fig.6: PlaceMaker, complex project map and caption

5. Conclusions

The case of Rome is not unique, as we all know Venice (Montanari and Muscarà 1995; Van Den Borg and Costa 2004) and many other European historic cities (Porfyriou 2010) are besieged by the constant increase of mass tourism and are being depleted (of their traditional civic values) and degraded (growing occupation of public property, disproportionate increase of trading activities, filth, bad smells, overcrowding). However not dissimilar is the situation in many other countries as for example in China (Anderson 2005; Cina 2005). Therefore, if we wish to safeguard the places of collective memory, we must immediately commit ourselves to finding ways to reconcile the needs of the tourist industry with those of life in historic centres and the conservation of their monumental cores. In this respect the final recommendations resulting from this research are of two kinds regarding a set of principles and a number of suitable tools to obtain-maintain place-identity.

The principles identified as the outcome of the various experiments carried out by using the PlaceMaker method, (Sepe, 2012) are specifically related to the place identity enhancement and are the following:

1. The identity resources of a place have to be protected and enhanced so as to give the place in question a distinctive character.

2. Place identity has to be determined with ad hoc methods.

3. Attention to context is to be understood from a social, environmental and urban perspective.

4. The maintenance of buildings, roads and public spaces should be programmed.

5. Places should perform functions which do not cause intensive use that can damage site quality.

6. Local business should be enhanced.

7.Users of a site should be questioned about place identity during both the survey and design phases, taking different needs into account.

8.Place identity should be monitored periodically.

9. Vehicle use in areas with heavy pedestrian throughput should be avoided or slowed down.

10. The safety of users is paramount.

11. Proper enjoyment of the physical characteristics and natural beauty of the place should be considered a priority.

12. Respect for place identity should be considered a sine qua non within the framework of a project's quality requirements.

The suggested tools to obtain-maintain place-identity are the following:

1. to introduce coordinated urban policies instead of fragmented ones;

2. to diversify tourist offer instead of simply increasing the incentives of demand;

3. to promote monitoring of enhancement policies and of tourist impact instead of repeating an urban policy without testing its results.

It should be kept in mind, however, that although the above mentioned tools should remain unaltered the principles elaborated should be considered in a dynamic way, thus keeping in pace with the increasingly rapid rates of change and allowing for a constant updating related to new procedures and requirements in site design.

How to Incorporate Environment in Water Resources Management: A river management approach for Çoruh Catchment Area

Dilek Unalan

School of Applied Disciplines
Bogazici University
Istanbul, Turkey
unalan@boun.edu.tr

1. Introduction

When water resource management is defined as a process of "optimizing the available natural water flows, including surface water and groundwater, to satisfy the competing needs of natural water cycles and human activities" (World Bank, 2011), it suggests managing things that cannot be managed (Jonker, 2002). A more suitable definition of water resource management can be managing people's activities in a manner that improves livelihoods without disrupting water cycles (ibid). Alongside the over-exploitation of water resources, devastation of environmental services and an increasing number of social conflicts, there is a growing body of work in the literature offering different approaches to water resource management, mainly integrated, participatory, adaptive and ecosystem based (De Groot and Lenders, 2006). However, implementation of these approaches demonstrates a wide gap between management practices and the objectives of sustainability (Rammel et al., 2007). This gap urges us to review these approaches carefully in order to determine both their short-falls and merits.

As a new approach to management, ecosystem-based management (ESBM) builds on existing management approaches of human activities affecting natural resources and natural cycles by recognizing the ecosystem as a third party (UNEP,

2011). ESBM reinforces the characteristic “co” in co-management and provides parties with a common footing before entering into their more adversarial roles (De Groot and Lenders, 2006:314). As a new approach to management, ESBM addresses shortcomings of traditional natural resource management, such as considering only single sectors or objectives and overlooking the value of ecosystem services (Tallis et al., 2010). What sets ESBM apart is its holistic and science-based approach to understanding how ecosystems work (Curtin and Prellezo, 2010). This approach recognizes ecological systems for what they are, the deep connectivity amongst all elements of the ecosystem including humans, as well as the underlying processes of producing the services people need and want (UNEP, 2011).

ESBM is based on solid knowledge and an understanding of ecological and social systems (ibid). Thus, the effectiveness of ESBM implementation depends crucially on data availability. Poor data poses a key challenge to its implementation as knowledge of complex ecological processes, interactions, cumulative effects and drivers depend on data acquisition. Poor data is the result of a lack of documented qualitative and quantitative information about the ecosystem, whether from published or unpublished research, experts, stakeholders, or local knowledge holders. Governance system characteristics may also pose a challenge to ESBM implementation. In weak governance contexts, the level of co-operation and co-ordination between government entities, the number of jurisdictions within the management region, and the ability of governments to enforce laws are factors inhibiting ESBM implementation. If laws do not exist or are not reliably enforced, rule of law is not stable, property rights are not defined or enforced, decision processes are not transparent and inclusive, and

stakeholders are in conflict over goals, the situation can be considered as weak governance (Tallis et al., 2010).

Under less than ideal conditions with poor data and weak governance, ESBM does not seem a productive management approach. However, as case examples to date have demonstrated, there is always an opportunity to progress towards ESBM regardless of how challenging the context may seem. There are cases with ample data; however, there are also cases of governance structures obstructing data sharing and access, and cases showing poor data conditions while stakeholder engagement has been fruitful in formalizing knowledge and meeting information requirements (see Samhourt et al., 2011; Tallis et al., 2010). These cases have inspired this study to investigate how ESBM can improve water resource management under poor data and poor governance conditions.

2. Implementation of Ecosystem-based Approach in Çoruh Catchment Area

2.1. Methodology

The case investigation (November 2011) started with an analysis of documents relevant to the Çoruh River Basin problem, i.e. reports of the State Hydraulic Works (SHW), the Ministry of Energy and Natural Resources (MoENR), the Union of Chambers of Engineers and Architects, and with determining the study area and the people involved. Interviews were conducted in Artvin (city), Yusufeli (town) and Altıparmak (village) with around 60 people from local authorities (governor, mayor and village governors, local tourism authority, local SHW authority), local communities, environmental NGOs, local councils, local organizations, as well as investors, scientists and researchers. The

interviewees were approached with three groups of semi-open questions about the real world, and the problem-oriented and solution-oriented loops, following the 10-staged SSDM framework. The first set of questions was aimed at their view on the problem situation in the Çoruh River Basin; the second set of questions targeted how they identify problematic sub-themes of the broader problem situation; and the third set of questions aimed to tap their suggestions on the solution of the problems. The most referred sub-theme was selected and analyzed as a sub-system in the rich picture by using the stages of the framework.

2.2. Water Management Problems in the Çoruh Catchment Area

The Çoruh River is among the 10 fastest flowing rivers in the world, and the fastest flowing and the wildest river in Turkey (State Hydraulic Works Report, 2006). It rises at Civilikaya Hill, located in the Mescit Mountains at the North of the Erzurum Plateau and flows through East Anatolia and the East Black Sea Regions of Turkey to finally reach the Black Sea near Batumi Georgia (UNECE). It is 427 km long, 400 km of which lies within Turkey's borders (Kibaroglu and Tigrek, 2011). The Çoruh River Basin is one of the most picturesque yet under-developed and poorest regions of Turkey. The main economic activity in small towns and villages along the river is agriculture. Rural incomes from agricultural activities are one third of the average for the country as a whole (Akpinar et al., 2010). Increased tourist activities in the basin area, such as rafting on the Çoruh River, has significant economic impacts on the local economy.

The Çoruh River valley lies within the ecological zone of the Caucasus, which is considered one of the 35 hot spots of biodiversity in the world by the World Wildlife Fund and Conservation International. The valley is rich in plant-life and contains 104 nationally threatened plant species of which 67 are endemic to Turkey (Ozhatay et

al., 2005). The area surrounding the river is rich in wild life, including brown bear, bezoar goat, wild boar, wolf, jackal, fox, badger, otter, rabbit, partridge, wild rooster, woodcock, white-headed duck, stock dove and golden oriole (Conservation International Biodiversity Hotspots, 2011).

2.3. Legal and administrative background of the energy sector

The rich natural habitat and water resources of the region remained undisturbed until Turkey's Electricity Market Law No. 4628 was issued. Since then, private sector companies have been authorized by the State Hydraulics Authority to approve, monitor and control hydropower plants. The Ministry of Energy and the water authorities have promoted the use of the region's hydropower potential as economic and environmental panacea. They prefer hydropower and consider it a clean and renewable energy source to meet the country's energy demand and rapidly rising growth rate. Development of hydropower capacity to 3,132.7 MW in the Çoruh Basin was planned to correspond with 29.4% of the country's energy needs (Turkish Electricity Transmission Company Statistics, 2007). Alongside the energy plan, a number of new regulations were released to facilitate the licensing procedures for hydropower plant projects, the expropriation of local settlement areas for public purposes, and environmental impact assessment (EIA). These new regulations, the 2003 Water Use Rights Consensus Legislation, the 2005 Law of Utilization of Renewable Energy Resources (no. 5346) with revisions (no. 5496) in 2006, and revisions to the EIA Regulation (eliminating the requirement for EIA reports for plants smaller than 10 MW) in 2008 (no. 26939) have facilitated the boom in power plant projects in the basin. Currently, there are 10 dam projects for the Çoruh River, and more than 100 regulator-type dams (117 projects), and innumerable small river-type plant projects on its tributaries.

2.3.1. Legal and administrative background of water resource management

The following are the main regulations relevant to water resources in Turkey (Moroglu and Yazgan, 2008):

(1) Water Pollution Control Regulation (2004/25687)

(2) Control of Pollution by Dangerous Substances in Water and its Environment Regulation (2005/26005)

(3) Fisheries Regulation (1995/22223)

(4) Quality of Surface Water Intended for Drinking Water Regulation (75/440/AB)

(5) Protection of Waters from Nitrate Pollution from Agricultural Sources Regulation (2004/25377)

(6) Urban Waste Water Treatment Regulation (2006/26047)

(7) Water Intended for Human Consumption Regulation (2005/25730)

(8) Bathing Water Quality (76/10/AB)

However, the EU Water Framework Directive (2000/EC/60) (WFD) is the most ambitious and complex piece of legislation about water resources, the adoption of which was commenced in 2005 and which has not been completed yet in Turkey (Sumer and Muluk, 2011). The WFD has been designed to be the centre piece of legislation for the management of European waters (ibid) and is considered to be the “constitution” of water-related legislation in the European Union (Cicek, 2010). It demands a fundamental change in the way water resource planning and management is understood (Estevan and Naredo in Mencio et al., 2010). WDF aims to cope with the problems of excessive use and quality reduction of water and requires Member States to aim to achieve ‘good ecological and chemical status’ in surface waters and ‘good chemical and quantitative status’ in ground waters by 2015 (WFD 2000/EC/60). In addition, it also requires that no deterioration in water status takes place and that the objectives of protected areas are met (Van Wijk et al., 2003). The WFD promotes integrated

management of water resources to support environmentally sound development and to reduce problems associated with excessive water abstraction, pollution, floods and droughts. The Directive provides the framework for water policy decision-making within the river basin (catchment) context. It requires the integration of industrial, agricultural, rural development, nature conservation and forestry programmes at the river basin level. Implementation of the WFD also requires the efforts of local government as well as NGOs and stakeholders. Environmental NGOs, public authorities and the private sector offer considerable support for the principles and purpose of the WFD (Moroglu and Yazgan, 2008).

Although some aspects of the Water Quality Acquis are already covered by Turkish legislation, only limited development in transposition of the WFD has been reported, especially concerning water quality (Water Framework Directive in Turkey, 2006). Significant efforts are needed in order to achieve full compliance with and implementation by the WFD (EC Turkey Progress Report 2005). However, there are institutional obstructions for a full transposition and implementation of the WFD in Turkey. The institutional structure for water management is complex and fragmented; it does not provide sufficient guarantees for implementation, and river basin-based management has not been set up yet (Moroglu and Yazgan, 2008). Decision-making within water management is highly centralized. The main governmental actors at the national level are the Ministry of Environment and Urban Planning (MoEUP), the General Directorate of State Hydraulic Works (SHW) of the Ministry of Forestry and Water Affairs (MoFWA), the Ministry of Agriculture an Rural Affairs (MoARA), the Ministry of Health (MoH) and the State Planning Organization (SPO).

Within the complex administrative structure of Turkey, the Ministry of Environment and Forestry (MoEF) is responsible for water pollution control, while SHW is responsible for the development and management of water resources. MoARA

has some water management tasks related to agriculture (e.g. fisheries), and MoH is responsible for drinking and bathing water quality. The SPO develops National Development Plans under the auspices of the Prime Minister (Moroglu and Yazgan, 2008). Division of responsibilities for water management among the relevant institutions and limited co-ordination between sectoral ministries on environmental matters are the cause of inadequate water resource management in Turkey.

2.4. *Challenges to ESBM Implementation in the Çoruh Catchment Area*

The government and the water authorities expected to enjoy socio-economic benefits from the hydropower projects. However, the hydropower plants, the ones under construction and those already in operation, have resulted in cumulative negative impacts and socio-ecological problems rather than offered benefits. The construction of one plant immediately after another, starting very near the source of the Çoruh River, has resulted in the deterioration of a nature reserve and of the high levels of biodiversity, and has threatened local residents of the surrounding villages.

Construction activities, including tree cutting, excavation, filling areas, road construction, blasting, and construction and excavation of supply channels have resulted in a large amount of damage to the basin area. The damage includes the loss of the riparian zone, the destruction of wetlands and the deforestation of the riparian forests. The construction of 1–6 km long water pipe-lines in extremely steep mountainous areas has resulted in tree cutting, erosion, excavated material and its dumping; also, the construction of water tunnels results in waste water in the tunnel site and excavations (Baskaya et al., 2011). Due to habitat fragmentation and alteration caused by these construction projects, fish and wild animal routes have been disrupted. Another impact

of the plant construction projects is the danger of flooding of the highly productive agricultural land surrounding the river.

The water basin ecosystem has been harmed by inadequate environmental flow, as well as by waste, dust and noise resulting from construction. The amount of environmental flow released into the river basin to ensure the continuity of natural life and its monthly distribution does not correspond to the right amount of water. The calculation method (Tennant Method) for environmental flow is borrowed from another country, the USA, with different climate conditions and slope. It is applied subsequently to the environmental flow calculations for each project without adjusting for the conditions of the Çoruh River Basin (ibid). Thus, inadequate water releases from the dams affect aquatic life and the basin ecosystems that depend heavily on the hydrological characteristics of the river environment (ibid). Unfortunately, effective assessments of the negative impacts on the ecosystems in the basin are not available. Regardless of the quality of the environmental assessments, almost all EIA reports on the hydropower plant projects have been approved by the authorities. Lack of a cumulative impact assessment for all projects in the basin is a major problem that needs to be addressed as a priority before the problem with the individual EIA reports for each single project.

Apart from the ecological problems, it has been observed that dam projects in the Çoruh basin result in significant social problems. Approximately 30 villages have been expropriated for the dams to be built. The affected people have moved to cities throughout the country where they are struggling to survive. Expropriation sums paid to landowners were higher per acre than in Central Anatolia due to higher value of land in the catchment area. However, as families owned usually small, but productive plots, the

total amounts paid to landowners were small. While some landowners still await compensation payment, landless residents were left to find new lives without any compensation or support whatsoever as no resettlement or income restoration scheme was developed. The insecurity of the population about their fate in the wake of the projected dams is a major social problem, as is the lack of meaningful participation of local people in decisions made about these projects. Local and central authorities are reluctant to notify and consult local people and NGOs, and there is no genuine scheme to share the benefits of the projects with the affected population. In some cases, NGOs are prohibited from calling for public hearings on the impacts of dams and hydropower plants. Despite the prevailing disputes over the social and environmental problems, there is no response from the ministries to pleas for a slowing down of plant constructions.

2.5. Findings of the Case Study

"Lack of strategic planning for regional energy development" has been expressed by the respondents as the most important problematic theme in the rich picture of the problem situation of the Çoruh catchments area. The Ministry of Energy and Natural Resources declares that "it is our mission to ensure efficient, safe and environmentally sensitive use of energy and natural resources in a way that reduces external dependency of our country, and makes the greatest contribution to our country's welfare" (Strategic Energy Plan 2010–2014). On the other hand, the Ministry aims at utilizing maximum hydropower potential for electricity generation and promotes development of hydropower plant projects without considering the adverse impacts on the environment and the aquatic ecosystems in and around the Çoruh River. The Strategic Energy Plan (2010 and 2014) considers hydropower as a clean, renewable, lasting and efficient

domestic resource with low operational costs and no fuel costs, which is not externally dependent and, therefore, can serve as a fuse for energy prices. The Electricity Energy Market and Supply Security Strategy Paper (2009) outlines the long-term energy targets and emphasizes maximum use of hydropower potential for the period until 2023.

The energy plan formulation currently used by the Ministry of Energy and Natural Resources of Turkey sees hydropower as renewable and everlasting, thus the best energy source to meet the demand in the Eastern Black Sea Region. It promotes the development of a large number of hydropower projects on the Çoruh River despite the opposition of the majority of the local residents and leads to conflicts between the locals and the authorities. Implementation of these projects affects all elements of the Çoruh Catchment Area which are ecosystems, including local residents. However, this problematic energy policy is implemented ceaselessly as planned regardless of the complaints from locals and experts.

4. Conclusions

This research has dealt with increasing the awareness and organization among local community members, whose interview responses have informed the study. The local community members who live in the Çoruh catchments area have identified key pressures on themselves and on their environment and criticized the unsustainable progress of the hydropower plant projects in their areas. They have marked the conflicts between the declared mission of the Ministry of Energy and Natural Resources, which addresses sustainable use of energy and natural resources, and actual approach, which ignores information flows about the impacts on the ecological and socio-cultural resources in the basin area. Subsequently, the local respondents have urged the energy

planning authority to exercise the political will to open up to the information flow from local communities and experts.

The most desired change suggested by the respondents has been stakeholder engagement in the policy-making process. The respondents have expressed their willingness to share experiences and information with the authorities to guard their environment from the adverse impacts of booming hydropower projects. The respondents have also suggested some long-term changes to improve the problem situation in the Çoruh River Basin. One of these changes has been suggested as the enforcement of existing national and international regulations in Turkey's legal system, which would imply development of integrated basin management plans, assessment of cumulative impacts rather than assessing impacts of single projects, and protection of water resources and water rights. Another change has been suggested as the priority-setting approach of the planners and policy-makers to give equal weight to environmental, economic and socio-cultural components.

This research reveals that establishing an effective information flow between the local community members and the planning authority is of vital importance; hence, the political will of the planners is the key condition to improve the problem situation in the areas under poor data and weak governance conditions. The research addresses the role of the strategic decision-makers in utilizing ESBM and underlines the fact that progress towards ESBM is possible even in a challenging data and governance context.

NARRATIVES OF DISASTER RESILIENCE IN L'AQUILA RECOVERY

Giuseppe Forino[1], Ph.D. Candidate in Economic Geography,

Abstract

Resilience is constantly emerging as one of the dominant concept in understanding the reaction of social and ecological systems to an environmental crisis. In case of post disaster recovery in urban environments, resilience should exploit the power of place and the grassroots capacities, as well as suggested by disaster management guidelines. On the contrary, often grassroots capacities are overwhelmed and/or marginalized by top down, centralized interventions from national governments. In this way, two differing paths of disaster resilience exists: one is covered by the State, aiming to reach a paternalistic and centralized outcome of assumed efficiency, and the other by grassroots, that autonomously and spontaneously try to reorganize their life. Here resilience is considered in the second path, as stated by Manyena (2006, p. 439): "a deliberate process (leading to desired outcomes) that comprises a series of events, actions or changes to augment the capacity of the affected community when confronted with singular, multiple or unique shocks and stresses, places emphasis on the human role in disasters". In this vein, the paper objectifies resilience as a process analyzing the recovery of L'Aquila, Italian city hit by the earthquake of 6th April 2009. The paper highlights the necessity to consider the process toward a new objectification of disaster resilience, leading to understand different strategies enacted by different actors. Toward this goal, the paper proposes a narrative of resilience through a qualitative methodology, based on semi- structured interviews to members of "emergent groups" (EGs), local associations and spontaneous committees born after the earthquake, taking part in the reconstruction process of the city. Particularly, it describes the resilience process of EGs, strictly focused on social issues in reconstructing L'Aquila and hidden by government strategies. The paper claims that an integration of these initiatives in urban recovery would facilitate the rehabilitation of L'Aquila. In the way to facilitate disaster management, the paper underlines that in urban recovery built environment and social issues should be considered in an holistic and integrated understanding. Finally, it remarks the necessity of strengthening grassroots capacities and involving in an inclusive way affected population.

1. Introduction

Resilience is constantly emerging as one of the dominant concept in understanding the reaction of social, ecological and socio-ecological systems to an environmental crisis. Resilience could be defined as "the ability of a system, community or society exposed to hazards to resist, absorb, accommodate to and recover from the effects of a hazard in a timely and efficient manner" (UNISDR, 2009, p.24). In this way, it has been

[1] La Sapienza-University of Rome, Rome, Italy – Giuseppe.forino@uniroma1.it

widely recognized as an helpful framework engaging with disaster management (Mileti, 1999; Manyena, 2006; Handmer and Dovers, 2007; Lettieri *et al.*, 2009; Kuhlicke, 2011).

This paper focuses on disaster recovery, within disaster resilience is defined as "the capacity of hazard affected bodies to resist loss during disaster and to regenerate and reorganize after disaster in a specific area in a given period" (Zhou *et al.*, 2010, p.28). The paper sheds light on the process of resilience enacted by spontaneous grassroots groups grown after the earthquake that struck the Italian city of L'Aquila on 6th April 2009. Quoting several contributions of disaster sociologists (Kreps, 1984; Saunders and Kreps, 1987; Kreps and Lovegren Bosworth, 1993; Stallings and Quarantelli, 1993), these groups could be considered as "emergent groups" (EGs), not existing prior to the events compelling their creation. EGs in L'Aquila are pursuing social and cultural initiatives reconstructing the city.

In this way, the paper highlights the relevance of these initiatives to deepen the understanding of victims' needs, and reveals mismanagements in reconstruction practices, due the marginalization of victims' "voices" in approaching to disaster resilience with a top-down perspective. Therefore, it suggests the necessity to consider resilience as a shared and dynamic bottom-up process, instead of a simplifying outcome (Manyena, 2006). The paper uses a qualitative methodology through semi-structured interviews (Secor, 2010), aiming to propose a narrative (Riessman, 1993) of grassroots resilience process considering as primary data the words of EGs' representatives. In this way, the paper further aims to encourage the use of qualitative methodology exploring disaster resilience in a holistic view, facing to the complexity of post disaster reconstruction (Zetter and Boano, 2010).

In literature, several attempts to identify characteristics of resilience exists, with the aim to evaluate system performances facing a disaster and to measure them in quantitative analysis (Bruneau *et al.*, 2003; Cutter *et al.*, 2008a; Cutter *et al.*, 2008b; Cutter *et al.*, 2010; Zhou *et al.*, 2010). On the opposite, it seems to exist the necessity to further develop qualitative methodologies in resilience studies (Berke *et al.*, 2008; Kuhlicke, 2011 and, mixing qualitative and quantitative approaches, Marschke and Berkes, 2006; Mills *et al.*, 2011; Keogh *et al.*, 2011). This paper tackles that, although is acknowledgeable the validity of quantitative approaches developing the debate about resilience, often they lack of relevant data in understanding the disaster as a social construct. Particularly, quantitative interpretations do not help to identify resilience experienced by different stakeholders coping with a disaster, the relations among different actors and their enacted strategies, or the political strategies and power relations besides resilience (Cannon and Muller-Mahn, 2010).

After justified the choice of qualitative methodology, in this way it reveals crucial the remarks of Manyena (2006) revisiting the concept of resilience. Manyena argues that two different visions of resilience exist, leading two different approaches in disaster management. The first considers disaster resilience as an outcome, simply identified as a 'shock absorber' ensuring to the system small-scale negative impacts. In disaster management, this view tends to reinforce traditional practices, following a paternalistic and top down approach, potentially leading to the skewing of activities

towards supply rather than demand. These typologies of programs for disaster resilience tend to adopt a command-and-control management (Alexander, 2002; Alexander, 2007) that centralizes decisional power, preserves the *status quo* and marginalizes aspects such as social and spatial inequality, oppression and lack of civil rights that could often result in case of disaster. In this way, they neglect and/or marginalize grassroots empowerment and participation activities (f.i community or generally "local" initiatives) that could be efficient on the set of response and recovery strategies (Manyena, 2006).

On the opposite side, the second considers disaster resilience as a deliberate process (leading to desired outcomes) that implies the enactment of events, actions or changes to strengthen the capacity of the affected community facing with shocks and stresses. Therefore, it emphasizes the human role in disasters, exploits the human capacities and poses attention on how human beings, both individual and collective, are capable to face a disaster and, therefore, on how they enact strategies. In this way, this vision highlights grassroots potentialities coping with a disaster and strategies and considers them as decisive for reconstruction practices.

On these statements, the paper poses two main question: does top-down strategies from government respond effectively to the needs of disaster victims, or exist a neglect and/or a marginalization of some of them? Is the objectification of resilience as a process rather than an outcome helpful to a more holistic and integrated interpretation of reconstruction period?

Initially, the paper describes disaster management in the Italian city of L'Aquila after the 6th April 2009 earthquake. Next, it presents the qualitative methodology to analyze the process of disaster resilience enacted by grassroots EGs in L'Aquila. Afterwards, results are presented about grassroots initiatives, in satisfying needs neglected by governmental strategies. Finally, conclusive remarks are offered about the qualitative methodology analyzing disaster resilience, the revisitation of resilience approach as a process and the holistic perspective of disaster management.

2. Analysis

2.1 Contextualizing disaster management in L'Aquila

On 6th April 2009, L'Aquila Municipality and its 14 surrounding villages have been affected by an earthquake with a record magnitude of 6.3, causing the death of 308 people in the main shock and the injure of 1500 people, 202 of them seriously (Alexander, 2010). The damage of residential buildings has been severe: more than 60,000 buildings have been entangled, of which 18,000 judged as unsafe for occupancy (Papanikolaou *et al.*, 2010).

In this case disaster management has been strongly addressed toward centralized solutions, replacing the local response with a national one, under the powerful guidance of Prime Minister Silvio Berlusconi and Italian Civil Protection Department (ICPD) (Alexander, 2010). In the emergency phase the historical center of L'Aquila

was declared unsafe and consequently off-limits (Red Zone) and militarized. The immediate step in the emergency phase was the implementation of tent camps for 22,000 evacuees and the recovery for other 21,000 in tourist accommodations (Alexander, 2010), as previously enacted for example in occasion of earthquake in Friuli region in 1976 (Geipel, 1978; 1991). The necessity of quickly providing shelters to survivors drove ICPD and Italian Government to opt for emergency management leading to reconstruction strategies aimed at a direct transition from homelessness to secure accommodation (Alexander, 2010). Afterwards, two different strategies have been enacted for reconstruction. The first was the construction, between September 2009 and February 2010, of new earthquake-proof buildings in peripheral areas called CASE Projects (*Complessi Anti-Sismici Eco-compatibili* - Earthquake-proof Sustainable Eco-compatible Housing Complexes) (Calvi and Spaziante, 2010; Alexander, 2011a) capable to host about 15,000 evacuees of L'Aquila city. This project included 184 buildings and 5,736 residential flats at 19 sites around L'Aquila (Alexander, 2010). The second was the implementation of MAPs (*Moduli Abitativi Provvisori*- Temporary Housing Prefabs) in 54 localities, both in peripheral areas and closer to the damaged sites within L'Aquila municipality for the recovery of 8500 people (Alexander, 2011b).

Figure 1: CASE Project areas, identified with 19 black shapes. These have been proposed by the Italian Government to build the new housing complexes in L'Aquila Municipality (ICPD, 2009).

Although this scattered strategy seems to indicate a successful recovery plan, emergency and reconstruction mismanagement, both from an environmental and social perspective, have been recently pointed out by Alexander (2010; 2011a; 2011b),

Calandra (2011) and Microdis (2011). The reconstruction strategy followed two parallel lines of intervention: the closure of the historic centre, still declared off-limits after more than two years, and the creation of new peripheral settlements in predominantly rural areas used for agricultural activities.

The CASE project was approved by legislative decree just 22 days after the earthquake. The Government's priority was to find a timely solution to housing recovery which was carried out without consideration of the long-term consequences. The rapidity of the decision provoked a misallocation of resources both in terms of an excessive expenditure of funds (Alexander, 2010) and of soil consumption.

Furthermore, one of the most significant critiques that the government has received is the lack of involvement and participation of citizens in the decision-making process (Alexander, 2010). As regards the reconstruction, this has been perceived as a lack of attention to the prioritized needs of the population affected (Calandra, 2011). In addition, the displacement of the population, from their prior locations to the new CASE project areas, has caused the fragmentation of the pre-existing communities challenging the re-creation of a new feeling of belonging (Microdis, 2011).

The reconstruction strategy, exemplified by the CASE project, is representative of a paradigmatic top-down and emergency-led disaster recovery approach, merely focused on achieving a quick response. Furthermore, governmental proposals were not based on sustainable and ameliorative aims. In this way, grassroots decide spontaneously to take responsibility for their place and, therefore, to enact a more appropriate response, aware of their needs.

2.2 Methodology

In analyzing disaster resilience in urban systems, a multi-level understanding is necessary (Resilience Alliance, 2007), particularly highlighting issues related both to built environment and to social relations (Vale and Campanella, 2005; Campanella, 2006). Specifically, this understanding reveals crucial in post disaster reconstruction period, that should be understood in an integrate and holistic view considering its complexity (Zetter and Boano, 2010).

As mentioned before, this paper proposes a qualitative methodology to analyze disaster resilience. This methodology reveals itself helpful in understanding how social processes are shaped and constructed and, in a more critical way, how the 'truth' is acknowledged and socially represented (Knigge and Cope, 2006). The paper argues that a qualitative methodology is relevant in understanding how social phenomena are diversified in relation to actions and networks contexts. Furthermore, it poses the dialectical conundrum about how they exist in the 'real' world and how they are represented in their social construction (Bailey *et al.*, 1999).

In this sense, the paper aims to go beyond mainstream 'truth' about reconstruction practices in L'Aquila, and to highlight grassroots necessities marginalized by centralistic strategies. In fact, one of the main characteristic of disaster management in L'Aquila has been characterized a distortion of events' description by mass media and

a rhetorical sensationalism describing the 'truth' (Felice, 2010; Carnelli *et al.*, 2012). In this way, it seems necessary to underline 'other voices' aiming to understand the social implications of L'Aquila earthquake from a marginalized standpoint. Therefore, primary data have been retrieved from semi-structured interviews, extracting grassroots voices. According to Crang (2002) about a re-examination of their validity within social sciences, here it claims that semi-structured interviews represent additional sources to a standard archival research in case of information about events and facts not recorded by documents (Secor, 2010). In this vein, Kumaran and Negi (2006) suggests these interviews in disaster studies if it is necessary to spread marginalized and hidden opinions. Additionally, in understanding resilience, this typology of interviews allows to shed light on how individuals experienced disaster and resilience (Kuhlicke, 2011).

The fieldwork in L'Aquila took place since 15th May to 20th July 2011. As previously mentioned, it consisted in conducting semi- structured interviews focused on the autonomous resilience process of several grassroots EGs, born after the earthquake. In this way, several EGs exist with different goals depending to the number of members, the scale (neighbourhood, urban) of proposals and the perceived priorities. In selecting EGs for the research, earlier screening has been based exclusively on their spontaneous origin and, therefore, in the analysis have been excluded groups affiliated to local or national pre existing organizations.

EGs aimed to find a solution for individual and community necessities for whom Italian Government has been not aware through its centralistic disaster management. Additionally, these interviews were supplemented by field notes taken in attending formal and informal meetings of the groups. Numerous informal discussions were also held with inhabitants of L'Aquila members about emergency and recovery strategies enacted both by Italian Government and grassroots. Other information have been retrieved by articles from local media and Internet sources, and studies and reports produced by government and local agencies. Therefore, next session will propose results from these research in order to realize a narration of resilience process, as the existing work in literature by Berke *et al.* (2008) about resilience in Thailand after tsunami in 2004 and Kuhlicke (2011) after floods in Germany in 2002. Regarding L'Aquila earthquake this paper aims to fit within the critical literature about disaster management: Alexander (2010) highlights the strategies enacted by Italian Government and ICPD; Frisch (2010) underlines the impacts of CASE Project on urban planning; Pisu and Zardetto (2010) sheds light on the impasse one year after the event; Calandra (2011) analyzes the new social geography in some of the areas of C.A.S.E. Project; Comitato 3.32 (2010) reveals the strongly market-oriented mould of the reconstruction; finally MICRODIS (2011) proposes empirical results about social, economical and health impacts of the earthquake.

3. Results

3.1 Origin of EGs resilience and its objectification as a process

EGs are not existing before the disaster. As underlined in literature about spontaneity mechanisms of post disaster community solidarity (Solnit, 2010) and in enhancing

resilience (Tierney, 2009), L'Aquila experience sheds light on a spontaneous and autonomous way to enact a process of resilience by grassroots. In the immediate aftermath of the earthquake, in tents camps and in an open space in front of a dismissed mental hospital, in a locality called Collemaggio, groups of unorganized citizens meet in spontaneous assemblies to propose their capacities in restoring the city. During following months these assemblies resulted in some public initiatives, as for example the "wheelbarrows rebellion" in 2010, (Farinosi and Trerè, 2010) to clean up rubbles in the city center, and in a legislative proposal to Italian government (PLIP, 2011), recommending precise guidelines for a better organization of disaster management in Italy. These initiatives strongly claimed the necessity to involve grassroots in the whole disaster management both in L'Aquila and in Italy, rejecting top-down strategies in decision processes for the reconstruction (Farinosi and Trerè, 2010; PLIP, 2011).

Notwithstanding these claims, interviews clearly show two different approaches to resilience: one institutional top-down, aiming to the outcome to timely, and the other bottom-up, a process enacted by grassroots, marginalized in the government activities.

The first is based on a paternalistic view of reconstruction, a lack of flexibility and short-term goals, aiming to timely reach the result in providing to housing solution (the CASE Project). Within this priority a strong centralistic management of L'Aquila emerged, and a member of EGs declares:

"…. It has been adopted the justification of urgency and emergency and democracy has been abolished in L'Aquila. Through Civil Defence Department the Government occupied the territory. Military solution have been applied. Furthermore, local institutions concealed behind this urgency/emergency. They abandoned our place in powerful hands of central govern because they had fear about the complexity of the problems and about their incapacity. Therefore, CASE Project has been imposed."

Thus, it clearly manifests that central and local institutions have taken initiatives unshared with the grassroots, without any attempt to enlarge the consensual base and to rely to grassroots capacities helpful to strengthen and integrate their efforts. Central levels, as Italian Government and ICPD, and local institutions (Mayor and City Council, identified as the closest to the grassroots in issues of urban planning and management) worked with civil defense and "command-and-control" methods. The abused slogan "from tents to houses", which briefly describes the strategy of a direct transition from emergency housing to residential building of CASE Project (Alexander, 2010), endorses the necessity to adopt a "state of emergency" to provide temporary housing to the population. Concretely, this slogan describes the perversion of the democratic functioning and of the assumptions upon which to develop and legitimize public policies coping with the disaster (Calandra, 2011).

In this dichotomous landscape, several EGs grew up with different goals. The interviews do not cover all targets of EGs in L'Aquila, but partially describe the existing scenario, constantly in evolution. Here resilience process is narrated based on story-telling by representatives of following EGs: artists' associations, neighbourhoods promoters of recovery plans and social spaces, occupiers of a disused kindergarten, founders of a new ecovillage, cultural associations, promoters of

participatory initiatives, students' associations. Their names will be not identified to preserve privacy of interviewees and according to anonymity requests by some of them.

The first step to frame their resilience process is to clarify why it could be defined as a process and not an outcome as Manyena (2006) stated. The objectification of resilience as a process is claimed by an interviewed that explains:

"….an idealistic recovery model does not exist in general and specifically for L'Aquila. Several difficulties exist in analyzing current needs for grassroots. In this way, citizens must be powerful, must be actors in reconstruction, everyone aiming to solve their problems and developing their theoretical and practical skills and capacities. They must share their ideas in a slow and dynamic process".

The interventions enacted by the institutions is considered reductive and not aware of the urban complexity of L'Aquila. In fact, the strategy of CASE Project does not consider both the past and the future of the city (Calandra, 2011). In this way, it rejects its history the acknowledged peculiarity of L'Aquila as a "planned city" of medieval foundation (Clementi, 2009; Clementi and Piroddi, 1988), with a precise urban form within the city center (now Red Zone) historically represented – still performing after more than eight centuries- the cultural, social and economical heart of the numerous surrounding small villages. Furthermore, it lacks of any mid-term and long-term evaluation of urban planning of the city, neglecting a vision necessarily perspective of recovery (Berke and Campanella, 2006) and an holistic view of reconstruction practices (Zetter and Boano, 2010). These remarks are strongly affirmed here:

"CASE Project is a wicked attempt to move inhabitants outside our historical city center, in the *periphery of the periphery* (emphasis added).The renaissance of L'Aquila must begin in the city center, our heart, where people lives. People can't move elsewhere, because this 'elsewhere' consists of buildings not existing as social, cultural and relational structure. They just exist as buildings on crossing roads, they are *non-places* (emphasis added)."

Additionally, the reference to the "non-places" of Augè (1995) seems to represent the core of the inputs for resilience process. In fact, EGs underline that institutional strategies of recovery marginalized the manifold issues related to the planning of social aspects, in the new areas of CASE Project and in the rest of inhabited areas of the city. In this way, interviews prove that EGs perceive as relevant the lack of generic spaces for sociality for the whole population and the necessity to regain a sort of 'everyday life' able to recreate community ties.

As stated by this interview:

" due the lack of places where we can meet, our group (*one of the EG, n.o.A.*) represents at least a partial solution to recreate a place to meet, to share ideas or simply to have fun."

Another interviewed declared that

"it does not exist more the *everyday* (emphasis added), children playing in green areas or in the square, benches taken by people chatting. There is an emptying of the public space."

3.2 Desired and enacted interventions of EGs

Based on the above statements, resilience process by EGs in L'Aquila is slowly shaping along these three years. Since the aftermath of the earthquake a permanent Citizen Assembly attempted to develop own ideas about emergency and recovery solutions. These solutions

"…have been elaborated and shared among citizens and laid open different options. However, we had a common goal: to avoid the spread of inhabitants after the emergency period in tents camps. We aimed to respect the historical peculiarity of L'Aquila and to maintain both the geographical and psychological continuity of inhabitants with their places. Therefore, we proposed to promptly implement more wooden buildings (the MAPs mentioned in the Analysis paragraph, N.o.A.) both close to the hamlets and to the city center. Furthermore, we propose to implement containers classified as A+, the highest standards of liveableness for these structures. These are earthquake- proof and they require small areas for the assembly and pitches of excavation, without large soil consumption".

Here it appears significant the proposal of the traditional approach to post-disaster temporary housing (Quarantelli, 1982 in Johnson, 2007): temporary shelter (tents camps), temporary housing (for L'Aquila, MAPs and containers A+), permanent housing (refurbishing or reconstruction of pre-existing buildings).

Regarding the villages around L'Aquila the resilience process is essentially based on three different interventions:

- reconstruction plans for some of the small historical centers of the villages around L'Aquila;
- construction of multifunctional center to regain a daily life in the struck villages;
- construction of multifunctional center supporting areas of CASE Project.

In these three cases, a strict relation exists between the reconstruction of the built environment and the restore of social aspects.

In the first case, EGs claim the physical reconstruction of historical centers is vital for their future, for the future of the village and for the community belonging. The resilience process has been exactly enacted to take responsibility about their place, and consequently about their future life.

"We absolutely want to come back in our neighbourhood, and for this goal we have necessarily to rebuild the historical center, even because is the place where we had our houses and usually met. We don't want to wait the slowness of Italian machine, we don't want to take the risk to spend 20 years to rebuild our place as well as the reconstruction for center of L'Aquila. Further, we want to come back together, at the same moment, in our houses. It is a nonsense coming back in different moments. For

this, we have planned to subdivide our historical center in five areas, assigning each of them to a building firm. Our goal is to come back in five years".

In the second case, EGs claim that in the post disaster period is relevant the emergence of a disorientation among grassroots, and that an intervention focused on *ad hoc* structures for the local social issues could lead to re-establish daily networking. In this way, a member of an EG declare:

"We deliberately are not focusing on housing reconstruction, because it is right the owners would personally decide about this. We think it is inopportune taking decisions instead of them……So, we pose our attention on public spaces and facilities concerning the community and not the individual. We wondered what would happen after the period in tents camps. Before the earthquake the social life of our neighbourhood took place in the main square and usually consisted in children playing football, women chatting on the benches and guys meeting in a room in the parish recreation center. After the earthquake our desires were to reestablish these forms of community life, even because people was disoriented. We decided to reevaluate or belonging to the place and to avoid the loose of our cultural roots. We found donors financing a multipurpose structure with a recreation centers for donors, a playground for children, a small auditorium with a library and a multimedia room…..In this way, we hope just to give the people some social spaces avoiding a strong emigration".

In the third case, the given reasons are identical, but the aim is to intervene both for grassroots of struck areas and for people moved on CASE Project areas. As stated in Calandra (2011) new social geography of these areas lead to an acceleration of community fragmentation and exacerbate individualized and atomized choice, whom EGs attempt to contrast through an own initiative. Regarding this, a member of an EG involved in this issue reported:

"Our aim is to realize a trait-d-union among our struck village and new CASE areas….The idea of a multifunctional center has been developed because we considered our current condition just as temporary, but this temporariness seems to stretch indefinitely. We were wondering about how integrate in our community people moved in CASE from the center of L'Aquila. This is not their place; people from the center know anyone and for them this condition is surely traumatic."

3.3 Taking relations with local institutions

The resilience process by EGs need institutional support in organizational, bureaucratic and technical issues. Nevertheless, difficulties in relations with institutions are relevant: missing or incorrect communication channels, lack of preparedness in solving problems in a quick and flexible way resulted as decisive in slowing this process. An interviewed states:

"Difficulties in communication with institutions exist. People have a blurred vision of post- earthquake administrative and bureaucratic machine. People rely mostly to technical staff as those can explain and solve the so-called "papers". This often creates a word-of-mouth, for which information are omitted, misrepresented or forgot.

Obviously, this happens because some people do not have such a background through whom you should filter information, and therefore real difficulties exist in understanding the current situation.

Another interviewed declares:

"There has been a great confusion because the institutions have never been able to relate with people in a satisfying way. When Civil Defense was responsible for emergency management (since 31/01/2010 decisional power passed to the Region Abruzzi President, N.o.A.) it was our first interlocutor. When local authorities became our referents, they really were just formally. People were so confused with so many leading figures but nobody gave us precise answers, often passing the buck. Also for our project we faced a long bureaucracy, every week going to municipal offices to understand what to do."

Furthermore, laconic is one commentary:

"I note really numerous difficulties interacting with the *politicians* (emphasis added). In town councils each politician has an own problem about which he barks, however citizens' problems seem to not exist, nobody cares about us."

4. Conclusions

This study considered disaster resilience *à la* Manyena (2006), as a process able to exploit human capacities facing a disaster. The resilience process has been analyzed from the standpoint of grassroots EGs in the Italian city of L'Aquila and, specifically, on how they have enacted initiatives aiming to satisfy their necessities reconstructing the city. Two main conclusions can be extrapolated.

The first is that, for L'Aquila case, EGs are born and have decided to take in action due the marginalization of some of their necessities in the institutional interventions. The neglect of their voices and the marginalization of a due attention both about social issues and built environment peculiarities motivate the grassroots to focus on these forgotten arguments. In this way several initiative took placed by EGs, particularly in restoring a sort of 'everyday life' that was impossible to maintain in new temporary housing areas. The second is that an objectification of resilience as a process provokes a shift in viewing post disaster period. This period is the most challenging and complex in disaster management (Zetter and Boano, 2010) and requires necessarily inclusive strategies to better restore urban environments. Such an inclusion could be better enacted considering the most vary capacities that grassroots have taking

responsibilities of their place. L'Aquila case shows that, in case of disaster, grassroots demands for involvement and participation as well as social spaces to share their ideas and their knowledge. The objectification of resilience as a process could help to activate more inclusive mechanism in post disaster management.

Furthermore, the use of a qualitative methodology allows to give voice to the victims of the disaster, that are usually marginalized in political and management discourse (Mercer *et al.,* 2008), and of whom instances are often underestimates in quantitative methodologies.

The building of public space and the insurgent citizenship in Palermo

Davide Leone[1]

Introduction

The idea that a city is no longer the expression of an average value of necessity, but it is an arena in which different actors face and meet each other is a new (post-modern) metaphor interpreting the urban space (Sandercock, 1998, 2003; Fincher & Jacobs, 1998; Sibley, 1995; Milroy, 1992). The difficulty of imagining urban policies and, also, new shapes for the city to ensure and augment this function is an issue of the actual city, and it remains hard to do.

Very often, the difficulty of interpretation of this paradigm justifies "doing nothing" which is typical of the administration of some cities, including Palermo. In this sense it is particularly interesting observation of what is happening in Palermo, where, compared to a general lack of political and physical interventions, we are witnessing a fervent self-organization "from below" to (informally) build some pieces of the city.

In Palermo, the lack of urban policy has stimulated a mobilization that amplifies the self-construction in the reuse and maintenance of city spaces. The construction of the physical elements that affect the public space by citizens' groups, "clandestinely" organized, together with the construction and occupation of public spaces by users of the city are the mirror of a post-modern use of the city. In this sense it is useful to study the case of Palermo with its informal characteristics trying to encode a taxonomy of actions that take place on and in the city. An initial categorization of the nature of the actions that take place in the city is listed below:

- Physical and durable actions
- Demonstration Events
- Replacement of basic services

The research focuses on the stories of different stakeholders acting on the city of Palermo trying to understand the organizational arrangements and strategies underlying interventions, following a search method described by Forester (1999) in which the stories take on a role for the understanding of problems. The aim is also to trace how the actions promoted by the new intangible technologies of web 2.0 material affect on the actions of the city.

A second taxonomy concerns how the movements, that affect the city, organize themselves. In this way It's possible to understand what aspects has to be increased to generate appropriate urban policies to govern the transformation of the city through post-modern city metaphor. These categories are:

- Communication on Internet
- Contacts and telephone
- Gathering places

In the background is the belief that the multiplication of opportunities for discussion among people is able to increase people's intelligence and, in some way to subsidize one of the functions typical of cities that have had since their "invention".

[1] Dipartimento di Architettura sezione città territorio e Paesaggio, Università degli studi di Palermo

Together with utilitarian functions, defense, trade and exchange, the city had, until now, a further and fundamental function: to boost the intelligence of man.
This is one of the peculiarities of the city, but it is also one of the functions less noticeable by the people because it is a consequence of living together and of the generation of community rather than a primary and founding of the city. That is to say: Innovation is a consequence of the cities, but is not perceived as a cause of their foundation. In this sense, no wonder the need to delineate the boundaries and conditions of the creativity that puts this function of the city in the foreground. According to one of the planning mainstream, that has been developing the 90s especially in the U.S. (Florida, 2003; Landry, 2000), this function is amplifiable engaging creative elements in the social texture of the city.
The city is the necessary condition for the construction of all the innovations of mankind (Mumford, 1961; Benevolo, 1993) because it can multiply the thoughts of men. Moreover, the production of thought has created the conditions and requirements to allow the accumulation of knowledge to spread it on from generation to generation.
Using a metaphor, which sees the city as a brain capable of generating innovation and people like ganglia, we are witnessing a real revolution in which the needs of neighbourhood (Synapses) characteristics of the city are flanked by the new possibilities due to information technology. In this sense we are witnessing a phenomenon that builds new creative energy in the city, but runs the risk of loose some of the reasons for the existence of the city itself.
From another point of view it’s clear that not only the quality of ganglia is useful to augment the innovation capabilities of a city, but the quality of connections (Synapses) is important too. For that the actions, which act directly on the public spaces of the city, are quite important, because they substitute the local administration in managing the transformation of public spaces and so, in a way, they build sense of communities (Lo Piccolo, 2008; Fera, 2008).
The paper tries to overcome the Creative City strategy for urban regeneration in which the urban policies wants to attract creative people (musicians, artists, etc.) to ensure the urban renewal.
This paradigm, although considered one of the mainstream of contemporary planning, has some critical issues both for the durability of the interventions that concerning the ability to encourage creativity self-generated by the city itself. the metaphor of the creative city does not explain the reasons that led some cities, at certain times, to be especially creative by building physical products and traditions that are perpetuated (durability) and are an expression of local culture.
In this framework the insurgent citizenships, as described by Holston (1998), have a strong role because they operate informally on the public spaces of the city building defining a new way of acting in the city.

Differences and similarities of insurgent citizenship in Palermo

The term "insurgent citizenship" is introduced by Holston (1998) with the intent to criticize the system of rational comprehensive planning typical of the '70s and

deriving from the tradition of CIAM. The insurgent citizenships are considered as a response to the stiffness of a template-directed plan. In the Italian context and even more in the southern, the reaction to a too rigid schedule (according to a controversial justificatory perspective) has been evident in a series of informality whose apex is the illegal building.

In the cities of southern Italy, the struggle between the blueprint and the informality of the city, seems to have been won by the latter. The city of southern Italy is the expression of other forces that don't express, the logic, languages and tools of Planning (Inzerillo, 1984; Cannarozzo, 2000; Zanfi, 2008). In this case urban spaces has constructed through the tension of three forces: on the one hand, the public project of the city (the blueprint), on the one hand the needs of citizens, and on the other hand, the criminality will of managing the spaces. These three actors contributed in shaping the landscape of Italian southern city. The use and construction of public space are the expression of these forces that often retreat, leaving unused space for manoeuvre, in which groups of organized citizens can express themselves.

In the case of Palermo insurgent movements, rather than confront the results of rational comprehensive planning, tend to answer to the construction and organization of a city whose spaces are defined between the management of organized crime and administration of public administration. In the folds of these managements there are spaces left by the conflict and not governed, managed and designed by none of these two forces. In these areas the phenomena of insurgent citizenship is moving, tending to remember the responsibility of local administration to ensure the common good.
Planning has accepted the need for participatory pathways to act on the public space of the city, reducing the gap between the blueprint of the city and the needs of citizens. Forester (1989, 1999, 2005) and Healey (1997) as well as many others, as Innes (1995, 1996), Innes & Booher (1999), Fischer & Forester (1993), have defined the critical nature of this type of participatory approach especially as regards the choice and selection of stakeholders and the will to build consensus around prebuilt projects.
In the case of Palermo, however, there is an overcoming the paradigm of participation in favour of direct action on urban places over which there are not actions by public decision-maker.

In Palermo, the issue of ethics of inclusion, (Bonafede & Lo Piccolo, 2010) is "tackled" by the local decision maker audience through inaction, this, for years, provided an opportunity for organized crime to move on urban space and this is the condition that generated the reaction of insurgent movements.

Palermo is a complex case in which the fluidity is evident between the three forces above expressed. Urban spaces left without care and functions are the privileged arena for the expression of insurgent movements, when these spaces are not already a criminal arena.

The insurgent movements in the city of Palermo

The cases explored in this brief paper concern the movements that act directly on the public space by giving a physical transformation. The various movements were collected in a multimedia map that identifies the sites of transformation and provides links to websites and videos that describe the actions[2]. The tendency to physical modification of public spaces exceeds the need of interaction with the administration and proposes actions that take place according to specific rules and procedures. The cases collected are far from each other for what concerns the spaces of the city on which they act, how to organize and objectives that arise, however, several cases have in common the desire to be subversive in the use of the city and by mode of action almost clandestine.

Figure 1 QR code use it with your smartphone to see the on line map

What makes these actions unique is to act with the purpose of building and shaping the public space. This occurs without conflicts because the citizen groups operate on marginal spaces in which it is expressed the indifference of the forces that govern the city.

The cases include:

- The Guerrilla Gardening actions and the Palermo flowerbeds,
- The Santa Rosalia Gardeners actions on the neighborhood Albergheria in the historical center of Palermo,
- The Committee for the collective good actions,
- Stories of struggle for the re / opening of parks and public spaces in cities,
- The Mafia physicalization use of public space;

We chose to bring a clearly negative example in the use and physical transformation of public space because the act physically and permanently over the city is not without problems. The insurgent movements, trying to respond to a lack of administration, are interpreters of a collective good that is not unique, is not codified and is elusive.

Along with these actions, the city of Palermo is the theatre as many other cities, within which other events are happening, that have subversive demonstration purposes and unsettling use of public space. The flash mob events are the best known of this trend, but they tend to do this demonstration also structured events such as Saddles of Stars, Critical Mass (Carlsson, 2002) and Milonga Blitz, which animate parts of the city with unusual uses. Saddles of Stars and Critical Mass are aggregations of cyclists that travel along a a path in the city pointing out the existence of alternative ways to move over the cars, the milonga blitz is a collective time to dance that takes place in some public spaces in the city. These are just some

2 http://maps.google.com/maps/ms?ie=UTF&msa=0&msid=212981471588689928612.0004bde05eccf1e5f7a14

examples of structured multi-functional public space can absorb very different uses. However, these uses are unusual manifestations of the simple need for expression, but not physically change and lasting space, while the actions of the insurgent movements are becoming dependent on these characteristics.

Assuming that these actions are certainly a creative element for the city, the effort that we are trying to do is to understand what are the factors that give rise to these forces and how they can design policies that can encourage these creative self-generated movements from the social context of the city, and how it's possible to prevent the problem of possible conflicts caused by the change in the public space. To better understand the sphere of influence has moved to the changes that were widely shared by citizens, who have generated very little opposition from the community, but this state of things it's not always possible. The actions on public space have shown how, doing something / anything is still preferred by citizenship in relation to doing nothing.

The Guerrilla Gardening actions and the Palermo flowerbeds

The Guerrilla Gardening is a form of radical gardening, which operates on the public flowerbeds degraded in the city. The movement was born in the 70s in the U.S. with the intention of operating on exposed sites where it was forbidden to act.
The first example of this is due to Liz Christy who has worked in New York working on a lot was empty with a garden that is still retained by citizens and is henceforth part of the city's parks department.

An example, which has even led research in formal actions, is the Garden of Eden, that was starter once again in New York by Adam Purple. The garden, created in the space left by the demolition of some lots in the Lower East Side of Manhattan, has continued to grow until 1986 when it was destroyed[3]. From a formal point of view, the garden is a very interesting case: its circular shape is able to grow without limit, compared to the blocks town, it always retains a recognizable form. In a sense, the implicit project of this garden is a metaphor of a plant that can continue to grow, while its architectural counterpart is the spiral of the museum of unlimited growth by Le Corbusier.

Figure 2: QR code Use it with you Smartphone to see a related video

he actions of the beginning had a strong symbolic sense facing with areas of private property. The aim of these interventions was, in fact, to struggle against excessive privatization of space in the city, while, in Italian and current configuration, the actions of guerrilla gardeners are oriented towards maintenance and new significance of public space. The early actions in New York are a model which inspired by the actions of disobedience by guerrilla gardening. The movement of guerrilla gardening

[3] http://www.youtube.com/watch?v=-VfBvdzgQxY

in Palermo began to operate in 2011 and scored nearly 50 operations on the flower beds in the city, they are public spaces in which the degree of conflict is quite low, because are abandoned by local administration and are useless for the criminal organization. Even in Italy guerrilla gardening are disobedient regarding the legislative framework, at least they clash with the Civil Code rules, governing the occupation of public land, but also with the Article 347 of the Penal Code that punishes the usurpation of public function.

The two years of activity by Palermo Guerrilla Gardeners have led to an evolution of the mode of action: the early actions had, in fact, had a demonstration function, aimed to highlight the lack of maintenance and care of public green spaces, new initiatives bring out the clear intention of wanting to create communities around the actions of re-signification. The events are an invitation for people to deal and take possession of their public spaces. To do this, the most recent actions have been carried out by a communication campaign and preventive involvement with the residents. This will produce more lasting effects on the city.

The involvement of citizens takes place the week before the event and activities include leafleting in condominiums and a signal on the site chosen warning the imminent arrival of a new garden. The direct participation in an event of Guerrillas increases the interest of the neighbourhood towards this strange action, which is illegal, it happens at night in the flowerbeds near the houses, which for years have been left neglect. People fall curious and realize a revolutionary concept: they, too, can take care of public space. The evolution towards actions on public space and the lack of enforcement actions are evidence of the limited sense of ownership of public space and the consequent neglect in which it is.

The mode of organization of the movement and aggregation of the guerrillas are held mainly on the Internet, through social networks. This mode of virtual aggregation gave the opportunity for a real and physical mobilization exercise. The social Network, in this case, has subsidized the typical function of the city to provide a space for formation of ideas, which are generated in a virtual space through a comparison of experiences and desires of people. Interestingly, these modes of aggregation encourage physical action on the city, but it is also worth noting how the city as an organism that can produce innovation by connecting intelligences is now in competition with other tools.

The Santa Rosalia Gardeners actions on the neighborhood Albergheria in the historical center of Palermo

The actions of the Santa Rosalia Gardeners are also ascribable to the movement of guerrilla gardening, but this group has decided to focus on a specific part of the city of Palermo, retracing more closely the mode of action of the beginning of the movement that concentrated their actions on a specific place for a long time, like the Garden of Eden stated previously or Green Guerrilla by Liz Christy.

The Santa Rosalia Gardeners actions take place within the historical center of Palermo. This area, paradoxically marginal (Lo Piccolo & Leone, 2008; Cannarozzo, 2000, 2008) is proposed as an ideal playground for the resignification actions proposed by the Gardeners. The empty spaces in the district are still often the outcome of the collapse of the Second World War, while the historic fabric of the medieval matrix has been replaced by partial demolition, the result of nineteenth-century project of the city continued throughout the twentieth century. These interventions have created a space in which schizophrenic hybridize languages and functions.

Figure 3: QR code Use it with you Smartphone to see a related video

In this arena Santa Rosalia Gardeners move, since the choice of name, evoking a poetic situationist. The reference to Palermo the patron saint is a pretext to ensure the involvement of citizens and the people using as a protective heritage the sanctity of Santa Rosalia. The reference to the Saint offers a consonance between the symbol most sacred and untouchable for Palermo and public spaces left without care, questioning, from a semantic point of view, affection and sense of belonging that is manifested in public spaces.

Figure 4: QR code Use it with you Smartphone to see a related video

The group's activities began in 2010 with the recovery of a flower bed on G. Barbieri street, between Porta di Castro street and the Mongitore street[4]. The group consists of residents and not, their choice to act on the neighbourhood Albergheria reveals the intention of highlighting the abandonment of public space and the peripheralization of a location physically in the centre of the city, but consistently ignored by the institutions. The Gardeners activity will be consolidated with the recovery of Mediterraneo Square, an urban void formally indistinct outcome of the collapse of a building unit, owned by the church[5].

Figure 5: QR code Use it with you Smartphone to see a related video

In this space the detailed plan for the Town Centre provided accommodation to green, but the use, before the Gardeners, was parking and landfill. The self-generated expression of the sum of the wills of individuals (parking and landfill) denounced a need and a necessity, while the field work by the Gardeners, the fact of dialogue with its citizens, has

[4] http://vimeo.com/40713786

[5] http://vimeo.com/40713785

created a shared understanding of the collective good which managed to go beyond the sum of the individual to become an expression of convenience goods (either the construction of the square). This empowerment should be the basis of institutional interventions on the city, because the generation of community is the only guarantee for a long-term management of the spaces.

The last intervention involving Gardeners, relates to a small garden space owned by the Institute for Independent Social Housing Palermo[6]. This space has been created within a unit buildings partially collapsed. This space created, but never opened and managed, was privatized and became a landfill before being recovered by the Santa Rosalia Gardeners. The story, in this case highlights an important aspect of these movements, rising as opposing forces, have an interest to do things, but not to be institutionalized.

The Gardeners were contacted by the result of their disobedient actions carried out around the garden, but they could not have direct management on the garden because they are not formally binding, or want to become. The garden was, therefore, assigned to the management of an formally association that has transferred the management informally to Gardeners.

This qualification of the story highlights an important aspect of spontaneous committees that act on the city. The purpose of most of these, in fact, is highlighting the need for public action and the Institutional city and not the will to replace it, as they tend to make associations formalized. To be clear the will of the formal associations of the third sector is to manage some parts of the public city, while the willingness of informal associations is to highlight the need for direct government intervention over the city. For this reason, the ethical approach to the work on public space is deeply different. From the point of view of urban policy this, leads us to consider carefully the generation of policies that tend to institutionalize the insurgent forces of a city. In many cases it is more appropriate to use these social forces such as the launch for institutional policies, in other words according to their side without overlapping groped or worse to attract them in an institution groove.

The mode of organization of the group are manifold and set up a more complex communication strategy refined than other groups. Social networks are used to gather ideas and organize group activities, a site is a sounding board to share and explain its nature and inspiration, and a newsletter keeps participants updated on the activities.

The Committee for the collective good actions

The actions of this committee are distinguished by a reasonable approach to design interventions, even before the demonstration. The purpose of the group is to create community around physical transformation projects. Their main interlocutors are the schools and aggregations of citizens who are asked to take the first step in working to

[6] http://vimeo.com/41490759

apply the action of the group. The instruments used are those of participatory planning, through which change is being proposed public space of the city.

In this case, actions do not focus only on urban green spaces, but come to define the furniture and made changes in the appearance of public space. The main purpose of the actions is to create a culture of collective good overcoming personalism and particularism. In this sense the action of the Committee is an interesting experience in the various reality of the insurgent citizenships in Palermo. The organization of events pass through a request by groups of residents who contact the committee to start along the path of participatory planning. The actions propose the construction of participated microarchitectures and paths of road adoption. In both cases, actions are proposed as a demonstrative element to increase the awareness of the collective good. The aim is to place under a way attention to act on the urban space based on the involvement of persons. Involvement modalities define a framework of action that requires a certain maturity from the citizens engaged, for this reason the Committee's actions were concentrated in some parts of town where the themes of participation are more mature and understandable.

Even for what concerns clandestinity of actions, the Committee has some positions less disobedient than other committees described. The need to make changes in physical space, in fact, has set up authorization procedures to achieve true partnerships with local authorities, as for intervention in Mario Francese square. Other work carried out on semi-public spaces or in which the use is public, but the property is private, have been carried out without the need of permits.

The Committee involvement Tools go through a web site that collects and amplifies the results of actions and social networks. However, the mode of action of the committee define it as a more restricted group when compared to other physical action has a prevalence of project action.

The Committee is proposed as a guide for building projects and urban micro-transformations in the city. His design approach provides a formal quality that no other movements have, but it puts on the background the direct and self building actions on the city and citizen involvement in the construction of public space.

Stories of struggle for the re / opening of parks and public spaces in cities

This section of the research brings together the experiences of insurgent citizenship that have highlighted the need for open public spaces of the city whose design process and construction is already completed or to be defined.

The physical actions on the city of Palermo are concentrated in certain areas that catalyze the insurgencies of citizenship. These locations represent physical evidence of the inefficiency of the local authority with respect to the need for maintenance of public spaces. Parks, theaters, meeting places, squares, docks already made are often left hanging waiting for a use. It seems more important that you do things rather than

use it. In Palermo, places physically retrained expect even decades before finding a use and before being opened to the public.

The story of the opening of the Park Ninni Cassara is the most valid to describe what often happens. The large green area, close to a very marginal district, has been the subject of a redevelopment began in 2005 and completed in 2009, but its opening in November 2011, should not be a decision of the local administration, but it's a conseguence of citizens committee action. Even between some difficulties, the park has become a particularly enjoyed place capable to renew a part of the city, generating flows of visitors who reach a marginal area of the city.

Figure 5: QR code Use it with you Smartphone to see a related video

Based on the successful experience of Park Cassara were born other initiatives that seek to pursue the opening of new public spaces with different instruments. The theme, as already mentioned, is slightly different than the other cases exposed. In this case is asked to the administration a specific question about a clear target. The municipality is placed in front of its faults and is asked to respond with consequent actions. The most direct derivation of the dispute over the Cassarà park is the movement that takes care of acqua dei Corsari park, also finished, but never really inaugurated[7]. In this case, the current administrative vacuum has not yet produced results, but the media tools and legal pressure are the same in all the two parks stories.

They have a different story, the actions born around the Uditore park and Luparello Fund in which the request of citizens' groups has been structured around places not yet built or planned. In particular, the Uditore park is an area where it was constructed an action of participatory planning to arrive to formally define the park. In this case the action of the committees was not antagonistic to the administration, that was an entity with which talk to get the actual construction of the park. In the case of Fund Luparello, however, the action arose in relation to the defense of green agriculture from Italia Nostra association, in relation to speculative uses proposed for the area, however, in contradiction with the master plan. The actions on cultural spaces have focused, in recent months, around two places strongly connoted: the Garibaldi theater and Cantieri culturali della Zisa. Very often some spaces have a strength and a legacy to connect these energies that are generated around them by taking a strong symbolic value (Kohn, 2001). Notwithstanding the reasons, the claims and the history of the movement, is important in this short paper, to outline what are the tools and channels used to build the insurgent movement or to facilitate the participation of citizens and movements to build dialogue between the Committees and other institutions. The two things go hand in hand and feed each other. In the case of Cantieri Culturali della Zisa antagonistic actions resumed places

[7] http://vimeo.com/40727333

and thoughts about an area already well equipped for the culture, but tragically unused. Reflections are channeled into a series of focus groups that summarize the results of the meetings. This mode of action has brought such a credibility to cause the Commissioner who administers the city to grant the use of the cinema of cultural sites to the Committee itself.

In this case it was established a relationship arduous but healthy between the institution and insurgent citizenships. Where the local authority takes note of the demands coming from below and give room to the inurgent movements. Where all this will lead is unclear, but certainly boosted and increased production of confrontation and thought on the city. Listed below are the main tools and strategies used by movements to pursue their claims and the main channels used to engage participants.

Cassarà and Acqua dei Corsari Parks

- Proposals and involvement actions for the citizens
  - Class action and legal notice act against the Municipality asking specific answers for the non-use of the spaces,
  - Demonstrative actions
- Main communication channels
  - Social Network

Uditore Park (U'Parco)

- Proposals and involvement actions for the citizens
  - Participatory planning,
  - Collaboration with the institutions
- Main communication channels
  - Internet site
  - Social Network

Fondo Luparello – Italia Nostra

- Proposals and involvement actions for the citizens
  - Awareness Actions,
  - document processing and scientific research to illustrate the situation of the site
- Main communication channels
  - Internet site
  - Social Network

Garibaldi Theatre

- Proposals and involvement actions for the citizens
  - Demonstrative actions (shows and happening) to improve the urban culture policies
  - Verification of the procedures for awarding public spaces of the city to associations.
- Main communication channels

    - Social Network
    - Word of mouth

Cantieri culturali della Zisa – The factory that we want

- Proposals and involvement actions for the citizens
    - Participatory planning,
    - Communication and descriptions on the sites
    - Physical actions for revaluation of the site
    - Development of a manifesto about the culture policies in the city
- Main communication channels
    - Internet site
    - Social Network

One of the preconditions generating insurgent movements such as those just described, is the presence of a strong speculative and intellectual context that has no methods and possibilities of work and expression and as such has the ability to regenerate the city using antagonistic actions and creative able that are underused.

To fully understand what happens in these places and through these movements has chosen to include in the text refer to certain videos that seem to be able to describe more fully the emotion that is also present in these movements.

The Mafia physicalization use of public space

The decision to conclude this survey with a pejorative use of public space is clearly provocative. You can not equate actions created to pursue the common good of an idea born from the will to manage and take profit from the public spaces, however, should highlight how the actions on public space are formally similar, so put a planter on a sidewalk is a similar action to put the bollards on a parking lot (as we shall see later), but they are well apart the aims pursued.

The Mafia is a complex organization, a powerful lobby with the specific characteristics also on the scope in the urban and city management (Cannarozzo, 2000, 2004, 2008). The main and the most unjust, perhaps, is to focus its attention on predatory goods that have little market value, but a high marginal value.
It is for vital goods, to be clear:

- Water,
- The air,
- The urban space
- ...

All these goods are shared by definition, are so common that their market value tends to be very low, but they are necessary so that their marginal value, or value that is assigned when the good is scarce, it is very high. The state, guarantor of such goods, not always claims their public nature.
In these folds the Mafia is organized to manage and pay for these goods to those who do use them, exerting a very strong power and coercion.

Very often these enforcement mechanisms are real but invisible.

The Mafia handles most of what is not managed and monitored daily by state and local authority: car parks, public spaces, water, garbage. This happens for various reasons, sometimes the state abdicates its role clearly, other times it simply fails to honour its commitments.

This hood above the town is not seen, acts on connivance, on coercion and conventions. But sometimes it happens that the management of criminal territory discloses even through physical signs. The extortion demand of lace Parking is a small sign and, basically, is possible to avoid it, but if an obstacle occupies the public space, which an operator authorizing the parking lot removes, is a different matter.

In the historical centre of Palermo if you want to park your car in a public road you can find some bollards, you expect a few seconds and it comes a "gentleman" who "authorized" to park by moving the bollards (also public) he took care to be taken from a restricted area and arranged in good order. The Mafia does not almost ever see!

In the following photos you can have the exclusive privilege: see the hood of the mafia of the city, where to park on a public space you have to ask permission to a person who has taken the bollards for the mobility of public properties and uses them for his private purposes with which appropriates public space. All this happens while the city is moving normally, and all is normal. This fake outrage of normalcy is another feature of the Mafia.
Perhaps this story does not speak of the great Mafia, who organizes one of the lace and peddles drugs, but talks a lot of relationships with rights and in particular with the public space that's in the city of Palermo.
Compared to virtuous cases that have been exposed previously is also assists in this case to a modification of the public space, but with very different purposes. It is also important to understand how thepublic space in Palermo is an arena within which they move a lots of different forces that do not all contribute to the definition of the common good.

Conclusions

The attention to the argumentative turn in planning outlined by Fincher and Forester (1993) is the framework that has structured the exposure of very different cases presented in this paper. The methods of research and action on the field in many cases allowed interacting directly with the movement coming to tell a story that is emerging as a revolution that comes to design autonomous geographies (Chatterton, 2006, 2010, Pickerill and Chatterton, 2006). However, it remains in the background a strong effort making claims to whom would be appropriate to give an answer in terms of urban policies.

The insurgent citizenships of Palermo are describing a path positively creative for regeneration of public space not promoted by urban policies. In this sense the schedules described by Florida (2000) in which creativity is a tool and a strategy to compete with parts of a city in decline, and even by Landry (2003) in which creativity is seen as a force capable of fighting some effects of globalization, are overcome and integrated into a new vision where creativity blossoms into independence as long as there are some preconditions. The spontaneity of the creativity is in continuity with the passing of the formulas set out by the urban marketing Palestino (2009) as ingredients and conditions to open paths of urban creativity.

The preconditions, encountered in Palermo cases, relate primarily to a technology shift that has been strengthened and structured in recent years.

The development of social networks has, in fact, given the opportunity to simulate and enhance an important social aspect of the city having a multiplicative effect of the ideas together with a sum function of thought.

The arrangements of the Internet already described by Castells (2001) in fact allow not only to add ideas and thoughts in a container, but to generate comparison on the same having a multiplicative effect. This has always been a function delegated to public places and is one of the preconditions for self-organization of insurgent movements. The second condition is the availability of a social and cultural context of high level that does not find room for expression and representation. The third is a state of disuse or underuse of public spaces. The fourth is the lack of cultural policies that generate a strong "hunger" of events, ideas and thoughts. These conditions are all present in the actual context of the city of Palermo and they are a very local expression and hard to find in other cities. The comparison of the reported cases

shows that none of the movement is free of an organization that passes through the social networks and the Internet. This has at least two aspects: on one side accentuates the features of the hedonistic contemporary society, and the other helps to organize thoughts and gives order to the history of outbreaks by providing a clear framework for those who decide to approach them.

Many questions remain suspended: the first one concerns the role of virtual communities. It is not clear how long these communities will need to get to propose a physical action on the city or if they do not come to a point of dematerialize their protest too.

It is an extreme example, but that should be taken into consideration because the city is risking to lose the primacy of the function to be an enhancer of intelligence in favour of virtual social communities. At present, the city seems to be a theater in which its occurrence and the casual relationship between physical and people seem unavoidable, but it will always be so?

The second aspect concerns the manner in which you can promote generation of creative energy self-produced, or what are the most effective policies to do so. In this case what is important and necessary, beyond spells and saving, is the ability to listen to the local authority to be able to build a dialogue with the insurgent forces of the city to prevent situations of conflict, but for channeling energies into durable paths and sustainable over time.

The insurgent movements described are deep affinities with the work of Danilo Dolci in Sicily in the 50s and 60s, especially with the reverse strike of 1956 in Partinico. In that case the principle was to strike working against unemployment. The action of Dolci, achieved by a process (Calamandrei, 1956), has many similarities with those conducted by insurgent movements.

Beyond the physical and tangible actions on the territory, the example of Dolci helps to understand how the generation of a conscious thought and creativity is the main legacy, more profound and lasting action to fight like those insurgent movements, even in the face to a lack of institutions.

ADAPTING TO CLIMATE CHANGE: THE NEED FOR EU COHESION POLICY TO ADJUST FUNDING

Kathrin Prenger-Berninghoff [1]

Abstract

Climate change is inevitable and is why the need for mitigation and adaptation has become obvious. Both approaches need to play an important role in future climate change policy. Until now mitigation has always played a bigger role in the fight against climate change than adaptation and policies implemented in the 1990s mainly focused on activities that foster mitigation. In the last decade more attention was paid to adaptation. But governments are still regarding the need for adaptation with different degrees of urgency. The problem of financing adaptation strategies is probably one of the most evident reasons for the current restraint. However, adaptation is of great relevance and should play a bigger role in the future.

One climate-change-associated area already trying to put in place measures and investments that help Member States and regions to mitigate and adapt to climate change is the EU Cohesion Policy. Climate change may cause certain impacts, which might negatively affect some regions, thus changing socio-economic patterns and exacerbating existing inequalities. It should therefore be of interest for Cohesion Policy to support regional adaptation strategies and to specifically invest in actions improving the adaptive capacity of a region, in order to avoid those effects that counteract its own policy objectives. Consequently the incorporation of adaptation into its funding efforts and the reduction of climate change risks are turning into a major task. However, a challenge will be the appropriate application of funds. Until now Cohesion Policy has concentrated on economic indicators only. The fact that the risks of climate change will be unequally distributed and that both developed and less developed regions can show low degrees of adaptive capacity is not taken into consideration. Hence, it is suggested that Cohesion Policy considers other indicators, such as the level of adaptive capacity or regional vulnerability, in the future, rather than just focusing on indicators such as the GDP per capita. Such an approach would benefit developed and less developed regions and thus comply with both objectives; efficiency and equity.

Due to the fact that adaptation has so far been rather neglected from the policy side, this paper highlights the need for an adjustment of the EU Cohesion Policy funds in regard to climate change adaptation. After first explaining why both mitigation and adaptation are equally important in handling the risks of climate change, this paper will demonstrate why action at EU level in the context of climate change adaptation is necessary and reasonable and explain the current funding approach. Cohesion Policy and the consideration of climate change-related vulnerability will then exemplarily be closer examined in the Italian Veneto region. The example will hint at the required changes and improvements that Cohesion Policy needs to make in

[1] Institute of Urban Development, Krakow, Poland – kathrin.prenger-berninghoff@tu-dortmund.de

order to further promote adaptation and resiliency. Finally, the current role of climate change in Cohesion Policy will be outlined and the reason for an adjustment of funding mechanisms clarified.

1. Introduction

1.1. Considering climate change impacts within the EU Cohesion Policy

Climate change is inevitable and is why the need for mitigation and adaptation has become obvious. Until now mitigation has always played a bigger role in the fight against climate change than adaptation – from a scientific point of view as well as from the policy perspective. Policies implemented in the 1990s mainly focused on activities that foster mitigation (Swart & Raes, 2007). In the last decade more attention was paid to adaptation. But governments are still regarding the need for adaptation with different degrees of urgency (Gagnon-Lebrun & Agrawala, 2006). The financing of adaptation strategies and measures combined with the uncertainty of the actual risks of climate change is probably one of the most evident reasons for the current restraint. However, adaptation is of great relevance and should play a bigger role in the future.

One climate-change-associated area already trying to put in place measures and investments that help Member States (MS) and regions to mitigate and adapt to climate change is the EU Cohesion Policy. Climate change may cause certain risks and impacts which might negatively affect some regions, thus changing socio-economic patterns and exacerbating existing inequalities (CEC, 2007a). It should therefore be of interest for the Cohesion Policy to support regional adaptation strategies in order to avoid those effects that counteract its own policy objectives. Consequently the incorporation of adaptation into its funding efforts and the reduction of climate change vulnerability are turning into a major task (European Commission DG Climate Action, 2010). However, a challenge will be the appropriate application of funds. Until now Cohesion Policy is concentrated on economic indicators only. The fact that the impacts of climate change will be unequally distributed and that both developed and less developed regions can show low degrees of adaptive capacity is not taken into consideration. Hence it is suggested that Cohesion Policy considers regional vulnerability in the future, rather than just focusing on indicators such as the GDP per capita.

1.2. Objectives

The objective of this paper is to highlight the need for an adjustment of the EU Cohesion Policy funds in regard to climate change adaptation. After first explaining why both mitigation and adaptation are equally important in handling the impacts of climate change, this paper will demonstrate why action at EU level in the context of climate change adaptation is necessary and reasonable and explain the current funding approach. Cohesion Policy and the consideration of climate change-related risks will then exemplarily be more closely examined in the Italian Veneto region.

The example will hint at the required changes and improvements that Cohesion Policy needs to make in order to further promote adaptation and resilience. Finally, the current role of climate change in Cohesion Policy will be outlined and the reason for an adjustment of funding mechanisms clarified.

2. Analysis

2.1. Mitigating and adapting to the impacts of climate change

As indicated by the IPCC, climate change is happening and is human-induced. Consequently, climate change scepticism and a cautious behaviour are no longer justifiable. In contrast, mitigation and adaptation strategies are more affordable and reasonable than inaction with its subsequent damages and costs (UNDP, 2007; CEC, 2009a).

Therefore, mitigation and adaptation should play an important role in future climate change policy. On the one hand, projected climate change impacts can only be limited or in the best case prevented, when the main driver of climate change – the current amount of greenhouse gas emissions – is being reduced. For that reason the EU has to implement measures that promote, for instance, a low-carbon economy. Ignoring the importance of carrying out mitigation measures might increase the risk of adverse climate change impacts. As a consequence, costs for adaptation measures could rise (CEC, 2007b). On the other hand, climate change is already underway. That is why, at the same time as mitigating, it is important to adapt to climate change. Adaptation is supposed to either reduce the risk of expected negative impacts or to deploy possible favourable effects. However, adaptation action should not be misinterpreted as an alternative to mitigation. According to the Green Paper 'Adapting to climate change in Europe – options for EU action', there are several reasons for this. First, certain climate change impacts simply cannot be reduced by adaptation. Second, with growing impacts adaptation becomes more cost-intensive. Finally, while mitigation measures have global affects, adaptation measures rather operate regionally and locally, so that lagging and less developed countries or regions are being disadvantaged (ibid.).

The regional impacts of climate change differ among Europe. Therefore climate change needs to be tackled at the regional level. However, the main problem is that not all the Member States, or regions respectively, have the same capacity to mitigate and adapt. Furthermore, not all governments regard the need for adaptation with the same seriousness. For instance, although all MS have included information on the current level of their adaptation plans in the Fifths NC's to the UN Framework Convention on Climate Change, by 2010 only twelve European countries had adopted national adaptation strategies (EEA, 2012). This implies two consequences: first, as not only the impacts of climate change will vary throughout Europe, but also the capacity of European regions to adapt to these changes, support from EU Cohesion Policy will be essential in order to avoid the deepening of regional disparities, which might arise when unprivileged regions are left alone to cope with

adverse impacts. Second, adaptation measures have to be adjusted to the potential climate change impacts, and the diverse impacts need to be tackled and adaptation measures realised at regional level. This is why MS should promote the implementation of national, but also of regional adaptation strategies.

2.2. The need for action at EU level

As stated above, different response strategies are needed at national and regional level. Certainly, the implementation of concrete strategies and measures is in the responsibility of national governments. Nevertheless the EU has a certain saying and also the duty to co-ordinate and offer support to its MS, in order to promote the preparation of national and regional adaptation strategies and to foster mitigation and adaptation across the whole European territory. As the EU has already been involved in certain climate sensitive policies (agriculture, energy, water etc.), an additional involvement in associated sectors is considered as useful (Rayner & Jordan, 2010). In fact, an adaptation policy at EU level will have several favourable effects in general.

Climate change is quite a complex issue. Actual effects of climate change depend on several aspects such as the exposure of a region, the sensitivity of exposed elements as well as its adaptive capacity or the stage of socio-economic development etc. Due to this enormous variability, a multilevel governance approach is necessary, where all actors and stakeholders from local levels to the EU level are involved. Although adaptation measures are usually implemented at the local level, the regional level is also very important in adapting to climate change. Regions with a low adaptive capacity would particularly benefit from more information and a better co-operation. The uncertainties of climate change cause problems in securing concrete information and knowledge and in guiding regional authorities which prevents effective policy-making (CEC, 2009b). So the regional level alone cannot cope efficiently enough with the adaptation to climate change.

As a result, the EU needs to be involved in order to provide for the co-ordination of regional adaptation initiatives across the European territory. By adopting a coordinative function, by ensuring a comprehensive and coherent approach and by supporting adaptation measures, major gaps between EU countries and regions may be avoided (CEC, 2009a; CEC, 2009b). The EU could also assist in the design of efficient adaptation policies. Furthermore, municipalities and regions will most likely be in need of financial support as they will not be able to enable adaptation when left alone with the funding, so that the questions of burden sharing and solidarity and the development of a new financial support framework shall arise (CEC, 2009b). Thus, there is no doubt about the importance of certain co-ordination at EU level.

2.3. The need for new funding mechanisms

Solidarity among Member States is a necessary prerequisite. The notion of solidarity should be contained within the adaptation strategies in order to help those who need

(financial) support most (CEC, 2007b; CEC, 2009b). In this context the European Commission also highlights the role of Cohesion Policy, which "can further contribute to address the consequences of new disparities between those regions which suffer most from climate change and those that can more easily cope with its impacts" (CEC, 2009b, p. 21). The Fourth Cohesion Report already pointed out the important role of climate change in the EU Cohesion Policy and the necessity to analyse, how climate proofing can be integrated in those programmes and projects that will be financed by European Funds such as the Cohesion Fund, the Regional Development Fund and the Rural Development Fund (CEC, 2007b).

Public funding of adaptation measures is a major requirement. Adaptation measures will most likely only receive private funding when located in less affected regions and when provided for economically interesting projects. As a consequence the less developed regions, especially those most at risk, will likely have difficulties obtaining private funding for their investments or risk coverage. If they receive appropriate funding at all, it will most likely only be at comparably high costs, which might lead to the creation or deepening of disparities and inequalities between stronger and weaker regions. For the latter regions, public funds are the most important source of financial support, mainly in cases when natural hazards or extreme weather events hit the region (CEC, 2009b). In order to fill this gap, the Commission plans new funding instruments which will serve to finance long term adaptation. But there will be a great competition for those funds, as many regions will be in need for them. All the more, investments into projects have to take future climate change impacts into consideration, i.e. promote those that support mitigation and adaptation measures and prevent those that hinder them. Accordingly, the Commission acknowledged the need to determine how EU funding mechanisms within the next multi-annual financial framework can better support MS in becoming more resilient to climate change (ibid.). Financial help will be necessary in order to develop and realise adaptation strategies that help reduce vulnerabilities and thus also contribute to the reduction of disparities.

An important step towards a more successful and target-oriented adaptation policy was the adoption of the EU White Paper on Adaptation to Climate Change. In the EU White Paper the importance of financing adaptation is acknowledged by the explanation, that "climate change is one of the priorities for the current multi-annual financial framework (2007- 2013) and it is important to ensure that the available funds are used to reflect this priority" (CEC, 2009a, p. 13). This means that funds and other financial instruments shall be applied better and more efficiently, especially in view of the fact that the total EU budget may not be increased, but only redistributed. Therefore all climate change relevant sectors need to define specific adaptation strategies including an estimation of adaptation costs, which can then be considered by the prospective financing schemes. In addition the Commission foresees actions which comprise an increased incorporation of adaptation actions into the EU financing schemes of the current period as well as a review of existing funds, in order to improve their use and capability when addressing climate change vulnerability in the coming framework (CEC, 2009b). For example, the Cohesion

Policy instruments of the current period should be used and exploited in a way that climate change adaptation can be supported. At the same time each project or programme that is applying for or already receiving EU funding shall be tested for its mitigative and adaptive capacity and its vulnerability to climate change respectively. It is important that adaptation activities are being considered when preparing Community funding programmes. This means that investments into infrastructure or buildings should generally take account of the projected changes in climatic conditions (CEC, 2007b). Thus, certain adaptation measures should already be integrated when designing a programme. Therefore the Commission is aiming at mainstreaming mitigation and adaptation in the EU's Operational Programmes. Further options for integrating the funding of adaptation into the next multi-annual framework should also be evaluated (CEC, 2009b). The actions proposed in terms of financing clearly highlight the necessity to integrate adaptation issues, i.e. in particular adaptation funding, in current funding instruments and in the financial framework after 2013. The Impact Assessment accompanying the White Paper points out once more the future task of Cohesion Policy, to take mitigation and adaptation into account when adopting the Operational Programmes and when deciding on and managing the use of EU funds.

However, some initial ideas that had been considered important before were not elaborated within the White Paper. For instance, the Commission's original plans to integrate adaptation measures into the EU budget and allocate funds directly to them were cut out (Rayner & Jordan, 2010). Rayner & Jordan (2010) also criticized, after examining the "Impact Assessment", that several options had been dropped too early. This includes those options that imply considerable adjustments in EU financing schemes, which are difficult to foresee under the current framework (CEC, 2009b). They concluded that the discarding of these options is a sign for the incapability of the EU to change its investment patterns and to purposely add the adaptation dimension to future funding schemes.

This means the Commission's intentions are honourable, but they lack an actual realization.

2.4. Cohesion Policy and climate change adaptation in the Veneto region

A closer look shall now be taken at Cohesion Policy in the Veneto region. Although it is usually the less developed regions that are in need of financial aid for adaptation measures most, the Veneto is insofar an interesting example region, as it represents a rather rich European region, but at the same time also one of the most climate change vulnerable ones (Figure 1). It is therefore essential to implement mitigation and in particular adaptation measures and to increase the adaptive capacity of the region in order to decrease its vulnerability. The region is covered by the competitiveness and employment objective and is thus supposed to generally invest less funding in mitigation and adaptation activities or has less funding available for these kinds of activities. However, the region is expected to actually have a great interest in improving its adaptive capacity in order to stabilise and preserve or even improve its

competitiveness and to protect its citizens, especially against river floods or flash floods, and its important cultural heritage.

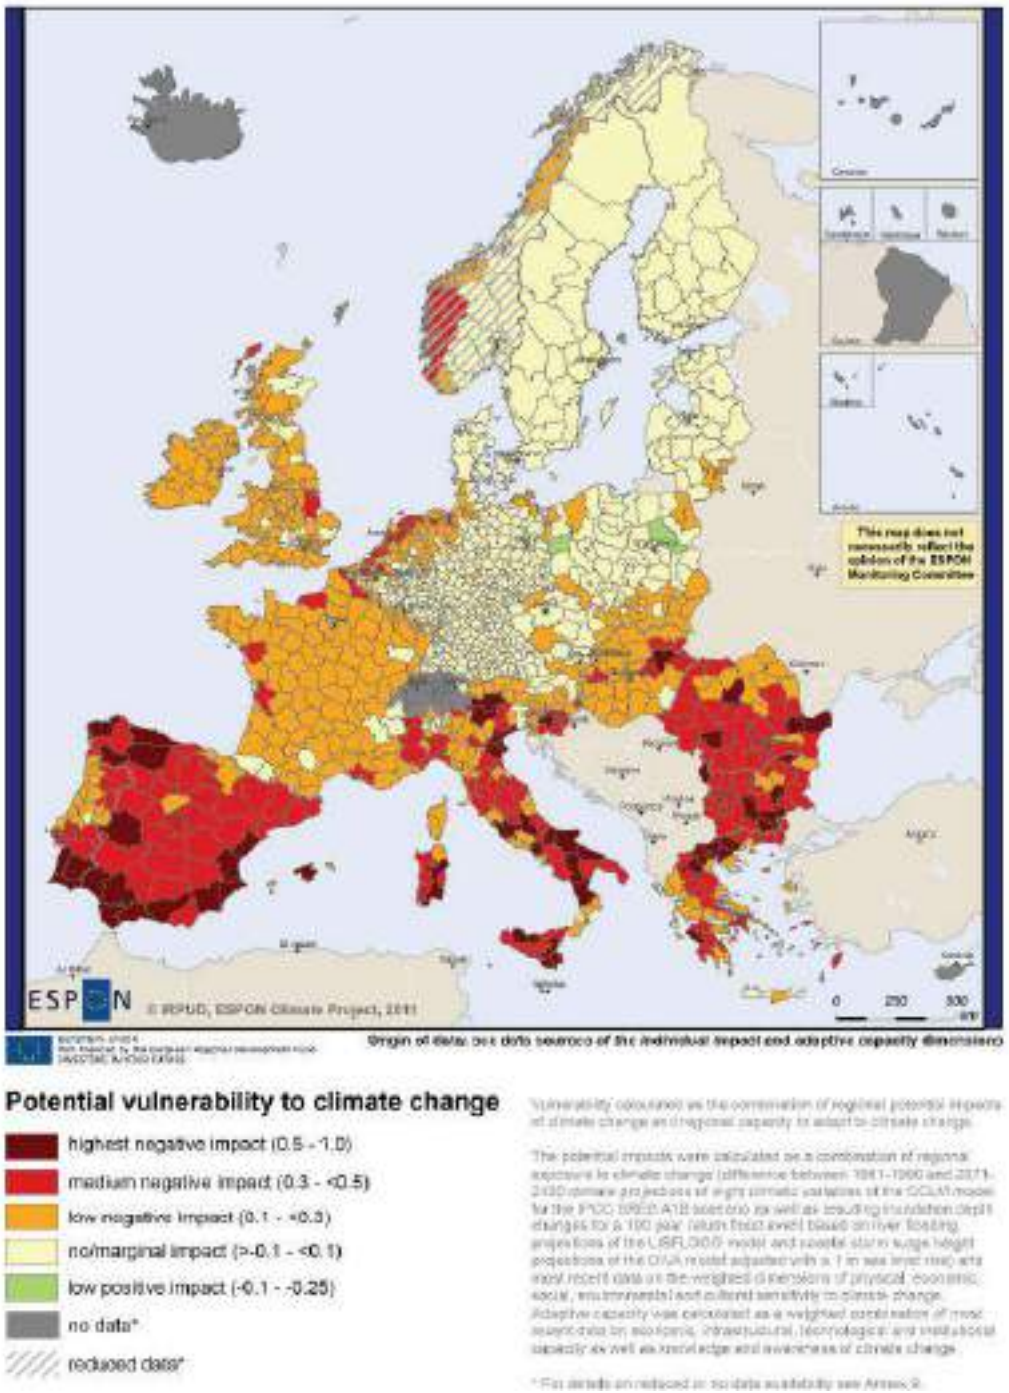

Figure 1. Potential vulnerability of European regions to climate change (Source: ESPON & IRPUD, 2011, p. 24)

In the current programming period, Italy receives around 28.8 billion Euros. Most of its funding (around 21.6 billion Euros) will be invested in the convergence objective, i.e. for the lagging regions in Southern Italy. The regional competitiveness and employment objective has a budget of 6.3 billion Euros. The national level adds

another 31.3 billion Euros funding for its regions within these two objectives. A major part of funding in Italy is directed towards the goals of the Lisbon Strategy: growth, jobs and competitiveness (CEC, 2007c; CEC, 2009c). It strikes that climate change activities or measures to fight or adapt to climate change are not taken into account in the national direction of Italian Cohesion Policy. Investments into climate-proofing as well as mitigation and adaptation measures are not mentioned, nor is risk prevention. The fact that investments in the field of climate change could also lead to economic growth, the emergence of new businesses and thus new employment opportunities and potential innovation is not being considered.

The Veneto region has a total funding amount of 452 million Euros available for its Operational Programme. In line with the above said, investments will mainly be made in fields that support the Lisbon objectives. However, one of the priorities of the Operational Programme is "Environment and risk prevention", which implies actions that try to minimize health risks as well as measures which are supposed to contribute to an intact environment by protecting the natural heritage and historic buildings (Zuliani, 2007). Even if the protection of the environment as well as risk prevention play a certain role within the Operational Programme of the Veneto region, at no point is the problem of future climate change impacts specified. "Risk prevention" is expected to be a rather general term and not necessarily directed towards risks posed on people, settlements and the environment by climate change. A concrete attacking of climate change-related risks and effects can therefore not be assumed. On the contrary, the priorities indicate a clear focus on the Lisbon Strategy objectives, by rather investing in economic growth and job creation.

European coastal regions generate a high share of the total GDP of the EU, thus they are not only economically important, but also economically sensitive. The Veneto is one of those productive coastal regions and generates a high economic activity, representing one of the most competitive regions in Italy. Since the costs of inaction in coastal areas, i.e. costs related to coastal flooding and erosion, would rise up to 6 billion Euros per year at EU level by the year 2020, adapting to climate change is quite essential for any coastal region. Accordingly, policy makers should be aware of the respective vulnerability of a region at local level in order to take adequate adaptation measures (CEC, 2009d). Severe risks in coastal areas could impact the local and regional economies and might harm a country in terms of GDP. Hence, not taking any adaptation measures might have severe consequences for a region's or a country's competitiveness.

The EU may support risk reduction and adaptation measures, for instance by providing for financial aid within the specific priorities under the funds of the EU Cohesion Policy (Structural and Cohesion Funds), which regions can apply for. Generally speaking, funds for coastal protection works can mainly be looked for at national and EU level. About 4% of the total investments into coastal protection and risk reduction measures are defrayed by the EU (Figure 2) (CEC, 2009d; CEC, 2009e). In the light of the economic importance of coastal region, this constitutes a comparably low share. The bigger part of investments (63% over the period 1998-

2015) still needs to be procured by the national governments of the MS. Both, national and regional authorities together, make up for 95% of all expenditures, which is a high share compared to the 4% the EU contributes. In view of the fact that decision makers usually do not consider the option of inaction, precisely because of the enormous socioeconomic effects of future risks, MS are financially challenged (ibid.). This might turn into a problem especially for less developed countries that have to procure a high amount of national funds which might also be needed for economy-related investments such as the promotion of entrepreneurship, the creation of jobs or infrastructure development.

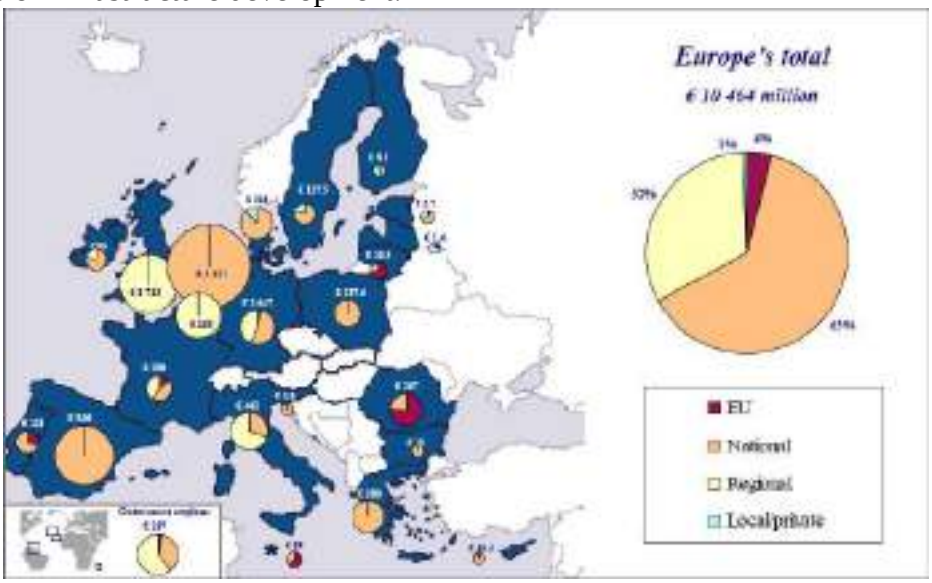

Figure 2. Normal coastal protection expenditure at European, national and sub-national level (regional, local and private) across Europe in € billion (1998-2015) (Source: CEC, 2009d, p. 11)

The Adriatic basin in northern Italy is supposed to be at high risk from sea level rise, coastal and river flooding, especially the Po Delta and the Venice Lagoon. The city of Venice, for instance, counts as a highly vulnerable part concerning flood hazards and extreme weather events. Reasons for the vulnerability of the Veneto region are its exposure to climatic changes as well as its sensitivity in form of existing socio-economic characteristics, such as a dense population and the presence of numerous economic activities, e.g. tourism, agriculture and industry (Carraro & Sgobbi, 2008; CEC, 2009e). Especially against the background, that the overall impact of climate change is relatively high in the Mediterranean, and especially in the Veneto region, the adaptive capacity needs to be equally high in order to cope with the projected future impacts.

In contrast, it has been proven within the ESPON Climate project "Climate change and territorial effects on regions and local economies", that the vulnerability of the region stems, among others, from a low adaptive capacity (ESPON & IRPUD, 2011). As noted above this would actually be essential to fight the impacts though. The more surprising it is that no EU funds are allocated in the Veneto region. In fact, no EU funds are allocated in Italy for coastal protection at all, but it is solely borne by national and regional authorities (CEC, 2009d).

Considering the fact that adaptation measures do not play a very big role within the Italian Cohesion Policy anyway, it can be concluded that the current EU Cohesion Policy is not paying much attention to the respective vulnerability to climate change of a region and that adaptation measures are handled rather carelessly. In Italy Cohesion Policy focuses on the Lisbon Strategy and tries to achieve economic growth and more jobs. However, it does rather neglect the fact, that climate change impacts could have an adverse impact on these efforts, by affecting local and regional economies, thus counteracting economic development by harming physical infrastructure and/or human workforce. This is against the spirit of EU Cohesion Policy, which actually intends to promote regional competitiveness and employment in the more developed regions to maintain the strong overall competitiveness of Europe as a whole. Consequently, EU Cohesion Policy should make sure that its own efforts are not undermined. A potentially greater contribution of Cohesion Policy in regard to climate change adaptation should therefore not be left disregarded.

2.5. Cohesion Policy weaknesses and the current role of climate change

Cohesion Policy is a very adequate tool to reach economic growth and prosperity as well as solidarity throughout the European Union. The DG Regional policy has an enormous funding capacity after all. Though, to ensure all the different benefits the policy holds, its funding must be appropriately applied, so that its value can be used to the full extent (CEC, 2010a). For instance, Cohesion Policy funds can guide investment decisions by preferring the funding of adaptation measures or by demanding that the funded projects take account of future impacts (European Commission DG Climate Action, 2010). As an allocation of EU funds for the improvement of adaptive capacity is quite an essential requirement, the involvement of the DG Regional Policy is of great importance.

The Europe 2020 Strategy, the follow-up strategy of the Lisbon Strategy, and Cohesion Policy shall be very closely aligned. As the benefits and targets of Cohesion Policy can only be ensured when funding is purposefully applied, a specific focus on the Europe 2020 objectives is not far to seek. The Europe 2020 Strategy offers not only specific priorities to focus on, but also a framework that helps identify funding priorities. The reason for aligning Cohesion Policy with the Europe 2020 Strategy is that this linkage can help promote both, a further development of poorer regions within the EU and further growth of the EU as a whole (CEC, 2010a). However, this points at a further strong concentration on rather unprivileged and less developed regions within the EU.

Cohesion Policy intends to advance a balanced development of European regions and Europe as a whole. Therefore it aims at reducing existing economic, social and territorial disparities. To promote a harmonious development, Cohesion Policy supports investments that tend to achieve improvements in the fields of competitiveness, employment, social inclusion and environment (CEC, 2010b). However, despite some successes achieved in regard to competitiveness and

cohesion, a report for the DG Regional Policy, compiled by Fabrizio Barca in 2009, revealed the limits on judging policy performance in quantitative terms. In an analysis of the policies' strengths and weaknesses, two conclusions could be drawn: First, a place-based approach or strategy should be implemented and the policy should concentrate on just a few priorities which play a big role for the union and its citizens (Barca, 2009). Second, there needs to be a general reform of Cohesion Policy in order to be able to meet all the different challenges the EU will face in the coming decades. The report outlines that the policy has to distinguish between two goals: 1) increasing income and growth, known as the efficiency objective, and 2) reducing inequalities, known as the social inclusion or equity objective. Choosing and determining the above mentioned priorities requires a comprehensive political debate. Six potential priorities were recognised, one of which is "climate change" as part of the efficiency objective (ibid.).

Often Cohesion Policy is equated with financial redistribution within the Union. However, neither the efficiency nor the social inclusion objective could be achieved by a mere redistribution of (financial) resources among MS. Instead, the main purpose of Cohesion Policy is institutional improvement. By providing the needed goods and services, the work of public authorities should become more efficient (ibid.). In addition, Barca (2009) points out, that Cohesion Policy should consider all regions and not only the poorer ones, as social exclusion and weak institutional capacity can arise everywhere. However, current and future Cohesion Policy still seems to stick to "business as usual". The DG Regional Policy bases its policies primarily on a model of economic competitiveness, where environmental factors are hardly represented (Rayner & Jordan, 2010). Dhéret (2011) refers to this approach as an outdated system and claims that cohesion funding should not be limited to GDP indicators only. And even for the next period the allocation of funds "would be differentiated between regions based on their level of economic development (measured by GDP per capita), drawing a clear distinction between 'less' and 'more' developed regions" (CEC, 2010b, p. 10). In consequence, the managing of financial support is not going to be altered for the next period.

The EU Budget Review introduced some proposals on how to better apply cohesion funding and maximise the benefits in the future. It is stated, for instance, that a greater concentration of resources on EU priorities will be essential. This corresponds to the arguments outlined in the report by Barca (2009). It could be done through an identification of specific, important priorities. Such a concentration on certain priorities would allow a better allocation of funds and the addressing of different needs (CEC, 2010a).

Furthermore the Budget Review mentions the necessity to improve the quality of funding expenditure. It recognises that the institutional capacity at all levels is a key element for successfully producing and implementing policies that are essential for reaching the Europe 2020 objectives (ibid.). In order to obtain high quality expenditure, the allocation of funds should consider the respective capacity of each MS and its regions to apply these financial sources in the most efficient way.

Consequently, it should be the task of Cohesion Policy to finance the capacity strengthening of the public sector, which includes also the improvement of adaptive capacity.

In his report on future Cohesion Policy, Barca also underlines the need to consider climate change, by admitting that "cohesion policy, as any policy aimed at delivering public goods and services, must take account of the impact on climate change when designing measures" (Barca, 2009, p. 136). The current EU funding period already tries to take account of the problems climate change induces. By allocating 1.3% (4.8 billion Euros) of financial resources to promoting renewable energy, 1.2% (4.4 billion Euros) for energy efficiency and 9.2% (31.7 billion Euros) to the support of green transport, a step in the right direction has been made (ibid.). However, these investments only regard mitigation, not adaptation. This means that there are still several weaknesses in the current allocation of EU funding.

It has to be acknowledged, that in the Fifth Cohesion Report climate change finally plays a bigger role than in previous Cohesion Reports. A whole section is dedicated to "Enhancing environmental sustainability", which concentrates on the future challenges of climate change and environmental degradation. In fact, the Commission even approves the territorial dimension of climate change and the role of Cohesion Policy to provide for a certain coordination at EU level by stating that "the growing threat of climate change and the political goal to radically increase the share of renewable energy in the EU underlines the fact that policies at different levels will need to be coordinated to respond to these various threats and opportunities in an efficient and effective way and to avoid them counteracting each other" (CEC, 2010c, p. 124). This shows the Commission's awareness of the future task of Cohesion policy in regard to fighting climate change impacts, although a focus on mitigation is obvious, so that certain limits and weak points still remain.

3. Why adjust funding?

Summarising, it can be stated that there are several weaknesses of Cohesion Policy that should be addressed in the near future in order to achieve the efficiency and social inclusion objectives. First, there is no real place-based approach and territorial perspective yet. Second, there is no focus on priorities and the efficiency and equity objectives are not being addressed specifically enough. Third, attention is mostly paid to financial aspects and Cohesion Policy lacks an intervention in all European regions. At a first glance it is reasonable that under current conditions and in view of a rather difficult financial situation Cohesion Policy (or EU policies in general) rather focuses on economic aspects such as cost-effectiveness and an output-driven performance (Dhéret, 2011). But when aiming at considering both objectives, efficiency and equity, it is necessary to go beyond this economic rationale.

Climate change does in fact need special consideration. Due to its different regional pattern it needs a place-specific approach. It was shown by the ESPON Climate project that countries which are highly affected by climate change also seem to have

the lowest level of adaptive capacity and are mainly less developed, poorer regions with a low competitiveness index. This hampers cohesion as it might actually widen existing disparities between Europe's heartland and the peripheral countries. This is why the unequal distribution of vulnerabilities to climate change requires particular efforts which should help in changing these vulnerability patterns and in reducing imbalances in order to meet the key challenge of Cohesion Policy. Hence Cohesion Policy needs to take account of these varied vulnerabilities and of the risk of widening territorial disparities when designing its next funding period (ESPON & IRPUD, 2011). Although Cohesion Policy is already aware of the problem and the fact that it has to take over responsibility in climate change issues, it lacks the actual process. The urgency of the matter requires yet an immediate adjustment of policies, with a distinct focus on the improvement of institutional, or adaptive capacity respectively.

It has also been proven that there are vulnerable regions in more developed parts of Europe such as the Veneto region. A generalization of the given conditions, i.e. a general assumption that high economic development also means a high level of adaptive capacity, would therefore not take reality into account. When these regions are affected heavily by climate change, this could also have negative consequences for cohesion. This fact implies the need to consider the vulnerability of a region and to try to improve its adaptive capacity for increasing resilience rather than just concentrate on economic values. It is essential that future Cohesion Policy considers other factors and indicators than just the GDP so that its contribution to the Europe 2020 objectives can be facilitated and advanced. Only when it pays enough attention to other driving forces that determine cohesion and competitiveness, future Cohesion Policy will be able to translate and achieve its main objectives.

This future mission has also been clearly formulated by Barca (2009) who claims that Cohesion Policy must inevitably consider the specific climate change impacts when elaborating and implementing measures. It has already been pointed out, that mitigation and adaptation are unavoidable necessities to stabilise and promote competitiveness and cohesion. The current EU funding period already tries to consider this, by allocating a comparably high amount to climate change mitigation. Although the Commission acknowledges, that a certain financial support in regard to mitigation and adaptation will be necessary and that funding can and should support the development and realisation of adaptation strategies, much more emphasis has to be put on the application of funds.

Consequently, the weaknesses in the current allocation of EU funding need to be tackled for the next period. An identification and improvement of the potential of funds should take place so that they can be better used for addressing climate change vulnerabilities. It should also be ensured that climate change aspects are included in the funding reporting. In general Cohesion Policy needs to make sure, that its instruments are applied for climate change adaptation. As stated by the IPCC, a high economic development and existing technology are not the only aspects influencing adaptive capacity. Factors such as human capital and educed institutional abilities are

just as important. Thus, it shall be pointed out, that the adaptive capacity of a region must be considered and not only the level of economic activity: a high level of economic development does not necessarily imply an equally high degree of adaptive capacity (Adger et al., 2007). Accordingly, Cohesion Policy needs to take adaptation into account when adopting Operational Programmes and when deciding on the use of EU funds. It also has to consider the distributional effect of climate change and its diverse consequences across Europe. Adaptive capacity determines the vulnerability of a region and thus impacts current and future territorial disparities. Therefore it is essential that Cohesion Policy not only focuses on economic aspects, as it does now, but also on indicators such as the adaptive and the mitigative capacity (ESPON & IRPUD, 2011), as these have a significant influence on the level of achievements of the cohesion objectives.

4. Conclusions

As the Operational Programme of the Veneto demonstrated, the region's objectives are strongly focused on the improvement of the competitiveness and on the reduction of regional imbalances, while the problem of future climate change impacts was not addressed. The priorities indicate a clear focus on the Lisbon Strategy objectives, without taking account of the necessity to adapt to climate change. The Veneto is a relatively competitive and economically high developed region, while at the same time being vulnerable to climate change impacts. Further economic growth will most likely trigger the current vulnerability and cause conflicts between economic development and adaptation to climate change. Nonetheless, investments in adaptation, especially in coastal protection, are urgently required in the short term in order to maintain its current status. Here, those strategies should be prioritized where synergies with economic development options exist. However, there are no EU funds allocated in Italy for coastal protection, which means that coastal protection in Italy is borne by national and regional authorities. This example implies that the current EU Cohesion Policy is not paying enough attention to regional vulnerability to climate change and that the need for adaptation measures in some regions is rather neglected.

The example of the Veneto region also hints to the importance of considering all vulnerable regions, not only the less developed ones. Mitigative and adaptive capacity has to be high, so that a region can cope with future impacts. Economic development is just one of many determinants of adaptive capacity. It should not be generalised that only less developed regions have a low level of adaptive capacity. Vulnerability also concerns more developed regions, which means the focus cannot be on the level of economic development alone. In fact, climate change impacts could have even more severe outcomes for the regional and national economy – and thus also for the regional and national competitiveness and the competitiveness of Europe as a whole – when the more competitive regions, i.e. those regions that are highly productive in economic terms, are being affected and weakened. All regions and citizens can be concerned with disadvantages and thus should be equally protected. A high GDP is not a guarantee for the ability to adapt to external changes.

In conclusion, it can therefore be stated that the allocation of Cohesion Policy funds should be based on more indicators than just on the GDP and that other indicators, e.g. those that determine the adaptive capacity of a region, must be considered. Such an approach would benefit various regions and thus comply with both objectives; efficiency and equity. Taking account of the respective vulnerability of a region could therefore help, allocating EU funds in a more reasonable way.

DOWNSIZING DETROIT: RESHAPING DETROIT O RESHAPING PLANNING?

Valeria Fedeli[1], Marco Facchinetti[2]

Abstract

Detroit: the images and numbers of the crisis of a city and an economic system have fed up the pages of local, national and international news during the last two years. In fact, the city has become the symbol of how a city can 'die'.

Actually this situation is not a recent one, dating since the sixties and seventies. But the recent economical crisis has particularly exacerbated the frailty of this, as many other cities in the American rust-belt. Press and media have grasped the importance of the case, providing chronicles of a dramatic urban condition, but also chronicles of research and projects, public and private, of ways to get out of the crisis. These include on the one side a particularly striking revival of the practice of urban agriculture, which has brought to the light the traditional role of this economic activity in the history of American cities, but also a challenging way to stress the same idea of "city" and the relation between "city" and "growth". On the other side this process is dealing with the challenged role of planning: where on the one side there is a new federal urban agenda, with a revived central action proposed by President Obama, and on the other a local administration, with a major, like Bing, which is proposing uneven programs to contrast foreclosures effects and dealing with NGOs action in order to save the city.

The paper will discuss the case under two perspectives .

The first is related to the reinvention of city-ness, in which the city is engaged. Where the city-ness (Brenner, 2009), is what makes a city such a place, livable and vivid (a "city that works", is the title of Major David Bing): which kind of city-ness for Detroit ? which kind of city-ness for the city after the crisis? What is the role of urban and nonurban, of density and proximity? All traditional urban paradigms seem in fact to be at stake. The second is about "planning": what is the role that planning can play and which challenges to planning is the financial crisis urban effects proposing?

1. Introduction: Cities under the current economic crisis.

Considering the 2011 Mc Kinsey report (2010), more than half of the Gross Domestic Product (GDP) produced in the entire world during 2007 has been generated by the economies of 600 cities, where approximately 22% of world population lives. The first 100 world cities in 2007 have produced the 38% of the world GDP; projections over 2025 contained in the same report assumed that more than 25% of world population would be concentrated in those 600 cities, engines of the entire economy, raising to 60% the share of the world GDP they would produce. During 2007, and more evidently during 2008, a large, sprawled financial and economic crisis has produced significant changes, as well as, the projections over the future and the paths of growths assumed for the future of the urban economies. From many points of view, the global economic crisis exploded in 2007 created a reduction of jobs and wealth in 7 out of 8 cities of the OECD countries. according to the GLOBALMETRO MONITOR 2011 Report (2010), (written by the Brookings Institute in cooperation with the "Cities Programme" sponsored by the London School of Economics), less than half of the examined 200 metropolitan areas increased their economic conditions if compared to the data before the crisis began.

The economic crisis that hit the world started from a financial crisis and it boomed when this latter touched the real estate market, first and above all the residential real estate market, something evidently connected to the idea of urban development in the last century. In fact since the beginning of the new century, many urban areas and systems around the world have pushed the local economy, supporting with low interests mortgages and huge public investments the transformation and growth of many urban environments, confirming to many national economies that urban areas and cities were able to boost the economy of the whole country. After the beginning of the crisis, this system began to be under pressure; the effects are now evident in several cities, deeply affecting their processes of growth and development.

The recent international literature has started reflecting upon the role that cities have played and are now playing during the financial crisis. At least, two points of view emerge: for many scholars urban development and growth are still the only possible answers to economic and financial crisis and the city is destined to play a key role in the economic recovering (Glaeser); on the opposite side, for many others authors urban development and many contemporary urban environments are responsible for the size of the crisis and cities are required to rethink their role accordingly to a different development model (Harvey, 2008). In both cases cities are central again, even if regarded as problems or solutions (Donzelot, 2008).

If the crisis generated different effects and different reactions in the western world urban environments, at the same time, also the answers and the solutions urban planning and planning policies gave to the crisis have been different. In any case it can be stated in this perspective, that not only cities have been questioned and

stressed by the crisis, but also urban planning is being questioned. Considering all the differences, it is possible to say that several fundamental pillars of contemporary urban planning are challenged by the current economical crisis: among those, we could consider, just as an example, the mechanisms and tools of public –private partnership. Lack of resources from the public sectors on the one side, involved in investing its limited resources to assist emergent social troubles, and lack of convenience on the other in investing in urban development processes from the entrepreneurs' point of view, together with a general reduction of the possibilities to borrow money, put into crisis this XX century mechanism. This sufferance is blocking many urban regeneration or redevelopment projects and shelved many sectors of the constructions processes, showing even in this case how weak was the world of contractors and builders, pushed to grow in the precedent lucky period but too weak to bear the new crisis. All the factors that helped the building sector to be one of the main actor on stage of the previous period of urban growth are now in sufferance, and the engine of urban development slowed its run, putting urban environments in a new condition of projects stalled, stopped, abandoned.

Simultaneously, therefore a new big pressure over urban planning started: urban planning is supposed, much more than in the recent past, to be able to address, if not to solve the problems, and find a way out the crisis. On the one side, as in previous crisis, public works are seen as a way-out of the crisis: on the other side planning can be considere a way to produce new courses of action and new common frameworks against uncertainties, both for public and private actors, both for citizens and economic actors.

Nevertheless planning is not at ease in this situation, since some of the tools on which it has based its approach to urban problems in the last decades can no more be taken for granted; at the same time the crisis is producing further effects on some of the most relevant and well-known problems of contemporary city (growing dualisation, for example), paradoxically lowering down others (the environmental dimension, or traffic congestion). This opens up the possibility, as in every crisis, to reverse the perspective and produce important innovations. As a matter of fact, if 1929 crisis has fostered the introduction of social welfare in developed countries, and the 1973 crisis fostered a renewed attention to environmental issues, we could expect that the current crisis could offer new space for innovation. Under which perspective it's hard to say: nevertheless we could try to contribute to this moment challenges, adopting a challenging perspective towards the contemporary urban question (Secchi, 2011, 2010) and the role planning and public policies can play.

In order to do that the paper selects a case study, which is considered interesting under many respects, even if not exemplar or exhaustive, because of its specificities.

The city of Detroit is in fact the object of this paper. The city has been at the centre of many attentions since many years under a more general perspective of

investigation on urban crisis; as such it is considered since quite a long time as the symbol of urban decay and urban crisis in American literature. Already in bad economic conditions since the sixties, the city suffered even more from 2008 and for the global crisis, that speeded up the process of abandoning homes and neighbourhoods, whose mortgages in many cases were no more affordable for residents.

The focus of the paper is twofold: on the one side the first paragraph presents reflections concerning the process of downsizing of the city, which has naturally occurred in the last decades and has been assumed as a general aim of the new urban policies of the Mayor Bing. The demographic size of the city has in fact been consistently changing in the last decades, producing a process of physical shrinking that is leaving many parts of the city without any kind of use; from an industrial metropolis to a strange discontinuous combination of CBD and suburbs, the physical downsizing of the city has become a central slogan for the preparation of the new plan. Actually "downsizing" Detroit, means at the same time reshaping the city, redefining its form and role: thinking the city form and the urban space and organization in a new way for a different population and for different uses from the consolidated ones. But how can a city like Detroit can be reshaped? If "downsizing" in fact can be more simple to be achieved, bulldozing entire neighbourhoods abandoned by people and activities reshaping the city is a hard task. Not only in terms of the form of the built environment, but also in terms of the entire urban organization.

In order to "reshape" Detroit a process of revision of the urban plan has been seen as the right solution to address the problems of the city. Actually two years after the decision to produce a new plan to reshape the city, taken by the mayor Bing, it became clear that in order to reshape the city (and not just to downsize it) a normal plan process could not be effective and a reshaping of planning itself was necessary. Also in order to address some of the long-term problems that the city has accumulated during the century, which have to do, not only with the economical crisis, but with the way in which the city has developed during the last century in relation with the urban region it is part of. As it is demonstrated by the fact, that, while the economic seems to be recovering, the city is now still living a very dramatic moment.

2.1 The recent past: a city too big for its population

In the last 50 years, Detroit has lost more or less one million of residents, about 57% of its population before the trend started. Many other Northern US cities have lost population during the last 50 years, as a national trend of residents moving from the historic cities to the suburbs, or to more economical and fiscal attractive cities. Many cities have seen numbers declining, and people moving out to find new jobs, new urban environments or new opportunities, but Detroit’s trend cannot be seen, studied and considered as part of a national trend. Its

exception is easily analyzable: the increase of population loss has been so evident in the last 10 years, that the recent Major Bing question:"who will live here?" has been the most justified question at the beginning of his job in 2010. Not considering here the trends of population mobility and population transformations, the most relevant aspect of this change has been the physical transformation of the city: when residents left, they left their homes and their neighborhoods so empty that more than 40 squares miles of urbanized and urban lands where considered in 2010 completely empty and no more lived by anybody. A size as large as San Francisco urban area[3]. In the two years between 2010 and 2012, these completely empty urban lands generated a big loss of employments, with more than 24% of unemployment rate, a number particularly high if compared to the national level of 9% of unemployment during the same years.

The crisis that hit the city comes from the very specific way in which the last 100 years have pumped it up very quickly, and then, as quickly as before, history has deflated it. Together with the fast growth of the automobile industry and its related world, Detroit grew and flourished maybe more than many other cities in the US, becoming the symbol of a town able to grow at the same pace than the main industries that shaped its urban environment. A well designed city center, a rationalized system of neighborhoods in between the city center and the industrial belt, a world-known designer for its major park, made the city of Detroit a symbol of how an industrial town can be attractive and economically very productive.

After few years, considering how long is human settlements history, and more or less in 30 years, Detroit became a different symbol, absorbing all the bad of economic changes that affected western world during the passage from fordist to post-fordist economy. The book "Origins of the Urban Crisis: Race and Inequality in Postwar Detroit" (Sugrue, T.J., 1996) focused on what was already happening more that 15 years ago and it is considered nowadays as one of the most brilliant and evident study about the so called "narrative of failures", addressing in particular urban policies failure. So, after having been a symbol of economic growth, with the same evocative power, Detroit has been described already more that 15 years ago as the symbol of a failure and today we can easily say that the image of Detroit is the example of Northern American urban policies failure. The urban crisis began to hit the Central Business District, and it became worldly renowned for its being able to close historic buildings, to leave abandoned masterpieces of past architecture and to keep value away from the most central and prestigious part of the central city and its downtown areas. Above all, many people, in a typical American way of facing troubles, considered first of all the city as a economic environment, and they judged it so unable to regain its past position to look for a different future without it, leaving it and searching for applications and jobs elsewhere.

2.2 The present: a shrinking city

[3] www.detroitworkprojects.com

This crisis in fact generated, soon after the reduction of the central city values, the continuous loss of population in the suburbs: it became thus evident that the entire city of Detroit was on the center of a stronger catastrophic phenomenon. All the urban aspects of the city are now under a particular attack: no people enough to populate commercial and recreational activities, no more city dwellers enough to live in the built up spaces, no more citizens enough to use public facilities and services or to claim the use of them.

Once again, many North American cities have lived such a dramatic change: from the rusty belt to upper New York State, the effect of economic changes has hit the central business district first and the inner residential city soon after. Cities like Albany, NY, Buffalo, NY, Rochester, NY, Cleveland, OH, Toledo, OH, even Chicago, IL have seen a decline of population in the city center and soon after in the first residential belts around it, seeing at the same time new suburbs flourishing as a different place to live and work.

In Detroit, for the first time in the urban American history, the city showed that even the suburbs where affected by the same problems and processes of abandon. Residents and users left the suburbs, the highways, the shopping complexes and the industrial areas. For the first time, Detroit showed that the crisis was so deep that even the physical result of the American Dream wasn't strong enough to resist, and the combination of residential suburbs, highways and commercial strips was about to surrender to the crisis.

We can easily argue that this aspect was not the core of the crisis, but only one of its aspects. The core of the crisis, clear in the way it emptied suburbs and highways, was the failure of the public policies of urban renewal mainly focused on the regeneration of urban central areas. Detroit and its crisis showed clearly that the crisis was able to hit a urban and territorial typology such as the suburbs at the same speed that was revealed when the suburbs where planned and built. The loss of population left abandoned the sprawled city keeping away very quickly the fragile sense underneath the origin of suburbs themselves.

In this way, and under these forces, the city began to shrink.

It is not the first time in human history, and in the history of cities, that a shrinking of the whole size of the city happens: European medieval cities were smaller that Roman Empire towns and villages; Colonial South American establishments were more than half of the pre Colombian cities. But the shrinking forces that affected Detroit showed for the first time in the US history that a modern city can be smaller instead of being larger; that suburbs can be the most awful places to be instead the epitomes of the American Dream; that urban renewal policies cannot be effective by default, resulting otherwise in a huge waste of money and time, that traditional planning is not able to cope with such a situation; in general that a certain kind of reasoning, adopted by a city (people, as well as politicians and economic actors) cannot address similar processes of change without a changed perspective.

At the beginning of 2010 the situation of the city was evident, well known and already so studied to be able to produce graphics, data, images, analysis absolutely clear: the economic change that affected the way productive processes re organized themselves during the 80's and the 90's generated huge changes in the economic organization of Detroit industrial economy, first of all reducing the first and most important product the Detroit engine was able to produce, automobile. And bringing together down to the paths of crisis the specific urban environment created by that world, suburbs and generally speaking, sprawled city.

In "Leaner, greened Detroit" (American Institute of Architects, Sustainable Design Assessment Team, 2008) this situation was already well described and evident, even if with a strange feeling, considering Detroit' situation as something that could always happen and as something a city can avoid easily, investing in its fundamentals and in its DNA's aspects. Detroit population in 2008 was around 800.000 residents, already less than half its 1950 population; 40 squares miles in the city were already without meaning, and something between 3000 and 5000 buildings set empty. Urban decay was the word used to describe the situation, in the 2008 report.

Describing the fast change from a sprawled city growth to a spotted city fast decline, the 2008 report introduced clearly the race matter and the struggle between white and blacks communities. By the 1950's, the movement of more affluent families to the suburbs had already begun, but the riots of 1967 turned that movement into full-fledged "white flight", changing the destiny of the central parts of the city and the history of the inner part of the city. From 1950 to 2000 Detroit population plummeted, as factory after factory closed, and its economic condition steadily worsened; and as white-collar employment moved to the suburbs along with large parts of the city's middle class, the population who remained in the city center and in the inner city, before the sprawled areas of the white suburbs, was poorer, and more highly dependent on public services. But the city, without enough affluent people paying taxes, could no longer afford to provide just those services. So, from the early stages of recent history to 2008, the fast changes of Detroit urban geography can hardly be separated from race's struggles and race's geography. In 2008, over 80% of Detroit's population was African American, with approximately 666,000 residents, plus a large part of population belonging to the Latino southwestern triangle. More or less, the same geography of 1970, showing that while white American population had the opportunity to leave the crisis and the declining city, the poorest part of population couldn't, and it became the largest part of its residents.

The 2008 AIA report turned to be very optimistic about the way Detroit could save its future and change its decline into a challenge, and it is from these years' perspective that Detroit has been seen as a "shrinking city". The report focused on the challenges of the city, many of them, after 4 more years today, still persisting, but considered at that time as central elements of a renewal strategy: the architectural heritage, history, legacy and physical assets, with a well recognizable CDB with a value in architectural, artistic and historic legacy is still to be

reclaimed to a contemporary beauty and prosperity; the power and cultural diversity of neighborhoods is still a problem, today, rather than being that opportunity able to glue together parts so different in the same urban environment; even the matter of the size of the city, that for the first time appeared during those years, is still a problem rather than being an opportunity to re-imagine the urban condition, and the city has been very close to bankruptcy, due to the relations between general, administrative size, number of taxes collected in that cluster and costs for maintaining everything the original size required.

The recent history and the last 5 years have in fact shown the deep relation between loss of population, economic crisis, tax collection reduction and territorial assets' troubles. When residents have left the city, in many cases they left the buildings where they used to live; without any customer and any dweller aiming at buying them, the buildings remained abandoned; the first self help for people already left, trying to balance the cost of owning an apartment or a building and not being able to sell it and to gain a rent from it, has been to stop paying taxes to the city. This way, the municipality of Detroit began to collect properties instead of taxes, finding itself as owner of more than 67,000 units, left abandoned, without taxes paid for years, and expropriated to relief the loss of tax gains. This policy, more or less natural for a municipality, brought to the situation we see today, with the municipal budget below zero and a huge concentration of derelict building without any possibility to produce any profit. In this respect the city council has acted in deep isolation from both the state and the county, behaving as a singular and individual actor on the institutional and political scene. In this sense the focus on the traditional urban renewal tools and objects, on the one side, on the other the isolation from the larger urban region and the institutional framework, as a result also of the contraposition between the black city and the white-state provoked a collapse larger than ever expected.

2.3 The future: downsizing Detroit or reshaping Detroit

From 2008, the real challenge began to be evident. With a very pragmatic way of doing, from many voices the main suggestion was the reduction of the size of the physical area of the city. Even in the 2008 AIA report, and in many studies that followed, the reduction of the size was considered the best receipt not only to solve the problems of a urban dimension that didn't represent anymore the real demographic and social geography of the city, but also the way to copy with a more sustainable way of thinking and planning the city.

The emphasis on the size came to be evident. And the main question started to change: Detroit began to be a smaller city and the question was whether a smaller city, and a smaller Detroit, could become a stronger, healthier and more sustainable city. From many points of view, even without investing in the way such a change could have been reached, local policies, expert studies started

considering enthusiastically Detroit as a test to show that the shrink of a city was an opportunity to reclaim urban lands to agricultural uses and to reduce the need of public money to make a urban environment work.

Under this cultural umbrella, the new mayor David Bing called an already awarded US planner, Toni Griffin, professor of urban planning at Harvard University. The aim of the mayor was great: considering what he found when he became mayor, a city declining, a continuous reduction of taxes, jobs and population, David Bing decided to invest in a new general urban project, but with a different aspect. Without considering the opportunity to start a new, comprehensive structural plan for the re-birth of the city, the project called for a 12/18 months perspective called "Detroit Works Project", aimed at producing "an effort to map the city's future" following what Prof. Griffin said in one of the first interviews after she has been called to Detroit. "This leadership saw now as the opportunity to create a shared vision for the city, across sectors, and inclusive of broad civic engagement. I was asked to join the mayor's team to assemble and manage a team to create the vision with members of his staff".

The first idea, calling Professor Griffin, was ambitious: even if the possibility to generate a comprehensive plan has always been seen as very hard, in the first stages there was a general curiosity and expectation toward the production of a long term strategy which could save the city. After several months, however, with the worsening of the economical crisis, the idea of such a plan, based on certain datasets, and able to find a solution to the variety of troubles the city was living, was abandoned, even after many critics.

It is important to say that many of the critics, and one of the reasons for which the plan didn't work, were underlining an evident disconnection between the idea of the plan and the size of the maps it was considering, and the real city that was changing within the plan and within the city limits. Local associations and local organizations in December 2010 contested very hardly the idea of plan the mayor was working at, and they showed the deepness of this disconnection, above all showing how more important were experiences gained on the ground, day by day, by the spontaneous effort of local associations rather then data, technical points of view, academic solutions. Reading the reports of the public meetings held during 2010 a growing concern about the effort of the mayor is evident, and a general disaffection over its aims. During these public meetings, the disconnection between plan, tools and the real situation of the city gave the possibility to contest also the democracy of the process, with a mayor representing even less population day after day, considered in charge of planning a city that was no longer existing.

This criticism paved the way to a period of confusion, and to a systematic announcement of a new plan, full of solutions and above all able to plan the downsizing of the city, the concentration of the population still living in the city in few neighborhoods and the general, planned shrinking of the city. The question then shortly became evident: no plan would be enough well planned to plan for a city whose destiny was to disappear; if the choice was the reduction of the city

and the reduction of the urban area, the idea of a urban plan was in strong, evident opposition, so strong that for many months the option "no plan" became to be one of the most realistic, as well as feared.

Mayor Bing began to face a totally new, but at the end evident situation: Detroit as a traditional city was no more existing. Population was declining, jobs were flying away, economy was not recovering even if US were experiencing a general change over the previous economic crisis, the size of the cancer that was emptying many neighborhoods was even growing and the number of houses and buildings abandoned was so high that entire neighborhoods were now empty and without anything that could assure them to be part of a urban environment. The fiscal crisis of the municipality brought the city to a collapse on April 2012: no more money to spend, no more urban facilities able to operate, no more services assured for population.

But beside these facts, a different geography was still enough strong to be evident, in this derelict atmosphere: local communities, small efforts to change the destiny to some few, small, groups of blocks, the city Hospital and the Wayne University city campus able to supportt very limited but evident processes of urban renewal on the one side, plus some spontaneous phenomena of people getting back to the city on the other, were the facts that pushed mayor Bing to change his perspective and start a different process of planning, more tailored to this new urban geography.

As a result of this, the idea of a plan was changed into the idea of a process of planning, helping the city in developing a mid-term strategy by July 2012. While in the previous period dedicated to the elaboration of a plan at the same time the municipality had started the demolition of 10.000 houses in the city suburbs, starting a process of physical shrinking of the urban areas, the new season is characterized by a new process of public dialogue and outreach. Enhancing and supporting even more the public debate, the municipality started investing into a two levels strategy: from one side trying to keep alive a city commission for the new plan, even if without assuring money enough to make it run, in order to produce at the end a vision for the future, in the form of a new plan, on the other side concentrating some special projects over three different neighborhoods of the city, developed with the help of the citizens, listening and learning from the lesson cities such as Cleveland were showing to US cities trying to fight urban decline4.

[4] Cleveland started some processes of urban renewal investing in the neighborhoods and trying to find new energy from the revitalization of their economic and social environments. The Cleveland Neighborhoods Development Coalition (http://www.cndc2.org/) was created in 1982 and still working to focus urban planning attention on urban neighborhoods. From this experience and others, the city published the new 2020 perspective plan, Connecting Cleveland, aimed at creating a stronger link between communities.

Also at the federal level, within Obama administration, with the Strong Cities[5] program, many things were learned from the Detroit case: if the city itself change its physical, human, economic and cultural reason and size, urban policies should change and they should come back in the agenda of all levels, from municipal to federal. A group of target cities has been selected by the federal level, even if it was not clear how the help of the federal level could work together the local municipal policies and in coordination with the state level policies; this aspect has been particularly evident in Detroit where the opposition between municipal and state level policies was very strong, from all the points of view. In this situation, the strategy of the city changed completely: a two level approach is now evident, with a first, locally based approach to urban policies, focused on three sectors of the city and a second, long term strategy, rather then plan, able to work even sighing but following the time and the pace of the city. Downsizing Detroit had its first evident result: the re-sizing of the approach to the way the city should be thought and planned.

From this new approach, a new awareness emerged, maybe in a really pragmatic way of approaching the urban phenomenon. The crisis of the urban environment is still very strong, and it is affecting also the small cities around Detroit (The title "Hyatt is leaving Dearborne"[6] shows how the crisis is affecting also the industrial, established Ford's city headquarter). The idea of shrinking the city became to be really the only one available, and once again the American Institute of Architects developed a strategy to organize the city investing in its urban core and in few, established urban villages around it, leaving the space in between empty, with greenbelts and banked lands. And in many ways, the shrinking of the city and the new geography of a multi polar local organization gave the possibility to think to a new land use for the vacant lands: agriculture.

As a result the size of the city seems to change once again. From the urban prairie as it has been described[7] to a real prairie, where agriculture becomes one of the land uses in the new land use plan; Detroit soils seem to have all the characteristics to help this process: there is open land, fertile soil, ample water, willing labor, and a desperate demand for decent food. And there is plenty of community will behind the idea of turning the capital of American industry into ad agrarian paradise, with many communities aspiring to change Detroit into the first one hundred percent food self-sufficient city of the world. And today, Detroit is already producing more food inside its borders than any other traditional American city: about five hundred small plots have been converted and created by

[5] Strong Cities is a pilot initiative, sponsored by Obama administration, to strengthen local capacity and spark economic growth in local communities while ensuring taxpayer dollars are used wisely and efficiently. To accomplish this, federal agencies are providing experienced staff to work directly with six cities: Chester, PA; Cleveland, OH; Detroit, MI; Fresno, CA; Memphis, TN; and New Orleans, LA. These teams are working with local governments, the private sector, and other institutions to leverage federal dollars and support the work being done at the local level to encourage economic growth and community development.

[7] http://www.detroitblog.org/?p=287

an international organization called Urban Farming, founded by the songwriter Taja Sevelle. Realizing that Detroit was the most agricultural promising of the fourteen cities in the five countries where Urban Farming now exists, Sevelle moved herself and her organization's headquarters there in the last years. The goal is to triple the amount of land under cultivation in Detroit each year.

The different size of the city created room also for other locally based phenomena, able to change step by step and little by little the geography of the city. Raising while the incapacity of the official efforts was evident, a movement of people buying houses at ridiculous prices began to be evident. Toby Barlow 8 wrote in a New York Times article about people buying up $100 houses, moving to Detroit and doing all sorts of interesting things with them. Artists and architects, painters and inventors are buying some derelict plots and houses investing few money and trying to transform them in a local workshop of new ideas. Local, very small things such as "Heidelberg Project"9 or "Ancient Evenings Project" began to happen in the interstices of the declining city, filling them with new, little forms of urban life. Many other cities, such as Buffalo, NY and Cleveland, OH or Cincinnati, OH have invested just on these small, local efforts to invent something new so strongly that nowadays those cities are seen as the new "Rust Belt Chic".

3. Conclusions

Alongside a series of significant contributions in the field of economic studies (see especially Glaeser, but also Landry and Florida, Trigilia, Kurz) that quantify the current financial crisis and explore its economic reasons and relationship with the 'city', in order to come to a general conclusion of this paper, a series of reflections coming directly from the world of urban studies shall be taken into consideration, which focus on the challenges that the crisis is proposing to planning.

Particularly useful in this sense is to consider the section edited by Soureli and Youn of Critical Planning and dedicated in 2009 to discuss "urban restructuring" processes in progress as the result of processes induced by the crisis, but also as the actions of individual agents and collective response to the crisis, among which, we could say also the responses of planning.

That multi-voiced debate between Neil Brenner, John Friedmann, Margit Mayer, J. Allen Scott and Edward Soja, in fact presented already a general reflection on the crisis of the city and its urban implications and challenges in the field of planning, policy and action. It was argued that the crisis has introduced elements of turbulence in society and in cities and urban regions, which require not only a

[8] http://www.nytimes.com/2011/04/06/us/06detroit.html?pagewanted=all
[9] http://www.heidelberg.org/

greater ability to analyze precisely the effects on the city, but to address some theoretical questions that have to do with the conceptualization of the city and related approaches to planning.

According to Brenner in fact, first, the current crisis shakes the city processes of urban restructuring and questions the "city-ness of cities", i.e. what has made the city such a thing; secondly the city, involved in the crisis, appears, even more than we have hitherto refused to acknowledge, grappling with problems of trans-scale governance, crossing global and local (Friedman) and spatial and social effects of particular relevance in forms different from those to which we are accustomed to name and map (Mayer). Nevertheless, thirdly, cities, as nodes of cognitive-cultural economy, are again at the centre of important tensions: in fact the materials that have fuelled the contemporary city can reveal to be highly fragile in terms of crisis response (Scott). As a result, fourthly, the condition of transition to a different economic and social model carries with it a transition to new urban models, such as what Soja defines a metropolitan post-transition, where cities have become spaces of high volatility and mutability, rather than elements of permanence and stability.

On this base, as the Detroit's case seems to show, it is necessary to change deeply the conceptual frameworks that have so far been used to study the processes of urban restructuring generated by the crisis. The challenges in the field of planning, appear equally relevant. In fact, the crisis not only calls into question a revision of the mechanisms of urban development linked to a neo-liberal season (Brenner) but also pushes to sight the possibility of producing a vision antagonistic to the forms of regulation and planning that we have developed in this perspective. At the same time, according to Friedman, there is the need for a new "progressive view" of planning, one linked to the necessity to accept the idea of a finite world adopting a perspective of sustainability for the city, to avoid a process of commodification of everyday life adopting the reference to a friendly city, capable of nourishing the spirit and restore a sense of civic obligation, and where there is an economic accounting system capable of taking in count both system use values and exchange values. In spatial terms, finally, Soja, proposes also to work on new urban models (community-based regionalism) and multi-scalar coalitions that shall take more seriously into account new emerging urban issues, responding to a renewed request of "right to the city".

The case of Detroit, presents traces of these challenges and provides materials to be studied in order to reflect upon them. The changing size and form of the city is in fact deeply affecting on the one side the city-ness of this city; at the same time it is challenging the role that planning can play in similar conditions, showing its limits, but also the symbolic power it is still asked to play.

A CONTINGENT AND FLEXIBLE APPROACH FOR URBAN PLANS

José Antunes Ferreira [1], João Pedro Reis [2]

Keywords: Planning process; Uncertainty; Contingency; Programming; Management

Abstract

When the whole world is facing a global crisis, the efficiency and efficacy of urban planning process must increase in order to achieve more "value for money", especially when we are dealing with diminishing public resources. This crisis, due to the increased uncertainty, affects significantly all kinds of projection exercises and, consequently, the planning process that requires a prediction of context evolution in order to adequately schedule the actions proposed.

Usually the urban planning process, even in the operational level, has its action in medium/long term (10 to 12 years), which requires the adoption of new, more flexible approaches, allowing for a continuous adaptation to an ever-evolving context.
Once the urban plan is approved, the implementation process starts. It is in this phase that the programming and management are fundamental.

We propose a new approach to the programming, and implementation management of urban plans that aims at improving its chances of success and make the most of good opportunities. The basis for this new approach derives from the methodologies used in project management, so it becomes useful to understand it through the discussion of the differences and the parallels between a project and a plan. An urban plan process can be seen as a very complex project, with a large expected time of duration, a lot of relationships with other different projects, strong dependence from external environment, stakeholders from distinctive areas, and no strict time and budget limits.

The Portuguese law imposes that all urban plans have an execution program and a financial plan to support their implementation, but the vague and insufficient requirements and guidelines lead to incomplete and lacking roadmaps for an effective implementation. Given this situation, there is a need to (re)think how to program and manage the urban plans, namely through the introduction of new themes (the phenomenon of uncertainty and contingency).

[1] CESUR-IST – Center for Urban and Regional Systems – Research Group on Urban Planning and Environment, Instituto Superior Técnico, Technical University of Lisbon, Lisbon, Portugal – antunes.ferreira@civil.ist.utl.pt
[2] CESUR-IST, Lisbon, Portugal – joao.p.reis@ist.utl.pt

According to all aspects referred above the main objective of this work is the development of a programming and management model for urban plans which is able to incorporate different kind of contingent factors and has the ability to adapt easily to an evolving reality – a model that will face the uncertainty without stresses, while providing a flexible and adaptive way to adequately implement the strategy drawn on paper in the real world.

1 – Urban planning theory

Urban planning has, for a long time, been seen implicitly as a process of professional activity though, until the mid-1960s, it was practiced principally as an art form within a traditional design context (Bracken, 1981).

In general, definitions of planning from the 60's and 70's, emphasized its proactive and rational nature, characterized as: a mental process and a method to achieve decisions regardless of the planned phenomenon (Weber, 1965); an activity centered between knowledge and organized action (Friedmann, 1974); and a mental process of influencing the future (Faludi, 1976).

(Faludi, 1973) distinguishes different dimensions of planning, or concepts related to the way of planning, which are expressed as opposites and that are related to the different attitudes of the planning stakeholders and the socioeconomic and political context in which it develops.

The 1st dimension opposes the *plan-document* to the *plan-process*. On the *document* are defined not only the objectives but also the precise manner of achieving them, while according to the *process* view the established plan is adapted during the implementation whenever new information requires changes.

The 2nd dimension analyzes the rational/integrated planning against the unbundled/developmentalist planning. The first type of planning believes that all possible actions should be identified and evaluated according to all purposes, while the second considers that it would be impossible and undesirable to evaluate all actions that will be undertaken for all purposes.

(Kaiser, 1995) introduces the adaptive rational planning model as a logical and systematic path, from the definition of the objectives through to implementation. This model considers feedback cycles which may produce revisions to the process all the way back to its starting point, unlike the rational planning model, which doesn't consider the necessary changes over the time in order to, namely, gain acceptance by the community and to respond better to the transformation processes.

Based on the presented framework the authors identify themselves with the *planning as a process* concept in which the plans shouldn't be seen as *plan-product*, an expression of passive planning that starts with a commission and ends with a delivery, but rather as a structure and framework to support the decision making.

2 – Planning process

The act of appropriating the territory requires a conscientious judgment and achieves its most proactive dimensions through the changes made to the land use (Costa Lobo et al, 2000). These changes in the territory can be made through a spontaneous mode or based on a planning process.

Nevertheless, the concept of *planning process*, through which these changes are introduced to the territory, can have diverse definitions:

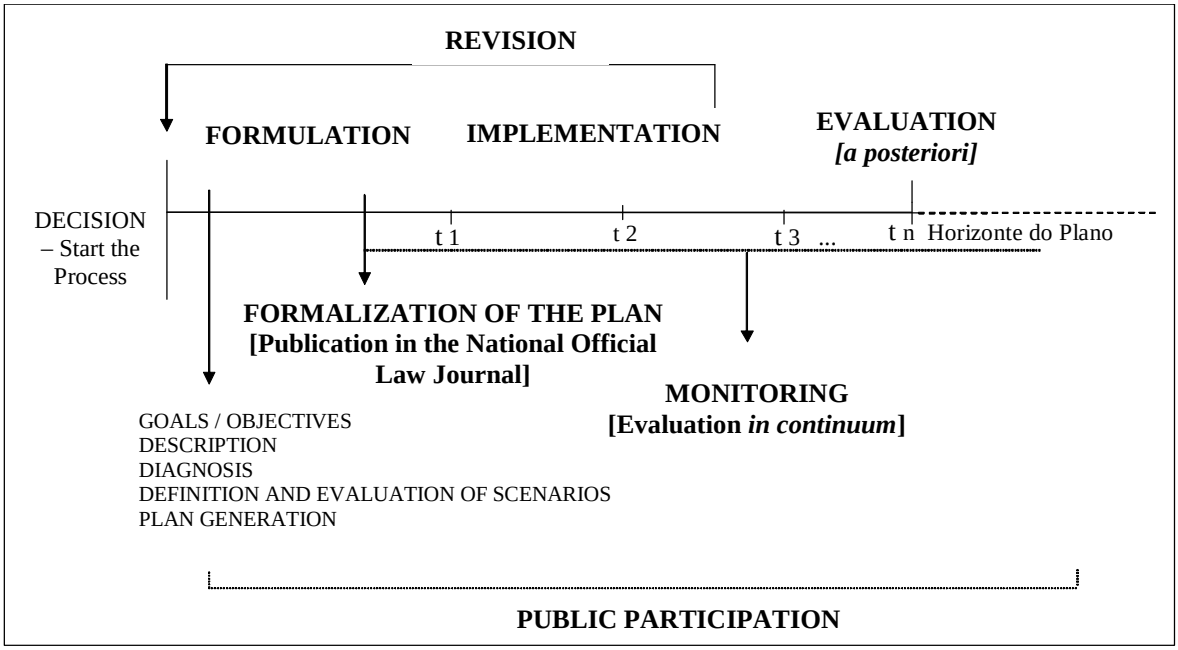
"(...)Planning is the deliberate social or organizational activity of developing an optimal strategy of future action to achieve a desire set of goals, for solving novel problems in complex contexts, and attended by the power and intention to commit resources and to act as necessary to implement the chosen strategy." (Alexander, 1992)

"Planning is an ongoing process that supports the practice of management which suppose a framework of responsibilities, skills and tools (…) Planning is therefore an optimization and urban management process which should be interactive in transversal subjects and in time line" (Costa Lobo et al, 1995)

For us the planning process needs to be continuous on the time and all its phases must be a sequence of cycles and not only one linear path. The figure of the *Plan* is very important throughout the process because it's assumed as the main tool for decision support in the implementation of objectives and actions.

The existence of the plan is important but not synonymous to the process' success because the reality isn't static, as such, the plan can't be limited to the status of administrative regulation without the management component. For this component to be effective, it is critical to conduct the monitoring and evaluation activities which allow the creation of alternative options and adapt the plan in face of new realities (not predictable at the first formulation).

Figure 1 – Urban Planning Process Model



3 – Portuguese planning system

The Constitution of Portugal is the highest regulatory instrument of the law at the national level. It intended to be a political project of desirable society. In it are laid down unequivocally the basis of a virtual model of territorial organization (…) with general objectives, based on principles of equality, economic and social justice in order to improving the quality of life, increasing social justice and defense the collective public interest (Alves, 2001).

During the 90's more attention was given to the organization and management of urban systems and to the deepening of the environmental component, in the context of territorial planning and the operationalization of the arrangements for safeguarding and protecting natural resources (Alves, 2001).

In 1998 was published the Law of Bases for Territorial Planning and Urbanism (Law n.º 48/98, 6th August) which sets the policy framework for planning and urbanism such as the territorial management tools that materialize it. This law also regulates the relationship among the various levels of public administration, between this one and population and with the different social and economic interests' representatives.

This law states the purposes, principles and objectives for land use planning and urbanism which should be pursued in the country, creates a territorial management system that is organized in 3 different scales (national, regional, municipal) and developed through a set of planning and land use management instruments. (Alves, 2001)

The regulation of the Law n. º 48/98 was made in the following year, with the Decree-Law n. º 380/99, 22th September. It defines the coordination between the different scales of the territorial management system, the general system of land use and the system for preparation, approval, implementation and evaluation of the territorial management instruments.

Table 1 - Type and scale of the Territorial Management Instruments: Portuguese context

TYPE		SCALE
PNPOT (National Program of the Planning Policy)		National
PS (Sectoral Plans)		National / Regional
PEOT (Special Plans)		National / Regional
PROT (Regional Plans)		Regional
PIOT (Inter-municipal Plans)		Regional / Municipal
PMOT (Municipal Plans)	**PDM** (Municipal Master Plan)	Municipal
	PU (Urbanization Plan)	Municipal
	PP (Urban Detail Plan)	Municipal

The issue of territorial scope (scale) plays a relevant role in the territorial management system embodied in the fact that the national, regional and municipal can't be understood singly. The main planning options and guidelines defined by the plans with a wider territorial scope and represented in small scales (eg. PNPOT-1.1000000; PROT-1.100000) need to be more detailed in the municipal level with the PDM (1.25000), PU (1.10000) and PP (1.2000) where the programming component is more tangible. In face of this reality, we think the most appropriate scale to address in this communication is the municipal (PMOT), whether by the proposed actions / interventions are more effective over the territory but also because in these plans there is a directly binding of the private landowners through spatial planning.

4 – Programming

4.1 What is it?

From the operational point of view a plan can be seen as a set of listed actions to respond to the defined objectives. To transpose the plan's objectives to the reality it's important to have all actions well described, scheduled over the time, with the allocation of available resources and funds and define the priorities depending on the imposed restrictions.

4.2 How to do it?

In the programming of urban plans there are some key procedures which are important to have a good roadmap for the implementation phase.

a) Inventory and description of the actions
A plan as a complex project needs to be structured into a set of actions which must be clearly defined with an individual codification and attributes for each action as well as the description of the tasks that integrate these actions.

b) Budjeting of the actions
In order to implement any action the balance between available financial resources and costs is essential. There needs to be an estimate of the costs through past similar actions or a compounded global cost based on the current unit costs.

c) Scheduling of the actions
On the actions' phasing it is crucial the estimation for durations which are many times associated with uncertainties. The scheduling procedure are influenced by some constrains such as sequential relationships, financial capacity and resources, and the political options. There are methods well known for scheduling that are very used in project management, such as PERT (Program Evaluation and Review Technique) and CPM (Critical Path method).

4.3 What the law requires?

The territorial management instruments that assume, clearly and unequivocally, a dimension of programming, are the PMOT's in the sense they are the only, together with the PEOT's, bind directly and immediately landowners. They are equally those for which the law gives the responsibility to pre-order the implementation and schedule tasks.

In the Decree-Law n. º 380/99 the programming for PMOT's is stipulated by the need to formulate an implementation program in association with a financing plan. To illustrate the law's requirements on this subject we present below the transcription of the articles.

Article 86. º nº2 d)[PDM] –implementation program, including namely indicative provisions about the provided municipal interventions as well as its financing means.
Article 89. º nº2 c) [PU] - implementation program, including namely indicative provisions about the provided municipal interventions as well as its financing means.
Article 92. º nº2 d) [PP]- implementation program for the provided actions and respective financing plan.

Thus we must take into consideration, to characterize this legally mandated programming, the level and type of PMOT that is in concerned.

In the case of a PDM (Municipal Master Plan), given the scale at which it's developed, this programming can not mean a rigorous definition of all steps, procedures and times of completion / achievement for the defined actions. This solution is moreover enhanced by its strategic nature which appeals for a programming type that, although it should maintains some accuracy, should not conform a very inflexible scenario in the implementation phase.

In the case of the PU (Urbanization Plan), being a planning instrument which focuses specifically on the use, occupation and transformation of the soil in urban and urban expansion areas, the programming must ensure that the main components of the urban system remain coherent between each other, and that the execution of needed interventions on it doesn't cause disruption on the urban life operations.

The Portuguese legal framework includes the figure of UOPG, an operational spatial unit for planning and management, which can appear either in PDM or at PU. These units admit a generous flexibility because only point their objectives and reference terms for future interventions or more detailed plans. Thus it's allowed a reasonable portion of modeling at the time of PDM's and PU's implementation, either by the possibility of actions re-priorization or still by identifying the concrete execution procedures.

The PP (Urban Detail Plan) establishes the distribution of functions, define the urban parameters, urban design, circulation and parking places, alignments, volumetric distribution, location facilities and green areas; it is the most detailed PMOT and very close to the architectural project concept. In this PMOT type the private biding has a high and strict level which, combined with its technical features, requires a programming much more detailed than in a PDM or in a PU. It is desirable that the land owners be involved in the plan since the beginning of the process.

4.4 Is the reality deterministic?

The concept of programming is appealing in pursuing the need for the plan to become more accurate, in terms of implementation; one must not forget, nevertheless, that the precise procedures / methodologies should be used only when

there is certainty in the possibility of effectively implementing the original plan, without further adaptation.

Planning is about changing the future, or at least the expected future. Therefore, understanding what is known and unknown about the future, the links between the past, the present, and the future, and how we act based on this understanding, are critical issues and challenges (Abbott, 2005). That is why planning means, essentially, controlling uncertainty – either by taking action now to secure the future, or by preparing actions to be taken in case an event occurs (Marris, 1987).

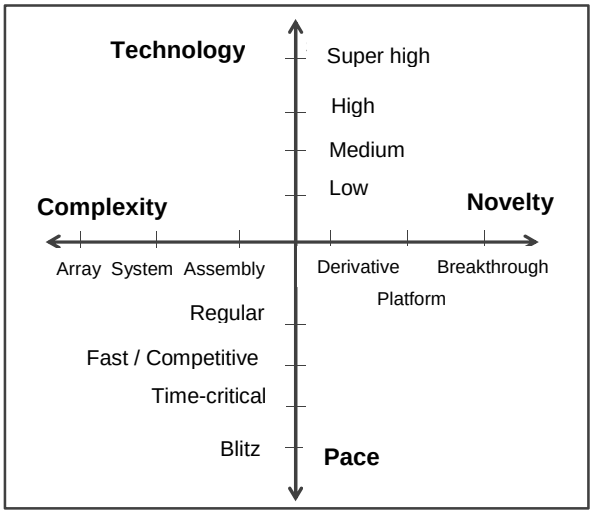
The definition of uncertainty isn't easy and clear but it is known that it is created either by the planning process itself, or through changes in the environment or planning context. A concept related with the uncertainty is the risk, which is more noticeable and well defined.

The PMBOK (Project Management Body of Knowledge), a reference in project management, defines risk as an uncertain event or condition that, if occurs, has a positive or a negative effect on at least one project objective, such as time, cost, scope or quality. For the authors, in the context of urban planning, a risk is an event that compromises the achievement of plan's fundamental objectives, which can be measured by quantitative (probability; intensity) or qualitative methods and be affected by internal or external factors.

A contingency approach, both at the programming and managing stage, can be a way to deal with the uncertainty and risk as well as their effects. The PCT (Project Contingency Theory) argues that the best approach to managing a project depends on context: different conditions require different project organizational characteristics, and the effectiveness of the project is related to how well organization and conditions fit each other.

According to Shenhar et al. (2005), the "myth" that a single method can fit all types of projects (one size fits all) has led to dissatisfaction with the field of project management. As a result of this, they argue in their research, that the ''one size fits all" approach is suboptimal, and that a project's structure and management practices should be tailored to suit its context. They proposed a model which is composed by 4 contingency factors (novelty-V; complexity-C; technology-T; pace-P), very focused in engineering-based projects, but which may equally have application in the programming and managing of urban plans.

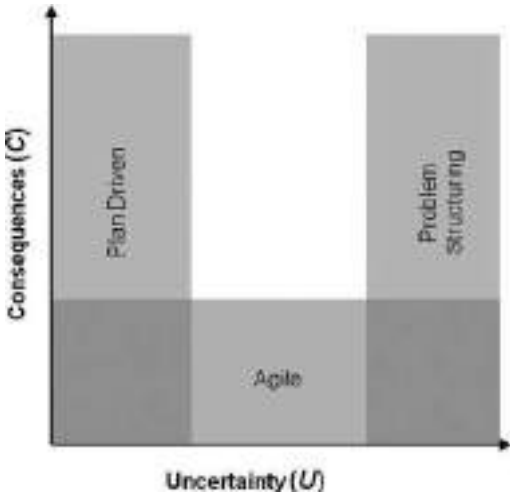
Figure 2 – NCTR Diamond Model



Source: *Adapted* Shenhar et al., 2007

A project contingency framework, proposed by Howell et al. (2009), UC Framework, can be used to identify which process models are appropriate for programming and managing a particular project, or stage of a project. It identifies three different examples of project management process models: ‘‘plan-driven”, ‘‘problem structuring”, and ‘‘emergent”.

Figure 3 – UC Framework



Source: Howell et al., 2009

The first process model considered is the “plan-driven”. This model can be defined as the group of methodologies which broadly consists of:

- Identifying project goals and the necessary steps to achieve them;
- Organizing the steps into an optimal sequence given resource and other constraints to form a project plan;

- Following the plan, with the objective of management being to administer the activities, to deal with deviations from the plan, and where deviations cannot be dealt with, to manage revision of the plan.

This process model includes methodologies such as PERT and CPM. For this model, the objective of planning is to anticipate and avoid surprises, their consequences are irrelevant and so the plan is inevitably based upon assumptions about the goal, methods, required effort and resource constraints among other things. As uncertainty increases, these assumptions will be less valid, but can be partially compensated for by increased planning effort; however, there are cost and practicality limitations to this, and in any case not all events can be anticipated – eventually the ‘‘unknown unknowns” (Pich et al., 2002) become significant factors.

The second model considered is the “problem structuring” model. This is defined as a group of methodologies which:

- Presume that the dominant issue to be dealt with in the project is the understanding of its objectives and environment;
- Attempt to elicit this information by modeling of cause/effect relationships.

The effectiveness of this process model is again independent of the C axis but varies again along the U axis. At low uncertainty levels, where the situation is relatively clear, the process of understanding the problematic situation becomes a trivial one. In this situation, problem structuring methods become irrelevant. The problem structuring process model is thus also limited by uncertainty, but the limit is at the lower bound, as shown in Figure 3.

The third model, the “emergent” model, is defined as the group of methodologies which involve:

- A presumption that the project goals will be ill-defined at the initial stages;
- A highly iterative process involving partial implementation of the goals, followed by redefinition of those goals based on feedback from this implementation.

In the ideal case, the emergent model’s effectiveness is independent of U (uncertainty). The approach assumes high uncertainty level so if in practice it is low, this has no effect on effectiveness. However the model’s effectiveness is limited in the C (consequences) dimension which means a lack of a robust overall project plan may run away to disaster if any event which the team is unable to handle occurs.

Finally, as the model relies on the team’s ability to react to events, it is less effective where the team is less empowered to do so. These factors mean that the process model is restricted to situations where the team’s ability to handle unexpected events is high (meaning small and expert teams), and ‘‘failures” cannot be overly serious: the model is “consequence limited”.

After this exposition, the main idea to retain is that the planning process needs to deal effectively with the uncertainty and risk and must have the capacity to adapt to all future events.

5 – Management

5.1 Implementation

Is in this phase that takes place the implementation of the objectives, goals and actions, which were just written words or intentions in the plan-document, therefore finally having to deal with bureaucratic delays and legal difficulties by adjusting the appropriate schedules and deadlines, as well anticipate alternative actions.

Planning and its implementation are often regarded as separate processes with their own actor networks and their interests and, as such, even considered as being rather opposed. We could say there is an "implementation gap" linked to the knowledge disconnection between plan formulation and implementation.
The modelling of a conventional urban planning and implementation process indicates that the end of a plan's formulation, the moment when it is "finished", is also a point where, usually, discontinuity occurs in the process. For this gap contribute some factors such as:

Time

The time periods between the 2 processes may be exceptionally long and so have the consequences of the actors in the network change over time, socioeconomic trends may shift their direction totally, and the preferences and tendencies may transform dramatically.

Political-institutional context

The political-institutional structure for the implementation process (eg. coordination mechanism for effective working and relations between the different entities/departments with responsibilities), the influence exerted by persons with political or economic interests during the implementation, and the role of the planning team in the implementation process have a large importance in the effectiveness of the plan's implementation.

Attributes of the plan

The planning techniques used, the goals articulated, and any other attributes associated with the quality of the plan have also importance. Here it's relevant to highlight that over half of the plans' report typically discusses existing data and proposals about different territory sectors such as facilities, environment, transport and infrastructure but have few information about the implementation mechanism for

those sectoral policies. So it seems to perpetuate an attitude "more interested in formulation plans than implementing them".

Due to the gap between these two processes there is the need to better articulate the programming and the implementation of the plan. For this articulation the monitoring and the evaluation procedures will have a relevant role.

5.2 Evaluation

Accompanying the era of the modernist planning approach, the focus of the plan evaluation (also known as plan assessment or plan appraisal) was on developing criteria for determining "good plans". As (Alexander, 1989; Faludi, 1989) noted "If planning is to have any credibility as a discipline or a profession, evaluation criteria must enable a real judgment of planning effectiveness: good planning must be distinguishable from bad."

Evaluation may be designated as an analysis process of outputs, outcomes, impacts, and also implementation mechanisms, aimed at setting how the objectives and results are to be achieved. In this process there are some strategic issues which should be listed such as:

a) Relevance – Are the proposed actions a good idea in terms of improving the current state?
b) Impact – What are the positive and negative outcomes of the plan?
c) Effectiveness – Were the objectives, activities and outcomes achieved? What is being done is the best way to maximize impact?
d) Efficiency – Are the resources being used optimally? What could we do to maximize the (positive) impact at an acceptable cost?

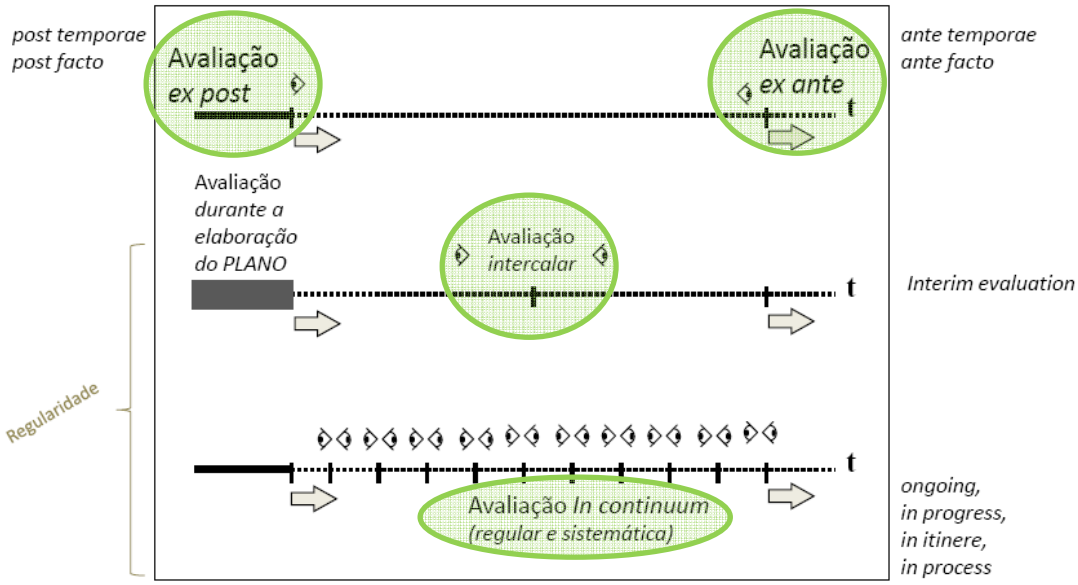
The evaluation process which occurs at different periods of the project or plan's lifecycle can be classified, according to (Voogd, 1983) and (Baptista e Silva et al., 1999), as evaluation *ex ante*, evaluation *in continuum*, and evaluation *ex post*. Recently, Baptista e Silva et al. (2009) introduced a new typology called intercalary evaluation.

In the evaluation *ex post* prevails the view about the past, focusing on what happened with the plan. It is primarily a retrospective assessment that checks whether the objectives and the actions programmed in the plan continue to make sense.

The evaluation *ex ante* has an anticipatory character related to a rational paradigm where the vision of future is dominant and the focus is on what will happen. Among the possible alternatives, the choice will go for the ones which are considered best to achieve better results and mitigate possible future shifts on the plan's implementation.

The evaluation *in continuum* is understood as an ongoing systematic process with a pre-determined frequency and which follow the entire duration of the plan. It is in fact a type of evaluation that intends to give meaning to the idea of plan-process, in view of the plan's ongoing appreciation. It equally aims to be a support for future decisions about the plan's revisions or changes.

Figure 4 – Types of evaluation: time perspective



Source: Baptista e Silva et al.

There is a set of tools that can be used for the evaluation process and much of them come from the management science. Our proposal will focus on some of these tools which we believe are applicable to the context of urban planning.

5.3 Monitoring

The notion of monitoring is not univocal: while some authors define it as a complementary method to the evaluation, others believe that it is only one type of evaluation.

For the authors, monitoring is related to the review, on an ongoing basis, of the degree to which the activities are completed and the goals achieved. This is an important tool for the planning process because it gives flexibility in face of uncertainty / risk and allows for taking corrective actions during the implementation phase.

(Baptista e Silva, 1999) indicates two basic concepts of monitoring: the perspective of compliance and performance. He argues that the first perspective corresponds to the classic monitoring vision, focusing on ex-post evaluation, means-aims reasoning,

correspondence between intentions and outcomes of planned activities, and can be subdivided into four sub-types:

a) Evaluation of the level of objectives' fulfillment: deals with the analysis of agreement between results and initial intentions;
b) Assessment of impacts: is concerned with all the results of the plan and not just those arising from the defined objectives;
c) Effectiveness evaluation: focuses on cause-effect relationship between the obtained results and the measures and actions implemented.
d) Performance evaluation: focuses only on the plan, trying to determine whether or not it is to be implemented.

Through the second perspective, the performance evaluation, results the idea that the mere compliance is not the only measure of a plan's success. In fact it is ever-more-clear that results less compliant to an original design or expectation don't necessarily entail a lower effectiveness in the achievement of the objectives and actions, and therefore a negative evaluation of the planning process.

One of the most important principles of monitoring is that by providing information for management it ensures a future benefit that will come from the changes to the process introduced based on that information.

So to collect the information referred to above it is imperative to define good indicators. The indicators must be simple, measurable, intelligible (easily understood even by those who aren't experts) and reliable. In the context of urban planning the indicators focused in the political choices must be concerted with the ones which refer to the planning solutions.

For the development of a monitoring system it is relevant that we are able to build a specific plan in which is determined: Who does what? How? What schedule is applied? What are the indicators to measure the effectiveness and the efficiency of the activities? and other elements that return important results for the planning process.

6 - Programming and management model for urban plans

After highlighting the relevant issues about programming and management of the plans, it is now time to present our proposal for a model that may contribute for a greater success of these.

This proposal intends to be applied to different PMOT (PDM; PU; PP) even though it may require some adjustments depending of the plan's scale.

The main objectives of this model's conception are to:

a) Generate a system which allows to compile, process and analyze the information regarding the progress made by the plan;
b) Provide information to the decision-makers on the compliance of the programmed activities;
c) Establish mechanisms for regular changes and reviews;
d) Create channels that allow the different actors in the implementation process to participate in the systematic process of reformulation and review.

Ahead we propose a few ideas for the programming and management phases, which represent the structure of the model.

WBS of the Plan

A work breakdown structure (WBS) is an usual project management tool which defines and groups a project's discrete work elements in a way that helps organize and define the total work scope of the project. This also provides the necessary framework for detailed cost estimating and control, along with providing guidance for schedule development and control. So from our point of view this tool can be applied and adapted to the context of urban plans.

To create a WBS for an urban plan, we identified the following fields, which are important to structure all information about the process in the beginning, and subsequently assist in the monitoring/evaluation procedure.

a) **ID** – In this field, apart from the chosen codification type, it is important to reveal clearly the hierarchical structure adopted;
b) **Name** – Must be concise and self-explanatory;
c) **Description** – Has more relevance in the levels of the WBS which have more detail (eg. tasks);
d) **Estimated duration** – Important for the scheduling all activities and its tasks;
e) **Priority** – It is relevant to allocate the available resources and means, especially the financial;
f) **Start and finish date**
g) **Status** – To understand at which stage we are and what is the volume of effort needed to implement the activity or task;
h) **% completed** – To see if the progress is on the right track and according to the programmed schedule;
i) **Monitoring dates** – Even if the monitoring is a ongoing process, a plan is much more complex than a project, and so there is the need to choose with which frequency the evaluation procedure is to be executed;
j) **Performance indicators** – They are the basis for the monitoring and evaluation procedure and for that it is relevant to collect all information about them;

k) **Risk level** – In the programming phase it is important to have an idea about the risk level of each activity or task in order to devote special attention to the higher risk level activities;
l) **Responsibility** – In any implementation process the responsibility is a key-issue because it allows to always knowing who to ask about something related to a specific activity or task.

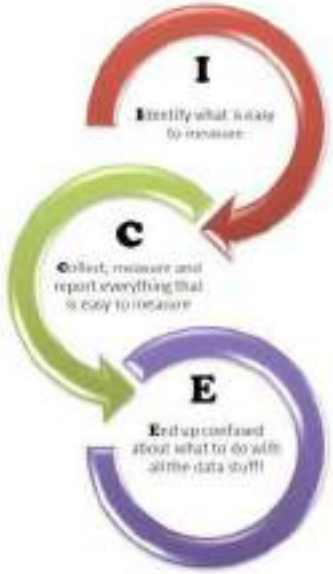
Concerning the risk level, we believe it is an added value to use a qualitative approach as NCTR Diamond Model, already exposed above, because it consists of a smart method and easy understandable for all people.

MES of the Plan

The monitoring and evaluation system (MES) of the Plan needs information and this is collect through indicators. The selection of indicators should be done responsibly and with caution, since its careless use can lead to loss of information, or on the other hand, create some "noise" and entropy in decision-making process.

In the management science there is the concept of Key Performance indicators (KPIs) which are commonly used to evaluate the organization's success or the success of some specific activity within the organization. For the specific context of the urban plans what we intend is to achieve specific indicators for each activity/task but also global indicators for the plan as a whole, characterizing the performance during its completion, and so as to allow comparisons between alternative implementation strategies.

Figure 5 – Identifying process of KPIs: ICE approach



Source: Advanced Performance Institute

Performance indicators' selection is often associated with the use of various techniques. One of these is the ICE approach presented at the Figure 5 which gives a simplified itinerary to define the best performance indicators for each case.

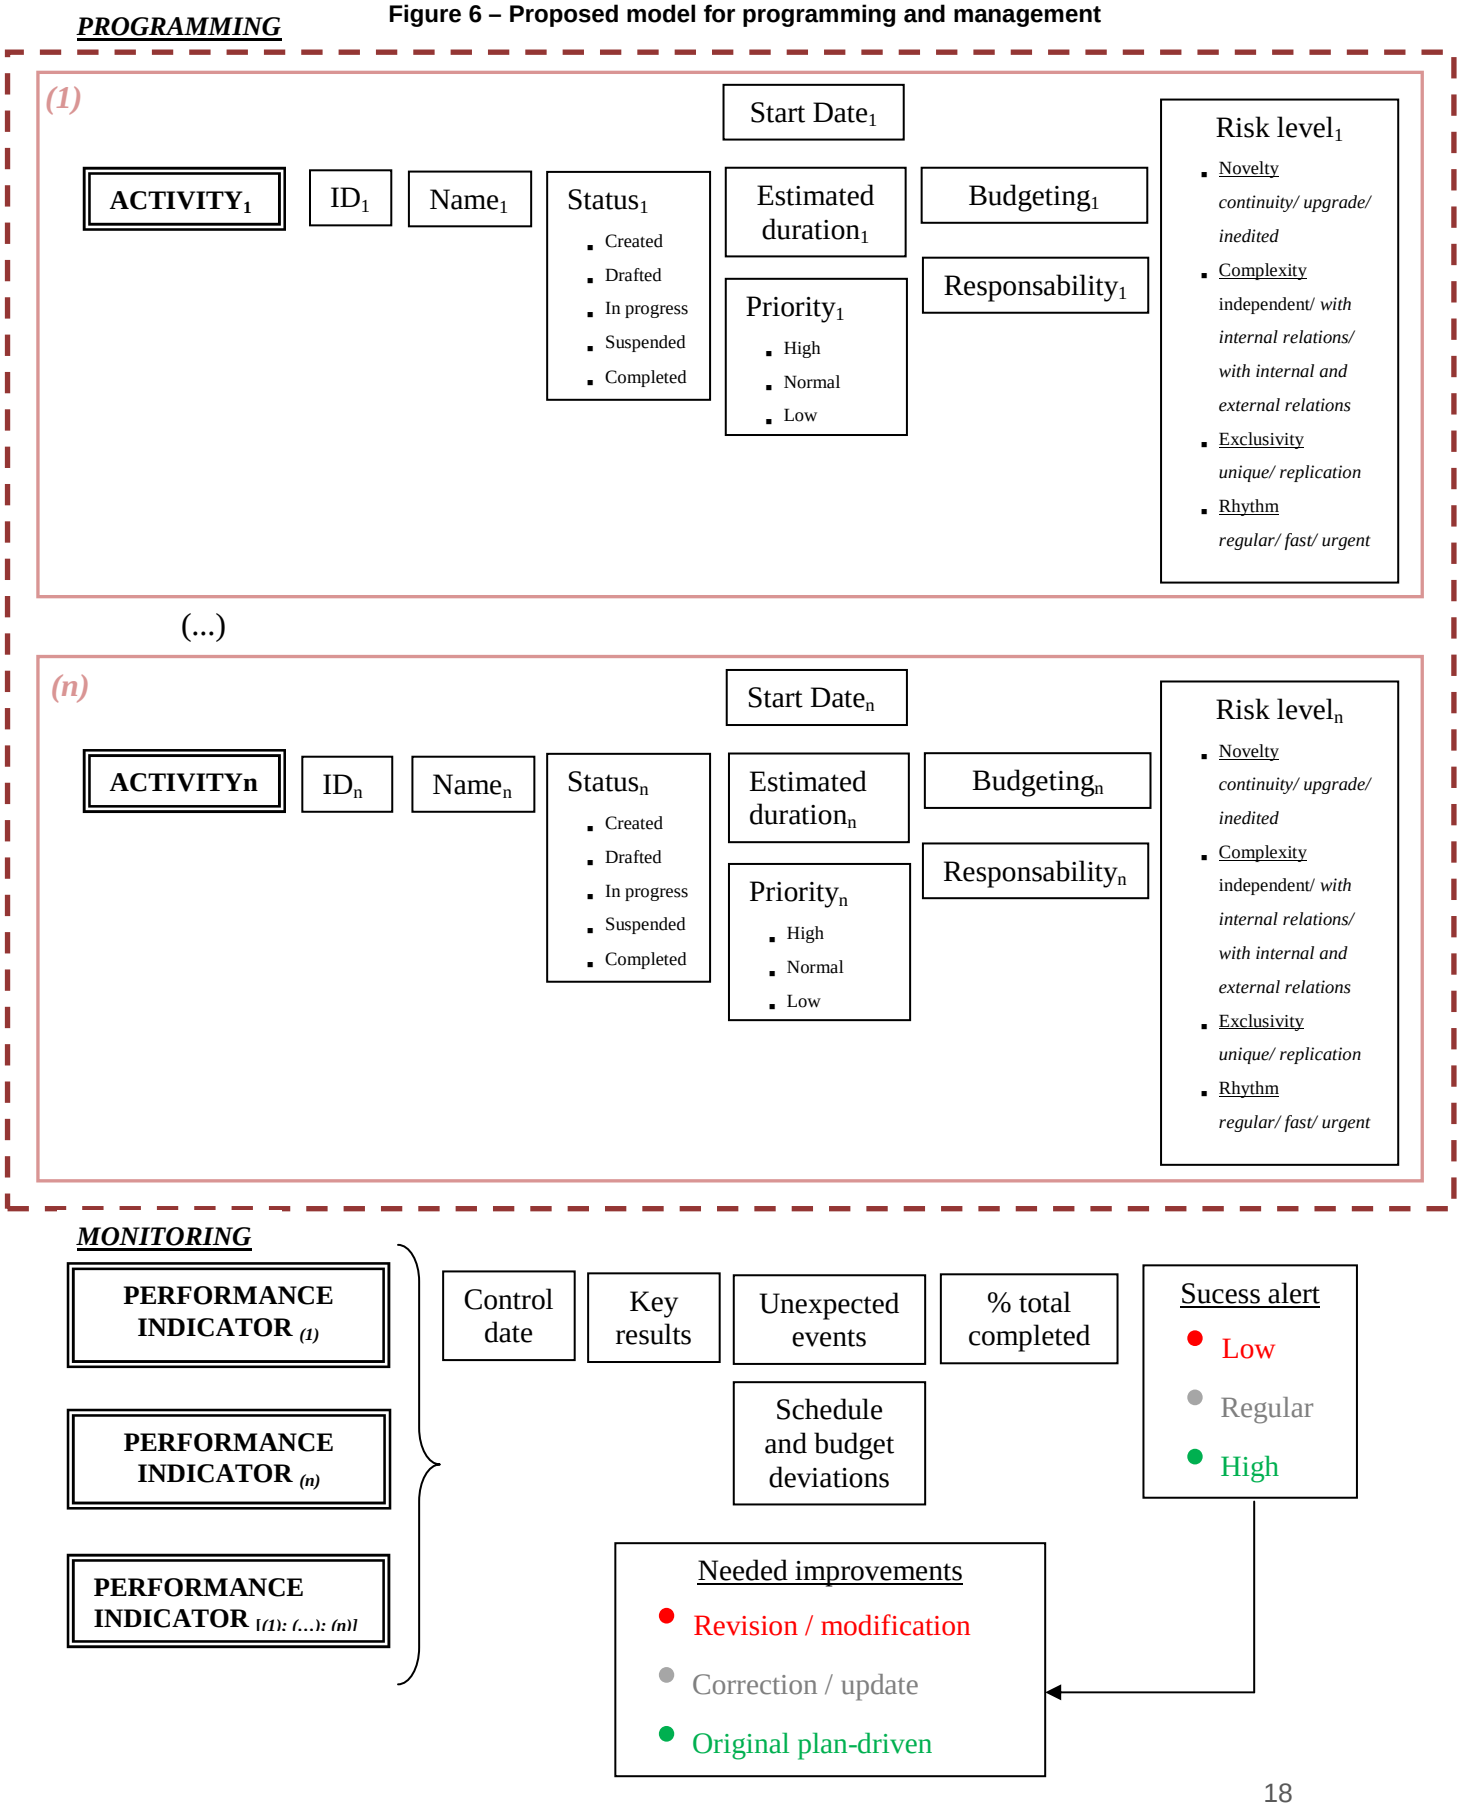
In our vision for the proposed model, after the definition of the performance indicators, an alert mechanism must be created that will allow the measuring and success rate of the initially programmed activities and tasks. This mechanism is relevant for its interpretative dimension and helps the decision-makers have an easier visual thinking capacity in the decision-making moments.

The monitoring process is many times associated to the identification of potential improvements, and as a consequence, performance indicators are routinely associated with performance improvement initiatives. So the proposed alerts mechanism intends to address the deviations from the future scenario that was built at the beginning of the plan formulation, and permit the adoption of improvement initiatives in a timely fashion. Finally it is noted that when almost all performance indicators are in red the decision-makers need to be careful about its analysis because it might mean that the scenario chosen at the beginning is no longer adjusted to the present reality and there is the need for a deep revision of the plan or even a new plan.

In our point of view, for managing the plan we can adopt the "emergent" model referred in a previous section. This takes full advantage of the monitoring and evaluation results and it remains a highly iterative process with the implementation of the activities / tasks being followed by the possible redefinition of those activities / tasks based on feedback from their implementation.

In the Figure 6 we present our global concept for the proposed model.

Figure 6 – Proposed model for programming and management



7 – Conclusions / Steps forward

To conclude the communication, we have more elements that can contribute to solve the problem of uncertainty and risk at the urban plan's implementation. In the complex context of urban planning it is impossible to generate a plan which covers all possible contingent factors; as such, the sole way to surpass this barrier is to have a flexible programming model associated to an ongoing evaluation system. Together, these will allow the adjusting of the plan to a permanently changing reality.

Our proposal intends to meet this challenge through a proactive model which does not only want to track the changes in reality but that provides an effective proactive stance for when these changes take place.

For the future, we aim to:

- Test adjustments of the model for the different type of PMOT (PDM, PU; PP);
- Develop performance indicators adapted to the urban plans;
- Study and propose the action mechanisms for needed improvements

LAND READJUSTMENT PITFALLS IN PORTUGAL AND THE ROLE OF EQUITY

Beatriz Condessa [1], Paulo Cambra [2], Ana Morais de Sá [3], José Antunes Ferreira [4]

Abstract

Planning has not always preceded the development of urban land. The rapidly increasing growth rate of urban territories can easily lead to the emergence of pieces of fragmented, unqualified and unconnected urban fabric. Land readjustment is a century old technique that is attracting growing interest worldwide as a means of achieving planned, equitable and efficient urban development. This practice has been adopted and adapted by various countries in order to accommodate differences in both legal frameworks and public-private relationships. Various levels of success and degrees of implementation have been reported as well as pitfalls and obstacles, some of the latter being common in and/or experienced by more than one country alone.

In the case of Portugal, land is predominantly privately owned and the public administration has played a passive role in the urban planning process, limiting itself to the issue of permits for isolated private operations. In the light of the principle of equity, Portuguese law establishes that urban development plans are obliged to provide land readjustment mechanisms to eliminate, or at least mitigate, the inequalities they themselves bring about.

After more than a decade of existence/practice, however, the application of these mechanisms still has not achieved a satisfactory output, and has come up against a number of obstacles and problems. These, in short, are related to property structure and records; land owners' engagement; technical expertise; availability of public funds; time consuming processes; ineffective dispute resolution instruments; and lack of reliable land evaluation mechanisms, truly embedded in the planning process, for calculation of reference values for both property and building rights in the context of the distribution of benefits and charges.

To address the latter aspect in particular, a methodology for the fair distribution of benefits and charges was developed and applied to the urban expansion of the Portuguese city of Sines. This paper will share how land value appraisal combined with property size was used as a distribution driver, together with a universal and

free property valuation tool – the national online property tax calculator. The global market value of the proposed urban plan was estimated and to each landowner was assigned a share of this value according to the surface area of each one's property. Also, the market value was estimated for the units one had the right to build. The distribution of development costs (infrastructure, public space) was made in proportion to the latter, that is to say, the higher the value of one's building, the higher the charges to be paid. For each proprietor a balance was made between the assigned plan value, the actual value of their building units and the development fee, resulting in a lump sum payable or receivable.

This approach made it possible to achieve better communication with and understanding of landowners, bringing transparency and equity to a process locally perceived as somewhat blurry. Better understanding and grasp of the land readjustment model by private and public stakeholders can be a step forward in achieving cooperation and plan implementation.

Keywords: planning practice, land readjustment, equity, land appraisal, land evaluation

1. Introduction

Statutory planning process itself is inherently discriminatory. Land use plans contain specific proposals for development that often represent considerable restrictions to urban development and strongly affect land value in the market.

Despite the fact that most western countries in Europe have adopted the principle that constraints on urban development are not subject to public compensation (Renard, 2007), the problem of inequitable treatment between property owners still persists. As several authors argue, the diverse approaches to this problem are deeply related with different ideologies about property rights and land ownership and rooted in different planning doctrines (Linchfield, 1980; Adams et al., 2001; Louw, 2008).

Concerning planning efficiency, social equity and the guarantee of public facilities provision, two major approaches can be identified that represent opposite ideological sides: that which advocates public ownership of land for broad political and social reasons; and that which defends private property, individual rights and the operation of a free market (Kivell and McKay, 1988; Louw, 2008).

Strong arguments on both sides are discussed by several authors. Nevertheless, public and private developers commonly recognise fragmented ownership and the difficulty of assembling land as major constraints to urban development (Adams et al., 2001; Connellan, 2002; Hong, 2007, Louw, 2008).

Planning literature and practice all over the world have already demonstrated that conventional land assembly methods (voluntary exchange or public intervention in the form of expropriation) commonly produce weak outcomes in terms of efficiency

and equity, whereby this is particularly true where public funds for any form of compulsory purchase and infrastructure provision are limited. In this context, land readjustment (LR), also referred to in literature as land pooling or land consolidation, is generally regarded as an attractive alternative to the methods mentioned above.

The precise scope of LR differs from country to country and author to author and it seems to be strongly related with specific institutional, legal, social and economical contexts. There are several models, each particular to its own country, as has been shown in the literature on LR experiences in countries such as Japan; in Europe: Germany, Sweden, France, Netherlands, Turkey; and other overseas countries: India, Australia, Taiwan, amongst others (see for instance: Doebele, 1982; Larsson, 1997; Sorensen, 2000; Müller-Jökel, 2004; Lin, 2005; Davy, 2007; Hong and Needham, 2007; Souza, 2009).

Although LR is a broad term without a precise definition there is a relatively high consensus about its relevance as a technique used for both the development of new areas and the reorganisation of the structured areas in urban regions (Larsson, 1997; Sorensen, 2000; Krabben and Needham, 2008; Turk and Altes, 2010); as an efficient tool to equalise the advantages and disadvantages between landowners resulting from urban planning; and as a means of financing the development process, allowing the public sector to capture part of the land value increment created by land use plans (Connellan, 2002; Müller-Jökel, 2004; Lin, 2005; Needham, 2007; Souza, 2009).

In other words, LR is potentially an effective tool for: assembling land parcels and therefore to improve the economic use of land (in long-term land assembly processes, landowners are tempted to keep their land out of the market in order to get higher market prices); facilitating the equal sharing of the benefits and costs of the project; and relieving the financial pressure on public authorities in providing the needed infrastructure and public facilities.

Despite the specificities of each country, in most LR processes, landownership and its physical structure is transformed and the land redistributed amongst landowners in the form of serviced plots or other economic compensation (established in proportion to either the surface area or the value of land inputs), whereas land for public usage comes to public ownership. Implementation is based on private agreements and exchanges of land, formalised in legal processes. However, very often, cooperation has to be facilitated or even instigated by public authorities, public enterprises or large private entrepreneurs (Larsson, 1997; Louw, 2008; Turk, 2007).

Pursuing planning efficiency, social equity and the guarantee of the provision of public facilities, and reducing financial pressure on public governments are, therefore, the main objectives LR processes aim to achieve.

Although the planning literature acknowledges the virtues of this method of land assembly (several case studies in developed countries such as Japan, Germany and France, as well as in developing countries in Asia and Australia, have revealed how

the LR method is applied efficiently and successfully in urban development), major constraints on its application have been experienced and outlined.

Some critical success factors are identified by different authors: the presence of a robust and rising land market; a strong and sustained atmosphere of trust amongst all the parts involved; a culture of collaborative and consensual decision making; and finally, a significant proportion of public will and finance to facilitate the process (Home, 2007; Needham, 2007, Hong, 2007; Sorensen; 2007; Louw, 2008; Souza 2009).

In Portugal, after more than a decade of legal existence and practice, the achievements with the use of LR mechanisms fall well short of expectations. A weak performance in terms of the critical success factors listed above could be, in itself, a reasonable explanation. However, other causes must also be highlighted.

In the first section of this paper, we will briefly examine the present legal framework of LR in Portugal. In the light of the international literature and of the Portuguese urban planning experience in the last decade, the main drawbacks, within the institutional framework for LR, will be outlined.

In the following section we will present a LR methodology developed for a detailed plan in the Portuguese city of Sines in order to cope with some of the major constraints identified. Particular emphasis will be given to the so-called distribution stage of LR processes, considered to be fundamental, as the principles of equity, transparency and fairness take form in this stage (Turk, 2007).

In the final section, discussion of results and final conclusions will be presented. We will start by arguing that the approach followed made it possible to achieve better communication with landowners, bringing transparency, equity and efficiency to the process. Improving the understanding and grasp of the LR model by private and public stakeholders proved to be a step forward in achieving cooperation and plan implementation and emphasises the idea that the core principle of LR is to build consensus and cooperation among the parties involved in land development (Hong and Brain, 2012).

2. Equity in Portugal and *Perequação*

2.1 Legal framework

The principle of equity was only legally formalised in Portugal in late 1990s. According to the law, *perequação* was designed in order to guarantee an equitable redistribution of the costs and benefits resulting from urban planning amongst landowners. Particular emphasis was also given to its potential as a way to promote efficiency and sustainability in financing the costs of urban development, traditionally mainly assumed by the public sector. As a consequence of these first two characteristics, a third category of objectives was expected to be accomplished:

improving the low levels of execution of urban plans, which has been referred to by different authors as a major problem in Portugal. In this sense, it seems fair to classify *perequação,* a term that comes from the Latin expression *per aequere* (meaning to make an equal distribution between different parts or to deal fairly and equally with all concerned) as an LR mechanism.

Prior to this, Portugal was indeed "ill equipped to deal with the urban development processes, which accompanied the significant migration flows of the 1960s and 1970s and the economic and spatial changes in the 1980s and 1990s" (Carter and Silva, 2001). Aiming to bring new drive to the role of urban planning against an out-dated and persistent practice dominated by *ad hoc* urban development schemes led by the private sector, for the first time the principle of equity was introduced and the planning system was strengthened with a set of execution instruments that were regulated by Decree-Law no. 380/99 of 1999 (the Legal Framework for Town and Country Planning Instruments – RJIGT).

Moreover, it was established that municipal plans, because they are binding for both public administration and private property owners, have to include compensation procedures to guarantee a fair redistribution of the resulting benefits and costs amongst the property owners involved and between them and the public administration.

The development of a *perequação* model requires that some questions have to be answered during the planning process and before the legal approval of municipal plans: what are the physical boundaries where *perequação* is going to take place? To what extent will local authorities be involved directly in urban development promotion or will they act mainly as facilitators between the different parts concerned? What are the equity mechanisms or the compensation rules that will be adopted? Which execution instruments will be required? Because of their specific nature, contents and scale, it is in detailed plans that these answers can be provided.

According to the RJIGT, plan implementation should take place in specific territorial units, designated as execution units, which are defined by local authorities at their initiative or, whenever required, by private landowners. This process implies the identification on a cadastral map of the physical boundaries of the area subject to urban development and the identification of all property owners.

For each execution unit the plan should define to what extent the municipal administration will be directly involved in urban development as "regulator", "enabler" or "provider". Three different types of execution systems are defined (Table 1):

Table 1. Execution systems

Execution system	Who takes the initiative?	Who defines the execution programme?	Who executes public infrastructures and public facilities?
Compensation	Private stakeholders	Private stakeholders	Private stakeholders
Cooperation	Public administration	Public administration	Public administration and/ or Private stakeholders
Imposition	Public administration	Public administration	Public administration directly or through a concession agreement

The approaches suggested by the compensation and the cooperation systems fit very well with the concept of LR, as it is presented in this paper through the literature revision. In both cases, replotting is an efficient instrument for formalising the required transfer of ownership and property rights.

Under the imposition system, local administration undertakes urban execution directly or through a concession agreement with a private developer. As the land developer, the municipality has to assemble all the land, ensure the costs of land acquisition and infrastructure provision, and, at the end of the process, it will benefit from the income derived from selling the serviced plots. In this case, a land baking process, as it described in the international literature of land assembly (see for instance: Louw, 2008), seems to be a better portrayal of the Portuguese imposition system rather than a LR approach.

In the compensation and cooperation system, the definition of the specific mechanisms that will guarantee equity between all parties involved, and support the compensation in the form of serviced land or cash is, indeed, critical, as the principles of equity, transparency and fairness take form in this stage.
According to international practice, RJIGT law suggest some equity mechanisms, namely: Gross Average Floor Area Ratio (FAR)[5] (also includes the surface of land parcels affected to public usage) and the allocation of the urbanization costs (redistributed amongst the property owners in proportion of the correspondent gross floor area). Nevertheless, local authorities have the power to define some others mechanisms, as long as the principle of equity is respected.

Taking the FAR as reference, two different criteria can be used to redistribute the so-called *redistribution mass* amongst original landowners (Müller-Jökel, 2002): the relative size or the relative value of their former plots.

[5] $FAR = \frac{\sum F_n}{S_g}$

where ΣF_n represents the sum of the gross area of each floor of the built area in the execution unit, being F_n the area of the n^{th} floor; S_g represents the gross surface of the execution unit.

Whenever there is a difference between the abstract developments rights (in sq. m. or the correspondent monetary value) and the effective redistributed built rights to each owner, the RJIGT law imposes that compensations have to take place.

In order to make these compensations more agile and flexible, the RJIGT law also considers the option for property owners of selling their *unused* development rights. This possibility sketches the legal framework for the introduction of transferable development rights programmes (TDR) in Portugal.

2.2 Major pitfalls to *Perequação* in Portugal

After more than a decade of legal existence, however, the application of *perequação* in Portugal still has not achieved a satisfactory output. Not only the number of legally approved detail plans with equity mechanisms is scarce (compared to the witnessed urban growth), but also their level of implementation is very low (Cardeiro, 2009; Antunes, 2009).

Taking into to account the background provided by the international LR literature review and the authors' knowledge about the Portuguese urban planning reality in this last decade, major pitfalls to *perequação* concerning the institutional framework, can, therefore, be outlined as follows:

The absence of a win-win negotiation culture between public and private sector;
Since urban development is mostly dominated by private sector, the implementation of *perequação* is highly dependent on the extent to which public planning authorities can successfully encourage landowners, developers, and investors to be committed with the plan. However, lack of appropriate technical expertise in the domains of collaborative and consensual decision-making processes, weakness the potential role of local authorities as the main driving force.

The lack of efficient and effective dispute resolution mechanisms;
Traditional methods of assembly land when voluntary negations are not possible, such as expropriation, often, lead to lengthy timescales processes and to higher costs, that end up to be supported mainly by public authorities, being this particularly critical as local governments' funds in Portugal are scarce.

The lack of efficient and effective mechanisms to induce perequação;
Not only more effective dispute resolution mechanisms are needed, but also, strong incentives to urban development within *perequação* have to be created (e.g. urban, financial, or fiscal incentives). The landowners' economical and financial gains from *perequação* must be larger than if they do not take part in the process.

The inexistence of land value evaluation mechanisms reliable and truly embedded in planning process;
The knowledge of land values and land evaluation processes is critical to create a sustained atmosphere of trust amongst all the parts involved in any kind of LR

project. In Portugal, however, land use plans and, in general, the planning system, do not consider in a comprehensive way the influence that planning rules have in land value. Not only the planning system does not incorporate independent land evaluation boards, as public administration, itself, uses different land evaluation processes for diverse public purposes leading, sometimes, to very different evaluation results (e.g. land and property taxation or the definition of the fair compensation in the context of expropriation processes). This ambiguous environment, combined with ineffective mechanisms for public capture of property value increase resulting from land use plans (and its transfer to the society), very often, contributes to threaten the sense of social justice and equity in urban planning, and creates the opportunity for land speculation.

The obstacles listed above do not pretend to be exhaustive. However, in conclusion, it can be highlighted that urban planning in Portugal seems to fail to understand the critical relationship between planning making and its implementation. In this sense, a more integrated approach to *perequação* within the planning system, urban economy and governance, is considered to be critical to improve the efficiency and success of its application.

In the following section we will present a *perequação* methodology developed for a detail plan in the Portuguese city of Sines in order to cope with some of the problems identified.

3. Study area: the city of Sines and the detail plan for expansion in the north of the city

3.1 Evolution of the city of Sines

The city of Sines is located on the coast of the Portuguese region of Alentejo, roughly 150 km south of Lisbon. Thanks to its deepwater port, it is part of a geo-economic context that is of strategic importance to Portugal. A small fishing town up until the 1960s, the urban development of Sines is closely linked to its development as an industrial hub and port. From the 1970s onwards, the decision to establish in Sines an extensive area for basic/heavy industries gave rise to strong urban growth. Since then, the municipality's urban policies have been dependent above all on decisions taken at the central administration level and on important public and private investments in the port, the industrial and logistics zones and transport infrastructures.

While in 1991 the city had 11,000 inhabitants, by 2001 the number of residents had reached 12,500. At the end of the 1990s major investments were earmarked for the port and logistics platforms, justifying the population evolution scenarios, drawn up in 2003, which indicated that the city's population would almost double by 2011. However, the greater part of the planned investments was not made and the results of the Census of 2011 (14,260 inhabitants) show that, although there was indeed a considerable rise in the population, the growth fell short of what had been expected.

This context of uncertainty as to the economic and social development of Sines requires that the municipal plans have the capacity to monitor and adapt to this development. It is therefore no surprise that the process for the drawing up of the Detail Plan for the Expansion Zone North in Sines (hereinafter the "PP Norte"), in which the methodology described further below was tested, has been a particularly lengthy one.

3.2 The PP Norte elaboration process

The process for drawing up the PP Norte began in 2001 and its first proposed version was finalised in 2003. This version, which was subject to public discussion, manifested the differing expectations of the various types of property owners. The greatest resistance to the proposed design came from those who already lived in the area of intervention, as they opposed to the demolition of their dwellings. Meanwhile, the postponement of some of the main structuring investments at the industrial and logistic levels, added to the delay in the execution of the new road and railway infrastructures and the accompanying slow-down in the population growth rate, led to Sines Council requesting alterations to the proposed design. A new detail plan proposal was presented in 2008.

The alterations are most visible in the eastern part of the PP Norte, where land ownership is divided into smaller fractions, with a view to avoiding that the implementation of the main infrastructures be dependent on the initiative of small property owners or their substitution by the local council. Also, responding to the main questions raised during the public discussion, the built structures that existed in this part of the intervention area that showed good conditions of habitability were retained and the offer of detached and terraced houses was increased.

Furthermore, in the 2008 version, the PP Norte did not present a clear indication of how much the property owners would have to pay or how much they would receive, so that, in the final version approved in 2011, the *perequação* model described in section 4 below was developed.

3.3 The area of intervention

The area of intervention – 36 ha in size – covers 34 property owners, two of which are public. One should point out the exceptional situation in the national context of the public sector owning more than one half of the area of intervention (52%). Of the other landowners, six are commercial companies (holding 37% of the total area), three are small groups of two or three private citizens sharing ownership of the land (only 2% of the total area), and the remaining owners are individual citizens (9% of the total area).

The average size of the land parcels is 5,600 sq. m, but there are large discrepancies in terms of parcel size. Figure 1 shows the distribution of the land parcels by size in the original land register and the types of property owners.

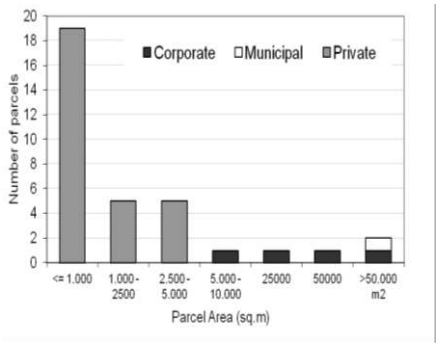

Figure 1. Distribution of the land parcels by size and the types of owners (original land register)

The final version of the plan clearly favours residential use, which takes up some 66% of the gross floor area (only residential) or 95% (including residential and commerce mixed use). The commercial and services areas (approx. 5% of the gross floor area) are located along the two main roads which are the most easily accessible and have an avenue profile. Table 2 shows the building typologies adopted in the plan.

Table 2. Building typologies

Use	Residential				Commerce & Services	Mixed Use (Res. + Com.)	*Total*
Type	Detached Houses	Semi-detached houses	Terraced single-family houses	Appartment Buildings	Buildings	Buildings	
N. of Units	22	30	76	16	3	13	160
Average lot Area [m^2]	478	310	237	1.874	1.348	1.311	---
Average Floor Area [m^2]	240	221	177	4.181	2.076	3.113	---
Total floor area [m^2]	5.272	6.640	13.427	66.898	6.226	40.472	138.935
% of Plan floor area	3,8%	4,8%	9,7%	48,2%	4,5%	29,1%	100%
Average Unit Valuation (by SIGIMI) [€]	194.463	175.381	138.037	2.926.086	1.321.967	2.168.998	---
Total valuation [€]	4.278.180	5.261.420	10.490.800	46.817.370	3.965.900	28.196.970	99.010.640
% of Detail Plan value	4,3%	5,3%	10,6%	47,3%	4,0%	28,5%	100%
Average Floor Area value (by SIGIMI) [€/m^2]	811	792	781	700	637	697	**713**

4. Methodology for distribution of benefits and charges

4.1 Objectives and assumptions

The particular characteristics of the PP Norte, namely in terms of the initial property structure – with the presence of large and small landowners, with some houses to be

demolished and others to be kept, but whose plots have characteristics that are reasonably homogeneous in terms of morphology and urbanistic situation – and in terms of final property structure – with diverse use typologies (commercial and service buildings and detached and terraced housing) with differing market prices per sq. m of floor area – led to a refinement of the most frequently used *perequação* method: the distribution of building rights.

Hence, the *perequação* process would have to incorporate other calculation mechanisms that would need to be simple and clear. The methodology we developed is based on the equitable division of the charges and benefits, based on the average valuation (in euros) introduced by the plan. The compensations to property owners are the equivalent of the difference between the average valuation and the valuation attributed to each owner. In other words, in terms of benefits, there is an equitable distribution not of the floor areas but of the value of the floor areas, given that the different typologies proposed have different market values. The distribution of the charges followed the same philosophy; they were distributed amongst all the owners based on the value of the floor area attributed to each one and not on the basis of the floor area itself.

The greatest challenge to overcome is precisely which valuation method to use to translate the benefits and charges into monetary values. It is essential that the plan's value calculation method is objective, transparent and easily accepted by the property owners.

In operative terms, the equity methodology used in the PP Norte was the result of the combined application of the following concepts: (a) the overall plan value, which is the sum of the values for each land parcel obtained by means of property appraisal; (b) an abstract value that is the equivalent to the fraction of the overall value corresponding to each owner in accordance with the surface area of the plot, given that it is assumed that there are no significant differences in value between those parcels; and (c) the concrete value, which is the equivalent of the value of the new lots attributed to each owner.

The following input data were taken from the initial plan situation (original register) and the proposed solution:

- Property owners, p_j
- Surface area of land held by each owner, s_j
- Built structures belonging to each owner, F_j
- Lots proposed by plan, i
- Building typology proposed for each lot, Tip_i
- For each proposed lot: floor area F_i; dependency surface area AD_i; lot surface area occupied by the principal building $A0_i$; lot surface area Al_i.

4.2 Methodology steps

In accordance with the objectives and assumptions identified in the preceding point, the following steps were defined for application of the methodology:

1) Defining the different types of players and the rules (benefits, charges, compensations) applicable to each player. This is followed by the classification of the owners by player type.

The description of the four player types identified and the distribution of the owners by type is summarised in Figure 2:

Player Types	No. of owners	% of Plan Area	Type of ownership
 **Player A** Land without construction > Lots assigned for construction (given typology)	9	67 %	Municipal (80%) Corporate (15%) Private citizens (5%)
 **Player B** Land with construction > Construction demolished Lots assigned for construction (given typology)	11	26 %	Corporate (87%) Private citizens (13%)
 **Player C** Land with construction > Construction maintained Lots assigned for construction (given typology)	8	5 %	Private citizens
 **Player D** Land with construction > Construction maintained Lots reconfigured without asssignment of new lots	6	1 %	Private citizens

Figure 2. Types of players

For each of these different player types there are corresponding reactions proposed by the plan:

- Player A

In this case there is the assignment of lots in proportion to the surface area of owner's land. The benefits result from the difference between the concrete value and the abstract value. The charges are calculated on the basis of the concrete value attributed, with no compensations to be received.

- Player B

Player B is similar to Player A, but existing structures are to be demolished. In this case, the compensation amount for demolition should be calculated on the basis of the building's registered value as given in the property registration document.

- Player C

Property owners in the Player C category keep their houses but their original property is reconfigured, with the portion of the plot that is not suitable for the design of the plan being separated. The same rights and charges as Player A are attributed to this portion of the land.

- Player D

Player D-type owners are similar to the Player C type, only with a difference in the assignments of lots, where, as the separated land surface areas are not large enough to translate to the attribution of lots, they directly translate to the attribution of benefits (in monetary units). As they are not involved in the plan's urbanisation, they are not allocated charges.

2) Calculating the net value of the plan – the value in euros of the plan proposal (total value) minus the cost of construction of the buildings.

The plan's total value is the sum of the values attributed to each lot as defined in the plan proposal. In order to value the lots, the national property tax calculator (SIGIMI) was used, which is a free Web-GIS based property valuation tool (see Figure 3). It takes into consideration a number of parameters for characterising a property, including location, floor area and typology.

Figure 3. Portuguese property tax calculator – SIGIMI
(available at http://www.e-financas.gov.pt/SIGIMI/default.jsp#)

For the valuation of each lot, the parameters to be entered in the SIGIMI include the proposed building typology (Tip_i, e.g., collective housing or single-family dwelling; shops and service buildings), the lot surface area (Al_i), the lot occupied area ($A0_i$), the floor area (F_i) and the dependency area (AD_i, which includes, for example, parking spaces or annexes within lots). One should point out that, as far as the dwelling typology, a valuation coefficient was taken into consideration for single-family homes in relation to collective housing, i.e. the coefficient was given a zero value for collective housing building typologies; 0.03 for terraced single-family houses; 0.06 for semi-detached houses; and 0.1 for detached houses.

Once the overall value of the plan is obtained one then proceeds with calculating its net value, i.e. subtracting the costs of construction of the buildings. The reference construction cost used was that taken into consideration in the SIGIMI at the time of valuation (€609/sq. m of floor area).

3) Calculating the abstract value attributed to each owner

To arrive at this value it is necessary to first quantify the value of sq. m of land before the construction, for which one divides the net value of the plan by the total area of land subject to *perequação*, resulting in a monetary expression of the construction rights to be attributed to each owner. By multiplying this land unit value by the surface area held by each owner one can calculate the abstract value in the plan for each owner.

4) Calculating the concrete value attributed to each owner

The concrete value is the sum of the value of the lots attributed to each owner minus the construction costs. The distribution of lots with capacity for construction amongst the owners is the most critical step in the whole process. With a view to, on the one hand, reducing conflicts and improving acceptance of the plan's solution by the owners and, on the other, minimising compensations amongst owners, the main concerns in this distribution process have to do with: (a) the lots attributed being located as much as possible in the original parcel of land or close to it; (b) the value of the attributed lots being as close as possible to the pre-calculated abstract value.

5) Calculating the benefits attributed to each owner

The benefits are calculated by the difference between the abstract value and the concrete value, as defined in the preceding steps, expressed as a monetary value. When the result is positive, i.e. when an owner does not realise the whole value they are entitled to, they receive monetary compensation. When the result is negative, i.e. when an owner realises greater value than that they are entitled to, a payment is necessary. The sum of the benefits attributed to each owner should be null. In other words, those who pay compensate those who receive.

6) Distribution of the urbanisation charges

Calculating the charges is based on the internal costs of the plan for infrastructures, public spaces, green spaces and proximity facilities, added to the compensations resulting from demolitions. These charges are distributed on the basis of the concrete attributed to each owner.

As already pointed out, calculating the compensation for buildings to be demolished should be based on the land register value of the properties given in the register records.

7) Calculating the final balance per owner

In the last step, the final balance, i.e. the net result of what each owner has to pay or receive on the basis of plan's proposals, is expressed in euros and represents the difference between the benefits and the charges, adding to this the value of compensations for demolitions.

The result of the application of the methodology was validated by Sines Council and that validated resulted in minor adjustments to the distribution of the lots amongst the owners. These adjustments were carried out in an easy and expedite way, given that all these calculations were based on a geographic information system.

Table 3 summarises the methodological steps described above and gives the respective calculation formulae.

Table 3. Methodological steps

Description	**Formula**
Calculation of area subject to *Perequação*, S	$S = \Sigma s_j$
Real estate valuate of each proposed lot, v_i	$v_i = f(F_i, AD_i, A0_i, Al_i, Tip_i)$
Calculation of the plan's overall value, V	$V = \Sigma v_i$
Calculation of the plan's net value, subtracting the construction costs, V'	$V' = \Sigma (v_i - 609 * F_i)$
Calculation of the value per sq. m in the plan before construction, u'	$u' = V'/ S$
Calculation of the abstract value attributed to each owner, $v'p_j$	$v'p_j = u' * s_j$
Calculation of the value of the lots attributed to each owner, v'_j	$v'_j = S (v_i - 609 * F_i)$
Calculation of the benefits attributed	$Benefits_j = v'p_j - v'_j$

Calculation of the unitary charges	Charge = (Internal costs + Compensations) / V'
Calculation of the charges per owner	$Charge_j = Charge * v'_j$
Final balance per owner	$Balance_j = Benefits_j – Charge_j$ + Compensation

5. Discussion and conclusions

One of the main achievements of the described methodology for distribution of the benefits and charges is the better communication with, and understanding of, landowners involved in the urbanisation process, bringing improved transparency to a somewhat blurry process.

One must bear in mind that the urbanisation process encompasses many different 'aspirations'. In a small/medium-sized city such as Sines the rural character is still dominant only a few meters away from the city's last buildings, both in terms of land use and way of life. Many people are out to gain from urban expansion plans, buying land and waiting for the right time either to develop it or to sell it to developers. For some the approval of the detail plan is the moment they've been waiting for, for others it is no more than a coloured printout and a list with more 'don'ts' than 'dos'. One must also consider that, in cases like this, people are to be told their land is going to be taken away from them, that their house is going to be demolished and that they will have to pay for the new roads that will be built on their land. People also are to be told they will make financial gain. Not only the professional developers will gain, but the residents also. And both will pay; and the amount of each one's potential gain and charges previously calculated is explicitly presented in a table included in the detail plan.

And that table will show 'the more you can get when you sell your land, the more you have to pay now for the plan implementation'. In other words, the more you get the more you pay, and the less the plan entitles you to, the less charges you will bear. By using the same valuation method that is used by the national tax board, which is freely available online, the property values obtained are to reflect the market values from an independent and impartial point of view.

By using this methodology it is expected that not only the communication and understanding of the urbanisation process will (desirably) be made clearer to the landowners and developers but also that it will be easier to manage from the local administration point of view. Knowing at this moment how much the benefits and charges are for each landowner within the detail plan is an urban management asset. Knowing how much they will be by the time a given landowner will develop their plot is a 'value added'. It is a 'value added' in the sense that it stands for the plan's own dynamics, allowing for the buying and selling of plots in a transparent way – the buyer will know how much they will have to pay (in addition to the land cost) to be able to pursue their building rights.

Caring for different players' 'aspirations' can be also understood as an equity measure, especially if it allows for the maintenance of the present social network – in the sense that it doesn't force the neighbours to leave, rather it grants them the right to develop their land and make a profit. But that profit comes with a cost. You can't have one without the other.

The Sines experience that is the object of this paper does not provide a full response to all the obstacles to successful plan implementation that are identified and described herein. The (non-)availability of public funds and the lack of reliable property records, to name just two, are hurdles that are not easily overcome. However, achieving the understanding and cooperation of the stakeholders is probably the most challenging issue.

One of the main problems in achieving equitable distribution of building rights and development costs is how to measure these benefits and charges. Instead of using the 'traditional' method based on land surface and floor areas, our approach relies on translating these benefit and charges into monetary values. The use of a universal and free evaluation tool for the calculation of the market value of the proposed plan proved to be very objective and was easily accepted by both public and private stakeholders.

To improve understanding of the application of equity in land use planning and how to overcome the lack of effectiveness of the instruments provided in the Portuguese legislation for achieving it, our team is now commencing a more comprehensive research project. This project – "Equity and efficiency in the urbanization process: a land readjustment execution model" – aims to contribute to proposing a more efficient land readjustment execution model with a view to addressing the problem of the conjugation of interests in the urban development process. The methodology developed and applied in the PP Norte may be considered as a first step towards that objective.

1. Introduction

Identity, and to a certain extent ethnicity, has been fundamental source of meaning throughout human history. It is a basic element of social recognition as well as of social discrimination. Locally based identities, in this context, have their expressions in spatial terms too. Their recognition, on the other hand, has shown an uneasy pattern in many contemporary societies through modernisation and post-modernisation periods. The experience of migrants living in western capitalist societies since the World War II has particular importance in this regard. In the context of asserting local identity, the experience of Turkish workers in Germany starting from simple urban demands on living conditions and ends up at conquest of local enclaves, deserves a close scrutiny. Today, three generations of Turkish citizens live in Germany. Majority of them have become adapted to the life in Germany. Migration to Germany is still continues with marriages and a tiny flow of workers. Reverse migration to Turkey was popular among first generation of guest workers.

Almost all of the migrant workers were without proper knowledge of the society they were heading to in 1960s. Christian culture and open society has shaken migrant workers' cultural and religious alignments. In time, population increase of the Turkish nationals in Germany has produced neighbourhoods predominantly mixed with Turkish culture. One way contemplate that these neighbourhoods have changed in land use and activities in order to fit to the Turkish customs, social and religious institutions. This retrospective study tries to explore the underlying dynamics of land use changes mainly caused by Turkish nationals to Germany, as guest workers first and permanent residents later.

The study is conducted by interviews with open ended questions with Turkish nationals in Germany, two cities, i.e. Wiesbaden and Dortmund. By retrospective and recall questions, we tried to entangle how social institutions and social cohesion have worked in transforming the land use pattern and activities that more or less satisfies the communal needs and sustain relationships. And also find out how local and/or central authorities' responses have changed towards these demands through time. Moreover, we also try to explore the effects of land use decisions on the society too. Whether the Turkish communities start to become inward

looking and semi-open, restricting itself to its neighbourhoods after respective land use changes in Germany or not is another aspect of the study we are trying to uncover.

2. Theoretical Framework: Spatial Aspects of Identity

Discussions of identity and space have become prominent in critical geography, in recent years (Massey, 1999, Castells, 1997). Identity can be defined as people's source of meaning and experience. It is primarily shaped by awareness of distinction between 'self' and 'other' (Castells, 1997).The construction of identities is an ongoing process which is nourished by complex synthesis of history, geography, biology, collective memory, religious affection etc. However, in the last stage, it is the power relation which predominantly shapes the identity. In other words, there is no such thing as a place or an identity by itself, but these are simple constructions of discourses and practices. Nevertheless, this does not deny the existence of spatial identities, but criticises it's often essentialist character by emphasising underlying power structures (Lefebvre, 1991)).

For Castells, the social construction of identity always takes places in a context marked by power relations. He goes on to argue that there are three forms of identity formation. These are:

"*Legitimizing identity*: introduced by the dominant institutions of society to extend and rationalize their domination *vis a vis* social actors,

Resistance identity: generated by those actors who are in positions/conditions devalued and/or stigmatized by the logic of domination,

Project identity: when social actors, on the basis of whichever cultural materials are available to them, build a new identity that redefines their position in society and, by doing so, seek the transformation of overall structure.." (Castells, 1997:8).

Through the complex procedure of identity formation, identities can start as resistance identity and later turn into a project identity and finally by the enforcement of institutions of the society it becomes legitimizing identity.

For the minority/ethnic groups this process is much more complicated. Ethnicity has a spatial aspect and always been associated with discrimination. To keep and sustain identity in a given territory is not an easy task especially for the ethnic minorities formed by immigrants. There are two alternative accounts explaining the immigrants' position in an alien environment. These are spatial assimilation theory and ethnic stratification theory.

The spatial assimilation theory emphasises the importance of the length of a stay in the host country (Massey, 1985). Assuming that socially and economically better positions can be obtained by a significant period of time, in due course immigrants can therefore obtain better living conditions in spatial terms. Studies on immigrants showed that better social and economic position in society would lead to moving better neighbourhoods where native residents dominantly live, making spatial assimilation much more easier.

The ethnic stratification theory, on the other hand, brings forward the importance of discrimination in social, economic, and spatial terms. Ethnic minorities are usually excluded from labour market making them disadvantaged in housing market as well. "This is evident also from studies showing that minority ethnic groups are more or less forced to buy a substandard dwelling when they are rejected by landlords in their attempt to get access to a rental dwelling" (Özüekren, Ergöz-Karahan, 2010:359). Concentration of a certain ethnic group in a certain spatial enclave increases the level of segregation not only socially but spatially too.

In short, for ethnic minorities, complex procedure of identity formation is heavily associated with the space. The level of interaction between identity and space, on the other hand, determines the levels of representation of identities in space. This would end up either in spatial assimilation or in ethnic stratification.

3. Turks in Germany

3.1. Historical Background

Migration of Turkish citizens to Germany dates back to the late 1950s. Transformation to capital intensive production in agriculture by the introduction of Marshall Aid[1] played an important role in dramatic increase in unemployment in rural areas. Majority of those jobless peasants migrated to the big cities like Istanbul and Ankara while some others tried their chances in abroad. These pioneering workers went to Germany by the initiatives of German firms with the idea of a temporary stay. Later on "emigration agreement" signed between Turkey and Germany in 1961, and workers started to be sent officially. "Although Turkey signed similar agreements later with other European countries, immigration figures to those countries have always been lower than to Germany" (Özüekren, Ergöz-Karahan, 2010:356).

Increasing demand for migrant labour in a rapidly growing economy caused masses to migrate to Germany from Turkey and some other less developed European countries like Portugal, Spain and Italy as well. However, "1973 oil crisis" put an end to the easy migration to Germany. Before 1973, migrants can easily bring their families to Germany without any restrictions. After this time immigration issues in Germany became more and more difficult. However, the number of Turkish citizens has continued to increase no matter how hard it became. During the 1970s few of these pioneering immigrants had to return to Turkey because of redundancies. Others stayed and by the help of the relatively loose family unification regulations in 1974 the number of Turkish citizens living in Germany reached to 1 million.

[1] Marshall Aid, offered to European countries in 1947, was rooted in American interests to revive the European economy as a strong trading partner, and to strengthen Europe politically against further Soviet expansion westward. Turkey was included Marshall Aid programme in 1948 with the political intentions. Marshall Aid was used mainly modernization of agricultural sector which employed 80% of the population. Under the Plan the number of tractors increased from 2,200 in 1948 to 26,000 in early 1952, more than one for every two villages, leaving most of them jobless in their own villages.

Starting from the 1980s pattern of migration to Germany has changed. Political asylum seekers fled to Germany and to other European countries just after the 1980 Military Intervention with the hope of reaching easy citizenship rights. Similarly, in the 1990s many asylum seekers run away to Germany with ethnic reasons.

At the beginning of the 2000s, there were almost 3.8 million Turks living in the European Union making them the largest foreign population. Around 2.5 million of them were living in Germany, the largest Turkish community in Europe. In 2004, the share of foreigners living in Germany's large cities was 8.1%, while only Turkish nationals constituted the 2.1% of them alone (Table-1).

3.2. Development of Turkish Settlement Pattern in Germany

History of Turkish people in Germany can be investigated in five periods according to their settlement patterns in Germany. The first period falls to 1960s when the Turkish were generally confined to guest houses (i.e. heim). "Turkish guestworkers (men and women) moving to Germany travelled by train from Istanbul to Munich and hence to their final destinations. As soon as they arrived, they were mostly housed in workers' hotels (*heim*) provided by employers" (Özüekren, Ergöz-Karahan, 2010:360). Their social and cultural as well as religious needs were satisfied by ad hoc solutions, generally confined to guest houses. At that time they lived in an isolated manner in a totally alien environment. In general their relations with the Germans were poor because of language deficiencies as well as hard working conditions.

In 1970s, guest worker flow to Germany slowed down. However, families began to reinstall themselves in the German soil and the number of second generation Turkish population started to increase. Families began to seek proper accommodation in the cities. This was the beginning of recognition era of Turkish ethnic population in Germany. This period marks the beginning of the German society getting to know Turkish ethnic population. And for the first time, Germans realised that they had to come to terms with living together. Turkish families, on the other hand, began to seek proper accommodation opportunities in the cities, both economically and socially. Since they still felt disadvantaged, they tried to live in a close vicinity with other Turkish fellows or if possible with their relatives. "The first generation tends to have very little education, do not have a specific profession, are classified as being labourers and tend to speak a rather poor German. Their social contribution to the German community is somewhat limited. The first generation tend to be rather ignorant about discrimination, because they do not feel the need for greater integration. Their group of comparison are their friends and family back in Turkey, who, from an economic point of view, are worse off than they are" (Kılıçlı, 2003:3).

Their vulnerable position in the society heavily affected their choice of living together with other Turkish nationals. In Berlin, for instance, many Turkish families started to live in relatively cheap rundown areas, especially in Kreuzberg. "But gradually politicians started to express their dissatisfaction about the concentration of Turks in particular neighbourhoods such as Kreuzberg, claiming that this concentration of former guestworkers in particular areas might hinder their integration into the host society. This resulted in regulation limiting the moves of foreigners into 'concentrated' boroughs, including Kreuzberg" (Özüekren, Ergöz-Karahan, 2010:363).

1980 Coup D'etat in Turkey caused a flow of Turkish immigration seeking political asylum. Unlike the guest workers of the 1960s, there were no ready jobs waiting them in industrial sector. Although started from 1970s, increasing service sector job opportunities absorbed some of the new wave of Turkish immigrants in Germany. On the other hand, 1980s marked the beginning of the increasing number of Turks getting into various businesses as employers. The closure of the heavy industries after the 1980s helped the acceleration of this process too. In spatial terms, economically strengthened Turkish immigrants started expressed their demands more explicitly. Apart from housing needs, social, commercial, educational, and religious necessities of Turks in spatial terms put the pressures on both local and central governments. "Germany began to realise that the social consequences and aspects of migration had up until the mid to late 1980s not been considered. Play-schools, schools, public authorities as well as health service facilities found that they were not equipped to handle the special needs of this part of the population" (Kılıçlı, 2003:1).

The 1990s worked in two ways. Firstly, faith based organizations increased their activities among Turkish population. The dominant Sunni sect in favour of the faith based organizations provoked the others, namely Alevis. Secondly, Germany witnessed another flow of political asylum seekers escaping from ethnic based civil war in Turkey. Turkish society in Germany began to crack on the lines of ethnicity and religion while Germany was uniting. Besides, German unification, the rebuilding of the East Germany and the collapse of the Iron Curtain

released millions of people seeking and demanding westerns ways of life and welfare in Germany too. “An important dimension of social change among the Turkish population within Germany is the development of Turkish entrepreneurs which accelerated in the 1990s. Between the period 1985 to 2000 the number of Turkish entrepreneurs went from 22,000 to 59,500. This indicates an increase of 170 % equalling an average annual growth rate of 7 %”(Kılıçlı, 2003:2).

Europeans views on Islamic ethnic populations changed during the 2000s after the 9/11terrorist attacks, and USA gave a wake-up call to all European countries for closely monitoring Islamic populations. Besides, all host societies in Europe developed “Islamophobia” in various ways; Germany was no exception to this. Besides, expansion of the European Union to the ex-communist countries increased ethnic diversities in European Union. All of these put the Turkish population in a difficult position with various outcomes in terms of land use dynamics.

4. Land Use Impacts of Turkish Migration to German Cities

4.1. Research Methodology

Field research was conducted in two German cities, Dortmund and Wiesbaden, where Turkish nationals have been living in since the early 1960s. Dortmund is one of the large cities of Germany with nearly 600 000 population. Turkish nationals constitute about 5% of this total. Dortmund has historically been an industrial area but now it is home to a number of medium-sized information technology companies. Wiesbaden is a city in southwest Germany and the capital of the federal state of Hesse. It has about 270,000 inhabitants. Wiesbaden hosts a number of international companies with its German or European headquarters. Apart from service sector there is also an industrial park specialized inpharmaceutical and chemical industry.

Empirical basis of this study are qualitative in-depth interviews carried out with different representation groups of Turkish nationals living in Dortmund and Wiesbaden. The analysis of interviews concentrates on the question of whether the Turkish communities become inward looking and semi-open, restricting itself to its neighbourhoods after respective land use changes in Germany as ethnic stratification theory suggests or they have been spatially assimilated.

Totally 30 interviews were undertaken, 16 in Dortmund, and 14 in Wiesbaden between March 28–April 4, 2012. Some of the interviewees are individuals in a family (8 in Wiesbaden) or individuals (22 individuals) at traditional Turkish coffee-shops called “kıraathane” in Turkish. Generally, interviews were conducted with groups in round table fashion. Open questions were asked in an order while conserving about life in Germany. The interviewers, the second and the third author of this paper, set the stage by providing information about the purpose of the study. In order to settle a historical reference point in time for recalling the past, a short account of coming to Germany is demanded first. The aim of the first question is to mark a

reference point in time and form a retrospective timeline into the past. When the first round ends, an interviewee whose recall is more detailed is selected for the next question: where did you stay/live when you first came to Germany? As some of the interviewees who had difficulty in recalling the past seem to remember, the answer helped them recall the details of the past.

a. Wiesbaden

b. Wiesbaden

c. Dortmund

d. Dortmund

Figure 1 Scenes from interviews.

At that point, the questioning then goes to the quest of this paper: did you move to a new location in order to be close to other compatriots? If so, can you give the details? When a common ground is formed, questioning goes in order to explore further details: how did the land use in your environs changed in order to meet your cultural, social and other needs? Commercial and cultural as well as religious activities are more thoroughly scrutinized during the conversations. Some of the following questions probe group behaviour of Turkish

immigrants in the city. Whether ethnic or cultural alignment is an important factor of moving or engaging activities in the city or not is one aspect of probing questions in the round table conversations.

The rest of the conversations try to unearth intergenerational differences between first, second and third generations of Turkish ethnic population. Some of the observations are also carried out by the interviewers in the field. Families were instrumental in this, because generally three generations can be observed in family group gatherings.

4.2. Findings of Case Study

One of the most controversial issues in Germany regarding ethnic populations is the ghettoization of ethnic groups in the cities and emerging parallel society of Turkish population in Germany (Schönwalder and Söhn, 2009). As regards ghettoization, we have found no traces of residential areas predominantly populated by Turkish. There are different explanations. The first one is economical. The first comers never thought of living close by and forming Turkish neighbourhoods, because they always maintained their contacts at their work places. Instead they were keener to economize on living conditions in Germany, and transfer whatever saved to Turkey. Turkey is abundant of building investments of the first comers. Instead Turkish development is found on non-residential activities in the later years. Of course, there are minor differences between different households. As the first comers were mostly single persons, they prefer to live in “heim” guesthouses attached to the work places. When families are formed, an appropriate housing is found relative to the work location, because most workers were bounded by agreements of working pledges.

On the other hand, widespread automobile ownership in Germany made house locations relatively less important in the city. In the later years, life of the households generally centred on the work locations too, but less intensively than before. Care of the children, schooling of them increased daily household chores. Therefore, home location decisions become more complex in time. But in always, economizing on living conditions in Germany dominated all decisions. This was mostly due to temporary nature of working in Germany; many thought that they would work for several years in Germany, and return to Turkey relatively richer. When the nature of staying in Germany turned into permanent nature, the living in Germany demanded Turkish social and cultural alignments too. This changed the land use in various ways too.

During temporary states of mind in Germany, Turks did not integrated to the German society. Besides, relatively rural origin of the Turkish families in Germany prevented them from utilizing opportunities of a modern welfare state fully. Therefore, in all conversations the second generation is generally tagged as a problematic generation in various ways. Although decreased significantly in the third generation, problems of school drop-outs, drug use, petty crimes etc. were generally associated with Turkish youngsters.

But in terms of parallel societies, there are certain indications of emerging traces of parallel societies between Turks and Germans, at least in their minds. Regarding this, a cynical view has just begun to flourish among the Germans (Schönwalder and Söhn, 2009).This is mostly

due to the permanent nature of the Turkish ethnic population in Germany. However, we have found no traces of ethnic neighbourhood formation because of parallel societies in Germany.

In fact, parallel societies are maintained in dresses, living conditions, customs and mostly in religious practices. The psychological shift in the western societies after 9/11 terrorist attacks approached all Mohammedans, whether non-religious or religious, into potential terrorist. This has generally worked well for Islamic faith organizations in Germany. They were very successful in gaining clients from all sorts of Turkish people with different backgrounds as they found these organizations as the sole supporters of their "honourable" existence in Germany. Yes, contacts of Turkish population with the German population are gradually decreasing in terms of daily activities as Turkish run businesses increase in Germany. But this does not mean parallelism similar to black-white separation in North America.

Although there are no "Turkishtowns" similar to Chinatowns, one can find Turkish enclaves, generally formed around mosques. These enclaves include a *cami* (mosque) where prayers are carried out, lodging for priest, and commercial premises that support the enclave economically. In fact, this type of organizing commercial activities around religious activities, partially supporting them, has historical roots in Turkey known as '*vakif*' (trust funds) formations. These enclaves support Turkish ethnic population in various ways, and form islands or refuge sites as little Turkeys.

Most of these enclaves visited during field work economically sustain themselves by renting its non-religious parts to commercial activities. Enclaves include Turkish cafe shops for males called as "*kıraathane*", barber shop, retail shop etc. along with a religious site, which is mostly a mosque. Especially, a barber shop is very handy for Turks with short hair and beards styled in Turkish Sunni way. *Kıraathane* is place to chatter with fellow compatriots and have religious talks with others. Imam maintains strong ties with Turkish practicing religion. Central position of imam is inherited from pre-republican era and pre-modernization era. Imams in rural areas still have central position in maintaining social order. As the first comers are predominantly from rural areas, *imam* in a Turkish enclave is a cherry on the pie that supports and feeds Turkish nationals, especially the male first comers, with all sorts of religious information.

"*Kıraathane*" in these enclaves is the place where pious Turk can find Turkish tea and have a talk with fellow Muslims too. These Turkish style rest houses in Germany were rare in the past, all Turks were employed. Instead, there were Turkish style cafes serving alcohol, populated after work shifts. The number of these cafes increased after the influx of refugees seeking political asylum from 1980 coup d'état in Turkey. Retail shops in these claves predominantly offer products of Turkey and *halal* food. Effects of this are twofold. While commercial premises attract Turkish population to a certain extent, Turkish enclave guarantees and enjoys patronage to a certain extent, at least in certain products, from the Turkish population.

Another form of Turkish land use effect in German cities might be the formation of commercial stripes. From interviews, we have found that there is an ecological process in terms of land use dynamics regarding Turkish commercial stripes (along certain streets)

mainly starting from 1990s. This trend is generally started with the closure of heavy industries employing Turks. Most blue collar Turkish workers have switched to tertiary jobs or formed their own businesses targeting their compatriots.

The development is generally initiated by a grocery store or a supermarket. Entrance of a market operated by a Turk and offering various sorts of Turkish products, e.g. tea, feta cheese, olives, signifies a potential Turkish commercial development nearby. As bilingual market attracts all kinds of people, be they fluent in German or not, the street and its close vicinity becomes a potential customer base. Streets relatively accessible by Turkish population, scattered in the city, forms a comparative advantage in becoming a Turkish commercial stripe.

a. An old “heim”

b. Turkish supermarket in a Turkish Enclave

c. Turkish commercial stripe in Wiesbaden

d. Starting point of commercial stripe

e. Supermarket in commercial stripe

f. Turkish bakery in commercial stripe

Figure 2 Examples of Turkish land use effects.

These streets with central positions and relatively with low rent levels are potential stripes for Turkish commercial development. These streets are found to be generally in the transition areas from commercial zones to residential areas of the city. Turkish commercial stripes contain carpet shops, travel agencies, call centres, coffees, doner/kebab houses, garment shops, jewellery shops, photo shops, shops offering garment for special events, e.g., circumcision, haj, marriages, etc. Composition of these stripes is affected by the composition of the Turkish population directly.

Among these commercial uses, Turkish restaurants show a certain degree of freedom from this ecological process as they serve for all of the population. Similarly, shops that offer traditional artisanal goods such as kilims and carpets are also scattered in the city. Both of these commercial uses attract customers from all ethnic origins. On the other hand, shops that offer Islamic garments predominantly locate at Turkish commercial stripes. Uses that specialize on the population such as photography studios for special events also locate on these stripes. Commercial stripes follow ecological processes such as invasion and succession, competition and accommodation. One another finding is that initiation of the stripe formation with a grocery store/supermarket offers a potential development. As other commercial uses for Turkish ethnic population comes to the vicinity, commercial uses for German population begins to lose customer base, which is an indication of moving out from the street.

5. Concluding Remarks

The experience of ethnic minorities in western capitalist societies has shown an uneasy development pattern. Turkish minorities, the largest foreign population in European Countries (almost 5 million), are no exception in this regard. Their 50 years encounter demonstrate a line starting from total alien in an unknown environment to a rooted citizens on their own rights. Turks in Germany deserve much more scrutiny since nearly 3 million Turks live in Germany today.

Identity formation and its maintenance for migrant population have different features than that of people living in home countries. As discussed earlier, the procedure of identity formation can start as resistance identity and later turn into a project identity and finally by the enforcement of institutions of the society it becomes legitimizing identity. The position of Turkish citizens can be regarded as between the project identity and legitimizing identity since the enforcement process of institutions has not been finalised yet. This is partly because of the enormous differences between two different cultures (namely Muslim and Christian) and partly because of the ignorance of German policy makers about the nature of the identity formation pattern.

Similarly, today's spatial expression of Turkish identity in Germany can be considered neither spatial assimilation nor ethnic stratification. Their location preferences have always been dominated by economic concerns. As we mentioned before, there are no "Turkishtowns" similar to Chinatowns in German cities ethically segregated from the rest of the city and the society. In spite of this, spatial assimilation cannot be applied to Turkish minority either, since

they mostly live in spatial enclaves formed around mosques. This rather peculiar land use formation prevent Turkish minority to live in a so-called "parallel society" as well. The latest development, as Turks sustain their position economically in German soil and become business investors, which reveals itself in the emergence of commercial stripes neither jeopardise their cultural, religious or national identity, nor make them ethnically segregated.

In short, Turkish presence in Germany exemplifies rather different pattern than other minorities. This is partly because of strong relationship with home country and partly because of their fortified position in German society both economic and social terms established in time. Although there is a perception among Germans that Turks are living in a "parallel society", in reality this is not the case since Turks integrated into the social and economic life intensely. However, whether the role of the religious organisations and the hostility among some Germans could change this situation in time, still remains to be seen.

Keywords: spatial fragmentation, public-private interactions, problems of organised complexity, jazz improvisation

1. Introduction

Flanders is spatially fragmented; a dispersed city (Gulinck et al, 2007). Fragments of age-old farmland border on generic villa allotments, oversized industrial areas, shopping centres surrounded by parking space, factories reconverted to garden centres, etc. The Spatial Structure Plan for Flanders (1997) considers spatial fragmentation as a negative process leading among other things to undefined leftover spaces, pressure on non-built-up areas and an increase in traffic. The Plan therefore offers concepts to halt and invert this process.

Rather than trying to invert this fragmentation, though, De Meulder et al. (1999) propose to work with it. Through meticulous reconstructions of spatial transformation processes, they set out to reveal spatial patterns and relations within the dispersed landscape. These patterns and relations are then taken as the starting point to structure this dispersion (Dehaene & Boon, 2006). What the reconstructions also reveal is that fragmentation processes are the result of numerous iterations of public and private initiatives which are hardly ever coordinated, let alone planned. Until the implementation of the Structure Plan, for instance, most decisions concerning land use were made at the level of the municipality, often without any planners being involved (Renard & Liefrink, 1995).

In this paper we argue that patterns and relations are not only found in the dispersed landscape, but also in the interactive processes between public and private initiatives which generate this landscape. We refer to these patterns and relations as *urban improvisation*. In jazz, an improvisation starts with one player setting a tune until another player decides to play along or comes up with his own tune. The result is a

complex and unpredictable interplay of action-reaction, at some moments very clear and coherent, at others totally fragmented. In this paper we will translate the concept of jazz improvisation to the context of spatial transformation by applying it to a number of cases: the construction of a neighbourhood, the transformation of a historic street and the development of a park, all situated within the city of Antwerp, Belgium. For each case, we will reconstruct the public-private interaction process and assess a series of spatial and social features by comparing it to locations where the public initiative prevailed and no improvisation took place. We will argue that urban improvisation can be considered as mode of planning in its own right and illustrate that it can lead to social and spatial quality, even while also producing fragmentation.

2. Fragmented Flanders

The Spatial Structure Plan for Flanders (1997) starts from the proposition that Flanders is spatially fragmented and that this fragmentation is increasing. Among the causes of this fragmentation, it points to a range of market mechanisms: "*For instance, the operation of the housing market results in massive suburbanisation with privately owned detached houses in its periphery, whereas changes in economic patterns lead to the (re)localisation of production and distribution facilities from the urban centres to he periphery or along international routes"* (p.44). The resulting fragmentation, it is claimed, has led to the displacement of urban dynamics, the decreased impact of planning and design, undefined leftover spaces, new typologies and programs, the development of non-spaces, strong pressure on unused spaces and increase in movements.

In other words, the Spatial Structure Plan regards fragmentation as a negative process which should urgently be neutered and replaced by "*a sustainable form of urban development which manages space in a way that benefits the present generation without endangering the needs of future generations*" (Art. 1.1.4). In order to achieve this objective, the authors of the plan propose - among other measures - to categorise urban centres on the basis of morphological and functional criteria and to define developmental options for each resulting type of urban centre, including desired density, permitted facilities and acceptable types of housing.

The principle of categorisation is reminiscent of Christaller's Central Place Theory (1933). Christaller shows in his theory that the growth and location of settlements follows a hierarchical pattern in which large centres are surrounded by smaller centres, which in their turn are surrounded by yet smaller centres. The distance between those centres is determined, among other factors, by travelling time. Up until the mid-nineteenth century, Belgium was a classic example of the Central Place

Theory. The widespread possession of cars, however, has diminished travelling time and upset Christaller's hierarchy. By limiting the developmental options of the various centres, the Structure Plan seems eager to counter the negative consequences of spatial fragmentation through a return to Christaller's original hierarchy.

The Structure Plan is now over a decade old and has partially achieved its objective. It has delineated agricultural, natural, residential and other zones and established awareness among the Flemish public that land is a finite resource. Developers have started building more compact constructions and authorities in other policy domains have adopted the principle of structural planning. However, these paradigm shifts have not succeeded in halting the process of fragmentation (Gulinck et al, 2007). Various explanations have been offered for this phenomenon, including the cumbersome hierarchical structure of the Plan, the limited resources of provincial and communal authorities, the complexity of newly emerging social problems and speculation by land owners (Voets et al, 2010).

3. From a Flemish to a regional scale

In *Patching up the Belgian Landscape* (1999), De Meulder et al describe how in the space of a century and a half Flanders has been transformed from a Christallerian geography into today's nebulous urban sprawl. The authors' central argument is that the underlying process of fragmentation is firmly anchored in cultural and socio-economic realities. The narrative starts in the mid-nineteenth century when the introduction of a dense network of regional and local railways rendered every nook and corner of Flanders accessible. One of the reasons for the development of this network was a desire to counter the explosive growth of the cities. Workers became commuters and were thus enabled to remain in their villages where they could rely on their traditional social networks in periods of crisis. This transportation policy was supported by a housing policy which aimed to enable every worker to own residential property. Land was thus transformed from an agricultural resource into an investment product, which set off a process of the allotment of land into small individual plots, a process which continues to this day. These twin policies have resulted in the very limited growth of Flemish cities in comparison with the surrounding countries and, as a consequence, a limited form of urbanisation which has mainly developed in the countryside along existing streets and routes and in close proximity of railway stations and crossroads.

This process accelerated considerably after World War II, when travelling by train became more comfortable and cars became affordable for everybody. Now the middle classes also started to commute. A law introduced by De Taye added 50,000 new detached houses in the countryside in the space of a decade. The policy was no

longer striving merely to limit urban growth, but was actively promoting an urban exodus. Thus, during the nineteen sixties and seventies, the middle classes collectively deserted the grey and polluted cities in search of a house with a garden in a natural environment, thereby slowly urbanising culture in the countryside.

As a consequence, a culture of land allotment and building one's own house has developed, characterised by small contractors, traditional construction techniques and a direct relationship linking contractors, architects and owners. This has led to a multitude of individual projects of low complexity with minimal intervention by the authorities – an effect which was further reinforced by the autonomic powers of decision held by communal authorities until the introduction of the Spatial Structure Plan for Flanders. This has meant that, for all practical purposes, there was no policy.

With each subsequent generation, the Flemish countryside was further urbanised and today the Christallerian model has completely disappeared. By introducing selective densification, the Structure Plan strives to return to the original conditions, which offered a clear distinction between built-up centres and open landscape. However, De Meulder et al stress the fact that the existing settlement patterns occupy large amounts of space and present a very specific, fine-grained and a-systemic structure which cannot be systematically densified. Moreover, as the above historic overview shows, the unit of measurement has been the individual allotment plot and there has been no intention to enter into a relationship with surrounding structures and the remaining open landscape.

In other words, the authors also recognise the disadvantages of fragmentation, but contrary to the Plan's authors, they do not believe it is possible to return to the Christallerian model. In their view, the main task imposing itself today is to transcend the logic of allotment. Individual plots cannot provide a locality or community with an identity. There is a need for structures which can generate cohesion at an intermediary scale and give common direction to a loose collection of unconnected plots. De Meulder et al state that the landscape could play this role. Thus, densification to them does not imply the increase of housing and facilities as prescribed by the Structure Plan, but rather the qualitative improvement of the remaining open space. In recent years, the authors have substantiated this view by developing concrete projects for a number of Flemish villages (cf. e.g. De Meulder & Devisch, 2002; Dehaene & Boon, 2006).

4. Fragmentation resulting from individual actions

In 1948, Weaver introduced the concept of *organised complexity* to refer to problems which seem complex when viewed on a macro-scale, but whose individual components on the micro-scale follow a set of simple rules of interaction. The

interaction of the parts thus generates a whole which is larger than their sum and which cannot be deduced from the behaviour of the individual components (‘emergence’). In other words, the components organise themselves without being managed by a central authority. With the concept of emergence, Weaver introduced the theory of complex systems. Beside organised complex problems, he also distinguished *simple problems* and *disorganised complex problems*. The latter term refers to problems which not only seem complex, but also behave in a complex way.

Following the historic reconstruction by De Meulder et al (1999), the fragmented Flemish cityscape can be considered as a system of organised complexity. From a distance it looks complex, but it actually behaves in a relatively simple way because it has a limited number of actors, namely private builders and authorities. Compared to the surrounding countries, planners, developers, investors, corporations and the like have historically played only a limited role in Flanders.

Weaver states that simple problems present a limited number of variables, which means that they can be described as mathematical equations with predictable outcomes. Disorganised complex problems, on the other hand, are characterised by a large number of variables, which means they can only be described in terms of probability theory and that predictions are virtually meaningless. Organised complex problems are the intermediate condition between these two extremes: the number of parameters is too large to describe the problem as a mathematical equation, but not so numerous as to exclude the usefulness of probability theory. Weaver proposes to use simulation models to deal with such problems, implying that the behaviour of the individual actors, rather than that of the system as a whole, can be described in equations called rules of interaction. It is the confrontation of these actors within a set of delineated conditions which structures the behaviour of the system. In order to determine the governing rules of interaction, a model made up of a number of generic rules is applied and the behaviour resulting from it is compared to the real problem and adjusted accordingly. When both are in harmony, the rules of interaction have been determined and predictions can be made concerning the future behaviour of the system within the set of delineated conditions.

De Meulder et al (1999) pose that intervention in Flanders’ fragmented urban sprawl presupposes insight into the spatial processes which have shaped this cityscape and which are propelled by regional landscape elements including topography, soil composition and water management (De Meulder & Dehaene, 2002), as well as by policy decisions and cultural and socio-economic behaviour patterns. Additionally, if this process of fragmentation is indeed an organised complex problem, intervention requires insight into the rules of interaction which govern the behaviour of actors participating in the construction of the cityscape. In this view, the governing spatial processes constitute the set of conditions within which the actors operate. Knowledge of both is therefore required for intervention to be successful.

Reconstructing the rules of interaction requires a specific analysis different from the analysis of the existing use of space which is employed in the Spatial Structure Plan for Flanders, and also different from the analysis of the evolution of spatial patterns used by De Meulder et al. It requires an analysis of the actors: what are their objectives, which are the tools they use and how do they react to each other's interventions? Such an analysis moreover requires the use of a different scale: instead of using as the unit of measurement all of Flanders, as the Structure Plan does, or regionial subdivisions, as De Meulder et al do, the analysis should be carried out at the scale on which the actors operate, which is that of the individual allotment plot. We are no longer looking at a quest for spatial structures and patterns, but at direct spatial experiences and relationships. From the bird's eye perspective, we need to descend to the level of everyday action.

The question remains, however, whether rules of interaction which can help explain the process of fragmentation actually do exist. Can we detect a certain order in the manner in which private builders react to the conditions imposed by authorities or to the behaviour of other private builders? Or will we see on the contrary that every situation is unique and no general rules apply? In other words, is the process of fragmentation in actual effect an organised complex problem or not?

5. Four case studies

In order to answer the above questions, we will briefly discuss four different cases – all of them centered on streets in the city of Antwerp: the *Milisstraat*, the *Bleekhofstraat*, the *Fruithoflaan* and the *Grote Steenweg*. In each case, we propose to reconstruct the origin and history of these streets and specifically to determine which actor (authority of private builder) has initiated a specific action and how these actions have interacted with each other. The scale for this reconstruction is that of the individual allotment plot and the individual actor. On this detailed scale, not every action has been documented and not all documents are readily available. The reconstructions should therefore be considered hypotheses. These hypotheses are of course based on historic sources, but to these are added the authors' extrapolations, associations, presuppositions etcetera. In general, the hypotheses remain within the strictly probable, but in some cases they have consciously been taken out of proportion in order to explore potentially interesting interactions. The following is a brief summary of these reconstructions.

5.1. Case 1: Milisstraat – Oedenkovenstraat (total length: 350 m)

The Milisstraat and Oedenkovenstraat are aligned streets located in the Antwerp district of Borgerhout. Both contain only terraced houses in completely closed rows. Virtually every house has a back garden. The origin and historical development of both streets is straightforward. The city of Antwerp imposes two general urban development rules: one aiming at the protection of privacy (‘the rule of lights and sights’) and one aiming to ensure visual coherence (‘the rule of harmony’). All builders have followed both rules, with the exception of just one who has built up the entire garden area.

In all, this makes for unambiguous interaction between the actors: the council determines the rules and the individual follows them. The rules are sufficiently open-ended to allow for personalisation: for instance, every house uses different building materials and presents a different building height, window distribution etcetera. Yet, because all houses are placed along a single straight building line, have the same width and similar facade compositions, the whole still presents a strong visual coherence.

This street type is promoted by the authorities as the ideal to be aspired to: a street composed of personalised terraced houses suitable for families with two children.

5.2. Case 2: Bleekhofstraat (total length 350 m)

The Bleekhofstraat runs parallel to the Milisstraat and Oedenkovenstraat, but contrary to them it is spatially fragmented. Beside terraced houses, it also contains two flat blocks, a school surrounded by green space, a number of unused plots, receding retail properties, reconverted former warehouses built perpendicular to the plot, … The use of space is equally diverse: some retail properties, for instance, have storage or parking spaces across the street, a number of buildings have windows in the side walls, others present a blind facade, …

Unsurprisingly, the origin and history of the Bleekhofstraat are not as straightforward as in Case 1 either. Although in principle the same two general rules of urban planning apply here, the street has always had a different program which has excepted it from those rules, involving bleaching meadows (hence its name), a candle manufacturer and a chocolate factory. A possible reason for this different development is the fact that the Bleekhofstraat is straddling the border between two city districts and therefore attracted a concentration of less desirable functions, which brought different building scales and construction types to the street. Both factors have remained constant throughout its history. The candle manufacturer, for instance, was replaced by the school and the flat blocks, the chocolate factory was partially broken down to make room for parking spaces, smaller industrial constructions perpendicular on the street were scheduled to be reconverted into collective housing

projects, … Recently, the city council has financed a project inspired by one of the historical construction types in the Bleekhofstraat, involving residential buildings with a patio perpendicular on the street. In this case, the authorities have introduced a new local urban norm in addition to the ideal image of the terraced house with a garden.

The interaction between the actors is more complex than in Case 1. The two general rules determined by the authorities formed the point of departure and the first residential buildings duly followed these rules. The larger non-residential program, however, departed from them and in the course of history private builders increasingly decided to ignore the rules imposed by the authorities – without, however, directly breaking them. They either chose not to build on certain plots or to reconvert existing structures to serve different purposes. Others avoided compliance by negotiating with the authorities – such as the builders of the school and the flat blocks. In the case of the most recent project, the authorities themselves, inspired by private interventions, decided not to comply with their own rules.

5.3. Fruithoflaan (total length 700 m)

The Fruithoflaan is situated in the district of Berchem. It is a relatively recent street characterised by high-rise flat blocks of between six and thirteen floors. The oldest among them include retail spaces on the ground floor level. The most recent blocks are placed perpendicular to the street and surrounded by green space. It is a relatively wide street with lanes separated by a central green space. All the surrounding streets are composed of terraced houses, which gives the Fruithoflaan an outspoken insular feel.

The origins and history of the Fruithoflaan are relatively unambiguous. The avenue was once part of a count’s estate. In the 1920s, the estate was subdivided into allotments by its owner who was inspired by similar lucrative development projects in the surrounding districts and communes. As Berchem then suffered from a pressing lack of housing, the local authorities did not object to the allotment. Both actors developed plans, but they did not reach agreement and in 1953 the count decided to sell his estate to a developer. A few years later, the latter did reach an agreement with the authorities, who allowed the developer to construct a relatively new type of housing with greater density than the surrounding construction types and presenting a relatively new urban layout. In return, the developer agreed to construct sports facilities and road infrastructure. In the following years, other developers copied this new construction mode. In the early 1960s, a second developer succeeded in convincing the council to build with an even greater density and in yet another layout, which involved merging plots, building higher, reorienting buildings and

retracting the building line. It is not entirely clear why the authorities gave their blessing to these changes, but again the model was copied by a number of other developers until the final construction phase ended in 1980 and the street was fully built up.

The interaction between the actors, then, follows an iterative pattern. Initially, as in the other cases, both rules imposed by the council apply. However, one developer wants more and negotiates with the authorities to get a tailor-made plan accepted. Other developers follow suit. Then another developer decides to renegotiate the conditions and obtain permission for yet another different model. This is again repeated until finally the avenue is built up completely.

5.4. Grote Steenweg (total length 700 m)

The Grote Steenweg connects the centre of Antwerp to the commune of Mortsel. The present case study, however, only looks at the stretch between the King Albert Park and the Binnensingel (the inner ring road) which is contained within the district of Berchem. This part of the road is mainly composed of retail properties and flat blocks, but also contains a garage, a school, a convent and a church. Building height varies between two and eight floors. The building line jumps in and out several times and is interrupted by squares and lawns.

The scale and statute of this road (a main access road) make for extremely complex origins and history. The following is a succinct summary of events happening in the last few decades. Older photographs clearly show that up until the first half of the twentieth century the road consisted mainly of terraced houses with two to four floors and retail spaces on the ground floor. A map dated 1912 shows the council's ambition to urbanise the road's statute: the road needs to be widened to accommodate the increasing traffic and the buildings need to become higher to respond to an increased demand for housing. We start from the hypothesis that the council could not just expropriate properties across the board and therefore needed to negotiate with many owners to implement its plans, which has resulted in a fragmented outcome in terms of types of construction, program, shapes, building line etcetera.

Presumably, the interaction between the actors developed along the following lines: the council imposed the two general rules and private builders complied – until the council adapted its vision on the road's statute. In order to convince private builders to accommodate this new vision, however, the council was forced to make concessions to suit their respective needs.

Each of these cases can be read as a generic script for interactions. In Case 1, for instance, all private builders comply with the framework imposed by the authorities. In Case 2, not all private builders comply entirely with the framework, but all do remain within the framework. In Case 3, private builders negotiate with the authorities and succeed in having the framework adapted. Finally, in case 4, the authorities themselves introduce a new framework. Case 1 is the most common scenario in Antwerp, but the other scripts also occur more than once, albeit sporadically. Cases 2, 3 and 4 give the impression of a spatially fragmented environment.

6. Urban improvisations

What is striking in the cases is that the spatial (planning) framework is constantly changing and that both authorities and private builders can initiate changes. Changes can be made directly through negotiations or indirectly when private builders decide not to comply with the rules or to explicitly break them. Whatever the case, the change always impacts the spatial processes which structure the cityscape.

A wide array of practices can be included under the heading of spatial planning, ranging from the development of an overall framework which private builders comply with on one end to the complete absence of such a framework and total freedom of action for private builders on the other extreme. Case 1 falls in the first category, while the other three occupy various positions between both extremes: the authorities have designed a spatial framework, but this is not unconditionally applied. Private builders have the ability to directly or indirectly modify it. This practice strongly reminds us of improvisation.

In jazz, improvisation is a term which indicates musicians interacting with each other, in a game of reaction and anticipation which does not follow a written script or score. A session starts off on an established *theme, rhythm* or *chorus.* Then one musician plays a solo part, after which the musician may return to the agreed theme and be joined by the others, or alternatively another musician may continue with a solo part inspired either by the first solo or by the established theme.

Improvisation is about interaction in the sense of people reacting to each other, but not about interaction in the sense of cooperation to create one coherent product with a consistent quality throughout. After all, players may deliberately work against each other, trick each other, choose to create their own story while disregarding the others etcetera, all while remaining guided by the established overall theme.

Santi and Illetterati (2010) distinguish three defining characteristics of improvisation. The first characteristic is the centrality of transgression (or transcendence) of the rules. The authors consider rules not merely as a prerequisite for improvisation but as the actual core around which an improvised session is constructed. Thus, a solo player will time and again challenge the established theme – turn it around, reduce it to its bare minimum etcetera – but nevertheless always return to it. Santi therefore states that the superficially opposed concepts of ‘rules’ and ‘freedom’ are in fact inextricably interlinked in improvisation.

A second characteristic is recognisability or familiarity. Improvisation is about interaction. According to Santi, this implies that each solo part must on the one hand be sufficiently surprising and innovative to challenge the other players, but simultaneously sufficiently recognisable for the other musicians to play along to it.

The third feature of improvisation is craftsmanship. Santi states that the musicians participating in an improvisation session on the one hand learn thanks to the repetitive character, but simultaneously also teach by time and again re-interpreting the existing elements. This reinterpretation presupposes craftsmanship: refining and bending the rules while preserving their identity (‘crafting and scaffolding’). Again, Santi affirms that ‘technique’ (i.e. rules) and ‘spontaneity’ (i.e. freedom) enter into a ‘mutual and inextricable relationship’.

Improvisation therefore requires training and perspicacity, insight both into one’s own playing and into that of the others. Today we observe that classically trained musicians have all but lost the ability to improvise, even though this ability has historically been an integral part of musical knowledge and musical schooling programs.

Finally, it is important to note that within jazz, there are different degrees of improvisation, ranging form one improvised solo part accompanied by the orchestra all the way to free jazz where nothing is agreed on beforehand and the process of action and reaction itself is the guiding theme.

The interactive processes as shown in the case studies could be rewritten as sessions of jazz improvisation: the authorities sketch a planning framework (cf. theme, rhythm or chorus). A private builder then initiates construction (cf. plays a solo part), whereby s/he can either stay within the framework, ignore it or modify it. Next, the authorities can decide either to allow the construction, to forbid it or just to tolerate it – or even to adapt the existing framework (cf. solo part). Then the private builder’s turn comes again. As in jazz improvisation the actors react to each other’s contributions without following a blueprint. Neither the resulting spatial product nor the evolution of the process are known beforehand.

In order to establish whether interactive processes can really be labelled ‘urban improvisations’, it is interesting to check whether they present all three characteristics identified by Santi and Illetterati.

The first characteristic focuses on the importance of rules as a precondition and calibration point for improvisation. In Case 1 - Milisstraat – Oedenkovenstraat – all private builders’ initiatives comply with the planning framework. The framework, however, is sufficiently open-ended to allow for a large amount of personalisation. As a result, each housing unit is different from the next one. In the other three cases, the planning framework is modified in the course of the process, either at the request of private builders or in response to their efforts. All cases explore or transgress the planning framework and thus comply with the first characteristic. However, the motives for the explorations and transgressions differ from those playing in jazz improvisation, in which each musician has the same motive: to collectively create a piece of music and arouse emotions. In urban improvisation, the different actors’ motives rarely coincide: private builders tend to act in their respective self-interest, while the authorities strive to serve the common interest.

The second characteristic stresses the balance between innovation and familiarity. Unlike what is the case in jazz improvisation, however, inspiring one’s fellow actors is not the main objective of builders - unless maybe in the indirect sense of offering an innovative solution to a specific problem. On the contrary, initiatives which are too innovative might cause other actors to quit, which is what happened in Case 4 - the Grote Steenweg – where broadening the road required expropriation and one private owner refused to sell his property, which forced the authorities to revise the planning framework.

The third property – craftsmanship – indicates a technique to refine and bend the rules while preserving the overall identity. The first two cases comply with this requirement: interventions do not transcend the scale of the individual plot. The perception of these streets has therefore not changed in any substantial way in the course of recent history. The other two cases, however, are harder to fit into this profile: while initiatives are also implemented incrementally, the difference between the various steps is larger. In these cases, the perception of the whole has changed to a considerable degree.

Based on these three properties, Santi and Illetterati state that jazz improvisation requires training and insight. Here, we discover a considerable difference with urban improvisation. In the case studies, actors who display spatial knowledge are rare. There is no tradition of improvisation. Another great difference is the collaboration between the actors, which is usually limited to a single construction project, after which the player disappears and a new one shows up. After all, most people only

construct one house during their lifetime and even those who build more than once are unlikely to do so in the same street. Urban improvisation sessions, then, continually change players.

Finally, as in jazz, we can distinguish various forms of urban improvisation, including those which stay within the prescribed framework and those in which the framework itself evolves. Moreover, the degree of open-endedness of the framework may vary widely. The result is an array of urban improvisations ranging from those evolving within a strictly defined framework on one end to pure free-jazz on the other extreme.

Despite the differences, however, there are sufficient resemblances to label the cases as ‘urban improvisations’. Rowan (2004) even goes so far as to state that spatial structuring cannot exist without improvisation. Thus, planning processes may start with proposals offered by a planner, but that is only the start of a long and unpredictable trajectory in which a range of actors evaluate and refine these proposals time and again – exactly as happens in a jazz session.

7. Conclusion: the quest for quality

In disciplines of art such as music, theatre or comedy, improvisation implies quality. In many other disciplines, however, improvisation is associated by many with tinkering, provisional solutions and cut-and-paste operations: in other words, it generates negative connotations. This is certainly so in the discipline of spatial planning.

However, the case studies show that urban improvisations can definitely result in (spatial) quality. On the other hand, quality is a very subjective concept. In the framework of this study, spatial quality is judged by the degree of spatial diversity and the presence of spaces for (alternative forms of) collective experiences.

In Case 1 - Milisstraat – Oedenkovenstraat – spatial diversity is limited to use of materials, building height, window distribution, application of colour, … This allows for a personalisation of the design of one’s own house. Improvisation has not here resulted in special spaces for the collective.

In Case 2 – Bleekhofstraat – a wide diversity has been achieved with respect to plot size, program, construction type, orientation, use of materials, … This variety allows for multiple functionality (e.g. a building materials retailer, an art gallery, a supermarket, …), offers breathing space for small (often immigrant) start-ups, mixes different types of housing (terraced houses, flats, high-rises, lofts) and enables a school to be surrounded by green space in the city centre. However, in between these

are many unused properties and spaces and conflict situations. The various programs, despite resulting from pure self-interest, have nevertheless in an unplanned way created special spaces for collective use. Thus, the low walls surrounding the high-rises function as seats for parents waiting for their children to finish class, the gardens of the perpendicularly oriented residential buildings provide green space for their neighbours across the street and the larger plots also serve interesting semi-public functions.

Case 3 – Fruithoflaan – also offers a large diversity. Contrary to what is the case in the Bleekhofstraat, the actors here are not individual private builders but developers and contractors. Yet we find a strong coherence, partly because of the recent construction of the buildings, partly thanks to the guiding role of the local authorities and partly because all buildings have been constructed within a relatively short period of time. By adapting the planning framework, the council has managed to respond to an increasingly pressing demand for construction. The result has been a new spatial condition, a small self-contained city with semi-public (collective) spaces to suit inhabitants. Although the building types were new, they turned out to be very popular: most of the original occupants are still there today and the facilities have adapted to the inhabitants.

In Case 4 - the Grote Steenweg – we find an equally large diversity and here too, the actors are mostly developers. However, in this case we are dealing with isolated renovation projects spread out over a relatively long period of time, which has not provided much coherence and created quite some leftover spaces and conflicting situations. The number of special collective spaces is low.

Both the measure of diversity and the presence of alternative collective spaces are the direct result of urban improvisation. In all cases we studied, however, this improvisation has come about as an ad-hoc affair without any training or insight on the part of the actors. This has created diversity but also unnecessary conflicts, which could have been prevented by the establishment of a tradition of improvisation with its own language, tactics and strategies, a platform for the exchange of knowledge, …

Substantial research has been done into the role of private builders within the framework of spatial planning (cf. a.o. Healey, 2005; Boelens & Spit, 2006; Dell & Van Vugt, 2010). Less attention has been paid, however, to the role of both private builders and authorities in the interactive process and its impact on the built-up environment. Most studies, moreover, look only at the regional or urban scale and do not descend to the scale of actors, objectives, strategies and tactics (Weaver, 1948). Yet this is the exact scale on which improvisation in Flanders takes place between small entrepreneurs, individual private builders, on individual plots and allotments. A

tradition of improvisation will only succeed in taking hold if it focuses on filling both of these gaps.

Track 6. Urban Change: Plans, Visions and Policies

Title: A Critical Analysis of the Concept of the World's Most Liveable City. Auckland: A Case Study

Author: Natalie Palmer

University of Auckland

natalie.palmer@aucklandcouncil.govt.nz

Abstract:

This paper interrogates the relationship between the concept of 'utopian fantasies' and the desire of cities to become the world's most liveable. Why do political figures paint a picture of a utopian vision for their city? This thesis challenges the reader to understand the 'fantasy' concept of the world's most liveable city.

It is argued that the global, capitalist order is producing networks of knowledge which have the same universal discourse for all western cities. Therefore, it is argued that the pursuit of the world's most liveable city is a 'sublime object of ideology' (Zizek, 1989, 1999). This is a concept which suggests that ideologies such as creating the world's most liveable city are beyond objective intelligibility. This builds on Kant's 'Critique of Judgment' written in 1790 (Kant in Bernard, 1951) which defines ideologies as not having limitations in terms of how majestic they can be, as opposed to something that has boundaries. However, this paper argues that the perception that something can be so majestic is a fallacy, because the most liveable city will mean different things to different people and will be unachievable in practice.

In the case of Auckland, the Mayor has set the Council the challenge of being recognised as the world's most liveable city. Liveability is measured by surveys such as that carried out by organisations such as Mercers. The argument advanced in this thesis, is that the Mayor's vision is a Lacanian 'utopian fantasy'. In other words, it is an unattainable, ideological, fantasy construct (Gunder and Hillier, 2009), which will not contribute towards recognising the diversity and the needs of the people of Auckland, particularly with regard to affordable living.

But is there a requirement for such a fantasy construct? On the one hand, a city can follow a vision to provide inspiration and increased certainty to residents. On the other, it can provide false hope and only serve to benefit certain sections of the community; for example the elites who dominate the overarching ideology, in this instance support for the neoliberal global order.

This paper proceeds to explore the dynamics of pursuing the vision for Auckland in three steps. One; to examine the underlying global neoliberal political order that has contributed to the push for cities to compete in terms of liveability. Two; to explore theories on creating a successful city, examining the criterion that organisations such as Mercers rely on when assessing liveability, and three; to understand the reasoning behind the pursuit of the world's most liveable city in terms of Lacan's concept of 'utopian fantasies' (1994).

A Critical Analysis of the Concept of the World's Most Liveable City. Auckland: A Case Study

Introduction

The concept of a city that is the 'world's most liveable' is perpetuated by surveys such as The Economist Intelligence Unit Survey and Mercers' liveability surveys. Melbourne was voted as the world's most liveable city according to the Economist in 2011 (www.economist.com), and Vienna was Mercers' choice (www.mercer.com). Western cities generally aspire to achieve this accolade. But what makes a city liveable? And is this title a positive mandate for a city? The Auckland Council's mayor is advocating this for his city (Auckland Council, September 2011), but is it something that should be supported?

The main problem with this concept is the definition of liveability. It is clear from the above that two surveys can have totally different outcomes.

Oscar Wilde (Wilde, 1891, p28) famously stated "A map of the world which does not include Utopia is not even worth glancing at, for it leaves out the country at which humanity is always landing". Wilde believed that the human spirit could only prosper and blossom in a utopian world. The writer opines that certain politicians certainly do try to land at this Utopia. This is clearly the intention of Auckland's Mayor in his pursuit of the world's most liveable city.

But where does the pursuit of this utopia come from? What are the underlying ideologies of the day? And is the model of the world's most liveable city worth pursuing?

The Underlying Ideology

Since the 1980s, and the advent of neoliberal politics, attitudes towards government have began to change. 'Whereas government had often been looked to as a problem solver, it was now viewed as the problem (Chapin, 2012, p.10). The role of the public sector was seen to be inefficient, unable to sustain social welfare programmes, and the private sector and the market economy was viewed as the means to improve the economic situation. Capitalism and neoliberalism became the dominant ideology. As Jameson (Jameson, 2003, p.73) states 'it is easier to imagine the end of the world than to imagine the end of capitalism'. Within the current, underlying neoliberal ideology, political agendas are embedded. In the case of Auckland, the Mayor's agenda is to pursue the accolade of becoming the world's most liveable city.

The writer opines that the focus of pursuing the world's most liveable city seems to be on capital accumulation, and not on affordable living, and equal access to services, for all residents. It is important to highlight the inadequacies of the neoliberal mantra of competing for most liveable city status, because it can lead to a focus away from providing affordable living options for those of lower socio-economic deciles. It can lead to a lack of social justice, and can also mislead people into believing that the pursuit of the vision of the world's most

liveable city will benefit them socially and economically. Individuals are susceptible to such visions.

This paper will argue that the concept of the world's most liveable city is a Lacanian 'utopian fantasy' and that we accept these fantasies to obscure emptiness, or a lack of certainty within ourselves (Lacan, 1994). The reader is therefore challenged to deconstruct the concept of the world's most liveable city, within the context of the dominant neoliberal ideology. This paper will analyse the concept of creating a liveable city, and will argue that this concept is pernicious. In particular, the criteria used to measure the attributes of a 'liveable' city by Mercers and The Economist will be discussed. This analysis will attempt to determine whether these criteria offer a realistic indication of a city's liveability in the case of all socio-economic groups. The paper will then develop an argument to understand Auckland's pursuit of the world's most liveable city accolade in the context of Lacan's concept of 'utopian fantasies'. The research will also look at the work of Kant, Zizek and Gunder and Hillier (2009) in terms of the possible philosophical and psychological reasons for cities pursuing these fantasies, and why residents will support this objective. The theories analysed, are Kant's 'Critique of Judgement' (In Bernard, 1951), Lacan's (1994) concept of 'utopian fantasies', and Zizek's (1989) 'sublime object of ideology'. Finally, the paper will look at the city of Auckland as a case study.

Measuring Liveability

According to the annual Mercers' World's Most Liveable City survey, a city must score highly in terms of safety, education, hygiene, healthcare, recreation, political-economic stability and public transportation (www.mercer.com). The Economist survey (www.economist.com) concentrates on very similar criteria, but also focuses on the availability of goods and services, as well as business start ups. The cities scoring highly tend to be English speaking, the exception to this being the Swiss cities of Zurich and Geneva and the Austrian city of Vienna. These cities are mid-sized, have relatively low populations, and are wealthier cities.

In the writer's view the criteria do not adequately address matters such as affordable housing and wider equality issues. The emphasis is on social stability, low crime rates, effective infrastructure, and enabling an economic environment conducive to business start ups. While these criteria have there place, it is argued, in accordance with the work of John Forester (Forester, 1989, p.4) that 'publicly orientated planners need to worry…about decent outcomes; they need to worry not only about satisfied customers but also about the food, housing and jobs the perfect market promises and the actual market fails to provide'.

The cities that scored highly in 2011 were as follows:-

Table 1 – The Economist 2011 Survey

City	Ranking
Melbourne	**1**

Vienna	**2**
Vancouver	**3**

■ **Auckland was number 10**

Table 2 – Mercers 2011 Survey

City	Ranking
Vienna	**1**
Zurich	**2**
Auckland	**3**

Vancouver had consistently scored number one in the Economist survey over the past nine years, but it has been suggested that the riots that ensued after an ice hockey game in June 2011 (www.citymayors.com) led to its score on social stability being reduced, and therefore it lost out to Melbourne for the top spot. Therefore, one incident can reduce the ranking of a city, which makes the ratings seem quite fickle.

Auckland was scored as number 10 in the Economist survey and number 3 in the Mercers.

Cost of Living

Affordable living or the 'cost of living' is taken into consideration by the Mercers survey but only in the context of a US expatriates perception of affordability. The Mercers cost of living survey examines the relative strength or weakness of a given currency against the US dollar, and compares price movements of certain items over the ensuing twelve months to a New York guideline (www.mercer.com). This, the writer argues, offers a much skewed perception of the cost of living in a given city. It would be preferable to compare the price of goods to the average salary in the country in question and calculate the average percentage of an individual's income which is spent on housing costs, rather than using a US expatriate baseline. This would provide a better idea of the liveability for those actually living in the city. Is this an indication, that despite the economic crisis in the US, it is still judged to be the benchmark against which other economies should be compared? It is argued that the US neoliberal model is the dominant underlying ideology of all western states. Subsequently, all cities are aiming to produce the same outcomes in terms of high GDP and economic growth. Planning theorists such as Susan Fainstein (2010) argue that the underlying global order is producing cities which are becoming identical. The writer opines that the global, capitalist order is producing networks of knowledge which have the universal discourse for all western cities. The lack of ideological difference in recent decades, according to Mishra, has been due to 'the collapse of the socialist alternative, the globalisation of the economy and the relative decline of the nation state' (Mishra, 1999, p.1), and it is argued that this has led to the rise of the post-political planning agenda.

The Post-Political

The post-political, as some commentators refer, seems to the writer to be a means for political figureheads struggling to make sense of the modern world, and trying to cling to an element of social justice, to modernise their political stance towards a capitalist standpoint, while appearing to hold true to their values. This post-political view, espoused by writers such as Ranciere (2006) has signalled the end of any truly democratic movements and has introduced post-democratic governmental techniques, which have reduced politics to mere social administration rather than representative involvement in the future direction of a city.

The move away from socialism has increasingly meant that the few who have control of capital have unfair access to positions of power and this 'spells a systematic distortion of the possibilities of all affected people coming to terms with events shaping their lives' (Gaventa, 1980, p.36). It is argued that capital controls the ideology of the day.

The Creative Class

Today, cities are the world are competing to be the most liveable, and they are also competing to attract key knowledge workers, or the 'creative class' as Richard Florida (Florida, 2002, p.80) refers to them, to generate wealth creation. Cities compete in this endeavour, and therefore wish to be viewed highly in terms of liveability. This, it appears, is a reaction to the uncertainty created by the neoliberal order. Due to the fact that 'multinationals are defined as being footloose, having the choice to move around the world (globalisation)…. Seems to present a policy framework of passivity, fear and insecurity' (UNCTAD, 2001, p.4).

Therefore, strategies to attract corporations and skilled migrants are high on the political agenda. But what makes a city liveable and attractive to these businesses and individuals? And, more importantly, how are existing residents, particularly those of lower socio-economic status fairing when it comes to the pursuit of these neoliberal ideologies?

Utopian Fantasies

The writer suggests that the most 'liveable' city, without equality, is surely a fallacy, or what Lacan (1994) and other writers would term a 'utopian fantasy'. Zizek would describe such a utopian fantasy as a 'sublime object of ideology' (Zizek, 1989). This is a concept which suggests that ideologies such as creating the world's most liveable city are beyond objective intelligibility. This builds on Kant's 'Critique of Judgement', written in 1790, as translated in 1951 by Bernard, which defines ideologies as not having limitations in terms of majestic they can be, as opposed to something that has boundaries. The translation of Kant's work states that 'the sublime….is associated with limitlessness' (Kant in Bernard, 1951, p.90). He also speaks of an individual's addiction or 'Eigensucht' when believing in an ideal. The writer argues that the perception that something can be so majestic is a fallacy, because the most liveable city will mean different things to different people, and be unachievable in practice. It

is argued by Lacan (1994) and Zizek (1989) that we accept utopian fantasies because they serve to obscure emptiness, or a lack of certainty within us. Zizek has built on this, in his 2006 work, and infers that we all have an inherent need to make sense of the world. He states that we try to turn "disorder into order" into a "new harmony" (Zizek, 2006, p.37).

As Stravrakakis suggests, a utopian fantasy allows us to experience a 'promise, embodied in the object-cause of desire' (Stravrakakis, 2007, p.78). This promise helps to stave off feelings of emptiness associated with Anthony Giddens' (1991) concept of 'ontological security', which is a 'desire to be safe, secure and to have control over their environment' (Gunder and Hillier, 2009, p.23). Lacan takes this concept one step further and argues that we are trying to replicate the maternal comfort that we experienced as a child, and are trying to recreate this by believing that the state has our best interests at heart and will strive to meet our needs (Lacan, 1994). Lavin presupposes that human nature is fearful of the future and states that 'our most primal fear is the unknown; of this Thing that haunts us' (Lavin, 2006, p.256). Therefore, politicians attempt to offer a guiding vision for their communities in order to provide some certainty. But does this provide residents with a false sense of security? The most liveable city is going to be the most liveable for whom? Whose interests will it serve? One utopian fantasy that individuals hold true is that the state 'can be relied on to protect us' (Gunder and Hillier, 2009, p.43). This concept can be pernicious, argues the writer. The current neoliberal global ideology which western cities pursue is based on capital accumulation and not economic redistribution. Therefore, the rich will get richer, and the poor, poorer.

Empty Signifiers

It could be said that the pursuit of liveability is a false promise or an 'empty signifier' as referred to by Laclau (Laclau, 1996, p.44). An empty signifier is a concept that is difficult to define, is not easily interpreted, and has no real meaning. Indeed, the concept of the world's most liveable city will mean different things to different people, and therefore could be described as an empty signifier. Gunder and Hillier discuss planning concepts as empty signifiers in their work *Planning in Ten Words or Less.* The 'contestable words' (Gunder and Hillier, 2009, p.17) are 'certainty, the good, risk, growth, globalisation, multiculturalism, sustainability, responsibility, rationality and planning itself'.

This paper would argue that 'liveability' could be added to this list as the eleventh key empty signifier in planning terms. Gunder and Hillier state:

> "spatial planning practice performs a dialogue between planning and urban governance that is full of signifying terms and labelling buzzwords, or 'weasel words' as Watson (2004) terms them, many of which imply innovative means to achieve desired states of urban well-being, such as deploying 'smart growth', 'new urbanism' or 'bohemian indexes' to plan for 'sustainable', 'globally competitive', and 'liveable' cities. We (Gunder and Hillier) argue that these terms, and many others, are mere 'empty signifiers', meaning everything and nothing – comfort terms – all things to all people. These desirous states of living and being, which most of us would aspire

towards, and accordingly, attempt to shape our cities to achieve, are often illusions, attained, at best, with limited success" (Gunder and Hillier, 2009, p.1).

Auckland: A Case Study

The Auckland Mayor, Len Brown, is pursuing both a utopian and ideological vision in the pursuit of the world's most liveable city for Auckland. The vision is set out as follows:

Auckland: The World's Most Liveable City – A city where quality of life means every citizen has the opportunity to reach their potential (Auckland Plan Discussion Document, March 2011, p.56)

This vision, which sounds to be egalitarian on the surface, could be viewed as a tool to gain support for his political term. The pursuit of a popular vision in the Auckland Council planning policy documentation will create a sentiment that individuals cannot argue with. It is argued that pursuing the accolade of the world's most liveable city through Auckland's planning policy documents is meaningless, as what citizen wishes to live in the world's most unliveable city. This vision therefore provides Auckland residents with a common, utopian goal.

The future of Auckland, following the amalgamation of the District Councils and the Regional Council, is unknown, but the pursuit of the world's most liveable city gives residents something to aim for, for the time being, anyway. It could be argued through the work of Mouffe and Laclau and their assessment of Gramsci's ideology that this vision would be subject to perpetual change. Mouffe and Laclau's analysis of Gramsci's concept of "the materiality of ideology', specifically the fact that ideology is 'an organic and rational whole, embodied in institutions and apparatuses' (Mouffe and Laclau, 1985, p67) is subject to Gramsci's conclusion that 'nothing in history, in social life, nothing is fixed, rigid or definitive. And nothing ever will be' (Gramsci in Mouffe and Laclau, 1985, p.31). Therefore, this vision could only be applicable to the Mayor's term in office. Another politician might favour a different direction for Auckland in future. Also, expanding on comments from Beattie (2010) shouldn't Auckland Council be concentrating on implementing its legacy visions and strategies? It is argued that it would be preferable to work with the current policy structure and implement it well, rather than creating a new policy structure. As Beattie (Beattie, 2010, p.3) states 'the biggest problem facing urban planning is not a need to create even more plans but our inability to implement the existing plans'.

The writer would like to point out potential pitfalls, incorporated in the emerging planning policy documentation, which in the writer's view are premised on fallacies. These relate to economic growth and housing projections and the affordable housing issue.

Results

The draft Auckland Plan sets an 'annual real GDP increase of between 5.1% and 6.2%' (Draft Auckland Plan, September 2011, p.80). This is when real growth for Auckland, over the past

two years, stands at around 1%. In 2010, growth of 0.93% was recorded on the Council's website (www.aucklandcity.govt.nz).

Therefore, this target would appear to be unachievable in the current economic climate, and its inclusion in the draft plan could be viewed as a way to mask the economic reality. Economic growth of 1% per annum would be more realistic. In terms of housing projections the draft plan proposes to provide 300,000 new dwellings, most within the existing metropolitan urban limit. The draft proposes to accommodate these dwellings through the intensification of only 6,000 hectares of Greenfield land (Draft Auckland Plan, September 2011, p.31), 70% within the metropolitan urban limit and 30% outside this boundary. This, in the writer's view, appears to be the utilisation of very little Greenfield land unless all of these households reside in apartments. The following table gives an idea of how the tenure of dwellings could be proportioned:-

Table 3 – Number of Hectares of Land Required to Accommodate Housing Projections in Draft Auckland Plan

Minimum Lot Size/Housing Type	Hectares Required (Ha)
1,000m2 lot size/low intensity suburban living – detached housing 10 dwellings per hectare	30,000ha
667m2 lot size/medium intensity suburban living – detached housing 15 dwellings per hectare	20,000ha
400m2 lot size/medium intensity city living – townhouses 25 dwellings per hectare	12,000ha
200m2 lot size/mid-rise apartment city living 50 dwellings per hectare	6,000ha
100m2 lot size/high-rise apartment city living 100 dwellings per hectare	3,000ha

The provision of mid-rise apartment living will do little to offer choice to residents and affordable, family housing, unless the Council adopts affordable housing policies such as those utilised in the UK and other parts of Europe. The draft Auckland Plan recognises that

there are ‘pockets of extreme deprivation’ (Draft Auckland Plan, September 2011, p.7) and goes on to state that ‘housing has become increasingly unaffordable, and many Aucklanders face significant housing stress’ (Draft Auckland Plan, September 2011, p.13). However, it is argued that the draft plan has advocated little to try to alleviate this situation.

The affordable housing problem is of high magnitude, and has been recognised by central government. The New Zealand Productivity Commission in a draft report, dated December 2011, found that house prices in Auckland were considered higher than the national average. The report states that ‘the distribution of house prices in Auckland vis-à-vis the rest of the country increased by over 260% in real terms between 1995 and 2006’ (New Zealand Productivity Commission, 2011, p.1).

The average house price in Auckland is $490,000 (taken from www.crockers.co.nz) and the national New Zealand median price index is $350,000 (taken from www.globalpropertyguide.com).

The Commission are currently undertaking an inquiry into housing affordability in New Zealand, so clearly there is a real issue that needs to be addressed. It is suggested that if Auckland is to become the world’s most liveable city, then it will require some decisive action in terms of future planning policy for affordable housing.

Summary of Results

This paper looked at the underlying neoliberal global order which supports the concept of the World’s Most Liveable City; the leading liveability surveys produced by Mercers and The Economist in 2011; and post-political theories such as Lacan’s ‘utopian fantasies’ and Laclau’s ‘empty signifiers’. The examination of the concept of the World’s Most Liveable City has found it to be a fallacy, lacking in substance. Each survey of liveability will produce a different result dependent on the assessment criteria applied. This neoliberal spatial governance model, which is being adopted by western cities, is premised on over-optimistic assumptions. This is evident in the analysis of Auckland, and in particular the emerging Council spatial plan. The writer opines that Auckland cannot be the World’s Most Liveable City if it is deficient in the provision of housing stock and has set unrealistic growth projections that the city cannot achieve.

Conclusions

In conclusion, this paper has found that the pursuit of the World’s Most Liveable City is a result of the dominance of the underlying neoliberal global order and its emphasis on wealth creation. It is a political manoeuvre to attract business and skilled migrants.

The leading liveability surveys, the Mercers and The Economist assessments, generate different results depending on the given assessment criteria. Therefore, this suggests that there is no accurate assessment of liveability.

It is therefore considered that the pursuit of the world's most liveable city is both a Lacanian, utopian fantasy construct and a Laclauian empty signifier, with no real meaning, which provides residents with false hope for the future of their city. In the case of Auckland, the Mayor's vision and the planning policy direction which the Council are pursuing through the Auckland Plan seem very ambitious, and it is considered, by the writer, that Auckland Council should adopt a more socially just vision which incorporates more realistic objectives such as more achievable economic growth and housing projections.

PLANNING FOR CERTAINTY IN UNCERTAIN TIMES – THE STANDARDISED LOCAL PLANNING SYSTEM IN NEW SOUTH WALES, AUSTRALIA

Abstract

In March 2006 the state of New South Wales (NSW) in Australia introduced a standardised or 'template' local plan (called the Standard Instrument Local Environmental Plan) that all of its 152 local councils must now use to prepare a new local plan for their local government area. Councils were given 2, 3 or 5 years to complete new plans, depending on their strategic importance and the age of their existing planning controls – meaning that all councils were to have a new plan in place by March 2011.

Implementation of this initiative came at a time when expectations about what local plans can and should deliver were escalating, while the worsening global financial situation has meant that most governments have reduced resources to allocate to good planning that will achieve liveable, sustainable communities, and to fund the infrastructure necessary to support them.

A new state government was elected in NSW in March 2011, on a platform of returning local planning powers and decision making to local governments. Concurrently the Australian Federal Government released *"Our Cities, Our Future: A national urban policy for a productive and liveable future"*. This policy includes a set of 9 criteria for future strategic planning of cities. Federal government funding for major state infrastructure projects is linked to providing evidence that planning systems meet these criteria.

There has been resistance from local governments to implementation of the standard local plan and progress has been slow. The 2011 target for completion was not met, with only 31 councils having competed plans by March of that year. The new plans have been unpopular with local government, communities and industry/development groups alike. The Federal government continues to mark NSW poorly for its planning system as a whole, meaning that funding for important infrastructure projects is not forthcoming. In the meantime, Australia's population continues to grow rapidly, while delivery of housing in NSW falls short of targets.

This paper describes the reasons behind introduction of a standardised local plan in NSW, the measures successive governments have put in place to accelerate its implementation, and considers why, to large extent, those measures have been unsuccessful. In doing so the relationship between central control and local governments is discussed, in the NSW context. It provides a practitioner's point of view on the issues surrounding introduction of a standardised system. The role of public consultation in shaping public policy is discussed and the need for different approaches in NSW is suggested.

1. Introduction

Planning and plan-making in New South Wales (NSW) Australia is, as it is in many places around the world, a contentious issue. Expectations about what planning systems can deliver, socially, environmentally and economically speaking, are increasing.

This paper tells the story of an attempt to standardise local plan-making in NSW over the last 6 years. It describes the reasons behind introduction of a standard local planning instrument, looks at the measures successive governments have put in place to accelerate its implementation, and discusses why, to large extent, those measures have been unsuccessful. In doing so the relationship between central control and local governments is discussed, particularly the tensions created by state imperatives to increase housing supply and densities while also purporting to hand planning powers back to councils

It provides a practitioner's point of view on the issues surrounding introduction of a standardised plan-making system. The role of public consultation in shaping public policy is discussed and the need for different approaches in NSW is suggested.

2. Brief overview of the political and planning system in Australia

2.1 Australian Federal Government

Australia has a three-tier system of government comprising federal, state and local jurisdictions.

Historically the federal government has had little influence on the states' planning systems. Constitutionally, planning is a matter for the states. In recent years this has changed significantly with the federal government taking much greater interest in urban planning matters. To quote its 2011 national urban policy, *Our Cities, Our Future*:

"The Australian Government has a role in planning for, and delivering, an urban Australia that is more productive, sustainable and liveable. The development and management of our cities affects national prosperity and the wellbeing of all Australians, no matter where they live". (Department of Infrastructure and Transport, 2011).

It is worth noting here that 75% of Australians live in 18 major cities with populations over 100,000. The federal government's interest is in a more productive Australia that can compete in the global economy, and the major cities generate approximately 80% of Australia's gross domestic product.

The national urban policy includes an objective and 9 criteria for the future strategic planning of cities. State governments are 'scored' on the ability of their plans and

planning systems to meet these criteria. Federal government funding for major state infrastructure projects is linked to providing evidence that planning systems meet the 9 criteria, and are integrated across land-use and transport planning, economic and infrastructure development, environmental assessment and urban development.

Performance is also monitored in terms of delivery – specifically delivery of measures related to 'liveability' of cities.

2.2 State and local government in New South Wales

Each of the 7 states and territories has its own system of local government, and its own planning system – and these vary markedly. New South Wales (NSW) is the most populous state and its capital is Sydney, the largest city in Australia.

The population of NSW is approximately 7.5 million people. It has 152 local government areas, each run by an elected local council. Sydney, with a population of approximately 4.6 million people, has 43 separate local government areas, each with its own local planning scheme controlling development. Sydney's population is forecast to grow to 7 million people by 2056. Cities in Australia are characterised by low-density development, typically spread over large areas (Kelly, 2010, p. 8).

Land use planning in NSW is governed principally by one piece of state legislation, the *Environmental Planning and Assessment Act, 1979* (the Act). While ground-breaking when enacted, embedding the principles of environmental assessment and protection into planning legislation in the state for the first time, it has now been amended and augmented so many times that it is considered by many to be overly complex and skewed too much towards development assessment or 'statutory' planning and processes rather than strategic planning. The new state government was elected on a pledge of a complete review of the Act, and this is underway.

The Act provides that the Minster for Planning and Infrastructure (the Minister) may make environmental planning instruments to control development – and broadly speaking these can be state environmental planning policies (SEPPs) or local environmental plans (known as LEPs in NSW but hereafter referred to as 'local plans'). Importantly, while only the Minister can approve local plans, they are developed by local councils in consultation with their communities.

Local plans in NSW are generally structured around a traditional system of 'zoning' land for different purposes, with land use tables setting out what types of development are permissible without approval, permissible with approval, or prohibited in each zone. While state governments over the years have issued guidance about how local plans should be prepared and what content they should have, it left the drafting of plans largely up to councils until 2006.

In summary, the planning system in Australia has been described as having "a (federal) level that has much direct influence – including raising the bulk of the

money – but is only occasionally involved, a state level which is the main provider of planning and services, and a highly fragmented local level" (Kelly, 2010, p. 12). It is this fragmented system of local government, and the related fragmentation of planning controls over major cities like Sydney, that lead the NSW state government to develop and implement a standardised local environmental plan.

3. A standardised local plan for NSW

In March 2006, following a series of Ministerial taskforces looking at ways of improving the NSW planning system, the state government introduced a 'standard instrument local environmental plan'.

The standard local plan was introduced through numerous changes to the Act, including a requirement that the Minister can not approve a local plan that is 'inconsistent' with the prescribed standard plan. It is a very formal, legal and mandatory system that for the first time in NSW sets out the structure and content of local plans. The State government and local governments disagree about what constitutes an "inconsistency".

3.1 Why introduce a standardised local plan?

There are 152 local government areas in NSW, 43 of these in metropolitan Sydney. At the time of introduction of the standard local plan, these local government areas had between them approximately 5500 local planning instruments in place (Department of Planning, 2008). Within these 5500 instruments were:

- more than 3100 different land use zones; and
- some 1700 land use definitions. There were, for example, multiple definitions of 'gross floor area', 'building height' and the like.

This made it very difficult, even within each local government area, to determine exactly what planning controls applied to an individual parcel of land. From the developers' point of view, there were vast differences between local government areas. With different development definitions and different land use zones from one suburb to the next in Sydney, it became a complicated and costly exercise to determine if a development was permissible, let alone what development standards and controls applied to it.

Many of the existing planning schemes were very old – sometimes 30 years or more old - and were in serious need of replacement.

The intention was to introduce a consistent, modern and transparent local planning system that cut red tape, provided certainty and clarity for all stakeholders, and reduced the time and cost involved in preparing and assessing development applications.

The standard plan is a template that includes:

- a standard structure to allow ease of navigation through the plan;
- 35 standard land use zones including residential, business, industrial and environmental zones, with some land uses mandated as being permissible or prohibited by the state;
- a dictionary of standard land use definitions that every council must use in its plan;
- compulsory and optional provisions dealing with a range of matters. For example, the state government decided that development standards such as allotment size, height of buildings and floor space ratio were so important that they should be included in the statutory plan rather than in other council policies;
- electronic maps. The standard plan is map based, with land use zones and development standards such as lot size, building height and floor space ratio mapped in accordance with standard technical guidelines. The maps form part of the plan that is approved by the Minister and they appear with the plan on the NSW Legislation web page, which displays all current planning instruments. As each plan is made, a state-wide data base of planning information is being developed. This is a significant benefit of the program – publicly accessible maps showing all the local planning controls, freely available. This aspect will also assist in the government further developing the concept of 'e-planning' across NSW – including the electronic lodging and processing of development applications.

Councils can add general aims and zone objectives to the plan, as well as 'local provisions' to address local issues - but they claim the state limits their ability to do so. They can also tailor the land use tables for each zone, to suit local conditions, by adding the development types that will be permissible without consent, permissible with consent, or prohibited.

The standard local plan was to be the consistent delivery mechanism for good strategic planning in the state. In its February 2008 Fact Sheet on the benefits of the LEP template, the Department of Planning said:

"Councils can use an off-the-shelf, ready-made template when creating new plans, rather than having to draft plans from scratch. This means they will have more resources available to concentrate on developing long-term planning policies for their areas." (Department of Planning, 2008).

3.2 How far have we got?

Progress has been slow. In March 2009, 2 years after commencement of the program, and when 92 of the 152 plans should have been completed, only 4 were finalised. In March 2011, when all 152 local plans were scheduled for completion, only 31 were done.

At the time of writing, in May 2012, 58 have been finalised. A further 64 plans have been given approval, from the Department of Planning and Infrastructure, to go to public consultation. So, while a lot of work has been done, the government's completion targets have not nearly been met, and the standard local plan program remains a point of tension and disagreement between the NSW State Government and local governments across the state. Some of the reasons for this disagreement are discussed in subsequent sections of this paper.

Local government elections occur every 4 years in NSW. They are scheduled for September this year, and many councils will make no further decisions on local plans until new councillors are elected and established – meaning that many of the new, standardised local plans will now not be finalised until well into 2013 or later.

3.3 Attempts to accelerate the program

Successive state governments have seen the standardised local plan program as an important initiative to reduce red tape for developers and introduce modern, transparent controls that will be easily understood and will stimulate economic growth in NSW. Australia is one of the few OECD countries with both a rapidly increasing population and a significant housing shortage (Kelly, 2011). NSW and Sydney in particular, has a problem with a lack of housing commencements compared to the rest of Australia.

This is despite a large amount of land being identified and rezoned by the Department of Planning and Infrastructure in two major growth centres on the outskirts of the city, and despite dwelling targets being set for each local government area in Sydney through the *Metropolitan Plan for Sydney 2036* (Department of Planning 2010) and its related subregional strategies.

To attempt to accelerate finalisation of new local plans, the government has provided additional funding to the Department of Planning and Infrastructure ($2.9 million AUD over 2 years) to facilitate the program, including formation of a 'flying squad' of urban planners, lawyers and mapping experts to directly assist councils to draft plans, resolve policy and legal issues and prepare maps.

Further, the government has provided $10 million AUD over 2 years in grants to councils through the Local Environmental Plan Acceleration Fund. The grants have been provided principally to help councils draft their local plans, and sometimes to prepare strategic studies to underpin the plans, either through the councils hiring planning contractors or by direct provision of contractors to councils by the Department. 79 of the 152 NSW councils received grants between $5,600 and $274,400 AUD. Progress payments are linked to achievement of key milestones in the plan-making process, such as production of a draft plan for public consultation.

The flying squad concept works well and has resolved many issues. On the whole it would have to be said that, while the Local Environmental Plan Acceleration Fund has provided much needed resources to councils, it has not significantly fast-tracked plan production. Only 25% of funded councils have achieved their milestones, and the 2 year funding program has recently been extended for a further 12 months.

To address concerns that the standardised local plan does not provide sufficient flexibility for local government to address local issues in local plans, the Minister has established the Local Planning Panel. The Panel comprises 3 independently appointed local government planning directors, one of whom is the Chair, and 2 Department of Planning and Infrastructure representatives. I am one of the department's representatives. The Panel is currently touring the state listening to the views of councils and a wide range of other stakeholders to hear their concerns about the standard instrument local environmental plan. The views and suggestions for improvement are diverse. Local government has a different view, one could say different 'definitions', of certainty and flexibility to those of the development industry.

The recommendations of the Local Planning Panel for improvements to the local plan and its implementation are to be provided to the Minister in August 2012. While the Panel is providing an excellent vehicle for various stakeholders in the planning system to express their views about the standardised local plan, and indeed has already recommended some fundamental changes to it, the process is, if anything, slowing delivery of new plans. Local councils see that there is some chance they will get the 'certainty' and the 'flexibility' they seek in their plans if they make representations to the Panel and postpone finalisation of new plans until the Panel's recommendations are considered and adopted by the Minister.

3.4 Expectations of the planning system in NSW

The expectations about what new local plans will deliver are high.

1. The community expects certainty – that the local plan will set out the parameters for development in their localities in the future and that there won't be any development 'surprises' next door;

2. The community also expects that they will be consulted widely on development matters and that their input will be listened to and will make a difference to the outcomes. Greater environmental awareness, ease of accessing information about development proposals, and a more informed community that understands that planning decisions have a significant impact on the liveability of neighbourhoods and cities, means that there is an increasing demand for public consultation on a wider range of issues in NSW;

3. The development industry expects that there will be certainty about what can be developed on any parcel of land, that the controls will be transparent and simple,

and that infrastructure issues (such as essential services and transport) will have been sorted out when the land was zoned for its purpose – and that for these reasons there shouldn't be much public objection to their development proposals;

4. The expectations the state government has about what new local plans might deliver are perhaps the most challenging of all. The government believes the new plans are critical to delivering an adequate supply of zoned, affordable land for housing and employment that, together with simplified controls, will kick-start housing commencements, drive down housing cost, and stimulate the NSW economy as a whole. In NSW it is the planning system which is increasingly blamed for impeding growth and development.

   The government has asked the Department of Planning and Infrastructure to review the *Metropolitan Plan for Sydney 2036*. The updated metropolitan strategy for Sydney, and the subregional strategies that sit under it, will update the dwelling targets required of each region and each local government area – and the new local plans are the key delivery mechanism for this housing.

5. The government hopes that new, modern plans will reduce the need for spot zoning amendments to facilitate new development proposals and reduce the need for 'major' or 'state significant' projects to be called in by the state and determined by independent Joint Regional Planning Panels – because both of these aspects of the NSW planning system are very unpopular with communities.

6. The federal government has set its criteria for good strategic planning by the states- and consistent, transparent local controls are part of its desired solution. If the standardised local plan isn't the mechanism that can deliver good strategic plans on the ground, NSW will continue to miss out on vital infrastructure funding from the federal government.

7. Local government, other government agencies (such as the NSW Office of Environment and Heritage) and communities expect that local plans will be able to deal with emerging environmental issues such as se level rise. Much of Australia's population live close to the coast and there are many NSW communities where existing dwellings will be directly impacted by sea level rise predictions for 2050 and 2100.

3.5 Has the standard local plan delivered on expectations?

1. The standard local plan has the capacity to deliver certainty. Local plans are still the key delivery mechanism for strategic planning and land use controls in NSW. However, the issue has been that the detailed strategic planning has not been completed in many local government areas. There is a lack of context, therefore, for assessment of projects that might appear to be out of character in a

particular locality. Major projects (over $20 million in value) are dealt with by the Joint Regional Planning Panels, and spot rezonings to change the controls on individual parcels of land or precincts are determined by the state government. So communities continue to see 'unexpected' projects appear and have to comments on them in short time frames in the context of a site specific development application or rezoning application, rather than in terms of the broader outcomes and directions they wish to see for their localities

2. Communities are demanding and to some extent getting increased opportunities to comment on planning matters. Overwhelmingly, however, the community participates and comments on specific development proposals (especially proposals in their neighbourhood) to a significantly greater degree than they comment on and participate in the broader - and ultimately more important – strategic planning that state and local governments undertake.

3. A lack of agreed strategic outcomes means that local development controls are drafted very tightly and conservatively, to pre-empt and prevent any unexpected or "out of the norm' development applications. The new state government was elected on a platform of handing local controls back to local government, and so it is allowing councils to have very restrictive controls in local plans. The NSW planning system does not currently allow merits based assessment and approval of developments that are prohibited by a local plan, yet may meet existing strategic outcomes.

   The development industry wants more flexibility in local plans to allow more development to be approved on its merits. Communities and local government on the whole want local plans to be restrictive and to provide 'certainty' about development outcomes. The development industry says this stifles innovation.

   Infrastructure provision and funding is not adequately linked to land use planning. The state government has reduced the contributions that developers must pay towards such infrastructure, in an attempt to stimulate more development. This is clearly counter-productive.

   There is an expectation in some communities that local plans will be able to prohibit open cut coal mining on rich agricultural land. Coal mining is one of the major economic drivers and sources of revenue for the state of NSW. For this reason the state has a state environmental planning policy (SEPP) that over-rides local plans to permit coal mining in all areas other than those with very high ecological value.

4. NSW has a housing shortage and very expensive housing. The state government wants local plans to deliver increased amounts of serviced land for housing and employment. Increasing density in existing suburbs of Sydney is very unpopular, particularly if infrastructure is inadequate. The Department of

Planning and Infrastructure's recently released discussion paper, *Sydney over the next 20 years* says*:*

"By 2031 Sydney will have 1.4 million more people and will need 570,000 more homes and 600,000 more jobs." (Department of Planning and Infrastructure, 2012).

The state government has promised local government it can have more control over the content of its local plans. This contradiction means the local plans will not deliver these targets unless the state intervenes to force an increase in development capacity and density.

5. The number of spot rezonings or amendments to local plans has not reduced since introduction of the standardised plans. The Department of Planning and Infrastructure processes approximately 300 local plan amendments each year, and this figure is not shrinking. This is probably because many of the new local plans do not reflect new and agreed strategic planning.

6. A recent federal government COAG Reform Council report, reviewing the performance of state governments in city planning strategies, found that none were meeting all 9 criteria set in the national urban policy. The report warns that Australia will not remain competitive globally if infrastructure issues are not addressed, and criticises 'politicisation' of planning issues at the state level, which it says interferes with their ability to settle on long-term strategic plans (COAG Reform Council, 2012).

7. Global environmental issues such as sea level rise will have a significant impact on Australian settlements. A new land use zone, the Coastal Protection zone, will soon be introduced into the standard local plan to allow councils to restrict and/or prohibit new development, particularly housing, on land in the direct hazard zone for coastal erosion. The direct hazard zone is based on government predictions for sea level rise by 2050 and 2100. Local governments, however, need to undertake detailed local studies, called Coastal Hazard Management Plans, before they are able to use such a zone.

In summary, it is contended that:

- the context within which local councils develop their new standardised plans;
- the fact that the majority of State Government planning outcomes are achieved through delivery of local plans;
- increasing expectations and requirements for consultation with local communities about plans and planning decisions;
- increasing expectations that local plans will deliver outcomes that stimulate local economies while also protecting the natural environment, dealing with climate change and sea level rise and creating sustainable, liveable communities;
- the need for new plans to meet national planning criteria in this regard; and

- the new State Government's election pledge to return local planning powers to local communities;

have set up a planning system in NSW that has inherent tensions and conflicts such that it is unlikely to deliver outcomes that satisfy communities while encouraging development and attracting funding to provide necessary infrastructure.

The state government has choices available to it. Two obvious ones are:

1. directly intervene and direct local government to increase the development capacity of local plans. The Act gives the Minister this power but this is in direct contradiction with the state government's election pledge to hand planning power and planning decisions back to local government; or
2. change the planning system and the way it is funded to work collaboratively with local government and communities to develop strong, clear and agreed strategic plans that can be delivered with certainty by the standardised local plans.

4. The key issue

The key issue affecting the timely and effective delivery of new, standardised local plans is the lack of adequate strategic planning to underpin them. Put quite simply, the standard local plan program has happened the wrong way around. Significant time, money and effort have been put into standardising a delivery mechanism, without any clear agreement on what it is we want to deliver. Solid strategic planning, broad at the state level and detailed at the local level, is needed to underpin these plans. It's at the strategic level that the debates need to be had, that the consultation has to be undertaken, and the agreements have to be reached.

Without those agreements, the arguments are had at the delivery level, at the statutory instrument level. The NSW standardised plan – and I would argue any standardised local plan - is not and cannot be designed to cope with a lack of strategic planning to underpin it. This is the cause of the delays in implementation. This is the cause of the tension between the state government, local councils and the development industry in NSW.

Without good consultation leading to agreed outcomes to deliver growth, and without the resultant and necessary uplift in land for housing and employment, the hard decisions, the trade-offs (including who pays for what infrastructure), get left until the development application stage. That is too late. The development application process in NSW is an adversarial process with tight time frames and no room for negotiated outcomes. It becomes "do you want this particular development, or don't you", rather than "we need growth in this locality, how and where would you like to see it happen, what trade-offs are you willing to negotiate and agree so that we can get a plan for growth that gives everyone certainty?". Many

development applications end up being determined by the NSW Land and Environment Court, at great expense to developers and objectors.

The new government's approach of giving planning powers back to local councils and communities is commendable – but not really working. Councils don't want to prepare new plans if development outcomes will still be uncertain, and if they cannot guarantee a level of certainty to their communities.

The statutory plan making process at present, with set time frames tied to funding agreements, is not providing local government with the time and resources it needs to engage with communities. It is not empowering local government or communities. It is not providing the good, clear plans we need.

The relationship between state and local governments in NSW needs to change. It needs to become less adversarial and more collaborative. The state government has to trust that local governments and local communities can make the hard decisions that have to be made. There is certainly a role for a more regional approach, given the large number of local governments in NSW – which delivers a fragmented response to important planning issues in many cases.

4.1 Experience from elsewhere

Plenty of people have written extensively about different approaches to local planning and this paper is not about repeating or critiquing those. Some of the most resilient and successful stories are now quite old – Jim Driers and his work with the Office of Neighborhoods in Seattle in the 1990's; the "Vancouver Model" and the extensive and comprehensive consultation that was undertaken by the City of Vancouver in developing its *CityPlan*, also in the 1990's, for example.

These models continue to appear in current Australian research, as best-practice examples of how to undertake local planning and achieve the trade-offs that have to be achieved – for example in the numerous research reports on city development prepared by the independent Australian think-tank, the Grattan Institute, referenced several times in this paper.

Some of that research, for example *The housing we'd choose* (Kelly, 2011), suggests that despite our best efforts to increase housing supply the market is not providing the type of housing many Australian people actually want. And we are not even providing enough of what people don't want.

The housing market is complex, and outcomes or lack of them can be influenced by factors like the taxation system in any jurisdiction just as much as it might be impeded by local planning controls. What experiences from elsewhere consistently tell us, however, is that we won't know what sort of development to provide for through our local controls, and we won't know where to provide it, if we don't ask the right people the right questions.

And that is the problem in NSW. We have provided the solution in a standardised local plan template, without first asking ourselves and our communities, with sufficient depth and rigour, what is the problem. It has been a top down approach to finding solutions at the local level, rather than a bottom up approach, lead by local governments that have a real chance of engaging with their communities and finding workable solutions.

5. What next for the standard local plan in NSW?

The future for implementation and acceptance of a standardised local plan across all 152 councils in NSW, in my view, looks positive. The state government is reviewing the planning act, the *Environmental Planning and Assessment Act 1979.* Indications are that there will be a place for a standard local plan in the new act. Even more encouraging though, are indications that the new act will have a far greater emphasis on strategic plans, and strengthening the links between strategic plans and the local plans that deliver the desired outcomes.

A standard local plan that is the delivery mechanism for agreed, and statutorily embedded strategic plans is likely to be embraced by local government in a way that the current standard plan has not been.

The experience of trying to introduce new controls across 152 councils with diverse issues and needs has taught us all a great deal. And it has reinforced the message that it is the strategic planning, the real engagement with all stakeholders in the plan-making process, and removal of some of the adversarial aspects of the current planning system in NSW, that is the main game.

If we can recognise that we are all players in that same game, and that if we work together to negotiate the trade-offs that each and every stakeholder will have to make to deliver good planning outcomes in tough environmental and economic time, then the standard local plan will be what it was always meant to be – a consistent and transparent way to implement good strategic planning. And it will be able to deliver the social, economic and environmental outcomes we all want.

6. Conclusions

Standardising local plans across a state like NSW makes sense and has benefits for many stakeholders. Improving planning instruments, making better planning law, doesn't of its own, deliver good planning outcomes. A transparent and simple statutory system is very important. But in the end, such a system is just the delivery mechanism for good strategic planning.

Without good and agreed strategic plans to underpin them, the new, standardised local plans in NSW can not deliver the outcomes the State government needs;

outcomes that its communities want or can at least accept; nor create the conditions that the development industry needs to make it all happen.

Global financial uncertainty affects Australia along with the rest of the world. At such times citizens in NSW seem to be seeking local certainty – about the strength of the local economy to support local jobs and the ability to live in affordable, sustainable housing close to those jobs. These aspirations were reflected in the reasoning for introducing a standardised local plan in NSW – certainty, transparency, jobs close to home.

The expectations of the standard local plan were high – too high. The expectation was that its introduction would go a long way to underpinning economic growth in the state. Such expectations are based on a misunderstanding of what the statutory instrument is. It is the delivery mechanism for good planning, for the planning we want to achieve. The challenge for the NSW government, with new planning legislation about to be announced and a push to complete and improve implementation of the standard local plan across all 152 local government areas, is to agree with its communities exactly what it is they want delivered.

Human health in *The London Plan*: How health is framed in a world city's spatial development and climate action strategy

Christopher Coutts

Florida State University

Abstract

Human health is among the original justifications for town planning, but it has been under-examined as one of the myriad benefits motivating cities to plan for climate change. A conceptual content analysis of the July 2011 version of *The London Plan: Spatial Development Strategy for Greater London* was performed to reveal how health was portrayed in a world class spatial development strategy that includes climate change mitigation and adaptation goals and actions. The coding of the 317 page plan resulted in eight distinct health frames and nearly 200 instances of the keyword 'health.' There are at least three conclusions that can be drawn from this analysis. First, the stated threats to health are truly localised. Second, the policies that address health acknowledge the health benefits derived from both adaptation and mitigation. Third, addressing health inequalities and creating an environment supportive of health are the most salient cross-cutting issues.

Introduction

Planning for sustainable urban development and climate change adaptation is, at a very fundamental level, an attempt to protect ourselves and our social systems from harm. In our attempts to adapt to a changing environment, there are many inter-related elements that must be considered. One of the most indispensable is the protection of human health and well-being. Therefore, it is critical to consider human health impacts and their relationship to the many social, political, economic, and environmental considerations in sustainable spatial development and climate change plans. In contrast to the many climatic phenomena and subsequent outcomes that require great speculation on current and future climate variability, sea level rise is a measured certainty that will affect the health and lives of the billions of persons living within coastal zones worldwide (Creel, 2003). Whether from sea level rise, flooding, drought, heat, or other extremes, the health of billions of people will be greatly influenced by the quality of the physical infrastructure designed to adapt to and mitigate severity of these events. The research conducted here addresses the following questions: How is the local co-benefit of human health portrayed in a world class spatial development plan, and how is health tied to the plan's climate change mitigation and adaptation actions? Is health tied to climate mitigation and adaptation actions in the plan and not yet being addressed by research examining the health impacts of climate change? These questions are addressed through a content analysis of the 2011 *Spatial Development Strategy for Greater London* (UK). London, as the capital of a nation leading climate change planning and as a world city, can act as a model for other major urban areas preparing for climate change and aiming to prevent its deleterious effects. There are lessons that

may be learned from a city with a history of connecting urban form and public health (Ashton and Ubido, 1991; Hebbert, 1999).

The apparent solution to addressing the effects of climate change has been to 'think globally by planning locally for public health' (Coutts, 2010, 54). Much like other climate vulnerabilities, the health impacts of climate change vary by location and are often most accurately considered at smaller geographic scales. Even municipalities within the same county, district, or province might face very different health impacts from drought, flooding, and heat due to proximity to surface water and micro-climatic effects. The scales at which the Intergovenmental Panel on Climate Change (IPCC) proposed adaptation included national/regional and individual responses, but no direction is given on more localised city-level efforts (Confalonieri et al., 2007). Despite this, '…a number of urban leaders have decided to take matters into their own hands, adopting solutions that already exist or inventing new ones for limiting greenhouse gas emissions and preparing for the effects of ongoing global warming' (Rosenzweig, 2011, 70). It is cities who have taken the lead in planning for their specific climatic vulnerabilities, and it is a city plan that is examined here to determine how city residents will be protected.

Health and Planning for Climate Change

Macintyre, Ellaway, and Cummins (2002) challenge us to better conceptualise and operationalise 'place effects' on health outcomes. Their suggestion—brilliant in its simplicity and fundamental importance—is to use a framework of universal human needs to examine how place influences one's ability to meet these needs and live a healthy life. Planning has a significant influence on many of the items in a hierarchy of human needs (Maslow, 1968). At a very fundamental level is the quality of the air, water, food, and shelter needed to maintain and perpetuate life. But beyond merely subsisting, planning provides the contextual support for

meeting other needs such as public hygiene, work, and transportation. Climate change poses a unique and long-term threat to the resiliency of urban centres to meet human needs and protect health. With impending climate variability, the ability to meet many of these needs will be threatened, and it is the duty of planning to propose actions that will allow the continued satisfaction of these needs amidst a changing environment. Failing to provide an environment in which these needs can be met will result in increased morbidity and mortality. The nascent literature connecting climate change to health offers planners some guidance on the impending threats to the health of the populations they are planning to protect.

Over the past five years, there has been a small surge in the literature exploring the potential health impacts of global climate variability. Although the volume of literature has increased, it is still sparse and the outcomes examined have largely been limited to the health effects of heat waves and air pollution (Ebi et al., 2009). A number of articles have provided a litany of anticipated health effects (Frumkin, 2008; McMichael, Woodruff and Hales, 2006), environmental health indicators (English et al., 2009), and have focused on the childhood populations that are most vulnerable to anticipated events (Kisten et al., 2010; Sheffield and Landrigan, 2011). Table 1 is a synopsis of the climate change and variability events and the corresponding health effects.

[Table 1 about here]

Although we can state with relative certainty that climatic norms are changing, expert opinion is also of the mind that the level and type of disease burden in all countries and regions will progressively increase with a changing environment (Confalonieri et al., 2007). Of course, projecting the level of increase in morbidity and mortality caused by climate change is extremely complex and fraught with uncertainty. Taking this difficulty, if not futility, into account, there

have been some efforts by public health researchers to quantify the added incidence of disease burden (Watkiss et al., 2003; WHO, 2003). In the Fourth Assessment from Working Group II of the IPCC, it was noted that 'at this early stage the effects are small but are projected to progressively increase in all countries and regions' (Confalonieri et al., 2007, 393). McMichael et al. (2004) calculated that in the year 2000 increased climate variability was reported to be responsible for over 150,000 deaths worldwide. Almost 90% of this increase in the disease burden fell upon children. Based on IPCC projections, these numbers are likely to rise as more people become susceptible to more severe climatic shifts. Although a precautionary approach would lead one to take these trends seriously, there are those who note the lack of definitive evidence to support an alarmist attitude (Rohr et al., 2011).

Most European countries either have a national climate change strategy or are creating one. The US, embarrassingly, has no national adaptation strategy (Ebi, 2010). The UK released an assessment of the health threats related to climate change in 2008 (Kovats, 2008). The perceived greatest threats to the health of UK residents included heat waves, flooding, drinking water contamination, increased ground level ozone, and UV radiation. The noted effect of increased heat on water- , food-, and vector-borne diseases was less daunting.

Likely motivated in no small part by the UK's heightened susceptibility as an island nation (Ebi et al., 2006), the UK Climate Change Act of 2008 was passed as '…the first legislation of its kind in the world, establishing a long-term legal framework to underpin the UK's contribution to tackling climate change' (Kovats, 2008, iii). This Act established the Committee on Climate Change. A report by this committee in September 2010, *How Well Prepared is the UK for Climate Change*, found that while information capacity is high, its translation into action has been minimal, and failing to act was noted throughout as detrimental to human health. The

report also touched on the scale of interventions to combat climate change, concluding that climate change mitigation and adaptation should be primarily a local function with national governments playing a supporting role. London's climate change planning is an example of how a local government, a very significant one on a global scale, is planning for actions that will ultimately have local, global, and both immediate and long-term influences on human health.

There exists analyses on the potential threats to health of global climate change, but there has been little, if any, attention given to how health is approached in our spatial development and climate change adaptation and mitigation plans, the plans that guide the development of cities and influence the actions which exacerbate climate change. This paper hopes to begin to address the lack of extant literature by examining how health is framed in the spatial development and climate change strategies of a world city. As the first major world city to produce a Climate Change Adaptation Strategy and as the birthplace of contemporary planning and public health collaboration, the London case holds great promise in not only guiding plan formation elsewhere but also in exposing new areas of research.

Data and Methods

Under the rules of the Greater London Authority Act of 1999, the Mayor of London is required to produce a Spatial Development Strategy for the 32 boroughs and the Corporation of the City of London that looks ahead approximately 20 years. The first London Plan was published in 2004. Development plans in the 32 boroughs must be in general conformity with this plan, and any planning decisions within London are legally required to take the plan into account. The plan must also conform to European Union (EU) legislation including the European Spatial Development Perspective.

A conceptual content analysis of the July 2011 version of *The London Plan: Spatial*

Development Strategy for Greater London was performed to determine the prominence and context of human health throughout the plan with particular attention to London's planned response to climate change. Content analysis is often used to 'reveal the focus of individual, group, institutional, or societal attention' (Weber, 1985). In this case the content analysis was performed to reveal the attention paid to health in the Mayor of London's comprehensive planning document. The 317 page document is organised into eight chapters: 1) Context and Strategy, 2) London's Places, 3) London's People, 4) London's Economy, 5) London's Response to Climate Change, 6) London's Transport, 7) London's Living Places and Spaces, and 8) Implementation Monitoring and Review. Preceding these eight chapters is the Mayor of London's Foreword and an Overview and Introduction chapter front matter. All eight chapters including this front matter were included in the analysis.

The entire portable document format (pdf) plan was digitally searched to determine the prevalence and context of the keyword 'health.' The number of occurrences of the keyword 'health' was summed for each section. The context of each occurrence of the keyword was evaluated to determine how health was framed within the plan. A number of frames were created after determining the similarities and discrepancies in the context surrounding health. The frame coding was performed solely by the author. Therefore, threats to reliability due to varied interpretations by multiple coders were eliminated. The validity of the frames is similarly robust. Unlike some forms of content analysis which seeks to organize text around various constructed themes that are prone to varied interpretations, the health frames here were created almost exclusively using explicit language from the plan itself. Very little subjective interpretation of the context in which the keyword 'health' was found was required.

Chapter 5, London's Response to Climate Change, was examined in great detail. The

occurrence of 'health' in the 22 policies in this chapter was measured to determine which policies considered health outcomes. A complete list of these policies is displayed in Table 2.

[Table 2 about here]

Results

There were a total of 176 instances of the keyword 'health' throughout The London Plan. The coding of the plan resulted in eight distinct health frames. Table 3 displays the distribution of the health frames per plan chapter. The descriptive distribution reveals that the health inequality and healthy environment frames are found in most of the plan chapters. Other frames are not as consistently distributed. Figures 1 and 2 also display the distribution of the health frames by plan chapter (Appendix A).

[Table 3 about here]

The *Health Inequality* frame was prevalent throughout the London Plan with particular, and expected, prominence in Policy 3.2, Improving Health and Addressing Health Inequalities. Reducing economic and racial disparities in health outcomes and access to care was integral to the plan and in line with the Mayor's Health Inequalities Strategy. The *Healthy Environments* frame was also quite prevalent. In line with the London Plan being a spatial development strategy, this frame encompassed elements of the built environment put forward as affecting health. Improved housing, brownfield redevelopment, the reduction of air pollution, and the promotion of non-motorised forms of transport were all seen as ways to create an environment supportive of the health of London residents. *General Health Promotion* captured all instances where improving the health of Londoners was mentioned in general terms. For example, in phrases such as '…promoting health and welfare' unaccompanied by detailed actions or outcomes. Within this frame was language from Policy 3.2 and mentions of mental health and

the health of children. *Health Facilities Infrastructure* captured not only the infrastructure of health care centres but also the health care delivery services. Among the *Health Policies* recommended to guide health promotion among Londoners were the *Mayor's Best Practice Guidance on Health Issues in Planning*; *Healthy Lives, Healthy People: Our Strategy for Public Health in England*; and the *Health and Social Care Bill*. There was also mention of the need for coordinated planning with other existing environmental and climate change policies. The *Health and Green Space* frame captured a number of clearly stated connections between the conservation of green space and the health of city residents. The ambitious green belt designed to surround London and curb sprawl was also held up as necessary to support health. Green spaces were also integral to London becoming a city that 'delights the senses.' A *Health Impact Assessment* (HIA) is a tool used to evaluate environmental threats to health. HIA was often used in conjunction with 'health checks' performed in local communities. Finally, the *Health and Economy* frame included mention of not only the maintenance of the overall health of the economy but also the role of the health sector jobs and research in supporting a robust economy.

In addition to 'health' there were also five instances of the term 'well-being' and six instances of the term 'welfare.' Four out of the five of the instances of 'well-being' were found in conjunction with 'health.' The remaining instance was used in conjunction with 'prosperity.' All instances of 'welfare' were found in conjunction with 'health' in phrases such as '…improving Londoners' health, welfare, and development' (e.g. Greater London Authority [GLA], 2011, 210) accorded to the *General Health Promotion* frame in the analysis.

A focus on the local health benefits of climate change mitigation and adaptation

London is striving to become a '…world leader in improving the environment locally and globally, taking the lead in tackling climate change, reducing pollution, developing a low carbon

economy, consuming fewer resources and using them more effectively' (GLA, 2011, 137). With this explicit goal, London recognizes its global role as a contributor to the emissions that exacerbate climate change and as an exemplar of city planning. Although the business conducted in London certainly influences global markets and behaviors, the spatial development and climate action strategies are decidedly local.

London is looking to its own vulnerability to flooding, higher average temperatures, and drought. The probability of sea level rise, heavier winter rainfall, higher tidal surges, hotter summers, and less summer rainfall increases with climate change (GLA, 2011). The latest UK climate projections support these trends (Jenkins et al., 2009). Heat, flooding, and drought '…could seriously harm Londoners' quality of life, particularly the health and social and economic welfare of vulnerable people' (GLA, 2011, 138). This language is consistent with what is found in other chapters and what was classified under the *General Health Promotion* or *Health Inequalities* frames.

Health is tackled more specifically in seven of the 22 policies listed in the climate change chapter of the plan (full list of policies listed in Table 2). The first one of the seven climate change policies that explicitly mentions health pertains to sustainable design and construction. The 'sustainable design and construction' of buildings is intended to ensure that they are 'healthy and adaptable' (Policy 5.3). This policy recognizes that structures are important for both climate change mitigation and adaptation. Reducing emissions through more efficient interior climate control and reducing the use of natural resources in construction will aid in mitigating future climate change. Reducing the urban heat island effect through green roofs and the use of shade and also enforcing construction standards designed to withstand natural hazards are adaptation strategies. Excessive ambient heat and flooding carry with them immediate and potentially

severe health hazards. Mitigating against future effects may reduce the severity of these hazards.

The use of green infrastructure to reduce the deleterious effects of the urban heat island (Policy 5.10) is not only an adaptation to increasing temperatures, but also a mitigation strategy. Green infrastructure reduces temperatures through evapotranspiration and also traps airborne greenhouse gases that may exacerbate future climate variability (Gill, Handley, Ennos and Pauleit, 2007).

Maintaining a sustainable water supply in the face of drought (Policy 5.15) is a public health issue with severe consequences, especially in dense urban environments where the city system is the sole source of potable water.

The most unique connection between health and climate change found in the plan deals with waste management. Waste is addressed in the climate change chapter due to its potential as an energy source and in the importance of promoting recycling and recovery. In addition to encouraging the minimisation of waste, the plan states that waste processing facilities should take into account the health and safety of those working within them and also that of adjoining neighbors (Policy 5.17). A more direct threat is hazardous waste, but the plan does not deal with the health threats associated with exposure to hazardous waste but rather the public concern over health and environmental impacts of the facilities that handle the waste (Policy 5.19).

Another unique aspect of the climate change strategies chapter of the plan is that this chapter includes brownfield remediation (Policies 5.21). Preventing environmental and health threats from contaminated brownfield sites is how health and brownfields are connected in the plan, but brownfield remediation also has indirect climate change mitigation benefits in that scarce urban land unusable with brownfield status can be used for redevelopment upon remediation of contaminants. This may alleviate pressure for greenfield development that consumes green

infrastructure and creates the need to consume fuels to reach development at greater distances from existing goods and services. Lastly, health is addressed in Policy 5.22, but only in the title of a directive that should be taken into account when there is exposure to hazardous substances and installations.

There is at least one health impact of climatic change *not* noted in The London Plan policies but supported in the literature. An increase in mean temperatures causing an increase in suitable habitat for the vectors that carry infectious disease (eg. mosquitos, ticks) has been put forward as a serious health concern (Table 1). Countries where a colder climate has kept diseases like malaria at bay could eventually host a climate that could harbor disease. One explanation for the omission of vector-borne diseases in the plan is a belief that since the UK eradicated malaria once, it is unlikely to reemerge (Kovats, 2008).

Conclusions

There are at least three conclusions that can be drawn from addressing the first of the two research questions: How is the local co-benefit of human health portrayed in a world class spatial development plan, and how is health tied to the plan's climate change mitigation and adaptation actions?

First, the threats to health and actions to address these threats are truly localised, but there is explicit recognition of London's influence on the global environment. The planning policy actions promise benefits to average Londoners but also situate London in a global context. It is beyond the scope of this paper to address fully, but the fact that London, as a local municipality, has taken steps to mitigate global climate change adds to the paradox of collective action witnessed in other cities worldwide. Local municipalities, namely cities, are taking the lead in planning for climate change even though the benefits of mitigation are global in nature and

shared. London operates in a country with national level leadership, but many of the countries responsible for the highest levels of greenhouse gas emissions do not. Still, in countries without this leadership and mandate handed to local municipalities, such as the US, it is cities who have taken the lead in planning for climate change. Untested but possibly driving this apparent collective action paradox is the realisation of local benefits. Health is certainly one of these benefits, and its role in driving local action is ripe for future research. How this research might be approached is presented briefly in the Discussion section.

Second, the policies that recognize health in the plan acknowledge the health benefits derived from a balance of adaptation and mitigation strategies. London's climate change mitigation strategies include its global contribution to improving health and welfare beyond the UK, but its adaptation strategies have more immediate and local health benefits. Current estimates reveal that even with serious mitigation efforts, the next 100 years of climate change will be determined by an atmospheric composition that cannot be changed (GLA, 2011, 138). Therefore, London appears resolved to adapt to what is to come over the next century, and likely beyond, considering concerted global mitigation efforts have been slow in coming. The most notable policies that explicitly tie health to adaptation and mitigation are those which address building design and construction and green infrastructure conservation. These policies will protect London residents from the risks associated with rising temperatures and flooding by adapting to these projected conditions in the near term and mitigating against their increased severity and frequency in the longer term. Adaptation and mitigation are not two opposing alternatives and rather must be viewed as complementary (Adaptation Sub-Committee, 2010).

Third, addressing health inequality and the creation of healthy urban environments are cross cutting issues throughout The London Plan. As opposed to a specific health condition, it was

health inequalities and increased susceptibility by vulnerable populations that was granted the most attention. The health and welfare of those who already bear the burden of the poorest health will likely be at the greatest increased risk of injury and disease from climatic events. The content analysis revealed that health language was strewn throughout the document, but it typically appeared as one among many benefits of a prescribed action. Although there exists a commendable recognition of health as an outcome of changes to the built, social, and economic environment, health certainly did not crowd out other important outcomes. Health tended to appear alongside the broader outcomes or education, welfare, development, and quality of life. It most often remained as a higher level goal.

The climate change policies that address health can be tied to the framework of human needs (Macintyre, Ellaway, and Cummins, 2002) because they were essential to meeting the basic human needs for water, shelter, and hygiene. The importance of the continued delivery of potable water likely needs no explanation. Shelter delivered by green construction practices not only provides protection from the elements like other non-green practices, but green practices also have the added benefit of employing materials that can sustain the natural resources needed to meet other needs. Green infrastructure in the form of protected open space also ensures the quality of natural resources necessary to maintain life. It can also provide a forum to meet the lower order needs for recreation and play. The remaining policies of waste management, brownfield reclamation, and reducing exposure to hazardous substances are hygiene issues in that they are aimed to reduce disease through protection from environmental toxins and pollution. It is by connecting these proposed spatial development and climate action strategies to human needs that their fundamental importance is revealed and the goal of planning to protect humans from harm and deliver on these needs affirmed.

Research needs uncovered by content analysis

In answering this paper's second research question pertaining to the plan's ability to elucidate research gaps in the planning for health and climate change literature, all but one of the health outcomes recognized in London's climate change policies are supported by the nascent public health literature. The one policy yet to be examined closely for its health effects, and with significant potential to affect both mitigation and adaptation responses to climate change, is brownfield reclamation. Exposure to the toxins that define a brownfield can certainly be detrimental to health, but reusing brownfield sites can contribute to climate change induced health outcomes in at least two other ways. First, reclaiming brownfields allows infill and greater urban density. Greater density creates shorter distances between trip origins and destinations and lower greenhouse emissions expended in travel. This would help mitigate future climate variability. Second, the conversion of brownfields to greenfields could reduce the urban heat island effect and help in adapting to increasing temperatures. There is great potential in research which tests the efficacy of geoengineering techniques using land use scenarios aimed at climate change adaptation and mitigation. The reclamation of brownfields, along with land conservation and connecting residential and commercial uses, could be one of these techniques.

Additional research needs could also be addressed by extending the study performed in this paper. A larger comparative study between The London Plan and the comprehensive plans of other major metropolises could reveal the prevalence of health as a global theme, its ubiquity in lofty goals or measureable objectives, its potential usefulness in justifying contentious action, and whether it is more often associated with either climate change adaptation or mitigation strategies.

Discussion

Some important questions remain as to the role of health in spatial development and climate change plans. First, can the immediacy and localness of health benefits be used as a vehicle to make sustainable development efforts more politically tolerable? It may be easier to 'sell' concepts such as fuel efficiency, waste reduction, and reduced consumption if they are framed as health and not solely environment driven even though the reality is that they are inseparable. The greater prevalence of health in sustainability/climate action plans in the US (American Planning Association, 2011) could stem from a greater acceptance of the health and environment connection, or it could be that health is taking its rightful and significant place as a motivation for protecting the environment human welfare is dependent upon. In the US, where private property rights are vehemently defended, it was the protection of public health that provided the legal foundations for the planning and zoning of land uses (Shilling and Linton, 2005, 96).

The question remains as to how national-level climate threats made their way into the localised planning of London's future. There has been progressive national leadership on the issue in the UK, but this is not the case elsewhere. The proliferation of climate change plans around the globe and in places with rather weak national leadership suggests that this national level leadership is not necessary to spur local governments to take action. The US has no national policy, but the latest *Global Climate Change Impacts in the US* report released in 2009 includes an abundance of health language (US Global Change Research Program, 2009). National level leadership may be important to guide local efforts and encourage health to be considered uniformly across the country. If the number of early-adopter local municipalities begins to wane and a national level strategy proves necessary to drive local plans, could it be the apparently forgotten core mission of government to protect health and welfare that is the impetus to devise a national strategy?

Lastly, similar to much of the health and climate change literature, the London Plan contains no quantifiable projections of the negative health effects of climate change strategies, only general talk about health outcomes and inequalities. There is no attempt at quantifying the negative health outcomes and suffering that will be avoided if the preventive measures in the plan are heeded. Watkiss et al. (2009) boldly begin to provide some quantitative basis from which planners can begin to prepare.

The wall, the door and the key? Exploring resilience in problem and solution identification in segregated Roma communities

Abstract

Segregation in its various forms causes myriad problems in the growth of and social cohesion in cities, nations and regions. The causes and consequences of segregation are complex and, at times, difficult to distinguish. Formal and informal responses to the negative consequences of segregation can be observed from the individual to the institutional level. Two distinct spheres where formal interventions against segregation have been carried out by both governmental and non-governmental agents are via housing and education.

The concept of resilience has been increasingly used to understand and ameliorate a range of social challenges through examining how individuals, families and communities respond and adapt to stressful conditions, such as those resulting from segregation. Resilience is appealing as it accommodates the complex, dynamic and multidisciplinary nature of the fields to which it has been applied, including in efforts to understand community functioning under strained conditions. Its value in designing solutions to social problems is of growing interest and may offer a new perspective on the problems of segregation.

In Europe, one group that overwhelmingly experiences segregation in all facets of life is the Roma, who chronically live in poverty, occupy sub-standard dwellings and operate at subpar education (and subsequent employment) levels. Interventions are ongoing at the local, national, regional and European levels; simultaneously, there is regular acknowledgment of the need for new and innovative approaches to the persistent challenges of realizing Roma integration.

The motivation underpinning this paper is an interest in how the concept of resilience has or could be used to design, implement and measure interventions made to improve the conditions of urban communities, such as the European Roma, that are considered to be living (to their detriment) under long-term stressful conditions.

Introduction

Interventions[i] that aim to address segregation – particularly housing programs and policies – have often not met expectations (Bolt et al., 2010). One glaring example of sustained segregation can be found in the case of the Roma, Europe's largest and most discriminated against minority group. The persistence of segregation and social inequalities found within the European Roma serves as evidence that an ultimate solution or formula has not yet been discovered for eliminating social segregation and

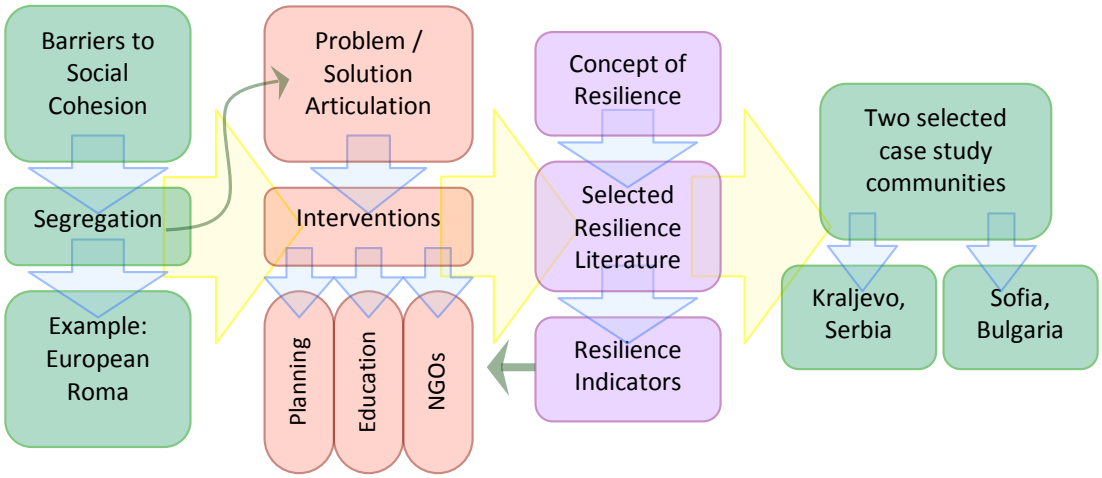
achieving cohesion. One concept that is of increasing interest for understanding and addressing social problems is that of resilience. Resilience in the social sciences refers to the ability of an individual or group to maintain their structure, cohesion and well-being despite difficult or trying situations, both traumatic incidents and long-term sustained stress.[ii]

This paper will consider the relevance of resilience in interventions related to segregation, specifically approaching resilience from three very different perspectives and scales: from the urban planning, education and non-governmental organization (NGOs) sectors. The selection of these three points of entry into the examination of resilience does not suggest their discreet compatibility; rather, the paper approaches each of them independently from each other (with some overlap seen in the case study analyses).

This effort will commence with a brief review of the literature on segregation; urban planning, education-related and NGO interventions; and the concept of resilience. This will be the basis of an attempt to examine the operational value of resilience by looking at its current and potential use in practice. In order to test the products of the literature review, the results will be examined through the lens of two case studies, both of which represent completed interventions intending to improving the living conditions in segregated Roma communities in Europe.

The purpose of this is to determine if resilience shows some potential as an innovative approach to understanding and addressing some of the core problems of segregation, which ultimately present barriers to social cohesion. Figure 1 illustrates the analytical framework developed and followed for this paper, which guides the paper from the broad issues of social cohesion and segregation to the specific case studies via specific interventions and the concept of resilience.

Figure 1. Analytical Framework



Background: Segregation, Interventions and Resilience

The Problems of Segregation

Segregation comes in many forms, including social, economic, residential and political. Segregated conditions disrupt the flow of knowledge and resources, ultimately hindering economic and societal growth. Segregation paradoxically has the ability to simultaneously constrain resilience (lack of access to information, economic opportunity, competence, social capital, and so forth) and encourage it (persistence, survival and coping) (Wang, 1995).

Just as assets, information and resources are often distributed inequitably in society, as is risk, with many of the poorest communities being exposed to excessive hazards (Norris et al., 2008). This applies to environmental conditions such as the tendency for poorer communities to live concentrated in geographical locations that are subject to more frequent natural disasters. Furthermore, the integrity of housing structures in impoverished communities is often not adequate to withstand extensive physical shocks. As a result, the damage experienced from natural disasters is frequently much more severe in poorer communities.

Taking into consideration that poorer communities experience more severe destruction, the fact that they are also often less able to access resources to recover only serves to further exacerbate this condition. Norris et al. present the “rule of relative needs” and the “rule of relative advantage”:

> Ideally, the distribution or mobilization of support follows the ‘‘rule of relative needs.’’ Simply put, the most support goes to those who need it the most. Often, however, the distribution of support follows the ‘‘rule of relative advantage’’ because one’s embeddedness in the community, political connections, and social class determine the availability and accessibility of resources (Kaniasty and Norris, 1995 and 2004, as referenced in Norris et al., 2008, p. 137).

In addition to increased risk to environmental hazards and decreased capacity to recover from them, segregation also creates conditions of long-term sustained stress. Lack of access to infrastructure such as water and electricity can result in poor families paying higher rates for essential resources (Hart, 1973). Residential segregation can result in long travel distances to places of employment. Educational segregation results in lower quality education, higher drop-outs and, ultimately, higher unemployment rates and less economic flexibility.

Articulating Problems and Solutions through Interventions

In light of the aforementioned increased vulnerability, many inhabitants of high-risk communities make independent efforts to ameliorate their situation and minimize risk. Strategies include making physical alterations to dwellings, building up stores of food and assets, diversifying income sources and developing social support networks (Jabeen et al., 2010).

Beyond community-driven or individual efforts, there are and have been efforts by external agents to address the problems of segregation. Here we will focus on those related to or implemented via urban planning, education and non-governmental organizations (NGOs). As mentioned in the introduction, the selection of these three perspectives does not propose their precise compatibility; the value and unique nature of each approach to understanding and ameliorating the negative consequences of segregation will be illustrated in the following background review.

Interventions via urban planning

In light of new trends in governance, participation and community involvement has become a high priority for planning departments worldwide (UN-HABITAT 2001), though achieving genuine participation has proven to be exquisitely challenging. Even in some of the best cases, minority groups, especially those that are segregated, are rarely engaged (Brand & Gaffkin, 2007).

Depending on the structure and guiding philosophies of a given planning agency, planning interventions are a potential tool for addressing and ameliorating social challenges. In his theories on advocacy planning, Davidoff presents the planner as an advocate that draws power on behalf of the powerless (Davidoff, 1996). Forester and Krumholz present the concept of equity planning, positing that planners are in a position to use their access to power and resource networks to influence and empower stakeholders (Forester, 1996). The theories of advocacy, equity and collaborative planning position the planner as a influential mediator with access to both resources and the communities that need them, describing the planning process as a mediating mechanism. According to Healey, if planners enter the process with this perspective, the result is a dynamic and cooperative discourse and an exchange and production of knowledge (Healey, 2003).

Relating planning interventions specifically with segregation brings us into the realm of housing policies and programs, one, if not the most implemented and examined forms of planning desegregation measures (Bolt, 2009). The following quotation speaks to the relative failure of the vast majority of housing interventions to combat residential segregation in Europe:

> "…although a wide array of desegregation and mixing policies can be found across Europe, they are united in their failure to bring about a significant drop in the level of ethnic segregation. Social class segregation also remains fairly resistant to policy interventions…mixing policies often not only fail to meet the expectations of policy makers, but they can also lead to negative effects, such as the break up of communities and constraints on housing choice." (Bolt et. al., 2010, p. 130)

If residential integration does not lead to increased social cohesion (and can actually decrease cohesion), then it can be argued that either residential segregation is not the core problem to be addressed or that there is a need for new approaches.

Education-related interventions

The education system has long been recognized as a means for class distribution and the maintenance of class divisions (Apple, 1995). "The causes of exclusion run deep in the architecture of schooling" as schools actively "reflect and refract social inequalities" (Slee, 2010, p. 102). Despite the longstanding tendency for the education system to hold people in their current levels of prosperity or poverty, some argue that the school is the ideal setting for significant social change. The classroom is where children are empowered and learn about democratic participation (Ladson-Billings, 2004; Radó, 2001; Szalai et al., 2009). The early school experience is where many social norms and rules are acquired, where students learn the "rules of the game" that become important in social functioning later in life (McDonnell et al., 2000). Condly discusses the value of the school as a vehicle for interventions due to the compulsory nature of education in most societies, the sheer number of hours that children spend there and the fact that schools simultaneously address academic, moral and health issues (Condly, 2006).

In addition to its use as a means for social development (McDonnell et al., 2000), education is often seen as a critical factor in the segregation of minorities, both in its causes and solutions. The exclusion of minorities from the education system can often been seen as a microcosm of their segregation in larger society (Szalai et al., 2009). Many of the root causes and solutions of the segregation of minorities can be traced to the quality and duration of their education (Goodenow, 1992).

Understandably, many agents working for the improvement of the lives of target populations focus on educational desegregation and eliminating unwarranted placements of minorities in special and lower quality schools and classes (Friedman et al., 2009). Indeed these efforts have shown some results (at various scales) in school desegregation, decreased drop-out rates and increased school enrollment. However, there are limitations to education in development at the regional and national scale, particularly in the absence of complementary resources.[iii]

Interventions implemented by non-governmental organizations (NGOs)

NGOs have and continue to play a significant role in community advocacy, often provide a sort of moral authority, have a sense of legitimacy and public trust and are perceived to represent the public independent of economic influence (Ghaus-Pasha, 2004). Historically, NGOs emerged as a direct result of changes in political power structures and the redistribution of power; this occurred when public funds were redirected to independent NGOs for the delivery of public services (Kaposvári et al., 1997; Powell, 1987). NGOs are also key in the production and distribution of culture and serve a "central role in molding public opinion" (Powell, 1987, p. 307). The professional advocates available through NGOs can increase formal access to resources and political power for communities. Regarding their roles in participation and governance, NGOs can serve as an organizing force in the absence of a community's capacity for self-organization.

Despite their unique positioning as an agent for positive social development, NGOs are not without their own challenges, criticisms and perceived failures. One area noted for improvement is the long-term sustainability of NGO initiatives:

> "Successful NGOs need to be both lauded for the successful extension of social capital, but also implored to work at further indigenizing it." (Buckland, 1998, p 237)

The Concept of Resilience

In terms of urban planning and development, resilience has largely been applied to disaster preparation and recovery, looking at how to minimise community vulnerability and improve response times and access to resources (Norris et al., 2008). Building on this work, persistent resilience looks at how communities survive and cope under conditions of long-term sustained stress, such as those resulting from segregation, poverty and oppression (Andres & Round, 2011).

Additionally, there has been some development of the concept that combine or supersede these two general categories. This includes 1) human agency, which differentiates between mere survival and intentional action to improve one's situation and 2) social and institutional resilience which suggests that the presence or lack of resilience at the individual, family or community scale may be symptomatic of a lack of resilience at a larger scale.

As the concept of resilience has produced new insights and a deeper understanding of social problems, the discourse has naturally led to the potential use of this understanding to prevent or minimise problems. The application of resilience in the design and implementation of interventions is naturally more developed in those disciplines that

were early adopters of the concept, namely child development and psychology (Walsh, 1996). Other areas are following suit, for example in the fight against increasing environmental vulnerabilities due to climate change (Cinner et al., 2009).
This then begs the question of how the concept of resilience is or could be translated into measurable characteristics or indicators. Figure 2 was compiled from the aforementioned literature to provide a general sense of the indicators of resilience that can be found across and between research and disciplines.

Figure 2. Summary of factors, criteria and indicators of resilience[iv]

Economics, Infrastructure & Resources
- Employment rates – diversity, flexibility and stability of economic activity
- Infrastructure – spatial (i.e. housing), social (i.e. community) and services (water, electricity, etc.)
- Distribution of power, knowledge and resources

Information, Communication, Skills & Competences
- Distribution and accuracy of information
- Language, communication, literacy and levels / equity of formal education
- Critical thinking, problem-solving and decision-making
- Collective and self-efficacy, ability to organize and take action

Social Capital, Social Networks & Relationships
- Inclusivity, exclusivity and legitimacy of as well as linkages with institutions
- Political representation and political will
- Social networks and interpersonal relations
- Presence of mediating structures and alternative spaces

History, Identity, Perspective & Other Psychosocial Factors
- Narratives, cohesion, self- and group esteem
- Sense of belonging, attachment to place and macro-belonging
- Interpretation of and approach to adversity and change
- Human agency, perception of humans as causal agents

Case Studies: Roma Integration in Europe

In order to test the potential application of the theoretical results of this paper, an analysis of two interventions aiming to improve the living conditions of segregated Roma communities was conducted. The following section provides a brief background on the European Roma and a presentation of the case study methodology and results.

The Roma in Europe

The European Roma are a population well-documented to be found to be living in poverty and segregation, suffering from discrimination and oppression at various

degrees of severity. It is generally accepted that the Roma originated from the Indian sub-continent and are thought to have been in Europe as early as the 14th century (Vajda & Dupcsik, 2008). More recent Roma migration has been attributed to conflict (e.g. in Kosovo) and European expansion (e.g. following Romania's ascension into the European Union).

Though they are classified as one ethnic group, substantial differences exist within the Roma population (Ringold et al., 2005). They do not, for example, necessarily share a common language or religion. One consistent characteristic shared by the majority of Roma is that they live in poverty and are deeply discriminated against in nearly all facets of society (Vajda & Dupcsik, 2008). Data on the various Roma populations are typically incomplete or non-existent due to such reasons as lack of formal registration and national regulations against collecting data based on ethnicity. This presents a challenge to understanding and addressing Roma-related issues; estimates on population sizes and specific cohorts can range wildly, in some cases by the hundreds of thousands (Baucal, 2008).

Many interventions to improve the situation of the Roma have been and continue to be implemented. One example of this can be found in the Decade of Roma Inclusion,[v] an international initiative to improve the situation of Roma in twelve countries.

Case Study Methodology

The data used for the selected case studies is a mix of primary and secondary, quantitative and qualitative. Background information on Case Study 1 was obtained through current and former UN-HABITAT staff, the texts and publications they provided as well as independent internet searches (predominately the UN-HABITAT[vi] and Kraljevo Municipality[vii] websites). Additional information was obtained through direct communication with the project manager via an in-person meeting in Belgrade.

Background information for Case Study 2 was obtained through documents provided by the international NGO the Roma Education Fund (REF),[viii] as the project was funded by (and thus subject to the reporting and monitoring requirements of) REF's grant program. More detailed information was acquired through participation in a routine REF grant program monitoring mission wherein the project's implementing agency and project sites were visited. Additional information was obtained through internet research and REF reports on the education system in Bulgaria.

Objectives and Methods

Following is the first of three main objectives of the full case study analyses and the corresponding method used to meet that objective. The remaining objectives and methods from the full thesis upon which this paper is based have been excluded here.[ix]

Objective 1: Determine the relevance of the identified resilience indicators in practical application.

Method 1: Review the relevant problems, solutions and outcomes and correlate with related resilience indicators.[x]

In order to compose a list of intervention-related resilience indicators, I returned to the list of indicators extracted from the literature reviewed on resilience (see Figure 2). These indicators were correlated with the literature on the three areas of focus; Table 1 summarizes the results. It should be noted that this list is not exhaustive; the aim was to produce a sufficient number of indicators for conducting exploratory case studies analyses.

Table 1. Distribution of resilience indicators by focus area

Resilience Indicators								
Agents of Resilience	Urban Planning	Empowerment & creating points of entry for participation	Education	Literacy, level/equity of formal education, training, language & effective communication	NGOs	Power (in terms of influence on pubic opinion) and distribution of information
		Distribution of knowledge, power & resources		Participation, social networks and a sense of belonging		Inclusivity/exclusivity of institutions & organizations
		Social capital, networks and relationships		Critical thinking, decision-making & problem-solving skills		NGOs as product or means of self-organization & leadership
		Distribution and accuracy of information		Mediating structures & alternative spaces		Relationships, social capital, trust & legitimacy
		Mediating structures & advocacy		Employment & economic diversity		Linkages with institutions & organizations
		Problem-solving & decision-making		Identity and esteem		Distribution of power and resources

Following this, the available documentation and interview results from the two case studies were reviewed, extracting instances where language correlating with the identified indicators emerged. A presentation of the two case studies and the results for each follows; as this analysis is being extracted from a larger text, it should be noted that only the urban planning-related resilience indicators are utilized here.[xi] A brief summary of notable findings concludes this section.

Case Study 1. Sustainable Improvement and Regularization of the Roma Settlement Grdicka Kosa 2 in Kraljevo, Serbia

Kraljevo is a city in central Serbia with 121,707 inhabitants recorded in the 2002 census.[xii] Due to historical regional conflicts, Kraljevo, like much of Serbia, is home to many refugees, Internally Displaced Persons (IDPs) and vulnerable populations. One group classified as vulnerable are the Roma.

In 2001, the Italian government committed €15 million towards a long-term settlement and integration program, to be overseen by UN-HABITAT. In 2005, implementation of the three-year Settlement and Integration of Refugees Program (SIRP)[xiii] began. SIRP aimed to achieve long-term integration through national and local policy and direct project activities. One direct activity component of SIRP was the Alternative Housing Solutions Project; Case Study 1 falls within this grouping.[xiv]

Grdicka Kosa 2, one of four Roma settlements in Kraljevo, is a five hectare site situated on the city's periphery. At the time of the project, 407 inhabitants were living in 87 houses. From 2007-2008, UN-HABITAT implemented the "Improvement and Regularization of the Roma Settlement Grdicka Kosa 2 in Kraljevo" project in partnership with the Municipality of Kraljevo and the Municipal Housing Agency (Ramirez et al. 2008). The project aimed to both improve the living conditions of the community and to fully integrate its inhabitants into the larger society.

Table 2 provides a synopsis of the analysis of the available information related to problem and solution identification and the recorded outcomes of the intervention.[xv]

Table 2. Analysis of Case Study 1

Project Name: **Sustainable Improvement and Regularization of the Roma Settlement Grdicka Kosa 2**
Problem *(as defined by UN-HABITAT)*
Distribution of knowledge, power and resources *Low income, low formal education levels, high welfare reception levels, land tenure issues, low quality housing, limited access to utilities.*
Solution
Distribution of knowledge, power & resources *Initial physical/socio-economic survey conducted, weekly project meetings, national design competition was means for developing community plan.* **Empowerment & creating points of entry for participation** *Citizen workshops, opportunities to actively participate in implementation, overall settlement improvement (including community committee that selected which families would receive housing improvements).* **Problem-solving & decision-making** *Trainings in communication and conflict management.* **Mediating structures and advocacy**

Long-term integration through policy, implemented by UN-HABITAT in partnership with Municipal Housing Agency, funded by Italian government. **Distribution & accuracy of information** *Project-specific survey generated new data, weekly project team meetings.* **Social capital, networks & relationships** *Formation of a team of municipal experts and settlement representatives, project manager encouraged direct communication (i.e. holding meetings in the settlement vs. municipality), main objective was inclusion and integration.*
Outcome
Distribution of knowledge, power and resources *Upgrading of settlement infrastructure, improvement of housing conditions for most vulnerable, construction of indoor toilets and extra rooms, completion of previously incomplete housing, creation of a draft programme for a Detailed Regulation Plan.* **Empowerment and creating points of entry for participation** *Community participated in workshops, trainings and meetings, housing upgrade recipients selected by community.* **Social capital, networks and relationships** *Framework of Cooperation to continue settlement improvements was generated, direct communication between municipality and community continued after the project ended, there was some political resistance that prevented the implementation of portions of the plan.*

Case Study 2. Equal Opportunities Initiative in the Fakulteta Community of Sofia, Bulgaria

The case of the Roma in Bulgaria is no exception to trends observed of Roma populations elsewhere – high rates of poverty, unemployment and residential and social segregation. One of the most well-known segregated Roma communities in the capital of Sofia is Fakulteta, which has an estimated 40,000 inhabitants and where low levels of educational attainment and high early school leaving rates are a significant problem.

In Bulgaria, completion of preschool and kindergarten is compulsory; a document stating completion is required for registration into the first grade. Therefore, not enrolling in and completing preschool more often than not effectively excludes students from the school system for life. In 2008, the Municipality of Sofia launched an internet-only registration process for preschool. Although this represented an advancement for the municipality, it simultaneously presented new barriers for the inhabitants of Fakulteta – lack of computer and internet access and low literacy rates make the internet registration process difficult.

It was under these conditions that the NGO Equal Opportunities Initiative Association obtained a grant from the Roma Education Fund (REF) to increase preschool and kindergarten enrollment of the Romani children in Fakulteta, primarily through assistance with the online registration process. The Equal Opportunities Initiative Association, founded in 2006, works to promote and preserve Roma culture and traditions in Bulgaria and facilitate integration of Roma in Bulgarian society through

legal and advocacy services, housing advocacy, fighting against discrimination and building the capacity of other Roma organizations.

Table 3 provides the analysis of the available information related to problem and solution identification and the actual and anticipated outcomes.

Table 3. Analysis of Case Study 2

Project Name: **Equal Opportunities Initiative in the Fakulteta Community of Sofia, Bulgaria**
Problem *(as defined by Equal Opportunities Initiative Association)*
Distribution of knowledge, power & resources *Low levels of education attainment, literacy, computer skills, access to computers/internet; high drop-out rates; inequality in all aspects of life for Roma; residential segregation, distance from most mainstream educational facilities; difficulty paying school fees.* **Distribution and accuracy of information** *Advertising campaign about electronic enrollment did not reach the community; enrollment communication and information only available through the internet; contact information obtained by school staff for Romani parents is often incorrect (school staff does not trust contact info from Health & Social Services).* **Social capital, networks and relationships** *Discrimination is high, Roma are not welcomed into mainstream schools; Romani children typically spend all of their time in the Roma community and are not well-prepared for integrated environment; tensions between school staff and parents; perception that NGOs only absorb money (there are more important investments).*
Solution
Distribution of knowledge, power and resources *Increase enrollment rates in mainstream schools, assist with school lessons, increase enrollment in the schools near to the community to prevent transportation need, provide books for additional at-home work, meet with parents about working with children using the books.* **Empowerment and creating points of entry for participation** *Regular and frequent communication with parents, enroll children in school to encourage early social integration, engage volunteers in project implementation, hold community meetings at beginning of project.* **Problem-solving and decision-making** *Visit surrounding schools, gather information about school's profile, distributed this information to parents to encourage informed decision-making.* **Distribution and accuracy of information** *Targeted information campaign about electronic enrollment process; assign a group coordinator to track registration, application, enrollment processes and attendance; hold weekly or bi-weekly meetings to monitor project implementation; meet with teachers to obtain supplementary data; develop relationships with Municipality.* **Mediating structures and advocacy** *Provide direct assistance with online enrollment process, meet with municipality and schools on behalf of Roma to identify and solve specific technical issues, monitor absenteeism to determine actual (vs. perceived) causes, addressed misunderstandings of both parents and schools.* **Social capital, networks and relationships** *Develop relationships with municipality and schools; implementing organization located adjacent to community.*

Outcome
Distribution of knowledge, power and resources *Increased understanding of parents and increased number of students enrolled.* **Empowerment and creating points of entry for participation** *Community meeting sessions and training for parents on working with children on supplementary activities.* **Mediating structures and advocacy** *Identified technical issues and negotiated solutions with municipality, worked with community to complete enrollment, maintained lists of existing enrollment profiles and required documents, monitored enrollment system weekly.* **Social capital, networks and relationships** *Obtained partnership agreement between NGO and municipality regarding project support.*

Results

Table 4 summarizes the results of the two case study analyses in terms of Objective 1.

Table 4. Synopsis of Case Studies 1 and 2 as related to Objective 1

	Case Study 1	Case Study 2
Objective 1 Determine the relevance of the identified resilience indicators in practical application.	Many observable correlations with a variety of indicators throughout the project. It is noteworthy that all of correlations identified in the problem section fit into one indicator category, that of the distribution of knowledge, power and resources. Other indicators emerged throughout the solution and outcomes sections.	Presence of resilience indicators was extensive, and likely not completely captured here as there were many. It was not difficult to identify instances of this.

Though perhaps not intentionally sought as an objective or aim as such, elements of resilience (as measured by the selected indicators) indeed emerged throughout both projects. That said, there is some variation in the profile and distribution of these interpreted indicators. In Case Study 1, the fundamental focus of the project was physical improvements to housing and infrastructure and the creation of an overall community plan. Housing and infrastructure both correlate to the distribution of and access to resources. This can be seen in the resilience indicators extracted from the problems defined in Case Study 1 – in fact, they all relate to the distribution of resources.

When looking at the solution and outcomes for the same project however, the distribution of resources as a resilience indicator carries over, but other resilience indicators emerge as well. If one were to create a resilience-based model, this case would likely show a predominant focus on just one just element of resilience in the

problem identification, i.e. access to resources, with additional elements found in the solution and outcome design, perhaps acting as a kind of added value towards the success or sustainability of the intervention, but not necessarily core to the motivation of the project or the implementing agency.

Compared to Case Study 2, one finds less of a concentration on one type of indicator in problem identification. Perhaps this reflects the nature of the implementing organization and may be explained by the mission-based nature of many NGOs – their interest is often based on an overall situation or trend perceived as unacceptable, in this case the discrimination, oppression and inequity that Roma suffer from in Bulgaria. Galvanized by this, the NGO in Case Study 2 works to solve the problem as such, subsequently revealing a full cadre of social spheres where these unacceptable conditions exist.

More may be learned from considering additional differences in circumstances between the two projects – for example, UN-HABITAT was a temporary element in the community, with their staff being involved only for the duration of the project. Perhaps this made making direct links that were not dependent on UN-HABITAT's presence essential and part of the implementation strategy. Further, the nature of the intervention should be considered; the UN-HABITAT project, while working in principal towards equality, was relatively finite and short-lived as just one component of a much larger program (SIRP). In comparison, the NGO in Case Study 2 is, to a degree, a member of the community itself, with its office located literally next to the Fakulteta community; the development of more long-term and established relationships directly with the community is perhaps more natural and appropriate as well as being an objective in itself.

Conclusions and Intended Future Research

Overall, this paper demonstrates that resilience is present in and has potential as a tool for urban interventions, though the extent of this potential is to be debated. The key hypotheses moving forward are that 1) fundamentally, examining the problems of segregation through the lens of resilience can reveal the root problems of segregation, 2) encouraging the development of elements of resilience is already innately of interest to many agents currently working to identify and solve social problems and 3) though resilience may offer common ground and complex consideration of community context, resilience and resilience-thinking still needs to be approached on a case-by-case basis and does not eliminate the unique features and nuances of any particular social problem.

Future research could work to further operationalize the concept of resilience via interventions aimed at improving conditions and participation in segregated communities, aiming to produce more precise guidance or articulate a clear formula for utilizing resilience in practice.

Evaluating Urban renewal priority areas in Taiwan: a case study of Tainan

Yu Sun[1], Tzu Yuan Chao[2]

Abstract

Urban regeneration projects have been considered as the major catalyst to revitalize deprived urban areas socially and economically. Proposing area-based comprehensive urban regeneration strategies are emphasized global wide. Many researches confirmed that urban renewal priority areas should be based on physical environment and the economic, social needs of local residents (Lee and Chan,2009; Council, 2006; DETR,1999a), the sustainability of regional development (DETR, 1999b; DOE,1994), and level of improvements of living quality (DETR, 2000; ODPM,2003) in order to ensure long-term benefits for the whole area. In Taiwan, although the idea of area-based regeneration projects has been advocated by many researchers, in practical, the main considerations for designating "priority areas" regulated by the current Urban Renewal Act 1999 are still dominating the decision making process. Blight areas bigger than one-block in size with worse deprived social and physical environment, near future major public constructions, or listed historical buildings are recommended for designation. Since 1999, there has been over 300 urban renewal projects proposed in Taiwan, but most are small-scale private sector-led housing development projects located in the Taipei City. It has further resulted in issues such as gentrification, housing affordability and social conflicts between rich and poor. In 2009, the central government has announced 30 priority areas and Tainan city government has announced 26 priority areas to promote urban regeneration by investing large amount of public funding. However, the criteria for designation include large area of public lands, major facilities and historic heritages. Clearly, the government is still based on the current status and easiness of implementation to designate the priority areas without taking into account the future demands, social–economic trends, and possible benefits from the regional development perspectives. Hence, this study intends to use analytical hierarchy process to identify evaluating criteria in terms of the physical environment, social and economic development potential, the future investment returns and other factors

[1] Department of Urban Planning, National Cheng-Kung University, Master Student, Tainan, Taiwan (R.O.C.), Email: brian324324@gmail.com
[2] Department of Urban Planning, National Cheng-Kung University, Assistant Professor, Tainan, Taiwan (R.O.C.), Email: tychao@mail.ncku.edu.tw

for designating urban renewal priority areas. A series expert survey will be conducted to confirm designated principles and establish urban renewal priority areas weight indicators framework as an assessment tool. Finally, 26 existing priority areas in Tainan city will be examined by the indicators to further review the appropriateness of the designation. The final result of this study is expected to provide recommendations for future legal and policy amendments of urban regeneration in Taiwan.

Key words: area-based regeneration projects, priority areas, weight indicators framework

1. Introduction

Urban areas often face periods of decline, and thus require government action to regenerate them. Urban renewal plans carried out in countries such as Britain, America, Germany, and Japan, work by considering urban economic, social, and industrial factors in order to improve the lives of local residents promote urban and regional sustainable development. At the meantime, hope to enhance the environment, economic and social development and revitalize urban function by integrated urban renewal strategies to show the vitality of urban sustainable development and energy for the urban to bring long-term benefits.

Taiwan's efforts at urban renewal have mostly focused on improving the physical environment of buildings and structures in a number of small-scale projects, chosen based on the degree of environmental decay and financial benefits, with few benefits for local residents. The mail object is to reconstruct new building and redistribution of the real estate property proportion. In addition, such projects do not bring new development opportunities to the city, and can even cause more serious urban social issues, such as the problem of gentrification, housing affordability, and a widening gap between rich and poor. It is thus necessary to rethink urban renewal area selection criteria and strategies in order to improve the overall city environment and achieve sustainable development, and not only works to make buildings more aesthetically pleasing. In recent years, the central and local governments in Taiwan have chosen a number of urban renewal priority areas, hope to boost the overall urban improvement through the implementation of urban renewal, but these efforts

have had limited success, and thus this work aims to improve the selection criteria of urban renewal priority area used to achieve more beneficial outcomes.

This study is divided into two parts; the first collects the priority area selection criteria and evaluation indicators from literature review, and the second focuses on sorting out a criteria system that are more suitable for use in Tainan City.

2. Literature Review

2.1 Urban Regeneration and Area-Based Regeneration

Roberts and Sykes, (2000) defined urban renewal as a process of adopting fully integrated points of view and actions to deal with urban problems, in order to enhance the physical economic, and social environments of urban areas. Roberts (2000) reviewed the literature on urban renewal from the 1950s to the 1990s (Table 1). In the 1950s such works were based on developing master plans and suburbs to reconstruct old urban areas. This work continued in the 1960s, although efforts also began to attempt to restore the original appearance of the urban environment. With the problem of urban sprawl due to the rise of suburbs in the 1970s, attention then turned to in-situ redevelopment and neighborhood planning. In the 1980s, urban renewal efforts focuses on enhancing economic competitiveness of such areas, while in the 1990s more attention was put on the idea of sustainable development, with more comprehensive policies and the implementation of integrated programs. Today, urban renewal efforts are often used to address a number of aims at the same time, including employment, economic competitiveness, social issues, community issues, urban vacant spaces, and environmental degradation, as well as achieve the goal of sustainable development.

Taiwan’s current urban renewal policies are regulated under the Urban Renewal Act, which aims to promote better urban land development and utilization plans and the recovery of urban functions, which include improving the living environment and promoting the public interest, pursuant to the Urban Renewal Act procedures within the scope of reconstruction, renovation or maintenance measures in urban planning areas.

Table1. Urban renewal main theme evolution from 1950s to 1990s

Time	Trend
1950-1960	Main themes were reconstruction of older areas and towns and cities based on a master plan and suburban growth
1960-1970	1950s theme continued and some attempts to conduct rehabilitation
1970-1980	Focus on in-situ renewal and neighborhood schemes and suburban development continued
1980-1990	Major schemes of development and redevelopment which aimed mostly at improving the economic competitiveness of cities were developed
1990-2000	More sustainable approach and more comprehensive form of policy and practice was enhanced and more emphasis on integrated action was given
2000-now	Aim to address issues that are associated with change in the economy and employment, economic competitiveness, social exclusion, community issues, vacant and deteriorated sites in cities, new land and property requirements, environmental quality and sustainable development, etc.

Source: Roberts, 2000

The concept of area-based regeneration first arose in 1930s Britain, when it was used on a regional basis to address the problem of urban recession in a short period of time. The main factors triggers area-based regeneration is the national policy, public-private partnership, public investments in empowerment relations, community involvement and community capacity. Area-based regeneration development strategies aim to solve specific problems in a region, such as industrial land use and slums, as well as to develop an area's potential, such as with the development of a central business district and re-use of idle land. Area-based regeneration policies have long been used as a regional development strategy by central governments, and government need to looking for necessary funding to carry out the project. There have been much fewer local, bottom-up community efforts in this regard (Dobbs, and Moore, 2002). Current area-based regeneration programs often aim to reduce the unemployment rate, stimulate local economic development, reduce crime, improve the quality of the environment,

promote social integration and increase local social capital, and increase participation in cultural and sports activities (Gabrielsen, 2008). Table 2 summarizes the objectives, methods and evaluation criteria for area-based regeneration that were set out in Meyer (1998).

Table2. Objectives, methods and evaluation criteria for area-based regeneration

Objectives	Environmental objectives	Better regional environmental conditions
	Economic objectives	Improved area-wide attractiveness to capital
	Community objectives	Reduced community disamenities and specific economic improvements
	Actual consultation on local community objectives	Potentially extensive;(although development agency may listen but not act on local concern)
Methods	Leads actor	Public agencies and Quasi-public authorities
	Public site assembly, preparation	Potentially extensive to achieve area change
	Public support mechanism	Complementary investments, planning changes
Evaluation criteria	Time horizon	Lon allowing time for expected spillover effects
	Policy efficacy	New capital flows into area; increase in area economic activity, incomes, and property value
	Public efficiency	Maximum leverage on public funds
	Public effectiveness	Increase in area economic activity, household incomes; reduction in area disamenities

Source: Meyer, 1998

2.2 Priority Areas

Taiwan's criteria for the choice of priority areas for urban renewal are based on the Urban Renewal Act (1999). Under any of the following circumstances, the County (City) authority can designate an area as a priority renewal target:

1.Buildings that are deteriorated and not having a fireproof structure or the space between neighboring buildings is insufficient, and the building is hazardous to the public safety.

2.Buildings those are in a dilapidated, dangerous condition that have been badly built or roads that are curved and narrow or in any way hazardous to public safety.

3. Buildings that do not meet the urban function.
4. Buildings those are not coordinated with important development projects.
5. Buildings that have historical, cultural, artistic, or other memorable value that urgently require preserving and maintaining.
6. Buildings which have a bad living environment as to constitute a hazard to public health or peace and order in society.

In 2002, the Institute for Urban Renewal Research Foundation in Taiwan stated that the key areas for urban renewal projects should include regional transportation hubs, old residential communities, the old central business district, downtown industrial districts and military barracks, post-disaster reconstruction areas and waterfront areas. In 2009 the Central Government and in 2011 the Tainan City Government both proposed urban renewal priority areas which focus on large areas of public land, and that strategic re-development efforts should focus on spaces near railway and MRT stations or other major construction and development areas, as well as work to preserve historical areas.

The international research literature indicates that the selection criteria for urban renewal priority areas should integrate the concepts of economic, environmental and social sustainability (Chan and Lee, 2007). In addition, renewal efforts should aim to make working and living areas more attractive (DOE, 1994), and improvements to the physical environment should meet the economic and social needs of the community (DETR, 1999, 2000). From a more comprehensive perspective, not only physical environment improvement but also economic and social development are consider as a sustainable development vision trying to figure out the maximum benefit for the urban and its surrounding area. Urban renewal drives urban development and enhances the quality of living and working environment, economic development, social welfare and other.

2.3 Indicators for Evaluating Urban Regeneration Areas

Evaluation criteria are needed to select areas for urban renewal. Many urban renewal area assessment indicators have sustainable development as the major goal of such projects. Hemphill, Berry and McGreal (2004) reported that the performance indicators used to measure sustainable urban renewal include factors such as the

economy and employment, resource use, building and land use, transport and mobility, and the community benefits, and these are considered in the criteria used to evaluate the cases in United Kingdom, Ireland and Spain. Chan and Lee (2007a; 2007b), writing in Hong Kong, also proposed a system of indicators to assess the sustainability of view urban renewal areas, and these include environmental, economic, and environmental sustainability. These indicators aim to provide communities with a high degree of operating convenience, open spaces, appropriate architectural forms, efficient and safe public transport and walking environments, good public facilities, community involvement, and retention of local identity. Amna Salman and Salman Qureshi (2009) examined the metropolitan area of the city of Karachi, and considered the issues of environmental, economic, social sustainability, as well as problems associated with buildings, noise, traffic, water, air pollution, traffic safety, healthy and mobility. The literature on urban regeneration area evaluation indicators is summarized in Table 3.

Table3. Summary of the literature on urban regeneration area evaluation indicators

Author	Case Study Area	Evaluation Criteria	Evaluation Indicators
Hemphill, Berry and McGreal (2004)	Belfast, UK Dublin, Ireland Barcelona ,Spain	Economy and work	● Number of jobs and enterprises created ● Quality of jobs ● Performance of incentive mechanisms ● Leverage ratio
		Resource use	● Reclamation of building material ● Retention of environmental features ● Water disposal ● Waste minimization ● Energy efficiency ● Conservation of built heritage resources ● Incorporation of environmental design ● Performance of environmental management

		Buildings and land use	● Ratio of open spaces to build form ● Ratio of redeveloped buildings to new build ● Reclamation of contaminated land ● Density levels in relation to plot size ● Mixed use combination ● Occupancy levels ● Quality of final product ,urban design ,public space ● Usage of public space
		Transport and mobility	● Land devoted to roads ● Land dedicated to pedestrians ● Reorientation of road network ● Work traveling habits ● Leisure traveling habits ● Public transport links ● Car-parking provision ● Integration of land use and public transport
		Community benefits	● Access to open space, leisure/retail/education /medical/entertainment/cultural facilities ● Housing affordability ● Community ownership ● Community group involvement
Chan and Lee (2007)	Hong Kong	Environmental Sustainability	● Access to work ● Sense of community ● Green design ● Building form ● Provision of open space ● Rehabilitation of repairable property
		Economic	● Access to public facilities

		Sustainability	● Green design ● Provision for establishment of different business ● Community involvement ● Compatibility with neighborhood ● Convenient, efficient & safe environment for pedestrians & public transport users
		Social Sustainability	● Provision for meeting special needs of disables, elderly/children ● Green construction ● Conservation/improvement of local distinctiveness ● Availability of local employment ● Access to open space ● Adaptability of non-domestic development to the changing need
Amna Salman and Salman Qureshi (2009)	Karachi, Pakistan	Environmental	● Buildings – construction materials, energy and land use ● Noise – number of noise complaints ● Transportation – construction material ● Water – construction material use, energy use, land use, chemical usage, contaminant ● Air-number of air pollution complaints
		Economic	● Buildings-capital and operation and maintenance costs, affordability of housing, expenditures in research and development
		Social	● Transportation – capital and

			operation and maintenance costs, expenditures in research and development, choice of mode, time of travel ● Water - -capital and operation and maintenance costs, service fees, access to portable water and sanitation service, quality of water ● Safety –feeling insecurity ● Mobility – number of people injured in traffic accidents ● Buildings – supply of housing ● Health -- indoor air quality, public satisfaction

Source: Hemphill, Berry and McGreal, 2004; Chan and Lee, 2007; Amna Salman and Salman Qureshi, 2009

Hence, from the literature review, we can clearly understand in Taiwan the mechanism of choosing urban renewal priority area is still limited in a narrow scale, instead of considering a comprehensive scale of the city like other country have done. Since urban renewal in Taiwan has become a hot issue, public sector choosing priority area to lead other private-led urban regeneration move up to act is a big issue need to concern. For the reason mention above, this study is going to base on Taiwan and Tainan's overall condition and circumstance, trying to sort out a bunch of indicators to evaluate the urban renewal priority area which proposed by government. Follow up study may try to do thorough study of indicator choosing and establish a priority area assessment indicator system.

3. Methodology

This study is mainly based on a literature review of the definition of urban renewal and area-based urban regeneration, the various selection criteria and evaluation indicators used for urban renewal priority area projects research. In addition, joining field survey to observe Tainan city's designated urban

renewal priority area to clarify the physical environment conditions and the local characteristic in order to filter the urban renewal area to assess. Follow up research will adapt analytical hierarchy process and conduct expert survey to confirm designated principles and establish urban renewal priority area weight indicators frameworks as an assessment tool. Also examines how such projects are selected in Tainan City, with the aim of providing better criteria for the selection of priority areas.

4. Study Area

Tainan City (Figure 1), one of Taiwan municipalities, has nearly 400 years of the development, it's Taiwan' earliest developed area while it has a rich historical urban environment, structure and richness of culture relic, it also faces a number of problems in conservation and development. In 2011, old Tainan City and Tainan county were merged to become a municipality, with the goal of achieving better and more sustainable economic, cultural and environmental development, while still persevere its historical characteristics.

Figure1. Taiwan and Tainan area

5. Result

Due to relatively low real estate values, there have been some problems in attracting developers to Tainan, and thus there has been unbalanced development between the urban and rural areas. Also, the preference for housing type, mostly urban renewal approach emphasis on reconstruction, lack of supporting mechanism for renovation and maintenance, the public lack of related knowledge in urban renewal leads hard to handle themselves, confusion of historic city's image and modern image of the city, a large-scale reconstruction may create conflict between maintained the historical image of the ancient capital and brand new development of Tainan, since it’s often encounter difficulties in the implementation of urban renewal.

Integrated consideration of the current conditions and the implementation of urban renewal in Tainan City, to effectively vibrant city area in various aspects of

functional activation, must be led by the public sector to conduct urban regeneration, but also hope that through the means of urban renewal can promote urban sustainable development. The goal of the implementation of urban renewal in Tainan City are both the overall sustainable development areas and keep well preserve of urban history and culture, by means of area-based urban regeneration to carry out.

In examining urban renewal efforts in Tainan City, this study considers the following three objectives: environmental, economic and social sustainable development. These will be used along with the ideas of urban history and cultural maintenance to produce a set of criteria to evaluation urban renewal priority areas (Table 4). The three objectives stated above each have eight assessment indicators, giving a total of 24 indicators preliminary chosen to do assessment.

Table4. Urban regeneration priority area evaluation indicators

Sustainable development	Environmental dimension	Building form&construction material
		Open space
		Heritage conservation
		Retention of environmental features
		Public lands
		Ratio of redeveloped buildings to new build
		Mixed use
		Green design
	Economic dimension	Number of jobs created, new enterprise created
		Quality of jobs
		Availability of local employment
		Encourage local business
		Potential investment
		Unemployment rate
		Incentive mechanism for economic activities
		Leverage ratio
	Social dimension	Community involvement
		Compatibility with neighborhood
		Housing affordability
		Meeting special needs of disables, elderly/children
		Conservation/improvement of local distinctiveness
		Historical conservation
		Public transportation
		Coordinate with public policy

6. Conclusion

By the current implementation of urban renewal and physical environment situation can understand the renewal of the single building in Tainan is not much incentive to private developers, only to put the vision into the overall region of Tainan of urban renewal is more able to reach the purpose of urban regeneration. The

private sector is not making much effort and reluctant involvement in the process of urban renewal in Tainan City, and thus moves in this area must rely on the public sector. It's not only can drive urban renewal process more progressed but also can attract private sector's investment to have the city an opportunity through the urban regeneration process.

Therefore, based on the goal of sustainable development and the preservation of the Tainan's history and culture, this work presents a number of assessment indicators can implement to identify the priority of the priority areas for urban renewal. A future study will conduct an expert questionnaire and hierarchical analysis of these indicators, and construct a framework of weighted indicators.

REDEFINING WALKING DISTANCE OF OPERATIONAL PLANNED WALKABLE NEIGHBORHOOD IN MALAYSIAN CITIES

THE CASE OF PUTRAJAYA CITY

Sabeen Qureshi[1] and Ho Chin Siong[2]

Abstract:

Urban planners, transport engineers and policy makers are emphasizing on creating environments to encourage people to walk. The concept of walkable neighborhoods is gaining prominence because evidence suggests that neighborhood socio-physical structure may affect physical activity for health and transportation purposes. It is evident that majority of our daily walk is comprised of activities such as walking for transport, work and domestic activity instead of active leisure pursuits. Understanding how people's local neighborhood environments affect their walking behavior is essential to create walkable environment. Existing literature regarding measures of perceptions of the environment related with walkability commonly depends on providing a definition of neighborhood with walking distance of 1 mile or 1.6 km around the home. Whereas traditional neighborhoods have some specific sizes which are based on walking distances which are equivalent to a quarter-mile radius or five minutes walking distance. The aim of this study is to examine the congruence between definitions used in literature review and residents own definition of walkable neighborhood. This aim will be achieved with the help of printed maps showing the neighborhood with road names and indicating places such as (Shop, Parks, Restaurant, Services, and Mosque) and the respondents were asked to draw their neighborhood walking area on the map and they have been provided three copies of the same map. For the three days, they were asked to mark areas visited on the map and later these annotated maps were scanned back into GIS software 9.3 versions for their analysis. The advent of GIS in physical activity research helps in objective measurement of the environment, linking geographical data with socio-demographic, behavioral and environmental data. When participants from residential precincts of Putrajaya were asked to draw their neighborhood boundary, the resulting areas were smaller than those calculated using GIS based on standard neighborhood definitions (1 mile or 1.6 km) Euclidean buffer area around the home. This shows a considerable variation in relative size of measured versus standard 1 mile walkable neighborhood definition. Thus it is concluded that adult's interpretation of their neighborhood area does not appear accurately to the definitions typically used 1 mile around the home into environment perception and walking related study and relate closer to estimated '5-minute walking' distances. It is also concluded that it would appear that operational definitions of neighborhood need to be smaller than those typically used.

Key Words: thresholds, walkable Neighborhood, GIS, Euclidean buffer.

1. Introduction:

Studies on the relationship between characteristics of an adolescent's neighbourhood and physical activity are numerous (Colabianchi et al., 2007). Although, some studies have found a positive relationship (Davison and Lawson, 2006; Ferreira et al., 2007), there is still no consensus across various studies in the operational definition of one's neighbourhood. This paper examines the various theories defining neighbourhood and offers a practical approach on how to measure thresholds of walkable neighbourhoods.

(Mujahid, 2006) noted that previous studies adopted census tract as the basis upon which neighbourhoods are described. More recently researchers From United States (Frank et al., 2006) and from Australia (Mc Cormack et al., 2007; Leslie et al. 2008) have begun to explore the importance of the neighbourhood scale down to (400 m buffer around respondent's homes). However, of recent, buffers surrounding peoples home are used as a proxy for a neighbourhood (Porter et al., 2004) In literature, commonly used distances that are adopted when creating buffers in the adolescent physical activity are 0.5-0.6 miles (800-1000 meters) (Braza et al., 2004;Timperio et al 2006) or 1 mile (1500-1600mts) buffer around homes. Buffers as very small as 0.25 miles (400meters) have been used (Jago et al., 2006) and as big as 5 miles (8.05 kilometres) . The need for more research in to selection of these distances have been stressed as empirical data for their selection is lacking (Timperio, 2006) noted that one of the ways for choosing these locations is that they match an easy walking distance though there is no existing empirical standard for defining an easy walking distance(Colabianchi et al., 2007). The average walking speed of a human is at approximately 3 miles per hour, which translates to ¼ of a mile in five minutes. The ¼ mile radius circle shows the distance as the crow flies. One rationale for selecting these geographies is that they correspond to an easy walking distance though little empirical evidence exists for defining an easy walking distance. (Smith G. et al., 2010)

Studies that have been carried out on to explore the perceptions of neighbourhood boundaries with adults are few (Coulton CJ 2001). Adolescent's perception of neighbourhood boundaries is likely to be different. Again, literatures on studies that examine variation in neighbourhood boundaries across other features, such as whether the person lives in rural or an urban area are lacking.

This paper comprises of two objectives. First, it provides a general summary of theoretical frameworks defining and measuring neighborhoods. Second this study examine the congruence between definations used in literature review and residents's own definition of their neighbourhood. The case study used in this study is conducted in

Putrajaya City Malaysia. Putrajaya is a planned garden city. Fig 1 shows the location of Putrajaya.

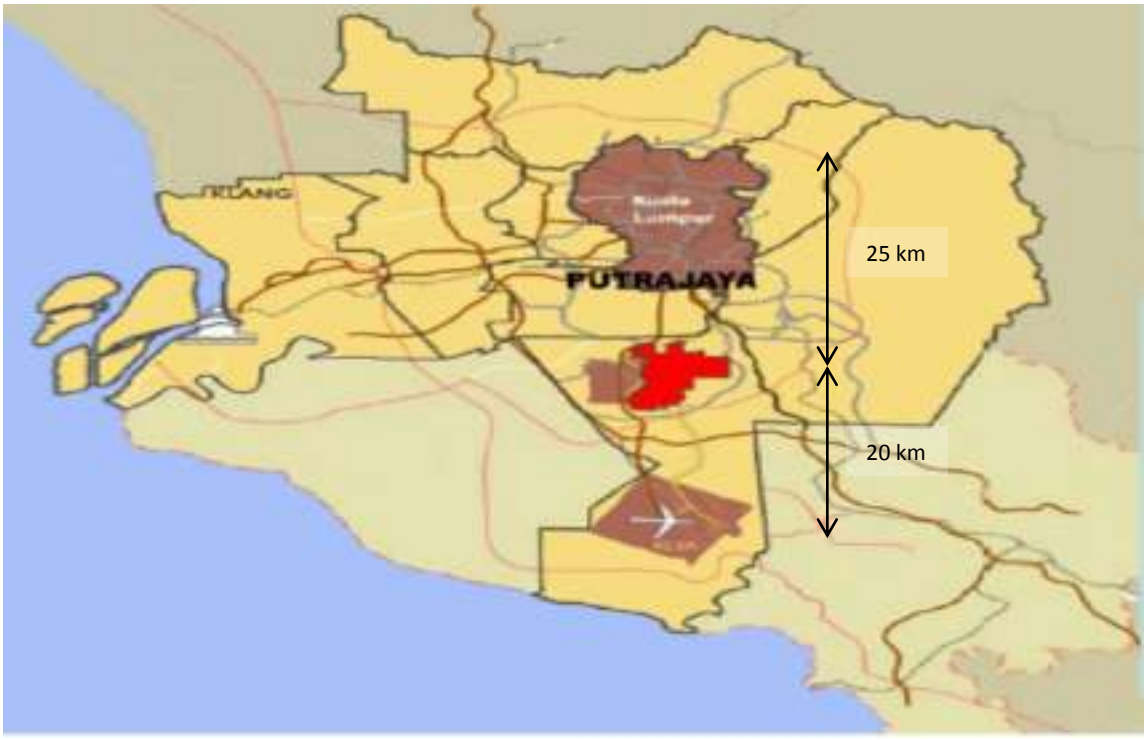

FIG.1: Location of Putrajaya (Source Draft Structure Plan Sustainable Putrajaya 2025 October 2011)

2. Theoretical Framework:

2.1Towards a Walkable Neighborhood theory:

The beginning of modern urban planning has been traced to Howard (1898) with his proposed garden cities. Howard was concerned about the over –crowded, unplanned and hostile British cities of his day, and recognized their relevance as sources of jobs and social infrastructures. Taking a cue from physics, Howard propounded the establishment of not only urban magnets that would attract workers to it but equally rural magnets that act as attraction force. He noted that doing this would involve the establishment of those human activities that can generate employment, self –containing, surrounded by all around by sphere of agricultural activities which serve as a green area to protect the establishment from external incursion.

Howard's great feat led to the launching of what became known as the new town movement. His idea was to transform urban planning from a public health exercise, to

one in which detailed spatial organizations of urban activities, housing unit, neighbourhood or as he called it the ward and town with respect to other places. Hence, neighbourhood for the first time became an essential part of urban planning activity. (Choguill, 2008).

From Ebenezer Howard Garden City theory, which modeled "new" (turn of the 19th and 20th centuries) British cities on small agglomerations of 6,000 to 30,000 people living within walkable distance to services and linked by rail transit. Today, conspicuous supporters of the New Urbanism have continued to advocate walkable neighborhoods, characterized alternatively as Traditional Neighborhood Design (TND), Transit Oriented Development (TOD), Pedestrian Pockets, Transit Villages, Urban Villages, and other sustainable models.

Following Howard garden city theory, the dawn of the 19th century saw the emergence of British cities on small agglomerations of about 6000 to 30,000 people residing within a walkable distance to services connected by rail transit. Today, many proponents of new urbanism have continued to canvass for walkable neighbourhoods characterized alternatively as Traditional Neighborhood Design (TND), Transit Oriented Development (TOD), Pedestrian Pockets, Transit Villages, Urban Villages, and other sustainable models.

In defining the walkable neighbourhood, it should go beyond pedestrian concerns as ability to move or walk freely in a neighbourhood shows not only a type of mobility and means of movement but also the kind of rapport that exist among neighbours which together affect their mental, physical , spiritual and health condition (Moudon AV et al. 2006)

Howard's concept was taken and developed by Perry (1929). (Choguill C.L. 2008) Perry propounded the concept of "neighbourhood unit" which allows children and families to move and walk safely from their dwellings to schools and recreational centres within the community. The educational and recreational facilities must be located within walking distance for all residents residing in the neighbourhood. Perry's theory is derived from social reforms that aim at growing urban population, and from Ebenezer Howard's (Moudon AV et al. 2006)

Perry was not only concern about the physical arrangements but also the involvement of the citizens in decision making about the neighbourhood. He viewed school as the right neighbourhood meeting point. Coupled with its educational function, it also serves as a community centre. He noted that school is preferable to clubhouses or churches because all members within the neighbourhood would see it as neutral.

The effect Perry's argument has on the present day urban planning is evident. Though he emphasized on the physical terms, his major concern was the building of social cohesion among residents in a well-defined neighbourhood. Most of Perry's concept was

integrated in to British public housing estates though sometimes not well incorporated, into British interwar (i.e., 1918-1939).

2.2 The Neighborhood Unit

The neighbourhood unit is defined as a physically defined unit with school, recreational areas and churches as its centre. The unit was sized to the catchment area of the typical elementary school (Kevin lynch, 1985). It is designed in such a way that residents walk not more than a quarter mile to get to these facilities and other nearby commercial areas without having to pass a major arterial street. Those streets that allow thorough traffic are not encouraged while arterial streets are located to the boundary, thereby allowing pedestrians to walk freely within the neighbourhood without any vehicular interference. Also, interior curvilinear streets characterize the neighbourhood unit's break with the traditional urban grid system. Perry proposed that that a 160 acre neighbourhood should be developed at 10 units per acre which can support between 5000-9000 residents. For more than Fifty years, it has been virtually the sole basis for formally organizing residential space (Banerjee and Baer, 1984). He even went further to suggest that 10 percent of the neighbourhood land area should be left for open spaces and parks for leisure and relaxation of residents. He equally advocated the building of schools with major play areas and community centre with various institutional uses. All these he noted, make up the physical nature concept. (Lawhon. 2009).

2.3 Principles of the Neighborhood Unit.

Perry organized the neighbourhood based on numerous physically oriented ideals. He noted that schools should be located centrally in the neighbourhood so that a child has to walk to a school only about one-quarter of a mile and no more than one-half mile without crossing any major arterial street as shown in Fig 2. Size the neighborhood to sufficiently support a school, between 5,000 to 9,000 residents, approximately 160 acres at a density of ten units per acre. Implement a wider use of the school facilities for neighborhood meetings and activities, constructing a large play area around the building for use by the entire community.

Place arterial streets along the perimeter so that they define and distinguish the "place" of the neighborhood. Bordered by arterial roads, neighbourhood units were to allow residents to do day to day activities on foot with little interference from vehicular traffic. The concept comprised pathways and internal street systems organized so as to discourage the through traffic (Pierre and Karen 2003).

FIG.2: CLARENCE PERRY'S "NEIGHBORHOOD UNIT" OF 1929

2.4 Neighborhood Concept in Putrajaya:

All residential areas within Putrajaya are developed on the 'neighborhood' concept. At the heart of this concept is that each distinct neighborhood within a larger residential precinct will be well-serviced, would have good access and vehicular and pedestrian movement routes, have ample facilities, or be well connected to such facilities, have adequate landscaped open spaces, be safe and secure, be well- maintained and equally important, have a critical mass of residents to make it livable, regardless of housing density. Each neighborhood would be defined by road ways, parks and open space or housing blocks. At the minimum, each neighborhood would have at least one neighborhood park and would be in close proximity to a larger park beyond its boundary (Review Master plan 1997). In figure (3) some of the concepts of Putrajaya master plan are depicted.

2.5 Measurements of Neighborhood:

The urban planners measure neighborhood by considering the street pattern and land use pattern, pedestrian accessibility, connectivity and environment. Their chief methodological instruments are field observations and spatial pattern analysis using maps and are occasionally complemented with survey of residents. Street pattern includes number of cul-de-sac or grid pattern and whether they have small block or big boxes. The number of intersections within the different neighborhoods corresponds to variations in the length of the street networks. Grid network provide better connectivity between the land uses of a neighborhood than curvilinear streets, crescents, and culs-de-sacs. Planners usually assess the pedestrian accessibility potential of each neighborhood by computing the number of residential units within 500 m of three categories of facilities which are supermarkets, convenience stores, and primary schools via the road network and pathways. Psychologists use mental mapping to measure individual neighborhoods. Sociologists identify common attributes of social, economic, cultural, and physical aspects of neighborhood bringing forth indicators of cohesiveness. Homogeneity and heterogeneity. However, they recognize that relevant sociologic measure vary by behavior, domain, and outcome of interest.

3. Methods:

Face to Face interview were conducted with residents (aged 10-63) of Putrajaya lasting 15-20 minutes. GIS maps were created using the scale 1:12,500. Maps displayed an area of 1 mile around the boundary of each residents (approximately centered on participants' residents) and included road names and places of local interest such as green space, shops, services, schools and physical activity facilities.

Each participant was shown the printed GIS map for their local area. The interviewer helped to orientate them by pointing out the location of their residence, main roads and local landmarks. Using maps for reference or simply from recall, participants were asked to:

(i) Recall last day walking destinations from their home. In the event those participants belonging to the pre-teen age group were unable to identify any walking destinations from the map with the help of interview using a mind mapping techniques they were ask to recall any places they had walked from their home without using the map their destinations using major landmarks like local shopping areas, family friends, eating and drinking.

(ii) Draw their neighbourhood area on the map. Participants were also advised that their neighbourhood area could be any size or any shape.

Annotated maps from all participants were scanned back into a GIS for analysis. All recalled destinations points and neighbourhood area boundaries were digitized and the annotation from the maps recorded as feature attributes. GIS analysis was used to create a number of Euclidean buffer and network distance buffers around the address location of each participant. A Euclidean buffer is a straight line circular radius around the participant address location. Whereas the networks buffer were calculated by measuring a define distance along the pedestrian network which is like roads and pathways used by pedestrians in all possible directions away from the participant resident The end point of these routes were joined together to form an enclosed area representing the total area within a defined walking distance of the address.

For each participant we produced 5(five) different neighbourhood areas as shown in (Figure 4): 1 mile (or 1.6km) around the individual's home, Euclidean and network buffers; 1 km around the individual's home, Euclidean and network buffers; and participant perceived neighbourhood area. The areas of the perceived neighbourhoods were calculated as a proportion of the different network and Euclidean buffer to explore discrepancies in area size [i.e., area within perceived neighbourhood boundary (m^2)/area within network or Euclidean neighbourhood boundary (m^2) x 100]

Reported walking destinations were placed into eight categories retail (e.g. Shops, Supermarkets, Grocers) local services (e.g. banks, libraries); eating and drinking (e.g., cafes, restaurants); Family and friends; work/school; bus stops; green space (e.g., parks and common areas and lakes); and physical activities facilities (e.g., leisure centres, Gyms, swimming pools). These were examined for the sample as a proportion of total walking destinations.

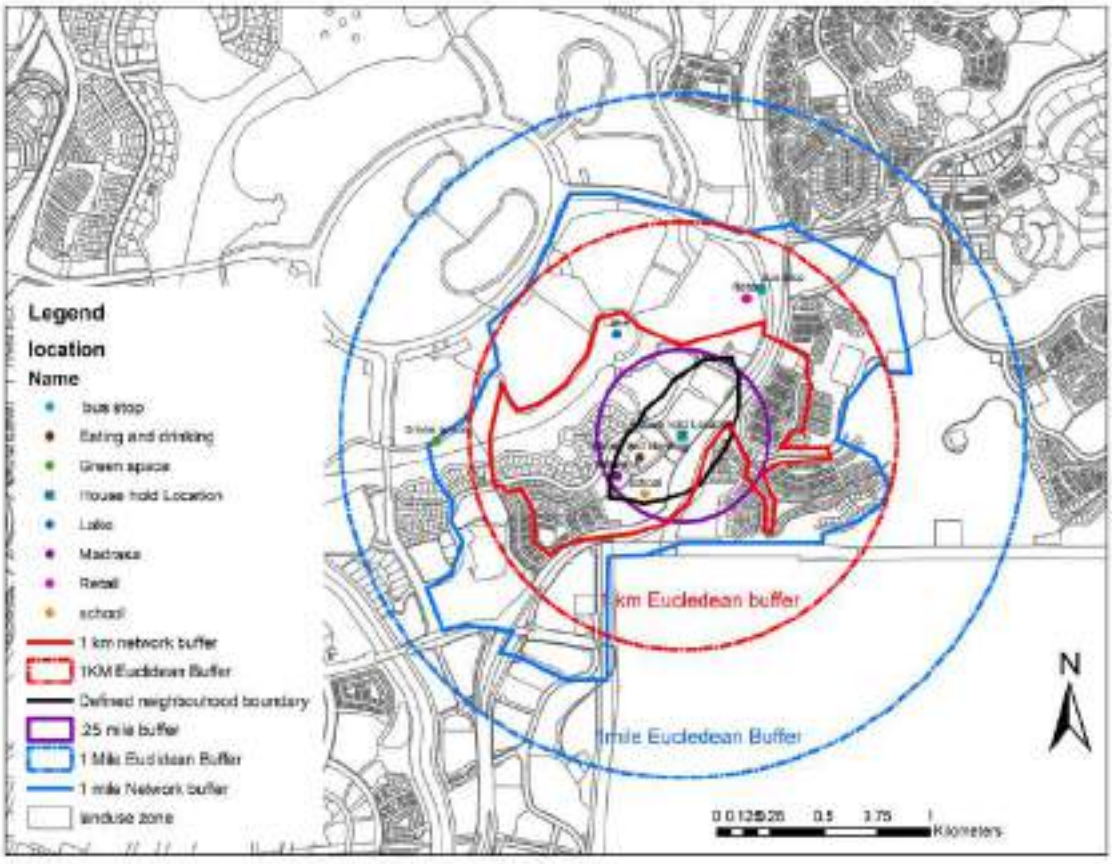

Figure 4: Illustrative figure of neighbor's perceived neighbourhood boundaries and GIS-defined boundaries and their walking destinations

4. RESULTS:

This study highlights important discrepancies among definition used in literature review and participants own definition of neighbourhood. The participants were generally conceptualizing a smaller neighbourhood area than those used in literature review.

When participants were asked to draw their 'neighbourhood' boundary, the resulting areas were smaller than those calculated using GIS based on standard neighbourhood definitions (1 mile or 1 km around the home). Perceived neighbourhood areas, on average, represented only 20 ± 25% of the commonly used 1 mile (1.6 km) Euclidean buffer area. Compared with a 1 mile network buffer area, the perceived neighbourhood area accounted for just 15±20%. This indicated a large discrepancy and considerable variation in relative size of perceived versus standard 1 mile neighbourhood definition. Analysis repeated using 1 km buffer areas revealed that, on average, the perceived neighbourhood still represented less than the 40±50% of the Euclidean buffer and 20±25

of the network buffer. This indicated a large discrepancy and considerable variation in relative size of perceived versus standard 1 mile neighbourhood definition.

Table 1 summarizes counts and proportions of the sample reporting different walking destinations. Most residents reported walking to retail destinations like supermarket, grocery approximately half walked to eating/drinking establishments and over one-third to family/friends and to local green spaces and lakes. This pattern was similar when looking at the contribution of each destination type as a proportion of the total number reported. Only 20% participants reported walking to physical activity facilities, whereas informal recreational activity through visiting green space was more frequently reported.

Table 2 indicates the discrepancies and variation between the percentages of walking destinations that fell within the variously defined neighbourhood areas. Whereas the network buffers captures relatively less. The most commonly used Euclidean buffer 1 mile area captures around 93% of destinations. The neighbourhood area calculated using definitions of 1 km around the home captures 84% of destinations.

Table 1: Percentage of participants who walked to different destinations types (n=50)

DESTINATION TYPES	n	%
Retail	42	84
Eating and drinking	30	60
Family / Friends	17	34
Green Spaces/lakes	17	34
Work /school	17	34
Bus stop	15	30
Local services	15	30
Physical Activity	10	20
Total	50	

Table2: Percentage of participants who walked to destinations types within perceived and objectively defined neighbourhood (1km and 1 mile) (n=50)

Neighbourhood definition	% of total destination	Mean Walk Time (mins)

1km buffer: *Euclidean* *Network*	 84 80	 12:50
1mile buffer: *Euclidean* *Network*	 93 90	 20.19 min
Perceived Neighbourhood	50	5.4 min

Conclusions:

It is concluded here that resident's interpretation of their neighbourhood area does not appear to relate accurately to the definitions used in research and into environmental perceptions and walking. But relate closer to Perry's definition of 5 minutes walking distance. It is also concluded that the average walkable neighbourhood area in our sample would be smaller than 0.75 miles and closer to estimated 5 minutes walking distances used elsewhere e.g., 0.25miles (Hoehner C.M. et al. 2005) 400m (Boehmer T.K. et al. 2006) this proves that operational definitions of neighbourhood needs to define smaller than those typically used particularly in hot tropical regions. This study explores that different age group interpretation of their neighbourhood area does not appear to relate accurately to the definition typically used in research into environmental perceptions and walking. The study suggests that bye laws used by Government agencies should use small buffers for walkability catchment areas and should do the Pedshed analysis for hot tropical climate of Malaysia.

APPLICATION OF SOUNDSCAPE DESIGN ELEMENTS IN URBAN STRRETSCAPE DESIGN

Jooyoung Hong[1], Jin Yong Jeon[2]

Abstract

Due to complicate interaction between sounds and human noise perception, many approaches to evaluate sound environment have been investigated as a concept of soundscape. Recently, considerable efforts have been made on standardization of perceptual soundscape evaluation in ISO/TC 43/SC 1/WG 54 for practical application. In this study, urban streetscapes based on soundscape design elements were evaluated through laboratory experiments. Road traffic noise has been chosen as a negative sound source in urban spaces and natural sounds (water and birds sounds connected to water features and trees, respectively) have been selected as positive elements to enhance urban sound environments. The experiments consisted of three parts: 1) a visual-only condition, 2) an audio-only condition, and 3) a combined audio-visual condition. Streetscapes with soundscape design elements were evaluated by 11 point numerical scale and 12 pairs of semantic adjectives. As results, the effects of the soundscape design elements have been examined.

1. Introduction

Sound environment in urban spaces is one of the critical factors in overall comfort. In fact urban acoustic and visual experience is closely related each other (Southworth, 1969). However, in the field of landscape and architecture, visual aspects in terms of urban planning were mainly discussed. Therefore, it is necessary to examine acoustical aspects to improve urban environment. Recently, many researchers have studied soundscape qualities in urban space. Influence of natural sounds including water sounds and bird sounds on soundscape perception were investigated (Coensel et al., 2010; Coensel et al., 2011; Jeon et al., 2012). However, practical approaches of soundscape in urban spaces are essential. In the present study, soundscape design elements for enhancement of urban environment were investigated through laboratory experiments.

2. Method

2.1 Stimuli

[1] Hanyang University, Seoul, Korea - st200045@hanmail.net
[2] Hanyang University, Seoul, Korea - jyjeon@hanyang.ac.kr

Individual soundwalks were performed in Seoul to assess urban soundscapes (Jeon et al., 2011). Among the evaluation locations through the soundwalk route, the site where its visual and acoustical environment was negatively evaluated by subjects was selected as a reference street view in order to investigate the effect of design elements for enhancement of streetscape. Based on the previous studies (Jeon et al., 2011; Coensel et al., 2011; Jeon et al., 2012) road traffic noise was chosen as a negative sound source in urban spaces and natural sounds (water and birds sounds) was selected as positive soundscape elements.

Audio recording of road traffic noise from the site was conducted, using a binaural microphone (Type 4101, B&K) and a digital recorder (Fostex, FR-2). For laboratory experiments, 6 sec audio road traffic noise sample was excerpted from the 3 min recordings. Two water sounds (drop and stream water sounds) were recorded from water features using binaural microphone and bird sounds (sparrow) were obtained from CD (Sony Pictures Sound). As shown in Figure 1(a), the spectral characteristics of road traffic noise and water sounds were similar presenting constant level at all frequency ranges while the bird sound was dominant at high frequency. In terms of time variability of sounds, road traffic noise and two water sounds were stationary and bird sounds were non-stationary and impulsive.

For visual stimuli, a reference street view was created using Rhino and Adobe Photoshop CS4 software. Two water features, drop (W1) water and stream (W2) water structures which are assumed to generate two water sounds respectively were constructed and an image of still water (W3) feature was created. Small (V1) and large (V2) trees connected to bird sounds were made. The image of low vegetated barriers (V3) was also constructed. A view point was fixed in order to avoid influence of different view angles. In total 16 photomontages of street views were used in the laboratory experiments as illustrated in Figure 2.

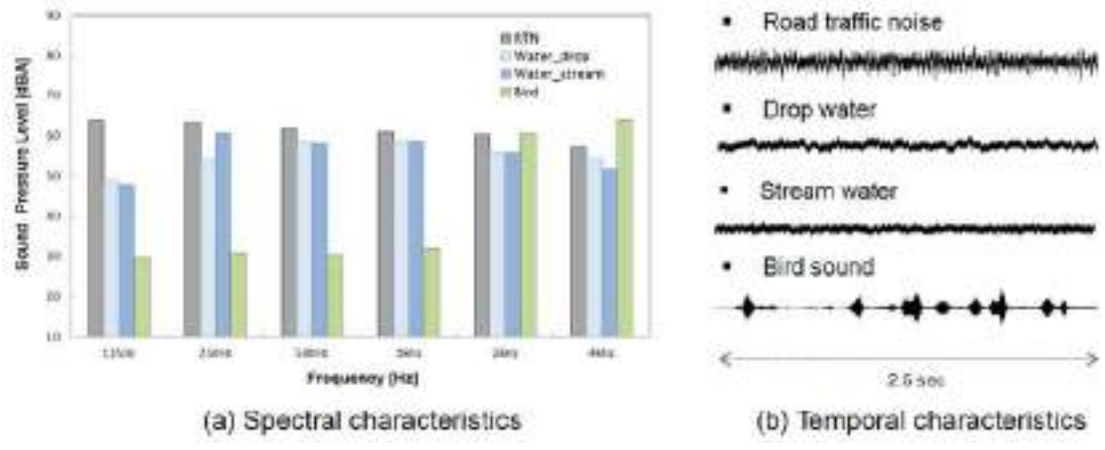

Figure 1. Spectral and temporal characteristics of acoustic stimuli

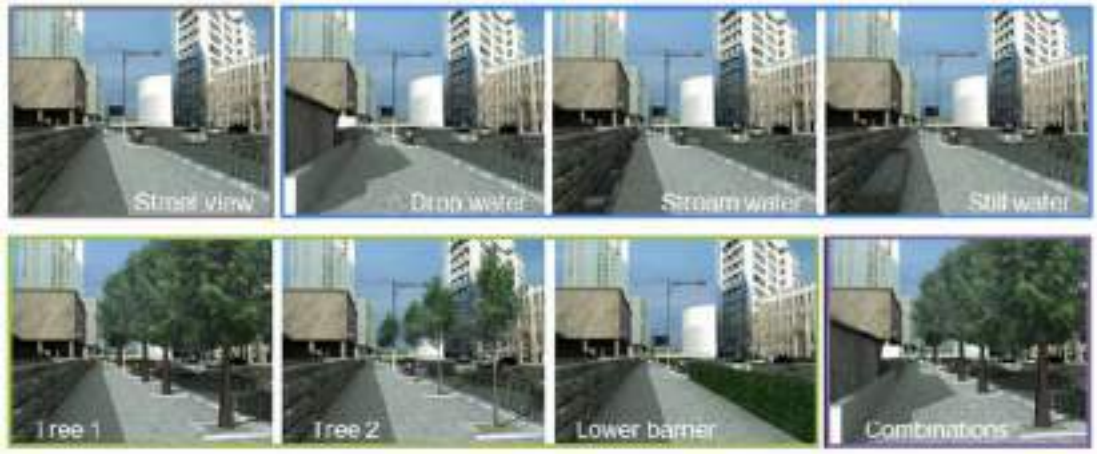

Figure 2. Samples of streetscape images

2.2 Experimental design

Laboratory experiments were performed to investigate the effect of soundscape design elements on soundscape perception of different streetscapes. The laboratory experiments consisted of three conditions: 1) a visual-only condition, 2) an audio-only condition, and 3) a combined audio-visual condition, where, images were provided along with the sound stimuli during the experiments.

A total of 9 experimental sounds were constructed: individual (road traffic noise, drop and stream water sounds and bird sounds) and combined sounds (road traffic noise combined with three natural sounds). The experiments were conducted twice with two presentation levels of road traffic noise: 55 and 70 dBA. The signal-to-noise ratios (SNR) between the water sounds and road traffic noise were set to -3 dBA so that the levels of the natural sounds were 52 and 68 dBA. Stimuli were randomly presented to subjects in order to overcome order effects. In the present study, the subjects rated their preference to each stimulus using an 11-point scale, with 0 representing ‘not at all’ and 11 as ‘extremely’. In addition, soundscape quality was assessed by using twelve pairs of adjective attributes (“open-closed”, “wide-narrow”, “quiet-noisy”, “calm-loud”, “pleasant-unpleasant”, “comfortable-uncomfortable”, “stable-unstable”, “harmonious-disharmonious”, “ordered-disordered”, “various-monotonous”, “distinct-ordinary” and “natural-artificial”).

A total of 20 subjects took part in the laboratory experiments. During the experiments, subjects were seated in a testing booth. Acoustic and visual stimuli were presented through headphones (Sennheiser HD 600) and a beam projector (Sony VPL-CX6), respectively.

3. Results

Figures 3(a) and (b) describe the preference scores in terms of stimuli from visual only and audio visual session when the level road traffic noise was fixed at 55 and 70dBA, respectively. In general, road traffic noise deteriorates the overall impression of environment. However, it was found that natural sounds contributed to an improvement in preferences under conditions with road traffic noise. In particular, stream water sound enhanced the environmental quality more than drop water did and the effect of bird sounds was most significant compared with selected water sounds. In terms of streetscape components, images of large trees improved urban streetscape quality.

The results of semantic differential test for 16 stimuli are listed in table 1. A factor analysis was conducted to classify 12 attributes and two factors were obtained in the session with 55dBA of road traffic noise while three factors were derived in the session with 70dBA of road traffic noise. For road traffic noise of 55 dBA, two factors were found: Factor 1—overall preference explained 79.5% of the total variance, Factor 2—spatial impression, explained 12.6% of the total variance. For road traffic noise of 70 dBA, three factors were: Factor 1—Harmony explained 70.1% of the total variance, Factor 2—acoustic comfort, explained 12.3% and Factor 3— spatial impression, explained 7.9% of the total variance. This indicates that when road traffic noise is louder, acoustic comfort becomes an important factor for evaluation of overall environment.

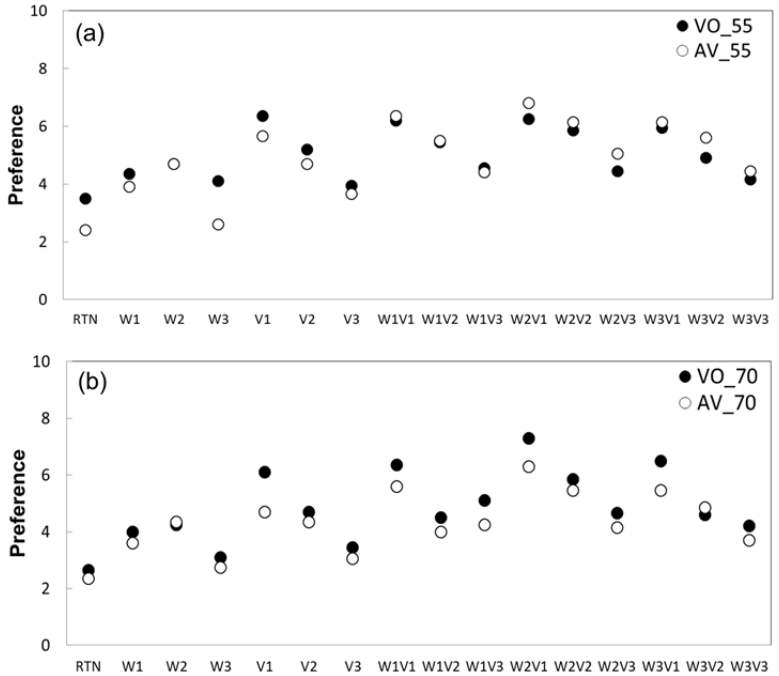

Figure 3. Experimental results for stimuli. black and white circles indicate the preference scores obtained from visual only sessions and audio-visual sessions, respectively.

Table 1. Results of factor analysis

Attributes	Component (55dBA)		Component (70dBA)		
	1	2	1	2	3
Open − Closed	-.187	-.944	-.400	-.184	-.874
Wide − Narrow	-.196	-.956	-.018	-.377	-.914
Quiet – Noisy	.938	.184	.080	.823	.303
Calm – Loud	.811	.307	.291	.914	.115
Pleasant − Unpleasant	.896	.371	.593	.738	.285
Comfortable − Uncomfortable	.947	.131	.850	.422	.208
Stable − Unstable	.862	.317	.828	.487	.116
Harmonious − Disharmonious	.885	.410	.853	.297	.273
Ordered − Disordered	.786	.035	.911	.060	.082
Various − Monotonous	.857	.481	.590	.697	.346
Distinct - Ordinary	.686	.597	.435	.617	.402
Natural − Artificial	.793	.516	.510	.687	.430

4. Conclusions

In the present study, enhancement of soundscape perception for the variation in streetscape design elements was investigated. Introduction of natural sounds including two types of water sounds and a bird sound was examined in terms of urban soundscape enhancement, when road traffic was a major noise source in urban spaces. As results, stream water sounds with image of large trees improve urban soundscape quality and acoustic comfort is a dominant factor affecting overall impression of streetscapes when road traffic noise level is 70dBA. In the future, the soundscape design elements in improving streetscape will be further investigated through multiple regression analysis.

Abstract:

In an increasingly competitive global world, urban managers are constantly seeking new and innovative ways to position cities strategically in order to enhance their identity, improve their amenity and attract capital investment. The policy directions that such endeavours spawn are diverse. However, the development and promotions of festivals has become a core strategy in city marketing and place making agendas. Festivals can be considered as a physical and temporal manifestation of policies that seek to promote places as being 'creative'. The creative city proposition, as advanced by Florida (2002), has proven highly attractive to policy makers and urban managers the world-over. Creative cities are construed to be dynamic places characterised by '…an openness to diversity and the freedom for creative people to validate their creative identities' (Miles 2010, p.44). Thus, the creative city ethos can be said to be imbued a sense of inclusion and progress. As a specific manifestation of this this ethos, festivals have been equally positioned as a positive form of '…celebration [that] can bind a community and… [act as] the instrument that keeps community a fresh and constantly renewing experience' (Derrett 2004, p.42). However, an emergent literature problematises these assertions, emphasising the potential negative stemming from festivals, from the seemingly benign general disorder and disruption to local places and their communities, to more serious issues of increased instances of anti-social behaviour and crime (see for example Peel 2005; Roberts and Eldridge 2009; Tiesdell and Slater 2006; Williams 2008). This literature reveals the complex and contested terrain that confronts policy makers and planners when considering or managing festivals as part of a wider city marketing and place making agenda.

This paper critically engages with these complexities drawing upon an Australian-based case study. Adelaide, the capital of South Australia, is marketed as Australia's 'festival city', a city of '…frenetic fun beneath an elegant exterior' (Tourism Australia 2012) that plays host to numerous festivals of local, national and international significance. However, belying this positive image, Adelaide's festival calendar brings disruption for the local community, while also heralding significant contestation between different community groups and key stakeholders, both internal and external to the city, over the uses of public space and indeed

the identity of the city itself. These disruptions and contestations are illustrated and explored through a detailed analysis of the Clipsal 500 V8 Super-Car race, which is held annually on an inner-city street circuit. Drawing upon analysis of policies pertaining to festival promotion, marketing agendas and materials, participant observation at the Clipsal 500 and interviews with key stakeholders from government and several non-government organisations and community groups, this paper presents a richly textured discussion of the opportunities and challenges facing policy makers and planners considering and managing festivals. In doing so, the paper contributes not only the literature on festivals and creative economies, but also the professional practice of festival governance.

Key Words: festivals, city marketing, creative cities, contestation, Adelaide.

Introduction

City marketing has become an important aspect of contemporary urban policy. Drawing upon the ethos of creativity, urban managers are increasingly concerned with urban identity. Cities thus are no longer viewed as just physical spaces, but as vibrant discursive spaces. Framed within the discourse of globalisation, urban identity management is now seen as a critical dimension in developing and maintaining a city's competitive advantage in an increasingly competitive urban world. As Kavaratzis and Ashworth (2005, p.507) astutely observe, '…the management of… [a] city's image [is vital] because, at its simplest, encounters between cities and their users take place through perception and images'. Urban identities are not inconsequential.

The scope of agendas and projects available to policy makers seeking to promote their 'place' are numerous and diverse. This paper is concerned with policies embedded in the creative city ethos, as espoused by Richard Florida (2003) and Charles Landry (2006). The fundamental tenant of Florida's work is that the emergence of a creative class has witnessed the development of a new geography premised on creative lifestyles as opposed to the dogma of traditional economic rationalism. As Florida (2003, p.9) argues:

> Creative people are not moving… for traditional reasons. The physical attractions that most cities focus on – sports stadiums, freeways, urban malls, and tourism-and-entertainment districts that resemble theme parks – are irrelevant, insufficient, or actually unattractive to many creative-class people. What they look for in communities are abundant high-quality experiences, an openness to diversity of all kinds and, above all else, the opportunities to validate their identities as creative people.

At face value, this challenges more 'traditional' policy agendas that place emphasis on large-scale infrastructure and urban design projects as a mechanism to drive development and spark confidence. The notion of creative places appears to be less formal and more grass-roots, flexible and organic. The notion of creativity itself is

significant here, for by its very nature it denotes new and innovative ways of perceiving, managing and experiencing the city. Creative places then need not be fixed. Rather, they may be temporary in nature and transitory in expression, such as the short-term use of derelict buildings or landscapes in innovative and unexpected ways (Stevens 2010). Consequently, the development of policies seeking to stimulate and nurture such places would appear to be extremely difficult. Regardless, the creative city ethos has been embraced with great enthusiasm. Indeed, an entire industry of place makers, and city marketers has emerged attesting to the attention and resources devoted to place promotion. This is not to scorn these undertakings, for urban identities are important. However, to blithely follow and promulgate creative city policies uncritically is naive. Rather, after Peck (2005), Atkinson and Easthope (2009) and Waitt and Gibson (2009) this paper critically engages with the opportunities, challenges and conflicts inherent in the development of temporary creative landscapes within the Australian city. Specifically, with the paper addresses the complexities inherent in 'festivals' as creative space generators and their use as vehicles for place promotion.

The term festival is extremely broad, encapsulating a range of events varying '…by size – including mega-events, hallmark events, major events and local or community events – and by form or content – including [cultural] festivals, sporting events and business events' (Allen *et al.* 2011, p.25). Regardless of their size or nature, festivals, it is asserted constitute a temporal '…celebration [that] can bind a community and… [act as] the instrument that keeps community a fresh and constantly renewing experience' (Derrett 2004, p.42). This is a contentious claim, for festivals can become the foci of conflict as various facets of the wider community struggle over space and contest the identity of place they create. Given the context of this paper and its emphasis on city marketing, we are concerned with large-scale, flag-ship events. Specifically, the paper presents a detailed case study of the Clipsal 500, a round of the Australian V8 Supercars Championship Series held in the city of Adelaide. While for some Clipsal, as it is commonly referred to, is a vibrant celebration of car culture, for others it is an inappropriate aberration within a refined city of culture.

The research presented in this paper draws upon both quantitative and qualitative methods. A multi-method approach was deemed appropriate as the juxtaposing of different methods holds promise to furnish more nuanced understandings of and insights into the phenomena under research (Johnson *et al.* 2007). In order to quantify the scale and significance of the Clipsal 500, a range of statistical data was gathered from both relevant local and state government bodies and the official Clipsal website. This material, particularly visitor numbers and revenue figures, are cited as indicators of Clipsal's popularity and value. Various government policies, most notably the *Creating our Future: City of Adelaide Strategic Plan 2008-2012* (2010), were subjected to textual analysis. This undertaking sought to not just engage with the explicit intent of these policies, but to uncover their implicit construction of Adelaide's identity as pursued through the staging of festivals. Such an undertaking is important, for discourse as communicated through texts ultimately

gives '…shape and lend[s] significance to our experience of reality' (Bignell 2002, p.30). This form of analysis is ideal for planning research as it contextualises the means through which power is exercised, as well as providing an opportunity for a critique of government policy-making and decision-making processes (Walter 2006).

Similarly, the landscape itself can be considered as a text to be 'read' (see Winchester *et al* 2003). Thus, landscape deconstruction was undertaken during the 2011 Clipsal 500. Finally, to generate deeper insights into and to contextualise the findings derived from the aforementioned methods, a series of semi-structured interviews were undertaken with 4 key-informants from 3 stake holder organisations. Interviewing is valuable as it fills 'knowledge gaps' inherent in other sampling techniques (Dunn 2011). Two interviews were conducted with staff from Adelaide City Council (ACC), specifically the Senior Manager of the Events and Festivals Portfolio and the Safer City Program Team Leader, with one interview each being conducted with a representative from the South-East City Residents Association (SECRA), the Young Women's Christian Association (YWCA). These organisations represent a diverse cross-section of the community and their specific interests. Both SECRA and YWCA have, at various times, been outspoken opponents of the Clipsal. Regrettably, the Clipsal organising committee declined several invitations to participate in this research. In the absence of their direct involvement, press releases and various comments within the media by this organisation have been supplemented to understand their position with regards to the purpose and significance of the festival.

The creative imperative:

The past decade has witnessed the ascendancy of a creativity ethos as a prime policy agenda. Spearheaded by Richard Florida (2003) and Charles Landry (2006) is the contention that 'creativity' is the driving force of contemporary, advanced economies. Arguably, this is not a fundamentally original contention and apes a well-developed literature exploring global cities and their competitive jostling at the macro-scale and local, place-based responses to these challenges, such as the regeneration of derelict industrial land as part of a post-industrial transformation at the micro-scale. Landry (2006, p.xiii) tacitly acknowledges this when asserting that the need for creative policy agendas stems has been '…brought about by the vigour of renewed globalization'. Atkinson and Easthope (2009) observe notions of creative economies nor some form of creative class, are not new (see also Peck 2005). However, with clever rebadging and astute promotion, the creative ethos has gained significant traction within policy circles. This in spite of Marcuse's (2003, p.41, cited in Peck 2005, p.746) stinging critique that Florida's work is simply a '…engaging account of the lifestyle preferences of yuppies'.

While both Florida and Landry promote creativity, they take subtly different approaches to it. Florida's (2003) emphasises the emergence of a creative class and how, in order to remain competitive places need to attract and retain them.

Espousing that creative places are those that embrace the *3Ts* of *technology*, *talent* and *tolerance*, Florida (2003, p.8) proposes that '…creative centers tend to be the economic winners of our age'. The notion of tolerance is an interesting one and would seem to resonate with other works espousing the city's scope for equity (for example Harvey 2000). However, Florida's measure of tolerance includes notions of social-mix reminiscent of a 'shake-and-bake' recipe, replete with Gay and Bohemian Indexes. Sweepingly, it is declared that '…statistical analysis on the gay population… [is] squarely in line with the creative capital theory… [as] the Gay Index is a very strong predictor of a regions high-tech industry concentration' (Florida 2003, p.12). Moreover, the '…Bohemian Index turns out to be an *amazingly strong predictor of everything* from a region's high-technology base to its overall population and employment growth' (Florida 2003, p.13) (emphases added). The solution to urban decline it seems would be to attract more '…gays, geeks and the creative class' (Bell and Jayne 2006, p.14). Landry (2006) follows a slightly different tact. He places greater emphasis on the creativity of planning, governance and policy. From this perspective, it is the '…creativity of those who… run cities [that] will determine future success' (Landry 2006, p.xiii). Developing this further, Landry (2006, p.7) contends:

> Cultural resources are the raw materials of the city and its value base, its assets replacing coal, steel or gold. Creativity is the method of exploiting these resources and helping them grow… the task of urban planners is to recognise, manage and exploit these resources responsibly. Culture, therefore, should shape the technicalities of urban planning.

As a resource culture then can be harnessed through creative policies that seek to unlock its potential in space. Thus, the notion of cultural creativity is not only highly strategic, it is equally highly spatial. Cultural events and/or festivals have been acknowledged as contributing positively to urban regeneration policies. Previously thought of as providing temporary consumption-scapes, events and festivals have been recast within the policy arena as creative clusters. Tallon *et al.* (2006, p.353) assert that such 'clusters' are '…concentrations of leisure and cultural uses... [that] combine authentic artistic and cultural activities with a variety of leisure and entertainment elements'. Kunzmann (2004) similarly asserts that festivals boost creativity for, as Alvarez (2010) argues, festivals offering moments of creative participation and engagement that contribute to the vibrant culture of the city. Herein lies the circular logic of the creative city ethos; that the fostering of creativity in place attracts creatives and creatives themselves infuse place with creativity.

Festivals; the good, the bad and the ugly:

Extremely diverse, festivals have come to be increasingly associated with place-making endeavours and as such have been identified as requiring significant and more critical policy attention (Campo and Ryan 2008; Gibson *et al.* 2010; Roberts and Eldridge 2009; Roberts and Turner 2005; Quinn 2005). Indeed, as Quinn (2005, p.928) observes that there has been a great deal of policy excitement '…about the theoretically catalytic effect that festivals can have in terms of attracting visitors, spearheading the regeneration of derelict city districts and reclaiming public time and space for communal celebrations, *hard evidence is in short supply* (Quinn 2005, p.928, emphases added). This is critical, especially as the ethos of creativity become ubiquitous within the policy landscape (Atkinson and Easthope 2009; Waitt and Gibson 2009).

At their most basic festivals may be thought of as temporary events where moments of pleasure, entertainment and leisure are offered and actively sought. Festivals transform ordinary places into energetic spaces that are alive with new possibilities and opportunities. Thus, festival spaces constitute the '…habitat where all forms of creativity – artistic and cultural, technological and economic – can take root and flourish' (Florida 2003, p.9). Within this 'habitat', groups preserve, celebrate, and develop their cultural and/or community identities (see Waterman 1998; Williams 2008; Derrett 2004; Bianchini 1995; Willems-Braun 1994). Further, festivals are said to operate in an inclusionary manner, inviting people from beyond the festival's core community to be immersed and participate in their practices and lifestyles. According to Waterman (1998, p.60), festivals thus constitute potential '…mechanisms for neutralizing social conflict'. These positive, emancipatory sentiments echo Florida's comments on creative spaces as being *tolerant*.

Another way of conceptualising festival spaces is as *other* spaces. Pløger (2010, p.851) asserts that festivals create, however fleetingly, other or liminal spaces that:

> …can *never be seen as fixed*...there must be *something distinct* about them... [that are] about *alternating spaces'* meaning and function *temporarily* - they are about avoiding them being only located within a common understanding - and this temporary meaning is made by actors by making distinct events as the *eventalisation of space* (emphases added).

This *eventalism of space* extends beyond the festival in space and encapsulates the way that festivals function as a celebration of place. Here is the crux of policy interest in festivals. It is the way in which festivals not only enliven space, but equally create a sense of place that may be *exploited*. Reflecting Landry (2006), policy makers and planners are increasingly taking advantage of festivals as, in the words of Quinn (2005, p.934), '…opportunities to challenge the status quo and push out boundaries' and so demonstrate the creative credentials of their city. In short, festivals are not just about the local, they are also about the regional, the national and the international depending upon the scale and scope of the festival.

Despite the ebullient rhetoric of creativity and the role of festivals in its nurturing and celebration, all is not as indubitable as would appear. Landry (2006, p.120) has contended that:

> City Centres… as '*neutral territory*' help creative ideas, because they are areas where people feel comfortably relaxed and simultaneously stimulated and challenged by contact with an environment that is more socially heterogeneous than normally experienced (emphases added).

The assertion that city centres are somehow a 'neutral territory' is breathtakingly naive. Places are not natural or neutral, but rather are shot through with power differentials, experiences and opportunities in a myriad of ways. Festivals spaces are not immune to this. Taking a more considered approach, Darrett (2003a) and Gibson *et al.* (2010) note the potentially exclusionary nature of festivals. This may relate to the function of the festival as a pseudo 'gatekeeper' to space and activity (Darrett, 2003b, p.38), or even the decision making process that selectively approving some festivals while rejecting others (Gibson *et al.* 2010).

Festivals, especially large-scale, flag-ship festivals bring a raft of other undesirable consequences. To return to the concept of other or liminal spaces, the literature defines a liminal space as one that is 'on the margin' (Shields 1991), within which '… everyday values and norms' (Pløger 2010, p.862) are relaxed or even suspended. The corollary is that participants within liminal space – liminars – may well embrace their place on the margin and act in ways contrary to their typical conduct. This intersects with the night-time economy literature , where issues of public nuisance, drunkenness, violence and vandalism have been reported as significant impacts upon the built environment and, more importantly, the quality of life for local communities in close proximity of these spaces feature prominently (Chatterton and Hollands 2002; Roberts and Gornostaeva 2007; Tiesdell and Slater 2006). Other facets of this literature comment on the impacts felt disproportionally by women as a consequence

of sexual harassment and assault and how this contributes adversely to the fear of crime (Lovatt and O'Connor 1995; Thomas and Bromley 2000; Roberts and Eldridge 2009; Tiesdell and Slater 2006; Williams 2008). These literatures constitute a stinging critique of and rebuke to assertions that the city is a neutral space. Further, policy approaches that unproblematically accept this assertion and take as a truism that creative policies and festivals can usher in landscapes free from conflict are certainly not creative in their thinking. This discussion alerts us to the central tension in the creative city ethos; this being balancing these policies against the needs and desires of local communities. As Roberts and Turner (2005, p.171) observe this is critical as it concerns '…the future form and management of cities'.

Adelaide, The Festival State capital:

Adelaide, founded in 1836, is Australia's fifth largest city and the capital of South Australia. With a small population, even by Australian standards, of approximately 1.2 million people, Adelaide is often derided as a city of marginal significance in comparison to other cities such as Sydney or Melbourne. Indeed Adelaide has been attacked by interstate political leaders as a 'boring' 'backwater' and even derided as a politically failed city where visions of creative development are '…masterpieces of floss and wishful thinking' (Montgomery 2008, p.13 cited in Rofe and Stein 2011). These external discourses are stinging rebukes and while motivated by readily apparent political agendas that reflect the cut-and-thrust of inter-urban competition, they are echoed to some extent by discourses internal to Adelaide. Foremost amongst these are the monikers of Adelaide as the 'city of churches' and Adelaide, despite being a state capital, as 'a big country town'. The former of these is a reflection of the centrality of religious tolerance and diversity, which underpinned much of the colonial planning and ideological foundation. The 'big country town' identity is both a reflection of the smaller population base of the city and its relative geographic isolation from other Australian capital cities. Combined, these are said to create a stable and comfortable community where social networks are deeply entrenched. Both the city of churches and big country town identities are replete with the notions of security, familiarity and stability that underpin much of the idyllic discourse that typically underpins romanticised notions of rural. However, Adelaide as constructed through these identities can alternatively be read as a conservative, stayed place at best and at worst an introspective, closed place. Recognizing the danger of this, Jory (2000, p.18) quipped:

> Come on Adelaide, hitch up your skirt and show us a bit of ankle. Give us some excitement. As a city Adelaide has become drab, grey and boring. There's no life, energy or vitality in the streets. It is a city going through the motions. It's entering middle-age without grace, style or pride. Walking through the city is a chore, not an experience.

Much political attention, albeit not necessarily in direct response to Jory's aforementioned challenge, has been directed to enlivening both Adelaide's landscape and identity. While the policy agendas pursing this are varied, the development of

flag-ship festivals is seen as critical to this undertaking. Seeking to reposition the city in the national and international marketplace more effectively, South Australia has declared itself as Australia's Festival State. Indeed, given the primacy of Adelaide within the State of South Australia, it is not incorrect to assert that Adelaide is the epicentre of the Festival State and thus is its animated heart. While Adelaide plays host to numerous small-scale events and festivals, as do all cities, there are five flag-ship festivals that constitute the core planks of the city's creative policy attention as articulated through festivals and tourism. These comprise three arts oriented festivals; the Adelaide Festival, the Adelaide Fringe and the WOMADelaide world music festival. The other two events are sporting events; one being the Tour Down Under an International Union of Cycling (UCI) World Tour event and the Clipsal 500. Of these, all but the Tour Down Under are staged during or over part of March. Colloquially, this period is referred to as Mad March. In reality, each of these is not a single event, but rather a series of events under a broader festival banner. Exemplifying this, Adelaide Fringe in 2011 comprised 759 events, the majority of which held multiple shows, with the combined sale of 3,34,000 tickets. Ironically, Adelaide Fringe (18th February - 13th March), WOMADelaide (11th - 14th March) and the *Clipsal 500* (17th - 20th March) not only co-occur temporally, but they also co-exist spatially. Figure 1 illustrates the clustering of these flag-ship festivals in the city's Eastern Parklands. Comparing Figure 1 with Figure 2, a detailed map of the fenced-off Clipsal 500 area reveals that Clipsal occupies them majority of Rundle Park 14 (*Mullawirraburka* [i]), all of Park 15 (*Ityamaiitpinna*) and the majority of Victoria Park 16 (*Bakkabakkandi*). Also worthy of note is that the Clipsal site directly borders the city's South East Corner precinct, which at the 2006 Census was home to 3623 residents. The scale and nature of these festivals are said to transform the city generally and the City East and South East Corner precincts and Eastern Parklands specifically and as emphasised by ACC (2011, p.52):

> The city's famous 'Mad March' is the time when our streets and parks fill with a carnival atmosphere, bringing culture and vitality to the capital. This season is great for the state's economy and well-loved by many, but also brings challenges for the city.

It is to a critical discussion of the opportunities, challenges and contestations over Mad March, with specific reference to the Clipsal 500 that we now turn.

Creativity Through Festivals. Opportunity and Issues:

Adelaide City Council's *Creating our Future Strategic Plan* 2008-2011 (2010, p.9) articulates the following vision:

> The City's vibrancy will flow from creating diverse communities that actively participate in every aspect of City life. People who work and study in the City will live and play in the City. Residents and visitors alike will enjoy the beautiful open spaces and facilities of the Park Lands, an exciting built form which respects our heritage, [and] shapes our future.

This vision posits a city moving confidentially into future. Worthy of note is the acknowledgement that this vibrant future is respectful of the city's heritage. It may be assumed that this respect if not only for the built form, but equally for the Adelaide's identity and sense of place. Furthermore, the explicit acknowledgement of diversity and participation echoes Florida's (2003) *T* for *tolerance*. It is should not be surprising then that Adelaide's creative policies promoting flag-ship festivals

as vehicles for place promotion should be equally diverse, embracing the cultures and desires of different social and sub-cultural groups. Encapsulating this, ACC's Senior Manager of the Events and Festivals Portfolio stressed the merits of promoting a diverse array of festivals, observing that:

> When you have a city that you can have a Clipsal and an arts festival, what your identity is showing is that you actually have many strengths to your bow... you have got a community that's broadly interested in many different things and I think it's actually a good positive view [to] brand Adelaide'.

As would be expected of a festival portfolio manager, the emphasis on place brand is here paramount. While the notion of nurturing and celebrating diversity in place is an important aspect of the creative city ethos, so too is its exploitation to present a vibrant, positive identity to external people and markets. However, the use of festivals in such an undertaking promises opportunities and can be bedevilled by pitfalls. Balancing these is extremely important.

By all *objective* indicators, the Clipsal 500 is a success. Since its inception in 1989, the event has never failed to attract fewer than 150,000 spectators over the festivals duration each year. In 2011, a reported 270,800 patrons attended Clipsal, with of these some 12,529 being identified as interstate or overseas visitors [ii]. In total, in the thirteen years from 1989 to 2011 the Clipsal has been attended by some three and a quarter million people. Naturally, the Clipsal represents a major economic boost for the State of Australia. Data from the Clipsal website reveals that the economic benefit derived from the event grew from A$13.7million [iii] in 1999 to A$33.76 in 2010 (see http://www.clipsal500.com.au/about_the_event/facts_and_figures/about_the_clipsal_500). The South Australian Minister for Tourism, John Rau (2011), announced that the 2011 Clipsal had attracted total earnings in the vicinity of A$55 to A$60 million, of which some A$34.03 million had been injected directly into the South Australian economy. Furthermore, the Clipsal has been reported as generating significant media benefit for the city of Adelaide specifically and the State of South Australia generally. In 2010, it was reported that the Clipsal was viewed in '…853 homes in 142 countries' (see http://www.clipsal500.com.au/files/360_history_of_clipsal_500_-_8.9.10.pdf), with an estimated media benefit in the vicinity of A$133million (see http://www.clipsal500.com.au/about_the_event/facts_and_figures/about_the_clipsal_500). The value of this cannot be underestimated and as Getz (2005, p.14) asserts, so significant can the benefits of such publicity be that '…some destinations will use this fact alone to justify great expenditures on attracting events'.

The success of Clipsal is not accidental. Like all flag-ship festivals, it is a carefully orchestrated and highly corporatized undertaking. At times criticised for being little more than a car race, the Clipsal is in fact a diversified endeavour offering a range of experiences and sub-events that augment the main spectacle of race-day. Over the four days of the festival, driver autograph sessions, aviation displays, support races and displays, a ladies day luncheon, fashion parades, a family play zone and rock concert entertainment over several nights are staged. Thus, the Clipsal is said to cater for a broad selection of the community beyond the stereotypical fans, who in Australia are referred as to revheads or bogans. As one Adelaide newspaper positively commented, Clipsal is '…not just a car race' rather it is a '…multifaceted entertainment smorgasbord' (Stoneman 2006, p.10). Internally, Clipsal's success has been recognised through its award with the Championship Series 'promoter of the year' award from 1999-2005. Further, in 2005 the festival was the first round of the series inducted into the series 'Hall of Fame', as this honour had previously been the domain of individual drivers. While internal accolades may be viewed as highly subjective, the festival has also received external recognition. Illustrating this, Clipsal has been awarded the highly prestigious Major Festivals and Events trophy at the National Australia Tourism Awards on four occasions (2003/2004, 2005, 2007 and 2008). However, with these successes have come significant challenges and problems that recur annually and cause much contention over the staging of the Clipsal 500.

A major area of contention over the staging of the Clipsal is its various disruptions to the city and how these impact upon the local and wider community. Street circuits, by their very nature require public road closures and the instillation of large-scale safety and amenities infrastructure. While Clipsal is only held over four days, the set-up and dismantling times required are considerable. In consultation with ACC, road closures are staged so as to minimise disruption. However, these inevitably result in traffic congestion and generate significant community ire. Preparations for the 2012 Clipsal, for example, began with parking restrictions as early as February 6th, lane restrictions from February 15th and the first road closures from February 22nd. Given that the 2012 Clipsal was staged from March 1st to 4th, this represents almost a month of disruptions prior to the event. All road restrictions and closures were scheduled to have been removed by 7th March.

While major road access is restored in a reasonable time-frame, access to the Eastern Parklands (see Figure 3) remains restricted for up to eight weeks post Clipsal. This is a major contention with many local community groups, in-particular with SECRA and Adelaide Parklands Preservation Association Inc. (APPA). Both of these organisations place great emphasis on the heritage and, their interpretation of, the cultural value of the Parklands. APPA's website (http://www.adelaideparklands.org/html/parklands_history.html) emphasises former Deputy Mayor of Adelaide Lewis Cohen's 1910 charge that:

The parks are the pride and glory of this city—the best and greatest asset it has, or ever can have. To every generation they are becoming more valuable. Let us, therefore, keep them inviolate, keep them intact, keep them sacred from the hands of the despoiler.

Figure 3: Restricted access to the Eastern Parklands following Clipsal

Source: Woosnam, 2011.

While the privatisation of this public 'asset' is taken to represent an erosion of their intended 'glory', environmental degradation and/or damage is another point of community contention. Concerns over damage to vegetation, both as a result of infrastructure set-up/removal and from acts of vandalism have been raised (see Figure 4). Indeed, following Clipsal sections of the Eastern Parklands needed to be restricted for public access so as to regenerate (see Figure 5).

Figure 4: Clipsal set-up in the parklands.

Source: Woosnam, 2011.

Figure 5: Remediating environmental damage.

Source: Woosnam, 2011.

Cohen's 'despoilers' are not considered to be the Clipsal alone. SECRA attributed a great deal of responsibility on The City of Adelaide for not enforcing its own environmental policies stringently enough. In the face of this, SECRA positioned itself as a public watch-dog protecting the interests of the parklands. As the SECRA respondent explained:

> …because of what people like our group have said, as well as many other groups and citizens across Adelaide, there is starting to be a bit more pressure on them [Adelaide City Council] about this [parkland destruction], but it's always seemed as though we've had to complain or point things out, rather than Council having the [appropriate] policies in place.

The position of watch-dog and public champion is a deliberate undertaking designed to legitimise the actions of SECRA. This is not to undermine their concern with the environmental condition of the Eastern Parklands. However, it should not be uncritically accepted that their motivations are entirely altruistic. Regardless, ACC's Festivals Portfolio Manager acknowledged that Council took note of such concerns, stating that '…once you start getting those warnings from your stakeholders you start to know you are getting at a tipping point and you've got to start paying attention to the impact'. However, this same respondent was equally adamant that notwithstanding the '…inconvenience… [Clipsal] cause[s]... the positive impact outweighs the inconvenience'. Ensuring Clipsal's long-term viability requires Council to manage the concerns of local groups, although tensions and conflicts are unlikely to ever be completely resolved. Indeed, such tensions would appear to be intractable, for as SECA flatly stated 'our group is not happy with the Clipsal'.

Whose City?

Issues of physical access aside, concerns over a sense of access are also discernible. While Clipsal, as indeed does Mad March, brings energy and excitement to Adelaide, it is undeniable that the festival has long been associated with overcrowded streets, rowdy anti-social behaviours and excessive noise, which have caused many tensions within the city centre. In effect operating as liminal spaces (Pløger 2010) festivals can erode social morays and so encourage participants to behave in ways contrary to accepted social morays. When combined with high levels of alcohol consumption, the spilling out of these effects beyond the margins of the festival can have

unacceptable consequences. Concerns have certainly been expressed regarding the intersection between motor-racings inherently hyper-masculine identity, alcohol consumption and the anti-social behaviours that can stem from these intersections. Exemplifying this, local journalist Amy Noonan (2009, p.22) reported that '…police were sick of dealing with the aftermath of alcohol-fuelled violence' and that a greater police presence was required to '…prevent… revelry from spiralling into violence'. SECRA was extremely forthright in their comments on this, commenting on the prevalence of public drunkenness leading to situations where '…a lot of people… were abusing us verbally... so there is an issue of safety and vandalism of property and people drunk and urinating in the front of homes during this event [Clipsal] period'. The response of many local residents according to SECRA was to leave the city during Clipsal. While this removed the threat, real or perceived, of physical danger instances of vandalism to property cannot be similarly alleviated.

Such negative outcomes are not to be unexpected. The night-time economy and entertainment precinct literature details problems associated with public drunkenness and anti-social behaviour. As Roberts and Gornostaeva (2007) suggests such issues engender a 'sense of threat' thereby reducing a 'sense of safety' in festival areas themselves and those in close proximity. Such risks, according to Valentine (1989), contribute significantly to the geography of women's fear. Echoing this, ACC's Safer City Program Team Leader recognised that '…people do not feel safer on the Clipsal weekend... and women generally feel less safe during this time'. Clipsal is, at its core, a masculine-oriented event. Clipsal's marketing explicitly positions it as such (see Figure 6) while its schedule of sub-events and *attractions* position women as passive objects for visual enjoyment and consumption (see Figure 7). While the V8 Supercar series has been seeking to build its female fan-base, the continued inclusion of scantily clad grid-girls and bikini parades as entertainment at Clipsal and other championship rounds simply perpetuates the objectification of women. Taking a philosophical approach, the YWCA observed that '…the V8 Supercar race draws a particular crowd and so there would possibly be cultural groups or minority groups that would feel [like] that event is not for them'. Notwithstanding this, the YWCA is adamant that many women do not feel '…safe in the city during that time and are not going into the city during that time'. These comments affirm to Waterman's (1998, p.67, emphasis added) concerns that festivals possess the power to '…exclude or include on the basis of ethnicity or class, *and perhaps gender*'. In turn, this refutes the notion of festivals as creative opportunities.

Figure 6: Gendering Adelaide through Clipsal

Figure 7: Problematic representations.

Source: *Adelaide Advertiser*, 1st March 2012, pp.12-13.

Conclusion:

Adelaide's Mad March brings energy and diversity that contributes to the temporary development of creative spaces where individuals can experience new forms of pleasure and entertainment. These festival spaces may be thought of as liminal in that they are outside the norm of everyday practices. The literature endorsing creativity as a policy direction positively endorses such undertakings. This literature proposes that festivals constitute creative spectacles that are founded upon and which promotes tolerance and openness within the claimed neutral space of the inner city. This paper refutes such assertions as simplistic. The lessons derived from the Clipsal 500 motor-racing festival provide a salient example of the complexities inherent in the staging of flag-ship events as vehicles for place promotion.

While it is accurate that festivals constitute a '…celebration [that] can bind a community and… also be the instrument that keeps community a fresh and constantly renewing experience' Derrett (2003, p.53), they are not necessarily inclusionary. Festivals are inclusive of some and exclusionary of others. This is not necessarily a negative. From the perspective of Adelaide City Council, having a diverse portfolio of festivals caters to a wider cross-section of the community's needs, interests and desires, while also showcasing to the world that Adelaide is not a stayed, mono-cultural city. However, where some perceive diversity others see conflict. The Clipsal 500 certainly brings moments of conflict to Adelaide. These can be thought of as occurring along a spectrum of significance. Arguably at the more benign end are issues of traffic disruption and congestion. While inconvenient, these can be dealt with through careful planning and management. At the more concerning end of this spectrum are issues of alcohol abuse, anti-social behaviour and violence. Addressing these issues is certainly within the remit of organisations like the Clipsal 500 and ACC. However, they are complex as they involve and impinge upon wider societal attitudes and also sub-cultural practices. Responding to these challenges is a much more significant and long term undertaking.

Ultimately, flag-ship festivals promise policy makers attractive rewards with regards to economic benefits. Clipsal is a case in point and makes a significant annual economic contribution to the local and state economy. However, the research presented in this paper demand that a more holistic perspective be taken by governments with regards to flag-ship festivals specifically and creative economy approaches generally. The lesson of the Clipsal 500 demands that policy makers and communities seriously question what types of places they want to foster, what values they will encapsulate and what senses of place they encapsulate and how this contributes to the complex identity of the city. Hence, creative cities require creative governments that engage critically and openly with policy ideas and direction in partnership with the community to envisage progressive and equitable futures.

Notes:

[i] *Mullawirraburka*, *Ityamaiitpinna* and *Bakkabakkandi* are the traditional names given to Rundle Park 14, Park 15 and Victoria Park 16 respectively by the Kaurna People. the authors wish to acknowledge the Kaurna People as the traditional owners of the land discussed in this paper.

[ii] Caution must be expressed regarding attempts to compare total festival attendance with the number of identified interstate and overseas visitors. The festival attendance figures cited are for total attendance over the four days of the festival. Thus, this figure will include persons attending more than one day and hence who are at least double-counted. The use of ticket-sales data would alleviate this issue. However, this data was note able to be obtained. Data recording total number of interstate/overseas visitors is derived from online ticket sales data and is unlikely to capture all such visitors. Further, these visitors are included in the total festival attendance figures.

The Study of Urban Fringe Development in the Risk Perspective

Wu Juan[1] Xia Nankai[2]

Abstract

At present, China is in the rapid growth period of urbanization and urban scale. Since 2000, the level of urbanization in China has made tremendous progress. The urbanization rate increased from 36.2% in 2000 to 49.68% in 2010, and China's urban population is nearly 666 million.

With the accelerating pace of urbanization , urban fringe, with its space and land resources, has become the most concentrated and rapid area of city's project development.

Urban fringe is constantly expanding outward extension, showing a dynamic process of development, and its space is filed with a lot of kinds of projects. However, due to the urban fringe is located in the urban and rural transition zone, it features economic development lag, complicated social structure, fragile ecological environment and so on. In the process of urban development, those problems need to be solved.

Based on the study of most of China's cities' development, the article make a conclusion of urban fringe development features in the perspective of functions, space sprawl, land structure and develop mode. In this paper, shanghai is used as a study case. Three decades of urban development and data are selected to analyze the process and characteristics and research the features of current project development in urban fringe.

With the productivity and the continuous development of science and technology, risk management has been accepted and developed by the economic, financial and other businesses. And with the accelerating pace of urban development, urban management aware of the importance of risk management. Urban development risk management is with the risk manage techniques to make the response of the risk influence during the urban develop process. Based on the previous paper study,

[1] Tongji University, Shanghai, China, cat_850811@163.com
[2] Tongji University, Shanghai, China, 84997347@qq.com

through the urban develop risk management system, take account of the features of urban fringe development, the article analysis its risk mechanism, identify the main risk subjects and their characteristics, then build the risk assessment system. In the last part of the paper, several risk response strategies of the urban fringe develop are suggested to the government, in order to make an explore of the risk management in the future, and Rich content of urban planning education.

1 The introduction of urban fringe

1.1 Urbanization and urban fringe

At present, China is in rapid urbanization growth period, and the urban scale is expanding very quickly. Since 2000, the urbanization of China has made great progress, urbanization rate rising from 36.2% in 2000 to 49.68% in 2010, with an average annual increase 1.13%. Now, China's urban population is nearly 666 million. At the same time, domestic urban constructed land is expanded by 50%. According to relevant statistics, China's urban constructed land from 21524.54 km2 in 1999, has grew to 39140.46 km2 in 2008.

Urban land is the foundation of city's social and economic development. Urban fringe is gradient integration region of city constructed area and the surrounding agricultural land. Urban fringe is closer to the city than suburbs, easily to continue the characteristics of urban space context. And it’s richer in land resources than city, with the convenient traffic. As a result, urbanization in urban fringe is very active.

1.2 The features of urban fringe

(1) Diversity in land type

Because of geographic features, there are city land and rural land in urban fringe. At present, land in China can be divided into two categories by the land’s ownership-urban land, which owned by the state and the rural land and suburban land which is collectively owned. At the same time, urban fringe is often used as urban prepared development land. And there are also some other types of land, such as approved land and undeveloped land, etc.

(2) Unstable in land structure

Land development in urban fringe is more rapid than central city or rural areas. It presents the unstable characteristics in land-use structure. The “unstable” refers to the land structure changes very quickly, which reflects urban fringe land development rapidly.

(3) Dynamic in land use

As the first choice of urban expansion, the land in urban fringe is often developed in a very short time. It means that the land-use structure changes very quickly, the city constructions are activity. As the words said “ Today’s fringe is tomorrow’s city”.

2 The risk research of Shanghai urban fringe development

Shanghai is located in mainland China central coast of the Yangtze estuary, which is the center city of Yangtze River Delta area. As China's first big city, Shanghai is China's economy, science and technology, industrial, financial, trade, exhibition and shipping center. It is famous of Shanghai’s style culture and international metropolis scene, and it succeeded to host the EXPO in 2010.

2.1 The definition of Shanghai urban fringe

(1) Idea definition

Urban fringe is gradient integration region of city constructed area and the surrounding agricultural land. It refers to the periphery of the concentrated constructed area. In this paper, the constructed area means the area which has been constructed is more than or equal to 50% in elemental area. And the urban fringe is the periphery of this area.

(2) Space definition

Based on the collection and processing of Shanghai historical urban construction

land use status maps and the figures, 1988-1997-2009 these three yeas are chosen as the research time node. According to the maps and figures, the article analyzes the urban fringe dynamic development process.

① The development of constructed area: automatic generating 1 km grid, the unit area ratio are classified into three categories: 80%-100%, 50%-80%, < 50%. According to the above definition, the unit whose constructed ratio no less than 50% is constructed area.

② The development of urban fringe: the people's square used as the center point, for 2 km radius to form the concentric circles which can cover the city range. Urban fringe is the periphery of the concentrated constructed area.

③ Urban fringe features analysis: the people's square used as the center point, selecting proper radius, 16 equal angle and area are divided. Then, it is superimposed with the 2km concentric circles, in order to easily get the urban fringe development features.

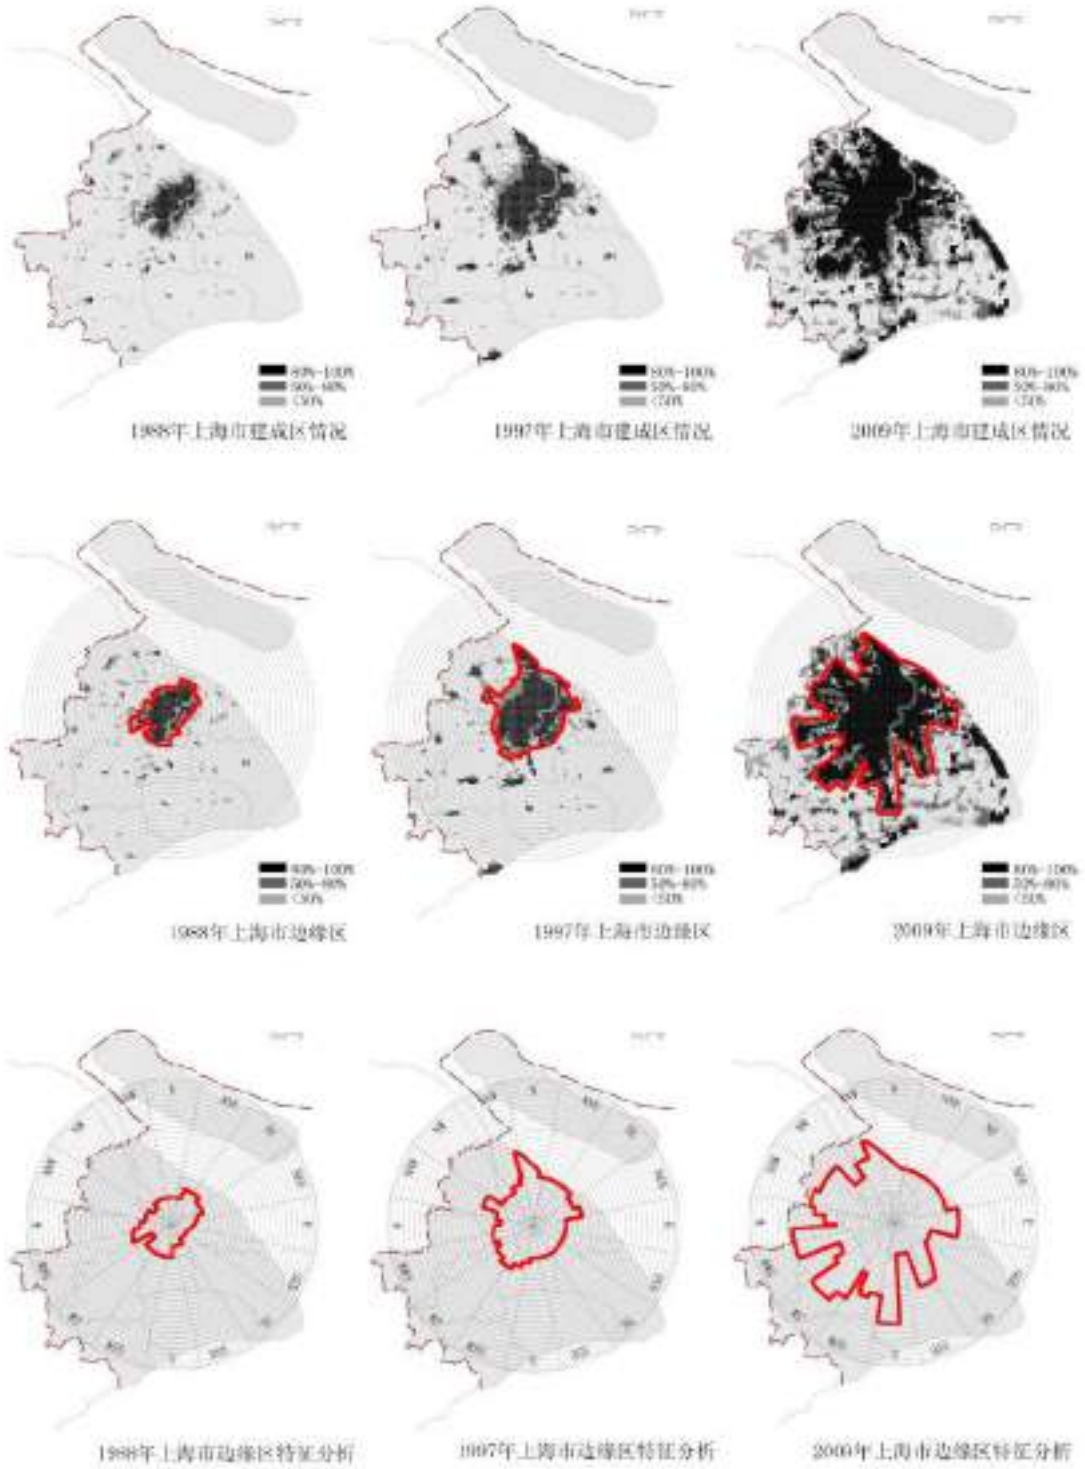

Figure 1. Shanghai urban fringe analysis

2.2 Research of Shanghai urban fringe features

(1) Space features

According to the three time nodes of urban fringe, making comparative analysis from distance to central city, length, space development direction and so on perspectives. Specific data is as the form below.

Table 1. Shanghai urban fringe space features

Time	Distance to central city（km）	Length （km）	Involved district	space development direction	Expanding style
1988	12	100	Putuo District, Zhabei District, Yangpu District, Pudong District ,Xuhui District, Minhang District, Changning District	-	-
1997	20	155	Jiading District, Baoshan District, Pudong District, Minhang District, Songjiang District	N/SW/NW	Sprawl Style
2009	30	340	Jiading District, Baoshan District, Pudong District, Nanhui District, Minhang District, Fengxian District, Songjiang District, Qingpu Distric	NW/NNW/W/SW/S/SSE/E	Axial-group style

The space features of urban fringe can be summarized up from distance, range, expanding style these three characteristics.

①Distance to central city is increasing year by year.

②The length of urban fringe is growing fast.

③The urban fringe expanding style is different. 1988-1997, it's urban sprawl without distinct directions. 1997-2009, urban fringe expands in axial directions. It's related to Shanghai "One city and nine towns" policy, promoting city track traffic construction.

(2)Land-use structure feature

Compared with 1997 and 2009 Shanghai urban land-use status map, to analyze land-use structure feature. Through all kinds of land figures study, making a summary of its feature. Specific data is as the form below.

Table 2. Shanghai urban fringe land-use features

Type	Time	Residential area	Public facilities area	Industry area	Warehouse area	urban outbound traffic area	Roads and Squares area	public utility area	Green area	Special area	Constructing area
Administrative city	1997	251.08	98.72	345.09	43.99	113.74	52.58	26.82	18.24	32.19	82.62
	2009	449.28	158.08	634.4	66.56	49.92	247.52	49.92	145.6	20.8	262.08
central city	1997	145.65	39.53	108.75	14.82	37.02	39.35	7.04	13.10	5.37	35.64
	2009	185.85	56.53	100.05	26.22	6.22	69.85	15.64	34.00	9.97	39.24

The urban fringe land-use features can be summarized up into two parts.

① Overall land trend fast growth . Urban fringe land increased by 900km^2, with an

average annual growth rate of about 7.5%

②land-use structure changed a lot. Constructing area increased by 175 km^2, reflecting fast and intensive of urban fringe development. In all kinds of urban land use type growth, the fastest growing is industrial land, followed by residential land and public facilities land

(3)Develop projects style feature

In 1997-2009 comparing urban constructed map, as the dynamic urban fringe, analyzing the develop project style features. According to the above analysis result, industrial land, residential land and public facilities land are the three increase fastest land style. So, in this part, the article will study industry park, residential district and public service facilities these three kinds of develop projects. Specific data is as the form below.

Table 3. Shanghai urban fringe projects features

	NO	Project Name	Develop Squar(km2)	Administrate district
Industry park	1	Baoshan Industry park	29.09	Baoshan district
	2	Jiading Industry park	62.55	Jiading district
	3	Jiading Auto Industry park	22.66	Jiading district
	4	Xinzhuang Industry park	16.45	Minhang district

	5	West-suburb Industry park	16.73	Qingpu district
	6	Songjiang Industry park	63.73	Songjiang district
	7	Songjiang technology Industry park	4.09	Songjiang district
Residential district	1	Jiading New Town residential district	18	Jiading district
	2	Anting New Town residential district	8	Jiading district
	3	Qingpu New Town residential district	6	Qingpu district
	4	Xujing residential district	7	Qingpu district
	5	Songjiang New Town residential district	20	Songjiang district
	6	Minhang New Town residential district	12	Minhang district
	7	Chuansha New Town residential district	5	Pudong district
	8	Baoshan New Town residential district	8	Baoshan district
public service facilities	Campus	Songjiang college town	5.33	Songjiang district
		Tongji jiading campus	1.67	Jiading district
		Jiaotong minghang campus	3.33	Minhang district
		movie artistic college	0.27	Pudong district
	Commercial	Auto trade center	0.2	Jiading

				district
		Outlets	0.40	Qingpu district
	Entertaiment	Meilan Lake golf club	2.25	Baoshan district
		Yingyi golf club	1.2	Jiading district
		Yintao golf club	1.33	Qingpu district
		Sheshan golf club	1.47	Songjiang district
		Zhongqi golf club	1.09	Minhang district
	Physical	F1 circuit	27.1	Jiading district

The urban fringe develop project features can be summarized up into two parts.

① Function feature

Shanghai urban fringe development project type mainly focus on industrial park, large residential area and city level public service facilities these three project function types. The city level public service facilities can be divided into college town, commercial facilities, entertainment facilities, sports facilities.

These city development project functions not only have large scale, but also strong functional characteristic. Its located in urban fringe area because of it has more abundant land resources, to improve the economic efficiency of the project; On the other hand, these functional project will build up large popularity in a certain time , easily to promote the whole urban fringe area develop.

② Traffic feature

Urban fringe expanding is relying on the urban transportation system. Different project's major transportation type is different. Industrial park is facility with workers' accommodation, in order to reduce commuting. Its main traffic type is freight and public transportation, and low dependency on public transportation. City large scale residential districts have to satisfy residents commuting requirements. Its main traffic type is public transport and private cars, high dependency on public transportation. Large public service facilities service wide scope area. The users income and traffic choice are very different. Its main traffic types for private cars and public transportation, relatively high dependency on public transportation.

Table 4. Shanghai urban fringe traffic features

Project function	scale	Main transportation	dependency on public transportation
Industry Park	large	freight and public transportation	low
Large scale residential district	large	public transport and private cars	high
city level public service facilities	medium	private cars and public transportation	relatively high

2.3 Risk research of shanghai urban fringe development

（1） Risk research framework

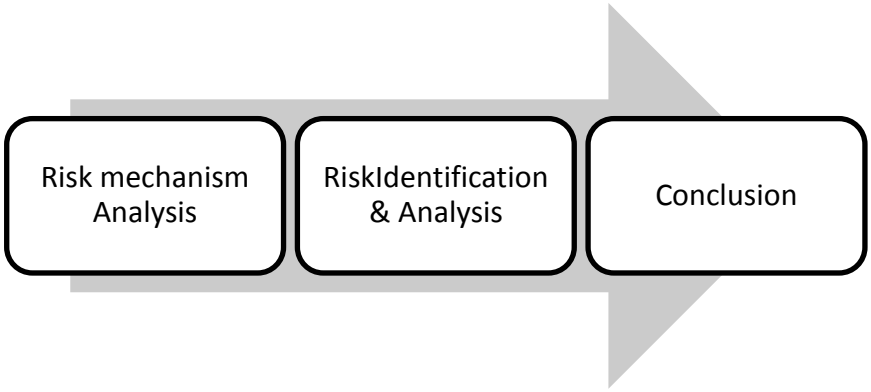

Figure 2. The risk study framework

The risk study framework can be divided into three parts:

①Risk mechanism analysis

The article analysis the develop mechanism of urban fringe area, based on urban develop risk research framework, identified risk subject and risk type, in order to set urban fringe development risk management study idea.

② Risk identification & Analysis

Risk identification & analysis is a particularly important part in risk research framework. According to the risk subjects, from different perspectives to identify and analyze the impact of the risk.

③ Conclusion

According to risk identification and analysis results, combined with the Shanghai urban fringe area feature, the article made the summary.

(2)The risk mechanism of urban fringe development

Urban development projects often involves many interest groups, the effect mechanism is also very complex. Identifying the risk subject and risk mechanism is important to making scientific risk assessment and proposing management strategies.

Urban development project risk can be divided into the original risk and consequential risk. Original risk is the risk or problem which is caused by un-considerable thought or improper disposal. Consequential risk is the harmful influences and consequences to the surrounding areas because of the project development and construction. Different types of risk, the risk subjects are different. According to the urban development risk theory, urban development risk can be divided into economic risk, social risk and ecological risk these three categories. Based on the characteristics, they belong to original risk and consequential risk in different stages of urban fringe project development. Because the involved interest groups are different, the risk subjects are urban government, project developer, urban residents, etc.

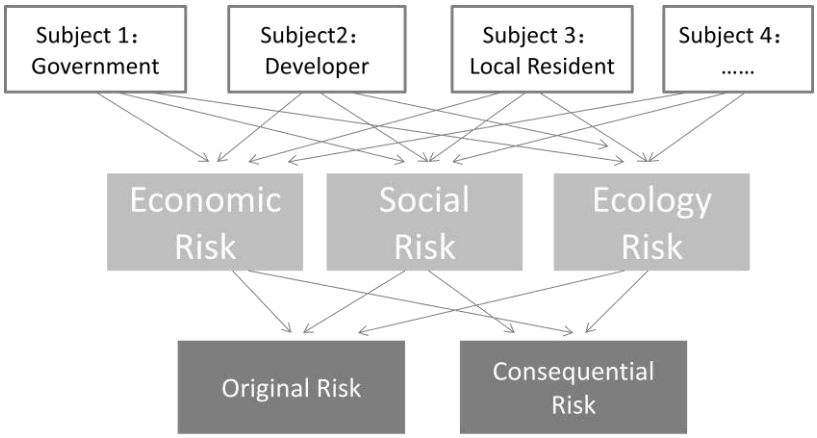

Figure 3. The risk mechanism

3 Risk Identify of Shanghai urban fringe area develop

Based on Shanghai urban fringe area development research, the article makes the risk identification of urban fringe develop projects features. The list of indicators are shown below：

Table 5. Shanghai urban fringe risk identification

Risk type	Risk categories
Economic Risk	Local Economic Standards
	Local Living Standards
Social Risk	Social safety and Harmony
	Social Culture
	Traffic Influence
	Service facilities impact
Ecological Risk	Landscape Standards

3.1 Economic Risk

The edge of the city economic structure and internal has a big difference between cities, because in agriculture to non-agricultural change, its own economy structure is relatively single, and the level of economy are weak.

(1) Local Economic Standards

With the guidance of "Shanghai Comprehensive Planning"， the projects in urban fringe area are often good to local develop. The projects construction in urban fringe area will increase the popularity and influence in short time, promoting the whole

area to develop, effects the local economic standards.

(2) Local Living Standards

Projects in urban fringe area construction and operation will provide jobs, leading the improvement of regional income. Or, it will cause negative influence to local living stands.

3.2 Social Risk

Project in urban fringe area development may lead the regional infrastructure, service facilities construction, and improve the social living quality. Because the residents living in urban fringe area is relatively complex, social sensitivity is high, and new projects will attract different kinds of people, which is very easily influent local social stability.

(1)Social safety and harmonious

City safety and harmonious is mainly evaluated from the following two aspects. Firstly, the new projects construction and operation will bring more traffic and complicated population structure, effecting regional security. Then is whether the projects cause conflict to resident. If the project safety is good and communication with local residents is well, it will promote regional security and harmonious

(2) Social Culture

Social culture is an important characteristic of city recognition, is also the key issue

in present city construction. Due to the geographical reasons, urban fringe area has both urban and rural culture features. And it formatted its own characteristics in the long time evolution process. The project construction attitude is determine the influence of social culture.

(3) Traffic Influence

Urban fringe is located in the edge area of central city and rural. It's a certain distance to central city. With the construction and operation, the projects will attract many people distribution, leading much traffic dependency. It may ascend regional road traffic conditions, enhancing public transportation.

(4) Service facilities impact

Urban fringe area project construction will promote the surrounding region as a whole to develop, complete the district public service facilities level. And the projects in urban fringe are often have a large scale, influencing local primary public service facilities system.

3.3 Ecological risk

The project in urban fringe area often marks area landscape features, become the symbol image. As the transition zone from inner city to rural area, urban fringe has the relative rich natural ecological resources. In the project construction and operation process, a great quantity people gathering will threat the ecological environment in a certain degree.

（1）Landscape Standards

Urban fringe area urbanization development will expand to the whole rural areas.

Therefore, how to manage them as a whole region to integrity development, make the image logo and driving regional landscape construction, not mechanization isolated-island effect, influence the fringe area ecosystem harmony and stability.

(2) Ecological Environment

Urban fringe area is adjacent to the vast rural areas. It has the rural ecological landscape, such as large scale greenbelt, river system and undeveloped land resource. With the construction and operation of new projects, it may generate pollution, such as: noise, waste gas, waste, etc, cause negative influence. Meanwhile, projects operation will attract abundant people, threaten local ecological environment.

4 Conclusions

As one of the most rapid urbanization area, urban fringe area has many obvious characteristics in land-use and project perspective. Through the research of Shanghai fringe area, analysis the features of space evolution, land-use structure and projects types. Combined with urban development risk research framework, making risk identification, and illustrates the economic, social and ecological three aspects risk.

Taking risk identification of urban fringe projects is good for local government to facilitate the related risk management measures, such as: risk aversion, risk and so on, in order to ensure the urban fringe healthy development.

The Affordable Housing Policy in Taiwan and UK： A Comparative Study

Yu-Min Hwang, Tzu-Yuan Chao

Abstract

With the rapid speed of economic globalization and urbanization in the developing countries, the implementations of sustainable development tends to encounter issues such as gentrification and increasing urban poor due to the escalating property prices in the urban area. In most urban renewal projects, to re-create the sense of spaces and provide higher-quality housing that attract middle class or higher income population would be the usual case. The controversial discussions on the gentrification consequence and the delivering affordable housing hence arisen. In Taiwan, Taipei Metropolitan is the only city that has successfully promoted prosperous urban renewal markets and more than 60 urban renewal projects have been granted permissions since 2008. However, the success of urban renewal projects has resulted in both economic and social problems i.e. young professionals or newly graduates are not able to afford living in the Taipei City. Meanwhile, Price and Income Ratio in Taiwan has increased from 7.1 to 9.2 in the past three years and it implies that pressure of purchasing house gradually increased in Taiwan as a whole.

To responding to the urgent needs of affordable housing, the very first Housing Act has just been legislated in the end of 2011 and two social housing projects in Taipei have been announced by the government that will deliver more than 4000 housing units at urban fringe of Taipei through public-private partnership. However, it is believed that without the stable supply of affordable housing, housing affordability will always be a long term issue. Many studies have indicated that it is feasible to provide affordable housing through urban renewal projects in the UK and other developed countries.

Hence, in this paper, we will focus on how to integrate the affordable housing supply with the urban renewal projects in the Taipei City, Taiwan from the legal and policy perspectives. A case study of England experiences will be undertaken. The final part of the paper will include a comparative study of Taiwan and the England in

the policy, legal and mechanism context.

Keywords：affordable housing, urban renewal projects, Taiwan

1. Introduction

From 1971 to the present, the Taiwan government has proposed a number of housing policies, such as Public Housing, Social Housing, Regulations for Young People Owning Housing and Suitable Housing, to resolve the different aspects housing problems. In 2011,the government has pass Housing Act which is legislated for the targets of integrating housing market, enhancing the quality of the living, all nationals living in suitable residential and having dignified living environment. However these policies were almost proposed from the perspective of living justice, especially the Suitable Housing and Social Housing. In recent years, the price of housing has soared, in particular metropolitan areas. But the limited areas cannot tolerate endless constructions, the need of housing is large in metropolitan. Therefore, the price of housing is rising rapidly; a lot of people can't afford the price to buy a house. Although government has proposed Suitable Housing and Vacancies Using, Suitable Housing or Social Housing still is restricted by laws; price of vacancies is rising for the need of living. So the affordable housing and housing supply are more important and Taiwan will confront the issue in the future.

In comparison with other countries, the housing policies or comprehensive development strategies include housing affordability. In the United Kingdom, Planning Policy Guidance Notes (PPG3) in 2000 has included the problems of affordable housing and the need of housing, and proposed solutions from different aspects as policy, finance, etc. In 2003, the Sustainable Communities Planning is involved in affordable housing object and supplied affordable housing with urban renewal.

Now, it confronts the subject of housing affordability in Taiwan, and the need of housing is large in Taipei. To resolve this subject, Taipei has proposed a concept of obtaining affordable housing with urban renewal. And there is a case which is proceeding in Muzha District. In Taiwan, the concept of obtaining affordable housing with urban renewal is argued and there are no regulations or policies to define it. So it is the motivation of this paper.

Based on the background and motivation, there are three purpose of this study：

1. Understanding the affordable housing policies transformed and implemented; compared with Taiwan and bring up the similarities and differences as reference.

2. Discussed similarities and differences about other countries and Taiwan urban renewal mechanism and operation

3. Discussed the feasibility of supplying affordable housing with urban renewal in Taiwan.

2. Analysis

2.1 Definition and Classification of Affordable Housing

In UK, affordable housing includes social rented, affordable rented and intermediate housing, provided to eligible households whose needs are not met by the market. Affordable housing should:

– Meet the needs of eligible households including availability at a cost low enough for them to afford, determined with regard to local incomes and local house prices.

– Include provision for the home to remain at an affordable price for future eligible households or, if these restrictions are lifted, for the subsidy to be recycled for alternative affordable housing provision. ***(2011c)***

Table 1 Affordable Housing Type in UK

Housing Types	Contents	Note
Social Rented Housing	1. Guideline target rents are determined through the national rent regime. 2. Rented housing owned or managed by other persons 3. Provided under equivalent rental arrangements to the national rent regime, as agreed with the local authority or with the Homes and Communities Agency as a condition	Social rented housing is owned and managed by local authorities and registered social landlords

	of grant.	
Affordable Rented Housing	1. It is not subject to the national rent regime but is subject to other rent controls. 2. Require a rent of no more than 80 per cent of the local market rent.	Rented housing let by registered providers of social housing to households
Intermediate Affordable Housing	1. Housing at prices and rents above those of social rent, but below market price or rents. 2. Include shared equity products (e.g. HomeBuy), other low cost homes for sale and intermediate rent but does not include affordable rented housing.	Registered providers of social housing to households who are eligible for social rented housing.

References：*(2011c)*

In Taiwan, affordable housing includes public housing, social housing, parity housing and affordable housing. But there is no act to make a clear definition of affordable housing.

Table 2 Affordable Housing in Taiwan

Housing Types	Contents	Note
Public Housing	The referred public housing in this act indicates the housing projected by the government and constructed through the following forms for sale or rent to low-income families, or conducted by such families themselves with government loan, or provides the subsidy of loan interest for families who bought the house by themselves	Building ways： I. Construction conducted directly by the government. II. Construction conducted by the people themselves with government loan. III. Construction by encouraging private investment. IV. People purchase the house by themselves

		with government assistance.
Social Housing	1. It indicates the housing conducted by the government or conducted by encouraging private investment and rental specially. It should provide at least 10% houses for renting to Special cases or status. 2.It should calculate reasonable subsidy in accordance with standards of fair rent in living area, income of families receive subsidy, household with disadvantaged status and standards of affordability indicators, etc., for the purpose of limit of rental and the subsidy of loan interest for families who bought the house by themselves.	Special cases or status 1.Low-income families 2.Special-circumstances families 3.Bring up more than three minor children. 4.People who can not return and under 25-year-old after the end of the placement of correctional services or foster families. 5.Over 65 years old 6. Victims and his/her children of domestic violence or rape 7.Disabilities 8.HIV or AIDS 9.Aborigine 10.Victims of disaster 11.Vagrant 12.Other confirmed by authority
Affordable Housing(Parity Housing)	1. The property belongs to country, public or state-owned enterprise. 2.To take the way of selling by announcing building investment. 3.Requesting private to provide rent for meeting the need of tenant and having priority to take care of low-income families or families which can't afford to pay.	There are affordable housing located at Fuzhou and Airport MRT A7 station.

References：*(2011b)* 、*(2005)*、*(2011d)*

It integrates the vocabulary about affordable housing in UK and Taiwan. In UK, all housing type is operated by public and private, but the operators alter for different house type. The objects are confirmed by evaluating income and local house price in UK, but the objects are almost disadvantage groups in social and economy in Taiwan. The properties are more rental in UK, but in Taiwan the opportunity of rent is as same as sale. The definition of objects in Taiwan is narrower than UK, but the chance of sale in Taiwan is more than UK.

Table 3 Affordable Housing Comparative

Nation	Housing Type	Operator	Objects	Property
UK	Social Rented Housing	Public/Private	Evaluating income and local house price	Rent
	Affordable Rented Housing	Public/Private	Evaluating income and local house price	Rent
	Intermediate Affordable Housing	Public/Private	Evaluating income and local house price	Rent、Sale
Taiwan	Public Housing	Public	Disadvantage groups in social and economy	Rent、Sale
	Social Housing	Public/Private	Disadvantage groups in social and economy	Rent
	Affordable Housing(Parity Housing)	Private	Disadvantage groups in social and economy	Rent、Sale

2.2 The Context of Affordable Housing

According to Delivering Affordable Housing which was published by Communities and Local Government in UK, we can understand government in UK believes everyone should have the opportunity of a decent home, which they can afford, within a sustainable mixed community. Although there is no clear definition

about affordable housing, we can find the related concept from living justice which is mentioned in Just society among eight visions in Gold Ten Year. The major policies are giving assistance of living, adjusting the housing supply and demand, improving housing market. The referred affordable housing in UK policies indicates the motivation and form(ex：mix-used communities), and in Taiwan indicates the operational ideas and models. The motivation of both is that everyone can own the house by sale or rent in a economy-affordable situation.

Next, it studies the policy evolution about affordable housing in UK and Taiwan.

2.3 The Affordable Housing Policy in the United Kingdom

Most nations make/set policies, acts, regulations about affordable housing for solving the issue of living. The evolution of affordable housing policies in UK is as follows：

1914~1949：The top priority is housing-providing for working-class and focusing on subsidy institution.

From 1914, government proposed three policies： rent control, providing housing subsidy for working-class and slum clearance. It is the first turning point in UK that introducing rent control and controlling private capital in long term. The construction was promoted by encouraging private investment in public housing for sale or rent in 1923. In 1945~1949, because of Keynesianism, a lot of public utilities become nationalization. The act removed statutory restriction of limited public housing for the working classes, at the same time, the government introduced improvement grants. In this period, the policies were almost implemented by subsidy and the objects were restricted to working-classes.

1950~1969：Slum clearance was the core policy ,and introduced the idea of urban renewal.

In this stage, the postwar construction boom ended the emphasis shifted to the removal of slum housing. In Housing Act 1957, regulated government must provide

dwelling to extended families or people with poor living conditions. Building association was brought in the housing project; government encouraged house ownership and improved old-house policy. Fair rent was introduced in 1965.

1970~1989：The rise in owner-occupation of older stock; successive governments provided grant aid to owner-occupiers and private landlords to assist them with renovation work.

Because of Free Market, it is the second turning point in 1979. Before 1979, government played the role of housing supplier, and thus transferred to the role of promoter. However, government made housing affordable by subsidies and financial mechanism; the construction was undertaken by private enterprises or semi-public housing companies. In 1980, owner-occupation of older stock was more general by introducing right-to-buy plan and mortgage market deregulation; government interfered in housing market and confirming public housing of selling or renting.

2000~present：There were a lot of mechanisms about equity shared for affordable housing.

Authorities were required to produce homelessness strategies for homeless youth. Housing affordable was an element in Sustainable Communities Plan and provided by public-private framework. Urban renewal and affordable housing were the way to achieve sustainable communities in Sustainable Communities: Affordable Housing and Socio-economic Relations. Now, the important guideline about housing is planning policy guidance notes (PPG3) in 2000. The guideline include that local authorities should meet the housing need, reuse the developed land, increase development destiny and provide affordable housing. Table below is housing policies history in UK.

Table 4 The History about Affordable Housing Policies in UK

Principle	Governing party	Year	Housing important policy	Period description
		1914	Three housing policies adopted by government：	The primary thing is providing working-class

			●Rent control ●Providing housing subsidy for working-class ●Slum clearance	housing which focusing on subsidy institution.
		1915	Turning point ●Introducing rent control ●Controlling private capital in long term	
Liberalism	Liberal Party	1919	Introducing exchequer The stage of housing increasing	
Social democracy	Labour Party	1923	Construction by encouraging private investment in public housing for sale or rent	
Keynesianism	Labour Party	1945	The nationalization of major industries and public utilities	
		1949	Removed statutory restriction that limited public housing to the working classes. Introduced improvement grants.	
	Conservative Party	1951		Slum clearance： After the postwar construction boom ended the emphasis shifted to the removal of slum housing. Renovation was mainly seen as a stop-gap measure until substandard dwellings were cleared.
		1959	Introduced building association into housing project. Encouraged house owned and improved old-house policy	
	Labour Party	1964	Established the Housing Corporation	
		1965	Introduced fair rents	

	Conservative Party	1970		Publicly funded private sector renewal：The rise in owner-occupation of older stock, growing criticism of clearance and municipal rehousing led to shift in focus to area renewal and renovation. Successive governments provided grant aid to owner-occupiers and private landlords to assist them with renovation work. ●The scope of grant aid was broadened to cover repairs as well as improvements(such as the installation of bathrooms and kitchens),and eventually to include adaptations to make dwellings suitable for people with disabilities. ●Subsides were increased to enable low-income home owners to benefit. ●Area-based focus
		1973	Conservative Party and Housing Corporation introduced four goals： ●Supported home-ownership arising ●Provided capital to private sector stably ●Stabilized housing price ●Provided a loan funding sufficiently	

	Labour Party	1974	Introduced ‘ Housing Action Areas ‘ and expanded the remit of the Housing Corporation. Emphasized interfering in housing directly and given more resources	developed through the designation of Housing Action Areas and General Improvement Areas. ●Enveloping and block repair schemes for groups of houses were stimulated by higher grant payments.
Libertariani sm	Conservative Party	1979	Second turning point： It went to privatization, personallization and non-public in the after ten years. Government transformed the role from house supply into promoter, and converted from providing funding to assisting with rent-paying when the houses supplied by government had declined in 1919.	
		1980	Introduced ‘Right to Buy’	
		1989		Means tested and targeted private renewal：A housing green paper asserted that ‘homeowners must carry the primary responsibility for keeping their property in good repair’(DETR,1985,p.1). The Local Government and Housing Act introduced mandatory grants to make

				dwellings ’fit for human habitation ’ (which increased funding demand). In 1996 mandatory grants were discontinued, apart from disabled facilities grants (DFGs). Overall grant expenditure fell and DFGs accounted for an increasing proportion of the total.
Free market	Labour Party	2000	Set direction for a number of housing reforms including option appraisals, ‘ Arm’s-Length Management Organizations and Private Finance Initiative options to meet, the Decent Homes Standard, rent restructuring, Housing Benefit reform and Choice-Based Lettings.	
		2002	Required local authorities to produce homelessness strategies. Amended priority needs groups to include 16-17 year olds. Abolished the duty to maintain housing registers. Repealed private sector grants and loans provisions, enabled local authorities to assist	Onwards public-private framework harnessing private investment in renewal：a regulatory reform order repealed the framework of grants and assistance to home owners and required all local authorities to develop strategies to improve local housing conditions and to

			housing renewal directly or through third parties such as housing associations and private sector loan finance.	invest a mixture of public grants and private funds in renewal. This led to initiatives to attract private funding. Housing Market Renewal Areas were designated (this new public investment stream was limited to seven areas nationally).The decent homes target and the health and safety hazard rating set standards for local strategies.
		2003	Gave higher profile to housing policy and responded to regional disparities. Led to the establishment of Regional Housing Boards, Regional Housing Strategies, additional investment in new homes in the South and the establishment of Housing Market Renewal Areas in parts of the Midlands and the North. Established ‘ community Right to Buy’, which enabled community bodies to purchase land from land owners.	
		2005	Set out the government’s housing priorities in the run-up to the general election. Placed strong emphasis on the promotion of home ownership. Introduced ‘ HomeBuy’ equity stakes scheme for housing association tenants and further help for first-time buyers.	

			Continued the themes of private finance for social housing and the promotion of choice through lettings and mobility schemes. Sought to reverse the growth in temporary accommodation.

2.4 The Affordable Housing Policy in Taiwan

The development of housing policies in Taiwan can be divided into four periods from 1945 to present. The following sections explain the four periods.

1950~1999：It is the public housing policy stage and is promoted by four steps.

In 1950~1954, the main policy was about housing subsidy for emergency, due to the tremendous amount of housing needs resulted from Nationalist Government of the Republic of China retreatment to Taiwan. In the stage of government housing loan between 1957~1975, government drew up the Housing Subsidy Act, defined the subsidies objects and performed redevelopment after disaster. In these two stages, the policy focused on provision of houses quantities and was implemented by subsidies.

In 1975~1981, the stage was targeted to resolve the issues of housing demands, living environment and the quality of life with the Building public housing six-year plan. Government drawn up Public Housing Act and it was one of the twelve key infrastructure projects. The referred public housing in this act indicates the housing projected by the government and constructed through the following forms for sale or rent to low-income families, or conducted by such families themselves with government loan, or provides the subsidy of loan interest for families who bought the house by themselves. In this stage, the objects are not restricted to public servants and teachers but also include other low-income families. Initially this stage was guided by government.

In 1982-1989, the Public housing construction and pre–sale stage encourages private investment and includes more objects of subsidies. But the housing policies still focused on subsidy of housing loan.

In 1990~1999, the primary housing constructors are private sectors and the government only plays an assisting role. Government promoted investment in construction project to increase interest in building public housing.

2000~2006：Drew up integrated housing policy

The policies changed from housing supply control to finance management. Integrated housing policy in 2003 was aimed to improve housing market, establish fair and efficient housing subsidy institution and enhance the quality of living environment. Social housing was first brought up in this stage. Finally it was decided to focus on housing welfare in 2005.In this stage, the purpose and objects are different from previous stages, but it was still carried out by maintaining the interest subsidy.

2007~2009：Integrated housing subsidy program

The purpose is to integrate all housing subsidies of all professions and the main considerations of housing subsidy are income and all disadvantaged states of the applicant.

2010~present：Social housing implementation program

The policy in 2010 is targeted to assist youth and the disadvantaged to resolve the living issue, but there is neither act nor regulation yet. Housing Act was confirmed in 2011, and the act referred that social housing indicates the housing conducted by the government or conducted by encouraging private investment and rental specifically. It should provide at least 10% houses for renting to citizens with special needs or status. The restriction of objects is stricter; most objects are disadvantaged group, but it does not take consideration of general public who can’t afford to own houses.

The affordable housing was introduced in Housing Act Draft in 2011, but there is currently no regulation. According to the draft, it referred to ‘construction constructed by government drawn investment and given priority to homeless and less a certain income families in standard price.’ Now there are two affordable housing located at Fuzhou and Airport MRT A7 station. The affordable housing in Fuzhou has ended the application process and the other has completed the investment contract. Both of them will provide lower than market price for sale or rent and if you own the house, you can’t gift or exchange it in first five years. It is guided by government and assisted by private sector, and private sector should be responsible for the housing management.

Table 5 The History about Affordable Housing Policies in Taiwan

Background	Governing party	Year	Important Housing policy	Period description
A lot of people came into Taiwan, because Nationalist Government of the Republic of China retreated to Taiwan In 1950, economy gradually stabilized by American aid intervening	Chinese Nationalist Party	1950~ 1954	Houses were crude and most of the properties belong to public. A lot of houses were illegal. The policy was about housing subsidy for emergency.	Public housing policy stage
		1957	The first legal basis for housing subsidy：The Loan For Building Public Housing Act Beneficiary：working-class, farmers, fishermen, public servants and teachers and general citizen who need house(given priority to low-income working-class and farmers) The key point was to resolve the issue of quantity. 3. Results

3.1 The different between Taiwan and UK in Affordable Housing Policy

At the beginning, the implementation of providing affordable housing was through subsidy institution, and the objects were restricted in UK and Taiwan. In the later period, the objects in Taiwan are mostly low-income or disadvantaged groups and few youth groups, but the objects in UK are groups with certain economy evaluation and youth group of 16~17 year-old .The provider in UK changes from government to private companies or public-private partnership over time, and the government transforms into promoter. In Taiwan, at first government guided the policies and in the later period, government guides policies, private sector assists in the policies with government drawing investment. The different between UK and Taiwan is development sector. There are public and private sectors in Taiwan, but there is also third party in UK. If Taiwan needs to refer to the cases and implementation in UK, the major concern is how Taiwan could integrate public and private to complement the duty of third party.

Table 6　Compared Affordable Housing Policy in UK and Taiwan

National	Taiwan	UK
Implement	Subsidy→Subsidy with building	Subsidy→Subsidy, building→Subsidy, building and renewal
Object	Working-class, farmers, fishermen, public servants and teachers→Low-income, youth→Low-income,	Working-class→economy evaluated group, 16~17 year-old

	disadvantage	
Provider	Public→public with private	Public→private with public
Policy development	Public housing policy stage(conducted with government loan→Building public housing six-year plan→Building and pre–sale public housing→New communities development plan) →Integrated housing policy →Integrated housing subsidy→Social housing implement program in short term	Rent control,providing housing subsidy for working-class→Slum clearance→Right to Buy, economy status evaluation, renewal by private→public-private framework
Affected concept	Liberalism	Libertarianism

3.2 Case Studies in Taiwan and UK

3.2.1. Plymouth in UK

The core strategy in Plymouth from 2006 to 2021 was drawn up in 2007.In order to make Plymouth a high quality and internationalization city, the strategy includes nine visions and one of them is to provide a mix of dwelling types, size and tenure, to meet the needs of Plymouth's current and future population. Based on the vision, the housing provision is that at least 30% of the total number of dwellings should be affordable homes and at least 80% of the city's housing provision to be delivered on previously developed land, such as Sutton Harbour, East End. Both of them provided affordable housing according to Section 106 of the Town and Country Planning Act 1990.(2007)

3.2.2. Wenshan District in Taipei, Taiwan

For contributing the image in Muzha, a lot of urban renewal units were planned in hope to bring development opportunitie; either announced by government

or designate the renewal area by private. With this policy, the two blocks in the south of Mucha Second Road and Mucha Second Road 138 Lane cross section were designated the renewal area in 2009(referred as case area below). According to Urban Renewal Act, the case area was going through a public evaluation and selection procedure, accepting other organizations (institutions) as implementer to undertake the business of urban renewal. Under the activity plan about assisted program of extended urban renewal into old and low-floor building community in Taipei, the case area quotes the guide of the appropriate scale of residential and refers the regulation of rent housing ‘Upon providing certain amount of houses for renting purposes (properties should needs to be gifted to the local government), the gifted parts will be treated as public facility and not be counted towards the total capacity. The awarded capacity is limited to 15% of the total capacity.

In this case area, after renewal process, government can get almost 200 public rent housing. However, not entirely affordable housing, but it is the first case provided affordable housing by urban renewal. So we know that providing affordable housing could be conducted by the government or guided by government and conducted by private and provided affordable housing partially by urban renewal in the future.(2011a)

3.3. The Different Between Two Cases

In both cases, affordable housing is provided by the vision of local development, but the visions are referred in different perspectives. In Plymouth, the vision is brought up by the core strategy of affordable housing, but in Wenshan District, the implementation of vision focused on the local development by urban renewal, and thus affordable housing is included. About proportion of affordable housing, the strategy of affordable housing defined the proportion clearly in UK, and in Taiwan, the affordable housing proportion is according to the regulation of rights transformation. In UK, Section 106 of the Town and Country Planning Act 1990 is the main act to provide affordable housing; in Taiwan, the program is the basis for affordable housing. After comparing UK with Taiwan, the concept and regulations in provided affordable housing by urban renewal are different, and the difference will be the reference for discussing the implementation in Taiwan.

Table 7 Compared Affordable Housing Case in UK and Taiwan

Case	Wenshan District in Taipei, Taiwan	Plymouth in UK
Policy/Regulation	Activity plan about assisted program of extended urban renewal into old and low-floor building community in Taipei/ Urban Renewal Act	Core strategy in Plymouth from 2006 to 2021/ Section 106 of the Town and Country Planning Act 1990
Affordable housing proportion	According to the regulation of rights transformation	At least 30% of the total number of dwellings should be affordable homes
Relationship between renewal and affordable housing	Urban renewal is the vision and affordable housing is the implementation method.	Affordable housing is the vision and urban renewal is the implementation method.

4. Conclusion

Based on the above sections, we realize that the policies and implementation methods of affordable housing changed gradually and are defined clearly when referred in policies and acts. However, there is no act to define affordable housing, but the concept was drawn up in the policy about housing affordable. In the case study, we learned that the way to provide affordable housing could be conducted by the government or private and it can be provided by urban renewal. Based on the well use of land and living justice, it becomes a trend to provide affordable housing by urban renewal. This study will refer to the case and analysis in UK, and discuss the possibility about affordable housing supply by urban renewal.

URBAN SPACE DESIGN IN HIGH-DENSITY CONTEXTS: PLANNING FOR SUSTAINABLE FUTURE

Zdravko Trivic [1] & Im Sik Cho [2]

Abstract

In the context of rapid urbanisation, increasing density and hybrid conditions, as well as global competitiveness in planning more iconic, yet more sustainable, more environmentally-friendly and healthier cities, the ways urban spaces are traditionally understood and designed are challenged and need to be reconceptualised both quantitatively and qualitatively. Once densities increase urban public space becomes a precious commodity, whose design and performance attributes are yet to be explored in order to fully respond to new citizens' needs and life standards.

In this paper we investigate emerging hybrid urban space typologies and their potential roles in improving conditions of high-density settings and turning them into more vibrant environmentally and socially sustainable spaces. Our main focus is on identifying critical parameters for new urban public space configurations within high-density conditions and led by holistic vision for sustainable urban future. In this paper we outline a tool that would be used to gather, classify, evaluate, analyse, speculate and guide design and planning of urban spaces, and thus ease policy and decision making processes in the context of highly dense Singapore. Drawing from the research by Gehl (1996, 2001, 2010), Carmona (2003), and Shaftoe (2008), among others, a conceptual research framework is developed. The framework recognises three key components that constitute the properties and performances of urban spaces, combining design, use and operational aspects, namely: hardware, software and orgware. As such, it is used as a basis for classifying and evaluating existing urban spaces, as well as speculating on how to generate new hybrid urban space typologies and conditions in high-density contexts. The framework challenges static and prescribed typologies, by proposing sets of positive descriptive and evaluative attributes and criteria that can be combined and compared across different typologies in order to create better urban spaces in high-density contexts.

The research method consists of three major parts, namely: (1) documentation of case studies and literature review, (2) development of classification and evaluation systems for selected cases, and (3) comparative analysis. A total of 48 local (Singaporean) and international cases in high-density contexts, including those from Beijing, Hong Kong, Tokyo, Osaka and New York, are documented, using structured first-person observational techniques, as well as on-site mapping, photography,

[1] Centre for Sustainable Asian Cities (CSAC), National University of Singapore - sdezt@nus.edu.sg
[2] Department of Architecture, School of Design and Environment, National University of Singapore & Principal Investigator, Centre for Sustainable Asian Cities (CSAC), National University of Singapore - akicis@nus.edu.sg

interviewing and secondary sources review. A structured observational checklist - consisting of a number of descriptors and evaluators grouped into five urban space values, namely: nodal, spatial, environmental, use & socio-perceptual and operational value - is used. Selected spaces range from small-scale to large-scale developments, from relatively homogeneous (such as residential) to highly heterogeneous hybrid complexes (such as infrastructural and commercial).

This paper will discuss key findings of comparative analysis, highlighting critical attributes for the performance of particular spatial configurations, as well as their inter-relationships. Additionally, the recommendations of design measures to improve urban spaces in local and international high-density contexts will be proposed. While drawing from existing recent tendencies and transformations in urban space development, this paper aims to trace future trajectories and identify the role of urban space and urban design in future sustainable development.

1. Introduction – High-Density Environment, Urban Space and Sustainability

Due to the rise of urban development and urban population the demands for more environmentally and socially sustainable planning and design are emphasised globally. More than a half of the world's population today live in cities, of which 27% are 19 mega-cities, and 11 of which are located in Asia (Keiner, 2005). Over the last three decades Asian countries experienced the most dramatic urban transformations, which is comparable to what the western world experienced over the last two centuries. From 1900 to 2000, the world's population increased from 220 million to 2.84 billion. It has also been estimated that between 2000 and 2030, Asia's urban population will increase from 1.36 billion to 2.64 billion.[3]

However, in contemporary urban planning and design research and practice, there is a considerable agreement that higher density, compact city and "high intensity urbanism" are desirable and more sustainable urban development strategies (Sabaté Bel, 2011; Chan and Lee, 2007). Such a favourable understanding of high-density conditions is, however, relatively recent. Negative experiences in the nineteenth century's industrial cities, when high concentration of people was associated with poor hygiene, diseases, fire hazards and deaths, led to favouring of low-density urban development. Such a discouragement of high-density urban development has also been justified by sociological and psychological research, which suggested that increasing urban density causes greater physiological and psychological stress, social disorder (increasing violence, crime, suicide rate, and drug addiction), ill health conditions and violation of personal space (Newman and Hogan, 1981). However, such a trend resulted in a number of problems driven by overconsumption of resources, some of which are higher energy consumption, car dependence and higher travelling costs, long daily travelling distances and higher infrastructure costs, as

[3] On the other hand, in spite of such urban population explosion trends, Hidetoshi Ohno (2012) estimates that the cities after 2050 would experience depopulation, especially those in Asian countries with ageing and declining populations.

well as social problems in often ghettoised suburban areas. On the other hand, benefits of higher density and higher intensity may be multiple, yet it is evident that the density of urban environment is not the only and sufficient measure of the good performance, sustainability and quality of urban living.

The majority of over 70 definitions of sustainability see economy, environment and social equity as its primary and interdependent components (Boyko et al., 2005). Most common definition describes sustainability as "a development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs" (WCED, 1990). Although sustainability paradigm has recently become mainstream concept in urban planning and architectural research and practice, such research has so far been of relatively poor quality (Mostafavi, 2010). Most of the sustainable practices and mechanisms are being spread globally without taking into consideration the specificities of the particular contexts, which led to a certain level of skepticism towards the concept of sustainability. Moreover, sustainability is often superficially equated to mere technological capabilities and energy performance measured quantitatively, focusing on either (super-)micro-scale of individual buildings or (super-)macro-scale of cities and regions.

As a result, the role and potentials of micro-scale urban spaces, including existing redefining and emerging new hybrid urban developments in high-density contexts have not been fully explored. Yet, the expectations of urban space are high, demanding for such spaces that would be able to accommodate the emerging diverse, dense, intense and flexible conditions. These recent demands brought new interest in urban design as one of the key means for achieving environmental, social and economical sustainability of contemporary cities.[4]

In this research, urban space is seen as a means with potentials to successfully bridge the gap between the micro-scale of individual buildings and the macro-scale of a city and contribute to the overall sustainable living. Furthermore, we understand spatial density as inseparable from intensity of activities and users, as well as in more subjective and experiential terms. Such an approach goes in line with Uytenhaak's (2008) interpretation of density, which states that density refers to higher diversity and intensity, coming from mutual proximity of urban activities, urban dynamism, efficient land use and ways buildings are arranged and related to one another. It is also supported by research in contemporary urban ecology showing that human perception of urban density defers from the scientific one; it is rather subjective and shaped by particular context (Cheng and Steemers, 2010). Density is indeed more frequently perceived in relation to legibility, intensity of use and information available in space (mess versus order), rather than in terms of spatial density indexes, such as Floor Area Ratio, Gross Density or Weighted Density, among others.

[4] Such a recent shift in understanding the role of urban design in sustainable urban development, that goes beyond beautifying public spaces, Madanipour (2006) calls "new urban revolution".

According to Gehl (2010), it is only when people, buildings and other objects are in close proximity (within 7 meters) that people can fully use all of their senses, see and experience all details, as well as exchange the most intense feelings. However, this research does not *a priori* favour high-density and hybrid conditions. It rather attempts to respond to challenges that such conditions pose on urban development and urban living today, as well as to investigate the role and capabilities of urban spaces to foster social and environmental sustainability within high-density contexts.

2. Background – Urban Space and Hybrid Environments

As a result of new attention that has recently been given to urban design and role of public space in sustainable development, a number of concepts, tools, guidelines and methodologies have been developed to better understand, evaluate and design urban open spaces (Gehl, 1996, 2004, 2007, 2010; Gehl and Gemzoe, 2001, 2004; Carmona et al., 2003; Project for Public Spaces, 2008; Chan and Lee, 2007; DETR, 2000; Uytenhaak, 2008, etc.). A plethora of measurable and intangible attributes have been identified that shape the performance of an urban space, such as connectivity, accessibility, legibility, user density, demography, space identity, safety and amenities, many of which are interlinked and interdependent. However, the majority of past and contemporary research has been predominantly focused on familiar models of urban space, such as squares, plazas, streets, parks and arcades, without consistent and definite rules in what constitutes good urban space, nonetheless what constitutes good urban space in high-density context.

The ease in which the term 'public space' is commonly used sharply contrasts its growing complexity, including typology, use, ownership and management aspects. Public space is typically defined as an accessible space for all citizens regardless of age, gender, race, ethnicity or socio-economic status with free circulations of people and goods (Carmona et al., 2003; Shaftoe, 2008). It is also described as a space of debate and negotiation, a symbol of democracy and sociability. However, recent critiques also tend to somewhat idealise the notion of public space, emphasising on traditional and nostalgic dialectics which oppose private and public, true and false publicness, space and place, aesthetics and ethics. Major debates revolve around the loss of public space primarily due to commodification and intrusion of private market into the realm of public culture. Accordingly, emerging hybrid urban spaces are characterised as 'quasi-public' (Dovey, 1999, 2010; Pimlott, 2008-9) or even 'non-places' since they have no roots in tradition, history and culture (Augé, 1995). Such a traditional attitude towards the public realm seems to be somewhat problematic and insufficient for understanding the contemporary contexts of emerging new hybrid urbanities and modes of publicness.

As a consequence, we still know too little about the expanding and increasingly hybrid urban space typologies in highly dense contexts emerging today. Instead of adopting classical definitions of public space we use the term 'urban space' which takes into account emerging types of spaces that may not be publicly owned or managed yet increasingly act as public. Such an understanding is closer to the notion

of 'collective space', suggested by Spanish architect Manuel de Solà-Morales (1992), where different groups coexist and interact on a competitive basis. For de Solà-Morales, the richness of a contemporary city at the end of the twentieth century should be found in the collective spaces, which are neither public nor private, but rather both simultaneously. They include both public spaces used for private activities and private spaces that allow for collective use. Collective space tends to be more social in nature rather than political, with interactions occurring on experiential rather than communicational level, and as such it is more comparable to the marketplace than to the Greek agora.

Madanipour (2003, 2006) also notes that as much as the private realm influences public, the society is also the realm of the private, pointing out that there is no clear cut separation between public and private. Publicness depends on how people characterise the private, and thus there are many shades of publicity and privacy creating a fluctuating, often tense, semi-public-private or 'neo-public' continuum (Dimmer, Golani Solomon and Klinkers, 2006; ZUS, 2006; Nielsen, 2004). Van Alen Institute's exhibition "OPEN: New Designs for Public Space" held in New York in 2003 well showcased this recent trend of hybrid urban space development across the world, exploring their typological, morphological, infrastructural, programmatic and operational complexities (Gastil and Ryan, 2004).

A number of such recent hybrid developments are investigated in this study. Yet the perennial question remains: can good public space deliberately be created and how? With increasing density and hybrid urban transformations, the ways we traditionally understand, conceptualise, plan, design, re-design and utilise urban space in high-density environment need to be revisited and reconceptualised both quantitatively and qualitatively. Once densities increase space (of any form) becomes a precious commodity, charged with intense competitions, tensions and negotiations between the diverse groups of users over it. Thus, uncovering new ways to create good urban spaces that would fit well in dense urban conditions yet are vibrant and environmentally and socially sustainable would be the main challenge.

3. Objectives

The existing literature and research offers no specific values and criteria that are purposely tailored for high-density environments. The scope of this research includes discerning the relationship between density and quality of urban public spaces based on key criteria that affect the space and their inherent relationship with each other.

The main objectives of this paper are thus: to outline new urban space framework and recommend parameters for emerging new types of urban spaces within the local (Singaporean) and international contexts of high density developments; to discuss key initial findings of comparative analysis, highlighting critical attributes for the performance of particular spatial configurations in high-density contexts, and to propose a tool that would be used to gather, classify, evaluate, analyse, speculate and

guide design and planning of urban spaces, and thus ease policy and decision making processes in the context of highly dense and sustainable Singapore.

4. Research Methods and Analysis

The research approach employed in this project is cyclic, non-linear, dynamic and self-investigative. The research process was carried out in three repetitive phases:

(1) Literature Review and Documentation of Case Studies – A number of local (Singaporean) and international case studies of urban spaces have been selected and documented using on-site observational and mapping techniques.

(2) Classification and Evaluation System Development – Based on literature review, a conceptual framework has been developed recognising hardware (design), software (use) and orgware (management) as major conceptual components that shape urban space performance. The framework consists of classification and evaluation systems based on a number of urban space descriptors and evaluators to categorise and evaluate selected urban space typologies, as well as a scoring system and circular chart to visually represent their performances.

(3) Comparative Analysis and Evaluation System Refinement – Comparative analysis of urban space performances primarily involves identifying critical criteria for specific spatial typologies using matching analysis. As synthesis of initial comparative analysis an interactive computational Tool for Urban Space Analysis (TUSA) has been conceptualised, with capabilities to catalogue, classify, evaluate, compare and speculate on hybrid urban space typologies and their performances, by filtering the critical attributes/criteria and design measures, and in such a way guide the initial stage of design process. In order to preserve the objectivity and clarity of proposed criteria, the framework has been tested and refined several times, based on on-site evaluation and comments reported by collaborating teams of architects, urban designers, planners and project managers.

4.1. Documentation of Case Studies

A total of 48 local (Singaporean) and international case studies in high-density contexts, including those from Beijing, Hong Kong, Tokyo, Osaka and New York, have been selected and documented. In selecting the case studies, spaces that are hybrid in form and programme or dense in terms of both spatial density and intensity of use have been prioritised. Case studies range from well-known recreational and residential public spaces to emerging highly hybrid developments and infrastructural spaces. Some of them include: intensified residential developments (such as Shinonome Codan Court in Tokyo; Linked Hybrid and Jianwai Soho in Beijing, etc.), commercial developments (Midtown Tokyo and Roppongi Hills in Tokyo; Sanlitun in Beijing), multi-functional infrastructural spaces (such as railway stations in Tokyo and Osaka) and elevated public spaces (High Line Park in New York; Central Mid-Levels Escalator in Hong Kong; roof-top parks at Pinnacle @ Duxton and Skypark @ Vivocity, Hendeson Wave bridge in Singapore) (Figures 1 and 2).

Figure 1. Hybrid Developments: Shinonome Codan Court, Tokyo, Japan [left], Midtown Tokyo, Japan [middle], Sanlitun, Beijing, China [right]

Figure 2. Elevated Public Spaces: Henderson Wave, Singapore [left], Pinnacle @ Duxton, Singapore [middle and right]

Documentation of each case study was primarily based on structured first-person observational techniques. It involved on-site recording of spatial typologies and features and intensities of uses through mapping, photography and interviewing as well as comprehensive secondary sources review of the design parameters and planning policies, including measures to enhance sustainability capabilities of the larger urban environment, that were difficult to observe on site. (Figures 3 and 4)

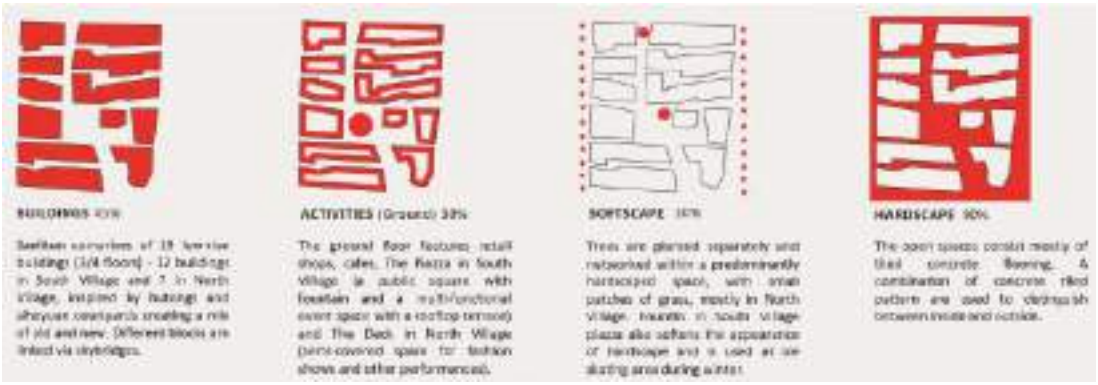

Figure 3. Initial Mapping: Sanlitun, Beijing, China

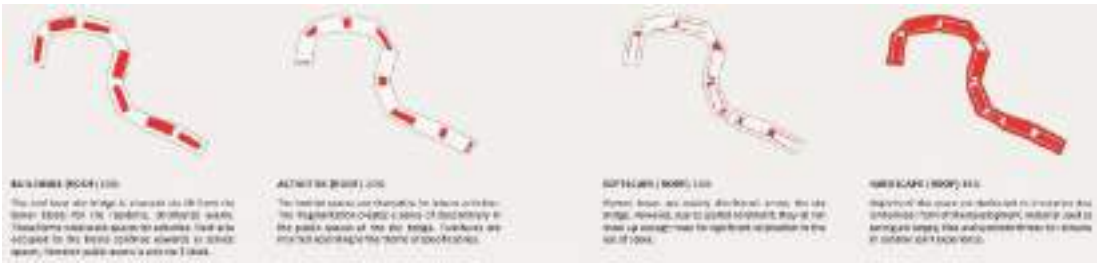

Figure 4. Initial Mapping: Pinnacle @ Duxton, Singapore

Rather than evaluating each selected urban space and recommending design measures to improve its performance, case studies primarily served as a means to test and further refine the research tool, which is the main objective of this project. Such a cycle has been repeated several times, ending with the original urban space framework.

4.2 Research Framework - Classification and Evaluation Systems

Drawing from literature review a conceptual research framework is developed, which recognises three key components that constitute the properties and performances of urban spaces, combining design, use and operational aspects, namely: hardware, software and orgware (Figure 5).

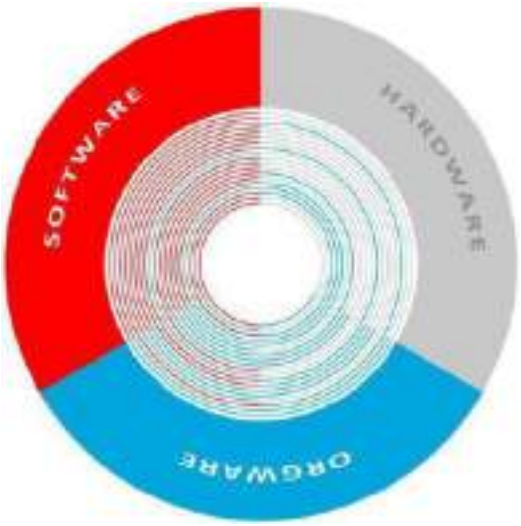

Figure 5. Urban Space Conceptual Framework: Hardware, Software & Orgware

HARDware component refers to physical and geometrical properties of space - design values, such as spatial quality, environmental design, accessibility and users' comfort. SOFTware combines activities, as well as socio-perceptual values of space, such as social interaction, character of space and diversity of uses and users. ORGware refers to operational and management aspects of public space, such as supporting services, security and regulations.

While there is a clear cut between hardware and software components, orgware in certain aspects, such as seating amenities or environmentally friendly strategies, overlaps with both hardware and software. As such, it links the two aspects focusing on how the spaces operate and perform. The research framework consists of Classification and Evaluation Systems.

Classification System

Classification System consists of a number of descriptors and tags that have neither intrinsic positive nor negative value. Their role is to describe urban spaces and classify them into key, secondary and hybrid typologies; to set the basis for in-depth qualitative analysis and comparison between spaces and their components; and to speculate on new hybrid typologies and their properties. All descriptors with their belonging tags are grouped according to hardware, software and orgware categories, some of which are: spatial density indexes, scale, elevation, enclosure (hardware), primary and secondary activities, users' age and gender profiles, subcultures (software), climate context, role, influence, time regulations, and governance (orgware).

Classification system establishes 5 default typologies defined by primary uses of space, namely: residential, recreational, urban centres, integrated mixed developments and infrastructural transit-led spaces. The default sub-typologies are further defined based on forms of urban footprint, which refer to geometry and role of urban space in urban fabric, such as: housing precincts, squares, parks, streets, promenades or bridges (Figure 6).

While the main analysis involves default types of urban spaces, classification system also provides ways to establish secondary typologies and/or their hybrids by selecting descriptors other than primary use and urban footprint. As such, it defies static conventional typologies, in response to emerging more dynamic and transformative new hybrid urban spaces, and provides basis to speculate on new urban space properties and performances.

Figure 6. Default Classification of Urban Space Typologies and Sub-Typologies

Evaluation System

Evaluation System consists of sets of evaluators and criteria that have intrinsic positive value. Their role is two-faceted - to describe and positively evaluate urban spaces. Evaluative Framework is organized hierarchically and consists of: (1) key urban space components (hardware, software & orgware); (2) components consist of 5 urban values, namely: nodal, spatial, environmental, use and socio-perceptual and operational value; (3) each urban value consists of 2 or 3 attributes (13 in total); (4) attributes are further defined by 2-5 Evaluators (46 in total); finally, each evaluator has 2 positive criteria, which makes it 92 in total (Figure 7).

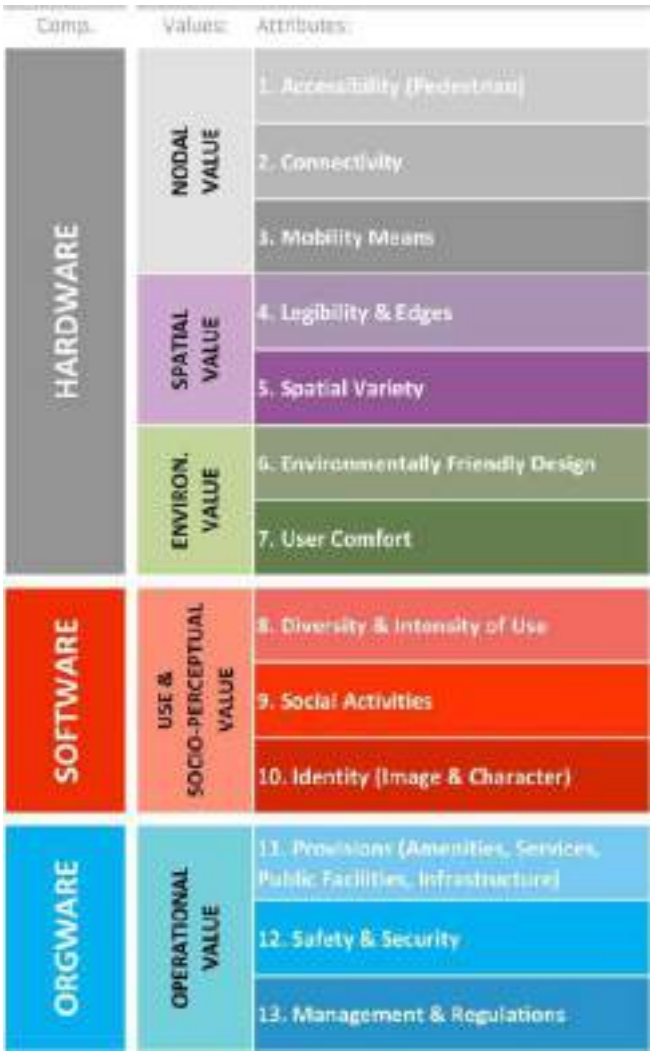

Figure 7. Evaluation Framework – Components, Values and Attributes

Some of the evaluators set by the evaluation system within hardware component are: physical accessibility, number and type of universal access, movement patterns, node connectivity, sightlines and wayfinding, cycling and public transport (nodal value); layout, landmarks, permeability, spatial variety and adaptability (spatial value); greenery and water features, bio-diversity, use of alternative energy, weather protection, shade and sunlight, air quality and noise control (environmental value). Software component and use and socio-perceptual value consist of: number and diversity of activities, number, type and condition of seating amenities, interactivity, privacy, imageability and space character. Some evaluators within orgware component and operational value are hygiene facilities, lighting and informational facilities, community services, safety and security, rules, regulations, and management.

Scoring System

Urban spaces are scored using structured evaluation check-list, which includes all criteria proposed in evaluation system. Space scores 0 if it fails to meet both positive criteria; it scores 1 if it meets one criterion; it scores 2 if it meets 2 criteria. Final scores are cumulative (sum of all met criteria) and form the overall Urban Space Value, which represents the overall performance of space shown in percentage. However, such an overall value is basic and serves for quick comparison only. Along with scoring, additional information on specific design measures that are used to meet particular criteria are also documented to provide the basis for design recommendations.

Circular Charts

To represent the evaluation process and urban space performances, a circular chart is crafted. It is an integrated device that can serve both as an evaluation sheet and a scoring chart. Circular chart is divided into three segments: hardware, software and orgware. The three segments are divided into stripes, each representing one criterion. Coloured stripes are criteria that are met by investigated space. Space's overall performance corresponds to a percentage of coloured stripe area, which is also summarised by the size and percentage of the central black circle (Figure 8).

To enhance visual communication and comparison of space hardware, software and orgware qualitative performances, another circular pie-chart is also crafted. It consists of 2 circles. Outer circle shows performance of space (in %) for each urban space value component. Inner circle (pie chart) shows to what extent each of the components take part in creation of overall Urban Space Value (Figure 8).

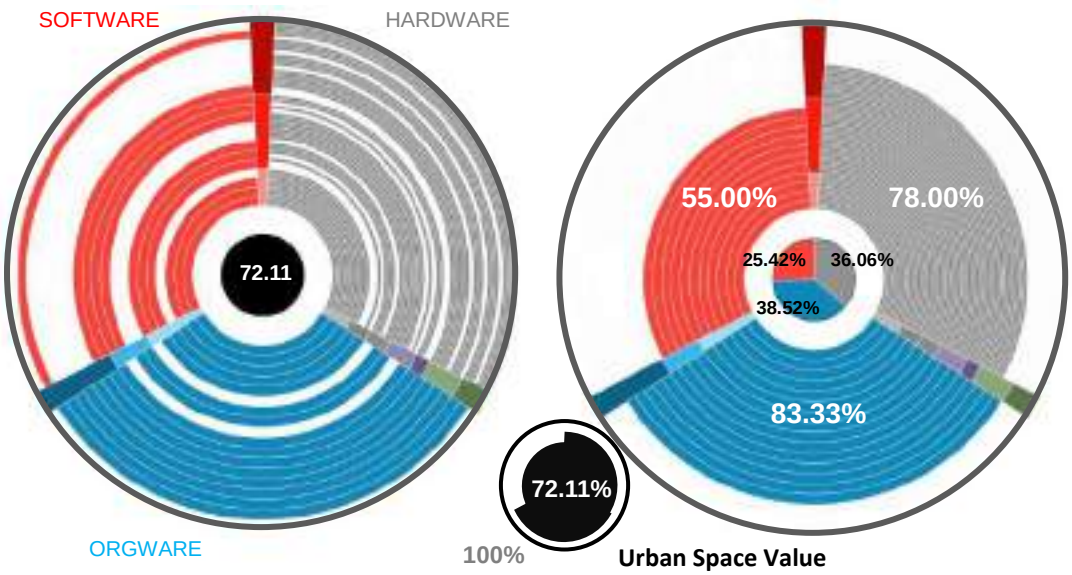

Figure 8. Examples of Circular Chart [left] and Circular Pie-Chart [right]

4.3 Comparative Analysis and Synthesis

After all selected spaces were classified and evaluated, a consistency or matching analysis has been conducted across all types of urban spaces in order to investigate the critical attributes that shape their performance. Based on such analysis a hierarchy of criteria has been established for each type of urban space. It recognises: basic, critical, desired and difficult sets of criteria.

The criteria most consistently met by all urban spaces of the same default type are considered basic or necessary criteria. Those criteria that are never met by all spaces of the same type are considered difficult criteria. Our main focus is on criteria that are most inconsistently met by the majority of spaces of the same default type. We assume that these criteria have the highest corrective factor in terms of overall space performance. The desired criteria are those which are inconsistently but often met by the majority of spaces of the same type. Accordingly, the recommendations for improvement rely primarily on critical and desired criteria, since they are the most feasible to meet by a particular type of urban space, rather than on difficult criteria.

While focusing on spaces that belong to the same default urban space typology, i.e. of the same primary uses, the matching analysis also involves spaces from other default typologies if their secondary uses correspond to that of investigated type of urban spaces. For example, when performing the analysis of primarily residential spaces, the analysis also involves spaces that are not primarily residential yet possess considerable residential activities closely linked to public spaces investigated.

5. Initial Findings – Areas for Improvement

The initial findings show that majority of investigated spaces score highest for hardware component, while software and orgware components seem to be generally weak and leave room for improvements. Yet hardware component can be the most feasibly achieved and thus the criteria belonging to design aspect also play an important role in recommending space improvements. Moreover, more hybrid environments in terms of both spatial complexity and programmes tend to gain higher scores in comparison to more spatially and programmatically homogeneous urban spaces.

Based on matching analysis and critical criteria the initial areas for improving urban space performance have been filtered for each default type of urban spaces. Schematic representation of findings across all default urban space typologies are shown in Figure 9.

Criteria and recommendations that have shown to be the most critical for most of the types of urban spaces are summarised below and illustrated drawing from good examples in data base of case studies. These examples are not limited to only one urban space typology, considering the assumption that with higher densities and intensified uses urban spaces would become more and more hybrid, less

distinguishable and would have to provide more functions for a greater number of diverse user groups.

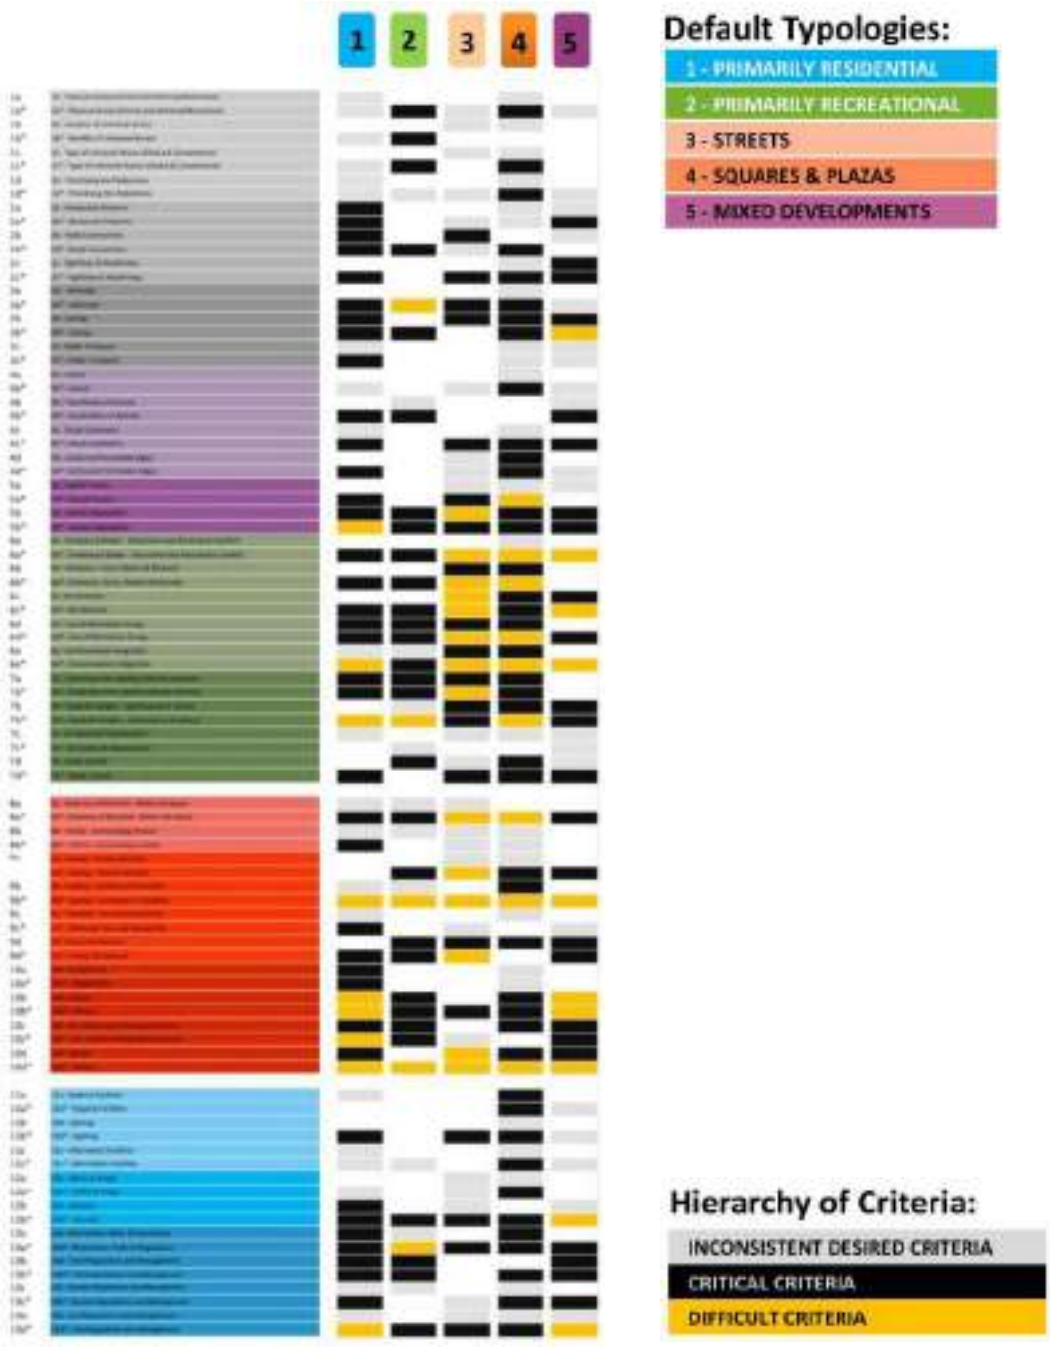

Figure 9. Critical Criteria across Different Default Urban Space Typologies

Spatial Adaptability (hardware)

One of the arias for improvement that has emerged from the analysis and applies to all types of urban spaces, is spatial adaptability within spatial value of hardware component, which refers to an ability of space to adjust to a number of different activities, to be flexible and dynamic in terms of both structure and functional programme in order to increase users' comfort and choice. The examples from New York and Tokyo include flexible and movable seating arrangements, adjustable means of shading and multi-functional spaces (Figure 10). Benefits of achieving structural and programmatic flexibility are multiple, ranging from increment of social interaction, sense of belonging and privacy to increased comfort level regardless the weather conditions, which all refer to strong links between hardware and software components.

Figure 10. Spatial Adaptability – flexible seating and multi-functional spaces: Times Square, NY, US [left], Bryant Park, NY, US [middle], Roppongi Hills, Tokyo, Japan [right]

Greenery and Water (hardware)

Another criterion critical for all default types of urban space is amount and diversity of greenery & water elements within environmentally friendly design attribute. Spaces that well integrate natural elements into physical environment provide better relationship and interaction with and within space, as well as means for users' participation, while also benefiting in better micro-climate, sensory comfort, healing environment, formal and informal community activities, and providing means for education on environmental awareness. Community gardens on the roof-top of Roppongi Hills in Tokyo and interactive water fountains are some of the good examples (Figure 11).

Figure 11. Greenery and Water – interactivity: Skypark @ Vivocity, Singapore [left], Pungol Central housing precinct, Singapore [middle], Roppongi Hills, Tokyo, Japan [right]

Image of Space (software)

Image of space is also critical attribute that seems to be important for the performance of all urban space typologies. Density is more frequently perceived on a subjective level, in terms of legibility, density of information and intensity of use (mess versus order), which can strongly contribute to character of urban space. The examples show ways to improve space character in reference to arts and culture, visual landmarks and interactivity, that have potential to incite creative use of space, users' participation, social interaction, environmental awareness, legibility and wayfinding (Figure 12).

Figure 12. Image of Space – arts and urban furniture: Sculpture Park, Singapore [left and middle], Roppongi Hills, Tokyo, Japan [right]

(Ambient) Lighting (orgware)

Finally, through better night signage and innovative use of self-producing or low-energy-consuming lighting, space may become more inviting and safe environment, with increased legibility and wayfinding, as well as more extensively used during night. This criterion is thus most critical for residential areas and urban centres. Also, this may be particularly interesting for the local context, since Singaporeans seem to use open spaces more intensively once the sun goes down, due to hot and humid tropical climate (Figure 13).

Figure 13. Ambient Lighting: Shinonome Codan Court, Tokyo, Japan [left and middle], Skypark @ Vivocity, Singapore [right]

6. Tool for Urban Space Analysis (TUSA) - Conclusion

As a result of the synthesis and integration of the documentation, evaluation and classification of urban space based on HARD-SOFT-ORG-ware conceptual framework as well as Circular Chart visualisations, an integrated computational tool is conceptualised. The Tool for Urban Space Analysis (TUSA) integrates classification and evaluation systems and has capacities to catalogue, classify, evaluate, compare and speculate on hybrid urban space typologies, their conditions and performances. The visual interface of TUSA consists of four rings, as shown in Figure 14.

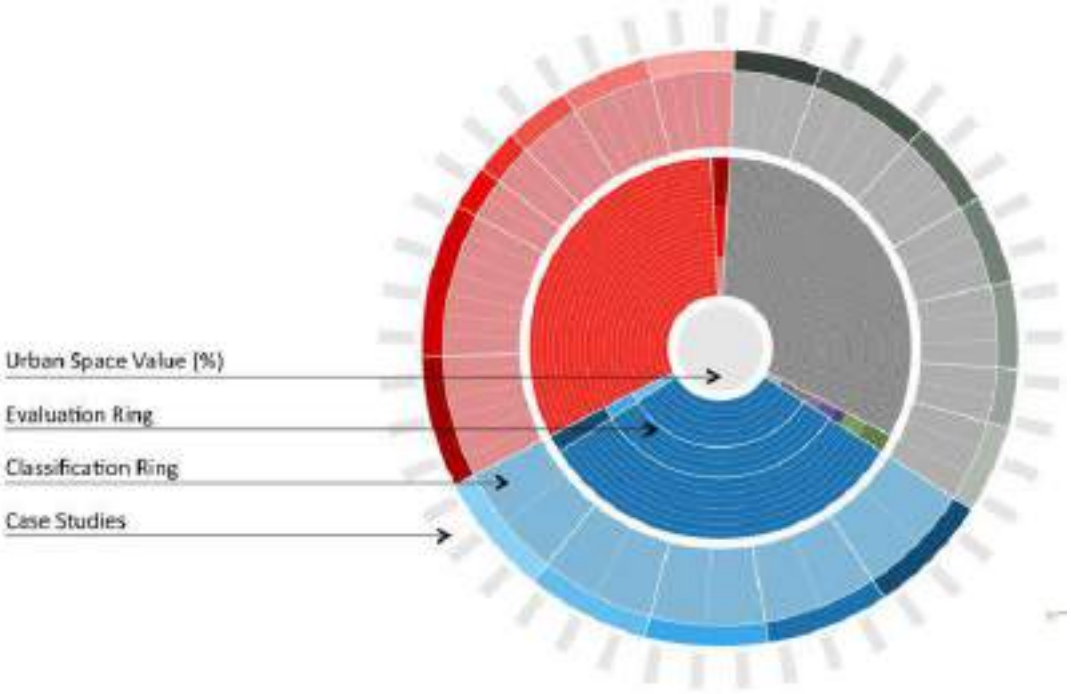

Figure 14. Tool for Urban Space Analysis (TUSA) – visual interface

While the Design Tool integrates an interactive catalogue, classification and evaluation processes, its primary role is in processes of comparison and analysis of urban space performances (as well as generating performance charts), self-evaluation (testing relations between descriptors and evaluators) and speculation on hybrid types of urban spaces and their performances. The tool would thus be helpful in both analysis and guiding the planning and design of urban spaces, drawing from the key attributes of successful urban spaces gathered by the team.

TUSA reflects the research process and analysis employed in this study of urban spaces and is self-evaluative. Additionally, it provides flexible, innovative and intuitive ways of design communication, where any user can define ways of search and analysis. With such capabilities, TUSA is a useful new tool for the study and evaluation of contemporary urban spaces in high density environments.

Acknowledgments

The research discussed in this paper is part of the research project 'Urban Space Planning for Sustainable High Density Environments' conducted at the Centre for Sustainable Asian Cities (CSAC), School of Design and Environment, National University of Singapore, in collaboration with URA (Urban Redevelopment Authority, Singapore), NParks (National Parks Board, Singapore) and HDB (Housing and Development Board, Singapore). The project is funded by the Ministry of National Development (MND), Singapore.

We also acknowledge valuable contributions to this work made by Dr Hee Limin as initial Principal Investigator, Dr Davisi Boontharm, Dr Erwin Viray, Dr Patrick Janssen and Professor Heng Chye Kiang, School of Design and Environment, at the National University of Singapore, as collaborators for the research.

Enhancing the effectiveness of spatial planning processes: the systemic interplay of analysis, visualisation and communication

Agnes Förster, Alain Thierstein

Abstract

Within the last decade, planning literature consistently reports on a gap between the activity of spatial planning and its impact on underlying planning problems. More recently spatial planning in Germany has received unsolicited attention in political circles and from the general public. Large-scale projects like Stuttgart's new underground main station provoked protest movements and calls for a mediation process even after construction had already started. At the same time the national government is cutting subsidies for urban development and demanding the municipalities increase the effectiveness and efficiency of public spending in urban planning.

The design of the planning process is regarded as crucial to the success of spatial planning. Planning theorys' core competence is to provide a knowledge base for the planning process. This paper presents the conception and provisional results of a research project dedicated to investigating the impact of planning methods on the "success" of spatial planning projects. The research project proposes a fundamental approach to the optimization of spatial planning processes' effectiveness. It hypothesises that analysis, visualisation and communication (AVC) are three basic components of planning methods which interact with each other. AVC can be understood as the basic skills set of professional planners that are as yet unequally distributed among the planning discipline's wide range of specialists. Based on the knowledge of the skills' systemic interdependency, more integrated and hence effective ways of their purposeful application in planning practice can be conceived.

The first part of the empirical work in the research project is based on a meta-analysis of multi-disciplinary planning literature between the years 2000-2010. In a multi-stage selection process, 40 international journal articles are chosen that report on the 'successful' application of planning methods that contain AVC in real case spatial planning processes. A profound computer-supported qualitative content analysis helps to identify the methods' major success factors and the associated patterns of AVC interplay. The results of the empirical work are validated in a one-day workshop with experts from planning theory and planning practice in German-speaking countries. Additional semi-structured expert interviews with practitioners help to check the relevance of the findings to today's planning practices in Germany.

The validation supports the importance of the findings to planning practice and education. Our approach is suitable for stimulating cross-disciplinary learning processes on the purposeful design of planning processes. It uncovers and connects the know-how and knowledge on planning methods of practitioners from different disciplinary backgrounds. Making implicit knowledge explicit is a precondition for productive teaching.

Workshop and expert interviews result in three major lessons to be addressed in the coming second part of the research project: 1) deepening the understanding of the 'fundamental particles' AVC and additionally examining the role of framing and conceptualising, 2) elaborating a framework of AVC's impact that also considers the time axis 3) investigating the role of context for the success of the methods, e.g. stakeholders with background knowledge and concerns, organisational structures, financial and human resources, balances of power, legal framework.

1. Introduction

There is a need to enhance the effectiveness of spatial planning. Indeed, current planning literature repeatedly refers to a gap between the activity of spatial planning and its actual impact on spatial development. The survey of planning literature over the last 15 years reveals substantial deficiencies in spatial planning that can be summarized as follows:

Spatial planning's shortfall with regard to complexity and current challenges in actual spatial development. Current challenges include growing scarcity of resources and land use conflicts, spatially significant trends such as mobility and the knowledge economy, generally accumulating complexity of spatial planning's substance, augmented importance of relations and processes in spatial development, or challenges such as the shrinkage of cities and regions (Friedmann 1998; Needham 2000; Altrock, Huning and Peters 2004; van den Berg 2005; Boelens 2006; Breckner 2006; Schönwandt 2006; Friedmann 2007; Schönwandt et al. 2007; Lendi 2008).

Spatial planning's insufficient implementation and target achievement. Planning literature criticises the diminishing steering capacity of public bodies at different spatial scales. There are a growing number of stakeholders that have to be involved. Under these circumstances spatial plans frequently lack feasibility and still await their implementation and target achievement (Archibugi 2001; Informations- und Initiativkreis Regionalplanung der ARL 2005; van den Berg 2006; Schulz 2007, 2007; ARL 2008; Jacoby 2008).

Spatial planning's insignificance, lack of political relevance and awareness. Kunzmann calls strategic spatial planning a secret science without public attention and only a few followers. He observes a growing gap between the planners – those who are professionally involved in planning – and society (Kunzmann 2000). Despite its institutional foundation spatial planning has little political value and is threatened by meaninglessness (Friedmann 1998; Kunzmann 2000; Kegel 2006; Schönwandt and Jung 2006; Lendi 2008; Tschirk 2008).

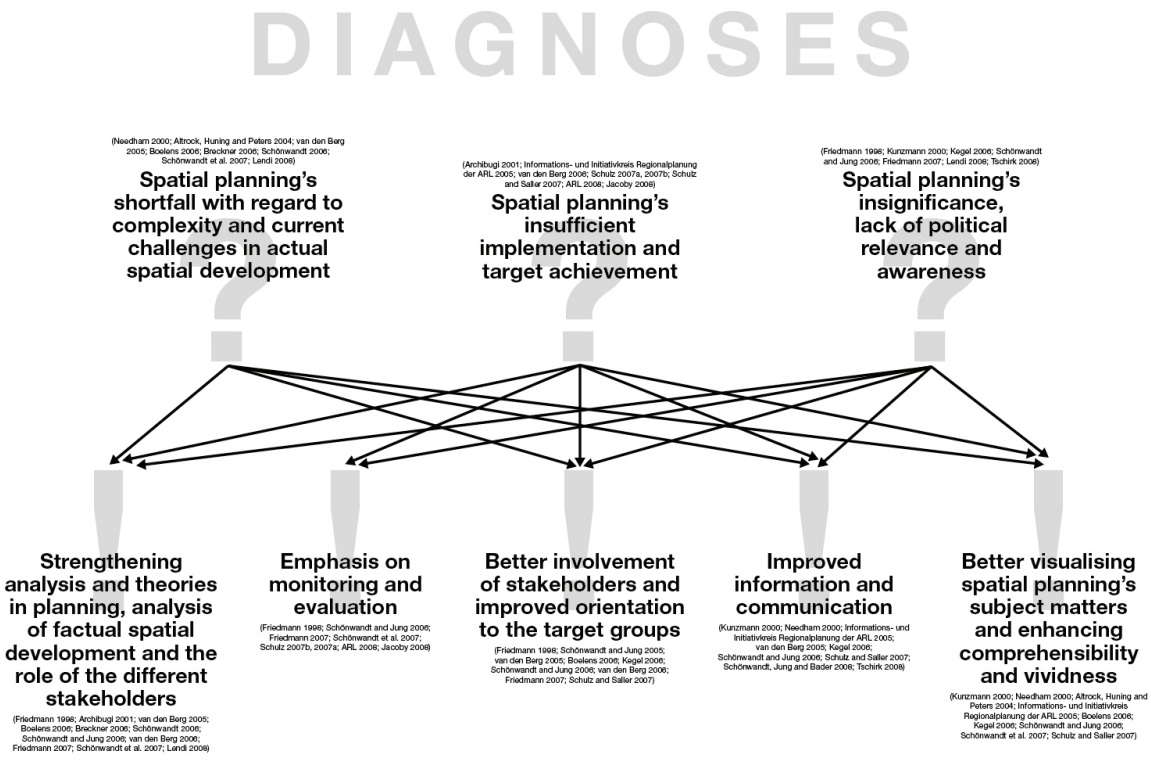

Figure 1: Comparison of diagnoses and recommendations to spatial planning.

Figure 1 shows our schematic overview of diagnoses and recommendations from the literature. Suggestions range from a stronger focus on analysing the factual spatial development and the role of the different stakeholders, to strengthening monitoring and evaluation within spatial planning, to a better involvement of stakeholders and improved orientation to the target groups; finally to better visualising spatial planning's subject matters and enhancing comprehensibility and vividness. The diagnoses open up a broad spectrum of suggestions. The crosslinks between the corresponding skills only become visible in the synopsis beyond the single articles.

"Planning, like most other professions, mobilizes a broad spectrum of skills. (...) The fact that planning calls on many different skills suggests the possibility, that each of these skills could be posited as the centre of planning. Then there would seem to be as many theories of planning as there are types of skilled professionals. This bizarre outcome can be avoided only if we can envisage how these skills work together (…)" (Harris 1999: 322).

Harris' quotation adumbrates the centre of the research project that we will outline in this paper. The project investigates the systemic interplay of three basic skills of spatial planners: analysis, visualisation and communication (AVC). It argues that there is great potential for enhancing the effectiveness of spatial planning when these three skills are knit together in an integrated way instead of further separating them into specialisation and differentiation.

When making planning skills and their effective application in planning practice an object of our investigation, we embed ourselves in an ongoing discourse on the design of planning procedures, planning methods or planning approaches. All three terms will be used synonymously in this paper. We deliberately distinguish planning methods from planning instruments. The latter point at interventions in the – natural, built, social, economic, cultural etc. – environment as the "reality" that spatial planning wants to change or preserve. This is the level of results and products of planning. Planning methods, on the other hand, operate in a preparatory stage to this kind of action. Thus we position this project in parallel to the public dispute on spatial planning in Germany that is currently dominated by themes such as Stuttgart's new underground main station ("Stuttgart 21"), cutting off national subsidies for urban development, angry citizens or energy turnaround. In each of these cases, attention is drawn much more to "how to plan" rather than on "what to plan". Planning procedures that are regulated by law are increasingly regarded as of solving the spatial planning issues at stake. From the planning practice's perspective, legal regulation provides not more than a minimum standard for the complex negotiation processes that are demanded for.

In addition, planning theory acknowledges the planning process as a determining factor in the success of spatial planning. Archibugi (2004) understands planning theory as action oriented analysis that provides a knowledge base for future planning practice. It thus supports the achievement of the goals set within the planning process (Archibugi 2004). Fürst (2006), who comes from the engineering tradition of spatial planning, claims that planning theory should contribute to enhancing the effectiveness of spatial planning in practice (Fürst 2006). Therefore the core competence of planning theory is the planning process (Needham 2000; Archibugi 2004; Fürst 2006; Keller 2006). At the same time authors recognize a lack of knowledge about the planning process that could inform the design of the planning process in practice (Fürst 2006; Keller 2006). The main deficiencies in the research on planning processes are: the predominantly normative approach, the lack of empirical work and the emphasis on single parts of the planning process instead of systems thinking (Huxley and Yiftachel 2000; Needham 2000; Archibugi 2004; Selle 2006, 2006, 2007; Newman 2008).

This research project investigates planning methods primarily from the perspective of the recipient or addressee and only secondarily from the operator or sender perspective. What makes this a useful approach? The project aims to assess the output, outcome and impact of planning methods and the way they contribute to the achievement of the goals of spatial planning projects. As planning is a human activity – carried out by human beings and directed towards human beings – the study of the impact of planning

methods has to centre on the recipients. For this reason planning procedures are intrinsically tied to matters of communication. As planning methods exist in a large, almost unmanageable variety of specifications, the research project investigates the basic skills or building blocks of planning methods. Communication, with its different characteristics, is one basic building block that is part of every planning method. We claim that additionally analysis and visualisation can be regarded as basic skills that form planning methods in their different combinations. The three components of AVC are the non-exhaustive building blocks of spatial planning methods. However, we hypothesise that AVC in their various formations significantly determine the potential impact of planning methods.

The paper firstly introduces the conceptual framework (with its basic definitions) that will be applied within the research project. The AVC approach is then linked to main lines of argument from current research. In the second paragraph we show the results of the first empirical research that is based on the meta-analysis of planning literature. The results are discussed in an expert workshop. Its main lessons are part of the third section. We conclude by outlining preliminary implications for planning research, practice and teaching as well as identifying further need for research.

2. Conceptual framework

The project is based on an exploratory and qualitative research approach. Within a tentative conceptual framework two empirical research modules explore the impact and the interplay of AVC within spatial planning processes. This approach aims to generate hypotheses that can be tested in further research. Our research is guided by a primary research question:

How and to what extent does the integrated application of analysis, visualisation and communication within spatial planning processes support the goal achievement of these processes?

In the following paragraphs we will provide a preliminary definition of our object of investigation and illustrate our understanding of spatial planning process. We base our work on Walter Schönwandt's basic scheme for planning that is part of a "Third Generation" in planning theory (Schönwandt 2002). This basic scheme conceives planning as a systemic cycle in which the "Planning World" is embedded in the "Life World". The "Planning World" includes planners as part of larger "Institutions" that use specific "Approaches" in order to solve spatial problems. The "Life World" has different issues on its "Agenda" set up by the different "Agents" that all together form the "Arena". The two worlds influence each other in a reciprocal manner through a circular process. The individual steps within the planning process split into three steps, that are directly influenced or shaped by the "Planning World", and three steps that operate outside the "Planning World" exclusively within the "Life World". The "Planning World" provides the organisational and theoretical background for the sections called "Comprehension of the Situation", "Elaboration of Instructions", and "Communication of Behaviour". The "Life World" contains the stages "Interventions", "Setting" and "Outcomes" (Schönwandt 2002) (see figure 3).

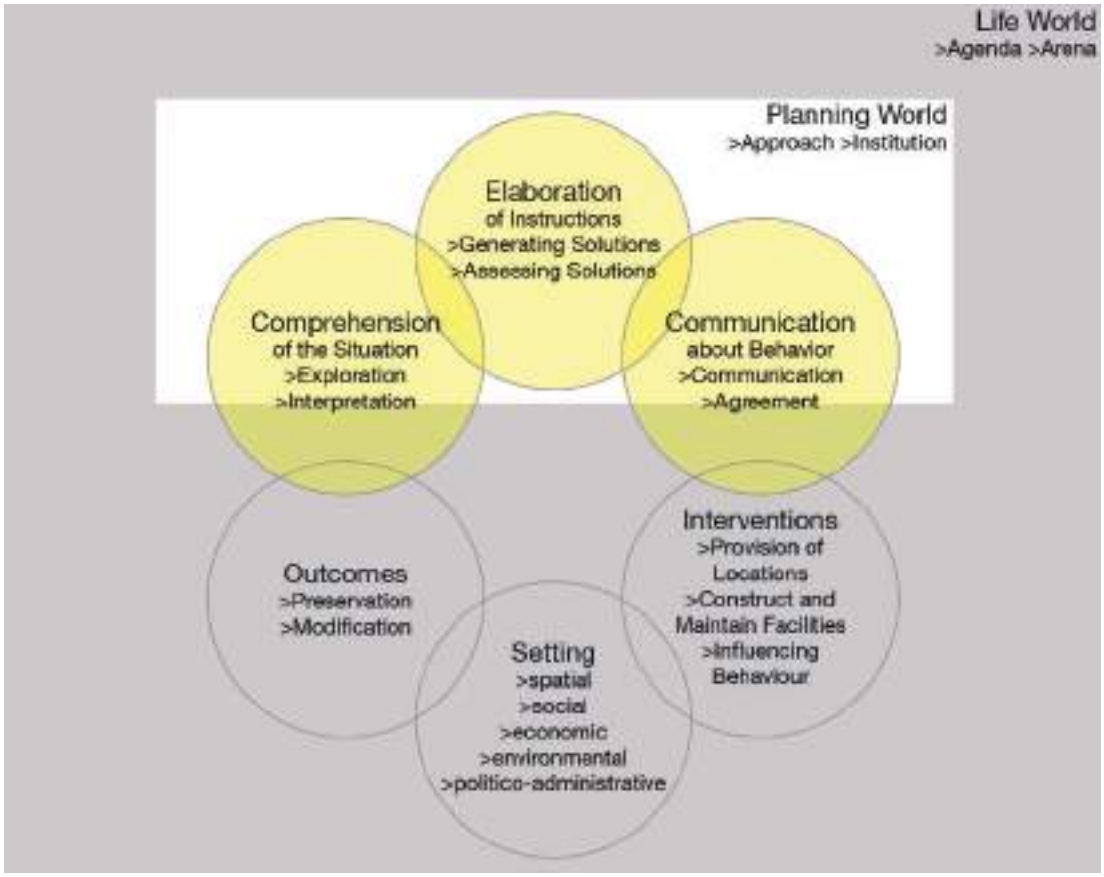

Figure 2: Walter Schönwandt's basic scheme for planning, the three stages that are directly influenced and shaped by the "Planning World" are emphasised in yellow (Schönwandt 2002, author's adaption).

Communicative planning methods

In our research project, this basic scheme for planning is a useful way to contextualize planning methods and their respective outcomes and impact within the circular planning process. We understand planning methods in a broad sense as the procedures that are applied within the three stages "Comprehension of the Situation", "Elaboration of Instructions", and "Communication of Behaviour" in order to work out the expected results of these steps. Planning methods are initiated, shaped and influenced by the "Planning World". We distinguish planning methods from planning instruments or "Interventions" that are to be implemented in the real world (Hübler 2005).
