Farming and organic food. Engaging in Farming activities themselves was a major driven for some rural incomers. They enjoyed planting vegetables and flowers, raising livestock and pets. One returnee (case ID: 222) shared, 'I come to enjoy the feeling of the softening change in soil and the sweating process from physical work on fields'.

Cheaper living expense and bigger space. For some rural incomers, purchasing or renting spacious and nice house in a megacity is financially unfeasible, whereas similar properties are more affordable in accessible rural areas. Due to the lack of high-end commercial facilities in the rural hinterland, overall living expense can be significantly reduced.

Enjoying the process of refurbishment and making their own home. Many incomers took pleasure in refurbishing old rural houses and creating gardens, activities that provided them with 'a sense of achievement' (case ID: 157) or helped them 'fulfil their garden dreams' (case ID: 510). Some professional social media posters can even generate economic benefits by sharing their refurbishment experience.

Caring for household members, including children, parents, or pets. Some rural incomers relocated mainly because they want to take good care of their household members, for example, living with their elderly parents—a more specific situation in China culture, providing happy, free and safe grow-up environment for kids and pets. One tenant expressed that she rented a rural mountain house after retirement mainly for the safety for her 13 dogs (case ID: 161).

Proximity to workplace or entrepreneurship opportunities. With the diffusion of employment such as factories moving to more suburb areas, some workers chose to rent house in nearby villages. Besides, young civil servants were encouraged by China government to stay in a village for several years. Additionally, some people who prefer rural life move to scenic villages to find ways to support themselves financially and fulfil their personal needs. Nostalgic attachment. For some people who were born and grown in the countryside they may have one kind of nostalgic feeling about rural life, such as the garden of their childhood house. Even when renting a house in a different rural area closer to their workplace, these individuals may create similar garden spaces to evoke familiarity and a sense of security. As one tenant reflected, 'when I was a child born and grown in the countryside, living in my own rural house with fields, I dreamed of tall buildings. But after growing up, working in a high-rise and on busy street, I came to realise that what I truly long for is the garden from my childhood' (case ID: 238). In Chinese culture, there is a traditional term, ye luo gui gen, which translates to 'falling leaves settle on their roots'. One tenant interpreted this as, 'as long as you know where you are from, you will not be afraid of how far you go' (case ID: 632). In this case, many individuals invest in refurbishing and prepare their rural home for retirement life.

4.2.3 Moving in

The village populated by rural incomers often has good transportation linkages and natural resources, as noted in section 4.1.1, although the availability of specific amenities varies depending on their proximity to cities. Metropolitan rural areas generally can benefit from enhanced infrastructures, such as direct bus service or metro connection to city centre, accessible kindergartens and primary schools, and convenient links to major transportation hub like railway stations and airports. The village size can even reach 1,000 households (case ID: 18). While rural incomers in remoter countryside also find it convenient to use the facilities in nearby towns. However, there are some rural tenants relocate to extremely remote mountain villages—consisting of a few households and lacking basic public infrastructure—in pursuit of pastoral seclusion (case ID: 231). But what in common is that most local long-term residents in the villages are elder population.

Rural incomers include both families and singles (Table 11). And rural tenants either rented a whole house or just a flat with one bedroom, one kitchen and one toilet. The tenancy contract varied from several months or years to 10 or 20 years. Both tenants—typically holding leases of over ten years and renting entire houses—and most

returnees undertook significant refurbishment work before or after moving in. The most expensive refurbishment case among returnees is ¥880,000 (case ID: 614) covering all renovation work, furniture and appliance. In comparison, expenditure among tenant is ¥600,000 (case ID: 159) associated with a 15-year tenancy.

Table 11 Household members of rural incomers

	Families	Families with children	Alone	Blank	Grand total
Tenant	8	5	28	101	142
Returnee	3	1	7	54	66
Grand total	11	6	35	155	208

Regarding move-in dates, recorded instances of counterurbanisation migration (Figure 5) began in 2020 for both returnees (12 complete cases) and tenants (22 complete cases) with an increase in entries during 2023 and 2024.

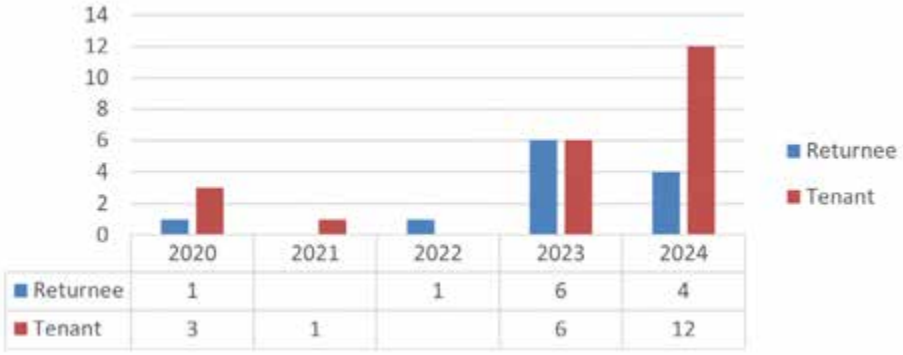

Figure 5 Recorded move-in dates of rural incomers

4.2.4 Post-move satisfaction

Generally, it shows a high level of satisfaction for rural incomers moving to or back to rural areas (Table 12), as identified by ChatGPT through the content analysis of social media posts.

For example, one tenant (Case ID: 463) shared a rural house with others in Shanghai metropolitan area and had lived there for half a year. This individual enjoyed exploring nearby nature areas, such as foraging for edible wild herbs in spring. At times, they found it hardly to believe they were still within the boundary of Shanghai—despite the presence of a metro station near the village. This person even expressed, 'I truly feel like a human being in the countryside, rather than merely a tool used for work in the city centre'.

Table 12 Post-move satisfaction levels of rural incomers

	Very Good	Good	Neutral	Bad	Very Bad	blank	Grand total
Tenant	29	20	10	3	76	4	142
Returnee	16	5	5	1	/	39	66
Grand total	45	25	15	4	76	43	208

Based on 45 valid cases, the cross-analysis results (Figure 6) generally reveal a consistently high level of satisfaction, regardless of the duration of stay in countryside. But rural incomers with longer duration of stay often have a more discreet attitude towards relocating to the countryside, recognising the effort required to adapt and maintain rural life.

For example, one returnee (case ID: 575) worked online and had moved back for 4 years mainly for the children to have a happy childhood. This person did not feel regret but warned that 'no matter where you live, it requires efforts for better living environment'. This returnee spent two years refurbishing the property, primarily working alongside family members. The renovation work was relatively costly due to larger size of a rural house. Moreover, cultivating seasonal vegetables is not an easy work, as it requires both physical efforts and self-directed learning about planting techniques and storage methods.

	days	weekend	seasonal	several months	half a year	one year	two years	three years	four years
Very bad				2					1
Bad								1	
Neutral	1			3		2			1
Good	1	1		4	1	2			1
Very good	2		2	7	5	5	1	2	

Figure 6 Cross analysis of Post-move Satisfaction and General duration of stay

However, some incomers had expressed concerns that contrast with their 'imagined rurality'. These includes the safety concern for living alone in a village, displacement when the demolishment required by the government happens, bad landlord or uncomfortable feeling to live with the landlord, bad living and hygienic conditions, poor employment opportunity, bad public transportation, unfair service fee required by village council and the like.

For example, one tenant (case ID: 6) rented a rural house for 10 years to escape from the noisy in city centre when she was trying to have a baby. She became regret soon and realised that she did not enjoy the 'imagined' rural lifestyle—activities such as planting vegetables and flowers, picking fruits and playing in the river. And she found herself uncomfortable with the insects and frogs there. After her baby was born, she had less time to use the garden of the house and were more concern about the hygiene condition for her baby. She had lived there occasionally for four years and found herself in a dilemma: she no longer wished to return yet could not bear to leave the house behind that she had so carefully built.

5 Discussion

5.1 Findings compared with existing literature

Recorded counterurbanisation migration in China presented to be in its early stage. Different from patterns observed in some western countries, currently most rural incomers in China were concentrated in 'a metropolitan area's "daily urban system"' (Robert and Randolph, 1983)—typically refers to areas located around 50km away from city centre requiring 1-1.5 hrs of travel by car or bus based on this research—and very few cases were recorded in remote countryside. Although identified counterurbanisation cases were found in the most developed areas in China, this research highlights the broader presence of counterurbanisation across general south and east of China—revealing many instances that have not yet been reported in existing literature. Additionally, apart from typical family rural incomers, single tenants or rural house shares were also observed in various areas.

Current research on migration motivations of counterurbanisation in China emphasizes tourism related activities, potentially influenced by China's Rural Revitalization Scheme initiated in 2017. However, this study identifies

a significant number of cases involving rural returnees and tenants moving to the countryside for long-term residential purpose. Besides, individuals of rural origin are particularly inclined to invest in refurbishing their home rural houses preparing for retirement life. This tendency is shaped by the unique context of permanent yet unpurchasable rural land rights—covering both residential plots and farmland—as well as by culture norms of returning to one's hometown in old age. And the opportunity to cultivate vegetables on the land attached to the rural house has emerged as a major motivation for rural incomers. Similarly, rooted in anti-urbanisation sentiments, the concept of 'imagined rurality' is also the key factor motivating individuals moving to the rural hinterland. Although most incomers reported a high level of post-move satisfaction regardless of their duration of stay, some expressed regret or adopt a more cautious stance towards rural relocation.

5.2 Social media data source

Monitoring migration trends between urban and rural areas in China has been challenging due to the lack of formal migration records. The social media platform, XiaoHongShu, has proved to be a valuable data source supporting both geographic overview of counterurbanisation and specific rural relocation cases, despite its limitations—particularly data being restricted to certain groups of population and inconsistent sample size across thematic analysis, which complicate comparisons. As with other incomplete data sources such as case study, the primary guidance for using social media data in research is to acknowledge the presence of certain phenomenon—such as various counterurbanisation movement examined in this study—rather than making quantitative comparison between different groups or regions. For instance, while it is valid to conclude that residential counterurbanisation has emerged in certain parts of China, it would be inaccurate to claim that most reverse movement in China is driven by residential motives. In addition, most recorded cases are isolated and lack of interconnection, making it difficult to identify the broader implication of counterurbanisation in specific rural contexts. Detailed case studies and fieldwork are therefore essential for a more comprehensive understanding.

5.3 AI-based processing methods

As noted in section 2.3, the primary concerns for AI-based processing methods include result accuracy, ease of use, and time efficiency compared to manual processing.

Although ChatGPT-generated results demonstrated almost 90% accuracy during pilot testing, the remaining 10% inaccuracy posed challenges for researchers, creating an uncertainty about which part of the output is reliable and which are not. While this sense of uncertainty must be acknowledged, researchers had come to recognise that ChatGPT-generated outputs should not be treated as a settled final result, but rather provisional data that requires a little further validation and interpretation. For example, there are several occasions when the researcher had to revisit the original data to correct errors made by ChatGPT. Corrections often had implications for earlier stage of analysis. Nevertheless, this iterative process was ultimately deemed acceptable. Besides, since the original data in this research is in Chinese, ChatGPT's limited proficiency with Chinese language posed more challenges for accurate processing. AI models such as DeepSeek, which are primarily trained on Chinese data, are expected to yield higher accuracy over generated results. But technical issues with DeepSeek's batch API service in early 2025—when the model gained widespread popularity—prevent this hypothesis from being tested.

As for ease of use, AI tools like ChatGPT currently are evolving to offer more user-friendly experience and interfaces. Batch scripts usually will be provided and hardly require any prior knowledge for coding. Alternatively, these tools can function as a professional data processor, enabling users to input their requirements and receive interactive, tailored, outputs—potentially improve the accuracy of results.

The primary advantage of AI tool is its time efficiency. For example, in this study, coding each social media post required an average of 10 min. With around 650 original posts, this amounts to 6,500 min—or more than 100 hrs—of labour-intensive and tedious work, equivalent to nearly half a month of full-time effort base on an 8-hour workday. Errors are still likely to occur, although potentially at a lower frequency. By contrast, when using AI models, a single click can process entire dataset in under 10min. Despite the risk of inaccuracy, rough results can be considered acceptable within a certain fault tolerance threshold. Achieving higher accuracy just need several

days of data cleaning and refinement.

5.4 Counterurbanisation in China

Despite the limitation of available data, counterurbanisation in China is beginning to take shape, with a growing number of urban residents opting for rural lifestyle. Given the general underdeveloped and population decline in China's rural hinterland, this tendency of reverse migration presents a significant opportunity for future rural revitalisation. However, some levels of Chinese government still exhibit a bias against the countryside, preferring to concentrate the rural residents to facilitate more convenient infrastructure provision. For instance, one tenant (case ID: 33) expressed high satisfaction with the five months of rural life but was compelled to leave due to the government's planned demolition of the village. In addition, rural tenants often face the challenge of independently locating a suitable house and negotiating rental terns with landlords. Rural housing has the potential to be a new growth driver of the real estate industry. Even though China government may uphold current rural land rights system—which prohibits land purchases—in order to maintain the societal stability, there remains room for the formalisation of rural tenancy. Such reforms could help safeguard the rights of both tenants and landlords, thereby encouraging more people moving to depopulated villages and fostering mutual beneficial outcomes. Future research could focus on potential inequity issues—such as housing affordability, gentrification and displacement—that may arise as the counterurbanisation trend progresses in China. It is also important to develop an appropriate framework that both encourage rural in-migration and mitigates associate challenges.

6 Conclusion

Counterurbanisation is an inclusive and useful concept for understanding the reverse migration from cities to the countryside. When comparing the Chinese context with western patterns, Chinese scholars have debate on how to classify migration flows—whether as counterurbanisation or failed urbanisation. There is also discussion about how these flows relate to similar concepts such as suburbanisation, deconcentration.

Despite ongoing debates, this research identified a significant number of rural incomers using social media data from XiaoHongShu platform. These include both returnees moving back to their home village and tenants renting rural houses, mostly in metropolitan rural areas within 50km or 1-1.5 hrs of travel from a city centre. Overall, counterurbanisation in China exhibits a widespread occurrence in general South and East China with several hot spots in Yangtze River Delta region (Shanghai, Zhejiang, Jiangsu), Beijing, Chengdu (Sichuan), Dali (Yunan).

Many of the observed cases represent long-term in-migration particularly for residential purpose, rather than short-term stay associated with rural tourism. Recorded rural incomers display a high degree of diversity, in terms of employment status, household composition and migration motivations. Given that counterurbanisation often involves very individualised decision, these incomers typically are driven by a range of motives: 'escaping' from cities and shifting to (imagined) 'rural life', farming and organic food, cheaper living expense and bigger space. enjoying the process of refurbishment and making their own home, caring for household members including children, parents and pets, proximity to workplace or entrepreneurship opportunities, and nostalgic attachment. Some of these factors are particularly rooted in Chinese context regarding rural land rights and traditional culture, such as returning to live with elderly parents, preparing a rural house for retirement, seeking pastoral seclusion in extreme remote villages. Most of these individuals reported a high level of post-move satisfaction regardless of the duration of their stay—some dating back to 2020.

Social media data source and AI-based processing methods like ChatGPT AI model were proven to be a reliable and efficient way for monitoring and accessing counterurbanisation trend in China.

Counterurbanisation in China appears to be in its early stage. Rural incomers face several challenges, including the risk of government-planned demolition of their living village, and, for rural tenants, the difficulty of locating a suitable rural house and dealing with landlords. Further research is needed to better understand the implications of counterurbanisation in China and developed an appropriate framework that both encourages more in-migration and prevents potential issues.

Unraveling the relationship between the digital platforms and gentrification: Evidence from Nanjing, China

Qianhui He

Abstract
Information-driven digital platforms are reshaping urban and social space, often intensifying gentrification. Using Nanjing (2019-2024) as a case, we combine Beike second-hand housing transactions with Weibo check-ins to map community gentrification stages, applying spatial autocorrelation, cluster and regression analyses. Gentrification correlates strongly with check-in density: commercial cores, tourist spots and university districts form "high-high" clusters, while peripheral zones remain "low-low". Check-ins by non-locals, KOLs and KOCs exert greater influence than those by residents. Algorithmic "discursive investing" turns informational capital into place branding, attracting investors and accelerating change. These findings highlight digital platforms as new engines—and amplifiers—of urban inequality, calling for governance that regulates platform algorithms and protects spatial justice.

Keyword: gentrification-digital platforms-Social Media Check-ins; SHAP

Introduction

Gentrification was initially used to describe the socio-spatial transformation in inner-city London, where the middle class moved into declining working-class neighborhoods, revitalised the physical environment, and established residential enclaves(Glass, 1964). Over the past half-century, research on gentrification has expanded from its early focus on class displacement in urban neighborhoods of Western Europe and North America to encompass narratives of socio-spatial change across the Global South and broader urban-rural contexts. The "planetary gentrification" (Shen et al., 2018) theory posits that gentrification has become an inevitable experienced phase in global urban development, emphasizing the need to examine its processes across diverse geographical, economic, political, and cultural settings worldwide. In the context of the informatised city, many scholars have begun exploring the relationship between geo-media(Hartmann and Jansson, 2024), urban mediatisation(Törnberg and Uitermark, 2022), digital platforms(Shan et al., 2023), and planetary gentrification. Against the backdrop of accelerating global digital transformation, platform capitalism is reshaping the logic of urban spatial production through location-based services (LBS). Traditional gentrification studies emphasize the linear relationship between physical space renovation and class displacement but overlook the hidden power of digital platforms in shaping spatial perception through information flows.

China, as the world's largest social media application market, sees platforms like Weibo and Douyin generating over 500 million daily location tags. Social-consumption platforms such as Weibo, Dianping, and Xiaohongshu are reshaping the visibility and appeal of urban spaces through algorithmic recommendations and user-generated content. These platforms not only alter consumption patterns but also invisibly accelerate the demographic and landscape reconfiguration of specific neighborhoods, creating a new transmission chain of "digital footprints-spatial value-capital flow." Against this backdrop, this study takes Nanjing as a typical case to reveal the relationship between platform activities, user behavior, and gentrification, offering a new perspective for urban research in the Global South context.

Digital Platforms and Gentrification

Currently, Western scholars have begun exploring the relationship between gentrification and digital platforms, including social media platforms, lifestyle service platforms, and the sharing economy. Concepts such as platform capitalism and mediated narratives of gentrification have emerged as key theoretical tools for understand-

ing gentrification in the new era. On one hand, cities and capital have always been deeply intertwined. Digital platforms have shifted capital's exploitation of urban space from explicit domination to implicit discipline. Through algorithmic "black box" operations and discursive construction, urban spaces are commodified as "idle" resources to facilitate capital accumulation. On the other hand, digital platforms reshape the terrain of identity formation. The middle class utilises these platforms as stages to showcase their aesthetic preferences, attracting like-minded groups and fostering spatial clustering. This leads to a more subtle form of cultural isolation and social segregation, where exclusion occurs under the guise of digital connectivity.

2.1 Digital Platform "Discourse" and Spatial Representation

Digital platforms possess the capacity to frame urban spaces as consumable commodities or investment opportunities, constructing specific discourses that shape spatial representation and attract capital to facilitate spatial valorisation. Törnberg et al. examined the portrayal of Vidigal across diverse media platforms-such as YouTube, Airbnb, and Flickr-demonstrating how these platforms strategically reimagined the neighborhood from a stigmatised, impoverished, and hazardous area into a dynamic space brimming with opportunity. By accentuating its "heterogeneity" and "authenticity," these platforms effectively drew in tourists, new residents, and investors. Consequently, new residential and commercial developments gradually eroded local cultural heritage and transformed community structures, accelerating the area's gentrification(Törnberg and Uitermark, 2022). Similarly, Erika Polson's case study of Denver's RiNo Art District analyzed the interplay between graffiti, Instagram, and gentrification. The study argues that social media platforms are reconfiguring the production, aesthetics, and consumption of graffiti and street art. The viral dissemination of Instagram imagery has repurposed street art as a tool for enhancing neighborhood cultural capital, making its commercial potential visible to upper-middle-class residents and investors. This process ultimately attracts capital inflows, further accelerating gentrification (Polson, 2024).

In a critical examination of Instagram and Facebook posts related to Brisbane's West End, Walters highlights the hegemonic influence of social media in constructing immaterial yet highly symbolic spatial narratives. The study contends that digitally mediated placemaking tends to obscure the complex, lived realities of communities, effectively erasing the socio-spatial diversity that originally constituted the neighborhood. This erasure indirectly facilitates gentrification by promoting a sanitised, marketable version of urban space. Real estate developers and marketers leverage social media platforms to rebrand and promote urban districts, selectively curating images and content that align with an idealised urban lifestyle-trendy cafes, boutique stores, fitness studios, and other aspirational commercial activities. These representations reinforce the upscale aesthetics of gentrifying neighborhoods, further aligning them with the tastes of affluent newcomers (Walters and Smith, 2024).

2.2 Platform User Identity and Gentrification

Digital platforms have fostered new modes of "consumption" and "leisure" that emphasize personalised experiences, cultural tastes, and identity formation. Within this framework, the middle class leverages social media to express their identity and social status, attracting like-minded groups to specific locations. This process influences neighborhood reputation, rent, and housing prices, ultimately driving gentrification. For instance, Zukin conceptualise user reviews on Yelp as a form of "discursive investing," where reviewers deploy their cultural capital through critiques, showcasing their tastes and preferences. These digital expressions attract consumer groups with similar socioeconomic backgrounds, shaping the developmental trajectory of entire neighborhoods and accelerating their restructuring and gentrification (Zukin et al., 2017). Platforms such as Yelp, TimeOut, and Eater further reshape consumers' geographical imaginations through user-generated content (reviews, descriptions, and ratings), influencing culinary and spatial aesthetics. By promoting certain local food cultures, these platforms attract new residents and investors-often at the expense of long-term residents and indigenous community culture, thereby hastening displacement and gentrification. Irene Bronsvoor's case study of Amsterdam's Javastraat district illustrates how social media platforms serve as stages for affluent groups to construct lifestyles and assert status. Through their online activities, these actors reinforce their social prestige and cultural capital, actively shaping the street's developmental direction. In doing so, they not only reflect but also amplify and reconfigure the dynamics of middle-classification, further entrenching gentrification processes (Bronsvoort

and Uitermark, 2022).

2.3 Digital Platforms and the Marginalisation of Vulnerable Groups

The technological barriers inherent in digital platforms, combined with profit-driven algorithmic content distribution mechanisms, may inadvertently contribute to the marginalisation of vulnerable populations and exacerbate social segregation. This phenomenon manifests in two primary dimensions. Firstly, digital technologies can function as exclusionary mechanisms that restrict access to specific urban spaces. For instance, coworking spaces (CWS), while ostensibly designed as shared work environments, effectively operate as exclusive domains for the "mobile elite." Through financial barriers, technological requirements, and access control systems (e.g., keycard entry), these spaces systematically exclude individuals "deemed unworthy," transforming ostensibly public platforms into high-end venues catering specifically to global network elites. These spaces thus serve triple functions: as consumption sites for elites, mobility hubs for privileged professionals, and networking nodes for exclusive social circles (Fast, 2024). Secondly, the profit-oriented nature of platform capitalism leads to algorithmic mechanisms that disproportionately prioritise young, affluent demographic groups with significant consumption potential. Berglund et al.'s study of digital platforms in Detroit's downtown gentrification process reveals how platform algorithms contribute to the social isolation of elderly populations. Their research demonstrates that promotional materials on digital and social media platforms predominantly target young professionals - exemplified by initiatives like the "live downtown" campaign designed to attract this demographic to urban centers. These platform-mediated place-marketing strategies typically present sanitised, aesthetically enhanced urban imagery tailored to younger sensibilities, which may unintentionally intensify the marginalisation of vulnerable groups (particularly elderly residents) while accelerating downtown gentrification processes. This dual dynamic of technological exclusion and algorithmic bias creates a self-reinforcing cycle where platform-mediated urban development increasingly caters to privileged groups while rendering vulnerable populations increasingly invisible in both digital and physical urban spaces (Berglund et al., 2022).

In conclusion, a growing body of evidence demonstrates that user-generated content on lifestyle service platforms and social media, coupled with platform capitalism-driven discourse construction and algorithmic operations, significantly impacts neighborhood reputation, investment patterns, and demographic shifts, ultimately influencing community restructuring and gentrification processes. However, substantial research gaps remain in this field. Current discussions on digital-era gentrification predominantly remain at the level of theoretical speculation or fragmented case studies of individual communities. Existing research has primarily relied on field investigations and small-sample data from specific neighborhood cases to examine digital platforms' influence on gentrification, while neglecting macro-level analysis of how platform-generated check-in popularity and content differentially affect communities at various stages of gentrification, with a notable lack of large-scale, longitudinal data support and systematic analysis. To address these research gaps, this study selects Nanjing's main urban area as a case study. By integrating multi-source platform data from 2019 to 2024, we aim to establish a multidimensional gentrification impact factor system. Incorporating machine learning and other quantitative methods, we will investigate how check-in popularity on digital platforms influences gentrification processes, thereby providing a more comprehensive understanding of platform-mediated urban transformation mechanisms.

3.Methods

3. 1 Study Area and Data Sources

This study focuses on the main urban area of Nanjing City, Jiangsu Province, China, which comprises 600 neighborhoods (as shown in Figure 1). As a major provincial capital undergoing rapid urbanisation and digital transformation, Nanjing represents an ideal case for investigating the impact of digital platforms on gentrification processes. The research utilises two primary data sources: Beike (China's largest real estate transaction platform) and Weibo (one of China's most influential social media platforms). Specifically, we collected 37,974 property transaction records from Beike covering the period 2019-2024 within Nanjing's main urban area. These records contain detailed transaction information including neighborhood location, transaction date, average price, and floor area, as well as property characteristics such as building age, floor area ratio, and green space ratio. Con-

currently, we obtained 693,638 geotagged check-in records from Weibo during the same period, each containing precise longitude and latitude coordinates, venue categories, user-generated content, engagement metrics (including reposts, comments, and likes), and user profile information (including followings, followers, gender, and IP addresses). This comprehensive, multi-source dataset provides a robust foundation for examining the mechanisms through which digital platforms influence urban gentrification.

Figure 1. The area of central Nanjing

3.2 Gentrification Measurement Methodology

In China's socioeconomic context, where residential property values serve as the primary indicator of household economic status (with real estate constituting approximately 70% of average household assets), the transaction volume of secondary housing markets provides an empirically valid measure of actual residential mobility patterns within urban neighborhoods (Shan et al., 2023). Based on this conceptual framework, our study employs property transaction data from the Beike platform to construct a multidimensional gentrification assessment system through three specifically designed indices: (1) the Average Social Stratification Index (ASSI), which quantifies neighborhood-level socioeconomic composition through property value distributions; (2) the Fixed Property Index (FPI), measuring physical asset appreciation while controlling for structural characteristics; and (3) the Value Change Index (VCI).

(1) Average Social Stratification Index (ASSI)

Based on the average transaction prices and floor areas of housing transactions in Nanjing in 2019, we first categorised the average transaction prices of properties in the main urban area of Nanjing into five tiers using the quintile method (Table 1). Through weighted summation, we obtained the community social stratification index. Given that housing constitutes the most significant household asset in China, this index can reflect the average economic-social stratification within each community. The formula is:

$$ASSI_i = \sum_{k=1}^{5} k \cdot P_{ki}$$

where k represents the weighting coefficient for each tier, with assigned values of 1 (less than 2 million CNY), 2 (2-4 million CNY), 3 (4-6 million CNY), 4 (6-8 million CNY), and 5 (greater than or equal to 8 million CNY). Pki denotes the percentage of properties in each tier within a given community.

Table 1. Property classification

Level1	Below 2 million CNY
Level 2	2-4 million CNY
Level 3	4-6 million CNY
Level 4	6-8 million CNY
Level 5	Above 8 million CNY

(2) Fixed Property Index (FPI)
The Fixed Property Index (FPI) is designed to measure whether the average household asset composition within a community exceeds Nanjing's 2019 average level. Using the mean TASSI (Total Average Social Stratification Index) of Nanjing's main urban area in 2019 as the benchmark, this index evaluates the relative asset level of communities within the city's central districts.The calculation formula is:

$$FPI_i^{2019} = \frac{ASSI_i^{2019}}{TASSI^{2019}}$$

Where:ASSI_i2019 represents the ASSI value of individual communities in 2019;TASSI_2019 denotes the aggregate ASSI value of all communities in Nanjing during 2019

(3) Value Change Index (VCI)
The Value Change Index (VCI) measures the transformation in household asset composition across communities between 2019 and 2024. By comparing the relative change in community-level ASSI to the citywide TASSI during this period, this index isolates gentrification-driven social replacement from general market fluctuations. The formula is expressed as:

$$VCI_i = (ASSI_{i2024}/ASI_{i2019})/(TASSI_{2024}/TASSI_{2019})$$

Where:
ASSI_i2019 and ASSI_i2024 represent the ASSI values for individual communities in 2019 and 2024 respectively.
TASSI_2019 and TASSI_2024 denote the aggregate ASSI values for all Nanjing communities in the corresponding years.

Finally, the gentrification stages of communities in Nanjing's main urban area were determined based on their FPI and VCI values, with specific classification criteria as shown in Table 2.

Table 2. Gentrification Stage Classification Criteria

Ungentrified	FPI2019< 1 and VCI < 1, set Gentri-type = 0;
Gentrifying	FPI2019< 1 and VCI > 1, set Gentri-type = 1;
Gentrified	FPI2019>1 and VCI < 1, set Gentri-type = 2;
Re-gentrifying	FPI2019> 1 and VCI > 1, set Gentri-type = 3;

3.3 Selection of Influencing Factors
Digital footprints have been empirically demonstrated to provide early-warning signals for urban gentrification processes. The "check-in" popularity on social media platforms, visitor demographics, and spatial distribution patterns exhibit strong coupling with neighborhood value reassessment and consumption upgrading (Chapple et al., 2022). In the Chinese context, Weibo's advantages - including its massive user base, real-time information flow, and geotagging features - have made it widely adopted for studies on urban vitality and public space utilisation. This study systematically constructs Weibo check-in independent variables across three dimensions:

check-in popularity, user demographics, and location characteristics.

Table 3. Independent Variables

Dimension	Variable ID	Variable Name	Mean
Neighborhood Check-in Popularity	X1	Total number of Check-ins	1170.15
	X2	Total interactions of Check-ins	14861.55
	X3	Total reposts of Check-ins	1592.56
	X4	Total comments of Check-ins	3157.81
	X5	Total likes of Check-ins	10111.19
Neighborhood Check-in User Demographics	X6	Normal user check-ins	927.50
	X7	KOC check-ins	203.47
	X8	KOL check-ins	39.18
	X9	Female check-ins	711.21
	X10	Male check-ins	458.94
	X11	Nanjing resident check-ins	398.74
	X12	Non-Nanjing resident check-ins	771.41
Neighborhood Check-in Locations	X13	Check-ins at residential locations	266.11
	X14	Check-ins at commercial locations	341.02
	X15	Check-ins at workplace locations	93.27
	X16	Check-ins at university locations	77.71
	X17	Check-ins at public service locations	62.67
	X18	Check-ins at parks	59.08
	X19	Check-ins at tourist attractions	95.21
	X20	Check-ins at cultural & sports venues	58.80
	X21	Check-ins at public transportation facilities	45.99
	X22	Check-ins at other locations	41.145

3.4 Local Bivariate Moran's I

To characterise the spatial coupling between Weibo check-in activity and different gentrification stages at micro-scale levels, this study employs the local bivariate Moran's index to detect spatial associations between these variables. The computational formula is:

$$I_i^{XY} = z_{x_i} \sum_{j=1}^{n} w_{ij} z_{y_j},$$

Where:

$z_{xi} = (x_i - x-)/s_x$ and $z_{yj} = (y_j - Y)/s_y$ represent standardised residuals of gentrification stage values and Weibo check-in counts respectively;w_{ij} denotes row-standardised spatial weight elements.

3.5 Random Forest Model

Given the multiclass categorical nature of the dependent variable, this study employs a Random Forest classification model (Breiman, 2001) as the primary analytical framework. As an ensemble tree-based learning algorithm, the Random Forest classifier comprises multiple decision trees, each constructed through bootstrap sampling of observations and random feature selection from the dataset. This non-parametric model demonstrates particular strengths in handling high-dimensional, multiclass data with complex nonlinear relationships,

while exhibiting superior generalisation capacity and robustness against overfitting - characteristics that have led to its increasing adoption in urban studies(Deb and Smith, 2021; Kim, 2022). The model was implemented using Python's scikit-learn library, with the dataset partitioned into training and testing subsets at an 80:20 ratio. Model performance was evaluated using standard classification metrics including accuracy and F1-score on the test set. To ensure model stability and reproducibility, hyperparameter tuning and validation were conducted through 5-fold cross-validation.

3.6 Shapley Additive Explanations (SHAP)

To elucidate the operational mechanisms and relative importance of predictive factors in gentrification classification, this study incorporates SHAP (SHapley Additive exPlanations) for both global and local interpretation of the trained Random Forest model (Lundberg and Lee, 2017). Grounded in cooperative game theory and Shapley value principles, SHAP provides a theoretically-grounded framework for quantifying the marginal contribution of each feature to model predictions. This approach not only yields feature importance rankings but also reveals the directional effects (positive/negative) of specific feature value ranges on classification outcomes, thereby effectively demystifying the "black box" nature of Random Forest models and enhancing overall interpretability. All modeling and visualisation procedures were implemented in Python 3.7, utilizing established open-source libraries including scikit-learn for machine learning, pandas for data manipulation, matplotlib for visualisation, and the specialised shap package for model interpretation.

4.Results

4.1 Spatial Distribution of Gentrified Communities in Nanjing

The main urban area of Nanjing comprises 600 communities, which were classified into four categories based on our indicator calculations: 107 non-gentrified communities, 246 communities undergoing gentrification, 155 gentrified communities, and 92 re-gentrified communities. The results demonstrate that most regenerated communities in Nanjing exhibit varying degrees of gentrification. The gentrified and re-gentrified communities are predominantly concentrated in several key areas: Jianye District, the old urban areas of Gulou and Qinhuai Districts, the riverside areas of Pukou District, the Southern New City of Jiangning District, and the eastern Zijin Mountain area of Qixia District. These areas correspond precisely with recent government-led urban redevelopment projects, including the urban renewal initiatives in Gulou District and Qinhuai old town, as well as new urban developments such as the Hexi New City in Jianye District, the core area of Jiangbei New District, Southern New City, and Zidong New District.

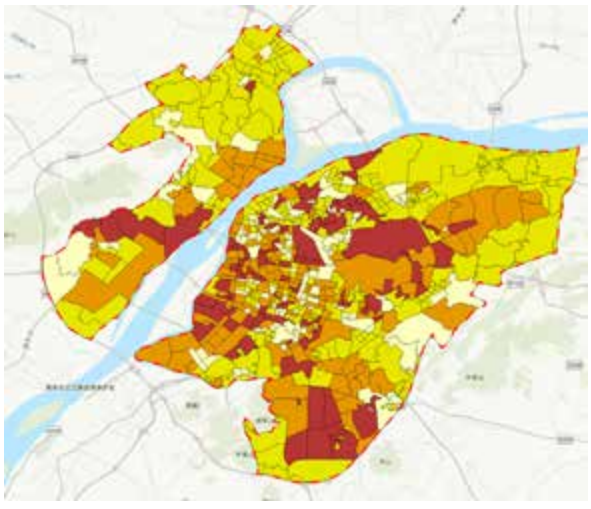

Figure 2: Gentrification Stages in Central Nanjing

4.2 Local Bivariate Moran's Index Analysis

The research findings reveal a significant spatial correlation between the gentrification index of communities in Nanjing's main urban area and the popularity of check-in activities on social platforms. Distinct spatial clustering patterns emerge: "high-high" agglomeration is observed in communities surrounding commercial centers, central business districts, tourist attractions, and university towns, while "low-low" agglomeration characterises peripheral urban areas. This spatial association demonstrates the close relationship between digital platform activities and urban gentrification processes, particularly in areas undergoing rapid urban transformation and redevelopment.

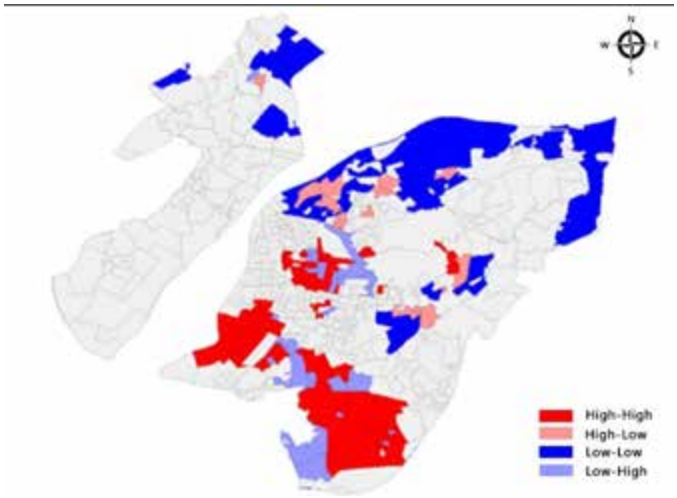

Figure 3: Gentrification Stages in Central Nanjing

4.3 Regression Results

To comprehensively evaluate the model's discriminative capability for identifying community gentrification stages, this study employed a dual analytical approach. First, we constructed Receiver Operating Characteristic (ROC) curves (Figure 4) and calculated the Area Under Curve (AUC) values for each classification category. The results demonstrate an average AUC≈0.68, indicating that the model exhibits reasonable feasibility in distinguishing communities at different gentrification stages.

For deeper insight into the key variables influencing gentrification stage evolution, we computed SHAP values from the trained multiclass Random Forest model and generated both global (Figure 5) and class-specific feature importance Pareto charts (Figures 6a-d). These visualisations present the hierarchical ranking and cumulative contribution of variables across all samples and for each of the four gentrification types, with detailed cumulative contribution rates provided in Table 4.

The analysis reveals three key findings regarding variable contributions: (1) Overall community check-in popularity metrics (X1-X5) demonstrate the highest explanatory power, accounting for 39.58% of cumulative contribution; (2) Neighborhood check-in user demographics (X6-X12) show moderate influence at 35.8%; while (3) Neighborhood check-in location characteristics (X13-X22) exhibit relatively minimal impact at 24.62%. This pattern underscores the predominant role of community check-in popularity in gentrification processes, particularly for communities in the ongoing and completed gentrification stages. Conversely, the specific types of check-in locations appear to exert comparatively weaker effects on gentrification dynamics.

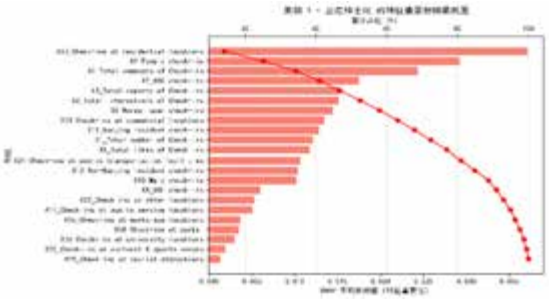

Figure 6-b. Pareto chart of feature importance for gentrifying stage

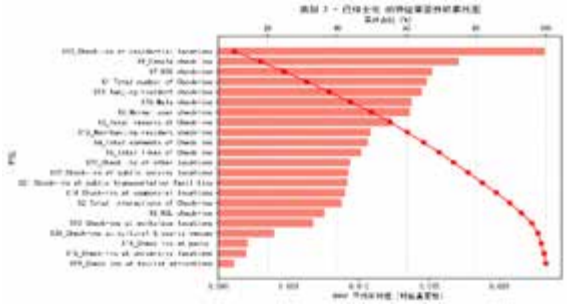

Figure 6-c. Pareto chart of feature importance for gentrified stage

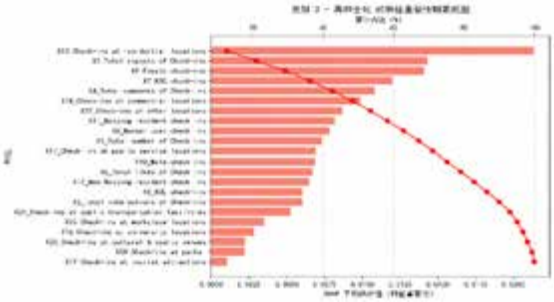

Figure 6-c. Pareto chart of feature importance for re-gentrifying stage

Table 4. Precision and Recall Values of the Random Forest Model

Stage of Gentrification	Neighborhood Check-in Popularity (X1–X5)	Neighborhood Check-in User Demographics (X6–X12)	Neighborhood Check-in Locations (X13–X22)
Average	39.58%	35.80%	24.62%
Ungentrified	35.79%	38.13%	26.08%
Gentrifying	46.72%	34.22%	19.06%
Gentrified	37.68%	35.82%	26.50%
Re-gentrifying	42.54%	32.65%	24.81%

To elucidate the specific mechanisms through which different variables influence model outputs, this study conducted interpretability analysis using SHAP value distribution plots (Beeswarm Plots) for the classification models of four gentrification stages, with results presented in Figures 6a-d. Each plot displays the SHAP value distribution of variables for the respective category, where the horizontal axis represents the marginal effect of each variable on model output, and the color gradient indicates the magnitude of variable values. Comparative analysis reveals significant differences in variable effect mechanisms across distinct gentrification stages.

The analysis reveals distinct patterns in the marginal effects of Weibo check-ins across different gentrification stages. Notably, check-in activities demonstrate predominantly negative marginal effects in non-gentrified and ongoing gentrification areas, while exhibiting significantly positive effects in gentrified and re-gentrified communities.

In ungentrified and gentrifying neighborhoods, model predictions primarily rely on variables including female user check-ins (X9), commercial location check-ins (X14), interaction metrics (e.g., X3 reposts and X4 comments),

and residential area check-ins (X13). The SHAP values for these variables predominantly cluster near zero, indicating relatively moderate influences on model outputs. Nevertheless, these patterns suggest that lower female activity and weaker commercial engagement represent key characteristics of non-gentrified areas. Overall, these communities exhibit distinctive features of limited platform engagement, low social interactivity, and predominantly residential space utilisation.

For gentrified areas, the discriminative factors concentrate on residential area check-ins (X13), female user check-ins (X9), Key Opinion Consumer (KOC) check-ins (X7), and total check-in volume (X1). These variables reflect high-frequency, targeted social activity patterns, indicating these areas have developed mature "internet-famous" attributes. Additionally, check-ins by Nanjing local residents (X11), male users (X10), and content dissemination metrics like reposts and comments demonstrate significant influences, suggesting synergistic effects between online reputation and local participation in reinforcing community stability.

Re-gentrified areas display complex, multi-source participation characteristics. Decision-making incorporates not only traditional factors like residential check-ins (X13), reposts (X3), and female check-ins (X9), but also variables such as KOC check-ins (X7), comments (X4), and commercial location check-ins (X14). This broad participation spectrum indicates that after one or multiple rounds of redevelopment, these areas have evolved into urban spaces characterised by diverse user coexistence and complex dissemination mechanisms. The more dispersed SHAP values and varied effect directions reveal higher dynamism and diversity in re-gentrified areas, potentially featuring composite social nodes that combine both consumption power and community cohesion.

5.Conclusion

This study pioneers an analytical approach that integrates multi-platform data from Beike and Weibo with interpretable machine learning models, establishing a behavioral-oriented research paradigm for understanding urban gentrification in the digital era. The findings yield significant theoretical contributions by demonstrating that social media engagement patterns - particularly check-in frequency and interaction levels - exhibit strong correlations with neighborhood gentrification processes. Notably, the activities of female users, Key Opinion Consumers (KOCs), and local residents exert disproportionately greater influence on gentrification dynamics compared to other demographic groups. The analysis further reveals that gentrification stages show the strongest association with check-in intensity in residential compounds and commercial districts.

The study elucidates how digital capital transcends spatial-temporal constraints to commodify urban space through platform-mediated mechanisms. Algorithmic governance structures guide social media users to anchor textual and visual content to specific physical locations through geotagging practices. This process of 'discursive investing' systematically attracts socioeconomically homogeneous groups and investors to targeted neighborhoods, thereby accelerating gentrification through subtle, digitally-mediated pathways. These insights necessitate critical policy considerations: urban governance frameworks must incorporate the impacts of high-engagement digital activities on community transformation, particularly regarding demographic restructuring and emerging gentrification landscapes. Concurrently, regulatory interventions should address platform algorithms and content curation to mitigate inter-neighborhood disparities and advance spatial justice in platform urbanism.

While this research provides macro-level evidence through the analysis of Weibo check-in data in Nanjing, the complex mechanisms of platform-driven gentrification warrant further investigation. Future studies should incorporate multi-dimensional data streams (including textual comments, visual imagery, and mobility traces) from representative urban contexts to more comprehensively capture the logic of digitally-mediated spatial reproduction. Particularly crucial is examining the symbiotic relationship between algorithmic recommendation systems and commercial capital accumulation in shaping gentrification outcomes. Such inquiries would strengthen the theoretical foundations for platform governance and equitable urban policy frameworks in the digital age.

Abstract
City Information Modeling (CIM) has emerged as a digital extension of Building Information Modeling (BIM), enabling integrated representations of urban systems through 3D spatial data, semantic modeling, and temporal dynamics. While its potential aligns with the digital transformation of cities, CIM research remains fragmented by conceptual ambiguities and limited practical implementations. This paper addresses these gaps through a dual-method approach: (1) a PRISMA-BSMS-based systematic literature review of 159 CIM-related publications indexed in Scopus, and (2) an empirical case study applying UAV-based photogrammetry to generate a neighborhood-scale 3D model for Emniyettepe, Istanbul. By integrating bibliometric analysis with a UAV-to-CIM workflow, the study aims to bridge theory and application, offering insights into scalable, cost-effective, and replicable city modeling strategies for planning and research.

Keywords: City Information Model; City Information Modeling; bibliometric analysis; systematic review; PRISMA; Drone.

Introduction

By providing a digital paradigm that expands the capabilities of Building Information Modeling (BIM) beyond individual buildings to the city scale, City Information Modeling (CIM) has become a game-changing strategy for managing urban complexity. CIM, which has its roots in the combination of 3D geometry, semantic information, and temporal data, makes it easier to visualize, simulate, and coordinate urban elements in a single digital environment. Unlike traditional GIS platforms that primarily represent spatial data in static layers, CIM enables dynamic, object-based modeling that can support real-time analysis, stakeholder interaction, and lifecycle planning.

This shift toward integrated urban informatics positions CIM at the intersection of architecture, planning, computer science, and geospatial technologies. It incorporates data from Geographic Information Systems (GIS), remote sensing, BIM, and urban sensors while embedding social, economic, and environmental dimensions into city models. Accordingly, CIM is increasingly linked to discourses on smart cities, resilience, and data-driven urbanism, promising to enhance urban governance, infrastructure management, and participatory planning.

Yet, despite growing scholarly interest, CIM remains underdeveloped in both conceptual clarity and practical deployment. Existing literature is often fragmented—ranging from semantic data models and technical ontologies to simulation tools and design case studies—without convergence toward a standardized methodology. Furthermore, real-world implementations, especially at the neighborhood or district scale in developing contexts, remain scarce. This is largely due to high entry costs, challenges in integrating heterogeneous datasets, and the absence of open-access, scalable tools tailored to CIM.

By providing a digital paradigm that expands the capabilities of Building Information Modeling (BIM) beyond individual buildings to the city scale, City Information Modeling (CIM) has become a game-changing strategy for managing urban complexity. CIM, which has its roots in the combination of 3D geometry, semantic information, and temporal data, makes it easier to visualize, simulate, and coordinate urban elements in a single digital environment.

Building on this potential, the study follows a dual methodology. First, it conducts a systematic literature review using the BSMS (Bibliometric Analysis, Systematic Review, Meta-Analysis, and Storytelling) process, urban research–specific adaptation of the PRISMA framework. This step maps the evolution, themes, and gaps in CIM-related research. Second, it presents a field-based case study in Emniyettepe Neighborhood, Istanbul, where UAV

photogrammetry is deployed to generate a localized CIM dataset and propose an adaptable workflow for future urban applications.

By bridging theory and practice, the study aims to inform both academic discourse and practical planning, contributing to the operationalization of CIM as a planning and design tool in diverse urban contexts.

Background and Theoretical Context

In order to facilitate the integrated modeling of urban systems, the interdisciplinary invention known as City Information Modeling (CIM) combines the fields of architecture, urban planning, geospatial science, and digital technology (Kolbe, 2009; Batty, 2007). CIM is a city-scale framework that uses semantically enhanced 3D models to visualize and manage urban form, infrastructure, and socio-environmental dynamics. It is theoretically and technically derived from Building Information Modeling (BIM). The capacity of BIM to manage the lifetime of buildings has led to its widespread adoption in the architectural and construction sectors; however, CIM extends this power by using layered spatial, temporal, and relational data to depict complex urban settings.

Buildings, roads, vegetation, and utilities are modeled as interactive entities with defined behaviors and attributes in CIM, in contrast to traditional Geographic Information Systems (GIS), which usually handle spatial datasets in a layered and frequently static manner. This method enables CIM to serve as a simulation and decision-support environment in addition to a geographic database. It may facilitate planning interventions, resilience strategies, infrastructure management, and public involvement through scenario modeling and digital twins.

In academic literature, CIM has been increasingly positioned within the larger framework of smart cities and urban digital transformation. Scholars have investigated the use of CIM in energy modeling, flood risk analysis, mobility optimization, heritage conservation, and sustainability evaluations. Gil et al. (2019), Biljecki et al. (2020), and Xue et al. (2022) are among the studies that emphasize the integration of CIM with cutting-edge technologies like blockchain, artificial intelligence (AI), the Internet of Things (IoT), and extended reality (XR) (Kitchin and Thrift, 2009). As a modeling tool, CIM may now be used as an operational platform for real-time urban management thanks to these interfaces.

Nevertheless, several critical challenges continue to limit the operationalization of CIM. These include:

1. The absence of widely accepted standards and workflows for CIM implementation;
2. The technical and conceptual difficulty of integrating multi-source and multi-scale datasets;
3. A lack of CIM-specific software ecosystems relative to the maturity of BIM platforms;
4. Expensive and technically difficult data collection techniques, such as satellite imaging and airborne LiDAR.

Despite the growing capabilities of UAVs and open-source modeling tools, existing literature lacks well-documented and replicable workflows that demonstrate how such data can be integrated into CIM frameworks at fine-grain scales. Most published examples focus either on theoretical frameworks or large-scale city-level models, often overlooking neighborhood- or district-scale implementations that are essential for detailed planning analysis.

This gap underscores the need for studies that not only evaluate the conceptual landscape of CIM but also present grounded methodologies for urban planners and designers. Addressing this need, the current study integrates a systematic literature review with an empirical UAV-based case study to offer a structured and replicable CIM workflow suitable for localized applications.

Methodology

This study applies a dual-method research design that combines a systematic literature review based on the BSMS process and a field-based UAV photogrammetry case study in Istanbul.

• Systematic Review Method (PRISMA-BSMS)

To investigate the current state of research on City Information Modeling (CIM), this study employed the BSMS review process—an urban-planning-specific adaptation of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework (Page et al., 2021; Abusaada and Elshater, 2022; Elshater and Abusaada, 2022). The BSMS process enhances traditional review methodologies by incorporating:

1. Bibliometric analysis to quantify research output and trends;
2. Systematic review to identify themes and conceptual models;
3. Meta-analysis to detect methodological patterns;
4. Storytelling to frame the insights within urban and planning discourse.

The search was conducted in May 2024 using the Scopus database, chosen for its wide coverage of peer-reviewed literature and its compatibility with bibliometric tools. The query focused on terms such as "City Information Model," "City Information Modeling," and their plural and alternate spellings. The search string used was:

TITLE-ABS-KEY("city information model") OR TITLE-ABS-KEY("city information modeling") OR TITLE-ABS-KEY("city information models")

The inclusion criteria were articles, conference papers, books, and chapters; publications in English; and relevance to CIM as a modeling, planning, or design approach. A total of 159 documents published between 2009 and 2024 were identified. The full dataset was exported for analysis and cleaned to eliminate duplicates and irrelevant entries.

• Bibliometric and Thematic Analysis

To analyze the structure and evolution of City Information Modeling (CIM) literature, bibliometric and network visualization tools were employed to extract quantitative patterns and semantic associations from the selected corpus. Two primary software tools were utilized: VOSviewer (version 1.6.18) for keyword co-occurrence and author co-citation analysis, and CiteSpace (version 6.3.R4) for temporal and structural mapping of citation networks, keyword centrality, and cluster evolution.

The bibliographic data retrieved from Scopus—including titles, abstracts, author keywords, and indexed keywords—served as the foundation for this analysis. A thesaurus file was developed by the authors to standardize terminologies and merge synonymous terms (e.g., "CIM," "City Information Model," and "City Information Modelling" were unified under "City Information Modeling"). This step was essential to minimize fragmentation in keyword frequency and ensure consistency across the dataset.

For VOSviewer, a minimum occurrence threshold of five keywords was applied to filter the dataset and focus on terms with sufficient network weight. This threshold yielded 42 valid keywords. The software then generated a network visualization based on co-occurrence link strength, allowing identification of clusters that reflect thematic groupings in the literature. A similar threshold was applied for author co-citation analysis, using a citation count of 30 as the minimum threshold for inclusion.

CiteSpace was employed to assess the structural significance of keywords using centrality and degree metrics. The analysis was based on a g-index with a scaling factor of k=25 to balance citation volume and influence. This tool enabled the detection of pivotal keywords that serve as conceptual connectors between research themes, as well as the identification of burst terms and citation turning points that suggest emerging directions in the field.

Results and Discussion

• Publication Trends and Growth

The Scopus database had 159 papers about City Information Modeling (CIM) from 2009 until the middle of 2024,

according to the bibliometric study. Peer-reviewed journal articles, conference proceedings, book chapters, and review papers are all included in this corpus, which shows how academic interest in CIM has grown over the last ten years. Figure 1 shows the number document count for the 159 documents by year, see figure (1).

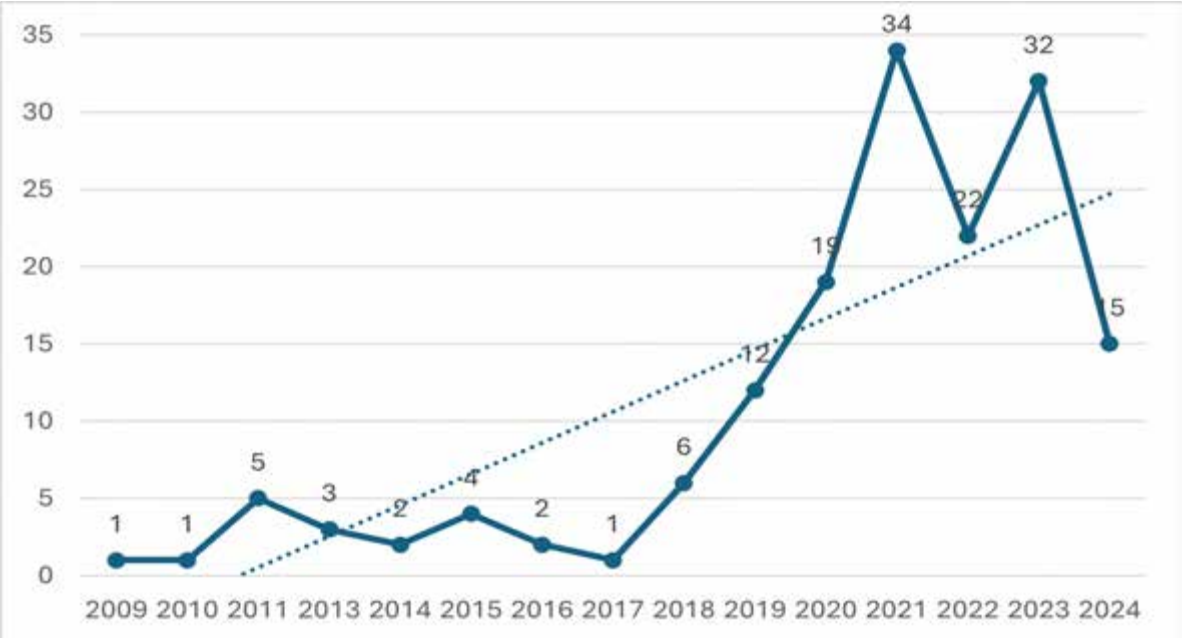

Figure (1): The document count for the 159 documents.

2009 was the first publication that was known to exist, and there was no rise in 2010. The number of publications increased 400%, or a high pace, from one to five in 2011. Following that, the trend experienced cyclical swings. 2013 had a 40% decrease, 2014 saw a little rebound, and 2015 saw a 33% fall. Interestingly, after a huge jump in 2018 (500% growth), the publications doubled in 2019 at a 100% growth rate. In 2021, 34 publications were released, a 79% increase over the year before. In 2022, there was a 35% decrease after this.

The number of publications as of mid-2024 indicates a preliminary 53% decrease from 2023. As more documents are indexed, this number is anticipated to alter by the end of the year. The average yearly growth rate for the examined time is almost 83%, if 2024 is excluded as an incomplete year. This indicates a persistent and growing interest in CIM, fueled by developments in digital twins, smart cities, and urban informatics.

• Geographical and Disciplinary Distribution

The geographic distribution of the 159 publications reveals a broad international interest in City Information Modeling (CIM). China leads the research output with 42 documents, followed by the United Kingdom and Portugal. These figures highlight the active engagement of both Eastern and Western academic institutions in advancing CIM scholarship. The prominence of China may be attributed to its parallel leadership in urban digitization, smart cities, and geospatial technology, while European contributions reflect strong ties between academic research and spatial planning practices.

In terms of disciplinary focus, the analysis reveals that Engineering and Computer Science dominate the subject areas. This suggests that CIM is still strongly rooted in technical and computational research, particularly in areas such as data modeling, digital infrastructures, and software development. However, substantial contributions from the Social Sciences and Environmental Science also point to an evolving interdisciplinary trajectory. These include topics like stakeholder engagement, participatory planning, and sustainable urban development—indicating a gradual integration of CIM into planning and policy-making discourses.

CIM's twin function as a technology platform for data integration and an urban planning decision-support system is reflected in this interdisciplinary collaboration. Because of this, scholars from a wide range of disciplines are coming together more and more around CIM to address issues of governance, resilience, and spatial justice in modern cities in addition to enhancing modeling accuracy.

• Citation Performance and Impact Indicators

The 159 documents retrieved from Scopus generated a total of 1,160 citations, underscoring the growing academic interest in CIM. When self-citations are excluded, the total citation count stands at 974, indicating substantial external engagement and cross-disciplinary relevance, see figure (2).

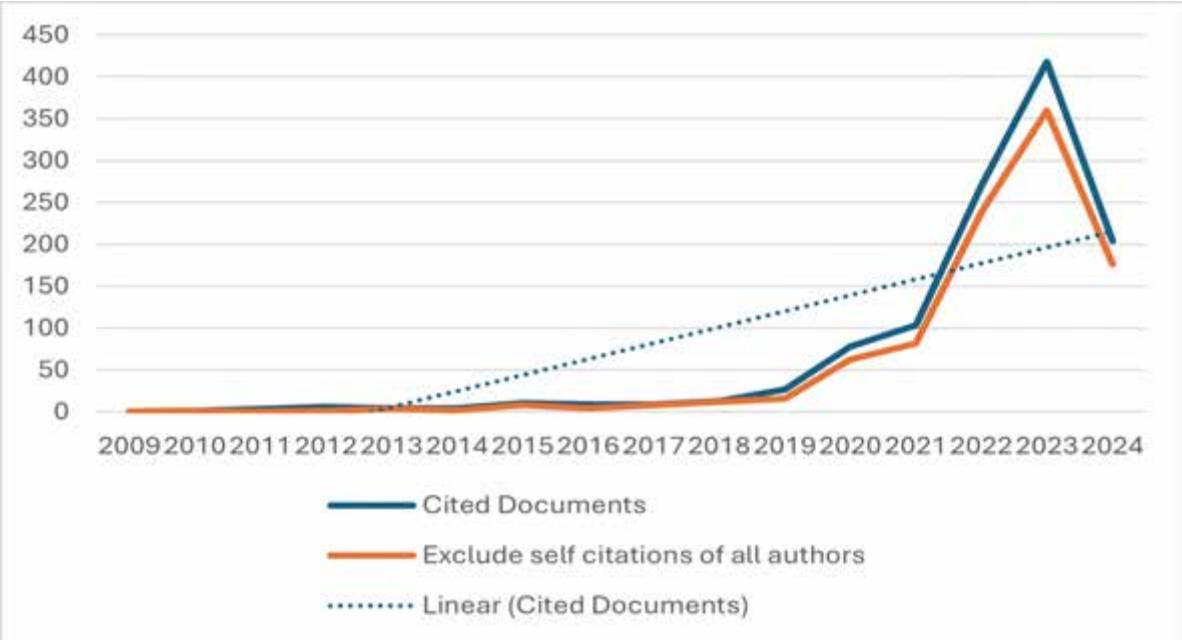

Figure (2): The citation count for the 159 documents, Self-citations included and excluded.

The annual citation trends reveal fluctuations typical of emerging research domains. After a slow start in 2009 and 2010, citations significantly increased in 2011 (200% rise). 2015 showed a 150% increase, regaining momentum after a 33% dip in 2013. Citations nearly doubled in 2019—a especially good year—and then increased by 163% in 2022. These peaks suggest that certain publications or themes triggered heightened academic attention at specific points in time.

The average annual attention rate, excluding the incomplete data for 2024, stands at approximately 77%, indicating consistent scholarly engagement with CIM topics. While 2024 data currently reflect a 53% decline, this is expected to adjust upward as new citations accrue throughout the year.

• Keyword Co-Occurrence and Clustering (VOSviewer Analysis)

To reveal underlying thematic patterns in the CIM literature, a keyword co-occurrence analysis was conducted using VOSviewer on the 159 Scopus-indexed documents. A custom thesaurus file was applied to harmonize keyword variants (e.g., "CIM," "City Information Model," and "City Information Modelling" were unified under "City Information Modeling") to avoid redundancy and improve consistency.

A threshold of five occurrences was set, resulting in 42 qualified keywords for inclusion. The resulting network visualization displays four major thematic clusters, each color-coded and indicating distinct lines of inquiry within CIM research:

• Cluster 1 (Red): Urban Modeling and GIS Integration
This largest and most densely connected cluster (14 keywords) includes terms like “three-dimensional modeling,” “urban design,” “urban planning,” and “geographic information system.” It represents the methodological backbone of CIM, highlighting the fusion of 3D spatial modeling with GIS technologies to support urban planning, simulation, and visualization.

• Cluster 2 (Green): Remote sensing and data systems
This cluster, which consists of 11 terms including “information systems,” “data acquisition,” and “remote sensing,” highlights CIM’s technological backbone. It shows interest in the collection, organization, and integration of urban data, especially via sensors and remote sensing technology.

• Cluster 3 (Blue): BIM-Driven Decision Support
With 10 keywords including “building information modeling,” “decision making,” and “urban growth,” this cluster illustrates how BIM methodologies are leveraged to inform policy and design decisions in urban contexts, extending BIM from architectural to city-scale applications.

• Cluster 4 (Yellow): Emerging Technologies and Sustainability
Terms such as “blockchain,” “sustainable development,” and “quality of life” are included in the smallest cluster (7 keywords). It covers themes that gaze ahead, examining how cutting-edge technologies and moral issues will shape urban futures.

While the thickness and number of connecting lines show the overall connection strength, or how frequently keywords appear in the same publications, node size in the network represents the frequency of keyword occurrence. The network’s node sizes reveal the frequency of keywords, with conceptual anchors such as “city information modeling” (74 occurrences), “information models” (68), and “building information modeling” (43) acting as prominent phrases. The overall link strength statistic emphasizes the importance of important phrases in the changing conversation by further quantifying the degree to which one keyword is related to others. The network map displayed in Figure 3 illustrates these interactions, with cluster colors, node sizes, and links reflecting co-occurrence strength, keyword frequency, and theme structure, see figure (3).

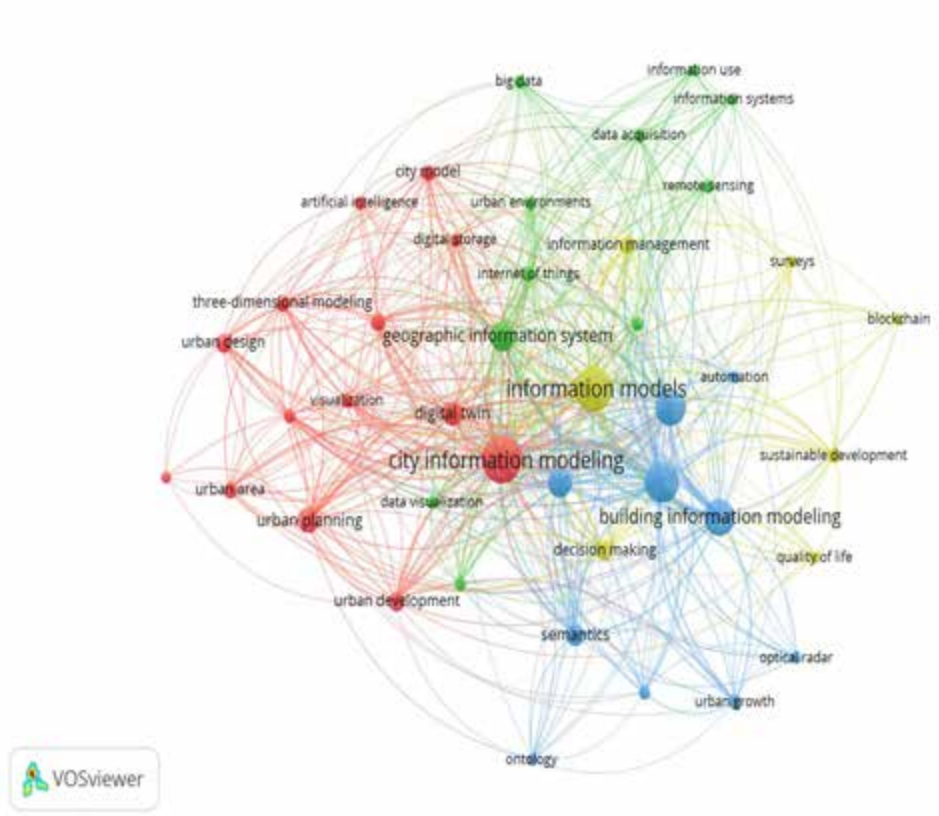

Figure (3): Analysis of the 159 documents retrieved from Scopus focusing on their keywords using VOSviewer (by authors).

• Author Co-Citation Network

To assess the intellectual structure of City Information Modeling (CIM) research, a co-citation analysis of authors was conducted using VOSviewer, with a citation threshold set at 30 citations. This approach identifies how frequently pairs of authors are cited together, highlighting core contributors and collaborative networks that shape the field.

The analysis resulted in a network visualization consisting of three author clusters, each representing a distinct epistemological orientation within the CIM discourse:

• Cluster 1 (Red): Multidisciplinary Pioneers

This largest cluster includes 13 authors with diverse disciplinary affiliations. Notable people include Biljecki, F. (56 citations; 1147 link strength) and Gil, J. (67 citations; 1171 total link strength), who are both acknowledged for their groundbreaking work at the nexus of spatial analysis, 3D modeling, and GIS. The cluster represents a wide range of study that combines planning techniques, data science, and urban informatics.

• Cluster 2 (Green): BIM-Oriented Scholars

Comprising 6 authors, this group is more tightly linked and focuses on extending Building Information Modeling principles to the city scale. Lu, W. (70 citations; 1110 link strength) and Xue, F. (65 citations; 1104 link strength) lead this cluster, contributing extensively to the development of semantic modeling, data structures, and BIM-to-CIM transition frameworks.

• Cluster 3 (Blue): Urban Design and Simulation Experts
With 5 authors, including Stoter, J. (59 citations; 1202 link strength) and Beirão, J. (43 citations; 733 link strength), this cluster specializes in spatial simulation, generative urban design, and visualization techniques. Their work bridges technical modeling and design-oriented inquiry, reflecting a synthesis between qualitative urbanism and quantitative modeling.

Across all clusters, the link strength metric reveals the intensity of co-citation relationships, underscoring the interconnectedness of leading scholars. The presence of well-known theorists such as Batty, M. (44 citations; 811 link strength) further reinforces the theoretical backbone of the field, see figure (4).

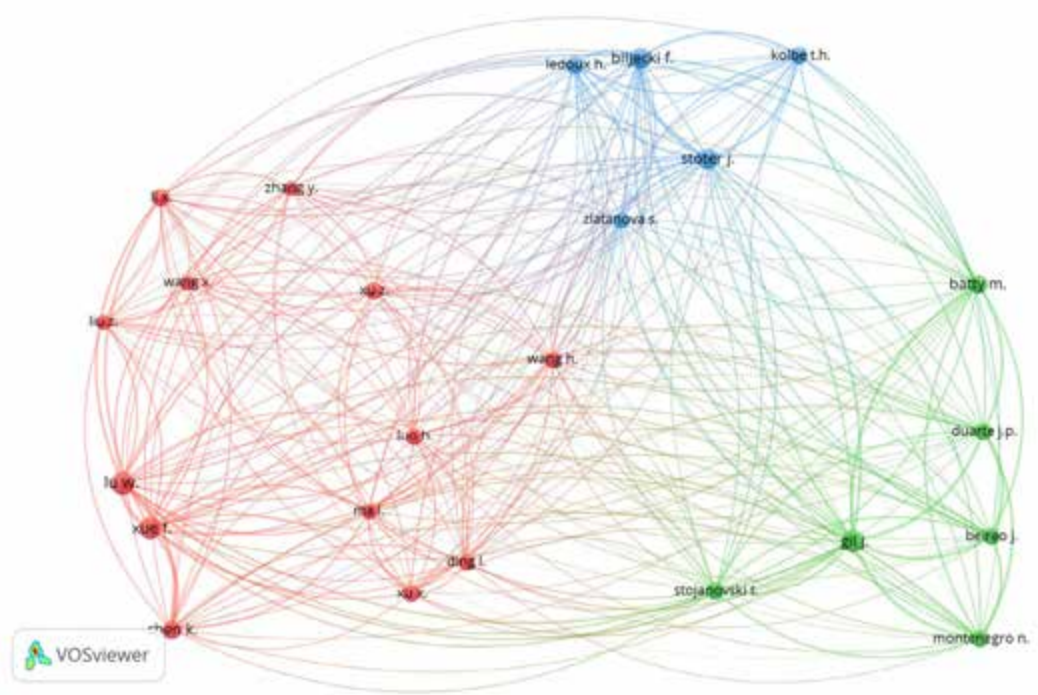

Figure (4): Network analysis based on co-citations of authors using VOSviewer (by authors).

• CiteSpace Keyword Network Analysis
To complement the bibliometric mapping of author contributions, a keyword co-occurrence analysis was conducted using CiteSpace software. This method enables a deeper understanding of thematic concentrations and emerging topics within the CIM literature by identifying central and highly connected keywords across the dataset. The analysis was based on keywords extracted from titles, abstracts, author keywords, and Keywords Plus. A g-index (k=25) was applied to define node inclusion thresholds, ensuring focus on the most influential terms.

The most frequently cited keywords reflect the foundational themes in CIM research:

Table (1): Keywords citation counts and node names by CiteSpace software (by authors).

Citation Counts	Node Name
67	information modeling
51	information theory
42	architectural design
29	cim
28	smart city
25	bim
20	digital twin
20	urban planning
15	gis
13	decision making

The importance of "Architectural Design" and "Information Modeling" attests to their function as conceptual pillars of the CIM discipline. The growing technical integration of CIM with urban digitalization and spatial analytics is indicated by keywords such as "Smart City," "Digital Twin," and "GIS."

Further insight is provided through degree and betweenness centrality metrics, which indicate the structural importance of each keyword within the network:

• Top keywords by degree (number of direct connections):
o BIM (55)
o Architectural Design (48)
o 3D Modeling (35)
o Big Data (33)
o GIS (29)

• Top keywords by centrality (influence as bridges between topics):
o BIM (0.33)
o Architectural Design (0.21)
o Information Modeling (0.19)
o Urban Development (0.19)
o 3D Modeling (0.17)

These metrics reveal that BIM functions as a pivotal bridge in the CIM discourse, connecting a wide range of subtopics from semantics and 3D environments to decision-making and sustainability. Similarly, architectural design serves as a core term linking design methodologies with information systems.

The keyword clusters derived from CiteSpace demonstrate that CIM research is shaped by three intersecting agendas:

• Technological Foundations: Emphasizing BIM, information modeling, GIS, and smart city tools.
• Design Integration: Highlighting architectural and urban design processes within digital frameworks.
• Analytical Expansion: Including big data, AI, and decision-support systems for adaptive urban planning.

UAV-Based Case Study and Workflow Development
This paper includes a field-based case study employing Unmanned Aerial Vehicles (UAVs) for 3D spatial data collecting in order to close the gap between theoretical investigation and real-world application in City Information Modeling (CIM). The objective is to assess the viability and efficiency of a UAV-to-CIM process that aids in neighborhood-scale urban planning. The Emniyettepe Neighborhood in Istanbul, Turkey's Eyüp District—an area experiencing significant urban change—has been chosen as the testbed for its execution.

• Study Area and Rationale
Emniyettepe was selected because of its diversified urban morphology, which comprises residential blocks, business corridors, green spaces, and underused areas, as well as its advantageous location close to Istanbul's central urban infrastructure. It is a typical model for testing UAV-based urban analytic technologies because of its diversity in land use and physical shape. The neighborhood's blend of public, commercial, and residential areas creates a diverse urban landscape, showcasing how flexible 3D modeling is for examining various urban typologies.

The region's usefulness as a case study is increased by its geographical and structural variety, which makes it possible to examine elements like building heights, terrain differences, and green areas. Additionally, the model could support future urban planning efforts, particularly if Emniyettepe is part of redevelopment projects or faces seismic risks, as seen across Istanbul. The practical benefits of choosing Emniyettepe include fewer regulatory hurdles for drone operations due to its moderate population density and lack of high-rise obstructions. By focusing on a moderately dense, underrepresented neighborhood like Emniyettepe, this project can showcase the scalability of drone-based modeling.

• Data Acquisition Using UAV and Photogrammetry
Data acquisition was conducted using a commercial-grade quadcopter UAV equipped with a high-resolution RGB camera. The choice of the drone depended on several aspects, firstly is its ability to capture high resolution 4k images, the images' size produced by the drone is 4000*3000 pixels, with 72 dpi resolution, all photos produced has geo-referencing according to the built-in GPS, with latitude, longitude and altitude measurements, the camera has gimbal that stabilize the image for less blurriness during the drone's motion and has the ability to capture different camera angle (oblique, aerial). Secondly, the DJI platform is compatible with different data processing tools like PIX4D mapper, Reality Capture, and Drone Deploy, Map Pilot Pro, along with its compatibility with the flight planning tools of the same platforms. Thirdly, the weight of the DJI Mavic air 2 is 570 grams, making the pilot license falls in the least license category according to the Turkish Civil Aviation Law. Lastly, the battery of the drone lasts for about 30 minutes, including the take-off and landing, giving about 18 minutes single flight maximum duration.

Flights were planned and executed under suitable weather conditions, adhering to Turkish civil aviation regulations. The photogrammetric mission covered approximately 1.2 square kilometers of urban fabric, capturing oblique images at an altitude of 80 meters. Flight paths were generated using Pix4Dcapture, ensuring 80% frontal and 70% side overlaps for accurate model generation. A total of 520 images were collected and processed in Pix4Dmapper, which generated a dense point cloud, digital surface model (DSM), orthomosaic, and 3D textured mesh. Ground control points (GCPs) were manually identified using local cadastral data to enhance the geospatial accuracy of the outputs. The final outputs serve as high-fidelity spatial datasets suitable for integration into CIM environments.

• Workflow Development: From UAV to CIM
The study proposes a replicable workflow that integrates UAV-derived data into CIM-compatible platforms. The workflow comprises the following key steps:

1. Flight Planning and Data Capture: Mission design with pre-defined overlaps and GCP targeting.

2. Image Processing: Use of Pix4Dmapper to generate georeferenced outputs, including point clouds and orthophotos.
3. Data Cleaning and Classification: Removal of noise points and classification into ground, vegetation, and structures.
4. Model Export and Conversion: Export of point clouds (.las/.xyz) and mesh models into interoperable formats (.obj, .fbx).
5. CIM Integration: Import into BIM/CIM platforms such as Autodesk Revit and InfraWorks. Point clouds are referenced using Dynamo scripts to support semi-automated model reconstruction.

This UAV-to-CIM pipeline not only enables spatially accurate modeling of existing urban conditions but also facilitates data-rich visualizations and planning simulations.

• Limitations and Technical Challenges
Several challenges were encountered during the field application. These include:

• Regulatory constraints: Flight restrictions in certain sub-areas limited full coverage.
• Data occlusion: Vegetation and narrow alleys reduced image clarity in specific zones.
• Model accuracy: While GCPs improved alignment, some distortions persisted at building edges.
• Software interoperability: Manual adjustments were required to align datasets across platforms.

Despite these constraints, the workflow proved robust in generating CIM-ready datasets with reasonable accuracy and scalability.

• Implications for Urban Planning Practice
The proposed UAV-to-CIM workflow offers a cost-effective and scalable alternative to traditional 3D city modeling methods. It enables planners, municipalities, and researchers to:

• Rapidly capture and model existing urban fabric.
• Conduct scenario testing for redevelopment or infrastructure projects.
• Integrate UAV-generated spatial data with semantic CIM databases.

This approach democratizes access to urban modeling tools, particularly for small and medium-sized cities or research institutions lacking access to high-end LiDAR or proprietary datasets.

Case Study: UAV-Based CIM in Emniyettepe, Istanbul
• Site Description and Rationale
The selected case study site for this research is the Emniyettepe Neighborhood, located within the Eyüpsultan District of Istanbul, Turkey. Emniyettepe lies at the intersection of historical legacy and contemporary urban transformation, making it a compelling environment for testing emerging City Information Modeling (CIM) techniques. The neighborhood features a mix of dense residential fabric, mid-rise housing blocks, narrow streets, and a variety of public infrastructure, characteristic of many transitional urban zones across Istanbul.

The rationale for selecting Emniyettepe is threefold. First, the neighborhood represents typical spatial conditions found in many post-industrial, middle-income areas of Istanbul, thus offering valuable insights for broader urban modeling applications. Second, it lacks recent comprehensive digital spatial documentation, presenting an opportunity to demonstrate the added value of UAV-based data acquisition in underrepresented urban zones. Third, its manageable geographic scale (approximately 0.3 km²) allows for detailed photogrammetric data collection and processing within the constraints of low-cost UAV technology and limited flight windows.

The area is also experiencing increasing planning interest due to infrastructural upgrades and population pressures. These dynamics further justify the implementation of CIM as a tool for scenario testing, urban analysis, and participatory planning processes. The study shows how UAV-enabled processes may facilitate granular, scalable, and reproducible CIM creation in congested urban environments by concentrating on a neighborhood-level site, especially in situations where the available spatial data may be out-of-date, insufficient, or unavailable.

• UAV Data Collection Methodology

A consumer-grade UAV with an RGB camera was used to collect photogrammetric data in order to create a high-resolution spatial dataset for the Emniyettepe area. Early summer 2024 provided ideal illumination and little wind interference for the airborne survey, which was carried out in pleasant weather. Pix4Dcapture software, which allowed for automatic path construction based on terrain elevation, flying height, and necessary ground sampling distance (GSD), was used to pre-plan the flight mission.

As mentioned, several flights were performed in a duration of two days. Details of these flights are as following, (1) Flight Day One: Dates 2nd of January 2025, the images were taken between 4:53 pm and 5:44 pm, the total number of the images taken were 120 images. The flight aim was mainly for the testing of the Map Pilot Pro platform after the failure in connecting the mobile app with the drone using other platforms in a free trial version. Also the timing of the flight was not accurate, which caused the images to be losing brigtness. (2) Flight Day Two: Dates 3rd of January 2025, the images were taken between 4:47 pm and 5:27 pm, the total number of images taken were 160 images, since there isn't distortion in the orthomosaic map, only oblique photos were taken, whereas all georeferenced images can be combined in the processing, see figure (5).

A total number of two oblique flights were performed, drone altitude was set to be 60 meters, in order to capture all buildings' elevations, front and side overlaps were increased to be 80% and 80% respectively, the camera angle was set to be 30 degrees not looking at grid centre (camera face along the grid lines). No ground control points (GCPs) were used in this preliminary workflow due to logistical constraints and to test the capabilities of a GCP-free approach. However, image georeferencing was performed using the UAV's onboard GPS and IMU data. While this introduces a margin of spatial error compared to GCP-aided methods, it demonstrates the feasibility of lightweight data acquisition in constrained or resource-limited urban environments.

Following data acquisition, the image set was imported into Pix4Dmapper for processing. The software executed key photogrammetric steps including image alignment (structure-from-motion), dense point cloud generation, mesh reconstruction, and orthophoto production. The outputs included a classified point cloud, a 3D textured mesh model, a digital surface model (DSM), and a high-resolution orthomosaic map.

UAVs have been widely applied in surveying, archaeology, and environmental monitoring (Fahlstrom and Gleason, 1993; Sauerbier and Eisenbeiss, 2010). The UAV-based data collection workflow adopted in this study highlights the potential of cost-effective photogrammetry for producing CIM-compatible datasets at the neighborhood scale. It also underscores the accessibility of drone-based urban modeling for researchers and planning practitioners working with limited technical infrastructure.

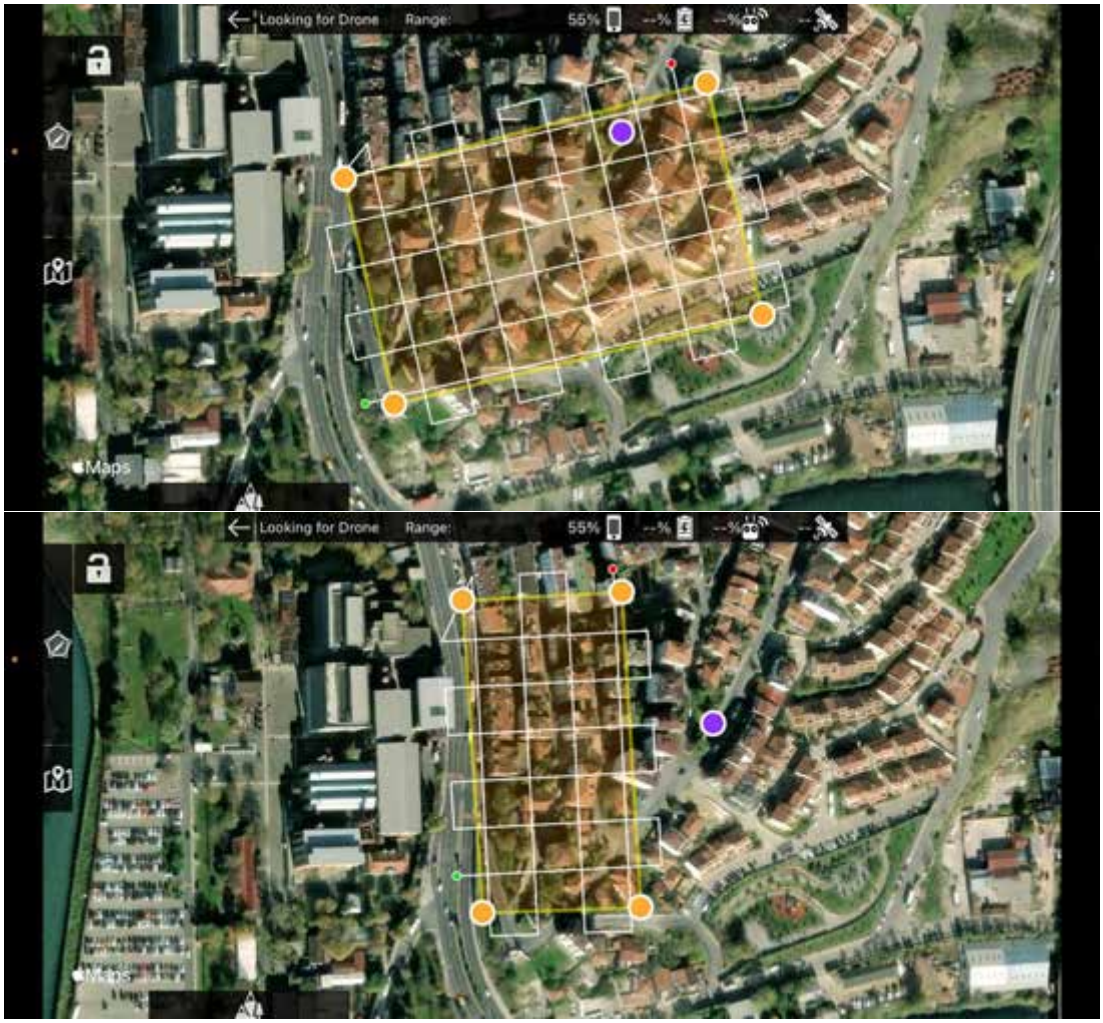

Figure (5): Map Pilot Pro platform.

• Point Cloud Processing and Model Preparation
Following UAV-based data acquisition, the image set was processed in Pix4Dmapper to generate a dense point cloud representing the Emniyettepe neighborhood's built and natural environment. This raw point cloud contained millions of georeferenced spatial data points, encoding x, y, z coordinates and RGB values for each sampled surface.

To prepare the dataset for integration into a City Information Modeling (CIM) workflow, several processing steps were undertaken:

o Noise Reduction and Point Cloud Cleaning
Initial filtering was performed to eliminate erroneous or floating points often resulting from poor lighting or reflective surfaces (e.g., glass facades, water puddles). The point cloud was then decimated to reduce density in less relevant areas while preserving critical architectural and morphological features. This process was conducted using CloudCompare, an open-source 3D point cloud processing software.

o Classification and Segmentation
Points were semi-automatically classified into ground, building, and vegetation categories using colorimetric and elevation-based rules. Manual adjustments were applied in areas where automated classification proved

insufficient, such as shadowed alleys or high-density tree canopies. Segmenting the point cloud into thematic layers allowed for greater control and selectivity during subsequent modeling operations.

o Mesh Reconstruction and Texturing
From the cleaned and classified point cloud, a 3D mesh was reconstructed using the Delaunay triangulation method in Pix4Dmapper. Textures extracted from original UAV images were overlaid on the mesh to enhance visual realism and enable context-aware urban analysis. The resulting textured mesh model provides an intuitive and scalable representation of neighborhood morphology.

o Format Conversion and BIM/CIM Compatibility
To enable downstream use in urban planning environments, the outputs were exported in open formats such as. LAS, .OBJ, and .FBX. Additionally, for future integration with Building Information Modeling (BIM) or CIM environments (e.g., Autodesk Revit, InfraWorks, or openCIM platforms), the processed point cloud was prepared for import into Dynamo scripts and Rhino-Grasshopper pipelines, facilitating procedural modeling and semantic enrichment. Through this multi-step approach, a photorealistic and spatially accurate 3D urban model was derived, serving as the foundation for neighborhood-scale CIM applications. The methodology underscores the adaptability of low-cost UAV workflows in producing structured urban datasets suitable for further analysis, simulation, and planning.

Drone-based imaging was conducted to capture high-resolution data for urban analysis, utilizing a DJI FC3170 camera. A total of 160 geolocated images were captured and processed using the Pix4D cloud platform, achieving 100% calibration success. The project was conducted using the WGS 84 / UTM zone 35N + EGM2008 height coordinate system, ensuring a consistent spatial reference for accurate mapping and analysis. The average Ground Sampling Distance (GSD) was 0.03617 meters, indicating the dataset's high spatial resolution and suitability for detailed 3D modeling and analysis.

The Pix4D platform's processing workflow highlighted exceptional quality checks throughout the project. The median number of keypoints per camera was 35,611, with an impressive 12,176 median matches per camera, demonstrating the robustness of image matching and calibration. Additionally, all 160 images were successfully geolocated, providing a solid foundation for generating accurate 3D models. The relative difference between initial and optimized camera parameters was 8.67%, further emphasizing the calibration process's precision. The dataset generated a 3D Ray Cloud comprising 774,731 points, which is critical for detailed reconstruction and urban feature analysis, see figure (6).

The quality checks also assessed absolute geolocation and orientation variances, with errors minimized across X, Y, and Z axes to ensure accurate spatial representation. Orientation errors for omega, phi, and kappa were similarly controlled, enabling precise 3D positioning and alignment of the images. The high density of observed keypoints and the low rate of weak matches validate the dataset's integrity and its potential for generating reliable outputs, such as Digital Surface Models (DSMs), Digital Terrain Models (DTMs), and orthomosaics.

Processing via the Pix4D cloud platform proved efficient and effective, particularly for a neighborhood-scale project. The integration of drone-based imaging with Pix4D facilitated the creation of detailed outputs for urban analysis. These include potential applications in infrastructure planning, land-use mapping, and environmental assessments (Shi et al., 2015). The ability to process a compact but detailed dataset underscores the feasibility of using drones for urban studies, with Pix4D providing a streamlined workflow for high-quality results.

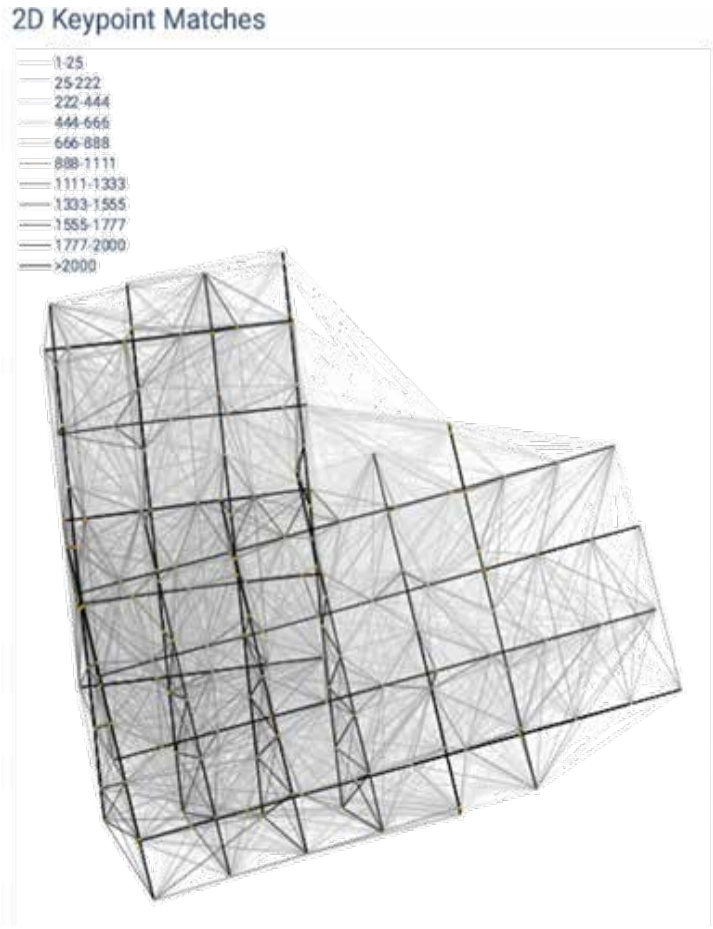

Figure (6): 2D key point matches of drone imageries.

• UAV-to-CIM Workflow and Integration

The processed point cloud and reconstructed 3D mesh were subsequently integrated into a City Information Modeling (CIM) workflow designed to support neighborhood-scale urban analysis and planning. This workflow aims to demonstrate how low-cost UAV photogrammetry can be translated into structured, analysis-ready models that are both visually rich and semantically informative.

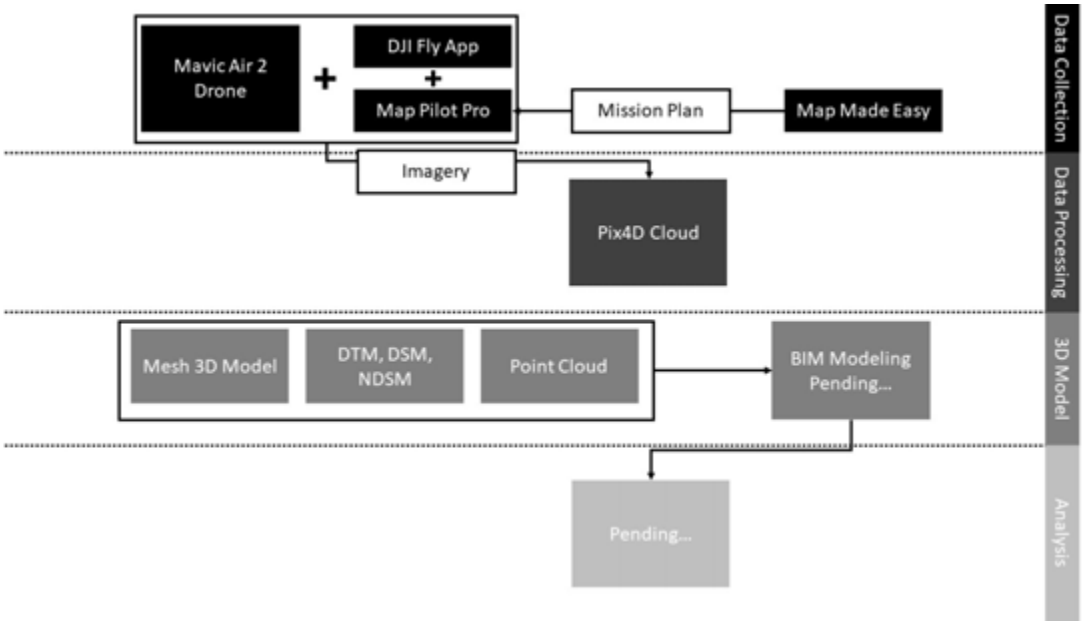

Figure (7): Workflow overview.

o Workflow Overview, see figure (7):
The UAV-to-CIM workflow developed in this study consists of five primary stages:

1. Aerial Data Acquisition (via UAV photogrammetry)
2. Image Processing and Point Cloud Generation (Pix4Dmapper)
3. Point Cloud Cleaning, Segmentation, and Mesh Reconstruction (CloudCompare & Pix4D)
4. Semantic Enrichment and Model Structuring (Rhino + Grasshopper)
5. CIM Visualization and Analysis (QGIS, Unity, or BIM tools)

This modular structure enables iterative refinement and potential expansion to include additional datasets such as cadastral layers, mobility networks, or environmental indicators.

o Semantic Modeling and Attribute Assignment
In order to transition from a visual 3D model to an information-rich CIM dataset, the mesh and point cloud were imported into Rhino and processed through Grasshopper scripts. Basic semantic attributes were assigned to key elements—such as building footprints, roof types, terrain surfaces, and vegetation clusters—allowing for basic querying and spatial categorization.

Where available, public GIS data (e.g., land use, parcel boundaries) were overlaid to spatially align real-world urban attributes with the drone-derived model. This integration facilitates early-stage urban assessments such as shadow analysis, density estimation, and accessibility studies.

o Use Case Scenarios and Planning Potential
The finalized CIM prototype enables a variety of planning-related applications, including:

- Neighborhood diagnostics: Visualizing built-environment morphology and open space distribution.
- Scenario testing: Modeling development options or simulating interventions at a detailed level.
- Stakeholder engagement: Enhancing communication with policymakers or community members through immersive and spatially accurate 3D models.

• Heritage documentation and resilience planning: Archiving current conditions of historically significant structures or assessing exposure to environmental risks (e.g., landslides, flooding).

The system remains scalable and open-ended, with potential for future automation via AI-based classification and integration with Internet of Things (IoT) urban sensing platforms.

• Workflow Limitations
Despite its strengths, the UAV-to-CIM workflow faces several challenges:

1. Data size and processing time: High-resolution point clouds and meshes require significant storage and computing resources.
2. Semantic limitation: Manual or semi-automated classification still relies on domain expertise and lacks standardized ontologies for CIM.
3. Scalability: While effective at the neighborhood scale, scaling to entire city districts requires adjustments in flight planning, data fusion, and computing infrastructure.

• Process Output
Below is a detailed overview of the generated outputs and their quality, as described in the quality report:

Point Cloud: The 3D point cloud generated during the processing included a total of 774,731 points, derived from the dense matching of 2D keypoints. The high number of observed 3D points reflects excellent feature extraction and matching. The distribution of 3D points indicates good coverage across the area, with keypoints observed in multiple overlapping images, increasing the accuracy and robustness of the reconstruction. The report indicates that most points were observed in 3-6 images, which enhances the reliability of their 3D coordinates. However, a small percentage of points were observed in more than 10 images, leading to high precision for specific features. The average ground sampling distance (GSD) of 0.03617 meters further underscores the high resolution and suitability of the point cloud for detailed urban analysis, see figure (8).

Figure (8): 3D point cloud.

Digital Terrain Model (DTM): The DTM created provides a clear representation of the terrain, excluding structures and vegetation. The processing used dense sampling and geoid-based height data (EGM2008) to ensure accurate elevation values. Given the GSD and the precise geolocation of input images, the DTM exhibits minimal vertical errors, as highlighted by the geolocation error checks.

The elevation of every element in the region, including plants, buildings, and other structures, is reflected in the Digital Surface Model (DSM). The DSM benefits from the high-resolution input images and accurate image matching, ensuring detailed height data for urban structures. Errors in height estimation were minimal, with the RMS error for geolocation at 0.826 meters, which is within acceptable limits for urban analysis, see figure (9).

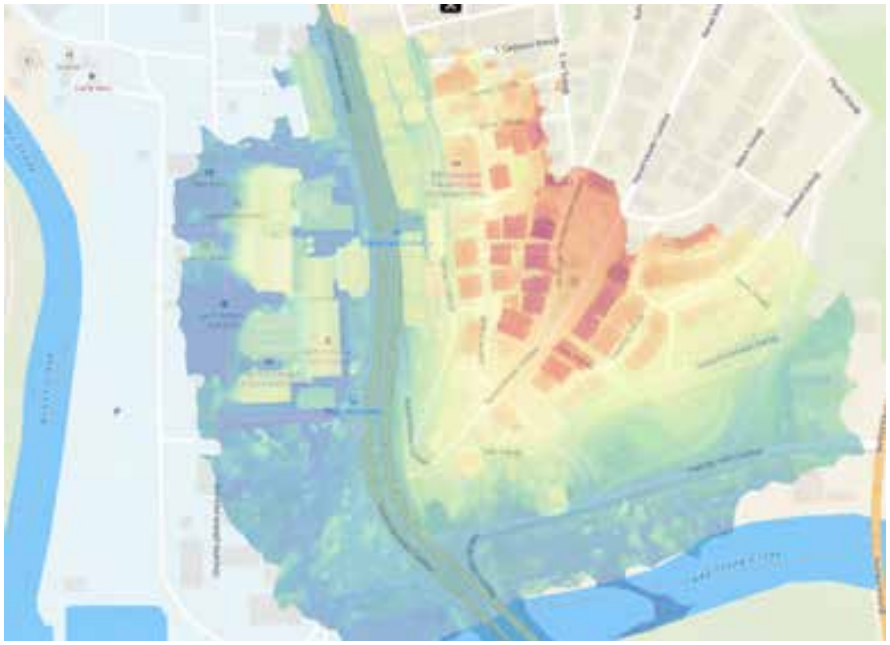

Figure (9): Digital Surface Model (DSM).

Orthomosaic: An orthomosaic was generated using the captured images, providing a georeferenced 2D representation of the area. The orthomosaic benefits from the high GSD, ensuring exceptional clarity and detail, with no major distortions noted in the quality checks, see figure (10).

Figure (10): orthomosaic was generated using the captured images.

3D Mesh Model: A 3D mesh model was created from the dense point cloud, integrating texture data from the input images. The mesh model captures the geometric and visual properties of the area, providing a detailed and realistic representation of the neighborhood (Nan and Wonka, 2017; Lafarge and Mallet, 2012; Oesau et al., 2016). The relative difference between initial and optimized camera parameters (8.67%) indicates successful alignment and calibration, ensuring the quality and accuracy of the mesh, see figure (11).

Figure (11): 3D Mesh Model.

The outputs generated from the drone data include high-quality DSM, DTM, point cloud, orthomosaic, and 3D mesh model, each with minimal errors and high precision. These deliverables provide a comprehensive basis for urban studies, including land use mapping, infrastructure assessment, and planning. The processing quality ensured by Pix4D highlights the effectiveness of the workflow for creating reliable and accurate models from drone imagery.

Findings and Discussion

This section synthesizes the insights derived from both the bibliometric literature review and the UAV-based field implementation. The dual-method approach provides a nuanced understanding of City Information Modeling (CIM), highlighting not only its theoretical evolution but also its practical feasibility in real-world urban contexts.

• Key Insights from the Literature Review

The systematic review conducted using the BSMS-PRISMA framework revealed several thematic and methodological patterns across the 159 CIM-related documents retrieved from Scopus:

1. Discipline Focus: While planning theory, social equality, and public engagement in digital modeling are covered in comparatively few publications, the bulk of CIM research are focused on the domains of engineering, computer science, and architecture.
2. Trends in Keywords: Words like “information modeling,” “BIM,” “smart city,” and “urban planning” showed up a lot, indicating a good desire to combine digital technology with urban administration. Emerging keywords like “digital twin” and “blockchain” signal the increasing diversification of CIM applications.
3. Author Networks and Citation Patterns: Co-citation and keyword network analyses identified a handful of pro-

lific authors (e.g., Gil J., Stoter J., Biljecki F.) who form intellectual clusters. These networks point to evolving research communities and schools of thought within CIM.
4. Gaps Identified: The review also exposed gaps, particularly in the standardization of CIM workflows, limited integration of environmental datasets, and lack of attention to citizen-centered or participatory modeling approaches.

• Key Insights from the UAV-Based Workflow
The practical application of UAV photogrammetry in the Emniyettepe Neighborhood demonstrated several capabilities and limitations of drone-based CIM integration:

o Feasibility and Accessibility: The UAV-based workflow proved effective in generating high-resolution, georeferenced 3D models using commercially available drones and software. This confirms the viability of cost-efficient data collection methods, particularly in under-resourced urban settings.
o Accuracy and Detail: The derived models captured detailed architectural and topographical features, suitable for various urban analyses such as land-use visualization, elevation profiling, and density assessment.
o Semantic Potential: While the point cloud and mesh were successfully processed into visually accurate models, the transition into fully semantically enriched CIM datasets remains partially manual. This presents a challenge for automation and scaling.
o Replicability: The proposed five-step UAV-to-CIM workflow is modular and adaptable, suggesting potential for deployment in other urban contexts with minimal reconfiguration.

• Theoretical and Practical Convergence
By pairing literature insights with real-world implementation, this study highlights the converging trajectories of theoretical research and applied urban modeling:

o From BIM to CIM: The strong conceptual link between BIM and CIM found in literature is mirrored in the UAV workflow, where BIM tools and logic were repurposed for urban-scale applications.
o Bridging Gaps: The empirical case study addresses gaps identified in the literature, particularly the need for standardized, low-cost, and scalable workflows for city modeling.
o Urban Planning Implications: For urban planners and policymakers, the findings suggest that CIM can be effectively initiated at the neighborhood scale, serving as a decision-support tool for both long-term planning and rapid diagnostics.

• Limitations and Considerations
Several constraints emerged during the study:

o Temporal Staticity: UAV-based models represent a static snapshot in time, limiting their ability to reflect dynamic urban processes without continuous data updates.
o Data Fusion Complexity: Integrating UAV data with other municipal datasets (e.g., cadastral, infrastructure, sensor data) remains technically and administratively challenging.
o Governance and Ethics: As CIM platforms increasingly incorporate detailed urban and citizen data, ethical concerns around surveillance, privacy, and data ownership must be addressed in future studies.
o Despite their benefits, UAV operations face evolving regulatory frameworks (Stöcker et al., 2017).

Conclusion and Future Work

This study investigated the evolving landscape of City Information Modeling (CIM) through a dual-method approach that combined a systematic literature review using the BSMS-PRISMA framework with a practical UAV-based case study in the Emniyettepe neighborhood of Istanbul. By identifying dominant patterns in the scholarly literature and assessing the viability of an approachable, reproducible workflow for urban-scale data modeling, the study sought to close the conceptual and practical gaps in CIM.

Although CIM has attracted increasing interest from a variety of fields, including engineering, computer science, and architecture, the literature analysis found that it currently lacks standardized tools, thorough frameworks, and extensive application in actual urban settings. In situations where traditional data sources could be out-of-date or unavailable, the UAV-based pilot research showed how drone photogrammetry might assist CIM operations in a technically possible and cost-effective way.

The study adds to the continuing discussion on the relevance, scalability, and integration of CIM within urban planning practice by contrasting bibliometric findings with actual application. The findings confirm that CIM is not merely a conceptual extension of BIM but a distinct paradigm requiring its own methodologies, toolchains, and interdisciplinary governance structures.

Future research should focus on several key directions:

1. Developing automated workflows for semantic enrichment of 3D models to reduce reliance on manual post-processing;
2. Using artificial intelligent powered platforms to generate 3D models using descriptive text and integrating them into CIM. (Liu et al., 2023)
3. Scaling the UAV-to-CIM framework to other urban environments to test generalizability and adaptability.

Final Remarks and Acknowledgements

It is important to note that the final conversion of the textured mesh model into a fully operational 3D City Information Model (CIM)—including semantic enrichment, object classification, and integration into BIM/CIM platforms like Revit—is still a pending task and constitutes a subsequent phase of this research. This work forms part of an ongoing thesis project, and further technical development and validation will be addressed in the upcoming stages. The author gratefully acknowledges Istanbul Technical University and Türkiye Scholarships (Türkiye Bursları) for academic support.

Abstract
This study evaluates the adaptive capacity of İzmir, Turkey, by applying sub-fractal and difference analysis to assess urban complexity from the 1950s to 2020s. Using principles of fractal geometry (Batty & Longley, 1994), it quantifies the morphological evolution of the city's road network to determine resilience to socio-environmental change. The findings identify a consistent Adaptive Capacity Range (ACR) of 0–0.25, indicating moderate adaptability constrained by structural thresholds (Özdemir, 2021; Erdoğan, 2021). Drawing on statistical mechanics and theoretical physics, the study introduces computational tools for modelling urban expansion (Salingaros, 2010) and offers a transferable framework for resilience assessment (Triantakonstantis, 2012; Jiang & Yin, 2014). This interdisciplinary approach advances understanding of urban complexity and provides a replicable model for analysing adaptive capacity in dynamic city systems.

Keywords: Adaptive Capacity, Sub-Fractal Analysis, Urban Complexity, Urban Planning, Fractal Geometry, Urban Growth

1. Introduction

The dynamics of urban complexity and adaptive capacity occupy a central position in contemporary urban planning theory. These constructs embody the multifaceted interactions between spatial configurations, infrastructural systems, and the socio-economic mechanisms that sustain urban life (Salingaros, 2005). Adaptive capacity, originally conceptualized within ecological and environmental sciences, refers to a system's potential—whether biological, ecological, or social—to adjust to disturbances and changes while preserving its fundamental functions (Salingaros, 2010). Closely tied to the notion of resilience, it denotes a system's ability to reorganize amidst disruptions without forfeiting its core identity and operational integrity.

This concept aligns conceptually with the principles of fractal geometry, which have proven instrumental in interpreting urban form and complexity (Batty & Longley, 1994). Fractal geometry elucidates urban spatial organization and developmental trajectories by revealing scale-invariant and self-similar patterns—allowing complexity to be both measured and visualized (Triantakonstantis, 2012). Situated within this analytical framework, the present study employs fractal methodologies to explore the morphological development of İzmir, Turkey, tracing the evolution of its urban spatiality across decades shaped by both deliberate planning and spontaneous transformation (Özdemir, 2021; Erdoğan, 2021).

As Turkey's third-largest metropolitan area, İzmir offers a compelling case for examining urban adaptability through the lens of sub-fractal analysis (Erdoğan, 2021). This technique dissects the granularity of urban forms across varying scales, thereby illuminating how spatial structure influences responsiveness to socio-econom-

ic and environmental perturbations (Jiang & Liu, 2009). In tandem, difference analysis tracks temporal shifts in fractal configurations, providing empirical evidence of the impacts of historical planning initiatives and unforeseen urban developments. Anchored in interdisciplinary theory spanning urban morphology and computational physics, the study utilizes quantitative methods to interrogate the nexus between form and adaptive functionality (Jiang & Claramunt, 2004; Jiang & Yin, 2014).

By integrating these analytical tools, the research articulates actionable insights for urban policy and planning, advocating for data-informed strategies that bolster urban resilience and adaptability (Salingaros, 2005; Özdemir, 2021). Ultimately, the study advances the formulation of standardized methodologies capable of evaluating adaptive capacity across diverse urban settings, contributing to a globally relevant framework for resilience assessment (Batty & Longley, 1994; Triantakonstantis, 2012).

2. Measurement Techniques and Data

Urban complexity constitutes a foundational dimension in evaluating cities' capacity to adapt to evolving socio-spatial and environmental dynamics. Among the most salient methodological tools for investigating this complexity is fractal analysis, which offers a quantitative framework for identifying recursive, self-similar patterns inherent in urban form—patterns that elucidate dynamics of sprawl, density, and morphological transformation (Batty & Longley, 1994; Frankhauser, 1998). Extending this approach, sub-fractal analysis interrogates the internal complexity of specific urban elements, thereby revealing fine-grained heterogeneities that are often obscured at broader scales (Allain & Cloitre, 1991). In the context of İzmir, such an analysis facilitates the exploration of inter-district variability in spatial complexity, closely tied to differential capacities for urban adaptation.

Difference analysis complements this by capturing temporal shifts in urban complexity through comparative evaluations of fractal dimensions across multiple historical junctures. This technique effectively foregrounds the impact of strategic planning decisions and unanticipated perturbations on the urban fabric, rendering visible structural discontinuities in density and sprawl patterns (Batty & Longley, 1994). Applied to İzmir, it enables a retrospective assessment of how specific interventions have altered resilience trajectories. To operationalize an assessment of İzmir's adaptive capacity, sub-fractal analysis is employed to measure the evolution of the city's road network across temporally distinct phases, as indicated by fluctuations in fractal dimensionality (Salingaros, 2010; Jiang & Yin, 2014). This methodological lens serves to index the structural plasticity of the urban grid by mapping its complexity dynamics over time. The empirical basis for this analysis comprises a series of high-resolution cartographic datasets from the General Directorate of Maps, each rendered at a 1:25,000 scale and covering İzmir's metropolitan territory during four historical intervals: 1958–1964, 1974–1980, 1996–2000, and 2012–2020. These maps, standardized in cartographic design and digitally harmonized via NetCAD software, provide a coherent temporal sequence for evaluating the morphogenetic evolution of the urban road network. Subsequent image processing and complexity quantification are conducted using Frac_Lac software, with parameters set at a 1%-pixel ratio and an R^2 coefficient consistently exceeding 0.999, ensuring statistical reliability. The spatial scope of the study is carefully delineated to coincide with İzmir's official metropolitan jurisdiction during each examined period, particularly aligning with the master planning boundaries that underpin the respective base maps of the urban transportation network. Within these demarcated regions, a corpus of sixteen geospatially referenced maps is analyzed to estimate the city's adaptive resilience. The master plans informing this analysis include:

- The 1952 competition proposal by Aru, **Özdeş**, and Canpolat, revised in 1955.
- The 1972 Metropolitan Planning Office's Plan, authorized in 1973 and revised in 1978.
- The 1989 1/50,000 scale plan by the Metropolitan Municipality.
- The 2012 1/25,000 scale plan by the Metropolitan Municipality of İzmir.

3. Methodology

3.1. Sub-fractal and Sub-fractal Difference Analysis

Sub-fractal analysis constitutes a refined methodological approach for interrogating the spatial intricacies of urban form by isolating and quantifying the geometric complexity of discrete urban components—such as transportation infrastructures or neighbourhood morphologies. Rooted in the theoretical underpinnings of fractal geometry, this technique elucidates scale-invariant, self-replicating patterns that typify urban spatial organization (Frankhauser, 1998; Chen, 2021).

Operationalized through a mesh-grid framework, sub-fractal analysis determines the minimal count of non-overlapping square boxes, denoted as $N_{(S)}$, necessary to comprehensively enclose a given urban structure at a specified box size S. The fractal dimension D, an index of spatial complexity, is derived from the linear relationship between the natural logarithms of $N_{(S)}$ and S, where the slope of the resulting log-log regression line yields:

$$D = \lim_{\Delta_S \to 0} \left(- \frac{ln\, N_S}{ln\, S} \right)$$

The regression model is typically expressed as:

$$ln\, N_S = A + D\, ln \left(\frac{1}{S} \right) + E_S$$

In this regression-based approach, A signifies the intercept, D denotes the estimated fractal dimension, and E_S represents the standard error term associated with the model. The robustness of this method is affirmed by its requirement for a coefficient of determination typically exceeding $R^2 > 0.999$, as demonstrated in the work of Thomas and Frankhauser (2013). For the application in İzmir, the sub-fractal analysis was conducted on the map encompassing the most extensive geographical coverage within the delineated urban planning boundaries. A minimum analytical window of 800 m × 800 m was employed, corresponding to a 1%-pixel resolution, which enabled a high-resolution assessment of spatial complexity across multiple temporal epochs (see Figure 2 for visualization). Building upon this foundation, sub-fractal difference analysis examines temporal shifts in spatial complexity. This technique involves computing the variation in sub-fractal dimension values for each individual grid cell across two temporal snapshots. The change is expressed as:

$$\Delta Sf = Sf_{post} - Sf_{pre}$$

Where Sf_{pre} denotes the sub-fractal value in the pre-plan period and Sf_{post} indicates the corresponding value in the post-plan period, the resulting ΔSf expresses the net change in spatial complexity. This differential value serves as a quantitative indicator of morphological transformation, signalling either an increase or a decrease in urban complexity (Chen, 2021; Thomas & Frankhauser, 2013). The computed ΔSf values are systematically grouped into fixed intervals, typically segmented using a threshold of 0.25, to establish what is referred to as the Adaptive Capacity Range (ACR). The ACR represents the standard interval within which complexity changes are considered typical across the urban landscape. Subsequently, a visual map is generated to spatially represent the variation in ΔSf values, employing a color-coded gradient to differentiate the magnitude and direction of change:

- Cool colors (indicating negative ΔSf values) reflect a reduction in complexity.
- Warm colors (indicating positive ΔSf values) signify an increase in complexity.

This cartographic output (see Figure 3) captures the spatiotemporal dynamics of urban transformation, illuminating how different zones within İzmir react to urban planning interventions. By analysing these fluctuations, the study provides a nuanced assessment of the city's adaptive responses over time, revealing patterns of resilience and structural evolution shaped by specific policy decisions (Sutton et al., 1997; Thomas & Frankhauser, 2013).

3.2. Statistical Analysis of *Adaptive Capacity Range*

Within the framework of urban systems theory, the capacity to adapt to environmental, socio-economic, or institutional perturbations is a foundational determinant of long-term sustainability and functional integrity. The Adaptive Capacity Range (ACR) serves as a diagnostic metric for assessing this resilience. A positive ACR value signifies that the urban system is endowed with sufficient structural and organizational flexibility to withstand and absorb external shocks, thereby maintaining continuity and performance under changing conditions. In contrast, an ACR value that approaches zero or becomes negative would imply an absence of adaptive mechanisms, effectively indicating systemic rigidity and heightened vulnerability to disruption—conditions that could precipitate breakdown or systemic collapse. Such a scenario is antithetical to the principles of urban resilience, which posit that adaptive capacity is an indispensable element in sustaining viable urban environments (Ahern, 2011).

Consequently, by theoretical and practical definition, ***ACR must invariably assume a positive value to meaningfully reflect the presence of adaptability.*** A zero or negative ACR would conceptually denote total incapacity for adjustment—an implausible condition for any operational urban system. Positive ACR values thus ensure the existence of a minimal threshold of resilience embedded within the spatial and functional structure of the city.

The Adaptive Capacity Range (ACR) is formally defined as:

$$ACR = [\mu - k\sigma, \mu + k\sigma] \ \ where \ \mu - k\sigma > 0$$

In this formulation, μ represents the arithmetic mean, σ denotes the standard deviation, and k is a coefficient corresponding to a selected confidence interval.

To ensure that the Adaptive Capacity Range (ACR) robustly captures the central tendencies of adaptive behaviour, both the mean and median values from each analysed time period are incorporated. The inclusion of these statistical descriptors is essential: the mean reflects the average tendency across all grid cells, while the median highlights the central point of the data distribution, mitigating the influence of outliers or skewed patterns. This dual-statistic approach allows for a more comprehensive representation of urban adaptability over time (Hu & He, 2018).

Without accounting for both the mean and the median across all measurement intervals, key variations in adaptive capacity may remain undetected, thereby compromising the reliability and interpretive depth of the analysis. ***Therefore, for the ACR to effectively capture the dynamics of urban resilience, it must systematically include the mean and median values derived from each temporal stage of analysis.***

Formally, for each time period ti, the ACR is defined as a function of both:

$$ACR(t_i) = [\mu(t_i) - k\sigma(t_i), \mu(t_i) + k\sigma(t_i)] \ \ where \ \mu(t_i) - k\sigma(t_i) > 0$$

In this framework, μ(ti) and i(ti) denote the mean and standard deviation of adaptive capacity at a given time point ti, respectively.

Sub-fractal analysis, by its design, enables the detection of fine-grained spatial variations embedded within the urban morphological structure. To preserve the analytical coherence of the Adaptive Capacity Range (ACR) as a holistic indicator of variability, it is imperative that differences in sub-fractal mean values across time intervals remain bounded within the limits defined by the ACR. This constraint ensures that abrupt anomalies or exaggerated deviations do not compromise the validity of the model, thereby sustaining the consistency and robustness of longitudinal interpretations.

Accordingly, the deviation between sub-fractal means at any two measurement points must not surpass the ACR. This stipulation guarantees that the variability in adaptive behaviour, as indexed by mean sub-fractal values, is effectively encapsulated within the expected bounds of system adaptability. It mitigates the risk of statistical distortion and upholds the integrity of the model's predictive and descriptive capacities. More precisely, to avoid overstating variability, the absolute difference in sub-fractal means must never exceed twice the amplitude (2A) of the ACR. Here, the amplitude A denotes the maximum permissible deviation from the central value (typically the mean) within the ACR. Constraining sub-fractal variability to within ±A ensures symmetrical balance, while enforcing the 2A threshold prevents the emergence of outlier patterns that could misrepresent adaptive trends.

This condition is formally expressed as:

$$2A \geq \left|\mu(t_i) - \mu(t_j)\right|$$

In this context, **A** denotes the amplitude, which defines the extent of variability within the Adaptive Capacity Range (ACR). A narrower amplitude reflects a more tightly bounded range of adaptive capacity, offering enhanced interpretive precision.

High data density within a confined interval signifies that a substantial proportion of the sub-fractal values are concentrated near the central tendency, thereby suggesting a stable and consistent characterization of the system's adaptability. This characteristic is fundamental for calibrating the ACR in a manner that ensures both statistical rigor and predictive reliability. A well-optimized ACR, grounded in high-density intervals, provides a resilient basis for assessing long-term urban adaptability under varying conditions (Weisstein, n.d.; Montgomery & Runger, 2014).

By focusing on regions of maximal data concentration, the methodology effectively filters out outliers and anomalous values, ensuring that the resulting metric reflects a dependable and coherent measure of adaptive behaviour. ***Thus, the ACR is defined as the narrowest range that encompasses the highest data density while satisfying all required statistical constraints. This ensures that the ACR functions not only as a bounded interval of change but as a robust and analytically sound index of urban system resilience.***

To further refine this characterization, a Gaussian (normal) distribution is applied to model the data, allowing for the identification of the central cluster and enhancing the accuracy of range determination.

The probability density function (PDF) of a normal distribution is expressed as:

$$P(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

where x is the variable of interest, μ denotes the mean, and is the standard deviation. The interval exhibiting the highest data density is selected to define the Adaptive Capacity Range (ACR), as it contains the most concentrated portion of the distribution. High data density within this range indicates that the majority of observations are tightly clustered around the mean, signifying a consistent and representative measure of adaptive capacity. This central clustering provides the statistical foundation for the ACR.

Mathematically, this density concentration can be represented by integrating the PDF over the interval surrounding the mean:

$$\int_{\mu-k\sigma}^{\mu+k\sigma} f(x)d(x)$$

This integral quantifies the total probability (or cumulative density) of data points lying within the range, where k is a coefficient determining the breadth of the interval. The selected interval is the one that yields the highest probability mass while maintaining analytical precision, ensuring that the ACR reflects the most stable and recurrent patterns in adaptive behaviour.

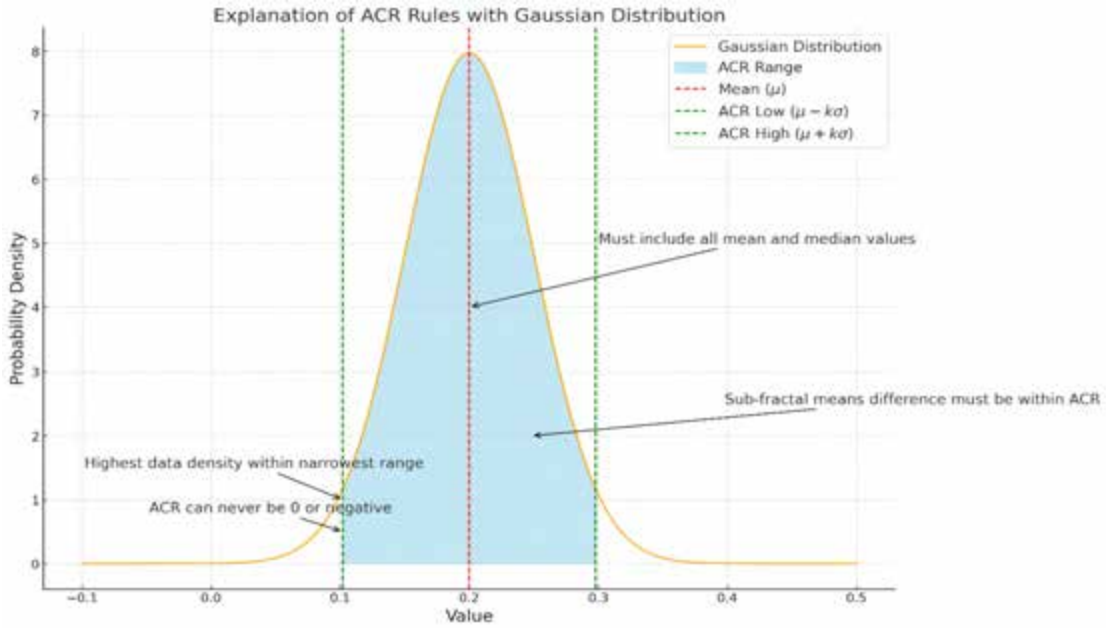

Figure 1. Conceptual Representation of Adaptive Capacity Range (ACR) Conditions Modelled with a Gaussian Distribution.

The graph presented in Figure 1 visualizes four fundamental criteria governing the definition of the Adaptive Capacity Range (ACR) within a Gaussian distribution framework:

• The ACR must remain strictly positive to signify the presence of adaptive potential, as indicated by the distribu-

tion's non-zero probability density.
• It must encompass both the mean and median values across time periods, visually marked by the red dashed line denoting the mean.
• Differences in sub-fractal mean values must fall entirely within the ACR bounds, illustrated by the extent of the blue-shaded region.
• The optimal ACR corresponds to the interval exhibiting the highest data density within the narrowest feasible range, also represented by the blue-shaded area, ensuring both statistical robustness and adaptive relevance.

4. *Sub-Fractal Analysis* of the Izmir City System by Related Plan Boundaries

The study operationalized sub-fractal analysis by structuring network data into spatial maps delineated by historical master plan boundaries. A total of sixteen sub-fractal analysis maps were produced, each corresponding to distinct phases in İzmir's urban planning history. For each planning interval, both the initial (pre-plan) and post-plan states were precisely defined, allowing for the accurate subtraction of sub-fractal box values to generate differential maps. These maps were constructed by calculating the change in sub-fractal dimension values between the two time points, denoted as t_1-t_0.

• Kemal Ahmet Aru's İzmir Plan (1955):

The initial state corresponds to 1950 (Period I), and the post-plan state to 1970 (Period II). The comparative analysis of urban network characteristics under the influence of the 1955 Kemal Aru Plan reveals significant transformations in İzmir's spatial structure over this 20-year span. Using a consistent analytical framework based on 81 sub-fractal boxes per network map (Figure S4), the fractal dimension increased from 1.49 in 1950 to 1.55 in 1970. This upward shift signifies an intensification in spatial complexity, likely driven by increased urban development and diversification. In parallel, the average sub-fractal box value—a finer metric for spatial distribution—rose from 1.188 to 1.341, yielding a net change of 0.152. This trend underscores the densification and increasing emergence of self-similar patterns in the city's infrastructural layout.

• İzmir Metropolitan Municipality (IMM) Plan (1973–1978):

The initial condition is set in 1970 (Period II), with the post-plan state established in 2000 (Period III). The comparative analysis across these three decades under the IMM Plan framework demonstrates continued evolution in urban spatial complexity. The sub-fractal assessment, employing 309 boxes per network map (Figure S5), identified an increase in fractal dimension from 1.43 in 1970 to 1.47 in 2000. Although the growth appears modest, it indicates a steady progression toward greater morphological intricacy. Concurrently, the average box values rose from 1.189 to 1.361, with a differential of 0.172. This increase reflects ongoing densification and the reinforcement of fractal-like, self-similar urban forms, likely shaped by both strategic planning interventions and organic spatial expansion.

• Metropolitan Municipality İzmir Plan (1989):

The initial state for this analysis is defined as 1970 (Period II), while the post-plan condition corresponds to 2000 (Period II). The investigation into urban network transformations under the 1989 İzmir Metropolitan Municipality (IMM) Plan reveals pronounced developments in spatial complexity and structural organization over the 30-year span. Utilizing a detailed grid of 413 sub-fractal boxes per network map (Figure S6), the analysis documented an increase in fractal dimension from 1.51 in 1970 to 1.57 in 2000. This growth reflects an ongoing intensification in the intricacy of the city's spatial configuration, indicating that the urban fabric has evolved in alignment with the transformative objectives embedded in the IMM 1989 planning framework.

In addition to fractal dimension changes, average sub-fractal box values—serving as a granular indicator of spatial distribution and internal variation—also exhibited a marked rise. The average value increased from 1.141 in

1970 to 1.383 in 2000, amounting to a differential of 0.242. This substantial increment underscores the processes of densification and the consolidation of self-similar spatial patterns within İzmir's urban infrastructure. The results highlight the effectiveness of the planning period in fostering more complex and resilient urban morphology.

• ***Metropolitan Municipality İzmir Plan (2012):***
The initial state for this phase of analysis is defined as the year 2000 (Period III), with the post-plan state corresponding to 2020 (Period IV). The evaluation of spatial complexity under the İzmir Metropolitan Municipality (IMM) 2012 Plan reveals continued yet moderated transformation in the city's urban morphology. Employing a high-resolution grid composed of 1,252 sub-fractal boxes per network map (Figure S7), this analysis facilitated a fine-grained assessment of structural evolution over the two-decade span. In 2000, the fractal dimension of the urban network was recorded at 1.39, representing the baseline complexity of the city's spatial structure at the beginning of the planning period. By 2020, this value had modestly increased to 1.41, suggesting a gradual enhancement in urban intricacy. Compared to earlier planning periods, this shift reflects a more restrained trajectory of spatial development—potentially indicative of more regulated urban growth or maturing morphological patterns. Further evidence of densification and internal complexity is provided by the average sub-fractal box values. These values rose from 1.150 in 2000 to 1.316 in 2020, yielding a net difference of 0.166. This increase highlights the persistence of self-similar patterning and the consolidation of spatial structure, albeit progressing at a more tempered rate than in previous decades. Overall, the findings suggest a phase of steady, controlled urban evolution under the guidance of the IMM 2012 Plan.

5. *Sub-Fractal Difference Analysis* of the İzmir Urban System by Planning Periods
The sub-fractal difference analysis delineates the temporal evolution of urban complexity in İzmir across four major planning intervals: the 1955 Kemal Aru Plan, the 1973–78 İzmir Metropolitan Municipality (IMM) Plan, the 1989 IMM Plan, and the 2012 IMM Plan. This assessment is based on variations in both the mean and median values of sub-fractal differences, which are visualized in Figure S8.

The mean values of sub-fractal differences, indicated by the solid blue line, exhibit the following sequence: 0.15 for the 1955 plan, 0.17 for the 1973–78 plan, 0.24 for the 1989 plan, and 0.17 for the 2012 plan. Correspondingly, the median values—depicted by the red dashed line—are recorded as 0.15 (1955), 0.09 (1973–78), 0.11 (1989), and 0.13 (2012). All measured values for both mean and median fall within the designated Adaptive Capacity Range (ACR) of 0 to 0.25. This alignment underscores a consistent pattern of manageable complexity shifts, indicating that despite varying degrees of planning intervention and urban growth, the city's adaptive transformation has remained within statistically and structurally interpretable bounds.

• ***Kemal Aru İzmir Plan (1955):***
Sub-fractal difference analysis conducted within the planning boundary of the Kemal Aru 1955 Plan, comparing network configurations from 1950 and 1970, revealed that 37 out of 81 analysed grid boxes fell within the Adaptive Capacity Range (ACR) of 0 to 0.25. This finding suggests substantial adaptive potential embedded within the urban system during this period (Figure S9). The frequency distribution of sub-fractal differences was assessed using a bin width of 0.05. The proportion of values within the ACR range accounted for 52.44% of the total dataset, reflecting a high degree of adaptability. A Gaussian curve was fitted to the data, yielding a mean (μ) of 0.15 and a standard deviation of 0.45. The distribution's peak corresponded precisely with the mean value, confirming central clustering. Both mean and median values were well-contained within the defined ACR, affirming its statistical robustness. The regression model exhibited an exceptionally high degree of fit, with an R^2 value of 0.9998, indicating an almost perfect linear relationship between the bin means and the fitted curve. Additionally, the

Q-Q plot for this period demonstrated close alignment between empirical quantiles and the theoretical normal distribution, further validating the Gaussian fit (Figure S10).

• ***İzmir Metropolitan Municipality Plan (1973–1978):***
An analogous sub-fractal difference analysis was performed within the boundaries of the IMM 1973–78 Plan, comparing urban network data from 1970 and 2000. Of the 309 sub-fractal box values examined, 127 were found to fall within the ACR (0–0.25), indicating that a considerable segment of the urban landscape demonstrated adaptive spatial characteristics (Figure S11). The distribution analysis revealed that 44.52% of all values resided within the ACR, slightly lower than the 1955 period but still reflective of a resilient urban system. The Gaussian distribution fitted to the data produced a mean (μ) of 0.17 and a standard deviation (σ) of 0.44, with the distribution peaking at 0.20. This central tendency illustrates a notable concentration of difference values within the adaptive threshold. The regression fit demonstrated strong linearity, with an R^2 value of 0.9998, validating the model's precision. Additionally, the Q-Q plot confirmed that empirical and theoretical quantiles were closely aligned, supporting the statistical consistency of the Gaussian approximation (Figure S12).

• ***İzmir Metropolitan Municipality Plan (1989):***
Sub-fractal difference analysis conducted within the spatial scope of the IMM 1989 Plan aimed to assess the impact of planning decisions on the city's spatial complexity. A total of 413 sub-fractal box values were analysed, of which 166 fell within the Adaptive Capacity Range (ACR) of 0 to 0.25—marking a substantial expression of the city's capacity to absorb change and maintain structural functionality in the face of planned interventions or emerging urban pressures (Figure S13). The proportion of values within the ACR constituted 42.03% of the dataset, indicating moderate but meaningful adaptability. A Gaussian distribution was fitted to the difference data, yielding a mean (μ) of 0.24 and a standard deviation of 0.44, with the distribution's peak occurring at 0.26. These statistical parameters suggest that the bulk of sub-fractal variation remained concentrated around the ACR's upper threshold, highlighting the persistence of adaptability within an increasingly complex urban form. The model fit was highly reliable, confirmed by an R^2 value of 0.9998. Moreover, the Q-Q plot demonstrated a strong correspondence between empirical and theoretical quantiles, reinforcing the validity of the normal distribution fit (Figure S14).

• ***İzmir Metropolitan Municipality Plan (2012):***
The city-wide sub-fractal analysis for the IMM 2012 Plan evaluated spatial complexity changes using 1,252 box values, providing a comprehensive account of adaptive patterns over time. Of these, 603 boxes displayed sub-fractal differences within the defined ACR (0–0.25), signifying a widespread capacity for structural adaptation and resilience across İzmir's urban landscape (Figure S15). The results indicated that 52.07% of the observed values were contained within the ACR, reflecting a high degree of adaptability during this planning phase. The application of a Gaussian fit produced a mean (μ) of 0.17 and a standard deviation of 0.45, with the peak of the distribution observed at 0.15. These outcomes suggest a well-centred and consistent distribution of difference values within the ACR, reinforcing the notion of sustained adaptability in the city's urban morphology. As with previous periods, the model demonstrated exceptional precision, with an R^2 value of 0.9998, and the Q-Q plot confirmed the close alignment between observed and theoretical quantiles, validating the Gaussian approximation (Figure S16).

- **Regional Sub-Fractal Analysis within the 2012 IMM Planning Boundary**
The 2012 İzmir Metropolitan Municipality Plan was subjected to a detailed regional analysis to evaluate spatial adaptability using sub-fractal difference values. This assessment involved calculating the mean, median, and standard deviation for each region and determining the proportion of data falling within the defined Adaptive Capacity Range (ACR) of 0 to 0.25 (Figure S17).

o ***Northern İzmir:*** Of the 228 grid boxes analysed, 73 (37.99%) fell within the ACR. The sub-fractal difference values exhibited a mean of 0.17, a median of 0.10, and a standard deviation of 0.62. The Gaussian model fit was confirmed with a robust R^2 value of 0.9998, indicating a strong correlation (Figure S18).

o ***Southern İzmir:*** In this region, 48 out of 131 boxes (40.15%) were within the ACR. The mean difference was 0.20, the median was 0.16, and the standard deviation measured at 0.46. The model's accuracy was validated by an R^2 value of 0.9998 (Figure S19).

o ***Western İzmir:*** Here, 82 of 191 boxes (46.88%) were within the ACR. The statistical outputs showed a mean of 0.19, a median of 0.15, and a standard deviation of 0.39. The Gaussian model demonstrated a strong fit with an R^2 of 0.9998 (Figure S20).

o ***Eastern İzmir:*** Of the 148 boxes assessed, 66 (51.01%) fell within the ACR. The region recorded a mean of 0.20, a median of 0.17, and a standard deviation of 0.42. The fit quality was high, supported by an R^2 value of 0.9998 (Figure S21).

o ***Tourism Region (Gümüldür Area):*** In this area, 17 out of 48 boxes (42.86%) were within the ACR. The mean sub-fractal difference was 0.14, with a median of 0.12 and a standard deviation of 0.46. The Gaussian fit held with an R^2 of 0.9998, confirming model validity (Figure S22).

o ***Central İzmir:*** Central İzmir demonstrated the strongest adaptive capacity among all regions, with 313 of 506 boxes (64.69%) falling within the ACR. The mean difference was 0.14, the median was 0.13, and the standard deviation was 0.37. The correlation between observed and theoretical values remained strong, with an R^2 of 0.9998 (Figure S23).

Collectively, the regional analysis confirmed the effectiveness of the 0–0.25 Adaptive Capacity Range in capturing the city's multifaceted ability to accommodate urban transformation. The consistent Gaussian distributions, relatively moderate standard deviations, and uniformly high R^2 values across all sub-regions reinforce the reliability of the model in representing İzmir's systemic resilience to planning and environmental pressures.

6. Discussion on the *Adaptive Capacity Range* of İzmir as a *Complex Physical System*

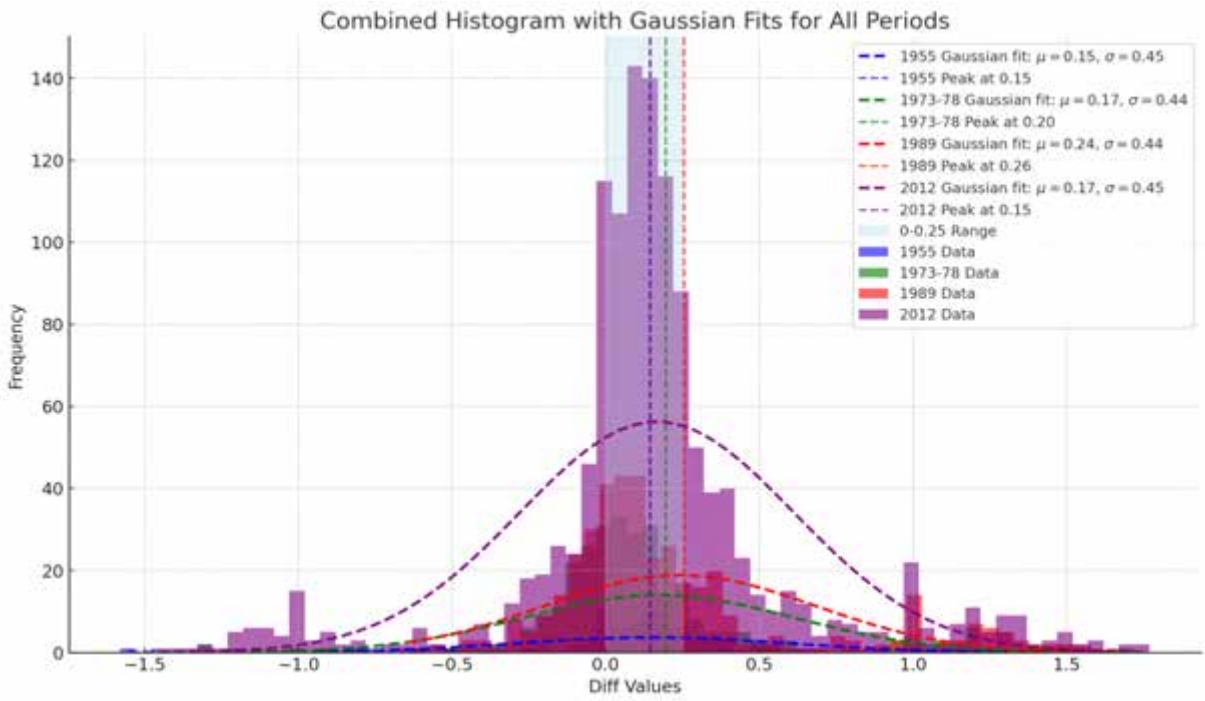

Figure 2. Combined Histogram with Gaussian Fits for periods (Distribution of Metric Differences across All Time Periods and Regions)

The longitudinal analysis of İzmir's urban development, employing sub-fractal and difference analysis methodologies applied to its road network, offers a nuanced understanding of the city's Adaptive Capacity Range (ACR) and its implications for resilient urban planning. This investigation spans network configurations from 1950 to 2020, with fractal dimension values extracted to trace the evolving complexity of İzmir's spatial structure in response to successive planning initiatives. Across all periods, the ACR was consistently situated within the interval of 0 to 0.25, suggesting a moderate but structurally meaningful degree of adaptability. This bounded range underscores the city's ability to reorganize and sustain infrastructural functionality amid socio-spatial transformations (see Figure 1).

Methodologically, the study synthesizes sub-fractal computation with difference analysis, grounded in the mathematical logic of fractal geometry and the dynamic principles of complex systems theory. Originally formulated by Mandelbrot (1982), fractal analysis offers a theoretical lens for interpreting the self-similar and scale-invariant patterns that characterize urban morphology. This paradigm is reinforced by Batty (2005), who posits that urban spatial forms inherently manifest fractal behavior, enabling their internal structural dynamics to be captured through rigorous quantitative measures.

The conceptualization of adaptive capacity is enriched by interdisciplinary analogies, particularly from statistical mechanics and quantum theory. In statistical mechanics, the notion of phase transitions and critical thresholds demonstrates how marginal perturbations can catalyze disproportionate systemic reconfigurations—a dynamic mirrored in urban environments, where minor policy adjustments or spatial interventions can induce marked transformations in form and function (Batty, 2005). Similarly, the probabilistic ontology of quantum systems provides an apt metaphor for urban complexity, wherein outcomes are shaped not by deterministic rules but by fluctuating probabilities and interdependent interactions (Mandelbrot, 1982).

Through this interdisciplinary integration, the research frames cities as complex adaptive systems and positions

the ACR as a predictive metric that operationalizes resilience. Functioning as a quantitative analogue to critical thresholds in physical systems, the ACR encapsulates the city's adaptive behavior by incorporating both mean and median sub-fractal difference values. This dual inclusion ensures that the analysis reflects central tendencies while preserving sensitivity to distributional asymmetries, thereby offering a comprehensive representation of urban adaptability. Such a framework aligns with broader ecological and socio-technical theories of resilience, notably those advanced by Folke et al. (2002), which emphasize the importance of systemic flexibility and transformative potential in the face of uncertainty.

The regional sub-fractal analysis further illuminates the spatial heterogeneity of İzmir's adaptive capacity, revealing distinct variability in resilience across different urban zones. Northern and Southern İzmir exhibit moderate adaptability, with 37.99% and 40.15% of data points respectively falling within the Adaptive Capacity Range (ACR). The Western and Eastern districts display comparatively higher resilience, with ACR coverage rates of 46.88% and 51.01%. Notably, Central İzmir demonstrates the most robust adaptive performance, with 64.69% of its data residing within the ACR. This pattern of variation substantiates the concept of spatial heterogeneity in urban resilience, as articulated by Folke et al. (2002), which posits that adaptive capacity is unevenly distributed across the urban fabric, shaped by historical, socio-economic, and infrastructural asymmetries.

The practical implications of these findings extend beyond theoretical analysis, offering actionable tools for urban planners and policy designers. By systematically quantifying urban complexity and delineating adaptive thresholds, this methodology enables planners to anticipate structural vulnerabilities and design targeted interventions. Such an approach aligns with broader urban resilience discourses, emphasizing the pivotal role of adaptive planning in guiding sustainable urban transformation (Batty, 2005). Moreover, the methodological integration of sub-fractal analysis with principles derived from theoretical physics highlights a novel and interdisciplinary pathway for urban systems modeling—bridging statistical mechanics, complexity theory, and spatial analytics to forecast urban evolution.

In conclusion, this study reinforces the necessity of embedding complex systems theory into the praxis of urban planning to effectively contend with the nonlinear and unpredictable nature of urban growth. The results suggest that urban environments characterized by higher degrees of spatial complexity, as measured through detailed fractal metrics, exhibit enhanced adaptive capacities—positioning them to more effectively absorb and respond to future socio-environmental challenges. Looking forward, the extension of this analytical framework to other metropolitan contexts, coupled with the integration of real-time geospatial and socio-economic data, holds significant potential for advancing our understanding of urban adaptability and fostering the development of more resilient and sustainable urban systems.

7. Conclusion

The analytical approach employed in this study—integrating sub-fractal and difference analysis—draws theoretical grounding from Mandelbrot's (1982) seminal contributions to fractal geometry and Goldenfeld's (1992) investigation of phase transitions within statistical mechanics. By transposing the conceptual apparatus of statistical physics to the domain of urban studies, this research establishes a robust analytical framework for interpreting and managing the nonlinear dynamics of urban expansion and adaptive transformation. The methodologies illustrate how micro-scale fluctuations—such as minor infrastructural or morphological alterations—can precipitate pronounced changes at the macro-urban scale, reflecting the emergent behavior described by Yeomans (1992) in relation to the aggregation of microscopic interactions into large-scale phenomena.

The quantification of Adaptive Capacity Range (ACR) within this context exemplifies a productive intersection between theoretical physics and spatial urban analytics. This convergence equips urban planners with advanced tools for anticipating and steering urban morphological evolution. Consistent with the principles of complex systems theory—which conceptualizes cities as adaptive, self-organizing entities (Bar-Yam, 1997)—this research applies fractal diagnostics to capture the intrinsic irregularities and hierarchies of urban form. In doing so, it contributes empirical support to Batty's (2005) assertion that cities inherently exhibit fractal structures, and that

these patterns can be rigorously interrogated to illuminate underlying processes of spatial complexity and systemic adaptability.

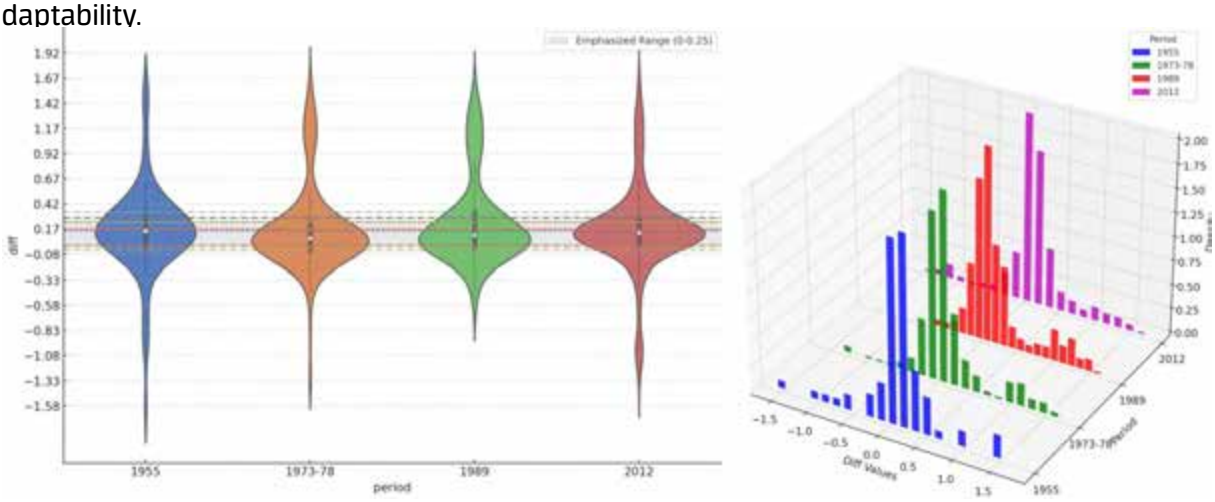

Figure 3. Density Distributions of Sub-Fractal Difference Values Across All Periods and Regions

This figure depicts the distributional characteristics of sub-fractal difference values across all examined temporal and spatial domains in İzmir. Utilizing both violin plots and 3D histograms, the visualization reveals the variability, skewness, and concentration of data points. Central to this representation is the highlighted 0–0.25 range, corresponding to the Adaptive Capacity Range (ACR), which encompasses the majority of observed values. This reinforces the notion that urban systems exhibit measurable, intrinsic adaptability, which can be captured through sub-fractal metrics. Beyond visual analysis, the findings underscore the methodological significance of ACR as a robust and transferable metric for urban adaptability. The empirical demonstration that ACR is not only computable but also meaningful within the urban planning context lays the groundwork for methodological standardization. Such a framework could be extrapolated to diverse urban contexts, enabling comparative resilience assessments and fostering evidence-based planning strategies. This aligns with Portugali's (2012) call for integrating complexity science into urban design and policy, advancing a data-driven, systemic approach to fostering urban resilience.

Future Directions

Future research should extend the application of sub-fractal and difference analysis to a wider range of urban contexts to evaluate the universality of the Adaptive Capacity Range (ACR). Comparative studies across cities with differing scales, complexities, and socio-economic profiles will help determine whether İzmir's patterns are generalizable or context-specific (Bettencourt, 2013; Arcaute et al., 2015; Ribeiro et al., 2019). Incorporating real-time data—such as traffic, mobility, economic activity, and environmental conditions—can enhance model accuracy and responsiveness (Calabrese et al., 2013; Hasan et al., 2013). Such integration would enable more dynamic assessments of adaptability, particularly during disruptions (Lu et al., 2016). The rise of smart cities offers further opportunities to leverage IoT technologies and big data analytics for tracking and modeling urban complexity (Batty, 2018). Combined with AI and machine learning, these tools can identify patterns, predict growth, and simulate policy outcomes (Harris, 1991).

Interdisciplinary collaboration is essential for advancing holistic models that incorporate social, economic, and environmental dimensions of resilience (Ahern, 2011; Folke et al., 2010). Engagement with planners, policymakers, and communities will also be key in translating academic findings into practical tools (Portugali, 2012; Adger et al., 2005). In sum, expanding geographic scope, integrating dynamic data, leveraging AI, and fostering cross-sector collaboration will deepen our understanding of urban adaptive capacity and support more resilient and sustainable urban development.

Abstract

This study employs Geographically Weighted Machine Learning (GW-ML) to analyze spatial patterns and influencing factors of off-campus rental prices near colleges in Taiwan. Using Moran's I, LISA, and K-means clustering, the research identifies rent clusters and segments the market. OLS, GWR, and GW-ML models were compared in terms of their performance, with Geographically Weighted LightGBM showing the best predictive accuracy. Key factors affecting rents include proximity to colleges, housing age, and access to public transportation. The GW-ML framework captures spatial heterogeneity and nonlinear relationships more effectively than traditional models. The results reveal that rental properties in city centres place more importance on rental area, while those in suburban areas focus more on building age for improving housing affordability and guiding policy in college neighborhoods.

Keywords: geographically weighted machine learning; machine learning; housing rents

1. introduction

In recent years, rising housing costs in Taiwan have highlighted challenges in property transactions, rental housing, and housing justice. For students living away from home, rising rents create financial burdens, compounded by information asymmetry and lack of market transparency, making the rental process stressful and complex. School districts, characterized by high rental demand, experience price fluctuations influenced by economic, spatial, and resource factors. Despite their importance, limited research addresses the spatial characteristics and factors influencing rental prices. This study investigates rental price spatial correlations and influencing factors near universities, thereby offering insights into rental market management.

2. Research Methodology and data sources

2.1. Study Area

This study investigates the spatial distribution characteristics of rental prices in areas surrounding school districts. To comprehensively analyse the factors influencing the rental market, the study encompasses eight administrative districts in Tainan City: West Central District, North District, East District, South District, Anping District, Annan District, Yongkang District, and Rende District. They are shown in Fig. 1.

Fig. 1. Location of study area.

2.2. Methods of Analysis

2.2.1. Global Spatial Autocorrelation

Moran's index method was adopted to evaluate the overall level of spatial autocorrelation of a specific attribute across a geographical area. It describes the spatial distribution characteristics of an observed variable, indicating whether it exhibits clustering, dispersion, or randomness within the study area. The calculation formula is as follows:

$$I = \frac{n}{\sum_i \sum_j W_{ij}} \frac{\sum_i \sum_j W_{ij}(x_i - \bar{x})(x_j - \bar{x})}{\sum_i (x_i - \bar{x})^2} \quad (1)$$

Where *n* represents the number of samples; x_i and x_j denote the attribute values at locations *i* and *j*; $\bar{x}$ represents the mean attribute value across all samples; W_{ij} is the spatial weight matrix between locations *i* and *j*.

The value of Moran's I ranges from -1 to 1. Moran 's I > 0 indicates a positive spatial autocorrelation, meaning the attribute demonstrates clustering. Conversely, Moran 's I < 0 suggests negative spatial autocorrelation, which is indicative of a dispersed pattern. When Moran's I = 0, it implies no spatial autocorrelation, signifying that the spatial distribution of the attribute is random.

2.2.2. Local Spatial Autocorrelation

Local Indicators of Spatial Association (LISA) is a measure of local spatial autocorrelation used to infer the extent of clustering within specific areas. It serves as a set of local indicators to identify the boundaries of clustered regions. The significance test primarily evaluates whether the clustering of spatial elements within a given study area is statistically significant. Higher levels of significance indicate more pronounced spatial clustering. Compared to the global indicator Moran's I, LISA focuses on detecting the variation of a specific area or unit and its association with neighbouring units. Proposed by Anselin (1995), the LISA indicator extends the concept of Global Moran's I by incorporating spatial weight considerations and calculating the Moran index for each spatial unit. The formula for calculating LISA can be expressed as follows:

$$I_i = Z_i^T \sum_j W_{ij} Z_j^T \quad (2)$$

Where Z_i^T and Z_j^T represent the standardized observed values (mean-centered) in vector form. W_{ij} is the spatial weight matrix indicating the adjacency relationship between spatial units *i* and *j*, W_{ij}=1: *i* and *j* are adjacent; =0: and are not adjacent.

Anselin (1995) categorized LISA into four quadrants based on the degree of spatial clustering, as shown in Fig. 2.: high-high (HH), low-high (LH), low-low (LL), and high-low (HL). This classification facilitates the analysis of spatial clustering intensity. HH and LL are also referred to as hot spots and cold spots, respectively. The quadrant diagram aids in analyzing the relationship between high or low observed values in a specific area and those in surrounding areas. It identifies spatial association patterns across the study area, highlighting local spatial anomalies and instabilities. Typically, the LH and HL categories reflect anomalies that are inconsistent or contradictory to their surrounding areas (Gray, 2011). These values indicate significant deviations and provide insight into local spatial heterogeneity.

2.2.3. OLS and HPM

The housing characteristic price model (HPM) often uses OLS for estimation, using OLS as the basic estimation technique to study how different characteristics of housing affect market prices. Its basic assumption is that housing prices can be predicted through the attributes of the unit's structure and location as independent variables, and it discusses housing prices as a heterogeneous product from a macro perspective (Ucal & Kaplan, 2020)using a hedonic price model with a large dataset and a single variable for locational attributes. Research Design & Methods: The analysis of consequent housing prices in İstanbul's counties with hedonic price modelling and the extrapolation of results by comparing the prices to the human development level of counties. We use multiple regression and Ordinary Least Squares (OLS. Many studies have proposed that various characteristics do indeed affect rent, and a regression model framework has been established to create a system for housing prices, further analyzing the effective analytical structure and characteristics of regional real estate prices. According to the research by Sirmans et al. (1989) , the impact of various local amenities and building characteristics on housing prices was studied, Davis et al. (2023) assessed the impact of green infrastructure on housing prices through a characteristic price model, including analysis of artificial wastewater wetlands, crystal gardens, ponds, etc., to further understand the property value of the ecosystem services they provide. The OLS calculation formula is as follow:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \cdots + \beta_n X_n + \varepsilon \qquad (3)$$

The HPM calculation formula is as:

$$lnP = \alpha_0 + \sum_{i=1}^{n} \alpha_i z_i + \epsilon \quad (4)$$

Where *P* represent the asset price, *lnP* is the natural logarithm of *P*, Z_i is the price characteristic, α_0 is the intercept, α_i denotes the coefficient of the price characteristic, and ϵ is the error term.

OLS serves as a method for estimating and calculating global regression coefficients, testing whether there is a relationship between variables and the dependent variable, and checking the independence of residuals. It has been widely used in real estate price research, but it cannot explain the interactions of spatial data with heterogeneous characteristics. Therefore, most studies use GWR to compensate for the shortcomings of OLS (Koohpayma & Argany, 2021; Liu & Strobl, 2023).

2.2.4. Geographically Weighted Regression

Geographically Weighted Regression (GWR) is a local analysis technique for spatial heterogeneity that is non-stationary and conforms to the first law of geography, primarily used to understand the relationships of spatial changes, calculating each local regression through data estimated by distance decay, using the function of spatial location as coefficients in the GWR model, and allowing them to vary spatially within the study area (Fotheringham et al., 2002), thereby identifying differences in the impact and intensity of features across the overall space. For example, Gutiérrez-Posada et al. (2017) use GWR to understand whether the determining factors of local population growth in Spain have uniform or non-uniform effects over time and space, analysing the local effects of spatial differences to plan appropriate local policies.

GWR has the core concept that regression coefficients are not fixed constants but vary according to different geographical spaces. Thus, it can capture the relationship between dependent and independent variables in space and the non-stationarity of housing prices, achieving higher accuracy and fitting effects than classical regression models(Cellmer et al., 2020; Iliopoulou & Feloni, 2022)as well as of real estate prices and values. The main aim of the study was to analyse an effect of these socio-demographic and environmental factors on average housing property prices and on the number of transactions in a spatial approach. In previous research conducted on a national scale, usually all variables were treated in a similar way, i.e., as global or local variables. During the research, an attempt was also made to answer the question of which of the variables adopted for analysis have a local impact on prices and market activity, and which are global. The study was conducted in Poland and used data from the year 2018 on 380 counties (Local Administrative Units. The impact range of spatial heterogeneity and observation points has now been widely applied in various fields, such as economics, environmental science, public health, and the housing prices. The key point to note is the need to choose appropriate distance weighting functions and bandwidth (Brunsdon et al., 1996), and it can only describe continuous heterogeneity, still requiring other methods to assist in describing complete spatial heterogeneity, such as spatial autocorrelation analysis. The GWR calculation formula is as follows:

$$y_i = B_0(u_i, v_i) + \sum_{k=1}^{p} B_k(u_i, v_i) x_{ik} + \varepsilon_i \quad (5)$$

Where y_i is the rental price at the *i*-th observation point; $B_0(u_i, v_i)$ is the intercept term at the *i*-th observation point, varying with spatial location (u_i, v_i); $B_k(u_i, v_i)$ represents the regression coefficient of the *k*-th independent variable at the *i*-th observation point; x_{ik} is the value of the -th independent variable at the *k*-th observation point; ε_i is the error term at the *i*-th observation point.

To estimate the location-specific coefficients in equation (5), GWR constructs a diagonal weight matrix W_i centred on each observation *i*. The most widely adopted choice is the Gaussian kernel, which assigns weights according to

$$W_{ij} = \exp\left(-\frac{d_{ij}^2}{2h^2}\right) \quad (6)$$

where d_{ij} denotes the Euclidean distance between observations *i* and *j*, and *h* is the bandwidth that produces smoother spatial surfaces, whereas a smaller value allows stronger local variation. The optimal bandwidth is typically selected by leave-one-out cross-validation or the corrected Akaike information criterion (AICc) (Brunsdon et al., 1996). The Gaussian kernel provides continuous, strictly positive weights, which stabilise local estimations and avoid singular design matrices (Fotheringham et al., 2002).

2.2.5. Applications of Machine Learning in Rental Market Analysis

The geographical distribution and influencing factors of rental market prices have been focal research areas. Traditional regression models, such as linear regression and geographically weighted regression (GWR), face limitations in handling high-dimensional features and non-linear relationships. Machine learning models, including Random Forest, Support Vector Regression (SVR), KNN, and gradient boosting frameworks (XGBoost, LightGBM), are increasingly replacing traditional methods, offering improved prediction accuracy and efficiency.

XGBoost and LightGBM stand out in particular. Research indicates that XGBoost effectively avoids overfitting and enhances computational efficiency through regularization and parallel computation, while LightGBM further accelerates large-scale data processing with improved accuracy (Chen & Guestrin, 2016; Ke et al., 2017). For instance, Takahiro Yoshida et al. (2021) demonstrated that XGBoost outperforms traditional regression models in accuracy and efficiency on large datasets. Similarly, Yue Ming (2020) verified XGBoost's precise prediction of Chengdu's housing prices, with a mean squared error (MSE) of just 0.04. These studies highlight the significant advantages of XGBoost and LightGBM in handling non-linear and spatially heterogeneous rental market data.

Taking advantage of its ability to evaluate spatial impacts and analyze nonlinear relationships, geographically weighted machine learning methods have been applied in research recently. Wang et al. (2024) used geographically weighted random forest (GW-RF) model to explore the local associations between crash frequency and various influencing factors in the US. Yang et al. (2023) introduced geographically weighted support vector regression (GWSVR) for analysing soil metal chromium (Cr) and PM2.5 concentrations. Assigning sample weights according to Gaussian kernel values—paralleling Geographically Weighted Regression—enhances model performance. Hence, the present study employs a geographically weighted LightGBM to describe spatial heterogeneity in the rental housing market. The geographically weighted approach is expected to outperform a LightGBM model that does not incorporate geographic weighting.

2.3. The factor selection and data sources

This study aims to explore the spatial distribution patterns of rental prices within school districts and examine the impact of various influencing factors on these rental prices, as shown in Table 1. Taking rental price as the research subject, the study adopts price per ping as the measurement standard for rental prices. The data are sourced from the Real Estate Transaction Price Inquiry System of the Ministry of the Interior, encompassing rental housing transaction records within the study area. The research period spans from January to September 2024, covering a complete three-season interval. The dependent variable for the GWR analysis is defined as rental price (NTD/ping).

In selecting potential influencing factors, this study considers the rental demands of student populations, which are typically constrained by commuting distance to schools and daily convenience. Starting from this perspec-

tive, the research identifies and analyzes nine potential factors that may affect rental prices, based on the residential convenience and accessibility needs of students, as well as the functional and structural characteristics of rental housing. These factors include: (1) distance to the nearest university, (2) distance to nearest convenience store, (3) distance to nearest supermarket, (4) distance to the nearest bus stop, (5) distance to the nearest bike stop, (6) house age, (7) rental area, (8) elevators, and (9) furniture. Table 1 shows the details of each factor. These factors serve as independent variables in the GWR analysis, which is employed to calculate the relative impact and spatial heterogeneity of these factors on rental prices within school districts.

Table 1. Potential impact factors on rental prices and valuation methods

Categories	Variables	Measurements	Data sources	Reference
Educational characteristics	Distance to nearest university	Straight line distance (meters)	Ministry of Education	Wen et al.,2015 Wen et al.,2018

3. Result

3.1. Spatial Autocorrelation analysis

3.1.1. Global Moran's I

Moran's I is used to determine whether the distribution characteristics of rent unit price in the overall space are agglomeration, dispersion, or random distribution. The value is between -1 and 1. A positive value indicates that the rental unit price is clustered in space, and near points have similar prices; a negative value indicates that the unit price of adjacent points has a large difference, which indicates a scattered data distribution; approaching 0 means that the space is randomly distributed.

The results of global Moran's I are presented in Fig. 3. It shows that the Moran's I value of the rental unit price in the school district is 0.3402, the Z value is 45.9976, and the P value is 0.000, passing the significance test. It shows that there is indeed spatial autocorrelation of the rental unit price. To have a more straightforward picture pre-

sentation for the following LISA analysis, we conduct Moran's I at the neighborhood scale to confirm whether the phenomenon of spatial autocorrelation still exists if the rental unit price is presented using polygon data. Calculate the average unit rental price in the neighborhood using the representative data here. The results are shown in Fig. 4. Moran's I value is 0.101, Z value is 3.684, and P value is 0.000, passing the significance test, the space shows a positive correlation. Although the value is closer to a random distribution, the significance test still shows a non-random spatial distribution of rental unit prices, and the polygon data can help present a clearer picture.

Both point data and polygon data illustrate that rents are spatially autocorrelated. The factors affecting unit rents may vary significantly across different regions. When modeling unit rents, the bandwidth and intensity of the impact of each variable on the local scale should be considered.

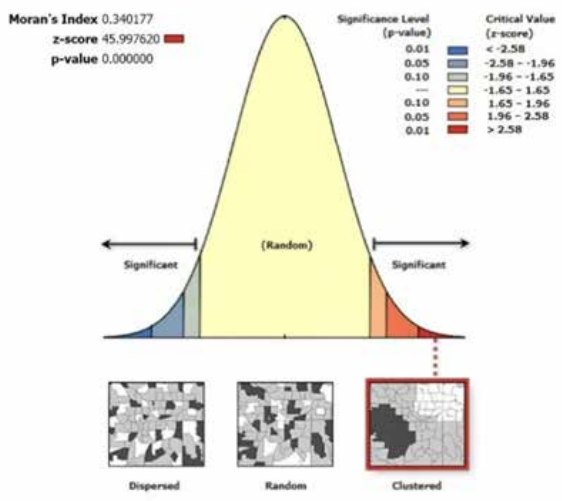

Fig. 3. Rental price data in point format; Results of spatial autocorrelation analysis by ARCGIS software.

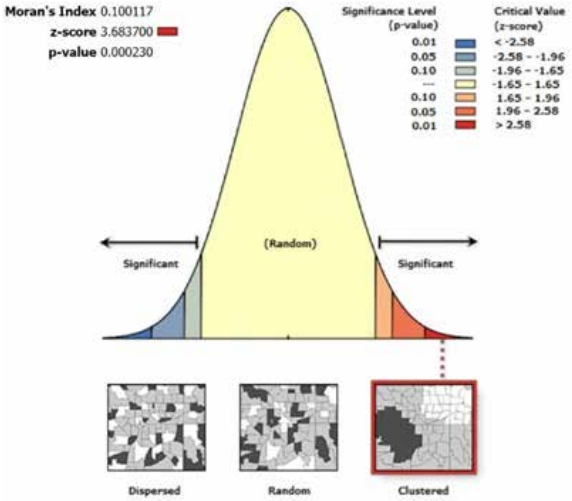

Fig. 4. Rental price data in polygon format; Results of spatial autocorrelation analysis by ARCGIS software.

3.1.2. Local autocorrelation analysis (LISA)

After confirming the spatial autocorrelation of rental unit prices, the neighbourhood scale was used to calculate the facet data of average rental unit prices. The LISA values were calculated to observe the clustering phenomenon of high and low values in each area, and the results are shown in Fig. 5.

High rent unit price clusters (H-H) are in the East, West Central, and North Districts, which are the city centre of Tainan. With complete living functions, and several colleges are clustered here, including National Cheng Kung University, Tainan Nursing College, and the University of Tainan, etc., leading to high rental demand, the rental price thereby increase; The low-rent unit price agglomeration area (L-L) is located near the sea in South District and Yongkang District adjacent to Xinhua District. It is a suburban area far away from the core development areas and schools of Tainan City. The convenience of life is low, resulting in the phenomenon of low-rent unit price clusters. In addition, the areas with a mix of high and low rent prices, H-L points, are located at the junction of the Yongkang District. It is speculated that the proximity to the Tainan Industrial Park and the Yongkang Interchange of National Highway No. 1 has resulted in higher rents in this area than in other areas. However, there is less rental data in this area, so bias due to insufficient sample size cannot be ruled out; L-H points are located in the West Central District and Annan District, which is the transition zone between the city centre and the suburbs. It results in a spatial distribution phenomenon where high-rent and low-rent properties coexist.

Then, we analysed the spatial cluster phenomenon on the main variables that affect housing prices. There are two variables in total, namely house age and floor area. The results are shown in Fig. 6. and Fig. 7. Aged housing areas are in the city centre and overlap with high-rent areas. Although the results of subsequent model construction show that the overall impact of house age on unit rent is negative, the unit rental price in areas with older houses is still higher in the city centre due to the location value and the impact of the specific rental market structure. Smaller floor area clusters also overlap with high-rent areas. Land resources in the city centre are scarce, and the unit area design tends to be smaller to improve space utilization efficiency. Furthermore, in response to the special target groups around the city centre, such as students, young tenants, etc., the rental price of the units is relatively high.

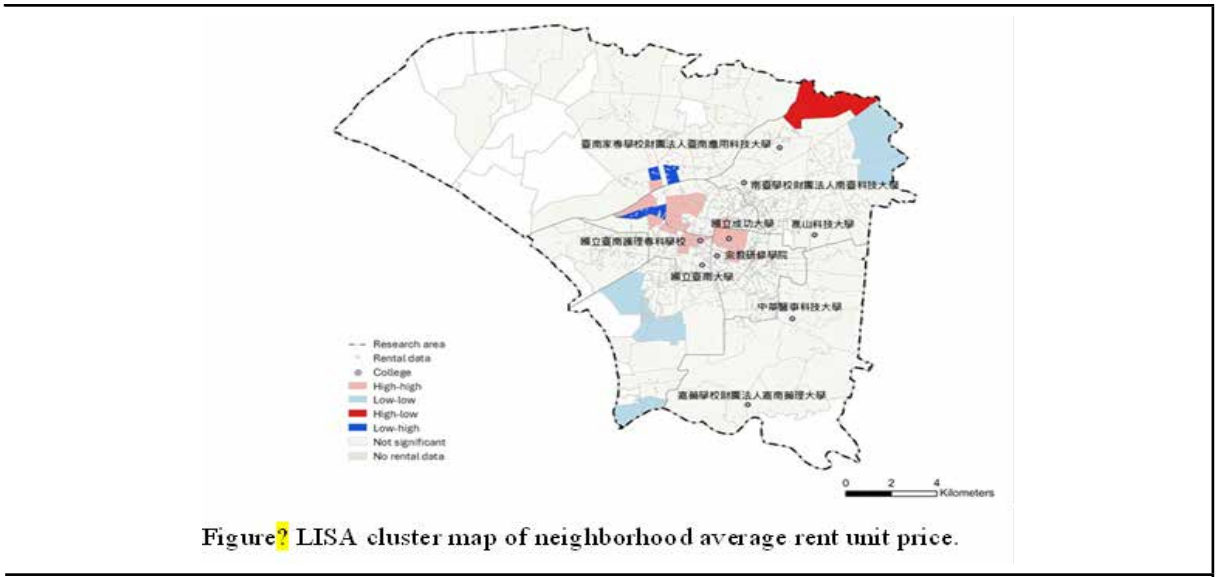

Fig. 5. LISA cluster map of neighbourhood average rent unit price.

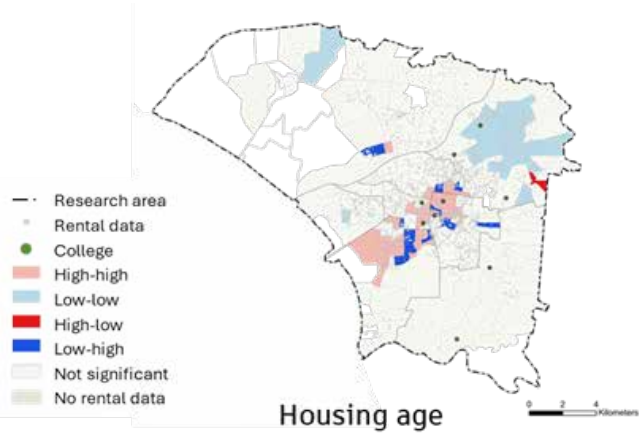

Fig. 6. LISA cluster map of average housing age.

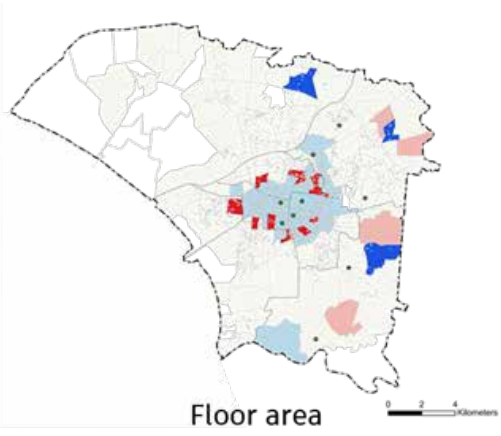

Fig. 7. LISA cluster map of average floor area.

3.2. Ordinary Least Squares (OLS)

Ordinary Least Squares (OLS) is a statistical method used to determine the relationship between two or more variables by minimizing the sum of the squared differences between predicted values and actual observed values. This method identifies the best linear relationship. The OLS estimation results are shown in Tables 2 and 3.

From the regression statistics, the model is based on an analysis of 4,942 samples, which is a sufficient sample size. The multiple R value is 0.289, indicating the correlation between variables ranging from 0 to 1. This suggests a relatively low correlation, meaning the model has limited explanatory power for the dependent variable. The R-squared value explains the proportion of variance in the dependent variable accounted for by the model, which is only 8.35%. This indicates that the explanatory variables in the model have limited ability to explain housing prices, and other important variables may not have been included. The adjusted R-squared is slightly lower than the original R^2 because it accounts for the number of variables, providing a more conservative measure of the model's explanatory power. The standard error, which represents the range of prediction errors, is 104.209. A smaller value is preferable, but the relatively high standard error indicates that the model's accuracy is suboptimal.

In the regression coefficient analysis, the coefficients show the direction of the impact of each variable on the dependent variable. When all independent variable values are zero, the predicted value of the dependent variable is 298.431. Among the independent variables analyzed, most were statistically significant, except for the distance to elevators and supermarkets, which were not significant.

Overall, the findings indicate that as housing age, distance to schools, convenience stores, bus stops, and bicycle lanes increase, housing prices decrease. Although the model is statistically significant, the R^2 value is only 0.084. It suggests that the model may be missing important variables, such as location, school district quality, and transportation. This causes limitations for the research.

Table 2. Result of OLS regression statistics

1.1.1. The impact of educational characteristics on rental housing prices

By comparing the distance map of each point to the nearest university (Fig. 8) with the results of the Geographically Weighted Regression (GWR) analysis (Fig. 9), it is evident that the closer the distance to a university, the higher the housing prices.

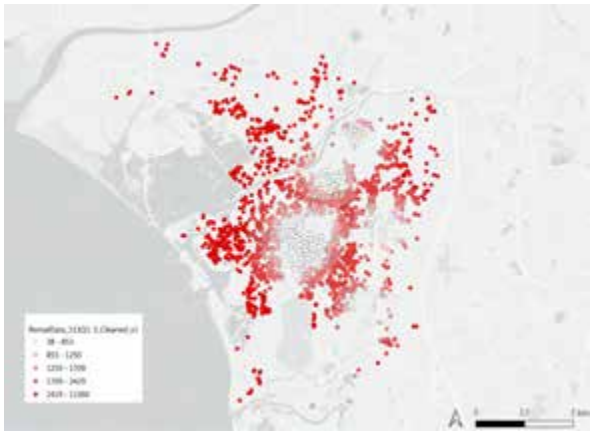

Fig. 8. The distance map of each point to the nearest university.

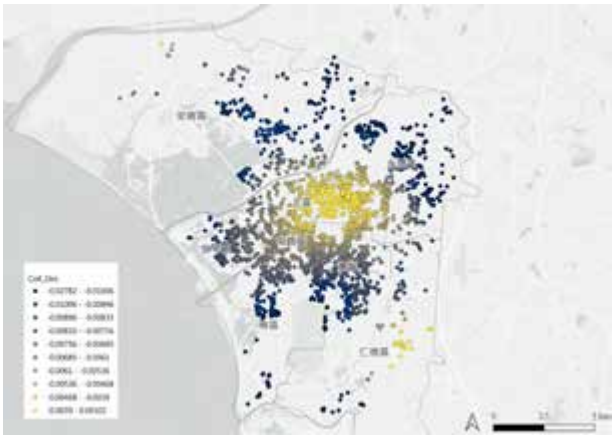

Fig. 9. The impact of educational characteristics on rental housing prices.

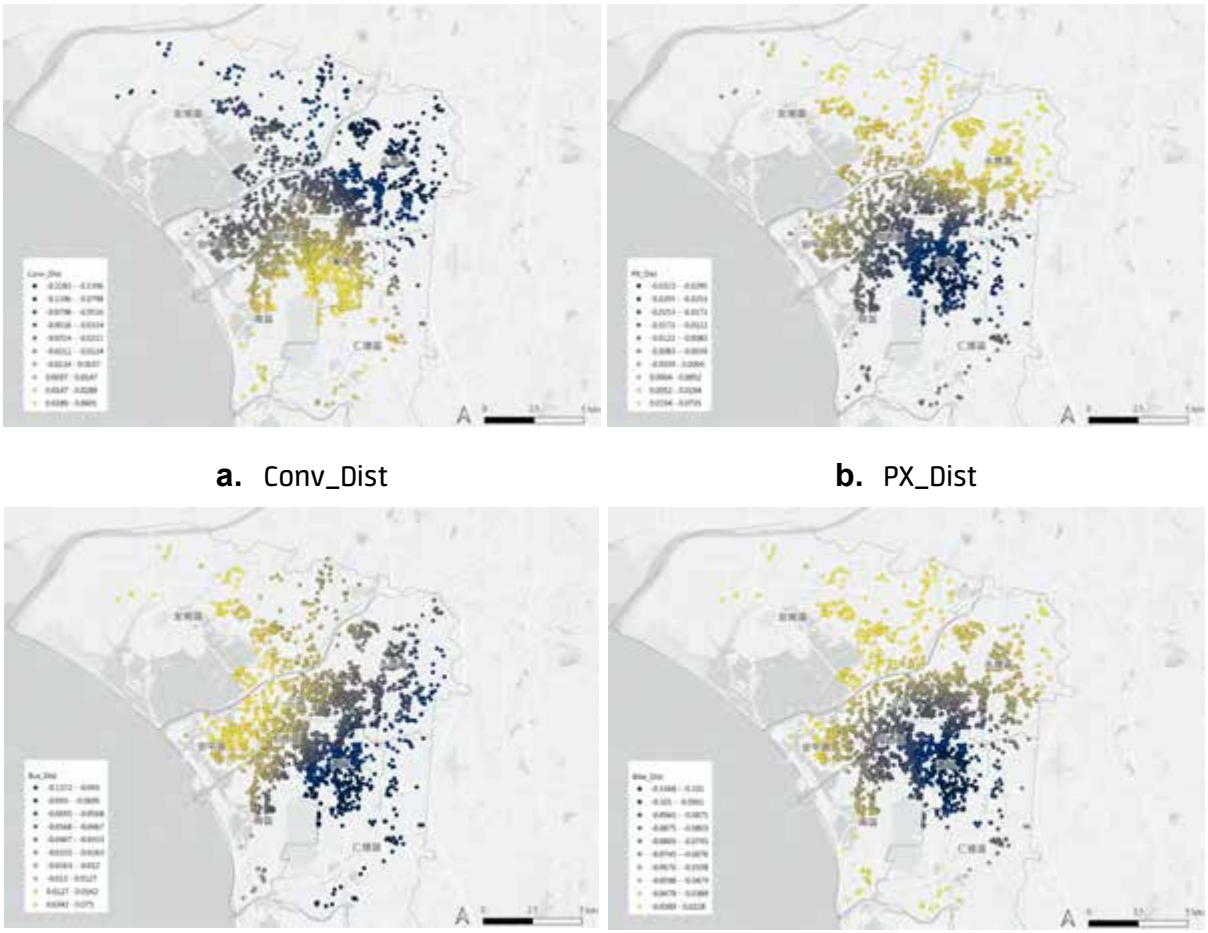
1.1.2. The impact of location characteristics on rental housing prices

As shown in Fig. 10(a-d), the distances to the five major convenience stores and shared bicycle stations are the primary variables affecting housing prices, while the distance to the nearest bus stop is a secondary variable. The negative impact of the distance to convenience stores on housing prices is more pronounced in Yongkang District and Annan District, which can be attributed to the density of convenience stores in these areas. The neg-

ative impact of the distance to shared bicycle stations on housing prices is more significant in the East District, likely due to the demand for bicycles and the number of station installations in this area.



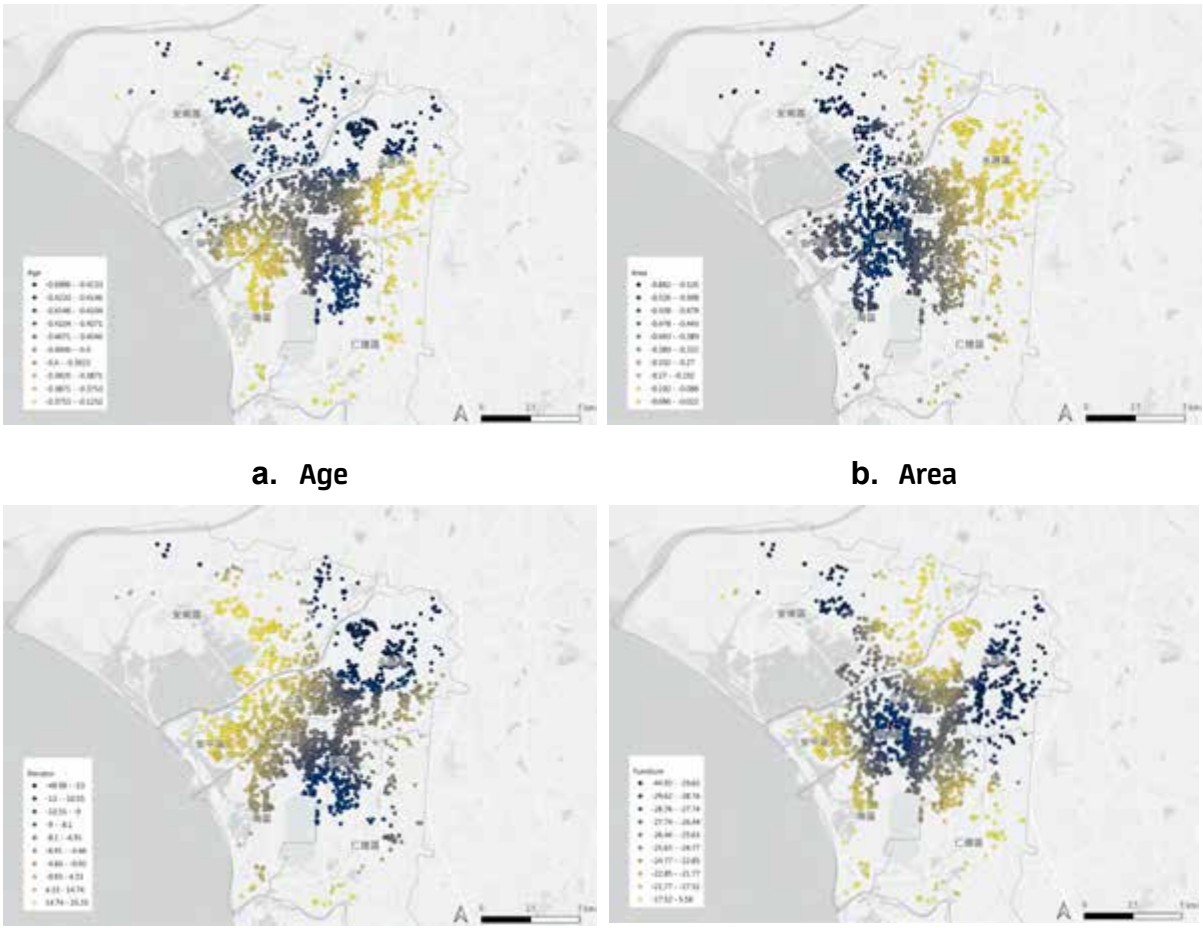
a. Conv_Dist **b.** PX_Dist

c. Bus_Dist **d.** Bike_Dist

Fig. 10. The impact of location characteristics on rental housing prices.

1.1.3. The impact of building characteristics on rental housing prices.

As shown in Fig. 11 (a-d), building age and floor area are the primary variables influencing housing prices, with the presence of furniture being a secondary factor. The negative impact of building age on housing prices is more pronounced in the East District and Yongkang District. Additionally, there is a significant north-south disparity in Yongkang District, with Provincial Highway 20 serving as a dividing line; this is likely because the southern area consists of older neighbourhoods, while the northern area features more newly constructed houses, resulting in a greater influence. The impact of floor area on the negative effects of building age is more significant in Annan District and the West Central District. Cross-referencing the analysis of building age, it can be inferred that Annan District contains newly constructed houses, leading to noticeable differences in floor area.



a. Age b. Area

c. Elevator d. Furniture

Fig. 11. The impact of building characteristics on rental housing prices.

3.4. Geographically Weighted Machine Learning

The study employed geographically weighted LightGBM (GW-LGBM) to capture spatial heterogeneity and nonlinear relationships more effectively than traditional models. The bandwidth selection and Gaussian kernel weighting scheme were used in the same way as geographically weighted regression (bandwidth = 0.023), so that each observation receives a distance-decay weight relative to the prediction location—the farther an observation lies from the test point, the smaller its weight becomes, as illustrated in Fig. 12.

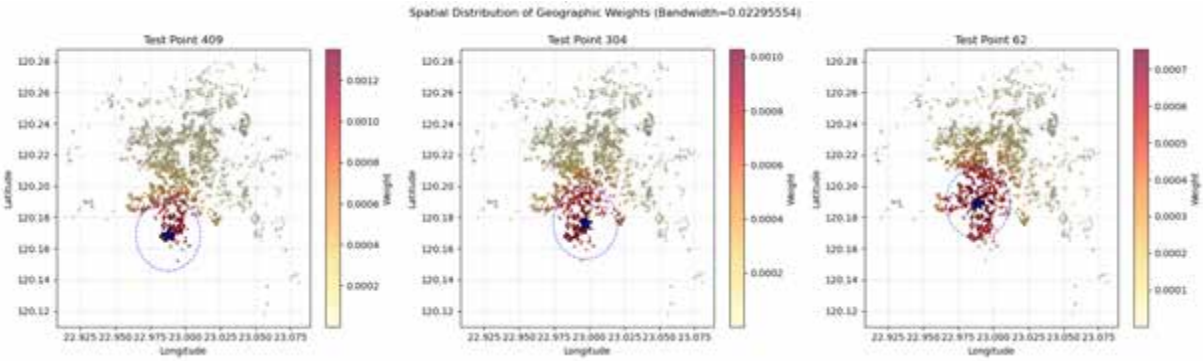


Fig. 12. Spatial Distribution of Geographic Weights.

The geographically weighted LightGBM (GW-LGBM) model attains a root-mean-square error (RMSE) 68.53 in predicting unit rental prices. Feature-importance analysis identifies floor area, building age, and furnishing status as the three most influential predictors, with floor area exerting a markedly greater effect than the others. SHAP analysis shows that its contribution to explaining unit rent diminishes as floor area increases. This attenuation is likely due to a neighbourhood-level rent ceiling. Once that threshold is approached, additional square metres generate progressively smaller rent increases, making unit-rent estimation more challenging for the model. Consequently, lower building age shows a positive association. Newer properties improve the model performance for the unit rental price. Furnishing status displays a highly polarised pattern: because most Taiwanese rental units are furnished, an unfurnished listing becomes a distinctive indicator that enhances predictive accuracy.

Spatial mapping of SHAP values demonstrates that predictor importance varies across the research area. In the city centre, the floor area contributes most strongly to the model's discrimination of unit rents, whereas in suburban areas, building age becomes the dominant explanatory factor. Furnishing status shows far less spatial variation. These results indicate that the GW-LGBM framework yields superior predictive performance and captures the rental market's inherent spatial heterogeneity when combined with SHAP diagnostics.

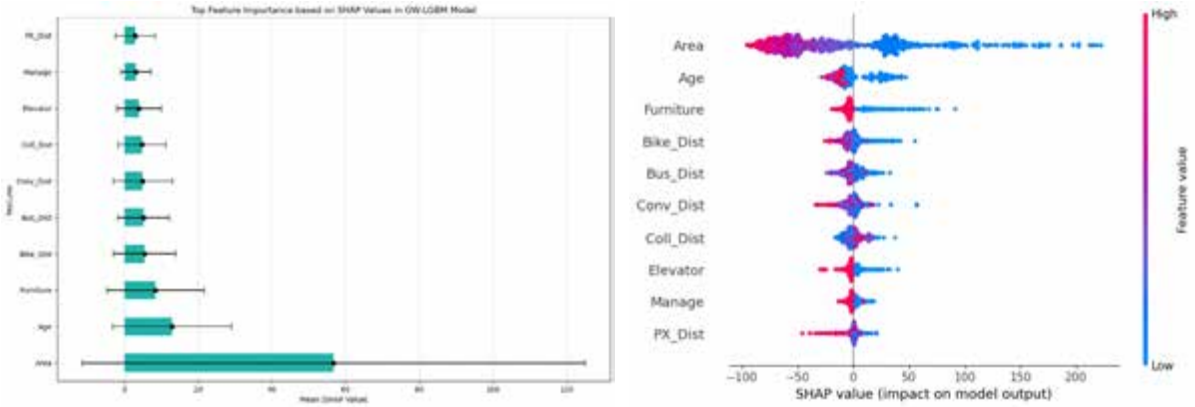

Fig. 13. Feature Importance on SHAP Value

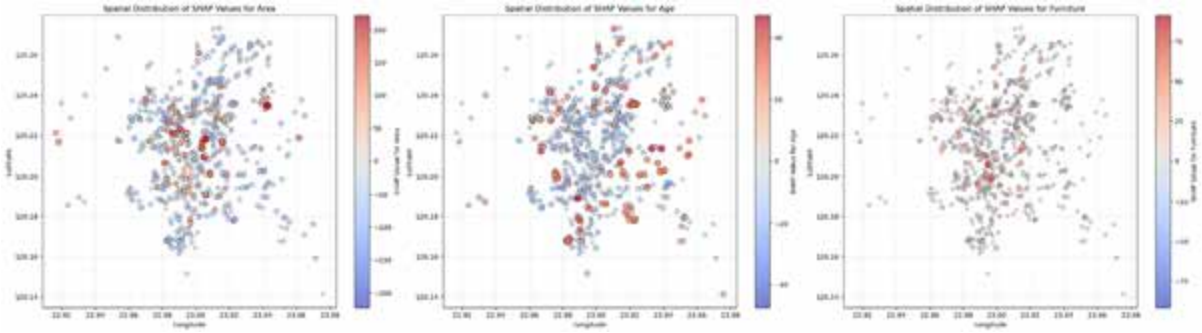

Fig. 14. Spatial distribution of SHAP Value for Area, Age, and Furniture

3.5. Model Comparison

In this study, geographically weighted models show better performance than original models. This study employed OLS, GWR, and GW-ML models to compare their performance. In order to evaluate the effectiveness of these models, a comparison was also made with general machine learning methods that do not incorporate geographical weighting. The comparison results were shown in Fig. 15. Previous studies have primarily compared linear regression models with GWR, demonstrating that GWR is a superior analytical method. This phenomenon is also confirmed in the present experiment, where the RMSE of the linear regression model is 112.36,

while that of GWR is 96.23, indicating a significant improvement in model performance. However, upon including machine learning models in the comparison, it was observed that the RMSE values of all machine learning models outperformed those of GWR. This suggests that machine learning provides a more effective approach to analysing unit rental prices.

The superior performance of machine learning models may be attributed to the inherent characteristics of GWR, which is a spatial statistical method specifically designed to capture spatial heterogeneity. Factors that influence unit rental prices exhibit limited spatial characteristics, rendering GWR effective in enhancing linear regression but insufficient for addressing the details of rental data. Consequently, machine learning models demonstrate better performance than GWR in this context.

The results showed that the geographically weighted machine learning model (GW-LGBM) achieved the lowest RMSE of 68.53, outperforming all other models. It significantly surpassed both the linear regression model and state-of-the-art machine learning models. This indicates that when data exhibits spatial heterogeneity, applying geographical weighting to the model can notably improve its performance.

Table 5. RMSE for all models

Model Type	Model Name	RMSE
	Linear Regression	112.36
	OLS	
	Bayesian Ridge	112.38
	Lasso	112.36
Machine Learning	Support Vector Regression (SVR)	108.84
	Random Forest (RF)	75.64
	Gradient Boosted Decision Tree (GBDT)	76.88
	eXtreme Gradient Boosting (XGBoost)	78.70
	Light Gradient Boosting Machine (LightGBM)	75.08
	K-Nearest Neighbor (KNN)	94.35
GWR	Geographically Weighted Regression	96.23
GW-ML	**Geographically Weighted LightGBM (GW-LGBM)**	**68.53**
	Geographically Weighted Random Forest (GW-RF)	70.81

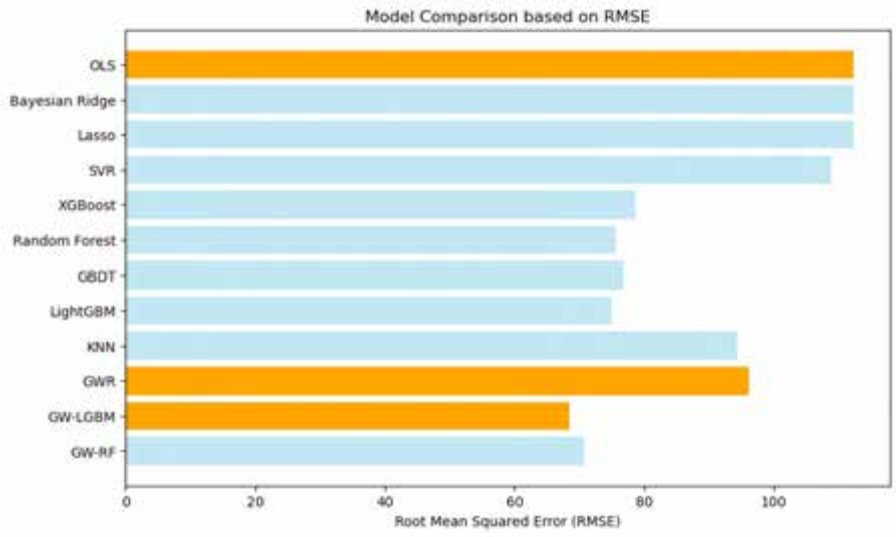

Fig. 15. Model Comparison

The aim of this study is to analyse the spatial characteristics of rental housing using various analytical methods, including Geographically Weighted Regression (GWR) and Geographically Weighted Machine Learning (GW-ML). The GW-ML model outperforms linear regression, machine learning, and GWR models due to its ability to simultaneously accommodate spatial sample weight adjustments and non-linear relationships that describe interactions with rental prices. The results reveal that, within the GWR model, factors such as rental area, building age, distance to universities, and the availability of management staff are the most significant determinants of rental prices. Meanwhile, in the GW-LGBM model, rental area, building age, and furniture availability are the most important factors influencing model performance. Both methods highlight rental area and building age as key factors impacting rental prices. From the GW-LGBM model, it was found that rental properties in city centres place more importance on rental area, while those in suburban areas focus more on building age. These findings can assist urban planners in understanding the preferences and spatial heterogeneity of rental populations, enabling the development of policies that provide appropriate subsidies or other measures to enhance overall social welfare.

However, the R-squared value for the GWR model in this study is only 0.22, indicating that it cannot fully explain the variations in unit rental prices. Although the GW-LGBM model performs better, some errors remain. Future research could leverage Graph Neural Networks (GNNs) or other models to further investigate the underlying causes of rental behaviour and price fluctuations.

Abstract
This study explores İzmir's spatial evolution from the 1950s to the present through an integrated dual-phase methodology combining sub-fractal and space syntax analyses. Grounded in complexity science, the city is conceptualized as a self-organizing system influenced by nonlinear urban dynamics. The exogenous phase applies sub-fractal analysis to assess macro-scale morphological changes across four time periods, identifying a progression from fragmented rural complexity to consolidated urban form, especially along a north–south axis. The endogenous phase analyzes changes in centrality through space syntax, revealing a decrease in spatial embeddedness until the 1990s, followed by renewed centralization. This multi-scalar approach contributes to planning strategies for managing regional complexity and urban growth.

Keywords: Urban Morphology, Regionalization, Centralization, Sub-Fractal Analysis, Space Syntax

1. Introduction

The transformation of urban systems in the 21st century is increasingly characterized by the recognition of cities as self-organizing, open systems shaped by dynamic, nonlinear, and adaptive processes. The complexity of an urban region emerges from micro-level changes that generate macro-level transformations. In other words, regional complexity arises intrinsically. Within this framework, fractal and syntactic methods have increasingly been used to explore the hierarchical and self-similar characteristics of urban form, aligning with the core tenets of complexity theory in urban studies.

This study adopts such a complexity-informed perspective to examine the evolution of regionalization and centralization tendencies in İzmir from the 1950s to the present. A dual-phase methodological approach is employed, integrating both exogenous and endogenous analyses by combining sub-fractal and space syntax methods at the regional scale. This integrated approach addresses the methodology of complexity studies by bridging analyses of macro-regional patterns and local spatial centrality.

The exogenous analysis focuses on İzmir's 30 districts, each exhibiting distinct development patterns shaped by tourism, industry, agriculture, services, and logistics. This phase investigates regionalization dynamics through macro-scale morphological changes, using district boundaries as analytical frames and applying sub-fractal analysis to road networks and administrative divisions. By disaggregating the urban system into smaller spatial units, sub-fractal analysis reveals variations in spatial complexity that diverge from the system's overall fractal dimension, highlighting the heterogeneous and often non-self-similar nature of urban growth. Four temporal intervals are considered: 1950s–1960s, 1970s–1980s, 1990s–2000s, and post-2010.

The endogenous phase explores centralization tendencies through space syntax analysis, focusing on the configurational properties of the urban road network. Drawing on patchwork theory, the study evaluates inter-segment relationships across radii ranging from 500 meters to 50,000 meters, capturing scales of both pedestrian mobility and vehicular commuting. Correlations between syntactic measures at different radii were used to determine the most representative scales of local complexity, which then informed the box sizes for sub-fractal analysis. The results indicate a contraction in centralization radii until the 1990s–2000s, followed by a subsequent expansion, reflecting a more dispersed urban structure and shifts in spatial centrality.

By combining these two analytical perspectives, the study demonstrates main findings of how regionalization and centralization processes interact over time to shape İzmir's urban morphology. The exogenous component reveals system-wide patterns of spatial integration, while the endogenous analysis captures internal structural dynamics. This multi-scalar approach contributes to a deeper understanding of urban and regional complexity and offers a foundation for more adaptive and responsive planning strategies in the face of spatial transformation.

2. Fractal and Syntactic Approaches to Urban Complexity

The term "fractal" was introduced by Mandelbrot in 1967 to describe shapes characterized by intrinsic asymmetry, scale invariance, and self-similarity. Fractal geometry serves as a spatial representation of chaos theory, reflecting interactions between chaotic and orderly elements across multiple scales in complex systems. Baranger (2000) emphasizes that fractals maintain their complexity at every scale, resisting simplification upon closer examination. Richardson's (1961), work on measuring the length of coastlines and national boundaries prompted Mandelbrot to expand the concept through his paper "How Long Is the Coast of Britain?" (1967). Fractals typically have a Euclidean parameter between 1 and 2—shorter than a plane but longer than a straight line. As with other natural fractals, such as mountain ranges, these features may have fractal dimensions ranging between 2 and 3, indicating greater complexity than a surface but less than a volume.

Unlike the classical Euclidean framework, which uses whole-number dimensions—0 (point), 1 (line), 2 (plane), and 3 (cube)—fractal analysis introduces fractional dimensions (Fd). Figure 1 illustrates how geometric complexity evolves with increasing dimensionality: from isolated points (0D), to a branching fractal (~1.2D), to nested cubes (~2.3D). This progression highlights how higher dimensions contribute to greater structural complexity in fractal and spatial systems.

Since the publication of Batty & Longley's seminal work Fractal Cities in 1994, numerous studies have adopted the complex systems approach to analyse urban morphology. These studies aim to calculate the fractal dimensions of cities and urban fragments, producing a range of insights into the structural complexity of urban form. One core theoretical contribution is the observed alignment between fractal dimensions, power-law distributions, and central place theory (Batty & Longley, 1994; Frankhauser, 1998; Lu & Tang, 2004; Chen, 2008; Myint & Liam, 2005; Thomas & Frankhauser, 2013).

Fractal dimensions of urban components can be measured using a mesh that identifies the minimum number of non-overlapping boxes (Ns) needed for a given box size (S). The optimal mesh size is achieved by adjusting the coverage-to-resolution ratio. As emphasized by complexity theory, urban systems are dynamic, involving scaling behaviors, power laws, and spatial centrality. Therefore, appropriate grid sizes may vary depending on centrality. To better understand the spatial complexity—or "metabolism"—of parts within an urban region, the most suitable mesh size can be identified through space syntax methods that assess spatial centrality in large urban systems. While fractal analysis emphasizes morphological characteristics, space syntax complements this perspective by

focusing on the relational configuration of space. Space syntax analysis is a morphological method developed to identify spatial characteristics of urban environments using axial maps and convex spaces. This set of theories and techniques, collectively referred to as space syntax provides tools to analyze spatial configurations(Hillier & Hanson, 1984; Volchenkov & Blanchard, 2008). Although space syntax is often applied to urban neighborhoods, several studies have extended its use to larger urban or regional contexts to investigate spatial hierarchy and boundary definition. On a regional scale, space syntax has been employed to understand spatial hierarchies, with centrality commonly represented by accessibility measures (Serra, 2013; Yamu et al., 2017; Yamu & van Nes, 2020).

As urban systems involve scaling, power law behaviour, and centrality, grid sizes used in fractal analyses must be adapted accordingly. The appropriate grid size—whether for measuring fractal dimension or evaluating connectivity—can be determined using space syntax by examining centrality across various spatial scales. Given these shared conceptual foundations, fractal analysis and space syntax have been jointly applied in several studies. Axial line maps, central to space syntax, exhibit fractal characteristics because urban street networks typically include a small number of long lines and a large number of short lines (Vaughan, 2007; van Nes & Yamu, 2018), noting that this results in a statistically nonlinear, long-tailed curve akin to power laws. This property aligns with fractal logic, where self-similarity across scales is expressed through hierarchical spatial organization (Yamu, 2014). Urban structures are therefore self-similar and partially scale-free. In line with this, studies have found that the distribution of integration values, choice values, and open space configurations in cities such as Rothenburg, Bielefeld, Amsterdam, Venice, and Manhattan conform to power-law behaviour (Volchenkov et al., 2008). Hillier et al. (2010) and Molinero & Thurner (2021) further argues that when power laws are observed, the scaling dimension remains relatively stable across all node pairs, consistent with fractal dimensionality. Since transportation networks themselves are fractal in nature, axial maps inherently reflect these properties (Hillier et al., 2010).

Although both fractal analysis and space syntax offer valuable tools for investigating urban complexity—particularly through the analysis of transportation networks—studies that integrate the two remain relatively limited.

Kaya & Bölen (2017) examined the morphogenetic structure of Istanbul using both approaches, likening settlement patterns to the DNA of living organisms. They classified spatial parameters into four categories: (i) geometrical, (ii) topological, (iii) visibility-perception, and (iv) complexity. The second and third categories were based on syntactic values, while fractal dimension analysis was incorporated as a complementary measure of complexity. Similarly, Yamu and van Nes (2017, 2020) and Frankhauser et al. (2018) proposed integrated models that combine space syntax and fractal analysis. These models, applied to metropolitan regions in Southern France, Vienna, and Bratislava, use space syntax to support the identification of multifractal strategic development patterns.

3. Methodology

Fractal analysis studies conducted at the scale of the entire city or region can focus on the macroform, road network, and built environment. In this study, the fractal dimensions of the road network were examined, taking into account both the preservation of comparability of historical data sources and the blurriness between the distinction of urban and rural areas. Urban road networks are commonly recognized as fractal systems and are considered effective for assessing complexity (Batty & Longley, 1994; Shen, 1997; Chen & Luo, 1998; Shen, 2002; Lu & Tang, 2004; Avineri, 2010; Thomas et al., 2011; Thomas & Frankhauser, 2013; Wang et al., 2016; Sreelekha et al., 2015; Lu et al., 2016; Lan et al., 2019; Wen et al., 2023; Yang & Fu, 2023; Abid, 2024).

Road network data for İzmir were obtained from 1:25,000-scale maps produced by the General Directorate of Mapping of the Republic of Turkey. These maps cover four historical periods—1958–1964, 1974–1980, 1996–2000, and 2012–2020—and include comprehensive depictions of roads, terrain, and infrastructure. A total of 123 sheets were digitized and georeferenced using NetCAD software to support comparative analysis across periods.

Fractal analysis was conducted using the box-counting method, which determines spatial complexity by counting the number of non-overlapping boxes of a given size required to cover the road network. The relationship is expressed as:

$$K=A.\ \varepsilon^{-Df}$$

Where "K" denotes the number of boxes, "ε" represents the grid size, "A" is a constant coefficient, and "Df" is the fractal dimension.

A consistent legend across all periods ensures uniform representation of road thickness, which is essential for understanding infrastructure hierarchy and changes. The analysis also integrates satellite imagery and open-source road maps to align historical data with current urban configurations. The road maps were analysed using Fractalysis software with non-linear estimation ($R^2 > 0.999$).

For endogenous analyses, space syntax tools are integrated with fractal analysis to evaluate centrality. As an important aspect of complex relational networks, centrality is one of the key elements sought by the analysis. The growth of settlements involves a reorganization of spatial systems, including the hierarchy of centres and sub-centres—referred to as 'centrality' and 'periphery.' Space syntax measures two primary relationships: (1) the to-movement potential of each street segment with respect to all others, and (2) the through-movement potential of each street segment with respect to all pairs of others. The integration measure indicates how well a street is connected to other lines, based on the shortest path from one node or line to the others. As a result, shorter paths correspond to higher integration values. The other measure, also based on shortest distance, is the "choice" measure, which evaluates the extent to which a given street lies along the shortest path between pairs of streets. In other words, choice shows how frequently a street would be used if pedestrians always selected the shortest path. The two primary centrality measures used in this study are choice and integration, along with total node count. Integration represents "to-centrality," while choice represents "in-between centrality" (Van Nes & Yamu, 2018).

Three main distance-based measures for system analysis can be defined as:

- **Metric:** Measures the network as a system of shortest paths
- **Topologic:** Measures the network as a system of fewest-turn paths
- **Geometric:** Measures the network as a system of least angle-change paths

Serra (2017) analyzed the road network of inside of Oporto's municipal metropolitan borders from local scale (400 meters) to the regional scale (30.000 meters) by closeness centrality analysis which is a measure of the average distance of each node to the entire network. The main outcomes of this study can be summarized as; at local scales like 400 meters, small centers can be visualized including small ancient towns, inner cores of larger settlements and emergent centers. By increasing the spatial scale, small centers disappear while the metropolitan core began to appear. This observation is reported to be maximized at 3800 meters while centrality disappears at larger scale while a very large central zone dominates the entire metropolitan region (from 14700 to 30000 radii). With respect to correlations depending on principal component analysis, three centrality scales are determined as; neighbourhood (400-1200 meters), city (1200 to 8200) and region (8200 to 30000).

A wider study is conducted for the complete road network of United Kingdom that the results of the study are compared by spatial socio-economic variables and movement flows by correlation analysis (Serra, et al., 2015). Three graphs for centrality algorithms are used by metric radius as; node count, angular integration and angu-

lar choice. The metric radiuses attained from 10 kilometres to 50 kilometres. For vehicular movement it is found that all measures are capable of measuring centrality in terms of movement flow for medium radii (from 10.000 meters to 20000 meters as the best fit).

The other study based on the differentiated radii effect is the study of Hillier et al. (2010). It is aimed to explore the nature of boundaries including internal structure of urban space and how this relates to external structure by exploring properties of the context rather than simply focusing on internal morphology. The suggested representation is called as fuzzy boundaries. Each axial line or segment in the whole map is taken as the root of the graph then by increasing radius, the rate of change of the numbers and axial lines are calculated. The rate of change value is assigned to original axial line and neighbouring trends can be observed for the central areas of London and Beijing. The other sole explanation of the study of Hillier et al. (2010) is to find which syntatic variable can be used to illustrate the process of embeddedness of urban space. One of the sole approaches identifying the radius in a larger urban system is "patchwork theory". It is based on spatial differentiation of the background urban network into a patchwork of local areas. The patchwork structure represents metric and local effects. The effect of radius on centrality is explained as;

"μ(v,r), of node v for radius r as local metric mean depth as;

$$\mu(v,r) = \frac{1}{N(v,r)} \int_0^r x \frac{\partial N(v,x)}{\partial x}\, dx$$

where $x = x(v, u)$ is metric depth of node from the reference node v and $N(v, r)$ is the number of nodes with $x(v, u) \leq r$ and

$$N(v,r) = \int_0^r \frac{N(v,x)}{\partial x}\, dx$$

$$\Theta(v,x) = \frac{\partial \log N(v,x)}{\partial \log x} = \frac{x}{N(v,x)} \cdot \frac{\partial N(v,x)}{\partial x}$$

Where the rate of change of node count Θ(v,x) of metric mean depth so;

$$\frac{\partial N(v,x)}{\partial x} = \frac{N(v,x)\Theta(v,x)}{x}$$

By substuting (22) into (20);

$$\mu(v,r)\, N(v,r) = \int_0^r N(v,x)\, \Theta(v,x)\, dx$$

where μ(v,r) N(v,r) is total metric mean depth; differentiating both sides of equation (5) with respect to r;

$$\frac{\partial \mu(v,r)}{\partial r} N(v,r) + \mu(v,r) \frac{\partial \mu(v,r)}{\partial r} = N(v,r)\, \Theta(v,r)$$

$$\frac{\partial \mu(v,r)}{\partial r} N(v,r) + \mu(v,r) \frac{N(v,r)\Theta(v,r)}{r} = N(v,r)\, \Theta(v,r)$$

$$\frac{\partial \mu(v,r)}{\partial r} + \frac{\Theta(v,r)}{r} \mu(v,r) = \Theta(v,r)$$

Since metric mean depth and radius have the same linear dimension, the first derivative term in equation (26) must be independent of r as; $\partial\mu(v,r) / \partial r < 1$. Sı equation (26) can be expressed as;

$$\mu(v,r) = r\left(1 - \frac{c(v)}{\theta(v,r}\right)"$$

By those equations it is expected that there is a positive correlation between node count change and metric mean depth. If radius increases, Hillier et al. (2010) explains three possible routes of development can be observed as;

(i) μ(v,r)can increase while decreases,
(ii) μ(v,r)can increase while remains stationary,
(iii) μ(v,r)can increase while increases

It is noted that these different development routes induce an inversion of centrality, whereby more central nodes at smaller radii tend to become decentralized at larger radii. This relationship depends on the scaling between the radius and its node count (Hillier et al., 2010). Another key explanation in the study was to identify which syntactic variable can be used to illustrate the process of embeddedness of urban space. As Hillier et al. (2010) state, Yang's measure of node count change—(NCr+r/2) / (NCr-r/2)—produces a result very similar to MMDr (Metric Mean Depth at the given radius), meaning that one measure explains the other. In addition, Dalton (2005) explains that for restricted radii, simple segment count is the strongest component of the integration measure, whereas the local urban correlations between total depth and integration break down for larger radii.

The centrality measures of this study are determined as choice, integration, and total nodes, based on a region-focused literature survey in the field of space syntax. The validity of the mapped representations is evaluated with respect to real-world data observed from the 1:25,000 scale maps, as well as from the narrated regional history. The reliability of the centrality measures for restricted radii is examined through principal component and correlation analysis (Serra & Pinho, 2013; Serra et al., 2015).

Three centrality measures are defined: integration, choice, and total nodes, including their segment length–weighted versions. For each of the four periods, different radii from 250 meters to 50,000 meters are analysed—including 250 m, 500 m, 1,000 m, 2,000 m, 5,000 m, 10,000 m, 20,000 m, and 50,000 m—to identify patterns ranging from the neighbourhood pedestrian scale to the entire regional system. The 50,000-meter radius is determined based on the system size, where the widest elliptical approximation of the network is around 100 kilometres, and the narrowest is 25 kilometres. To identify the global system, an analysis with radius "n" is also calculated.

The axial model corresponds to a total network length of 7,469, 11,206, 25,660, and 32,671 kilometres for each of the four periods, respectively. First, the axial maps are produced via the digitized road network for each period. Then, these maps are converted into segment maps. As identified by Serra & Pinho (2013), segment analysis allows for a finer-grained assessment. The historical space syntax terms of "integration" and "choice" are equivalent to the more general terms of "closeness" and "betweenness centralities" (Hillier & Iida, 2005; Serra et al., 2015; Vaughan et al., 2025). Therefore, three centrality measures are investigated: angular integration, angular choice, and metric node count, for different radii ranging from 500 meters to 50,000 meters.

For each period, correlation analyses are run to identify the radius at which the correlation level is highest before decentralization effects are observed. The results of the process of embeddedness of urban space—analysed through varying radii—are observed and compared with the centrality measures and with real-world data ac-

quired from maps and a literature review on regional history. For each period, a "breaking point" is identified as the centrality-embeddedness scale—in other words, a radius at which local centrality becomes most evident. Subsequently, sub-fractal analysis is conducted using the Frac_Lac software and the box-counting method, with the mesh size set equal to the radius obtained from the syntactic measure.

4. Main Findings

The major findings discussed here encompass the results of both the exogenous and endogenous phases. In the exogenous analyses, which were conducted for 30 districts within the entire city-region of İzmir, the findings reveal that during the initial period (1959–1964), rural areas exhibited higher spatial complexity than urban cores, suggesting a fragmented pattern of urbanization. In the second period (1976–1980), regionalization trends intensified, and the system's overall complexity surpassed that of its individual components. Notably high fractal values were recorded in central İzmir, including Karşıyaka and Bayraklı. By the third period (1996–2000), a pronounced north–south axis had emerged, reflecting spatial consolidation. In the most recent interval (2012–2017), a general decline in fractal dimensions was observed across the region, including coastal districts, indicating a plateau in growth and a redistribution of spatial complexity. Changes in the fractal dimensions of the districts from the first to the fourth period are presented in Figure 1.

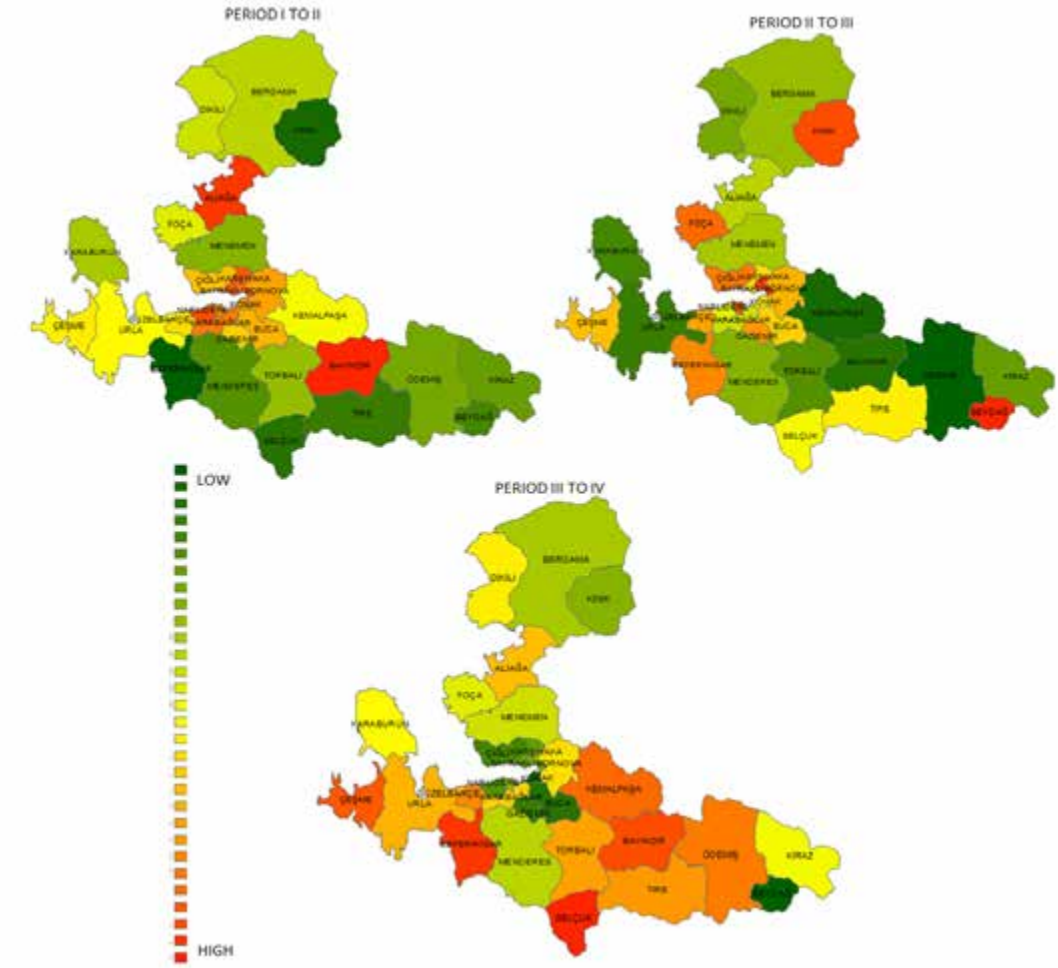

Figure 1: District-level changes in fractal dimension in İzmir across the first to fourth periods

For endogenous analyses proposing main arguments about centrality and regionalization, space syntax analyses and sub-fractal analyses are run for the third period. This period is selected since the highest fractal dimen-

sion values are observed during this time interval from 1996 to 2000 both in terms of parts (districts) and the whole system.

In space syntax analyses it is observed that the local betweenness centrality are observed for small radii by segment length weighted measure. In addition, the local centres can be observed for the radiuses of 500 meters to 1000 meters while could be best observed for the radius 500 meters. The medium scale is observed between the radii 2000 to 20.000 meters that until the radius of 10.000 meters, only the paths connecting the central core could be visualized (Figure 2).

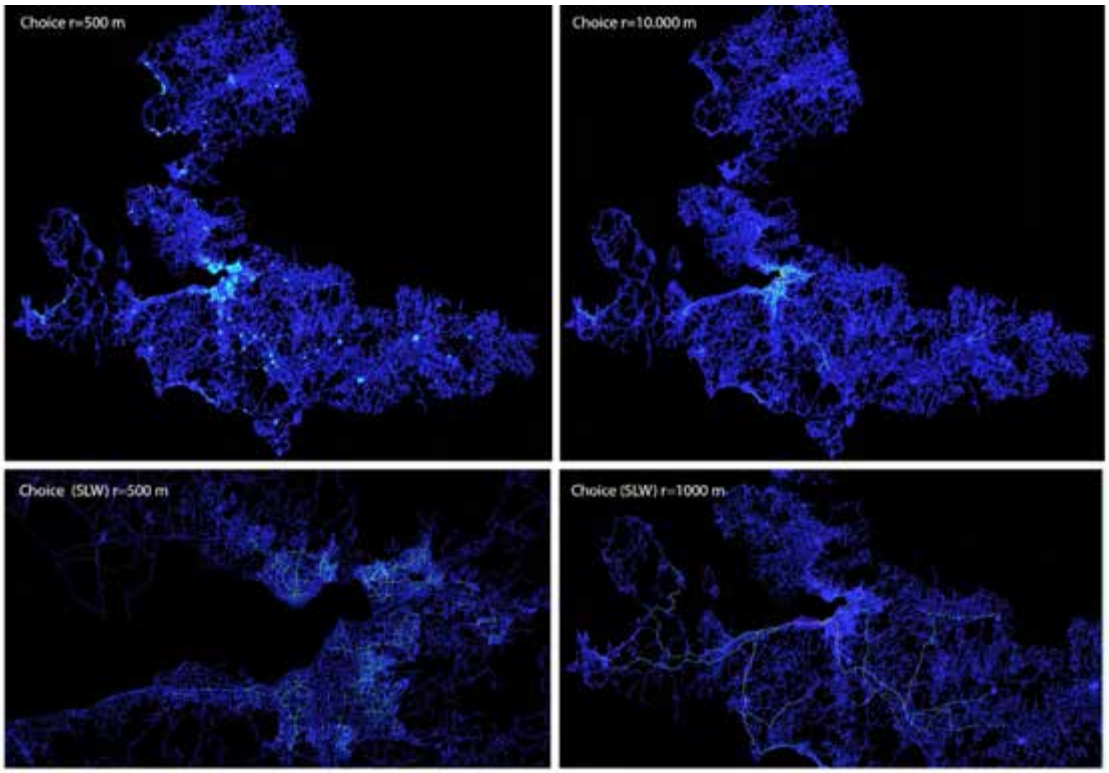

Figure 2. Angular choice analysis for small and medium radii during the third period (1996-2000)

For small radii, the main differences in centrality are not clearly visible for the declining core of Konak. However, the central paths of Alsancak and Eşrefpaşa Road can still be visually identified. Aside from the informal housing stock identified through the analysis—particularly around Tepecik and Kadifekale—local central paths have shifted toward Bayraklı. The highest choice value is calculated for Girne Avenue, the main artery of Karşıyaka. Karabağlar has gained betweenness centrality, while İnönü and Mithatpaşa Roads are identified as central paths near the Poligon area. These altered centrality measures closely correspond with the core's development trends in the late 1990s.

When the regional system is analyzed for small radii, the dominance of central İzmir persists. Although all district centers can still be distinguished, the rural pattern is no longer clearly identifiable. On the other hand, coastal developments become increasingly visible in Çeşme, Dikili, Seferihisar, and Urla. This finding aligns with the expansion of coastal towns, particularly those focused on tourism and seasonal housing during the mid- to late-1990s. Although the regional rural network has declined, decentralization of the central paths can be observed around the core—toward Çiğli-Menemen in the north, Gaziemir in the south, and Kemalpaşa in the northwest. The prima-

ry central paths are concentrated in the southern part of the Bay. The highest centrality is observed along the İzmir–Çeşme Highway. Connections from the highway to Seferihisar, and from the core to Torbalı, are also identified as central paths. Additional central paths can be differentiated along the coastal route toward Karşıyaka, and in the connections to Buca, Kemalpaşa, Çeşme, and Karaburun. The larger radii range—defined as 20,000 to 50,000 meters—applies to the third period based on the information from the choice measure maps. The highest choice value within the central core is observed along the coastal road connecting Kültürpark to Bayraklı. The connections between Karşıyaka and Bayraklı, as well as between Kültürpark and the Gaziemir junction, represent secondary central paths. Links to peripheral districts such as Çiğli, Gaziemir, Bornova, and Kemalpaşa constitute the third-level differentiated central paths for the restricted 20,000-meter radius. For the 50,000-meter radius, a similar pattern emerges, with areas like Çiğli and Torbalı gaining centrality due to the expanded metric radius (Figure 3).

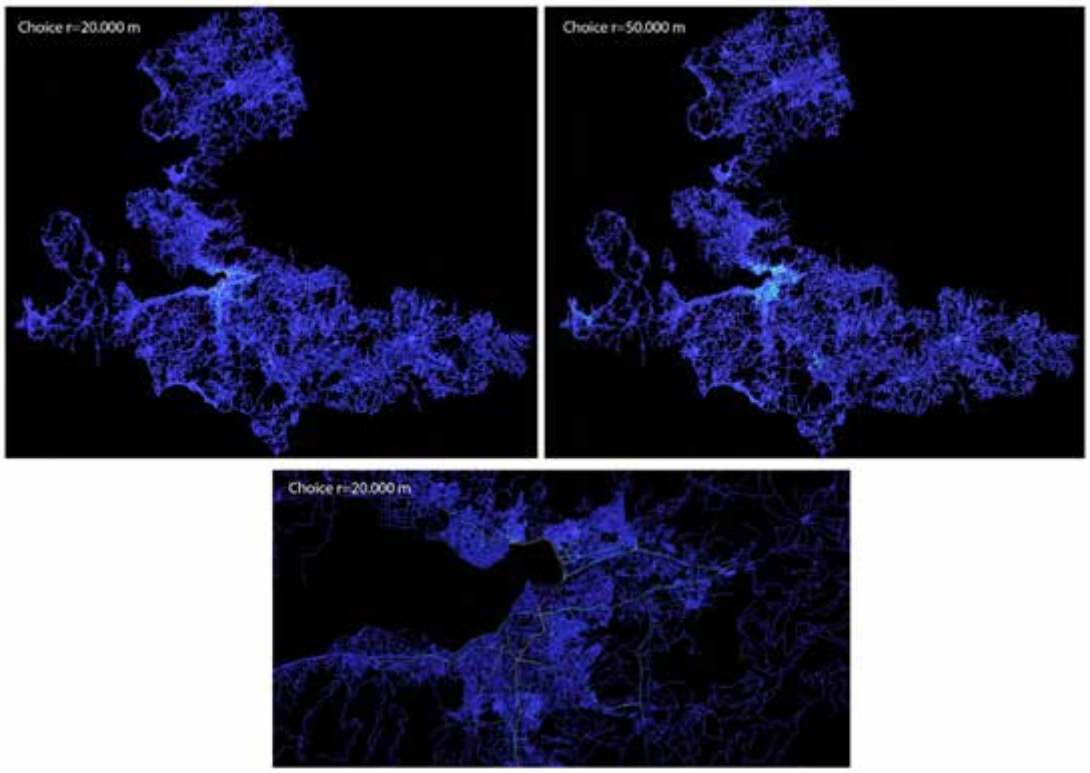

Figure 3. Angular choice analysis for large radii during the third period (1996-2000)

Angular integration analysis is also employed as a centrality measure. For small radii, similar to previous periods, irregular housing quarters are identified as distinct features exhibiting higher integration values within the central core. The main difference compared to earlier periods is the decline in integration values in the Konak vicinity. This result aligns with the findings from the choice measure and real-world data. The most integrated quarters are observed in Bayraklı, followed by Karşıyaka. As with the choice measure, differentiated integration patterns are seen around the metropolitan core. Additionally, coastal developments such as Çeşme, Dikili, and Seferihisar display higher integration values. For medium radii, a more regionalized pattern emerges. Within the central core, the highest integration values are observed along the coastal road from Kültürpark to Bayraklı, Gaziler Road, and the connection to Gaziemir. The regional medium-radius analysis, conducted at 20,000 meters, provides insight into the broader network. The strongest regional connection is observed between the central core and Torbalı. Linear development patterns radiate from the center toward the south and north, accompanied by coastal development along the Çeşme Highway (Figure 4).

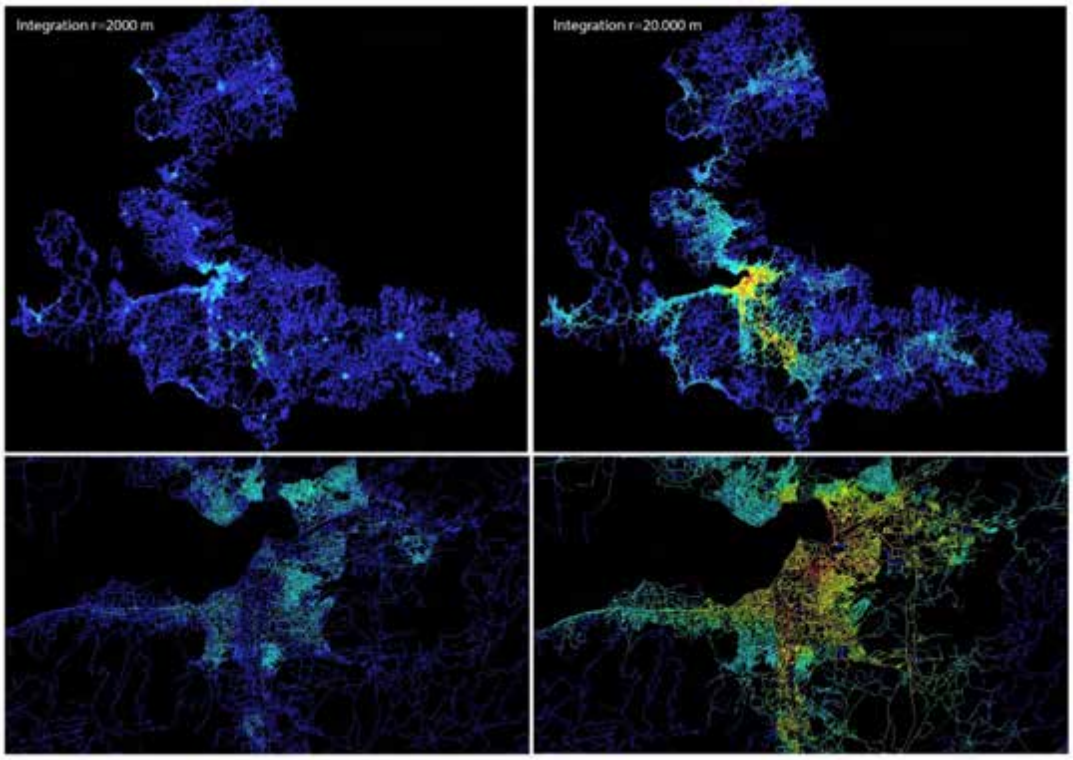

Figure 4. Angular integration analysis for small and medium radii during the third period (1996-2000)

During the initial period, sub-fractal analyses reveal higher fractal values in rural areas located in the northern, southern, and eastern parts of the region. These elevated fractal values are associated not only with urban activity but also with fertile agricultural land reserves. Despite exhibiting higher levels of spatial complexity, these areas did not display notable centrality. In the second period, the complexity of agricultural patterns decreased, while centrality increased alongside spatial expansion. Both complexity and centrality became more visibly aligned with urbanized areas, although some agriculturally dominant central districts still retained elements of centrality.

A significant transformation of the network system is observed during the third period. The complexity of former ex-urban areas rose once more. The key difference is the emergence of centrality nodes throughout the region, indicating a shift from purely rural characteristics to a more transitional spatial pattern. Moreover, the metropolitan core began to disperse along major corridors, blurring the distinction between rural and urban structures. In this context, peripheral and coastal towns gained both centrality and complexity, functioning increasingly like urban cores.

When sub-fractal analyses are integrated into the endogenous analysis, the results are found to closely align with those of the exogenous phase, indicating that centrality continues to manifest in the metropolitan core and in select districts that function as rural centers. An integrated representation of the sub-fractal analysis with a 1% pixel ratio and the connectivity map is presented in Figure 5. The sub-fractal analysis for this period reveals higher fractal values compared to previous decades. The lowest calculated value is 1.02, while the highest reaches 1.903. The most elevated values are observed in the central core, particularly in Karşıyaka–Bayraklı, Buca, Karabağlar, and Gaziemir. Although the urban core exhibits high sub-fractal values, regional complexity becomes more spatially varied compared to the second period. High sub-fractal values also appear in peripheral

urban centers such as Urla, Çeşme, Aliağa, and Menderes. Additionally, scattered high fractal values are found around Kemalpaşa, Torbalı, and Seferihisar. The transition from agricultural divisions to peripheral development has resulted in increased complexity along key corridors. The eastern part of the region shows generally lower fractal values, punctuated by isolated complex nodes. Although Bergama retains its sub-regional pattern, the dominance of its integrated network has diminished relative to the first and second periods. A significant macro-form transformation is observed for the İzmir metropolitan area: formerly peripheral districts have become functionally integrated into the core. A continuous and cohesive urban structure now includes Buca, Bornova, Karabağlar, Çiğli, Menemen, Menderes, and Gaziemir, with coastal development extending southward along the Bay toward Urla.

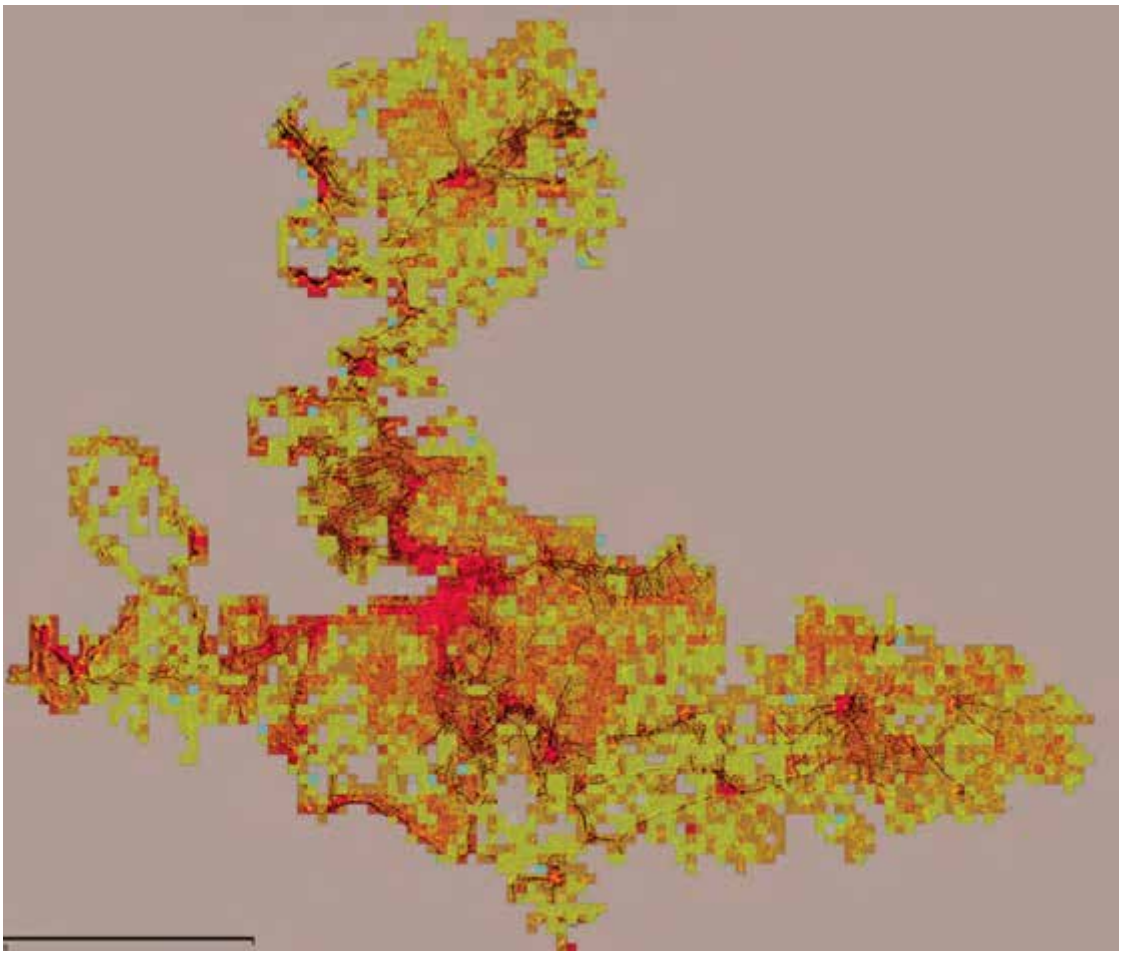

Figure 5. Integrated representation of the road network of İzmir in the third period using sub-fractal and space syntax analyses (1996-2000)

When centrality is assessed in conjunction with the revised patchwork theory, the radius exhibiting the highest correlation before decentralization begins is found to be the smallest during the third period (1996–2000). This suggests that spatial embeddedness declined up to the third period but increased again in the fourth period. Notably, the fractal dimensions of both the overall system and its constituent parts reached their highest levels during this final period. The results of the centrality and fractal dimension measures are presented in Table 1.

Table 1. Change of embeddedness and complexity

	r (m)	FD of the whole system	Mean FD of the parts
Period I (1959-1964)	5000	1,502	1,313
Period II (1976-1980)	1000	1,581	1,343
Period III (1996-2000)	500	1,819	1,521
Period IV (2012-2017)	5000	1,724	1,492

5. Conclusion

This study presents an integrated method for exploring the regional complexity of İzmir, a multi-layered and multi-sectoral city-region. By combining sub-fractal and space syntax analyses, the research advances a dual-phase approach to investigate the interplay between regionalization and centralization across different historical periods. Unlike conventional studies that narrowly focus on urban macroforms or the internal structure of road networks, this analysis extends to the broader regional fabric—capturing complexity within both urban and non-urban contexts, including agricultural, touristic, and industrial landscapes.

Fractal analysis serves as a quantitative measure of spatial complexity, spatial coherence, and urban sprawl. In parallel, space syntax analysis captures the relational properties of urban form, such as connectivity, integration, and centrality. The integration of these two methodologies enables a multi-scalar assessment of urban morphology, revealing how systemic shifts in complexity and centrality shape urban evolution over time. This approach uncovers critical transitions—from fragmented rural complexity in early decades to concentrated centrality and integrated regional structures in later periods.

The analysis identifies several key findings: In the initial period (1959–1964), rural areas displayed higher spatial complexity than urban cores, indicating fragmented urbanization. The second period (1976–1980) showed increasing regionalization, with complexity and centrality rising in core areas like Karşıyaka and Bayraklı. By the third period (1996–2000), a north–south urban development axis emerged, while peripheral districts such as Çiğli and Kemalpaşa began integrating into the urban network. In the final period (2012–2017), a decline in overall fractal dimensions was accompanied by a rise in complexity and centrality in coastal towns, revealing the influence of touristic and seasonal dynamics. Centrality shifted from traditional hubs like Konak to emerging centers such as Bayraklı, Karabağlar, and Karşıyaka, while roads like the İzmir–Çeşme Highway and Girne Avenue gained strategic importance. These changes reflect a blurring of rural–urban boundaries, as transition zones expanded and spatial embeddedness fluctuated. Correlation analyses identified threshold radii at which centrality peaked before decentralization, reinforcing the relevance of patchwork theory and multiscale syntactic measures. Sub-fractal values were highest in central and peri-central areas and validated through their spatial alignment with syntactic centrality, demonstrating the coherence between complexity and movement networks. Ultimately, İzmir has evolved into a polycentric metropolitan region, where formerly peripheral districts now function as secondary centers in a distributed urban system. From a planning perspective, the study highlights the utility of complexity-informed tools in guiding spatial development strategies. Two key applications are proposed: (1) employing fractal and syntactic measures as diagnostic indicators to inform regional planning frameworks, and (2) using complexity analyses as evaluative tools to assess compactness, sprawl, green space distribution, and development potential. As the conceptualization of cities as complex adaptive systems continues to gain traction, the integration of these methods offers valuable insights for planning resilient and adaptable urban futures.

Email:yuzhuoyu@zju.edu.cn

Abstract
The global aging problem is becoming increasingly severe, and the innovative application of robotics technology has emerged as a key driver for upgrading the elderly care industry. In the face of the dual challenges of accelerating global population aging and the surging demand for elderly care services, how to rapidly and effectively integrate robotics into elder care has become an urgent issue. This study innovatively proposes transforming complex robotic operational requirements into three-dimensional architectural spatial models by analyzing the dimensional and motion space needs of eldercare robots in community environments. Through in-depth analysis of the functions, dimensions, movement angles, and ranges of eldercare robots, combined with spatial layout principles from architecture and urban planning, the study constructs a tangible model of the workspace requirements for robots. And starting from the six tasks of caring for the elderly, the key points of design and planning for bedrooms, living rooms and bathrooms based on the needs of care robots in architectural space are proposed.This approach not only ensures sufficient mobility for robots to perform various tasks but also enhances their operational efficiency and safety within elderly care communities. It opens new pathways for the precise renovation and optimisation of smart elderly care communities, driving deeper integration between technology and daily living.

Keywords: Smart elderly care community, robots, spatial planning, spatial design, elderly care space

Introduction

Amid the rise of smart eldercare, the innovative application of robotic technology has become a key driving force in upgrading the eldercare industry. Confronted with the dual challenges of a rapidly aging population and the surging demand for eldercare services in China, how to enable robotic technology to effectively support and care for the elderly has emerged as an urgent issue. In January 2024, the Opinions of the General Office of the State Council on Developing the Silver Economy to Enhance the Well-being of the Elderly explicitly stated the need to foster new models of smart healthcare and eldercare, and to promote the integrated application of intelligent nursing robots, household service robots, and other devices across home-based, community-based, and institutional eldercare settings [1]. Subsequently, in June 2024, the Shanghai Action Plan for the Innovative Development of Eldercare Technology (2024–2027) further emphasised the importance of accelerating the development of smart eldercare technology communities and advancing age-friendly home modifications. In particular, the plan highlights the application of advanced health equipment such as rehabilitation devices, exoskeletons, and nursing robots, and underscores the crucial role of technology in improving the quality of life for older adults [2]. As a vanguard in the smart eldercare domain, robots are increasingly becoming a critical force in enhancing the living standards of the elderly and advancing the development of smart eldercare communities.

Currently, eldercare robots primarily fall into three categories: rehabilitation robots, domestic service robots, and social companion robots [3]. Existing research mainly focuses on technological dimensions, such as human–robot interaction and social engagement, perception and navigation systems, as well as rehabilitation and health monitoring [4]. While each type of eldercare robot features unique design characteristics, studies examining their practical deployment within smart eldercare environments remain limited. Moreover, their physical dimensions are often constrained by a combination of technical feasibility, functional requirements, and safety considerations, making it difficult for them to achieve the same level of flexibility and spatial adaptability as human caregivers. As shown in Figure 1, the extended reach of BUSBOY's remote manipulation arms, the robust support structure of ROBEAR, the wheeled chassis of Stardust Intelligence, and the bipedal humanoid design by Unitree Robotics all demonstrate impressive technological advancements. However, they also underscore the diversity and challenges in robot size and movement range. In various eldercare settings—including home, community,

and institutional environments—different robot morphologies (e.g., bipedal humanoid, wheeled, tracked) may face limitations in terms of spatial compatibility, which can hinder service efficiency and negatively affect user experience. Therefore, it is imperative to adopt architectural approaches to assess and optimise care environments, ensuring the seamless integration of eldercare robots with diverse dimensions and forms into homes, communities, and eldercare institutions.

The age-friendly transformation of smart communities is, in essence, a bidirectional process of empowerment between technology and spatial design. The integration of these two dimensions enables the creation of intelligent eldercare scenarios, thereby enhancing the well-being and sense of fulfillment of older adults in the digital age [5]. At present, research on age-friendly residential design is relatively extensive, encompassing psychological and physiological needs of the elderly [6], barrier-free design principles [7], and smart home systems [8], among other topics. However, current community retrofitting efforts remain largely centered on the needs of older adults, with insufficient attention paid to the operational characteristics and spatial requirements of service robots. Existing studies related to the application of eldercare technologies are mainly focused on regulating the physical environment of residential buildings and monitoring the safety of older individuals [9], while research on the spatial integration of eldercare robots into residential settings is still in its infancy. To ensure that robots become effective assistants in the daily lives of older adults—rather than spatial obstacles—it is necessary to undertake a comprehensive restructuring and functional upgrading of home environments. The key research challenges are twofold: first, how to incorporate the operational characteristics and spatial demands of robots into the core of a human-centered design framework; and second, how to overcome the inefficiencies of in-situ adaptation testing by leveraging spatial modeling technologies to conduct multi-scenario simulation analyses. Such an approach can support and guide the precise transformation and optimisation of smart communities and residential spaces.

In the field of robotic modeling and simulation, advanced platforms such as Gazebo and V-REP provide researchers with powerful virtual testing environments, enabling preliminary validation of robotic system performance and adaptability without direct interaction with physical hardware. However, when applied to the specific context of eldercare communities, the widespread adoption of such tools faces notable limitations. While these platforms excel at simulating robotic dynamics, sensor integration, and complex interactions, they present significant challenges in accurately reconstructing the architectural nuances of real-world living environments—particularly with respect to furniture arrangements, soft furnishings, and the personalised characteristics of residential spaces. Given the complexity and variability of eldercare community environments, relying solely on robotics-focused simulation tools often fails to capture the fine-grained spatial distinctions that directly affect robotic navigation, task performance efficiency, and operational safety. Therefore, from an architectural perspective, it is essential to translate the functional requirements of eldercare robots into a design-oriented vocabulary and conduct in-depth spatial modeling and simulation tailored to residential care scenarios. This architectural reframing represents a critical bottleneck to be addressed in order to facilitate the effective deployment and integration of robotic technologies within eldercare communities.

The research objective of this paper is to optimize the layout of the home environment through scientific and reasonable spatial planning, enabling robots to operate freely under different spatial dimensions and activity angles, and meeting the diversified needs of the elderly. By analyzing the motion characteristics, working range and spatial requirements of robots, combined with the spatial layout principles of architecture, it is possible to create elderly care communities that not only conform to the operation norms of robots but also take into account the quality of life of the elderly. On this basis, by using advanced modeling and simulation technology, the potential obstacle areas are accurately marked, the working paths and activity Spaces of the robots are

optimized, and the design key points of the three areas of the bedroom, bathroom and living room based on six nursing tasks are proposed. Ensure that the robot can seamlessly integrate into the environment of the elderly care community during actual deployment to achieve efficient, safe and humanized services.

2. Methodology

2.1 Research Subjects

Eldercare Robots:This study focuses on general-purpose eldercare robots that are either currently available in the market or under active development in research laboratories. These robots typically possess functions such as care-giving, companionship, and health monitoring, and are designed to assist older adults with daily living tasks in residential environments. The research will examine the spatial requirements, behavioral patterns, and environmental interactions of these robots during actual operations, with an emphasis on how their physical and functional characteristics influence their performance within domestic settings.

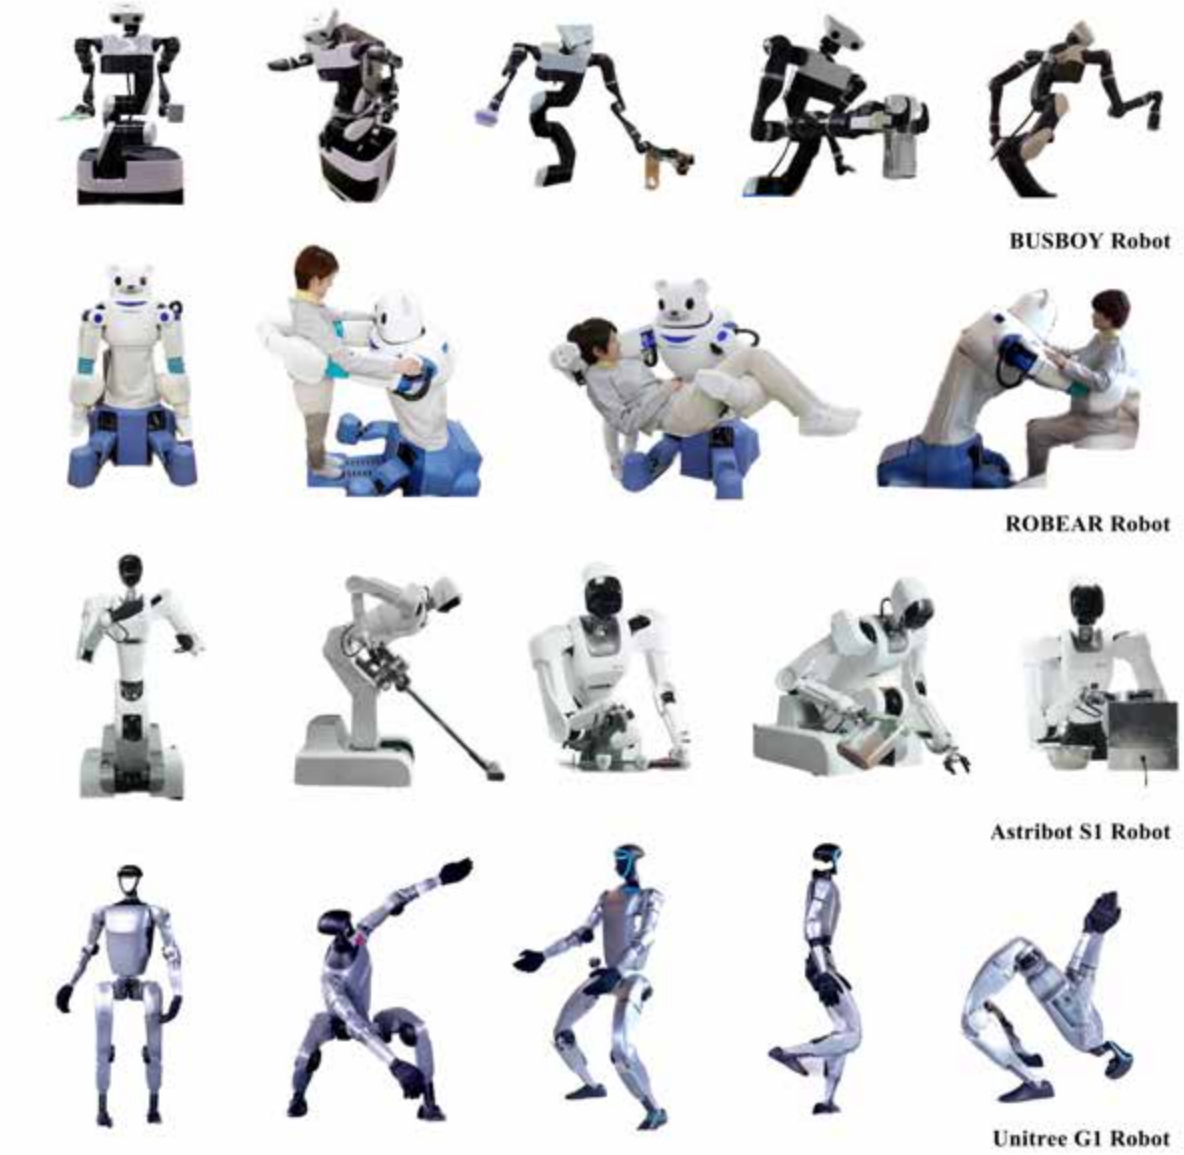

Figure 1. Display of various forms and motion ranges of the nursing robot

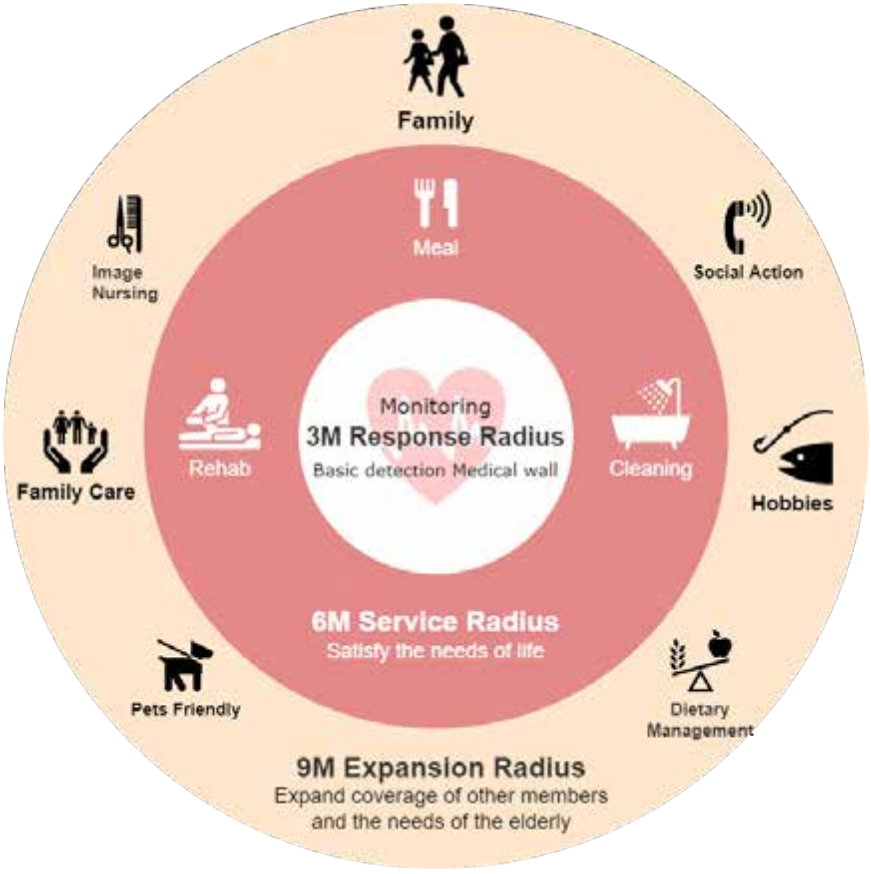
Residential Spaces in Smart Eldercare Communities:The study also targets the spatial layout and functional configuration of residential units within smart eldercare communities. Particular attention is given to analyzing how existing residential configurations—such as room layouts, furniture arrangements, and corridor designs—can be adapted or optimised to accommodate the integration of eldercare robots.In the elderly care scenario, nursing robots mainly undertake six key auxiliary tasks, namely: feeding, pushing wheelchairs, assisting with getting in and out of bed, helping with dressing, assisting with bathing and using the toilet. Ensuring that robots can operate efficiently and unobstructedly within these environments, while also supporting the daily needs of elderly residents, is critical for achieving seamless human–robot coexistence. In the design of smart eldercare communities, spatial planning must prioritise adequate mobility space for robots and prevent furniture from becoming obstacles to their movement. The introduction of robots imposes new spatial demands, including the allocation of walking paths, the establishment of interaction zones, and the assurance of universal accessibility. These spatial modifications must simultaneously address the physical and psychological needs of older adults and align with the dimensional and operational requirements of robotic systems.



2.2 Research Methodology

To accurately simulate and optimise the deployment and operational scenarios of eldercare robots with varying dimensions in smart eldercare communities, this study proposes a systematic methodology consisting of three core stages:

(1) Spatial Requirements Analysis and Robot Model Reconstruction:The study begins with an in-depth analysis of the functions, dimensions, and operational ranges of eldercare robots. Utilising robotic kinematics, key actions such as arm lifting, body rotation, and object manipulation are examined to determine the spatial footprint associated with daily tasks. By precisely measuring and simulating the trajectories of these movements, a three-dimensional entity model of the robot is constructed, effectively translating its operational space requirements into physical forms. Through virtual simulations, these models are used to replicate the robot's motion within residential environments, allowing early identification and resolution of potential spatial conflicts.

(2) Path Verification and Charging Zone Selection:In conjunction with SLAM (Simultaneous Localisation and Mapping) technology, the study investigates robot navigation paths within residential spaces to ensure unobstructed mobility—particularly in narrow corridors, doorways, and densely furnished areas. SLAM enables the real-time generation of environmental maps and supports path planning and obstacle avoidance algorithms, thereby ensuring that robots can complete tasks safely and efficiently in complex settings. Additionally, path optimisation algorithms are applied to analyze and select suitable locations for charging stations, ensuring robots can reliably return for charging without disrupting the daily routines of elderly residents. This technical framework provides scientific support for spatial layout and path planning tailored to robotic operations.

(3) Space, Furniture, and Soft Furnishing Validation Based on Task Simulation:A combined application of Sketch Up and Unity is used to conduct three-dimensional reconstructions of eldercare environments and to simulate robot adaptability. Sketch Up is utilised to build precise residential space models, into which dynamic robot models are embedded to assess spatial adaptability and predict potential obstacles. Unity is employed to simulate robot–furniture interactions, optimise path planning, and enhance task efficiency and operational safety. Furthermore, personalised validation of soft furnishing elements is conducted to ensure they align with the preferences of elderly users while avoiding interference with robotic operation. This process integrates principles from environmental behavior studies to identify suitable soft furnishing configurations that support harmonious human–robot coexistence. Ultimately, simulation results inform spatial optimisation strategies that facilitate the seamless integration of robots into eldercare environments, while simultaneously meeting the everyday needs of older adults—achieving a deep fusion of technology and daily life.

3.Case Study

3.1 Multi-Scenario Spatial Demand Analysis and Dynamic Model Construction for Eldercare Robots

An in-depth analysis was conducted on the functions, dimensions, and movement angles and ranges of eldercare robots to determine the spatial requirements for performing various tasks within elderly residential environments. Employing robotic kinematic analysis methods, this study examined key operational actions—such as assisting elderly individuals in standing or walking, performing household chores, and pushing wheelchairs—across a range of common care-giving scenarios. By precisely measuring and simulating the motion trajectories of these actions, the required spatial envelope and joint movement angles for each task were accurately derived.

The research focused on mapping the task-specific operational needs of eldercare robots across different residential settings. For each scenario, the robot's primary tasks were defined based on the functional zones of the living space. Corresponding motion postures and spatial operation strategies were then carefully designed to accommodate these tasks. Given the high spatial precision required for robotic flexibility, stability, and accuracy in residential settings, three-dimensional entity models of the robots were constructed based on measured data to convert operational requirements into physical spatial representations (Figure 2). By translating task motions into spatial forms, these models enable realistic simulation of robotic trajectories and workspace coverage in virtual environments.

The construction of robot entity models not only facilitates precise residential space planning but also allows for the early detection and resolution of potential spatial conflicts through virtual simulation. This modeling process lays the foundation for creating living environments that accommodate robotic assistance effectively and harmoniously.

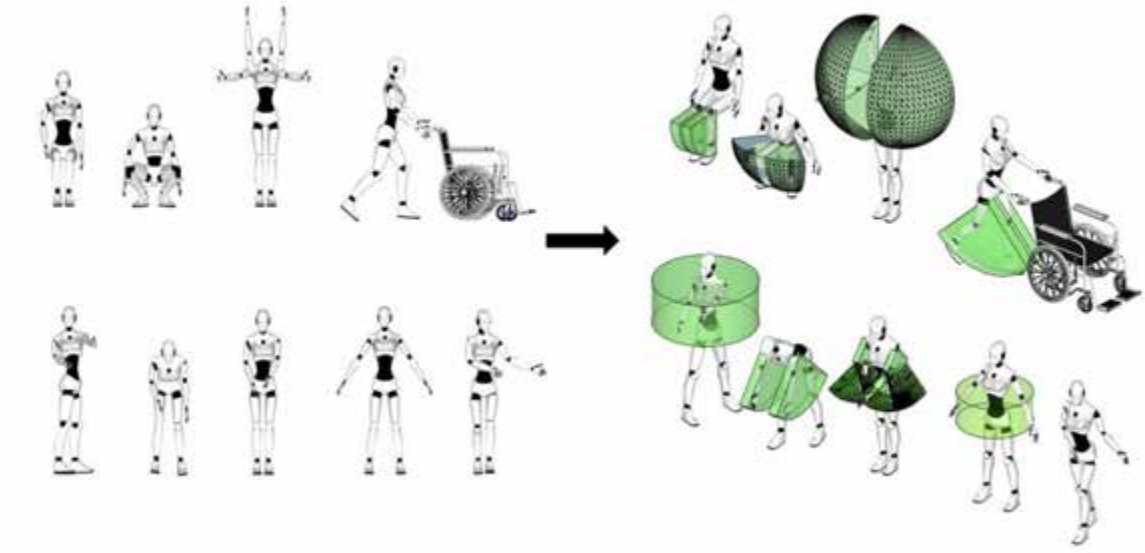


Figure 2 Construction of Dynamic Models of Spatial Requirements for Robots in Different Scenarios of Smart Elderly Care Communities - Taking bipedal humanoid robots as an example

3.2 Accessibility Analysis and Barrier-Free Optimisation Design for Care Robots

From a refined two-dimensional spatial perspective, this study systematically verifies the navigational accessibility of care robots within home environments and evaluates the rationality of charging and storage area layouts. A key innovation lies in the integration of SLAM (Simultaneous Localisation and Mapping) technology into the analytical framework. Based on dynamic models representing the spatial requirements of robots during actual operations, the robot's physical dimensions are defined as the unit scale for grid-based spatial processing. Functional zones within elderly residential spaces are then transformed into planar grid maps accordingly.

This process not only accounts for the geometric configuration of rooms but also carefully distinguishes critical factors such as furniture placement and corridor widths to ensure the accuracy and practical applicability of the model. The grid-mapped spatial layout is further subjected to scientific verification of movement flow lines, with detailed annotations of obstacle locations and the corresponding obstructed areas. This enables the construction of a comprehensive robot navigation map, providing a precise spatial reference for assessing movement feasibility and guiding subsequent optimisation strategies (Figure 3).

Figure 3 Spatial streamline verification of elderly care robots based on the SLAM principle

3.3 Simulation of Spatial Interaction and Environmental Perception for Care Robots

This part of the study focuses on simulating and verifying care robot interactions within eldercare residential spaces. High-precision three-dimensional reconstructions of the living environment are created using architectural modeling software. Through meticulous measurement and accurate modeling, the structural layout of rooms, furniture arrangements, and spatial dimensions are faithfully reproduced to ensure a high level of model fidelity. A dynamic model of the robot, constructed based on its actual dimensions and motion characteristics, is then embedded into the 3D residential space (Figure 4). Using this integrated model, the robot's movement trajectories and posture variations across different scenarios are simulated to assess its spatial adaptability and to identify or predict potential mobility barriers and spatial conflicts.

The Unity platform is employed to simulate the complete process of robot task execution within eldercare environments. Unity provides a realistic representation of interactions between the robot and household furniture. Simulations include daily tasks such as cleaning, transporting objects, and assisting with mobility. Throughout these scenarios, the robot's motion smoothness, operational stability, and physical interactions with furniture are observed and recorded. Based on the simulation outcomes, targeted spatial adjustment strategies are proposed.

Furthermore, the study incorporates the preferences of elderly users and the functional requirements of robotic sensors to evaluate and optimise soft furnishings within the residential space. It examines whether elements such as curtains, carpets, and decorative items interfere with robotic operations—particularly during movement or task execution—and whether they impact sensor performance. Methods from environmental behavior studies are utilised to understand how soft furnishings influence spatial use and robotic functionality, ensuring that such elements do not hinder sensor performance or cause disruptions in path planning. Additionally, the effects of soft furnishings on task efficiency and robot stability are assessed through simulation testing, allowing for the identification of soft furnishing configurations that meet both the preferences of older adults and the oper-

ational needs of robotic systems.

To enhance the environmental perception and human–robot interaction capabilities of care robots within residential spaces, this study proposes the deployment of an environmental sensing system to optimise the robot's ability to interpret its surroundings and respond to the needs of elderly users. For example, depth cameras, Li-DAR sensors, and smart detectors can be strategically installed in key areas such as bedside zones and bathrooms to assist robots in accurately recognising spatial structures and dynamic obstacles. This setup improves the efficiency of path planning and task execution. In addition, integrating voice recognition technologies enables multi modal interaction—such as voice commands and gesture recognition—allowing elderly users to communicate with robots more intuitively and conveniently.

Following simulation-based validation and analysis, the study integrates elderly users' physiological and psychological needs, behavioral habits, and the operational requirements of robots to propose an optimised spatial layout and functional configuration. This optimised scheme is designed to meet the dual demands of eldercare and robotic functionality. It includes the generation of annotated maps illustrating the robot's activity ranges and proposes a series of spatial optimisation strategies. These include: public space and circulation design, dedicated charging and storage zones, barrier-free accessibility features, privacy-preserving spatial segments, smart home integration systems, and environmental perception and interaction interfaces. Together, these recommendations provide both theoretical support and practical guidance for the development of intelligent aging-in-place environments within smart eldercare communities.

Figure 4. Take the bipedal humanoid robot as an example - schematic diagram for verifying the spatial dimensions of the working scene simulation

3.4 Key points of spatial design for nursing robots

-1-Bedroom : Intelligent Spatial Reconfiguration for Dressing and Bed Transfers

As the most frequently occupied and private area for elderly residents, the bedroom must be proactively adapted to accommodate robotic assistance in two critical tasks: dressing and getting in and out of bed. Although dressing appears simple, it involves frequent posture changes (sitting, standing, arm-raising), garment delivery, and fine manipulation. During these operations, the robot must maintain a stable working distance from the bed and frequently transition among the bed, wardrobe, and dressing chair. Therefore, the spatial layout around the bed should allow 360-degree accessibility, and storage elements such as drawers and hanging rails must be adjusted to robot-reachable heights, potentially integrated with smart lift systems. This multi-point coordination not only improves task efficiency but also lays the spatial foundation for transforming the bedroom into a wearable-assistance unit in future designs (Figure 5).

Bed transfers, on the other hand, rely more heavily on the robot's ability to support body weight and stabilize the user's posture. The conventional layout—where beds are placed against walls on both sides—prevents parallel robotic access and must be reconsidered. A lateral clearance of at least 80 cm should be maintained along at least one side of the bed. Additionally, the bed frame itself should comply with robot-compatible structural standards, including appropriate height, unobstructed bed edges, and built-in sensor interfaces. Such a forward-looking design approach transforms the bedroom from a purely human-centered spatial model into a human–robot collaborative environment, enabling a new paradigm for intelligent caregiving at home.

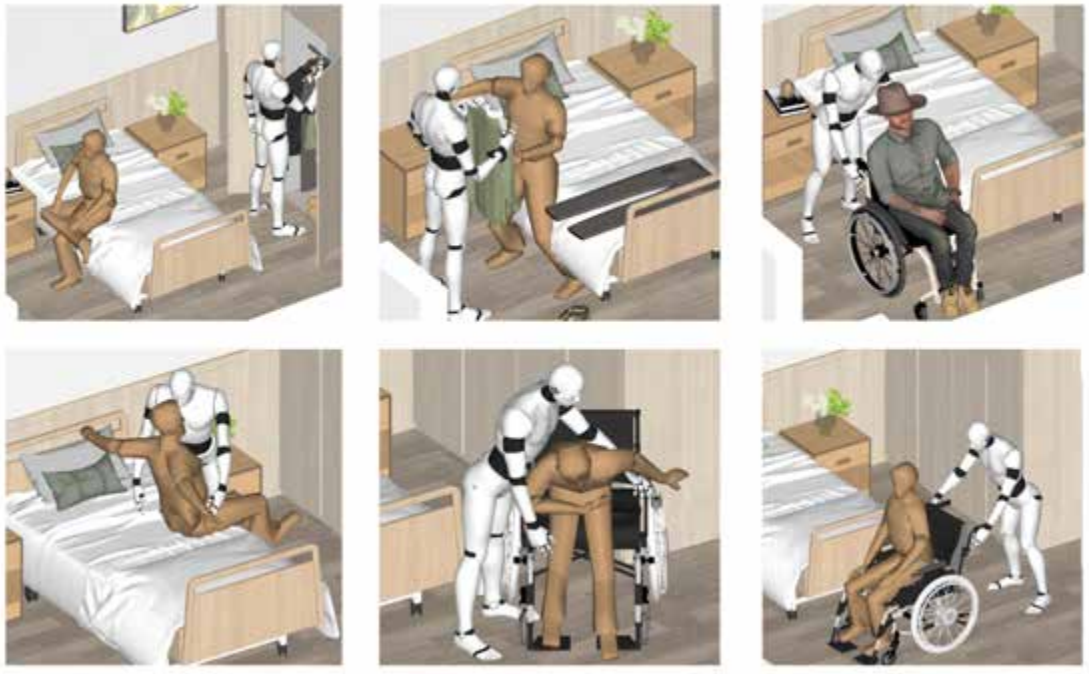

Figure 5. A schematic diagram of a care robot assisting the elderly in the bedroom space

-2-Living Room : Adaptive Upgrades in Public Zones Triggered by Feeding and Wheelchair-Assistance Behaviors
In the living room, where robots assist with tasks such as feeding and wheelchair propulsion, the space functions not only as a site for leisure and social interaction, but also as a dynamic caregiving operations platform. Feeding tasks require the robot to maintain a stable front-facing position relative to the elderly person, perform lifting actions, and deliver food with precision. This necessitates a layout that ensures accessibility and interaction compatibility—particularly in terms of adequate clearance between furniture, movable chairs, and slip-resistant flooring with guided navigation features. Future intelligent living rooms should adopt behavior-driven layouts, enabling real-time responsiveness to action chains such as "feeding – turning – obstacle avoidance – repositioning," while reserving zones for information interfaces and power docking points to support seamless human-robot-environment integration (Figure 6).

Wheelchair-pushing tasks demand precise spatial adaptations in terms of continuous circulation paths, doorway widths, and turning radii. The robot must detect and navigate through spaces at a height below 1 meter, avoid obstacles, and stably maneuver a weighted object, all while monitoring the elderly user's posture in real time. Common mixed-function household furniture layouts may hinder such mobility, introducing unpredictable obstructions. Therefore, design measures such as pathfinding cues, clearance control, and furniture-aided turning zones are necessary to optimize routes. The future senior-friendly living room will incorporate service flow logic, planning both primary and fallback robotic circulation paths, and will evolve into a truly intelligent and inclusive residential environment—where pets, home appliances, humans, and robots coexist in harmony.

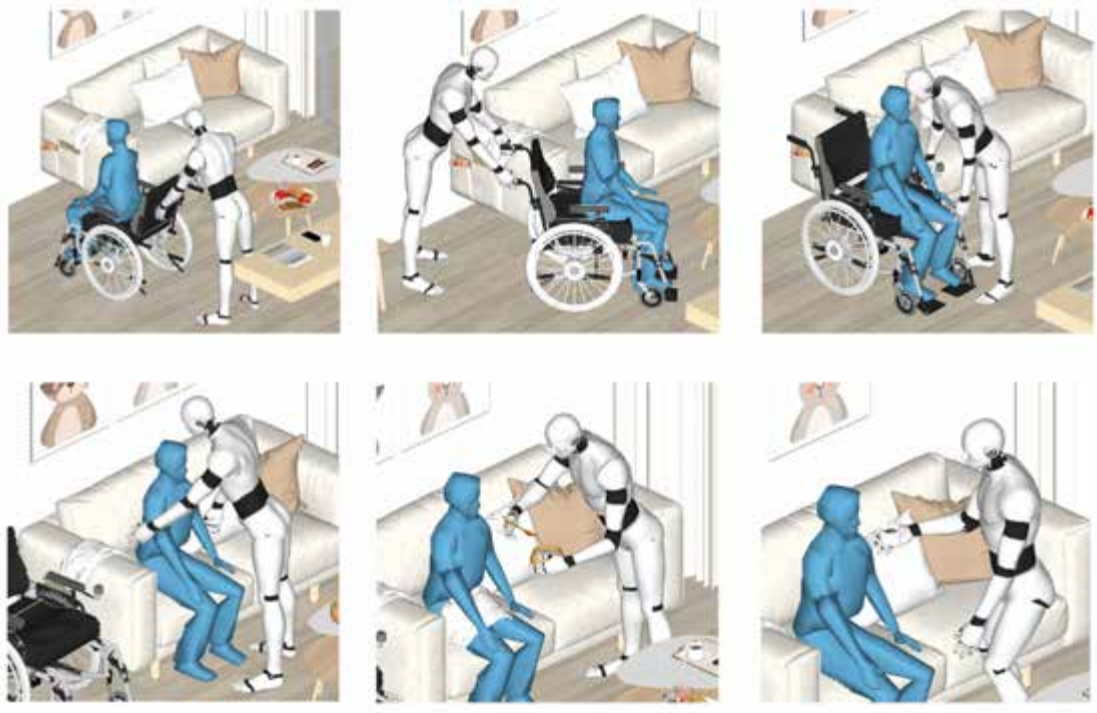

Figure 6. A schematic diagram of a care robot assisting the elderly in the living room space

-3-Bathroom : Fine-Tuned Spatial Responses for Bathing and Toileting Assistance

As the functional capabilities of caregiving robots continue to advance, assisting elderly users with toileting and bathing within the bathroom has become a crucial component of intelligent eldercare systems. Compared to traditional human-assisted care, robotic operation demands a higher degree of spatial precision and accessibility. For example, during bathing, the robot must perform a sequence of actions—supporting, washing, and transferring—typically from a lateral or rear position relative to the user. This necessitates not only sufficient rotational and extension space for dynamic movements, but also the integration of wet-zone electrical safety separation, non-slip waterproof materials, and proper drainage slope. Thus, bathrooms can no longer be designed solely based on minimal usable area standards; they must be redefined through a three-dimensional coordination model that aligns robotic motion, operating space, and embedded safety infrastructure (Figure 7).

Toileting tasks, on the other hand, require the robot to assist with sit-to-stand transfers, provide posture stabilization, and manage clothing adjustments—all within constrained spatial envelopes. This introduces new layout standards for the bathroom, including minimum clearances in the toilet zone, unobstructed side access around the toilet, and handrail configurations that accommodate the robot's arm reach and movement trajectories. Future intelligent bathroom design must go beyond conventional aging-in-place principles and evolve toward dual compatibility with humans and robots. By anticipating robotic workflow and movement patterns, such designs can embed both physical and digital interfaces, laying the groundwork for fully automated care environments in residential and institutional eldercare settings.

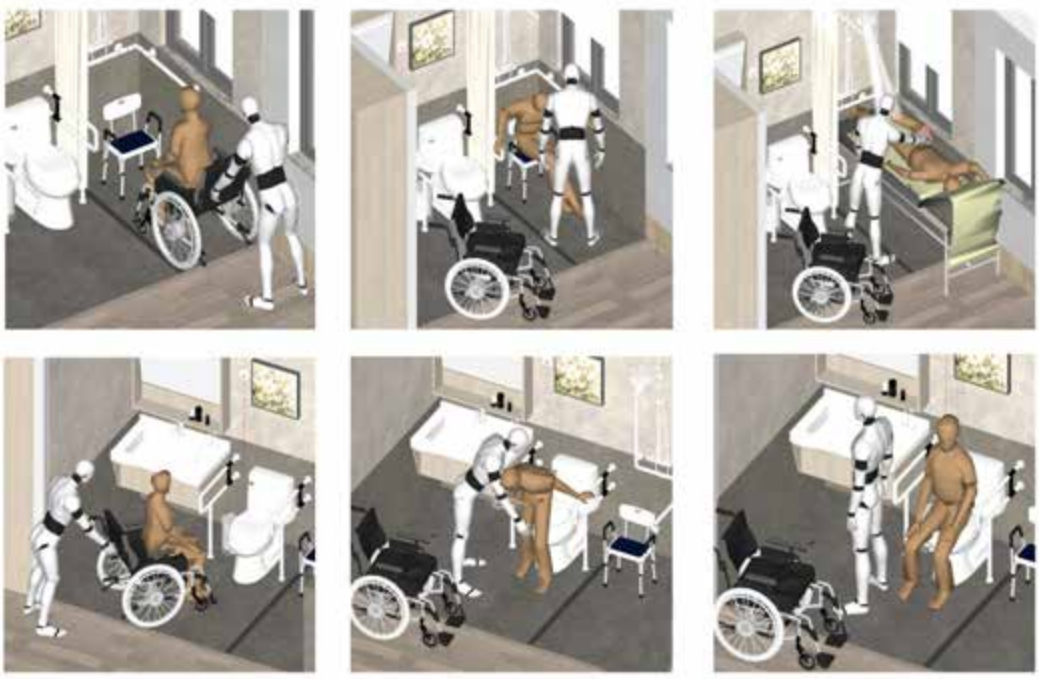

Figure 7. A schematic diagram of a care robot assisting the elderly in the bathroom space

4 Conclusion

As elderly care services continue to evolve toward greater intelligence and diversification, the integration of robots represents not only a technological innovation but also a fundamental shift in the organization and spatial logic of architectural environments. The spatial demand modeling method for care robots proposed in this study serves as a bridge between intelligent devices and architectural design, offering high scalability and practical applicability. By analyzing the motion characteristics of care robots in various caregiving tasks and applying principles of robotic kinematics, this research constructs an environmental requirement model to quantify the spatial needs associated with different tasks. It further assesses the mobility and accessibility of robots within typical eldercare spaces such as bedrooms and living rooms, and proposes environmental layout optimizations to enhance compatibility with robotic movement and operational zones. Additionally, the study explores the interactive relationship between robots and furniture, soft furnishings, and barrier-free facilities, and incorporates smart perception systems to improve robotic adaptability to complex residential environments.

Starting from six core caregiving tasks in real-world eldercare scenarios, this study provides an in-depth analysis of spatial adaptation principles and design requirements for robotic assistance in three representative spaces: bathroom, bedroom, and living room. A three-dimensional translational framework of "task–motion–spatial demand" is proposed to uncover spatial compatibility bottlenecks inherent in traditional human-centered residential layouts when confronted with robotic operation. Looking forward, this framework may be further enhanced by integrating machine learning, behavioral simulation, and multi-scenario dynamic optimization techniques, leading to the development of multi-scale design models that support human–robot–space co-evolution in intelligent eldercare communities offering both theoretical grounding and practical pathways for healthy aging in the urban context.

Abstract
Urban Digital Twins (UDT) are transforming the way cities are designed and managed while also fostering trust, collaboration and transparency for all, including citizens. UDTs are a virtual built-up environment model, primarily adopted to digitally deliver data insights and evidence-based decision-making capabilities to policymakers, city managers and planners. The essential nature of data in UDT requires that its implementation and adoption follow an ethical, robust and secure data governance practice. This paper stems from a research collaboration between the ADAPT Research Ireland Centre and Dublin City Council, via the Smart Dublin unit. The authors distil their situated experiences and knowledge into 12 key principles, organised under the pillars of Data, People, and Platform, and conclude with actionable recommendations for facilitating ethical and inclusive UDTs.

Keywords: Urban Digital Twins, Ethical Principles, Smart Cities, Data Governance, Responsible Innovation

1. Introduction

Europe's digital decade policy programme has developed a comprehensive network of digital transformation projects, setting clear objectives and targets to advance concepts of Data Spaces, Local Digital Twins, Interoperability, etc. Smart city projects aim to utilise technology to address urban issues, enhance public service delivery, city infrastructure management and create long-term business competitiveness through extensive data collection and constant urban surveillance through sensing devices (Angelidou, 2015, Kitchin, 2014). This tendency to oversimplify complex, unpredictable social systems into controllable, measurable units and a technocentric approach raises several ethical concerns (Cureton and Dunn, 2020). Technical advancements now are able to support big data analytics, artificial intelligence and edge computing for near real-time response and autonomous systems as envisaged by smart cities (Batty, 2018; Yigitcanlar et al., 2020). This has resulted in a rising global trend to utilise digital twins as one of the emerging technologies by smart cities, promising urban intelligence, policy testing, future scenario visualisation, and outcome prediction before infrastructure is even constructed (Jeddoub et al., 2024; Ketzler et al., 2020).

Urban Digital Twin (UDT) is a virtual model of the physical built-up environment that digitally overlays geographical location-based processes, socio-economic information, historical datasets and real-time sensor inputs on a single platform (Raes and Ruston McAleer, 2025). The main advantages of UDTs entail enhanced urban decision making, novel ways to engage with stakeholders and citizens, immersive visual experiences, high-performing resilient infrastructure seeking to support the entire construction value chain (investors, owners, asset managers, contractors, consultants, suppliers, etc), better risk management, financial savings and improved resource efficiency (Bolton et al., 2018). Overall, data is at the heart of a UDT aiming to enable better outcomes and superior results for higher public value. However, managing this digital-urban fabric requires complex, multifaceted approaches because its formal and de facto processes can create structural and epistemic tensions within socioeconomic, cultural and environmental conditions.

The combination of big urban data obtained through passive and non-consent from sensors, further processed and analysed using unexplained large language models, can potentially lead to data biases and discrimination, creating uncertainty and fear among urban communities and planners, as well as policymakers (Sanchez et al., 2024; Sherman, 2023). Moreover, this process of urban-digital replication, if coupled with automated decision-making, can threaten human autonomy and lead to mechanistic decision systems for existing cities and their

societal frameworks (Zwitter and Helbing, 2024). A human-centred approach, thus, becomes even more challenging and necessary in modern technological urban development, the emerging regulatory policy landscape and multilateral governance structures (Pellegrin et al., 2021).

This paper investigates ethical problems that may occur when UDT technology is deployed for urban decision-making through a case analysis of Smart Dublin. It draws from an extensive literature review, along with direct and sustained engagement with Irish Local Authority staff through the collaboration between ADAPT Research Ireland Centre for AI-driven Digital Content Technology and the Smart City Unit at Dublin City Council (DCC). The outcome of this paper further outlines fundamental principles that public authorities should be mindful of when implementing UDTs into their operational procedures and institutional structures. The authors conclude by emphasising that ethics integration at the outset increases the chances of responsible innovation and value sensitivity in UDT experimentation through methods that preserve citizen autonomy and build strong governance structures for smart cities and societies.

2. Literature Review

The digital twin concept is not new and dates back several decades to when NASA first applied a mirrored system for their Apollo Missions during the 1960s (Glaessgen and Stargel, 2012). The term itself, however, later appeared in 2002 in the context of a product lifecycle management project and later spread to multiple sectors, including manufacturing, healthcare and urban planning during the 2010s (Grieves, 2014; Tao et al., 2018). Smart cities globally began focusing more intensely on digital twin applications for city design and management, evidenced by an exponential increase in Scopus-indexed research articles on UDTs and their widespread adoption by public bodies. According to a European Commission's report, there are nearly 135 UDT platforms across Europe, primarily at the city-level, primarily focusing on urban planning, environmental and mobility use cases (Correia et al., 2022). This section discusses some of the envisaged risks of a UDT project by city authorities and highlights a few frameworks which have been developed for their ethical and trustworthy implementation.

2.1. UDTs' Envisaged Risks and Challenges

Digital twin platforms can cause risks of stakeholders ignoring crucial sociological, political, historical and environmental factors that affect urban environments. The success of a UDT project relies on data quality since the system will produce results that match the quality of its input data. An attempt at total representation of people, their behavioural patterns, and dynamics of social and spatial systems through quantitative models and digital twins presents notable challenges (Cureton and Dunn, 2020). On the one hand, cybernetic governance embodies an optimism towards enhanced operational efficiency and financial savings, while on the other hand, without enough human agency, it is challenging to develop value-sensitive solutions which protect human rights and respect cultural and social aspects.

A surveillance-based society which relies heavily on data-driven AI control and indicator-based approaches might lead to poor problem identification of complex issues (Breuer and Pierson, 2020; Kerr and Pierson, 2025; Zwitter and Helbing, 2024). Some projects, such as the 'Replica' and 'Cord' by Sidewalk Labs, are examples which exemplify dataveillance practices through a massive collection of urban data for public decision-making, leading to systematic personal data collection, people's behavioural monitoring, raising multiple ethical and privacy-related issues (Helbing and Sánchez-Vaquerizo, 2023). Wang and Burdon (2021) documented that nine million New York City residents became part of algorithmic decision-making systems that determined policing actions and transportation routes. However, the entire system failed to provide New Yorkers with an understanding of these decision-making processes, resulting in opaque 'black box' cities.

Barcik et al. (2023) posit using Rotterdam as a case study that since UDTs rely heavily on interconnected data systems, they are more susceptible to cybersecurity threats, leakage of sensitive personal and location-based asset information, and unauthorised access. The incorporation of intellectual property provisions in contractual agreements can address some of the foreseen copyright and ownership issues by specifying permitted use and access rights to UDT and underlying datasets (Simpson, 2020). This is critical since the loss of access to a

data source during project execution may create negative impacts on the model's performance, validity and accuracy. These formidable challenges require the non-negotiable implementation of responsible innovation principles and maintaining sufficient reliability of a UDT system to build trust and minimise social risks (Helbing and Sánchez-Vaquerizo, 2023).

2.2. Existing UDT Frameworks

UN-Habitat (2022a) emphasises that governments must take responsibility for their actions, together with the effects of technological adoption in cities. Few frameworks already exist for ethical processes in a UDT design and adoption. The UK government's Gemini Principles (Figure 1) are the most common, with nine values suggested, serving as a guidance system for their National Digital Twin (NDT) programme (Bolton et al., 2018). The National Infrastructure Commission's report 'Data for the Public Good' resulted in the development of their NDT programme to enhance government services and asset management. The Gemini Principles consist of three core themes which encompass Purpose, Trust and Function. Each element of the UDT needs a defined purpose that matches organisational goals while creating sustainable value distribution between all parties for enhanced productivity and risk management, according to Gemini Principles. They posit that UDTs should be designed with ethical and secure features to build public trust and avoid any possible data breaches.

Figure 1. Gemini Principles (Source: Bolton et al., 2018: pg. 7)

The emerging digital twin technology can benefit from early foundational frameworks like the Gemini Principles to ensure trustworthy UDT development. It must enhance city system functions through transparent, accountable operations with an aim to serve the needs of the city residents. The trust model proposed by Wang and Burdon (2021), shown in Figure 2, suggests that perceived trustworthiness of a UDT exists in opposition to perceived risk, which relies on the trustor's tendency to trust. According to this model, perceived trustworthiness is a result of three aspects of a UDT – their ability, integrity and benevolence. The ability of UDT immensely depends on system robustness for handling data with care and using high-quality information to make decisions and offering authentic city insights to citizens. An automated decision-making process of UDT systems can diminish city organisations' capability to display benevolence toward citizens (Wang and Burdon, 2021). The platform architecture of UDTs needs to be completely examined for their ability to verify both the validity of assumptions and the competence of algorithms. The second point of Integrity requires UDTs to match the socio-political goals of the territory in addition to the technical aspects, i.e. digital twin's common data environment needs to have a design framework that incorporates legal, social and political considerations.

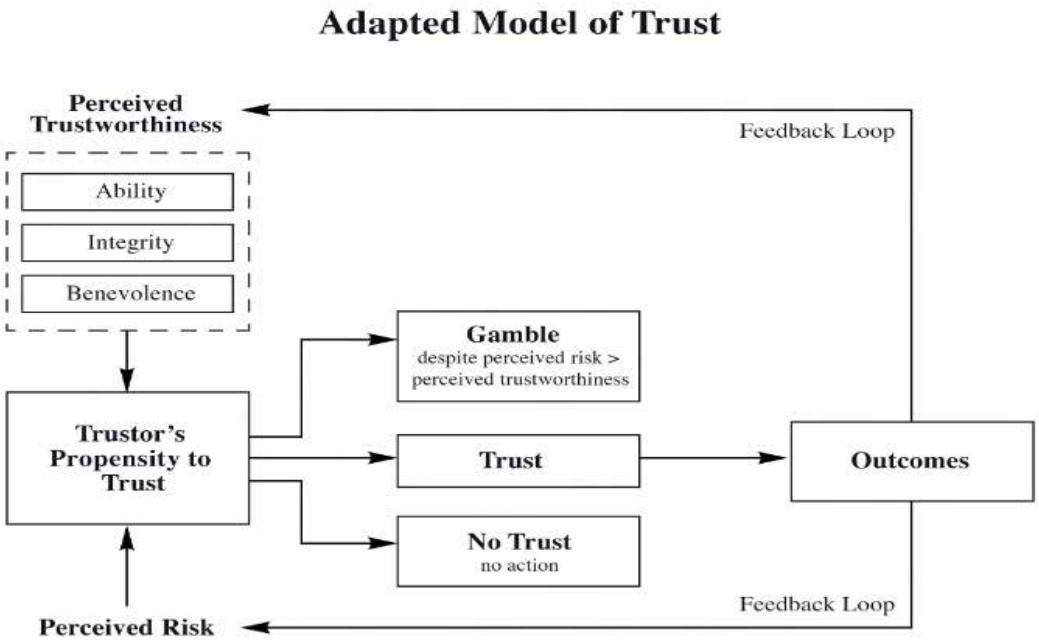

Figure 2. Adapted Trust Model for UDTs proposed by Wang and Burdon (2021: pg. 11)

Benevolence enables citizens to exercise their freedom to participate in social and cultural activities, as well as protect their fundamental human and digital rights. Citizens maintain the right to choose and maintain autonomy through their decision to participate and share their data. The acceptance of UDT can be increased if all stakeholders, including citizens, are able to understand how underlying datasets and algorithms in a UDT system align with democratic rules and city-making processes, also if they possess the ability to contest automated decisions at any time (Sadowski and Leurs, 2024). Human oversight mechanisms should therefore be established through human-in-the-loop, human-on-the-loop and human-in-command approaches for proper oversight (High-Level Expert Group on Artificial Intelligence, 2019).

The High-Level Expert Group on AI published Ethics Guidelines and a self-assessment list for Trustworthy Artificial Intelligence (High-Level Expert Group on AI, 2020; High-Level Expert Group on Artificial Intelligence, 2019), including AI principles from the Organisation for Economic Co-operation and Development (2019) and the Flemish AI Strategy (Digitaal Vlaanderen, 2024). UDT projects must comply with these trustworthy AI principles by following the three key principles of AI systems being a) lawful regarding all applicable laws and regulations, b) ethical regarding most of the moral values and c) robust regarding both technical aspects and social environment (High-Level Expert Group on Artificial Intelligence, 2019). It lays down seven requirements of equal importance, as shown in Figure 3, which must be deployed and monitored throughout the AI system's life cycle. Data protection alongside privacy needs to be respected while implementing adequate data governance systems, which prioritise data quality, integrity and validated data access. Moreover, the implementation of traceability systems can enable organisations to achieve transparency by providing decision explanations that match the level of understanding of their concerned stakeholders (City of Brussels, 2022).

Figure 3. Seven requirements for Trustworthy AI proposed by High-Level Expert Group on Artificial Intelligence (2019: pg. 15)

The three frameworks covered in this section aim to ensure trustworthiness and public value for the implementation of a UDT project. They serve three questions in general (Figure 4) – a) why a digital twin technology was chosen and whom does it serves, b) what steps can be taken towards improving trustworthiness, accountability, and transparency of a UDT system, and c) how technically competent is the UDT to support human decision-making processes. UDT should deliver public benefits, societal and environmental well-being, while ensuring diversity is respected throughout its project lifecycle.

Existing Frameworks relevant for UDTs

	Gemini Principles	Trust Model	Trustworthy AI
Why are we building a UDT and who are the beneficiaries?	**Clear Purpose** i. must be used to deliver genuine public benefits in perpetuity ii. must enable value creation and performance improvement iii. must provide determinable insight into the built environment	**Benevolence** *Is the system oriented toward public good and citizen wellbeing?* • active protection of privacy and dignity • allows user control and engagement • Support participatory city-making • Produce inclusive social outcomes	**Societal and environmental wellbeing** **Diversity, non-discrimination and fairness**
What makes UDTs trustworthy & transparent?	**Trustworthy** i. must enable security and be secure itself ii. must be as open as possible iii. must be built on data of an appropriate quality	**Integrity** *Does the digital twin act consistently with shared values and legal standards?* • transparent and accountable • ensure compliance with regulations and ability for users to consent and correct data about them	**Accountability** **Privacy and data governance** **Transparency**
How will UDTs enable data driven decision-making?	**Function effectively** i. must be based on a standard connected environment ii. must have clear ownership, governance and regulation iii. must be able to adapt as technology and society evolve	**Ability** *Can the digital twin perform effectively?* • Interoperable, secured, and ensure data portability • technically competent and functional	**Technical robustness and safety** **Human agency and oversight**

Figure 4. Existing Frameworks relevant to UDT implementation (Source: Authors)

3. Methodology

This study emerges from embedded research conducted through a collaboration between the ADAPT Research Ireland Centre, a national government-funded multi-institutional and interdisciplinary research centre, and Dublin City Council's Smart City Unit under the Smart Dublin umbrella (Dhingra and Kerr, 2024). The project between ADAPT and DCC began in December 2022 as a partnership aimed at trialling and testing ethical practices in the design and development of UDTs for public sector planning. It moves away from a technology push and prioritises an ethical, realistically achievable, and inclusive approach for UDT adoption (Dhingra and Kerr, 2024; Fernandez et al., 2024). Like drones and GenAI, digital twin is an emerging technology which is identified as one of the key priorities under the recently launched DCC's Digital Transformation Strategy 2025-2030 (Dublin City Council, 2025). This is seen as an opportunity for DCC to redefine its strategic roadmap for working towards embracing organisation-wide digital transformation management.

Figure 5 shows the project timeline, with the first phase focused on desk research to understand the concept of UDTs, its widely accepted definition, applications in urban planning, and the challenges raised by other scholars. Also, existing digital twin initiatives and bespoke pilots across Smart Dublin were mapped, enabling the understanding of key implementation barriers faced by stakeholders in Ireland. Phases 2 and 3 of the project streamlined the development of new use cases through a collaborative approach among the public sector, academia, and the research sector in Ireland. This includes a partnership with the Irish Centre for High-End Computing as part of the Digital Innovation Flagship call 2023, resulting in an engaging UDT platform architecture using the open data ecosystem, Google photorealistic 3D tiles, open-source gaming platforms like Unreal Engine and real-time APIs (Irish Centre for High End Computing, 2023).

Figure 5. Project Timeline (Source: Authors)

Parallelly, an INTERREG Northwest Europe (NWE) co-funded Twin4Resilience (T4R) project running from November 2023 to June 2027, led to the co-creation of an ethical framework for UDTs. T4R acknowledges the different levels of UDT maturity currently existing within EU member states and promotes transnational cooperation to enhance the adoption of UDTs by public sector bodies for data-driven resilient territorial planning. It is based on four co-developed frameworks – technical design, governance, ethics-inclusion-democratisation and training. DCC led the co-design of the ethics-inclusion-democratisation framework through an in-depth literature review and desk study, capturing the experiences of T4R project partners, their local stakeholders and the transnational community of practice. A detailed methodology is shown in Figure 6, highlighting how local, European and international experiences led to a participatory, iterative and structured approach for this study. Currently, the project is moving to align with other digital initiatives, such as strategy development of building information modelling for all public sector capital projects, a centralised common data environment, geospatial database management, etc, thus contributing to DCC's Digital Twin Programme.

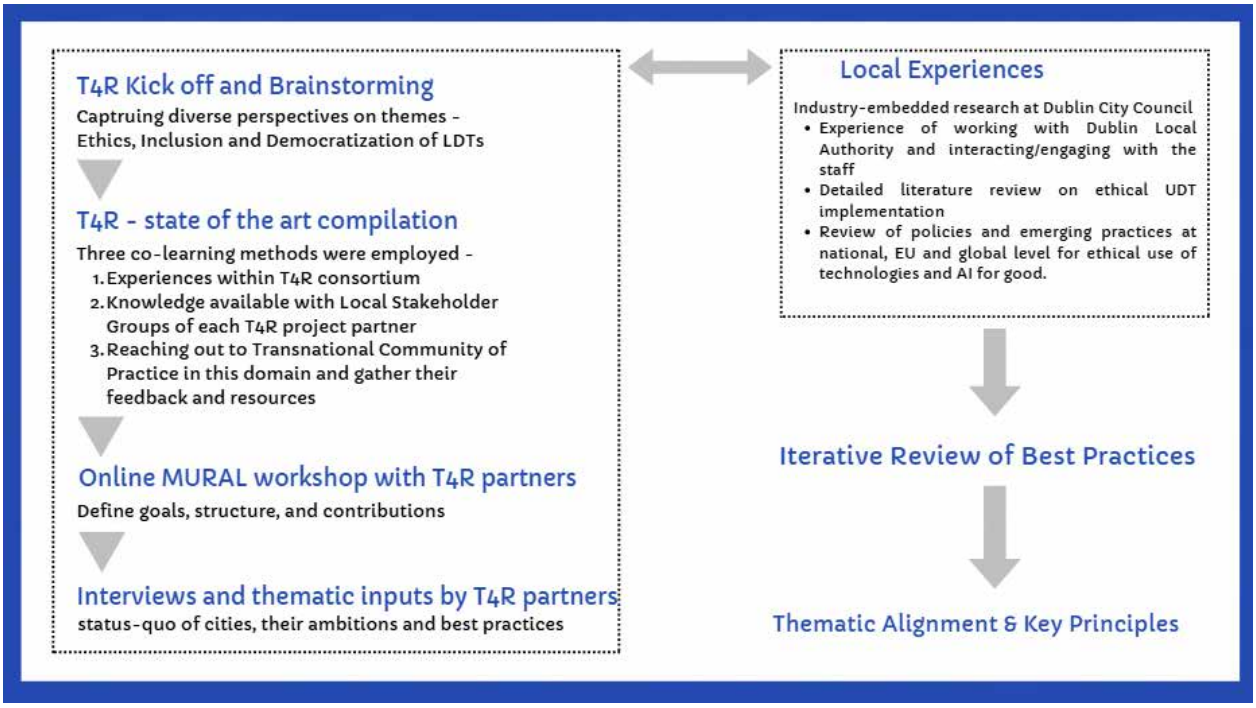

Figure 6. Methodological approach (Source: Authors)

The outcome of this study is also building on the UDT conceptual framework proposed by Dhingra et al. (2024), which placed People, Data and Platform at the core of UDT implementation while aligning with the ethical practices, robust governance mechanisms, high-impact use cases and continuous stakeholder engagement (Figure 7). The project simultaneously focusses on identifying high quality datasets for potential use cases, their management, storage and metadata requirements, exploring various enterprise and open software solutions available to DCC, evaluating best practices available locally and globally, building a dedicated stakeholder network across Ireland representing the quadruple helix model with academia, private, public and community partners, bridging current knowledge gaps with inspiring case studies and suggesting ways to mitigate potential ethical and social concerns.

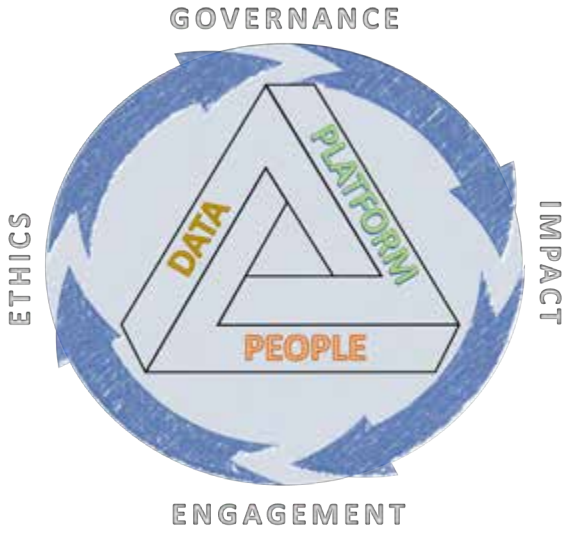

Figure 6. Proposed UDT conceptual approach (Source: Authors)

4. Findings, Discussion, and Recommendations

This section discusses findings of the study in terms of the issues that can arise during UDT implementation, understanding the current policy landscape in the EU, recommending contractual safeguards, best practices and some exemplars. This resulted in 12 key principles of UDT implementation, explained in the next section.

Figure 8 illustrates key implementation challenges identified as part of the ADAPT-DCC project. The most critical being a lack of high-quality datasets in standard data formats, and a realistic-looking 3D model of the whole city. The non-existence of interoperable solutions led to instances of vendor lock-in and an inflexible working environment. Data privacy, the possibility of surveillance of public spaces, potential biases, risk of techno-solutionism and black box AI systems also raise significant ethical and social concerns. Besides technical barriers, non-technical challenges such as lack of finances, under-skilled local authority staff, insufficient leadership buy-in, etc, are found to be of paramount importance.

Figure 7. UDT adoption barriers (Source: Authors)

4.1. Regulatory Compliance

Clarity of purpose, together with trust, openness, security, quality and effective UDT operation, are emphasised by the Centre for Digital Built Britain's Digital Framework Task Group (Bolton et al., 2018). An efficient information management system can enable better decisions, financial savings, improved performance of the built environment and urban services. This makes it imperative for an organisation seeking to implement a UDT to build a data-driven culture through open, transparent and inclusive processes combined with accessibility and accountability (European Commission, 2020; OECD Public Governance and Directorate, 2014). A UDT project must follow any applicable local, regional, federal, European and international laws. Some examples are listed in Table 1.

Table 1. Regulations relevant for a UDT project in the EU (Source: Authors)

Data Governance Act (DGA) (European Parliament, 2022)	A cross-sectoral framework to enhance trust in voluntary data sharing for the benefit of businesses and citizens and regulate the reuse of publicly held/protected data through proper data sharing intermediaries. This covers both personal and non-personal data.
General Data Protection Regulation (GDPR) (GDPR.EU, n.d.)	Europe's data security and privacy law has been effective since 2018, and sets clear guidelines to collect, store and process any personal data of citizens. It has seven principles: lawfulness, fairness and transparency; purpose limitation; data minimisation; accuracy; storage limitation; integrity and confidentiality; and accountability. Wherever personal data is concerned, GDPR legislation is applicable, implying it is critical to consider inbuilt safeguards to increase trust in data sharing and reuse.

Cybersecurity Frameworks	GDPR reflects some cybersecurity frameworks to comply to. Other security frameworks include the IoT Security Foundation (IoTSF), offering guidance and best practices for securing IoT deployments: iotsecurityfoundation.org, and NIST Cybersecurity Framework, providing a risk-based approach to managing IoT security.nist.gov.
Data Protection Impact Assessment (DPIA) (GDPR.EU, n.d.)	Required when using any new technologies tracking people's behaviour/location and monitoring publicly accessible spaces on a large scale, etc. It maps out the privacy risks of data processing in advance and helps to identify measures to reduce these risks.
Freedom of Information (FOI) Act	Requires organisations to maintain transparency with citizens. Subject to this Act, every person has the right to request and access any public record held by an FOI body.
EU AI Act	World's first comprehensive AI law (European Parliament, 2023) requires incorporating model contractual clauses to guide procurement of trustworthy AI services and systems (Naves et al., 2023)
Open Data Directive (European Parliament, 2019)	Regulates the reuse of publicly available information by the public sector, which is not of a protected nature, ensuring transparency for all stakeholders, including underserved communities and implements governance mechanisms that monitor fairness, accountability, and bias in AI-driven twin systems

Among these, GDPR's Privacy by Design principle is one of the most critical when it comes to any UDT project. It refers to data protection and privacy embedded into the design of data processing operations and information systems (European Parliament and Council, 2016). EU-based organisations are required to conduct an information audit to determine what information they store, process and who has access to it. Organisations can consult their Data Protection Officer (DPO) for each new data-collection service or technology and process implementation to pursue for their UDT use case. This will ensure that there is a legal justification for planned data processing activities and collected data is useful and necessary. Privacy Impact Assessments (PIAs) can be carried out to safeguard sensitive information within the organisation and align with legal requirements.

Besides ensuring compliance with legal requirements and secured cyber systems, the EU Digital Rights Principle of Sustainability requires digital products and services to experience their entire life cycle from creation through use, disposal and recycling while minimising economic, social and environmental impacts (European Commission, 2022a). AI-enabled applications in the minimal risk category include UDTs, which are subject to the EU AI Act requirements for transparency and non-binding codes of conduct. UDTs as government applications need to follow the EU's (High-Level Expert Group on Artificial Intelligence, 2019) ethics guidelines and code of conduct.

4.2. Contractual Safeguards

Trust-building relies on transparency in contracts and compliance with open data licenses. The legal definition of data ownership helps protect individual rights as well as shared copyright materials and resolves ownership disputes for the entire model, especially for UDTs when data is shared for public benefit use cases (Simpson, 2020). The licenses for data access need to have an extended duration which spans the entire twin lifecycle. The twin model benefits from various access permissions which protect against security breaches and information sensitivities among multiple users. Regular security assessments can be conducted, such as vulnerability assessments of devices and networks, penetration testing to evaluate the resilience of IoT devices and infrastructure and third-party inspections to engage independent auditors and verify compliance with security standards. Some extra-legal and contractual safeguards regarding data management for UDT projects are summarised in Table 2.

Table 2. Contractual safeguards for UDT projects (Source: Authors)

1. Data Protection Agreements	• Anonymise sensitive data to protect individual privacy and comply with regulations like GDPR, CCPA, or other relevant frameworks, which often prioritise the rights of the individuals whose data is collected. • Draft robust agreements, such as Data Processing Agreements (DPAs) or Service Level Agreements (SLAs), that define roles, responsibilities, and data handling requirements. • Incorporate model (standard) contractual clauses developed by the EU to guide the procurement of trustworthy AI services. These clauses align with the EU AI Act framework and assist public buyers in acquiring AI solutions that are ethical, fair, and secure.
2. Liability and Remedies	• Specify liabilities for breaches or misuse of data and include remedies such as penalties or termination of contracts.
3. Jurisdiction Compliance	• Address potential conflicts arising from cross-border data transfers and jurisdiction-specific ownership rules.
4. Data Ownership Clauses	• In principle, the ownership of the data remains with the government. This is undoubtedly the case when it concerns personal data. • Specify ownership of data generated, collected, or processed through external software or services in contracts. • In contracts with the private sector, the rule is that the ownership remains with the contracting authority. However, when purchasing private sector data, the use and ownership are part of negotiations. • Clearly distinguish between raw data collected from sources like sensors or user inputs and processed data as insights, reports, or models derived from the raw data.
4. Intellectual Property (IP) Rights	• Clarify who owns derivative works or outputs generated using proprietary software. For example, a public entity might retain ownership of raw traffic data collected by IoT sensors, but the company providing analytical services might claim ownership of proprietary algorithms used for processing.
5. Evaluate Data Licensing Terms	• Exclusive vs. Non-Exclusive Rights: Ensure the agreement specifies whether ownership is exclusive to one party or if data can be shared or resold. • Usage Restrictions: Define the permissible uses of data (e.g., no resale or use outside the project without explicit consent). • Licensing Models: Choose licensing agreements that favour public interest, such as open data models, while safeguarding sensitive information.
6. Secure Ownership Through Technical Measures	• Data Segmentation: Use separate environments for raw data storage to maintain control. • Encryption: Encrypt sensitive data to limit unauthorised access, even by the service provider. • Metadata Tags: Use metadata to tag data with ownership identifiers.
7. Conduct Due Diligence	• Vendor Assessment: Evaluate the vendor's data handling policies, IP claims, and track record regarding data ownership disputes. • Audit Rights: Include provisions for auditing the vendor's adherence to data agreements.

8. Address Ownership in Software Agreements	• Ensure Service-Level Agreements (SLAs) specify who owns data stored or processed by software solutions. • Include provisions for retrieving data in accessible formats if the contract ends or the software changes.

Highest standards of data governance, quality management and ownership clauses can also be ensured through adopting international standards on data quality, such as ISO 8000-150 "Data quality and ownership standards" (ISO - International Organization for Standardization, 2022). FAIR data principles can ensure that the used data is easy to find, use and access, has clear added value for your UDT, is interoperable and compatible with most of the platforms (Wilkinson et al., 2016). The European Commission (2023) also laid down a list of high-value datasets illustrated in Figure 9, which can provide important benefits for society, the environment and the economy, but are also open by design, free of charge, are populated with extensive metadata, and published in machine-readable formats.

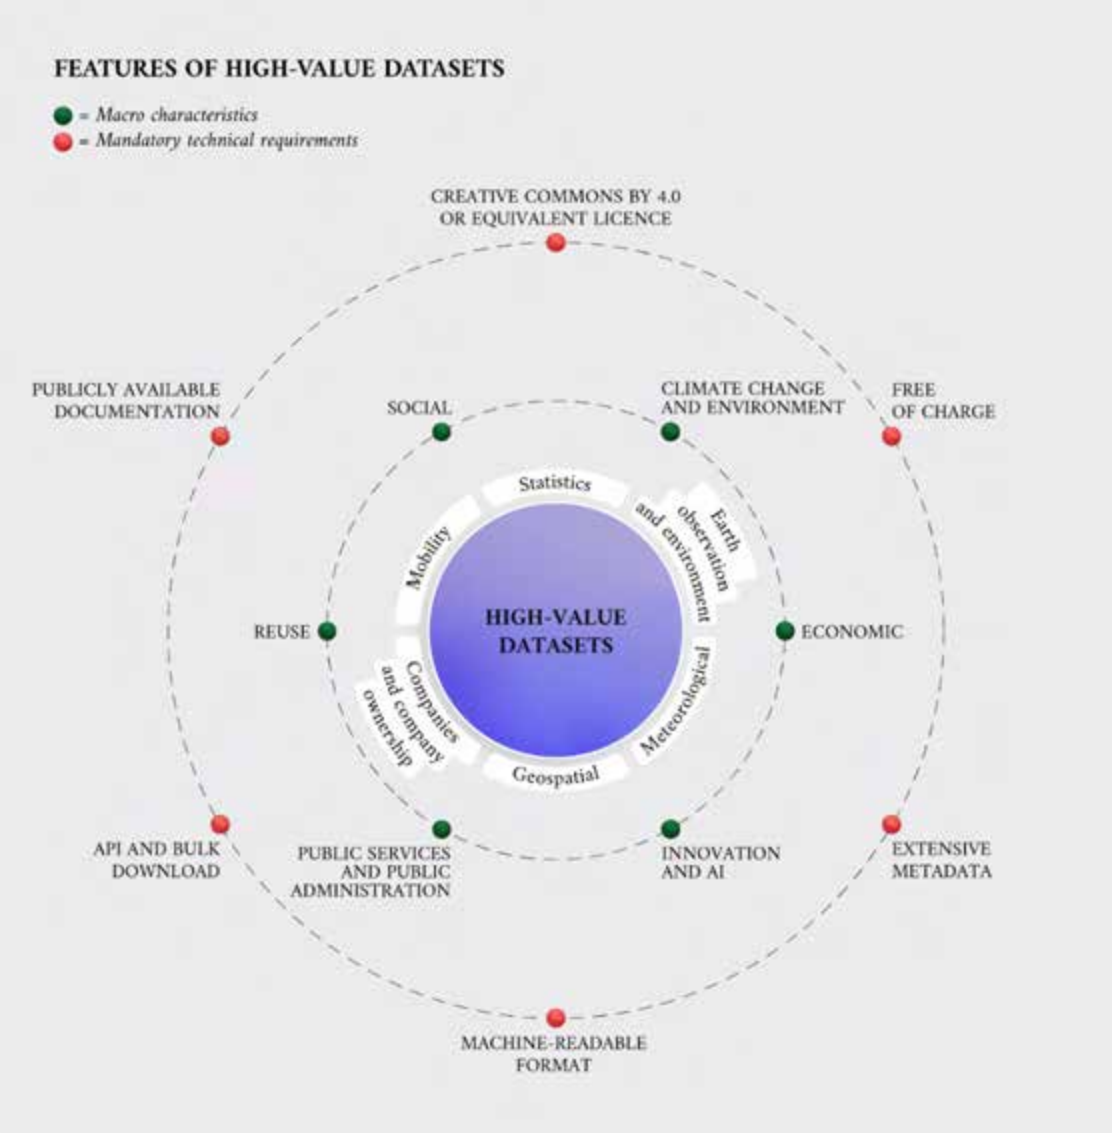

Figure 8. Features of high-value datasets. (Source: European Commission (2023))

4.3. Fundamental Rights-Based Approach

The democratic function of UDTs requires public social outcomes as their basis (Wang and Burdon, 2021). According to the European Declaration on Digital Rights and Principles for the Digital Decade, people stand as the primary focus of digital transformation in the European Union. A UDT must function for everyone who resides in the EU to provide secure empowerment that respects their fundamental human rights (European Commission, 2022b). It also emphasises that digital transformation should exclude nobody, i.e. it must benefit every person while delivering equality and protecting the vulnerable population.

The global design of UDT requires organisations to maintain cultural and social relevance by including people and local communities throughout the whole process. Any technological implementation must avoid uniform solutions because such approaches fail to respect the ingenious and diverse knowledge systems. The combination of social values along with soft data such as human behaviour, emotions and opinions within a UDT project can enhance the model's reliability to simulate complex real-world systems that contain human participation. Public or shared ownership models of technology products can potentially support communities to exercise control over technology management and deployment practices.

The principle of accessibility-by-design means products and services should be usable by most people without requiring special adaptation, and respect user diversity (Engineering Design Centre, n.d.). The curb cut effect described by Blackwell (2017) is an interesting example because accessibility features intended for marginalised groups often help a wider population. Some functionalities started as minority-specific tools but evolved into widespread standard elements, such as television and video content industry implementing closed captions initially designed for hearing-impaired viewers but now serve viewers in noisy settings, language learners and content creators, etc.

The public can also exhibit fear about UDT because of the unclear nature of privacy concerns and data control. Raising awareness can eliminate uncertainty by revealing the essential components of the UDT platform, including its purpose and method of operation, alongside its advantages and potential risks to those directly or indirectly affected by it. Breaking this fear requires good internal and external communication strategies, together with active citizen participation. Therefore, it would be fair to say that the governance structure of the digital offering relies on transparency as its main principle. Herrenberg in Germany (Dembski et al., 2020) and Malvalaan in the Netherlands (Najafi et al., 2023), are some examples of UDTs which use virtual reality technology for public participation (Figure 10).

Figure 90. Examples of public participation using UDTs (left - Herrenberg in Germany (Dembski et al., 2020: pg. 10), right - Malvalaan in the Netherlands (Najafi et al., 2023: pg. 13))

5. Key Principles for Ethical Implementation

Dhingra et al. (2024) proposed a conceptual approach advocating constant prioritising of ethics, governance, engagement and impact assessment. This section presents recommendations and best practices as 12 key principles under the pillars of People, Data, and Platform to implement an ethical approach for UDTs (Figure 11).

Figure 10. Key Principles for Ethical Implementation of UDTs (Source: Authors)

5.1. People

Any UDT project should start with the aim instead of technology, i.e. clarity of purpose is must, as suggested by Gemini Principles (Helbing and Sánchez-Vaquerizo, 2023; Wang and Burdon, 2021). It is critical to identify the urban issue which UDT should address, its scale and data requirements. Validation and verification of outputs of the model can ensure that it responds to the problem statement, and if underlying data, assumptions and uncertainties are considered (Herzog and Probst, 2024). A UDT must also align with the values, goals and mission of the organisation. For instance, in Amsterdam, the Municipal Executive has included the principles of the TADA Manifesto in the Coalition Agreement (Amsterdam Municipality, n.d.). It sets out important values such as inclusivity, a

say for residents, human scale, legitimate and verified data, openness and transparency for a responsible digital city. A rigorous check on the Tada values is now mandatory for every digitisation and data project at the municipality. Also, in 2023, the City of Brussels launched a Digital Rights Charter, which includes both the commitments on digitalisation and a list of actions to reflect these commitments.

To ensure a people-centric approach, stakeholders and beneficiaries must be identified at the inception of the UDT project. Some techniques, such as the Inclusive Segment Cards, can serve as a tool to understand target groups while ensuring everyone's viewpoint is considered in the design process (Friesinger, 2024). Also, impact assessment of UDT before the deployment can mitigate potential risks and harms often associated with it. A few best practices emerge from the Municipality of Amsterdam, which organises workshops and training for making moral decisions in technological projects, resulting in "ethical leaflets" (Schmidt, 2019). The Municipality of Utrecht has created a "Uthics method for ethical assessment" of digital projects based on the Data Ethical Decision Aid (DEDA model), shown in Figure 12 (Utrecht Data School, 2022). DEDA allows mapping of ethical dilemmas surrounding every digitisation process in the city that affects the residents in a Uthiek (Utrecht ethics) assessment. Rennes Métropoles works with a non-profit organisation, Ekitia, for an ethics assessment on their LDT Coopterr platform, as well as on other building blocks of their data ecosystem (Ekitia, 2022) .

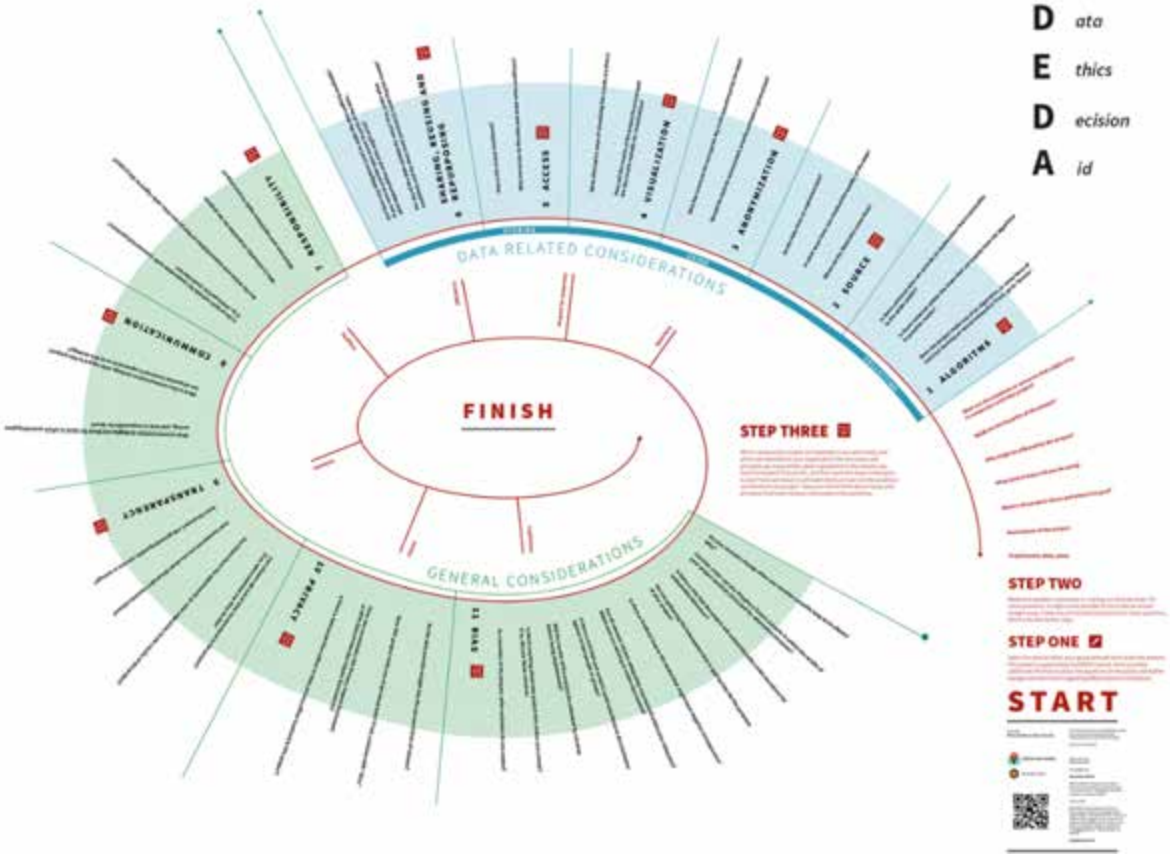

Figure 11. Data Ethics Decision Aid (DEDA) model proposed by Utrecht Data School (2022)

5.2. Data

Ensuring safe data handling practices and soft data integration which respect local socio-cultural settings can build trust in UDT decision making. Consider gender and age-sensitive design while developing a UDT (Nunes Inês et al., 2023, United Nations Human Settlements Programme (UN-Habitat), 2022) to avoid the emergence of new forms of digital exclusion (i.e. not being able to take advantage of digital services and opportunities) (OECD Public

Governance and Territorial Development Directorate, 2014).

The TEA-DT (Trustworthy and Ethical Assurance for Digital Twins) platform is an open-source tool for teams (and their host organisations) to show how specific goals or objectives have been realised within the context of their UDT project, and to communicate this clearly with relevant stakeholders and users (Burr et al., 2024). Figure 13 illustrates a word cloud of the definition of assurance for digital twinning, with the size of each term representing its frequency.

Figure 12. Definition of Assurance for Digital Twinning. Source: Burr et al. (2024)

Some cities already have specific GDPR processes in place to facilitate data ethics, such as Amsterdam Municipality using Quality Assurance Acceptance (QAA) Criteria procedure and Ethical leaflet, while Rennes Metropolis follows Ethical Charter for Data Usage (Ekitia, 2019). Many European cities, such as Dublin and Utrecht, conduct Data Protection Impact Assessment (Data Protection Commission Ireland, n.d.) for any new technology and data-related intervention/deployment under the EU GDPR Regulations. Both Utrecht and Amsterdam also maintain a publicly accessible camera and sensor register to inform citizens about the data that's collected via these tools and to reassure them that their privacy is respected.

5.3. Platform

To ensure sustainability, procurement clauses that foster open-source solutions and the reuse of open code are suggested. PIANOo, the Dutch Public Procurement Expertise Centre, provides comprehensive information on sustainable public procurement (SPP), also referred to as responsible and sustainable procurement (RSP). The information has been prepared specifically for public purchasers, focusing on the environmental and social impact of procurement and the price of the products or services in question (PIANOo: the Dutch Public Procurement Expertise Centre, n.d.). Tools such as the AI Ethics Card (Ideo, 2019) in Figure 14, Impact Assessment Human Rights and Algorithms (Ministerie van Binnenlandse Zaken en Koninkrijksrelaties (The Netherlands), n.d.), and Algorithmic Equity Toolkit (AEKit) empower non-technical stakeholders to engage with algorithmic systems (ACLU Washington, 2019).

Figure 13. AI ethical compass cards (Source: Ideo (2019))

The user interface (UI) and user experience (UX) design must reflect the cognitive and cultural preferences of the target audience. This could mean adjusting interaction modes (e.g., voice interfaces, gesture controls), making communication multi-lingual and culturally appropriate to suit users' preferences. Accessibility criteria as suggested by Digital Inclusion by Design Index/toolbox (DigitAll, n.d.), as illustrated in Figure 15, can assess the final UDT product. User tests with a group of people with diverse abilities, languages, and demographic profiles can open their resistance to new technologies by allowing them to work, play and interact with the UDT prototype. Digital means of communication (social media, website, online press articles, videos, etc.) should complement and not replace non-digital methods (paper magazines, presentations, workshops, trainings, panels, etc.) to be as inclusive as possible.

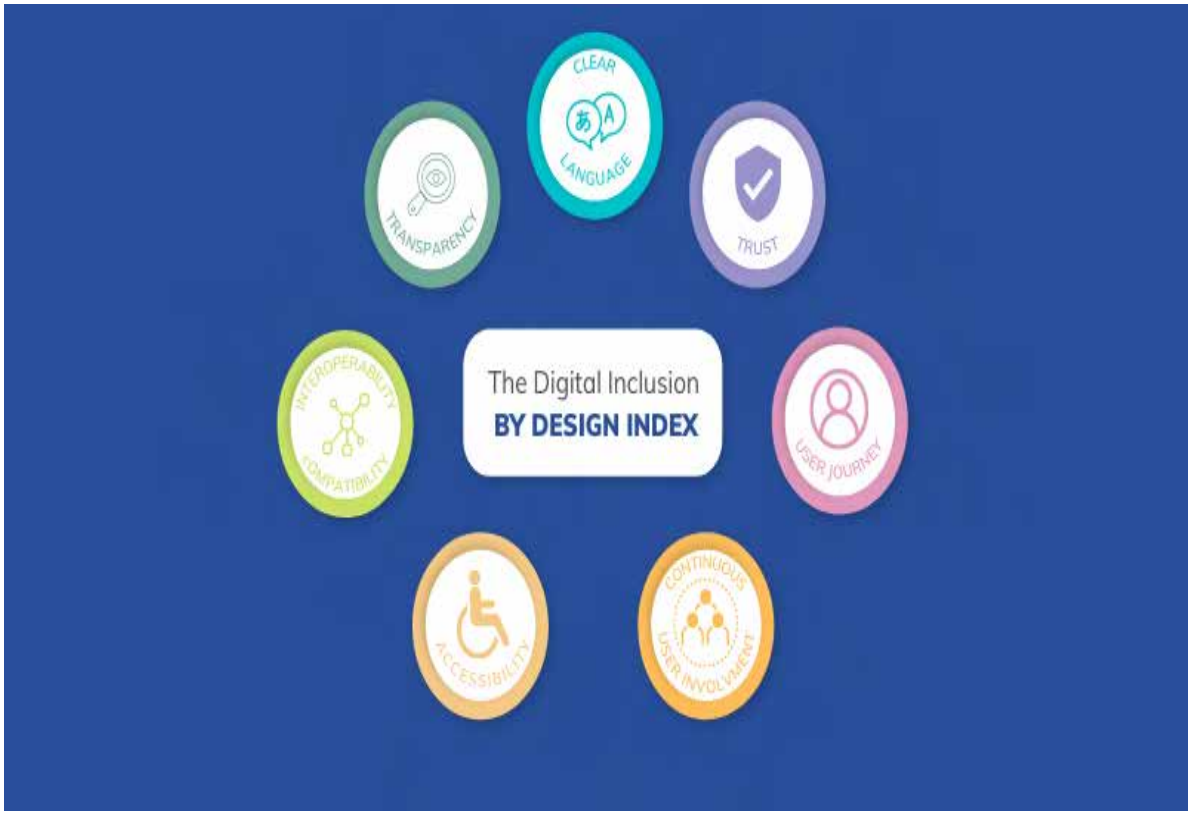

Figure 14. Accessibility criteria (Source: DigitAll (n.d.))

6. Conclusion

Smart cities encompass a range of complex socio-economic, cultural and environmental factors (e.g. Meijer and Bolívar, 2015; Kitchin, 2013). The cross-cutting nature of digital twins as an emerging technology increasingly engages multiple organisational, legislative and governance contexts. While the role of digital twins is increasingly referred to as crucial for contemporary spatial planning, they may raise many ethical, social and legal concerns (Helbing and Argota Sánchez-Vaquerizo, 2022; Wang et al., 2024). Technical barriers, such as achieving interoperable, open-data standards, are further compounded by non-technical hurdles, including capacity building and upskilling of local authority staff, privacy risks, cybersecurity threats, dataveillance, technological lock-ins, and potential social discrimination and democratic backsliding (Weil et al., 2023; Mazzetto, 2024). Sufficient evaluation of the performance and efficacy of twin products in smart cities is therefore contingent on a comprehensive approach to stakeholder input beyond extant technocratic remit — an input greatly enhanced by active and sustained citizen engagement.

A balanced framework for ethical, sustainable digital technology implementation in urban areas requires integration of the vision and objectives of organisations for their people and citizens, and high-quality datasets into a single digital twin software system. All UDT products must demonstrate digital inclusion and compliance. The triadic approach proposed by the authors combines public institution capacity-building with wellbeing and public value metrics to ensure smart city technologies create democratic and ethical and resilient futures. Starting with the people pillar is seen as an opportunity to establish digital equity and participatory governance as its core priorities. Cities can establish co-creation processes through living labs, active public engagement and cross-sector collaboration, combining experimental approaches with local knowledge.

To address privacy and cybersecurity concerns, trust in safe data handling is paramount. The foundation starts with two essential principles: data minimisation and contextual integrity. The system achieves its goals through transparent data processing methods, which enable users to understand consent and ownership mechanisms.

Open standards, ethical data governance frameworks and secure architectures with data stewardship integration form the basis of these on-the-ground implementations. The platform layer supports these values through interoperability for system flexibility, openness and algorithmic accountability for bias reduction, fairness maintenance and lifespan thinking of digital infrastructure. The operationalisation of these ideals happens through ethics-by-design approaches and auditable governance mechanisms to support vendor-neutral procurement policies and promote public value.

Sufficient human agency, integration of explainable procedures and frequent checkpoints to assess the performance of UDT in alignment with established values for the project can ensure trust in UDT decision-making. The pursuit of more inclusive and participatory models in the public sector has contributed towards more effective urban development strategies and their extended technological deployment. In a departure from singular or one-off consultation practices, ongoing feedback loops can help foster a dynamic environment of continuous and iterative improvement in urban planning delivery. Such engagement can be facilitated in a diversity of ways, such as via surveys, public forums, and digital platforms, enabling citizens to voice their experiences and suggestions to enhance and refine public service provision.

Nevertheless, the propensity of smart cities to prioritise market-led solutions can often overshadow the inclusivity required (e.g. Cardullo and Kitchin, 2018; Kitchin, 2013), meaning that many aspired frameworks run the risk of becoming a tick-box exercise, particularly when submersed into governmental and other organisational policies. This necessitates explicit efforts for aforementioned active and sustained engagement beyond 'business as usual' mentalities, whereby regular audits of twin products' integration and implementation are required to ensure quality assurance processes. Future research should embrace and advance these principles for their UDTs but also contribute to practical ways of implementing democratic UDT systems which ensure that no one is left behind.

Email: karatuna@itu.edu.tr, ekurkcuoglu@itu.edu.tr

Abstract
As the metaverse grows into a new kind of shared and personal space, companies in Türkiye's information industry are turning to virtual offices to better support employees working in hybrid setups. This study looks at what drives these companies to choose certain locations in the metaverse, with a special focus on how environmental and urban design can make these digital workspaces more appealing and effective. Using an online survey and correlation analysis, the research identifies key design features that impact corporate preferences. It aims to bridge theory and practice in metaverse platform design and contributes to the literature by revealing environmental design elements unique to virtual environments, which may align with or diverge from those in the physical world.

Keywords: Metaverse, Environmental Design, Site Selection, Information Industry

Introduction

In recent years, the rapid advancement of technology and digitalization has led to radical changes in the business world. Information industry companies are experiencing a significant transformation from the physical world to digital environments. An important reflection of this transformation has emerged with the development of virtual universes such as the metaverse. The metaverse is a concept that offers a digital environment independent of the physical world, shaped by the combination of virtual reality (VR), augmented reality (AR), blockchain and other digital technologies. This new environment has the potential to reshape both working methods and corporate location strategies for companies.

Virtual offices and workspaces in the metaverse are drawing attention as an alternative that can replace or complement physical offices. Information industry companies, especially those operating in the technology and service sectors, have begun to adopt hybrid strategies that combine physical and virtual forms of doing business in digital spaces such as the metaverse. This situation brings about a transformation that affects not only business processes but also corporate layout planning, design approaches and environmental factors.

Many companies take environmental design elements into consideration when designing virtual offices and workspaces, aiming to increase employee productivity, strengthen interaction, and contribute to sustainability goals in workplaces in the metaverse. In this context, moving environmental design beyond the physical world is becoming an important factor guiding corporate location choices in the metaverse.

The purpose of this study is to examine the environmental design elements that information industry companies take into consideration when choosing locations in metaverse environments and the effects of these elements on the companies' corporate strategies. Environmental design aims to provide a sustainable and interaction-oriented environment that meets not only the aesthetic or functional needs of virtual workplaces in the metaverse, but also the psychological and social needs of employees. In this process, the impact of environmental design elements is of great importance in understanding the shaping power of the metaverse on the future business practices of companies.

Urban design implementation tools are divided into three levels. At the first level, there are physical tools that create designs and are developed in the form of design controls, including design programs, design principles,

design plans and design guidelines. The second level addresses the entrepreneurial process and financing, while the third level addresses management tools. Design guidelines, which are part of project implementation tools in urban design, provide a conceptual framework that urban designers, urban planners, municipalities and other urban management bodies should use to organize physical spatial changes caused by urban development and to guide new urban renewal projects and activities. The purpose of design guidelines can also be defined as the systematization of social and physical programs and design expressions related to problematic urban areas (Karaman, 1992).

Founded by Ronald L. Mace in 1989 and named The Centre for Universal Design at North Carolina State University in 1996, the centre published seven principles in 1997, consisting of "egalitarian use," "flexibility in use," "simple and intuitive use," "perceivable information," "tolerance for error," "low physical strength requirement," and "appropriate size and space for approach and use," in order to make the concept of "universal design" understandable and to make recommendations (Story, Mueller, & Mace, 1998).

In their study on urban design quality frameworks, Nase et al. (2015) examined and compared the design frameworks of Kevin Lynch (1981), Bentley et al. (1985), Jacobs and Appleyard (1987), Tibbalds (1992), Congress for the New Urbanism (1996), CABE and DETR (2000), Llewellyn-Davies (2000), Barnett (2003), and Savills (2007) and conducted a frequency analysis based on a score of 1-9 for the concepts under the titles of character visual scope, spatial relationship, building design quality, adaptation and flexibility, mixed use, movement and accessibility, density, design for society/public benefit, social mix, user participation, sustainability, and management in the context of design frameworks.

• According to Lynch, the conceptual infrastructure components of urban design are control, suitability, feeling, liveliness, access,
• According to Bentley, personalization, durability, richness, noticeability, variety, permeability, visual suitability,
• According to Jacobs and Appleyard, identity, control society and public life, urban self-confidence, imagination and pleasure, liveability, originality and meaning, access to opportunities, an environment that appeals to everyone,
• According to Tibbalds, addressing and consulting all segments of society, being long-term and adapting, human scale, incomprehensibility, pleasure and visual pleasure, avoiding very large-scale changes, spaces before structures, visually noticeable environments, combining uses, freedom to roam, learning from the past and respecting the context,
• According to the New Urbanism Congress, cities and districts shaped by community organizations, pedestrian and transit-oriented design, physically defined public spaces, diversity in use and population, universal accessibility, commemorating local history, climate, ecology and building practices,
• According to CABE and DETR, it has been implemented through the eight characteristics of urban form: compatibility, character, continuity and preservation, public space quality, visibility, diversity, ease of movement,
• According to Llewellyn and Davies, it has been managed investment-design for change, work with the landscape, mixed forms, places suitable for people, mixed uses, establish connections, enrich the existing.

Character visual scope, **spatial relationship**, **mixed use** and **design for community/public benefit** ranked first with 9 points each, **building design quality** and **movement and accessibility** ranked second with 8 points each, and **sustainability** ranked third with 7 points.

As a result of the literature review, it is revealed that the studies conducted mostly address urban design parameters in terms of urban quality. As a result, urban planning and urban design are disciplines that complement each other. While urban planning shapes the city with large-scale strategic decisions, urban design implements these decisions in a human-centred, aesthetic and functional manner. This interaction between the two fields ensures that cities are more liveable, sustainable and aesthetically pleasing.

Developments in the real estate market are directly affected by various elements of urban planning. The balanced planning of different usage areas in the city – such as mixed-use projects, commercial areas and residential areas – positively affects real estate values by increasing economic activities in the region (Ferm and Jones, 2016). Mixed-use projects increase economic vitality by providing not only residential areas but also commercial, office and social areas in the city, and this creates more attractive opportunities for investors (Duany, 2000). The urban planning process requires the development of appropriate strategies to establish a balance between supply and demand. Overbuilding or lack of infrastructure in cities can lead to a decrease in real estate values and a decrease in the quality of life.

A comprehensive classification of the value created in the built environment is provided by Macmillan (2006), who identifies six different types of value. **Exchange value** views the built environment product as a commodity to be traded, whose commercial value is measured by the price the market is prepared to pay. **Use value** considers the contribution to organisational outcomes such as productivity, profitability, competitiveness and repeat business. **Image value** arises from the built environment's contribution to corporate identity, prestige, vision and reputation; it demonstrates commitment to design excellence or innovation, openness or being part of the brand image. **Social value** arises when the built environment creates or enhances opportunities for positive social interaction, strengthens social identity and civic pride, increases safety and reduces vandalism and crime. **Environmental value** is created through the application of the principles of adaptability and/or flexibility, durability and low maintenance, and a whole-life cost approach. **Cultural value** relates to the concepts of context and sense of place and may involve consideration of rather abstract issues such as symbolism, inspiration and aesthetics.

Metaverse, Urban Design, Real Estate Relationship

Planning, design and real estate have undergone a major transformation with technological advances. Digital technologies, big data analytics, artificial intelligence and automation have made urban planning and design processes more efficient and harmonious. The information industry is a sector that includes the processes of information production, processing, storage, distribution and consumption and plays a central role in economic structures. This industry can be defined as a rapidly growing and transforming area with the increasing integration of digital technologies and information processing tools (Drucker, 2012).

With the developments in information and communication technologies, the virtual world is becoming a broader expression of our personal and collective space, and a two-way shaping is emerging. This situation reveals the uncertain area between a person's physical existence, their actions in the physical environment, and their virtual identity (and actions) in digital networks (Ulubaş Hamurcu & Terzi, 2022). Until the twenty-first century, the transformations experienced in technology have greatly affected both the city and urban life. Growing and developing cities are turning to smart applications to offer quality life opportunities to the public, increase the level of efficiency, expand the level of sustainability, facilitate urban life, and find innovative solutions to problems. In this process, the use of technology instead of traditional methods is very important (Terzi & Ocakçı, 2017).

The concept of the metaverse has emerged as a reflection of the historical and technological developments explained above and as a response to this area of uncertainty in the transformation of spatial areas from physical to digital. In general, the Metaverse is considered a fully immersive, hyper spatiotemporal, and self-sustaining shared virtual space that blends the physical, human, and digital worlds. The Metaverse is a virtual platform where one can immerse themselves in a three-dimensional digital space through avatars and NFTs, a type of cryptocurrency derived from blockchain-based smart contracts, by bringing real and virtual environments into interaction (Mystakidis, 2022).

The Metaverse platform today offers users opportunities in various areas such as attending concerts, watching

movies, communicating, visiting museums, playing games, and attending meetings and trainings in three-dimensional environments using virtual reality, augmented reality or mixed reality tools (Arvas, 2022). Today's important metaverse platforms and their basic features are shown in Figure 1.

Decentraland		Blockchain-based virtual world. Users can buy, build, and trade digital land. All assets are tokenized on the Ethereum blockchain.
The Sandbox		A platform focused on digital games and virtual property. Users can create, sell, and trade in-game assets. Blockchain-based.
Roblox		A platform for creating and playing games, popular among young users. Users can design their own games and hold social events.
Meta Horizon Worlds		Metaverse platform of Meta (formerly Facebook). Provides social interaction, games and participation in virtual events. Provides three-dimensional interaction and virtual life experience.
Somnium Space		Virtual reality focused metaverse platform. Users can buy virtual real estate, host events, and trade.
Cryptovoxels		Blockchain-based, low-resolution virtual world. Users can create digital art galleries and trade.

Figure 1: Important Metaverse Platforms and Their Basic Features

In the coming years, as service provision becomes more widespread in the Metaverse, social interactions and knowledge increase, and opportunities are unlimited, people will help increase liveability by using their resources for purposes such as personal development, health, and social development (Allam et al., 2022). As examples of developments in the private sector, Nike has created its own digital universe for virtual products that can be purchased in the Metaverse, Disney has begun work on creating a theme park, and Gucci has begun selling its own NFTs (Wise, 2023). In addition, Samsung has brought its Samsung 837 concept from New York City to the metaverse, and fashion chain Forever 21 has opened a branch in the virtual universe (Tekin, 2022).

The metaverse provides a synchronous platform for urban governance as it allows for the digital delivery of urban services and assets. Augmented reality, virtual reality, mixed reality, the internet of things (IoT), digital twins, and blockchain are the key technologies that are vital to the meta database, and cities are benefiting from these technologies in many areas of use (Aksu & Ercoşkun, 2022). For example, cities such as Orlando, Las Vegas, and Boston already have virtual replicas that allow local governments to envision and consider various scenarios, such as the impacts of planned land uses and new roads. Such efforts can be positively complemented by the meta database, where urban planners, developers, managers, and other stakeholders have equal opportunities to interact and collaborate in the digital realm while creating plans and finding solutions to various urban problems (Allam et al., 2022).

The basis of the urban metaverse is the merging of the consumer metaverse and industrial metaverse visions. From a general perspective, it can be said that the urban metaverse has the following main characteristics (Dienhart et al., 2025):

• Digital twins: virtual copies of physical objects, processes and systems in the city. These digital twins are constantly updated and interact with each other in a virtual environment.
• Real time and progression over time: an important aspect of the urban metaverse is that time in the virtual world progresses in parallel with the physical world (continuity). This can happen in real time or at regular intervals, depending on the usage scenario.
• Immersion: virtual reality (VR) and augmented reality (AR) technologies provide an immersive experience by allowing users to be fully immersed in the virtual environment.
• Interactivity: citizens, local governments and companies can interact in the virtual environment, perform simulations with objects and systems and make data-driven decisions.

The processes of creating virtual cities in the Metaverse have taken the concept of digital twins one step further, and in June 2022, DEIP Metaverse City opened a space in the metaverse for architects, urban planners and artists from all over the world to develop a creative virtual city industry. DEIP Metaverse City consists of a three-story exhibition area, a labyrinth of dozens of intersecting streets, tunnels and a square with an amphitheatre (Kashiripoor, 2023) as shown in Figure 2.

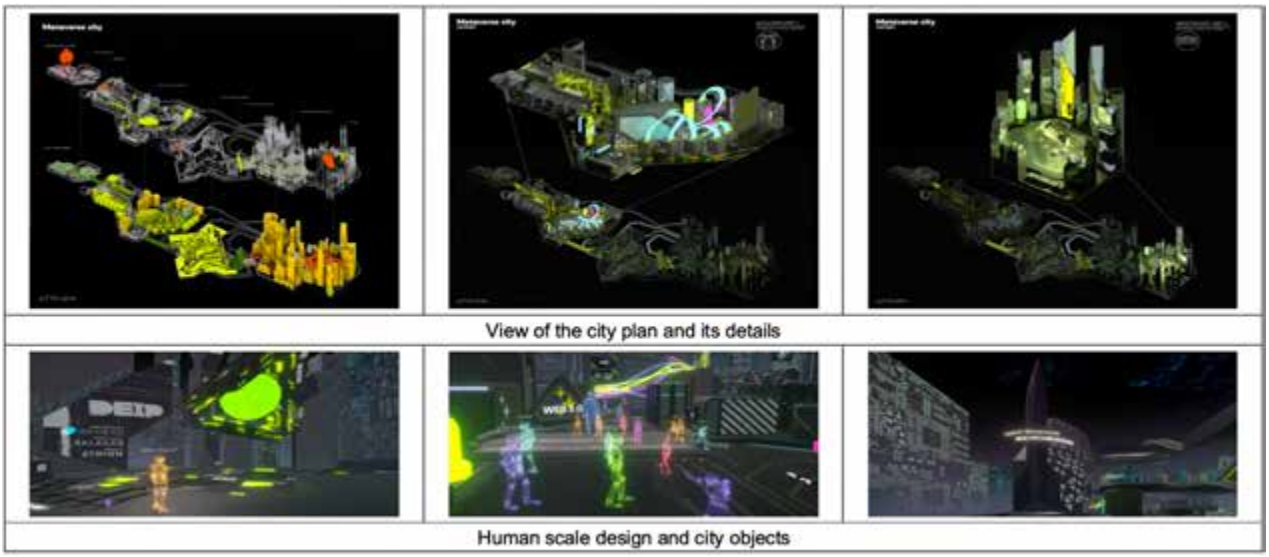

Figure 2: DEIP Metaverse City (Kashiripoor, 2023)

Liberland Metaverse, a major urban scale metaverse application, is a joint venture between four organisations: Liberland (client), Zaha Hadid Architects (design), Mytaverse (technology) and ArchAgenda (management). Liberland is a political initiative that aims to create a free micro-nation on a small, arid and disputed seven square kilometre area on the Danube River between Croatia and Serbia. Liberland, a city construction project by transferring a real-life space to the metaverse environment, has a decentralized financial structure-based approach and aims to reflect Web3 details representatively on space in the context of urban design. Figure 3 shows the urban design of Liberland located on the banks of the Danube River, while Figure 4 shows the effects of Web3 reflections on urban design as representations of the structures located in the city centre of Liberland.

Figure 3: Liberland Metaverse – Zaha Hadid Architects – 2022

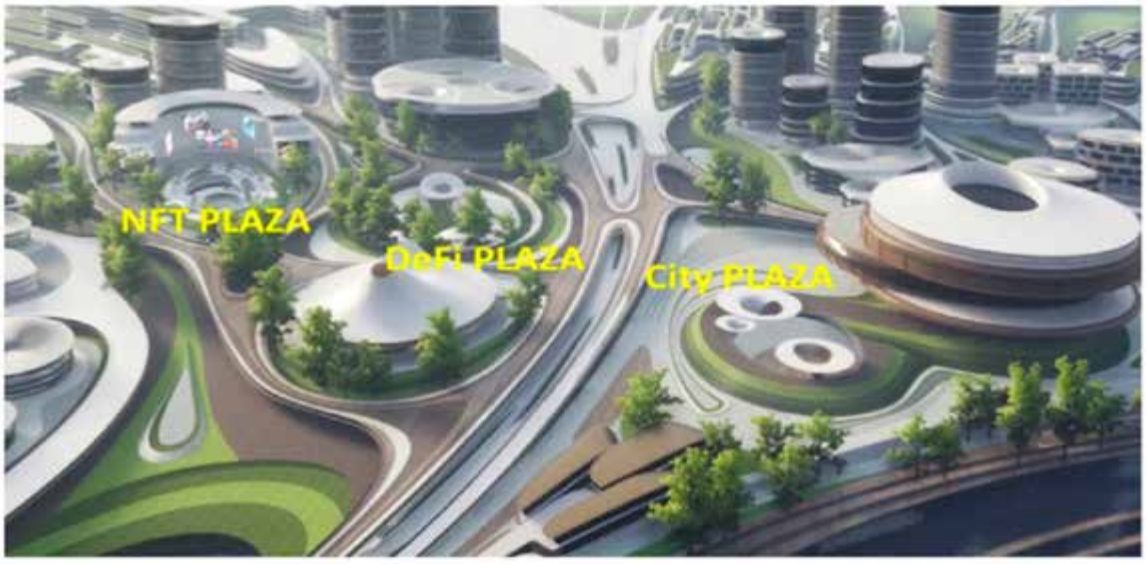

Figure 4: Naming Structures with Web3 Terms in the Liberland Metaverse Environment

Real estate activities in the metaverse provide people with a place and opportunity to connect with people in remote locations around the world. Developers can monetize their virtual properties to advertise services, host events, and provide unique visitor experiences. Like physical land, real estate can also be rented. Therefore, investing in metaverse real estate can be profitable for key players in the architecture-engineering-construction (AEC) industry. The expected market size data for the real estate sector in the entire metaverse between 2022-2030 is shared in Figure 5.

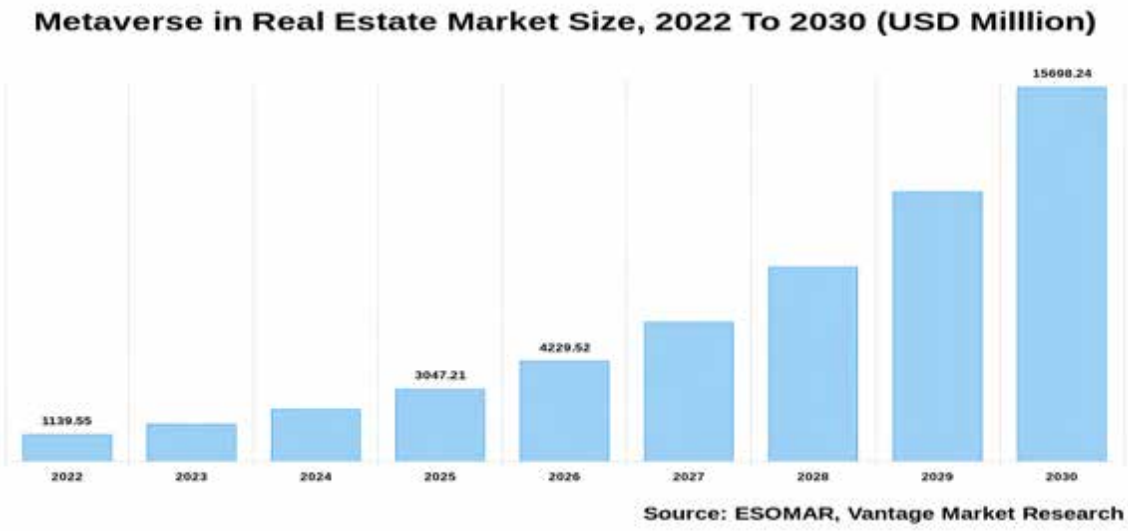

Figure 5: Expected Market Size of the Real Estate Sector in the Metaverse Between 2022-2030 (values are in millions of dollars)

The most important benefit of metaverse real estate is that it compensates for the lack of space in the physical world. For example, if an office lacks physical meeting spaces, employers can create conference rooms and event rooms in the metaverse. The metaverse also provides a seamless collaboration experience that allows people living in different parts of the world to communicate with each other. The value of location in the metaverse depends on the environmental conditions around the property rather than the travel distance (Güven & Ercan, 2022).

As a result of the literature review, it is revealed that the studies conducted mostly address urban design elements in terms of urban quality. After the process of associating these elements in the literature with strategies for increasing real estate value in urban space, urban design, regional identity, mixed uses, open spaces, building heights and appearances, spatial relationship, sustainability, visual and morphological concepts have become the most associated keywords as environmental design elements. The correlation of the keywords encountered regarding urban design/environmental design elements in the urban design literature review and the parameters suggested by Tiesdall and Adams for increasing real estate value in urban space strategies has been objectively interpreted because of the readings. Accordingly, **urban design, regional identity, mixed uses, open spaces, building heights and appearances, spatial relationship, sustainability, visual** and **morphological** concepts have become the most associated keywords as environmental design elements.

This study, which is addressed with theoretical and practical frameworks, aims to reveal which elements can determine the institutional location selection decisions of information industry companies in Türkiye on the metaverse platform and how added value can be created with urban/environmental design tools. Another aspect that makes this study unique is that it aims to reveal how environmental design elements that overlap with environmental design elements in the real (physical) world or completely different and new environmental design elements find a counterpart in the metaverse world. The research questions for this study are listed below.

Research Questions:
1- How do urban and environmental design elements affect the location selection decisions of companies and institutions operating in the Information Industry for their offices to be established in the metaverse?

2- Which urban and environmental design elements are most important for companies for the offices or facilities they will establish in the metaverse?
3- Are there other design elements that do not appear in the physical world or are not important but may affect the location selection decisions of information industry companies in the metaverse?

Methodology

The study aims to identify the factors influencing corporate site selection decisions of information industry companies in Türkiye within metaverse platforms and to explore how urban/environmental design tools can create added value. The structure of the study is concentrated on the relationship between the "metaverse and urban design" with also "real estate and urban design" through remarkable subtopics which have emerged as the key terms most frequently associated with environmental design elements such as regional identity, mixed uses, open spaces, building heights and appearances, spatial relationships, sustainability, visual and morphological concepts.

The method of this study involves an online survey application based on key elements encountered in literature review and other environmental design elements predicted in light of urban planning/urban design formation, to determine which environmental design factors influence corporate site selection decisions of information industry companies in the Metaverse.

This survey study aims to determine the general thoughts of the owners or authorized managers of companies and institutions operating in the information industry in Türkiye on institutional location selection in the metaverse environment and which environmental design elements they give importance to in location selection.

In total 26 respondents from information industry in Türkiye who represent their companies/institutions at executive level responded the online survey between December 2024 – May 2025 period. Based on the survey results, the relationships and importance evaluation of environmental design elements were conducted using correlation analysis in the SPSS software.

In the survey study, a scale application was made by selecting elements corresponding to the metaverse world from the table of corporate location selection determinants in the physical world (Figure 6) compiled from previous literature studies in Ramantswana's doctoral thesis (2019) titled "Determinants of headquarters location and site selection for companies listed on the Johannesburg Stock Exchange".

Table 2.2: Determinants/factors of location

Country	Author	Human resource (skilled labour force)	Labour costs (wage/salary/benefits)	Access to markets, customers, clients, services, and suppliers and information	Favourable sector-specific regulation	Government policies, tax and regulatory environment	Quality infrastructure (telecommunication and transport)	Political risk	Business environment	Economic incentives/favourable financial environment	Availability and cost of support services for employees housing	Same industry specialisation/ agglomeration of same sector	Location of Management/Executive

Figure 6: Determinants Affecting Location Selection Literature Review (Ramantswana, 2019)

Findings

Based on the initial findings of the pilot survey (with 26 respondents), environmental elements within the accessibility cluster have a more significant impact on the corporate site selection decisions of companies or institutions operating in the information industry compared to the urban space design elements cluster and building design cluster. It can be said that the dominance of this result is largely because the survey was conducted in Türkiye, particularly reflecting the responses of company representatives based in Istanbul. This is because Istanbul is a metropolitan city where traffic and accessibility issues are particularly pronounced. Therefore, environmental design elements within the accessibility cluster have become the most prominent criterion even when making site selection decisions in the Metaverse.

The average rating of level of knowledge about virtual/crypto investment instruments on a scale of 1: very little to 5: very much is **3.35** among the respondents whereas the level of knowledge about the concept of the Metaverse is rated **3.00** on average. Respondents are slightly more knowledgeable about crypto investment instruments compared to the Metaverse. However, the knowledge levels for both topics are around the mid-range, indicating that while there is a growing awareness, a deep understanding has not yet been achieved.

Demographic distribution of the respondents are 20 male (77%) and 6 female (23%). Among the survey participants, 14 are university graduates (55%), 8 hold a master's degree (30%), and 4 have a doctoral degree (15%). Of the institutions represented by the participants, 11 were established before the year 2000 (42%), 2 between 2000 and 2010 (8%), 7 between 2011 and 2020 (27%), and 6 after 2020 (23%). Out of these institutions 24 have a physical office as their headquarters. Additionally, half of these institutions have branch offices, while the other half are managed solely from their headquarters. Among the institutions where the survey participants work, 6 have between 1 and 10 employees (23%), 8 have between 11 and 100 (31%), 7 have between 101 and 1,000 (27%), and 5 have more than 1,000 employees (19%). The institutions with more than 1,000 employees have an extensive branch network across Türkiye. According to the 23 respondents, the average age of employees across all institutions is approximately **36.65 years**. The distribution of employees per age groups is detailed in Figure 7. Baby Boomers mostly

fall into the Lowest category (73%) with none in the Highest. Millennials (Generation Y) stand out with the highest percentages in Highest (35%) and High (38%), and no one in the Lowest category. Generation Z is more divided, with significant portions in both High (38%) and Lowest (38%) categories. This suggests a strong upward trend for Millennials compared to older generations, while Generation Z shows more polarization.

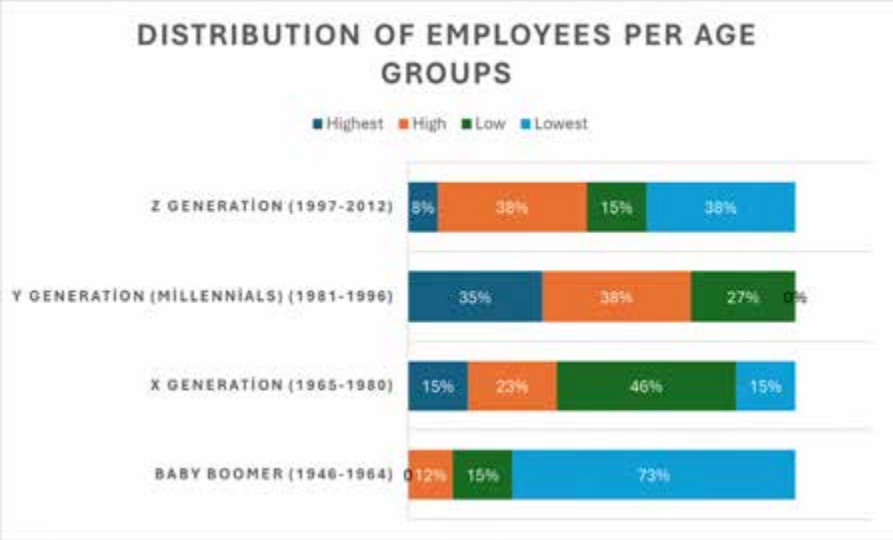

Figure 7: Distribution of Employees Per Age Groups

Institutions are nearly evenly divided between classic, independent buildings and large-scale, corporate-style plazas, with a noticeable move toward smaller or virtual spaces. This diversity reflects varying operational styles, from traditional roots to agile, modern models. Figure 8 depicts the distribution of central offices location types. Two most common office types are detached building with garden and plaza (higher than 10 floors), each with 27% - showing a split between traditional standalone buildings and modern high-rises. About 19% operate from small business centres (1–5 floors), reflecting a preference for mid-sized, cost-efficient office spaces. Virtual offices (8%) and apartments (8%) remain in the minority but still represent a shift toward flexible or unconventional setups. Only 12% are in 6–10 floor business centres, suggesting these are less favoured, possibly due to cost or practicality.

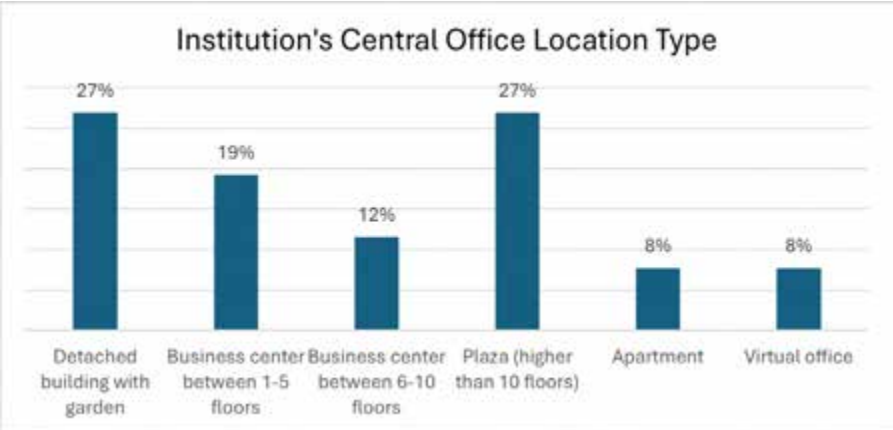

Figure 8: Distribution of Institution's Central Office Location Type

The respondents were asked to rate the importance of various environmental elements that affect the location selection of their current institution's physical head office under three main categories: accessibility factors, elements of urban space design, and elements of building design. Figure 9 provides the rating of each factor with a heat-map analysis.

Group Name	Environmental Element	Rating				
		1	2	3	4	5
Accessibility	Ease of access by public transportation	8%	0%	23%	31%	38%
	Ease of access by private vehicle	4%	4%	15%	31%	46%
	Access to parking	4%	4%	8%	15%	69%
	Access to recreational areas (urban green areas, parks, etc.)	8%	15%	31%	19%	27%
	Access to food and beverage facilities	4%	4%	31%	38%	23%
	Proximity to customer offices/locations	12%	8%	23%	46%	12%
	Access to public areas (squares, streets, etc.)	15%	12%	38%	23%	12%
	Affordability of rental costs	4%	4%	23%	42%	27%
	Located in a prestigious area of the city	8%	8%	12%	42%	31%
Elements of Urban Space Design	Livability and liveliness	4%	8%	23%	38%	27%
	Safe spaces	0%	12%	4%	35%	50%
	Diversity and flexibility	4%	8%	19%	50%	19%
	Density (people, vehicles, structural density)	8%	8%	19%	38%	27%
	Urban furniture (benches, street lighting, stops, waste collection units, flower pots, etc.)	23%	4%	27%	27%	19%
	Urban art (sculptures, murals, performing arts, etc.)	31%	0%	38%	15%	15%
	Necessary-sufficient office space size	4%	4%	4%	58%	31%
Elements of Building Design	Building - environment - street relationship	8%	4%	23%	42%	23%
	Urban form and building type	8%	8%	12%	38%	35%
	Space scale	4%	4%	15%	38%	38%
	Natural light and ventilation	4%	4%	19%	23%	50%
	Architectural identity and details	19%	0%	15%	31%	35%
	Material (types of materials used in the building)	12%	0%	12%	38%	38%

Figure 9: Current Office Location Selection Environmental Factors Heat Map

Figure 10 shows the distribution of ratings for each element affecting respondents' current office location selection. Institutions prioritize **functionality, safety, and accessibility**, especially for accessibility. While aesthetics and design quality are appreciated, decorative urban elements like public art rank lower. The findings reflect a preference for **practical, secure, and well-designed spaces** that support comfort and efficiency. **Access to parking** (69%) and **ease of access by private vehicle** (46%) are highly valued, showing the strong importance of car-friendly environments. **Safe spaces** (50%) and **natural light & ventilation** (50%) are also top priorities, emphasizing **safety and healthy work environments**. **Sufficient office space** (31% rated 5, 58% rated 4) stands out as a critical functional need. Architectural identity and building materials both receive 35%–38% 5-star ratings, suggesting **aesthetic and construction quality matter**. On the other hand, **urban art** (31% rated it only 1) and **urban furniture** scored lower, indicating these elements are **less critical** in office location or building evaluations. **Proximity to customer offices** and **access to public areas** are considered **less decisive**, possibly due to remote work trends.

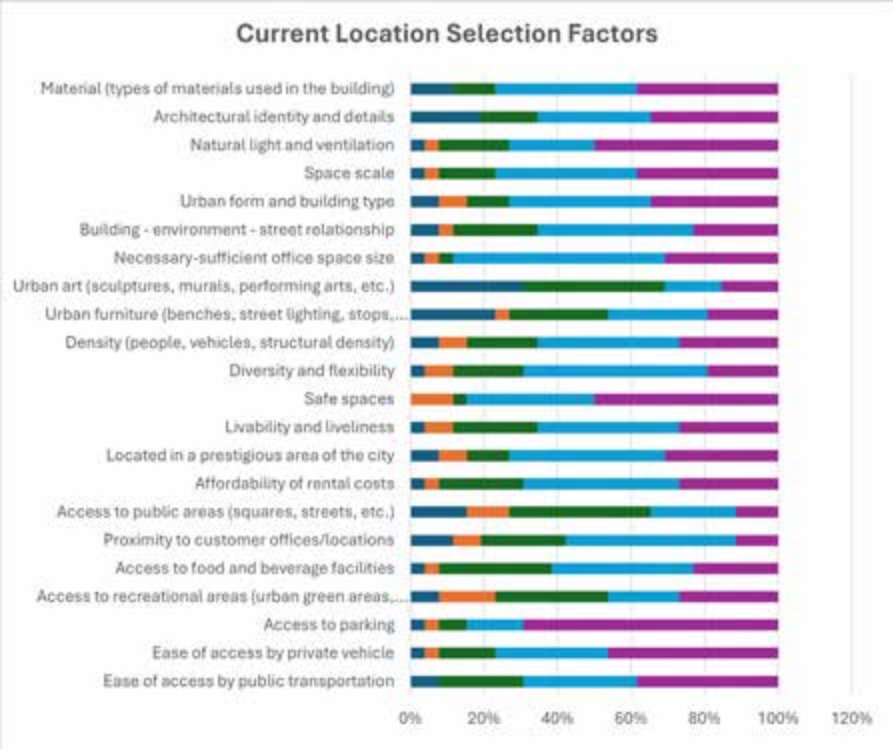

Figure 10: Distribution of Ratings for Each Element Affecting Respondents' Current Office Location Selection

Correlation analysis of ratings for each element affecting respondents' current office location selection is depicted in Figure 11. There is an **exceptionally strong correlation (0.99)** indicating that respondents ranking areas with better **access to public transportation** often also rank better **natural light and ventilation**. There is a very high correlation **(0.97)** between **access by private vehicle** and **natural light and ventilation**. The high correlation between **access by private vehicle** and **access by public transportation (0.95)** shows that areas with good access to one type of transportation often have similar importance to the other. This might point to areas that are centrally located or well-connected, where urban planners ensure that both private and public transportation options are available to accommodate various needs. A very high correlation between **building-environment relationship** and **natural light and ventilation (0.94)** suggests that buildings designed to complement their surroundings tend to also benefit from optimal natural light and airflow. This likely indicates that spaces with a strong connection between the building and its environment are intentionally designed to maximize comfort, taking advantage of environmental factors like sunlight and breeze. The strong correlation between **access to parking** and **ease of access by private vehicle (0.89)** suggests that locations with better access to private vehicles tend to have more parking available. The positive correlation between **urban art** and **architectural identity (0.85)** indicates that places with a stronger architectural identity often include significant artistic elements, such as sculptures or murals. This is because both urban art and architectural details contribute to the overall aesthetic and cultural richness of an area, and they are often planned together as part of a cohesive urban design strategy. **Urban art** contributes positively to **liveability** and **liveliness (0.72)**, suggesting that spaces with more urban art tend to be considered more vibrant and liveable.

These observations illustrate the strong interconnections between various design elements and their impact on accessibility, environmental quality, and the overall urban experience. For instance, **transportation access** (both public and private) is strongly linked to **natural light** and **ventilation**, while the **relationship between buildings and their environment** has a notable influence on both aesthetic and functional qualities. Similarly, the presence

of **urban art** often enhances **liveability**, suggesting a clear link between creative urban design and the vibrancy of a space.

Under virtual working experience section of the survey, majority of the respondents (81%, n: 20) confirmed that their organization have a remote (virtual/hybrid) working principle in place. Naturally, the year 2020 shows a spike of remote work implementation year due to COVID-19 restrictions experienced (Figure 12).

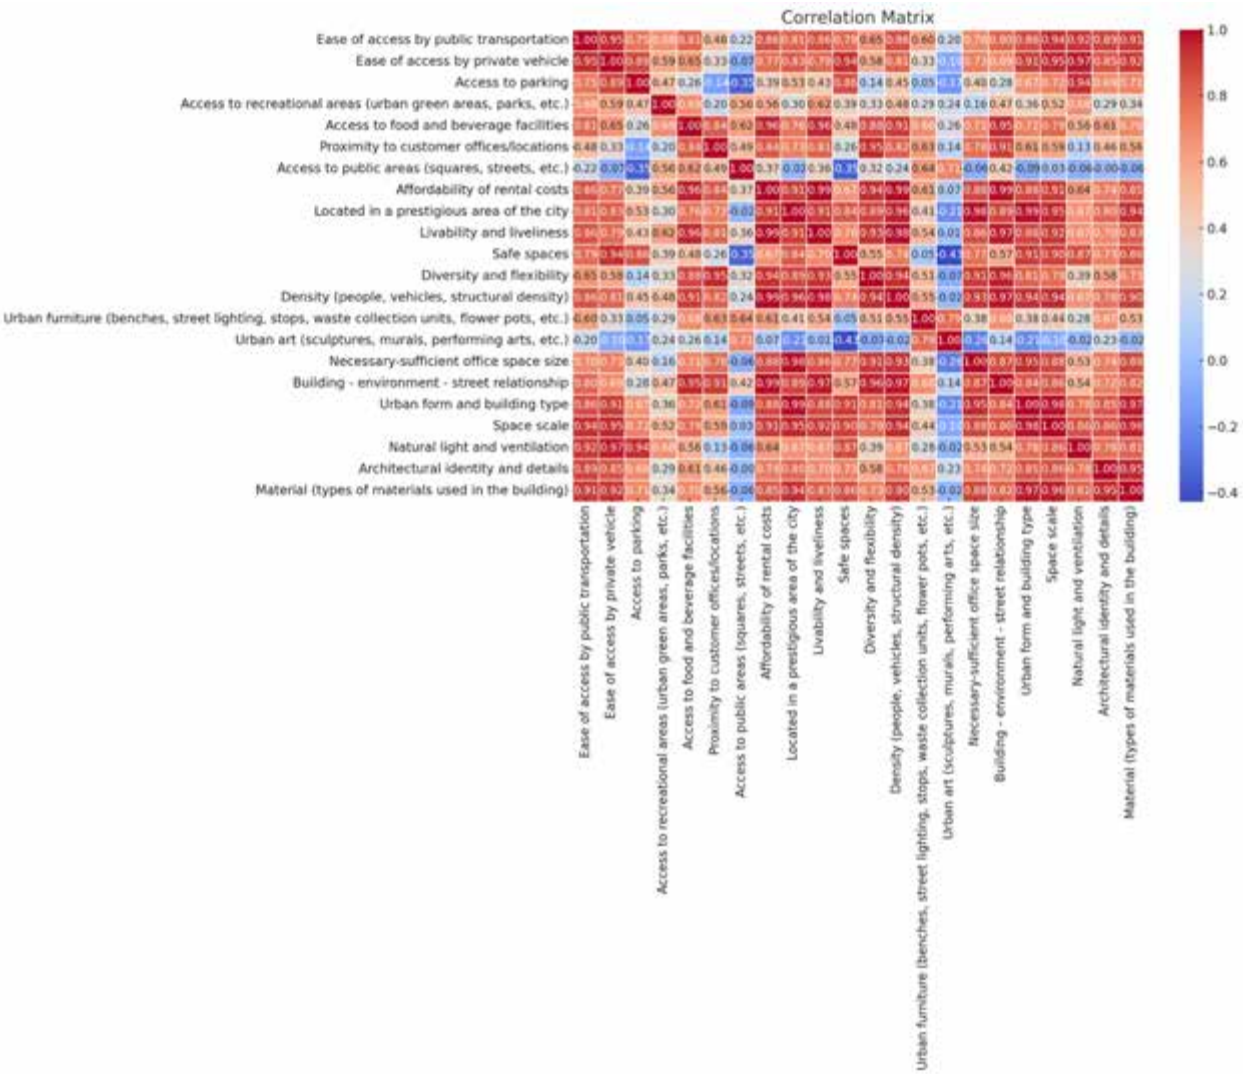

Figure 11: Correlation Analysis of Ratings for Each Element affecting Respondents' Current Office Location Selection

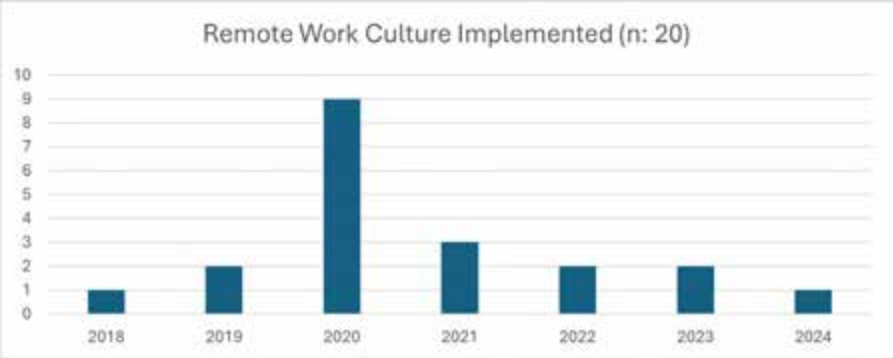

Figure 12: Remote/Hybrid Work Culture Implementation Year

Continuously, hybrid/remote work has been widely accepted among the information industry institutions. The dominant hybrid working trend is **2–3 days in the office**, often combined with **employee autonomy**. Organizations are clearly leaning toward **flexible**, **balanced setups** that maintain both collaboration and remote work benefits. Most common model preferred is 2 days a week (8 responses) suggesting a balanced hybrid approach (Figure 13).

Figure 13: Employee Office Days

There is general awareness and growing concern about the future of work, but not yet a fully mature or widespread focus. The **average rating of 3.65** indicates a moderately high level of interest and awareness regarding **future working conditions**. While it is not at the maximum, the score suggests that most respondents recognize the importance of evolving work models as this is strongly supported by 96% of the respondents that they plan to integrate new technologies into their working conditions in the future but there may still be room for deeper engagement or knowledge development. Rating of adapting technologies is shown in Figure 14 as a heat map and in Figure 15 with distribution.

	Rating				
	1	2	3	4	5
Virtual office work and meeting platforms (Microsoft Teams, Zoom, etc.)	4%	0%	12%	31%	54%
Virtual reality / augmented reality glasses	23%	8%	35%	23%	12%
Digital twin office (digital twin of your current office)	12%	15%	42%	19%	12%
Metaverse office	15%	15%	42%	12%	15%

Figure 14: Rating Heat Map of Adapting Technologies

The data indicate that traditional virtual meeting platforms like Microsoft Teams and Zoom are highly favoured, with most respondents giving top ratings. Emerging technologies such as virtual reality (VR)/augmented reality (AR) glasses, digital twin offices, and metaverse offices receive more mixed and moderate ratings, reflecting uncertainty and varying acceptance levels. This suggests that while virtual meeting tools are well-established and widely accepted, newer immersive technologies are still in the early stages of adoption and evaluation.

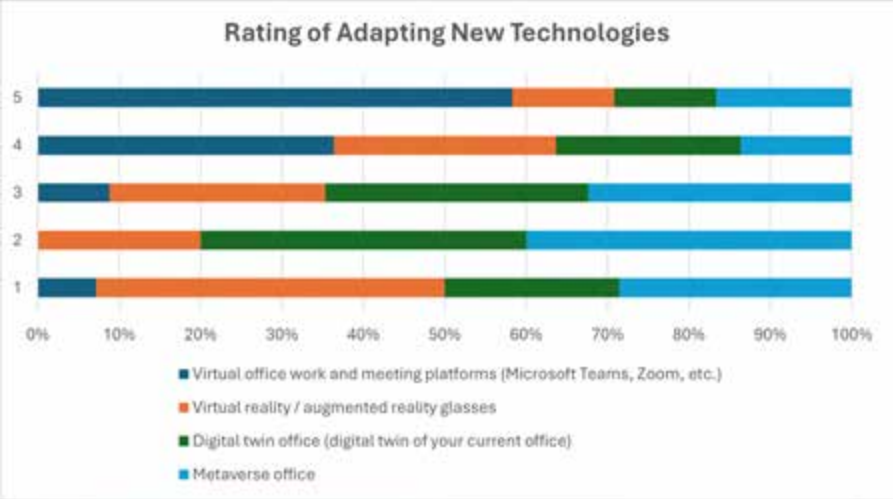

Figure 15: Rating Distribution of Adapting Technologies

Correlation matrix for adapting various technologies is shown in Figure 16. There is a slightly negative correlation between **virtual office work platforms** (such as Microsoft Teams and Zoom) and **virtual reality/augmented reality glasses (-0.19)**. This suggests that these two technologies are somewhat independent in usage, with some users favouring traditional virtual meeting platforms, while others may prefer immersive technologies like AR/VR. Also, there is a slightly negative correlation between **virtual office platforms** and **digital twin offices (-0.22)**. This could suggest that people who prefer traditional virtual office platforms may not be as interested in digital twin technology, which is a more advanced and immersive concept. As with the previous observation, the negative value is small, showing only a weak association. Similarly, there is a slightly negative correlation with **virtual office platforms** and **metaverse offices (-0.24)**. The metaverse office is a more futuristic concept, so it might appeal to different user segments compared to more established platforms like Microsoft Teams and Zoom. A strong positive correlation exists between **virtual reality/augmented reality glasses** and **digital twin offices (0.78)**. This suggests that users who engage with AR/VR technologies are likely to also be interested in digital twin offices. Both technologies share immersive, 3D modelling characteristics, and this correlation indicates that users interested in one may also gravitate toward the other. There is a strong positive correlation between **AR/VR glasses** and **metaverse offices (0.71)**. This makes sense because both involve immersive virtual environments. Users who engage with AR/VR technology are more likely to be interested in virtual worlds like the metaverse, which are designed to provide rich, interactive, and 3D virtual experiences. The very strong positive correlation between **digital twin offices** and **metaverse offices (0.93)** suggests that these two concepts are closely linked. Both are cutting-edge virtual environments, and users interested in digital twin technology (which replicates real-world offices in a digital format) are also highly likely to be interested in metaverse offices (virtual workspaces that provide immersive experiences). This indicates a shared interest in next-generation virtual environments. The correlation matrix shows that the virtual office work and meeting platforms have weak negative correlations with the more advanced technologies (AR/VR glasses, digital twin offices, and metaverse offices). These technologies, while related to the digital workplace, represent different levels of immersion and technological advancement. In contrast, **virtual reality/augmented reality glasses**, **digital twin offices**, and **metaverse offices** show strong positive correlations with each other, signalling a shared trend toward more immersive and futuristic work environments.

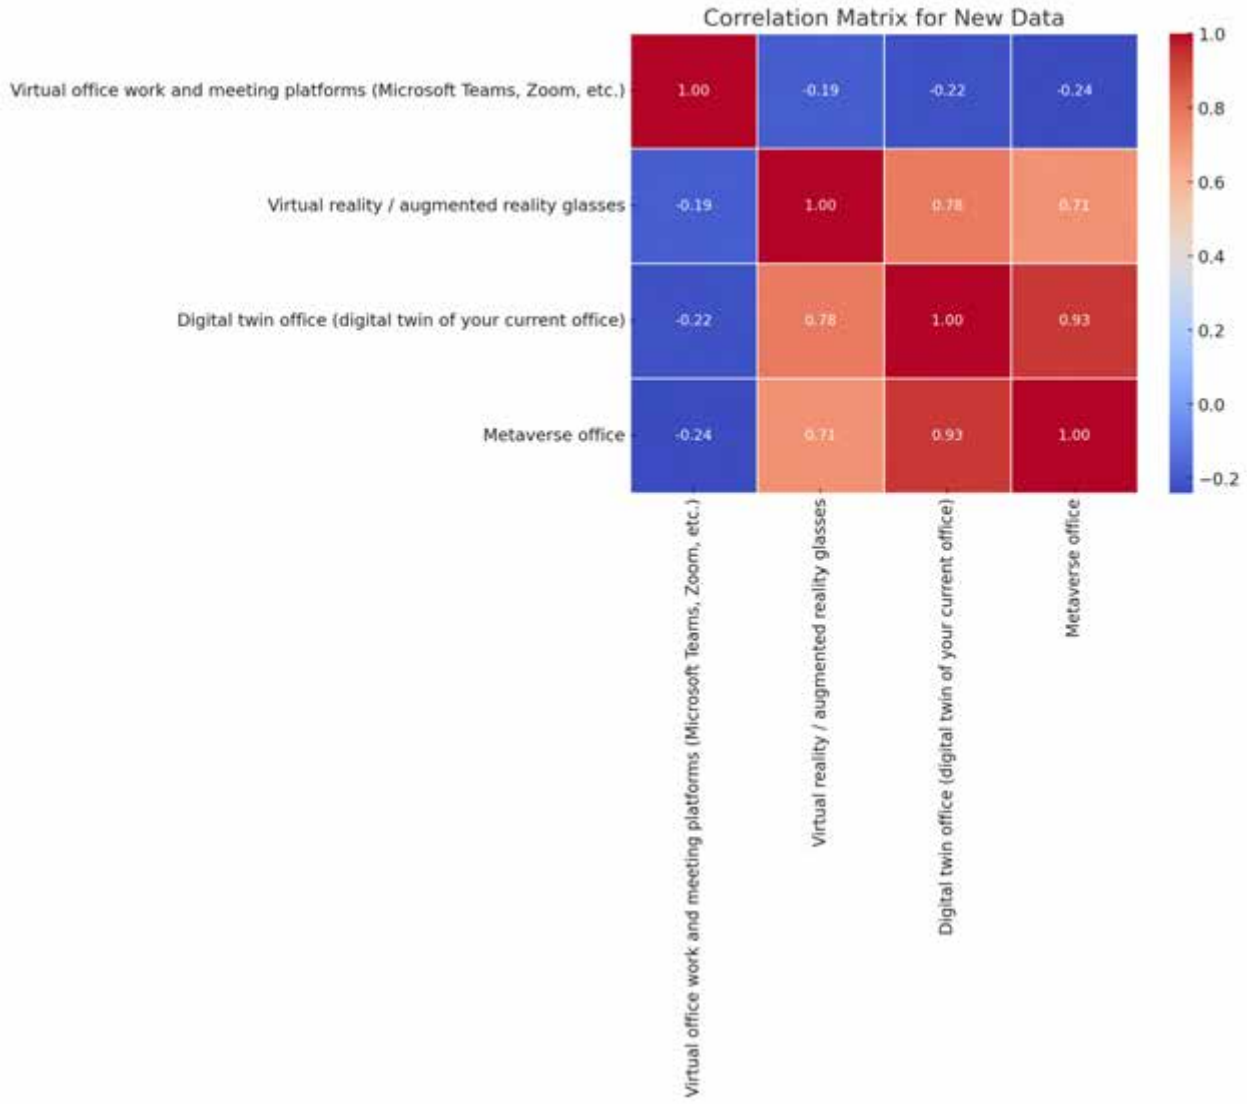

Figure 16: Correlation Matrix for Adapting Various Technologies

While understanding the virtual real estate investment details of the respondents, great majority (88%) responded that they have not invested in this area yet. The rest (12%) have invested in that area individually. No response is received regarding investment on virtual real estate on institutional level. On the other hand, 19% indicated that they plan to create an office in the metaverse environment for their institution. This highlights that there is a slight room for institutional metaverse office development opportunity with the existing trend. When analysing further to better understand the room size, respondents were asked in how many years they were planning to create an office in the metaverse (Figure 17). While majority just like their virtual real estate investment trend are not planning to create an office in the metaverse yet, about 16% aims to create metaverse office in the long term (8 years and beyond). In contrary, 20% of the respondents are supporting creation of metaverse office for their institution with the next 5 years. This situation sheds light on the fact that there will be a tendency to adapt to the metaverse concept over time.

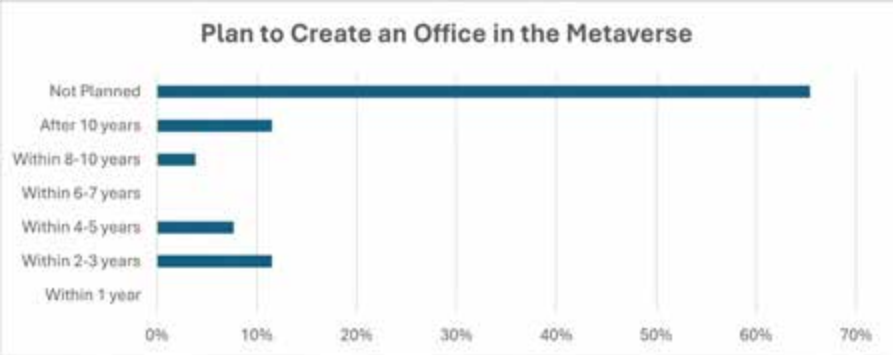

Figure 17: Respondents Tendency to Create an Office in the Metaverse

When asked how much they would invest to create a metaverse office, 21 out of 26 respondents who participated in the survey were reluctant to invest, while 60% of the respondents who found it appropriate to invest in metaverse office levelled the value at 20,000 USD.

Considering an office that can be created in the metaverse environment, the building where the office is located and the immediate surroundings of this building, respondents were requested to rate all of the elements shown in Figure 18.

	Rating				
	1	2	3	4	5
Ages and requirements of current employees	0%	12%	8%	50%	31%
Ages and requirements of new employees joining your organization	0%	12%	0%	54%	35%
Increasing employee experience	0%	4%	8%	54%	35%
Access to a talented workforce	0%	8%	4%	54%	35%
Inter-organizational competition	4%	8%	15%	42%	31%
Access to new markets	4%	12%	4%	35%	46%
Political risks	8%	8%	23%	35%	27%
Creating in-house events	8%	4%	12%	46%	31%
Locating in a prestigious area of the city	15%	8%	8%	38%	31%
Location costs	4%	8%	12%	35%	42%
Necessary-sufficient space size	4%	8%	15%	46%	27%
Time savings due to elimination of transportation (traffic-free)	4%	4%	0%	42%	0.5
Changeable/adaptable interior (architectural) design experience	4%	0%	15%	54%	27%
Changeable/adaptable exterior (urban) design experience	4%	0%	15%	54%	27%
Savings in operational (OPEX) and capital (CAPEX) investments	0%	4%	8%	27%	62%

Figure 18: Rating Heat Map of Elements Affecting Metaverse Office Creation

62% of respondents rated **savings in OPEX & CAPEX** as a top priority (5) - the highest among all factors. **Location costs** also received strong importance with **42%** scoring it 5. For both **current and new employees**, over **85%** rated **ages and requirements** at **level 4 or 5**, indicating a high focus on aligning workplace dynamics with workforce demographics. **Access to talented workforce** and **employee experience** both saw **89%** rating them as important to very important. **Changeable/adaptable architectural and urban designs** are valued, with **over 80%** rating these elements as 4 or 5, highlighting a demand for **agility and adaptability in workspace design**. Surprisingly, **time savings due to elimination of transportation** had very low importance (only 0.5% rated it 5). This suggests organizations may **undervalue the benefits of commute-free options**, possibly due to hybrid or on-site work preferences. 46% rated **access to new markets** as top priority, making it one of the most decisive external factors influencing organizational decisions. Cost and Efficiency are top priorities, workforce and talent are central concerns, flexible design matters, timesaving through reduced commute is overlooked, and market expansion is a key strategic driver. Figure 19 shows the rating distribution of elements in an office created in the metaverse.

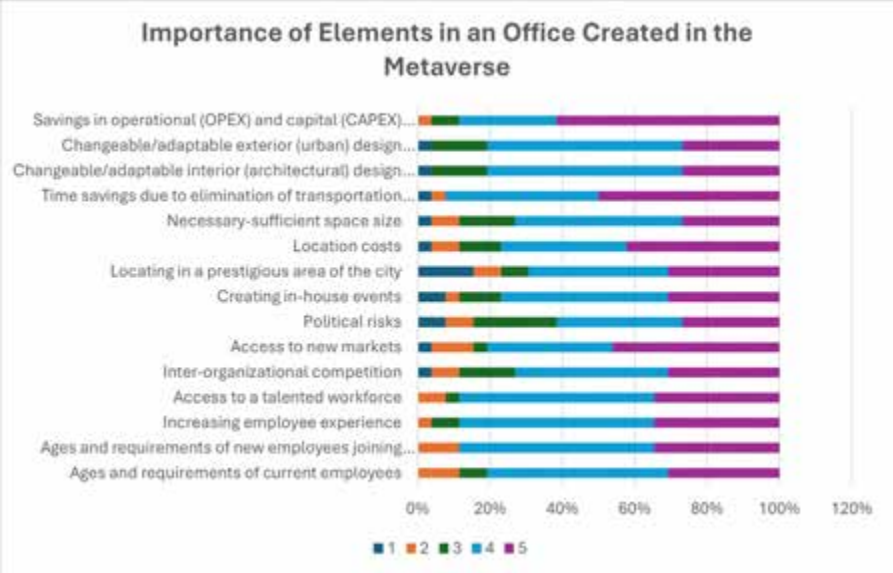

Figure 19: Rating Distribution of Elements in an Office Created in the Metaverse

Figure 20 details the correlation analysis of elements in an office created in the metaverse. There is an extremely strong positive correlation between **the ages and requirements of current employees and new employees joining the organization (0.99)**. This suggests that the age profiles and needs of new employees are very similar to those of current employees, indicating that the organization might be attracting employees with similar needs and characteristics. Similarly, **age and requirements of employees** are strongly linked to efforts in **increasing employee experience (0.99)**. This implies that understanding the demographic and professional needs of employees can play a critical role in improving their overall experience in the organization. There is also a very strong correlation between **ages and requirements of current employees and access to a talented workforce (0.99)**. The strong correlation here suggests that as the **age and requirements of employees** This could indicate that organizations are able to attract talent that aligns well with their current employee base and requirements. A very strong correlation exists between **increasing employee experience** and **access to a talented workforce (0.99)**, indicating that efforts to improve the employee experience are often associated with a higher ability to access top talent. A high correlation suggests that organizations focused on **improving employee experience** are also likely to be actively engaging in **inter-organizational competition (0.99)**. The drive to enhance the employee experience may be a strategic effort to stay competitive in a crowded market for talent. **Political risks** show a moderate correlation with **inter-organizational competition (0.85)**, indicating that the external political environment can have an impact on how organizations position themselves competitively. The moderate positive correlation **(0.72)** suggests that organizations engaged in **inter-organizational competition** may also be more likely to focus on **savings in operational (OPEX) and capital (CAPEX) investments**. This implies that staying competitive may drive organizations to optimize their costs and make more efficient investments.

Figure 21 evaluates how respondents value various urban space and architectural factors on a 1 to 5 importance scale. The most highly rated factor is **necessary-sufficient office space size** with **65%** marking it as level 4 and **19%** as level 5 — showing a clear priority on **having the right amount of space**. **Location costs** also remain a top concern (81% rating it 4 or 5), confirming **cost-efficiency** as a major driver, as seen in the previous table. **Safe spaces** scored very high, with **73%** of responses at levels 4 and 5. Safety continues to be a **non-negotiable baseline for workplace liveability**. **Liveability and liveliness** received mixed responses, with only 23% rating it as top importance, suggesting that **vibrancy** is seen as nice-to-have, not essential. Factors like **urban form, architectural identity,** and **building–environment–street relationship** scored fairly strong (50–65% at levels 4 or 5), indicating an appreciation for cohesive urban and architectural design, though not as pressing as cost or safety. Overall, there is a consistent emphasis on functional and contextual elements of office location and design, especially those tied to comfort, cost, and prestige.

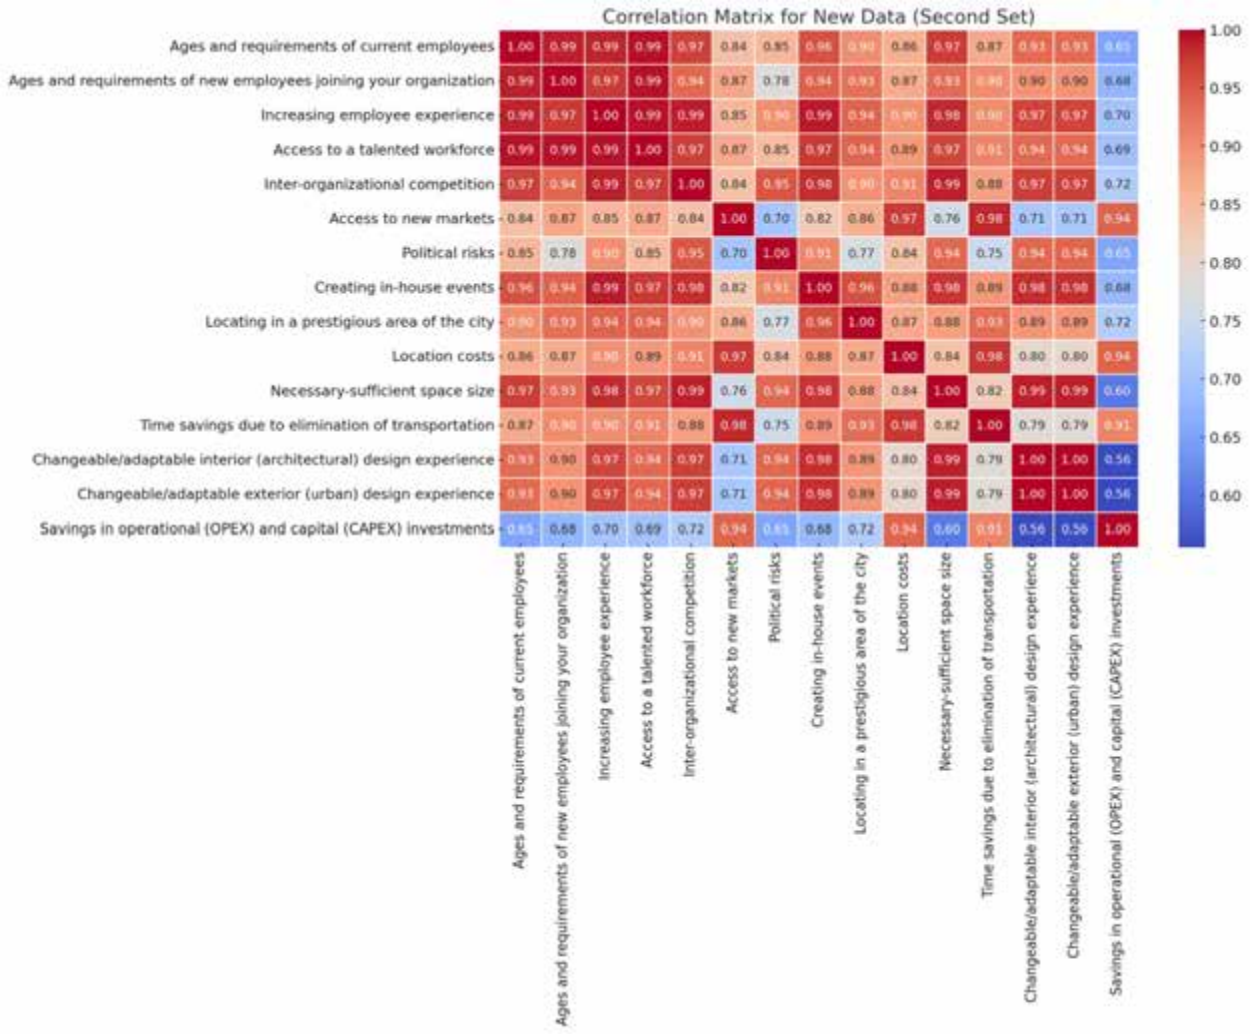

Figure 20: Correlation Matrix of Elements in an Office Created in the Metaverse

		Rating				
		1	2	3	4	5
Elements of Urban Space Design	Livability and liveliness	15%	4%	12%	46%	23%
	Safe spaces	12%	4%	12%	38%	35%
	Diversity and flexibility	12%	4%	19%	46%	19%
	Located in a prestigious area of the city	12%	0%	15%	31%	42%
	Necessary-sufficient office space size	4%	4%	8%	65%	19%
	Location costs	4%	4%	12%	46%	35%
	Density (people, vehicles, structural density)	8%	0%	19%	58%	15%
	Urban furniture (benches, street lighting, bus stops, waste collection units, flower pots, etc.)	12%	8%	23%	50%	8%
	Urban art (sculptures, murals, performing arts, etc.)	23%	4%	19%	42%	12%
Elements of Building Design	Building - environment - street relationship	12%	8%	19%	35%	27%
	Urban form and building type	12%	8%	15%	46%	19%
	Space scale	8%	4%	15%	54%	19%
	Natural light and ventilation	15%	12%	12%	46%	15%
	Architectural identity and details	8%	19%	8%	38%	27%
	Material (types of materials used in the building)	12%	8%	15%	50%	15%

Figure 21: Rating Heat Map of Urban Space and Building Design Elements

Figure 22 shows the distribution of urban space and building design elements influencing motivation of office selection in the metaverse ratings. Companies/institutions are prioritizing space efficiency, safety, and cost-ef-

fectiveness over aesthetic or cultural features of urban environments. While design cohesion and architectural quality are appreciated, factors like public art and urban furniture are seen as luxuries rather than necessities. The high importance given to prestigious location reveals a continued reliance on brand signalling and status value in workplace positioning.

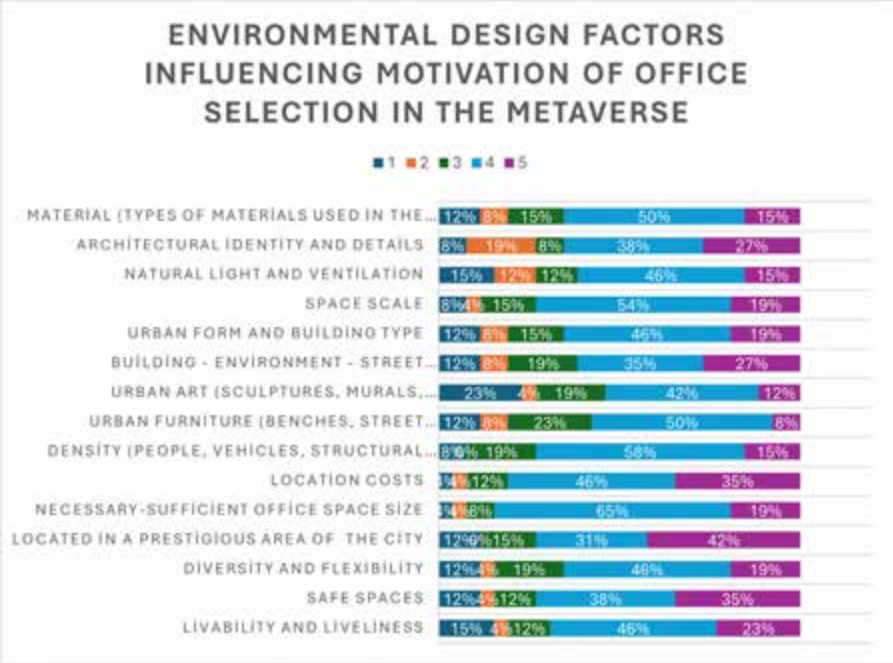

Figure 22: Environmental Design Factors Influencing Motivation of Office Selection in the Metaverse

Figure 23 depicts the correlation matrix regarding environmental design factors influencing motivation of office selection in the metaverse. The almost perfect correlation between **space scale** and **office space size (0.99)** highlights that larger office spaces tend to have a more expansive layout, offering employees more room to move, work, and collaborate. There is a very strong correlation between **natural light and ventilation** and **office space size (0.98)**. Larger office spaces tend to be designed with better natural lighting and airflow, contributing to a healthier and more comfortable work environment. The strong correlation between **urban furniture** and **density (0.97)** suggests that in densely populated areas, there is a greater need for urban furniture such as benches, street lighting, and bus stops. The high correlation between **liveability and liveliness** and **diversity and flexibility (0.96)** indicates that areas with a more diverse and flexible environment are perceived as more liveable and lively. There is a very high correlation between **diversity and flexibility** and **office space size (0.96)**. This is likely because flexible spaces require more room to accommodate different types of work styles and activities, offering employees the freedom to choose their work environment. **Urban art** contributes significantly to the **liveability and liveliness** of an area **(0.94)**. The correlation suggests that areas with more art installations (e.g. murals, sculptures) are perceived as more vibrant and engaging, enhancing the overall quality of life in urban environments. The strong correlation between **safe spaces** and **location in a prestigious area** (0.93) suggests that people tend to feel safer in prestigious areas. This could be due to better infrastructure, more surveillance, and generally lower crime rates in such locations. This relationship highlights how security and location prestige are interconnected in urban planning.

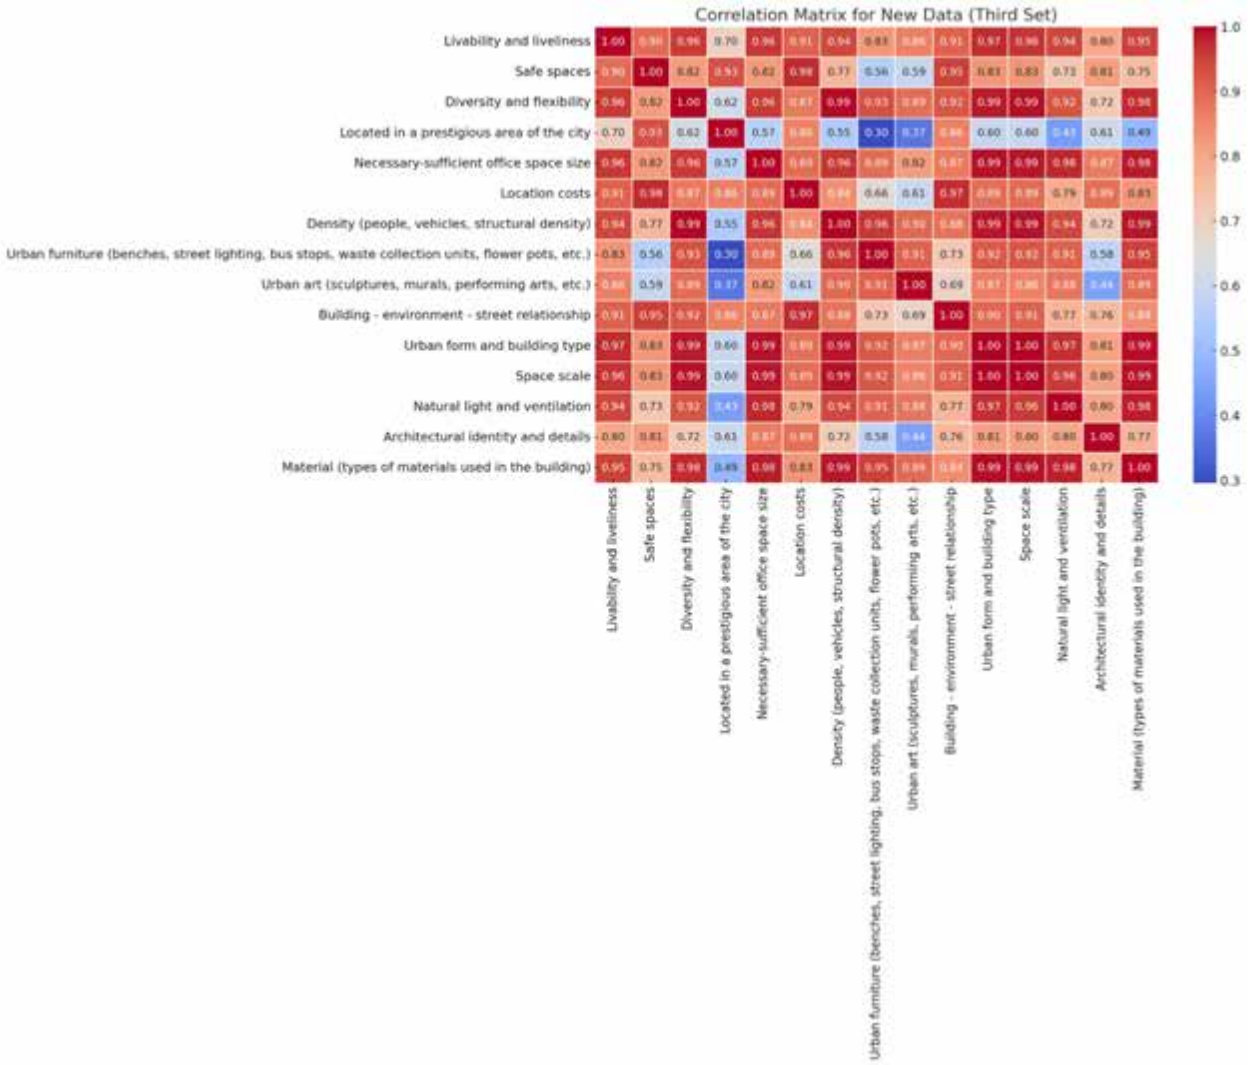

Figure 23: Correlation Matrix Regarding Environmental Design Factors Influencing Motivation of Office Selection in the Metaverse

Discussion and Conclusion

This study aimed to connect established theoretical frameworks of environmental and urban design with the evolving practice of corporate site selection within metaverse environments, with a particular focus on Türkiye's information industry. By aligning empirical findings with insights from existing literature, this research provides a valuable foundation for identifying and understanding the environmental design elements most likely to influence the creation of effective and engaging future metaverse workspaces.

The literature review highlighted key environmental and urban design elements traditionally associated with high-quality urban environments and value creation in real estate. When comparing these well-established concepts to the findings of this study, several noteworthy parallels and divergences emerge:

• **Accessibility** remains a fundamental concern in both the physical and virtual domains. In the survey, access to talented workforce, location costs, and flexibility in architectural/urban design were among the most influential factors shaping metaverse office selection. Similarly, in physical environments, accessibility and location quality are core drivers of real estate value and user satisfaction.

• **Safety** and **comfort-related elements** such as safe spaces and natural light & ventilation scored highly in both current office and metaverse-oriented responses. This suggests that even in virtual environments, companies value perceptions of security and comfort, mirroring psychological needs that underpin design principles in the physical world.

• **Architectural identity**, **building-environment-street relationship**, and **spatial relationships**—elements frequently emphasized in physical urban design frameworks—also emerged as relevant in metaverse considerations. Respondents valued cohesive, adaptable, and visually engaging virtual environments, signalling a continued importance of spatial and aesthetic coherence even when freed from physical constraints.

• **Diversity and flexibility**, a recurring theme in physical urban design literature (mixed-use spaces, flexible environments), was highly correlated with perceptions of liveability and employee experience in metaverse environments. This underscores the necessity of creating adaptable virtual spaces that cater to varied organizational needs and dynamic user preferences.

Conversely, several differences between the two domains were apparent:

• While **public art** and **urban furniture** are traditionally seen as important contributors to public life and identity in physical spaces, they were deprioritized in metaverse site selection. Respondents generally rated these elements lower in importance for virtual offices, possibly reflecting the current lack of mature design standards for virtual public realms and a stronger focus on functional and operational drivers at this stage of metaverse evolution.

• **Time savings from eliminating transportation**, a frequently cited benefit of remote and virtual work, was surprisingly undervalued by respondents. This indicates that while the metaverse reduces physical commute needs, organizations may still prioritize in-office experiences or hybrid models, diminishing the perceived importance of this particular advantage.

• The metaverse introduced new, distinct drivers of site selection not directly paralleled in traditional urban design literature. These include **OPEX & CAPEX savings** and **access to new markets**, both of which scored highly in respondent ratings. The virtual realm enables cost efficiencies and global market reach that are difficult to achieve in purely physical settings, marking a strategic shift in corporate priorities.

The **correlation analyses** further revealed critical interdependencies:

• Strong correlations between **employee experience**, **workforce access**, and **spatial/architectural flexibility** suggest that organizations view virtual office design as a key lever for talent attraction and retention—an emerging theme that aligns with evolving workforce expectations for hybrid and flexible work environments.

• The nearly perfect correlation between **space scale** and **necessary-sufficient office space size** highlights a persistent emphasis on spatial adequacy and comfort, even in virtual settings where physical limitations are less constraining.

• The close relationship between **urban form**, **architectural identity**, and **prestigious location** in metaverse decisions mirrors the symbolic and branding roles of corporate real estate in physical cities, demonstrating that virtual offices must similarly contribute to organizational image and culture.

This study has several limitations that must be acknowledged. First, it was conducted with a relatively small sample of 26 executive-level respondents, all from the information industry in Türkiye. The results, while indicative, cannot yet be generalized across different industries or geographies. Additionally, participants' varying levels of familiarity with the metaverse may have influenced their responses, particularly in relation to more advanced

technologies and design elements. Future studies should aim to expand the respondent pool to include a broader and more diverse set of industries and international contexts.

In conclusion, this research provides early evidence that **environmental design elements remain highly relevant in corporate site selection for metaverse offices**, but with important adaptations:

• **Accessibility**, **safety**, **architectural identity**, **spatial coherence**, and **employee experience** emerge as key priorities, paralleling traditional urban design concerns.

• **Cost efficiency** and **market access** are elevated drivers in metaverse contexts, reflecting new strategic opportunities offered by virtual environments.

• Elements tied to traditional public space design (urban art, furniture) currently play a lesser role but may gain relevance as virtual public realms evolve.

An important outcome of this study is the identification of a core set of environmental design elements that companies value when considering future metaverse office investments. Specifically, **flexible architectural/urban designs, natural light & ventilation, safe spaces, space adequacy, location costs, and workforce-related factors** are poised to be the most influential in shaping corporate location strategies in the metaverse.

Looking ahead, the next stage of this research will involve developing a **metaverse-based test environment** that simulates these identified environmental design elements. Companies will be invited to experience and interact with this environment, followed by a **post-survey study** to capture new insights and validate the practical relevance of these design factors. This iterative process aims to refine both academic understanding and practical design guidelines for building effective and engaging corporate spaces in the evolving metaverse landscape.

Abstract
Positive Energy Districts (PEDs) are urban areas strategically designed to reduce climate impact and promote sustainability by maximizing renewable energy use and optimizing energy consumption. Aligned with the European Strategic Energy Technology (SET) Plan, the aim is to establish 100 PEDs by 2025. This study utilized the Best-Worst Method (BWM) from Multi-Criteria Decision-Making (MCDM) techniques to assess criteria influencing PED boundaries. It also evaluated the effects of two-dimensional (2D) and three-dimensional (3D) data analyses on these boundaries. The findings suggest that combining 2D and 3D data yields more comprehensive results, with 3D data enhancing assessments of solar and wind energy. Regions with access to clean energy and favorable climate are ideal for PEDs, particularly where socio-economic status and education levels are high.

1. Introduction

Positive Energy Districts (PEDs) are urban areas designed to minimize climate impact and promote sustainability by maximizing the use of renewable energy sources and optimizing energy consumption (RISE, 2025). The concept of PEDs emerged to facilitate the energy transition and contribute to climate neutrality through enhanced energy efficiency and achieving a net-zero energy balance (Derkenbaeva et al., 2021). After extensive discussions with stakeholders, including cities and urban actors, the PED Programme developed a Reference Framework. According to this framework," Positive Energy Districts are energy-efficient and energy-flexible urban areas or groups of connected buildings which produce net zero greenhouse gas emissions and actively manage an annual local or regional surplus production of renewable energy. They require integration of different systems and infrastructures and interaction between buildings, the users and the regional energy, mobility and ICT systems, while securing the energy supply and a good life for all in line with social, economic and environmental sustainability." (JPI Urban Europe, 2025).

The action plan titled "Smart Cities and Communities" developed as part of the European Strategic Energy Technology (SET) Plan, aims to facilitate the planning, establishment, and replication of 100 PEDs for sustainable urbanization by 2025 (SET Plan Action 3.2). In this context, several European Union-supported projects, such as MAKING-CITY, CitxChange, POCITYF, and PED4ALL, have played a significant role in achieving this goal. This study is also conducted under the PROPEL project, which is one of the initiatives supported by the European Union (MAKING-CITY, 2025; CityxChange,2025; POCITYF,2025; PED4ALL, 2025; PROPEL, 2025).

Significant distinctions exist among regions concerning their renewable energy landscapes, encompassing factors such as the availability of renewable energy sources, energy storage potential, population demographics, energy consumption patterns, costs, and regulatory frameworks. These elements collectively influence the design and operation of PEDs, resulting in unique characteristics for each district (Lindholm et al., 2021). In the process of identifying suitable areas for PEDs, a comprehensive analysis is conducted that considers various critical factors. These factors include the potential for solar energy, the options for district heating and cooling, the availability of wind and geothermal energy, and the density of the population in the region. Additionally, the local context regarding renewable energy source potential and the geographic location, along with related mobility considerations, are essential. Future environmental projections, particularly regarding carbon-free energy demand and supply, are also evaluated. Furthermore, financial assessments, renewal strategies, dynamics within energy communities, welfare and security implications, and marketing considerations play crucial roles in this planning process (Civiero et al., 2021; Zhang et al., 2021; Schneider et al., 2023). Research aimed at determining optimal PED locations often employs a flexible, Geographic Information Systems (GIS) - based Multi-Criteria Decision Analysis (MCDA) approach. This methodology is effective in identifying the most suitable areas for achieving an annual positive non-renewable energy balance. MCDA is instrumental in emphasizing the critical criteria influenc-

ing potential locations for positive energy outcomes, while GIS enhances the accuracy and comprehensiveness of the results obtained (Alpagut et al., 2021).

This study aimed to identify the criteria that influence the boundaries of the PED and to establish their respective weights and importance rankings utilizing the Best-Worst Method (BWM), a Multi-Criteria Decision Making (MCDM) approach. The contributions of both two-dimensional (2D) and three-dimensional (3D) data and analyses to the mapping of the PED boundaries were examined through comprehensive analyses. The novelty of this study is derived from a comparative assessment of results obtained through both 2D and 3D analyses. Additionally, it includes a comprehensive 3D evaluation of the potential of renewable energy sources about PED. The findings were assessed from both environmental and social perspectives, resulting in the successful conclusion of the study.

2. Data and Methodology

2.1 Study area

This study focuses on the Kadıköy district of İstanbul, Türkiye, as illustrated in Figure 1. Kadıköy is recognized as one of the most developed districts situated on the Anatolian side of Istanbul, alongside the coast of the Marmara Sea. It encompasses a land area of 25.20 km² and, according to TURKSTAT data for 2024, has a population of approximately 462,189 with estimates suggesting it is nearing half a million residents (Kadıköy Municipality, 2025; TURKSTAT, 2025). The district is known for its high socio-economic status and is primarily composed of residential and commercial areas. It features numerous older buildings that are currently being transformed through urban development. With its cosmopolitan atmosphere and strategically central location, Kadıköy provides a vibrant environment that blends historical and contemporary architecture, appealing to both local and international residents. Kadıköy offers a wide variety of urban activities, including social, cultural, and sporting events, as well as facilities for entertainment, recreation, and shopping. Additionally, it serves as a key transportation hub, featuring seven Marmaray train stations, five metro stations, tram and bus stops, and a ferry terminal. Together, these attributes contribute to a significant daily influx of visitors to the district.

Figure 1. Kadıköy District.

2.2 System Architecture

The system architecture of the study is presented in Figure 2. This methodology encompasses four stages: determining criteria for ped boundaries and calculating weights of criteria, 2D data for mapping PED, 3D data for mapping PED, and evaluating results.

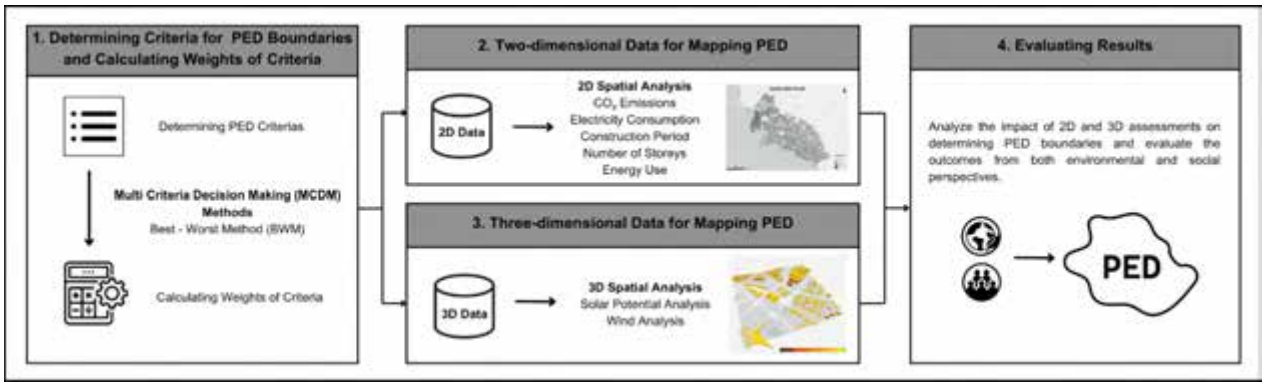

Figure 2. The proposed framework.

This study initially identified the criteria that are essential for establishing the boundaries of PEDs. A thorough review of the literature was conducted to ascertain these criteria, focusing on sources related to PED, sources associated with Zero Emission Districts (ZED) that contributed to the evolution of the PED concept, and relevant projects such as MAKING-CITY and CityxChange (MAKING-CITY, 2025; CityxChange,2025). Subsequent to the identification of the criteria, BWM, the well-known MCDM technique, were applied to evaluate the influence of the criteria and to calculate weights accordingly. After calculating the weights, analyses utilizing both 2D and 3D data were performed to determine the appropriate boundaries for PEDs. These analyses facilitated an evaluation of the advantages provided by both types of data. Open-source data, along with information from the European Union-funded MAKING-CITY and PROPEL projects, were employed in this investigation (MAKING-CITY, 2025; PROPEL, 2025). Data encompassing electricity consumption, greenhouse gas (GHG) emissions, energy types of buildings, and the structural characteristics of these buildings were sourced from these projects. Additionally, socioeconomic data and educational attainment information were obtained from the National Smart City Open Data Platform (Ulusal Akıllı Şehir Açık Veri Platformu -ULASAV) (ULASAV,2025). For the 3D analysis component, a building model was generated based on 2D data of buildings in Kadıköy. Ultimately, the study evaluated potential PED areas in the Kadıköy district, integrating various criteria alongside environmental and social factors.

2.2.1 Determining Criteria for PED Boundaries Calculating Weights of Criteria

As part of this study, a comprehensive literature review was conducted to identify the factors influencing the boundaries of PEDs. This review encompassed an analysis of existing research on the PED concept, as well as the foundational ZED concept. Furthermore, it included an examination of notable projects such as MAKING-CITY and CitxChange (MAKING-CITY, 2025; CityxChange,2025). The findings related to the criteria that affect the boundaries of the PED are presented in Table 1.

Table 1. Criteria about PED boundaries.

Main Criteria	Sub-Criteria
Energy	Biomass
	Natural gas
	Electricity consumption
	Solar energy
	Wind energy
	Greenhouse gas emissions (GHG)
Environment and construction profile	Building density
	Construction period
	Number of storeys
Social	Education level
	Socioeconomic status
	Population

After establishing the decision criteria, the weights for the sub-criteria outlined in Table 1 were computed using the BWM within the context of MCDM. Developed by Jafar Rezaei in 2015, the BWM is a systematic approach that employs two vectors of pairwise comparisons to determine the weights of the criteria (Rezaei, 2015). This method involves identifying the decision criteria, as well as the best and worst criteria. It requires the evaluation of the preference of the best criterion over all other criteria using a numerical scale ranging from 1 to 9, followed by an assessment of how each criterion is preferred over the worst criterion, utilizing the same scale. Finally, the optimal weights are calculated based on these evaluations (Rezaei, 2014).

2.2.2 Two-Dimensional Data for Mapping PED

A multitude of criteria significantly influences the establishment of PED boundaries. MCDM methods are employed to ascertain the relative importance of these criteria. Through the application of MCDM approaches, the impact of each criterion on the decision-making process can be quantitatively assessed and appropriately weighted. Subsequent to these analyses, GIS are employed to spatially evaluate the identified criteria, thereby facilitating the determination of PED boundaries. In addition to providing geographical data pertinent to urban environments, GIS provides essential spatial analysis functions critical to urban design processes (Xia et al., 2022). Moreover, GIS enables the integration of geographical and attribute data with spatial analysis tools and modeling methods, allowing for comprehensive analyses and visualizations of geographical, environmental, and natural resources, thereby supporting quantitative assessments of urban structures (Xia et al., 2022; Wu et al., 2017). Information about the data used in 2D analyses, including data types and sources, is presented in Table 2.

Table 2. Data used for 2D analysis.

Data	Type	Source
Biomass	Vector	PROPEL Project
Natural gas	Vector	PROPEL Project
Electricity consumption	Vector	PROPEL Project
Greenhouse gas (GHG) emissions	Vector	PROPEL Project
Building density	Vector	Derived from PROPEL Project
Construction period	Vector	PROPEL Project
Number of storeys	Vector	PROPEL Project
Education level	Raster	ULASAV

Socioeconomic status	Tabular Data	ULASAV
Population	Vector	TURKSTAT

2.2.3 Three-Dimensional Data for Mapping PED

Another important factors in determining the boundaries of a PED is the potential for solar and wind energy. Solar energy is beneficial for residential areas due to its practicality and cost-effectiveness. 3D spatial analyses can be performed to evaluate these factors in the context of a PED. For this purpose, a 3D building model of the study area was created using existing 2D spatial data. After this model was created, solar energy potential and wind energy analyses were performed using Autodesk Forma with a student license, and solar energy analysis was performed using the open-source Ladybug Tools.

2.2.4 Evaluating Results

In this study, the BWM was employed to identify suitable areas for PEDs. The evaluation criteria were established through a literature review and were organized to encompass environmental, structural, and social dimensions. Criterion weights were calculated using the BWM method to assess the importance of each criterion. Moreover, data related to renewable energy sources, including sun hour, solar energy potential, and wind potential, were analyzed as part of the environmental suitability assessments. Indicators related to biomass and natural gas usage were also examined to identify regions with the capacity to utilize clean energy sources. Social indicators, such as socioeconomic status and educational levels, were incorporated into the analysis due to their connection with technological adaptation and sustainability awareness. All criteria were spatially integrated using GIS-based datasets to create a comprehensive evaluation framework for the applicability of PEDs.

3. Results and Discussion

3.2.1 Determining Criteria for PED Boundaries Calculating Weights of Criteria

In the context of this study, the weights assigned to the criteria were computed utilizing the BWM, an approach within the realm of MCDM methodologies. This process was undertaken to ascertain the significance levels of the criteria presented in Table 1, which were established through an extensive review of the existing literature. The weights of the criteria derived from the application of the BWM are presented in Table 3.

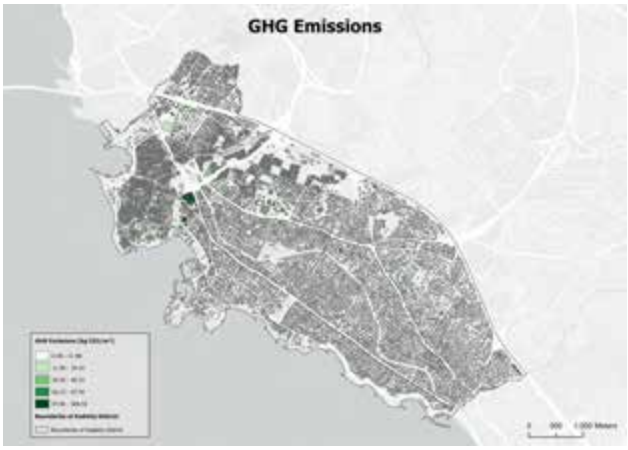
Table 3. Weights of criteria calculating using BWM.

Main Criteria	Sub-Criteria	Weight
Energy	Biomass	0.086
	Natural gas	0.072
	Electricity consumption	0.335
	Solar energy	0.108
	Wind energy	0.034
	Greenhouse gas (GHG) emissions	0.174
Environment and construction profile	Building density	0.041
	Construction period	0.034
	Number of storeys	0.024
Social	Education level	0.011
	Socioeconomic status	0.032
	Population	0.048

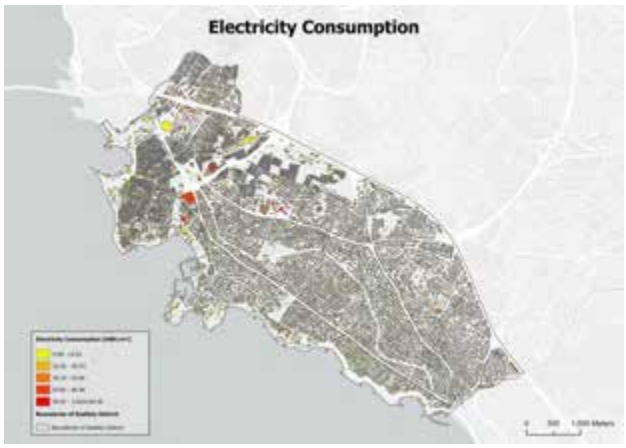
3.2.2 Two-Dimensional Data for Mapping PED

As part of the study, both 2D and 3D spatial analyses were conducted to assess the criteria detailed in Table 1. The 2D spatial analyses examined several factors within the Kadıköy district, including GHG emissions (a), electricity consumption in buildings (b), the utilization of biomass and natural gas as energy sources (c and d), the socio-

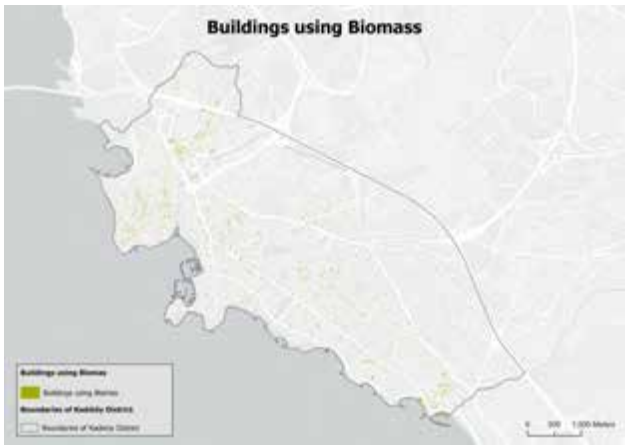
economic score (e), education levels (f), the year of construction of buildings (g), the number of floors in buildings (h), building density throughout the district (i), and population (j). The maps generated as a result of these spatial analyses are indicated in Figure 3.



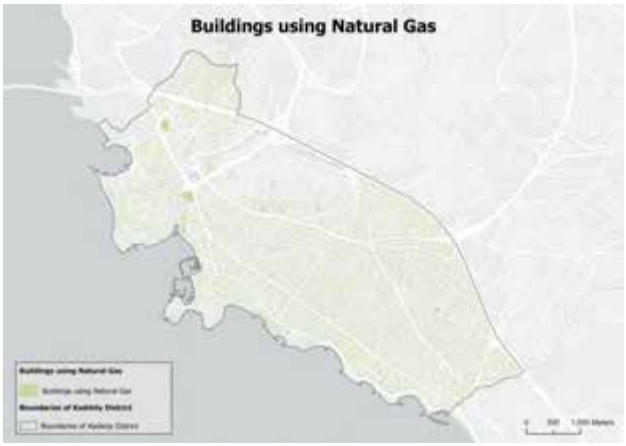
(a)



(b)

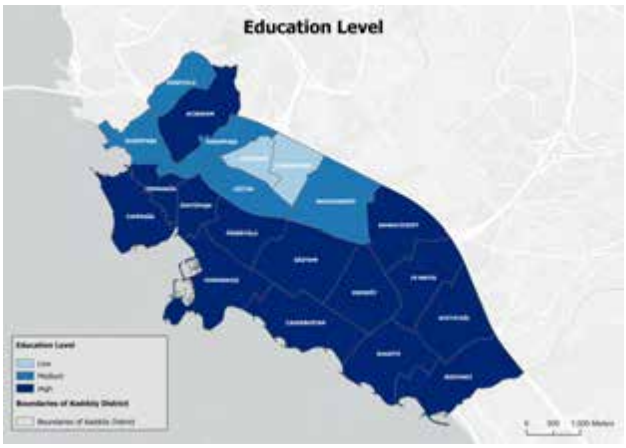


(c)



(d)

(e)



(f)

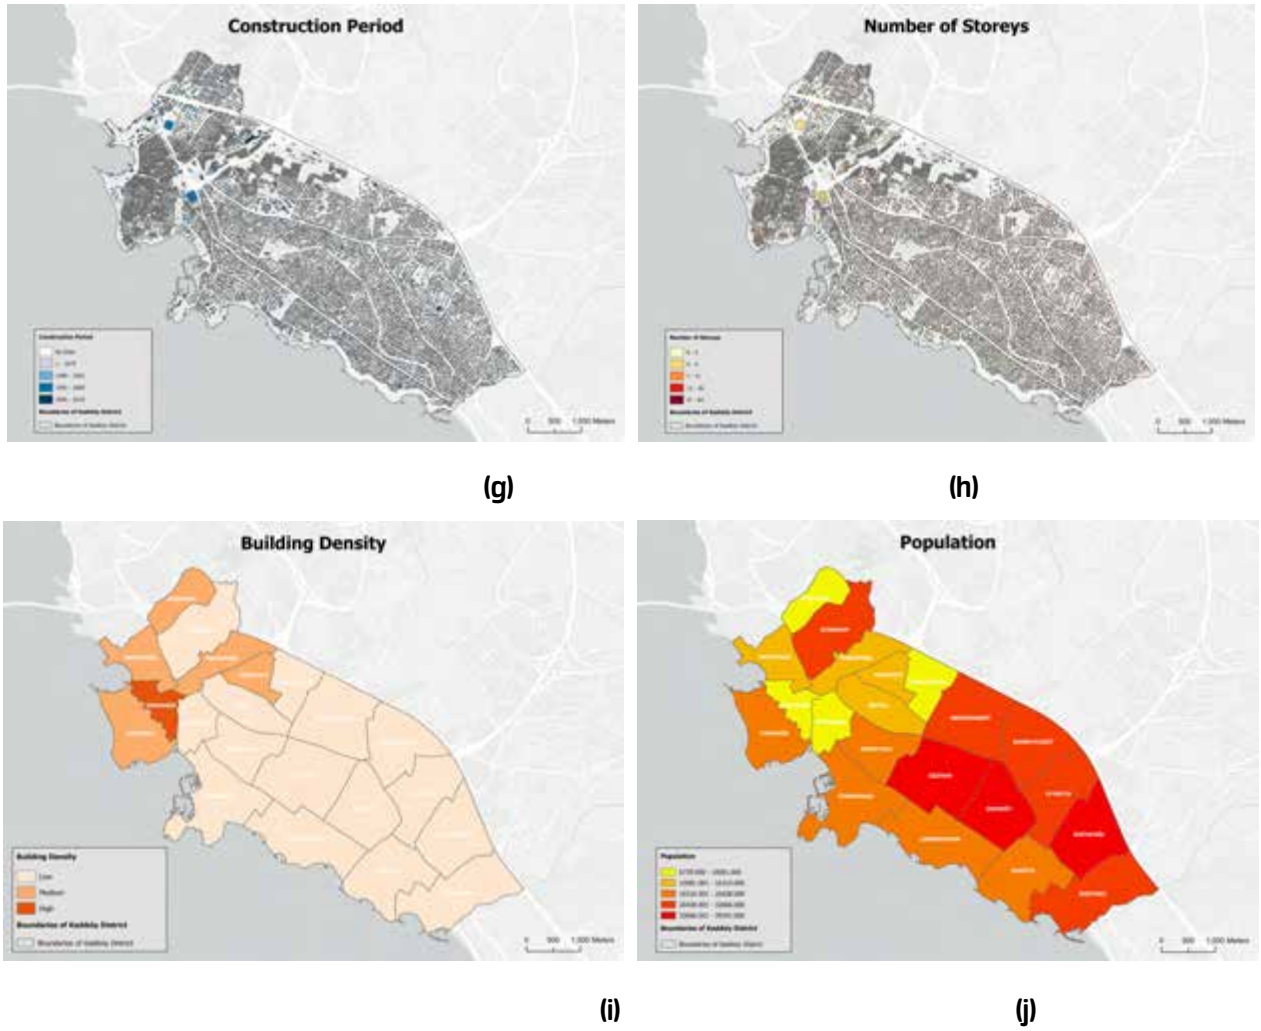


Figure 3. Results of 2D spatial analyses.

Following the creation of criterion maps through 2D spatial analyses, an examination was conducted on the effects of these criteria. The evaluation of the criteria weights presented in Table 3 indicates that the most significant criteria are electricity consumption and GHG emissions. The PED concept aligns with smart city initiatives that aim to reduce energy use and GHG emissions (JPI Urban Europe, 2025). Therefore, an analysis of the 2D spatial results depicted in Figure 3 reveals that regions characterized by low electricity consumption and GHG emissions are conducive to the designation of PEDs.

However, it is essential to recognize that the determination of PED boundaries should not be limited to these two criteria; a comprehensive assessment of additional factors is necessary. While PEDs derive benefits from energy-efficient buildings, smart grids, and advanced renewable energy technologies, they concurrently enhance urban resilience and make substantial contributions to achieving net-zero carbon targets (Bruckner et al., 2025). In this context, factors such as the age of construction and the number of floors in buildings significantly influence PED boundaries. Moreover, the type of energy utilized plays a pivotal role in this determination. To meet net-zero carbon targets within PEDs, the deployment of clean energy sources is imperative, making the use of biomass and natural gas appropriate for these areas. Although high-density construction is often perceived as a threat to open spaces, it can yield ecological advantages, such as optimized land, material, and energy utilization. Additionally, it provides socio-cultural benefits, including functional diversity at the ground level and improved urban organization (PED–ID, 2025). Consequently, areas characterized by high building density may be suitable for PED

development. The identification of viable locations for energy infrastructure installations presents a considerable challenge, particularly in densely populated urban regions that experience spatial constraints (Derkenbaeva et al., 2021). As a result, population density must be factored into the determination of PED boundaries. Finally, it is crucial to consider social factors, as a higher socio-economic status and level of education among residents will facilitate awareness and adaptation to the PED concept.

3.2.3 Three-Dimensional Data for Mapping PED

The study analyzed solar energy using Ladybug Tools and both solar and wind energy through Autodesk Forma. Direct sun hours were assessed using Ladybug Tools, while solar potential and wind analysis were conducted with Autodesk Forma to evaluate Kadıköy in terms of its solar energy potential and wind energy. The results of these analyses for a designated segment of the study area are presented in Figure 4, Figure 5, and Figure 6.

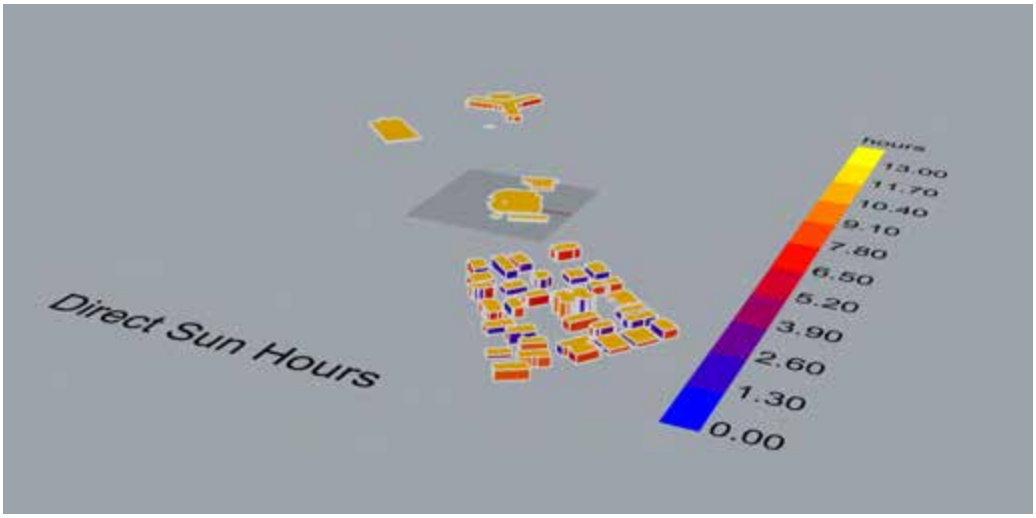

Figure 4. Results of direct sun hours analysis.

The Direct Sun Hours analysis, presented in Figure 4 and utilizing Ladybug Tools, enables a thorough evaluation of the historical sunlight exposure experienced by the roofs and facades of various buildings. In this analysis, the duration of sun exposure for the region depicted in the figure during August was examined. The study revealed that the maximum duration of sun exposure was 13 hours. This analysis is instrumental in identifying the most suitable locations for the installation of solar panels, thereby facilitating the generation of solar energy from renewable sources. Such insights are critical for the development of PEDs and allow for a comprehensive assessment of the solar potential of buildings across different seasons.

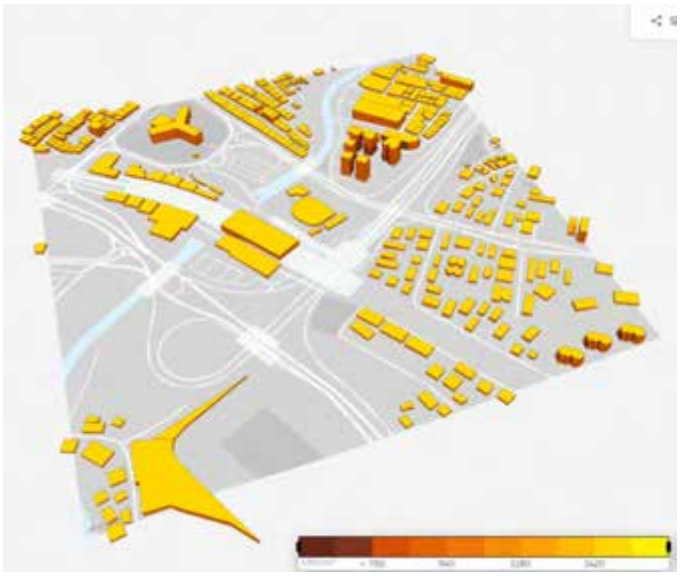

Figure 5. Results of solar potential analysis.

The solar potential analysis carried out utilizing the Autodesk Forma platform, as illustrated in Figure 5, facilitates the assessment of solar potential across various buildings, including their roofs and facades. This comprehensive analysis enables the calculation of the overall solar potential for the region, as shown in the figure. The results indicate that the annual solar energy generation for the area represented in the figure amounts to 221,000,000 kWh, with an average solar energy yield of 1,080 kWh/m².

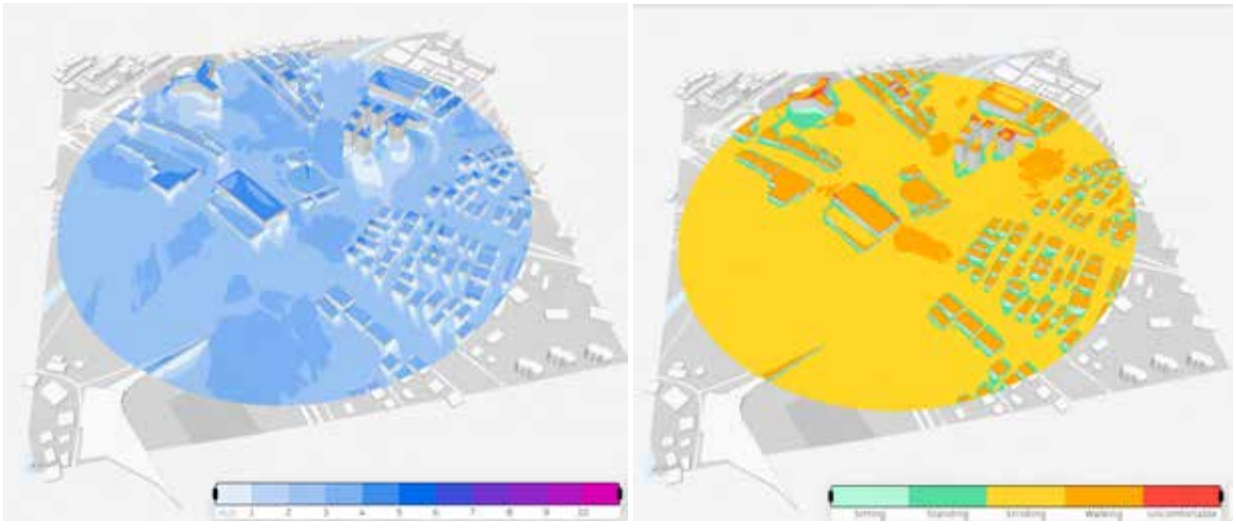

Figure 6. Results of wind analysis.

The wind analysis illustrated in Figure 6 facilitates the examination of how winds originating from various directions affect wind potential and variations in wind speed within the region. Furthermore, this analysis permits an assessment of the wind potential for both buildings and the surrounding terrain. By conducting this evaluation, stakeholders can gain insights into the wind energy potential in urban areas and identify regions with significant capacity for renewable energy production.

3.2.4 Evaluating Results

This study identifies that electricity consumption and GHG emissions are the most critical criteria for assessing suitable areas for the development of PEDs, as determined by the BWM used in MCDM. Regions with low levels of these two criteria are considered more favorable for PED development. However, it is essential to consider additional factors, such as building age, number of floors, type of energy source, building density, population density, socioeconomic status, and education level, which also significantly influence the suitability of development areas.

From an environmental standpoint, regions capable of utilizing clean and renewable energy sources, such as biomass and natural gas, are deemed appropriate for PED development due to their potential for producing clean energy. Furthermore, an analysis of solar and wind energy potential demonstrated that areas with extended sunshine durations and favorable wind patterns are advantageous for renewable energy production.

From a social perspective, the findings indicate that the PED concept can be effectively implemented in regions with high socioeconomic scores and elevated education levels. Residents in these areas typically exhibit greater awareness and sensitivity towards sustainability. Additionally, as education levels rise, individuals' understanding of innovative energy technologies and their ability to adapt to these advancements also improve. This adaptability facilitates the integration of technological infrastructures, such as smart grids, energy monitoring systems, and energy production and sharing applications, all of which are essential for the successful implementation of the PED concept.

Neighborhoods with higher socioeconomic levels often feature more organized and planned urban areas. Consequently, projects developed in collaboration with local governments can be executed more efficiently, leading to increased effectiveness. These characteristics enhance urban resilience and improve adaptive capacity in the face of climate change, contributing to the successful and sustainable implementation of PEDs.

4. Conclusion

In this study, the integration of both 2D and 3D spatial analyses together with a holistic approach to determining the boundaries of PEDs significantly increased the accuracy and applicability of the findings. The use of 2D data was effective in assessing the spatial distribution of PED criteria. Variables such as electricity consumption, GHG emissions, population density, building density, education level, and socio-economic indicators were mapped, and more favorable areas for PEDs were evaluated. Regions characterized by low GHG emissions and energy consumption, in particular, emerged as significant criteria. Additionally, building stock characteristics, such as building age and number of floors, were analyzed in terms of energy efficiency and the integration of renewable energy sources.

The use of 3D data, combined with 3D analyses, facilitated a comprehensive and detailed assessment of solar and wind energy potential. Studies of sunlight duration and annual solar energy production potential conducted using 3D building models allowed the determination of optimum roof and façade surfaces for solar panel installation. These assessments also allowed the assessment of energy potential in various temporal dimensions. Similarly, wind energy potential was analyzed at a micro-scale, taking into account prevailing wind directions. These analyses directly contributed to the shaping of energy production strategies for PEDs by enabling the assessment of local renewable energy resources. By synthesizing both 2D and 3D data, the study presents a comprehensive assessment that addresses horizontal dimensions, such as urban sprawl and density, as well as vertical factors, including sunlight, building height, and wind effects.

To conclude, the findings emphasize the need for a multi-criteria approach to PED planning that transcends energy-centric considerations by integrating social, structural, and environmental dimensions. This comprehensive approach provides a vital foundation for the development of PED models consistent with sustainable urbanism principles.

Leveraging Social Media Big Data and Large Language Models to Quantify the Temporal Dynamics of Cross-Border Spatial Identity: Evidence from Shenzhen-Hong Kong Region

Luyao Niu [a,1], Yurun Wang [a,1], Wenjia Zhang [b,*]
[a] School of Urban Planning and Design, Peking University Shenzhen Graduate School, Shenzhen, Guangdong, China
[b] College of Architecture and Urban Planning, Tongji University, China

Abstract
Cross-border spatial identity refers to the multifaceted, individually constructed perceptions that residents form through cross-border interactions and daily behaviors. It has emerged as a critical metric for evaluating the integration of cross-border regions, playing a pivotal role in fostering regional community cohesion and advancing integration initiatives. In the context of the Guangdong-Hong Kong-Macau Greater Bay Area, the Shenzhen-Hong Kong corridor exemplifies as a significant yet complex cross-border zone, where divergent political systems, administrative practices, and cultural norms impede seamless integration despite a shared national affiliation. Consequently, examining residents' subjective identity perceptions within cross-border spaces, as reflected in their daily activities, becomes imperative. However, the social, cultural, and linguistic heterogeneity in cross-border spaces complicates the clear definition of measurement dimensions, hampers the collection of long-term, high-quality data, and limits the ability to discern complex, multi-dimensional emotions. As a result, existing research has not adequately captured the temporal dynamics and addressed the multi-dimensional heterogeneity of cross-border spatial identity. To address these challenges, this study introduces an innovative measurement framework that integrates extensive long-term social media data with the semantic analysis capabilities of large language models. Focusing on the Shenzhen-Hong Kong cross-border space as a case study, we analyzed a comprehensive dataset of social media text from platforms such as Weibo and Xiaohongshu, covering the period from 2018 to 2023. By employing the chain of thinking prompt engineering of large language models (LLMs), we quantitatively assess the identity perceptions of Shenzhen and Hong Kong residents across three dimensions: spatial imagery, spatial satisfaction, and spatial sense of belonging. Our findings reveal that the spatial identity of Hong Kong residents experienced marked temporal fluctuations during critical events and policy shifts, such as the COVID-19 pandemic and the implementation of the Greater Bay Area development plan. Moreover, distinct variations in identity perception were observed across different types of cross-border spaces, with shopping and consumption areas displaying a notably positive spatial identity. This research provides a robust, efficient and scalable framework for the long-term tracking of cross-border spatial identity, offering valuable theoretical insights and quantitative evidence to better understand the temporal and spatial evolution of identity perceptions in cross-border populations. It offers important theoretical support and quantitative evidence for the evaluation of the cross-border region integration process.

Keyword: Cross-border spatial identity; Large language models; Social media data; Shenzhen-Hong Kong region.

1. Introduction

Globalization has blurred national borders, increasing resource sharing and economic-cultural interactions among border cities. Cross-border integration is a key to achieving spatial cohesion and regional equilibrium. Therefore, cross-border spatial identity is defined as the emotional attachment, psychological identification, and sense of place that residents develop through their cross-border activities. This identity, in turn, shapes the intensity of cross-border mobility, residents' willingness to participate in regional policies, social environment, and economic activities. Furthermore, it plays a pivotal role in the implementation of cross-border cooperation and cohesion policies, providing intrinsic motivation for resource sharing, social stability, and policy coordination within border regions. As such, cross-border spatial identity offers valuable insights into the mechanisms underpinning regional integration and serves as a crucial lens for evaluating the processes of cross-border spatial cohesion.

The Shenzhen–Hong Kong corridor exemplifies the highly complex dynamics of integration within the Guangdong–Hong Kong–Macau Greater Bay Area (GBA) Strategy framework, primarily shaped by deep-rooted structural differences and political disparities between the two systems. . Specifically, new cross-border transportation infrastructures, such as high-speed rail, metro, and maritime routes, have significantly boosted cross-border interactions, and strengthened cross-border spatial identity. However, complex social tensions in Hong Kong, exemplified in social movements such as the "Occupy Central" movement and the "Extradition Bill Protests", deep-seated cultural differences, mobility restrictions, and disparities in urban space complicate both regional

1 These authors contributed equally.

integration policy implementation and the assessment of residents' psychological connections to the integration.

The conceptualization of spatial identity is inherently multidimensional, encompassing cognitive, affective, and behavioral dimensions. Cognitively, it is shaped by individuals' mental representations of space, influenced by spatial perception, historical narratives, and collective memory (R Hay, 1998)such as aesthetics and a feeling of dwelling. Insider status and local ancestry are important toward the development of a more rooted sense of place. Three contexts are used to examine the development of sense of place: residential status in the place (superficial, partial, personal, ancestral, and cultural senses of place. Affectively, it is built through emotional attachment and place-based belonging from lived experiences and spatial interactions (Hernández et al., 2007). Behaviorally, it manifests in mobility patterns, spatial preferences, and engagement in place-based social practices (Dorfman et al., 2021)place, and partners, with emphasis on the impact of the social environment on spatial behavior and on how individual spatial representations converge to form collective spatial behavior - i.e., common places and routes. Recent studies suggest that in addition to their mental representation (cognitive map. Given this multidimensional nature, any attempt to measure spatial identity must account for these interrelated components, making its quantification particularly complex.

In cross-border regions, factors like intricate socio-political and cultural landscape further complicate the measurement of spatial identity. These regions are often characterized by linguistic diversity, institutional fragmentation, and historical legacies that shape distinct spatial perceptions among different groups (Laven and Baycroft, 2008). Socio-cultural tensions, policy discrepancies, and asymmetries in economic development add further complexity, shaping individuals' sense of belonging and attachment to space (Gardner and Richards, 2017)an indigenous people divided by the Guatemala-Mexico border, identify collectively. We further existing sociological literature on collective identity "boundary work" by demonstrating how it is shaped by spatial, and not just symbolic, boundaries. Mam individuals and organizations define symbolic boundaries that sustain political-administrative borders (such as municipal divisions within Guatemala and Guatemala's border with Mexico. Moreover, the dynamic nature of cross-border interactions further underscore the fluidity and heterogeneity of cross-border spatial identity. As a result, traditional approaches of measuring spatial identity (e.g., surveys and questionnaires) are challenged in fully capturing the nuanced and evolving aspects of spatial belonging in cross-border contexts.

Existing studies on spatial identity primarily rely on qualitative data, such as surveys and interviews. However, these approaches are often limited by small sample sizes, high costs, and low temporal efficiency. Moreover, as they are typically based on cross-sectional data, they fail to capture the temporal dynamics of spatial identity. Additionally, such studies are geographically constrained, which limit their ability to address the complexities of cross-border contexts. Recently, the use of large-scale social media text data to capture residents' emotional perceptions has emerged as a promising method. Social media text data with geolocation information, provides a novel source of linguistic emotional feedback for measuring spatial identity (Gao et al., 2022). This approach offers significant advantages, including large scale data availability, low collection costs, extensive geographic coverage, and the ability to track long-term temporal dynamics.

However, collecting high-quality labeled social media data for measuring cross-border spatial identity remains challenging. First, divergent social media platform preferences on each side of the border lead to fragmented data access and varied data. Second, linguistic and expressive difference (e.g. Mandarin, Cantonese, English,...) further complicate data processing. Moreover, cultural diversity in cross-border regions creates a range of expression styles that can also introduce biases in emotion interpretation, making it harder to accurately capture spatial identity using computational models.

Based on social media data, machine learning algorithms have proven effective in extracting textual emotions. These algorithms automatically identify nuanced user opinions and detect emotional fluctuations by training models to classify sentiment polarity(positive/negative) (Mutanov, Karyukin and Mamykova, 2021) and quantify

intensity levels using features like lexical patterns, contextual embeddings, and temporal dynamics in posts (Mandhasiya et al., 2022). However, these methods face several challenges when applied to cross-border spatial identity measurement. They struggle to capture perceptions of abstract concepts accurately, rely heavily on large amounts of labeled data, interpret the prediction process, and their performance is limited by the quality of training data. The multi-source and heterogeneous nature of social media data in cross-border regions increases the costs of data labeling, reducing the efficiency and transferability of model training. Additionally, linguistic diversity in cross-border settings presents further challenges, as a single machine learning model typically struggles to conduct cross-lingual analysis. Furthermore, the black-box nature of machine learning models undermines the interpretability and credibility of prediction outcomes. Therefore, a critical research challenge lies in developing a spatial identity measurement framework tailored to cross-border contexts—one that effectively leverages large-scale social media data, addresses the complexities of multilingual and multicultural environments, and enhances the interpretability and reliability of analytical processes.

LLMs have shown potential in large-scale text analysis, semantic understanding, and complex emotion recognition tasks. Compared to traditional sentiment analysis models based on lexicons or supervised learning, LLMs offers clear advantages in capturing complex and implicit semantics(Xing, 2024), performing zero-shot or few-shot learning without heavy reliance on labeled data(Gandhi et al., 2024), and improving interpretability through self-explanation capabilities (Randl et al., 2024). These features open new avenues for conducting complex sentiment analysis based on social media data and for quantifying cross-border spatial identity perceptions.

Therefore, this study proposes an innovative framework for measuring cross-border spatial identity by integrating social media data with LLMs. We utilize a three-dimensional theoretical model that conceptualize cross-border spatial identity through spatial imagery, spatial satisfaction, and spatial sense of belonging. The framework involves several key steps: collecting and processing social media data, recognizing regional identity, developing chain-of-thought (COT) prompt engineering, and applying LLMs to quantify spatial identity scores. This approach enables precise and scalable measurement of cross-border spatial identity. [Specifically, incorporating LLMs introduces a novel semantic reasoning layer. By leveraging COT prompting, the framework decomposes complex spatial narratives into structured elements (location, activity, sentiment). Consequently, this approach supports dynamic, cross-lingual, and context-aware spatial identity scoring that surpasses traditional keyword-based methods, while also facilitating an analysis of the drivers behind spatial identity beyond conventional interpretability limits.] Using the Shenzhen-Hong Kong cross-border region as a case study, we employed mobile phone signaling data to identify the primary cross- border activity spaces for Hong Kong residents in Shenzhen and collected corresponding social media text data. We then examined the temporal fluctuations of spatial identity in Shenzhen's cross-border areas, the heterogeneity of identity perceptions across different functional spaces, and the differences in cross-border spatial identity between Guangdong and Hong Kong residents.

By systematically exploring the dynamic spatiotemporal patterns and underlying mechanisms, the framework contributes to a deeper understanding of spatial identity dynamics in complex cross-border environments. Compared to traditional methods, this research not only tackles the challenges such as multilingual and multicultural complexities and the heavy reliance on labeled data, but also significantly enhances semantic understanding and emotional analysis capabilities in large, heterogeneous datasets through LLMs. The findings from Shenzhen-Hong Kong cross-border region provide robust empirical evidence for understanding the cross-border integration dynamics and offer valuable theoretical foundations and practical insights for optimizing cross-border spaces and informing regional integration policies.

The remainder of this paper is structured as follows: Section 2 reviews the existing literature; Section 3 introduces the construction of the cross-border social media dataset; Section 4 presents the cross-border spatial identity analysis method based on large models; Section 5 discusses the experimental and analytical results using the research method; Finally, Sections 6 and 7 discuss the significance and limitations of this study and summarize the research conclusions.

2. Literature Review

2.1 Cross-Border Spatial Identity Measurement

Spatial identity refers to the emotional attachment, psychological affiliation, and cognitive bond that an individual or group has with a specific place. When a space's social and material resources meet residents' needs and preferences, they form a positive identity and attachment, which in turn encourages behaviors that support positive interactions with their environment.

Spatial identity develops through sustained interaction and comprehensive perception of both the physical environment and socio-cultural context (Robert Hay, 1998). Its abstract nature makes it challenging to represent concretely or intuitively. Researchers have constructed theoretical frameworks to measure spatial elements across multiple dimensions. For instance, Proshansky and other environmental psychologists proposed a three-dimensional model of spatial identity, which includes cognitive understanding, emotional experience, and behavioral intention (Proshansky, Fabian and Kaminoff, 1983). Breakwell, focusing on individual psychological needs, categorized spatial identity into distinctiveness, continuity, self-esteem, and self-efficacy (Breakwell, 1993). Knez further refined the concept of continuity into place-oriented coherence and place-consistent continuity, proposing a five-dimensional model of place identity (Knez, 2005)climate, place attachment and place identity using Breakwell's four processes model of place identity (e.g. Twigger-Ross, Bonaiuto, and Breakwell. (2003. In contrast to purely theoretical approaches, Lalli introduced the urban identity scale, dividing place identity into five dimensions: external evaluation, general attachment, commitment, continuity with personal past, and familiarity perception (Lalli, 1992)the following problems are seen to characterize the psychological research on 'place identity': heterogeneity of terms and their spatial extension, differing theoretical foundations and fragmented formulations, lack of adequate measuring instruments, and a scarcity of empirical work. This paper aims firstly, to present a systematic analysis of the theoretical traditions of the work on 'place identity'. Secondly, it uses constructs of medium range in order to systematize theory and research. An example of the latter is presented with respect to urban-related identity. A framework for conceptualizing urban-related identity and identification is developed on the basis of social psychological work on self-concept. The second part introduces a measuring instrument (the 'Urban Identity Scale'. This work marked the first quantification of spatial identity, providing an operational tool for theoretical inquiry.

Cross-border spatial identity emerges when residents traverse geographic, cultural, and institutional boundaries through ongoing engagement with cross-border activity spaces, developing emotional attachment and cultural affinity toward the border region (Newman and Paasi, 1998). Distinct from spatial identity confined within a single country, cross-border spatial identity is shaped by three fundamental asymmetries: political system disparities, uneven economic development, and cultural and linguistic divides (Pedersen, 2018), resulting in inherently multi-dimensional complexity. It demonstrates dynamic temporal evolution: individual level development occurs through cultural adaption, social integration, and life course progression (Rishbeth and Powell, 2013), whereas regional level transformations respond to historical trajectories and socio-political dynamics(Laven and Baycroft, 2008). Furthermore, exogenous shocks (e.g. pandemics) and planned interventions (e.g. economic zone development) affect both the intensity and structure of spatial identity. These factors make cross-border spatial identity a complex, dynamic phenomenon and position it as a critical interdisciplinary research focus, bridging geographical inquiry with political studies, psychological analysis, and urban planning (Robert Hay, 1998).

Existing research delineates cross-border spatial identity along several dimensions, reflecting its formation and connotations. For example, thereby building on Scannell and Giddord's three-dimensional model, Rishbeth et al. incorporated memory triggers, comparisons, and symbolic markers of local culture. (Rishbeth and Powell, 2013). Similarly, Pedersen et al. introduced the social interaction networks to examine changes in cross-border spatial identity (Pedersen, 2018), while Kajić et al. emphasized the significance of residents' perceptions of regional boundaries, emotional attachment, and socio-cultural and political systems in the construction (Kajić, Bogdanić and Fuerst-Bjeliš, 2022).

However, quantifying cross-border spatial identity presents considerable challenges. These difficulties stem

from the interplay of emotional, behavioral, and cognitive factors, including subjective conceptual boundaries (Peng, Strijker and Wu, 2020), intricate cognitive mechanisms (Arbab, Azizi and Zebardast, 2018), multi-dimensional interactions(Raymond, Brown and Weber, 2010) and diverse socio-cultural conflicts (Fikfak, 2009). While current theoretical frameworks offer valuable insights, they often neglect the key spatial elements, fail to capture dynamic evolution of spatial identity, and lack verified its cross-border applicability. Consequently, measuring cross-border spatial identity remains problematic, hindering further research.

Traditional methods for measuring spatial identity primarily rely on surveys, in-depth interviews, and participatory observation. For example, researchers have used random sampling with the place identity scale to quantify spatial identity in specific areas (Williams and Vaske, 2003), employed Likert scales to explore characteristics during its formation(Lalli, 1992)the following problems are seen to characterize the psychological research on 'place identity': heterogeneity of terms and their spatial extension, differing theoretical foundations and fragmented formulations, lack of adequate measuring instruments, and a scarcity of empirical work. This paper aims firstly, to present a systematic analysis of the theoretical traditions of the work on 'place identity'. Secondly, it uses constructs of medium range in order to systematize theory and research. An example of the latter is presented with respect to urban-related identity. A framework for conceptualizing urban-related identity and identification is developed on the basis of social psychological work on self-concept. The second part introduces a measuring instrument (the 'Urban Identity Scale', and conducted in-depth interviews to examine shifts in individuals' identity perceptions (Chow and Healey, 2008). However, these methods are often limited by small sample sizes, restricted coverage, high costs, lack of timeliness, and potential biases from self-reporting and researcher interpretation. They struggle to capture the intricate features of cross-border spatial identity. As surveys and interviews typically yield cross-sectional data, they inadequately reflect the temporal dynamics essential for deeper research.

With the advent of the "humans as sensors" concept (Resch et al., 2016), social media data, as a sensor for residents' emotions, offering new perspectives for urban emotional perception research (Kong et al., 2022) and serving as a critical tool for measuring urban sentiment. As an essential component of urban emotional perception, social media data holds significant potential for measuring spatial identity due to its unique advantages. Specifically, it provides extensive geotagged, long-term time series information that transcends geographical and cultural boundaries, captures cognitive patterns across spatial scales, and offering long-term, continuous, large-scale data coverage. Public emotional responses and cognitive characteristics toward spaces can be effectively captured, enabling more refined spatial identity measurement. For instance, Kong et al. quantified the positive emotions of park visitors using long-term Sina Weibo check-in data(Kong et al., 2022); Felasari et al. analyzed Twitter text related to tourism sites to explore the emotional connections between visitors and attractions across dimensions like understanding, psychological involvement, and self-identity fusion (Felasari et al., 2017); Jang & Kim employed Instagram image hashtags and geotags for text semantic analysis to reveal the public's collective cognitive and emotional connections to specific urban spaces (Jang and Kim, 2019).

To efficiently analyze large volumes of social media data, machine learning and deep learning methods have been increasingly introduced. Machine learning models, such as support vector machines, random forests, and logistic regression, have been applied to identify spatial emotions, place attachment, and spatial identity perceptions within social media data. For instance, Zhou et al. used Biterm topic modeling and other NLP algorithms to analyze residents' emotions expressed in social media texts about urban green spaces (Zhou et al., 2023); Jang & Kim used self-organizing map (SOM) algorithms to cluster social media text keywords, revealing latent patterns in spatial identity, and providing graphical representations of semantic relationships that enhance both analysis efficiency and interpretability (Jang and Kim, 2019), offering a comprehensive understanding of place attachment when integrated with text-based analysis.

Despite their capacity to parse complex semantics in large-scale data, current machine learning models remain facing limitations in the context of cross-border spatial identity research. Cross-border spatial identity is complicated by socio-economic disparities, diverse historical cultures, varying political systems, and cross-border

political dynamics. Its conceptual definition and measurement are inherently dynamic and multi-dimensional (Peng, Strijker and Wu, 2020). Moreover, these models typically require abundant high-quality labeled data for training, yet data collection in cross-border contexts is hindered by dispersed sources and heterogeneous data structures. They often exhibits poor generalization across different scenarios, performing optimally only within specific contexts. The complex socio-cultural environment of cross-border regions-characterized by multilingual and multicultural challenges, further complicates semantic understanding and emotional perception; a single machine learning model struggle to adapt effectively to cross-language text analysis. Finally, the “black-box” nature of machine learning models precludes transparent explanations for their outputs, thereby hindering insights into the underlying sources and mechanisms shaping cross-border spatial identity.

2.2 Utilizing LLMs for Measuring Spatial Identity

LLMs demonstrate advanced capabilities in reasoning, analysis, and generation, excelling particularly in tasks involving noisy data, complex contextual scenarios, and implicit semantic analysis. Their capability to capture bi-directional contextual dependencies facilitates the efficient analysis of large text corpora (Wan et al., 2024). Their extensive model parameters enable few-shot and zero-shot learning, reducing the dependence on labeled data and supporting transfer across diverse downstream tasks. LLMs trained on multilingual datasets can process and generate text in various languages, enhancing performance in cross-lingual tasks and enabling effective scenario transfer(Lai et al., 2023)large language models (LLMs. Furthermore, emerging approaches leveraging LLMs aim to provide more transparent reasoning process, potentially enhancing the interpretability of text-based quantification. Consequently, LLMs represent a promising tool for measuring spatial identity, particularly for capturing and quantifying it within cross-border regions characterized by cross-lingual and multicultural contexts.

The robust semantic understanding capabilities of LLMs provide a distinct advantage in interpreting implicit emotions like sarcasm, irony, and subjectivity, leading to strong performance in sentiment analysis tasks. Specifically, LLMs provide effective analysis pathways for tasks involving subjective and abstract emotional concepts, such as accurately distinguishing between moral foundations like care and fairness (Rathje et al., 2024). These capabilities allow LLMs to effectively address complex and ambiguous concepts to spatial identity, including place attachment (Zhou et al., 2024), social ideology (Liu and Shi, 2024), and personal values (Brigola, 2024), providing effective tools for its analysis.

LLMs inherently possess zero-shot and few-shot learning capabilities, which are among their most essential features. They can perform downstream tasks with little or no annotated data, bypassing the traditional reliance on large labeled datasets. This advantage reduces annotation costs and increases efficiency. For example, Kojima et al. introduced the zero-shot reasoning framework (Zero-shot-COT), demonstrating the effectiveness of zero-shot conditions in complex tasks (Kojima et al., 2022). Under zero-shot conditions, LLMs exhibit strong generalization and transfer capabilities across diverse tasks and scenarios. These zero-shot and few-shot capabilities are widely applied in sentiment analysis tasks. Studies indicate that LLMs effectively address sentiment reasoning tasks, including emotional inference, outcome reasoning and target identification, even with zero-shot prompts (Gandhi et al., 2024).

Training on multilingual data endows LLMs with robust cross-linguistic analytical capabilities, leading to superior performance in multilingual tasks. Lai et al. evaluated ChatGPT on 37 tasks, observing strong performance in high-resource languages like English, Chinese, and Spanish (Lai et al., 2023)large language models (LLMs, while also demonstrating consistent performance in cross-linguistic sentiment analysis. Consequently, the cross-linguistic capabilities of LLMs offer effective solutions for addressing the cross-cultural and cross-linguistic challenges inherent in measuring cross-border spatial identity.

LLMs can generate self-explanations based on instructions, thereby enhancing transparency and interpretability. For instance, Randl et al. distinguished between extractive explanations (e.g., identifying "the most important phrases") and counterfactual explanations (e.g., "modifying input text to change the prediction outcome"), verify-

ing the effectiveness and consistency (Randl et al., 2024). Similarly, Fragkathoulas & Chlapanis (2024) demonstrated that instructing LLMs to generate self-reasoning chains improves contextual understanding and accuracy (Fragkathoulas and Chlapanis, 2024). In addition, incorporating self-explanation prompts reduces information loss and contextual misunderstanding, thereby enhancing comprehension. Research has explored the deep interpretability of LLMs, particularly their attribution capabilities. In attribution analysis, LLMs support their response by generating attribution paragraphs or identifying source texts, thus verifying authenticity and reliability. For instance, Bohnet et al. validated attribution-enabled question answering (Bohnet et al., 2023), while Hu et al. combined knowledge graphs to automatically generate attribution categories, underscoring the advantages of LLMs in complex attribution tasks(Hu et al., 2024). Therefore, integrating the self-explanation and attribution capabilities of LLMs into the measurement of cross-border spatial identity can reveal more reliable emotional associations and attribution mechanisms. This provides urban planners and policymakers with precise sentiment feedback tools and critical insights for optimizing regional integration policies.

In summary, LLMs offer a groundbreaking approach for measuring cross-border spatial identity, leveraging their efficient text parsing, advanced semantic understanding, zero-shot and few-shot learning, cross-linguistic proficiency, and self-explanatory features.

3. Data

This study investigates cross-border activities between Shenzhen and Hong Kong, focus on the primary locations in Shenzhen frequently visited by Hong Kong residents . As a highly mobile groups within the Guangdong-Hong Kong-Macau Greater Bay Area, Hong Kong residents predominantly use Shenzhen as their main entry point to the mainland China. Their activities usually encompass shopping, dining, cultural engagement, leisure, and transit through border checkpoint (Wang, 2004). Furthermore, the diversity and density of these activity spaces provide rich contexts for the expression of spatial identity.

In order to...., this study constructs two key datasets to measure Shenzhen-Hong Kong cross-border spatial identity: (1) A spatial dataset derived from China Unicom's mobile signaling data for Shenzhen, utilized to identify hotspots of cross-border activities, and (2) A social media text dataset comprising posts from Weibo and Xiaohongshu related to cross-border spaces, employed to assess spatial identity scores.

3.1 Shenzhen-Hong Kong Cross-Border Spatial Data

The study focuses on the Shenzhen region (Figure. 1), specifically targeting areas characterized by frequent and representative visits by Hong Kong residents. To identify hotspots of activities for Hong Kong residents, we utilized mobile signaling data sourced from China Unicom's Smart Footprint platform, covering the month of May in each year from 2018 to 2023.It contains user identifiers, card registration locations, dates, and activity locations with geographic coordinates, comprising approximately 3.27 million Hong Kong-registered users and about 32 million mobile signaling records representative of Hong Kong cross-border population.

The process for defining the cross-border activity space is illustrated in Figure.2. First, based on the primary cross-border activities of Hong Kong residents, five types of cross-border spaces were identified: shopping and consumption, leisure, socio-cultural, border checkpoint, and policy spaces. Specifically, shopping and consumption spaces encompass retail, dining, and service areas in major Shenzhen commercial districts, catering to the consumption needs of Hong Kong residents. Leisure spaces include outdoor areas such as parks and tourist attractions, offering relaxation and social opportunities. Socio-cultural spaces comprise venues like museums and cultural centers, fostering cultural exchange and social interaction. Border checkpoint spaces refer to key transit points-including train stations, ports, and land crossings-serving as primary conduits between the Hong Kong and Shenzhen. Finally, policy spaces are delineated by regional cooperation policies, exemplified by the Shenzhen-Hong Kong Cooperation Zone in the Qianhai and Lok Ma Chau Loop.

Spatial boundaries for shopping and consumption, leisure, socio-cultural, and border checkpoint spaces in Shenzhen were extracted using the 2023 Area of Interest (AOI) data from Baidu Maps, whilst policy spaces were de-

lineated based on planning documents pertaining to the Qianhai and Lok Ma Chau Loop innovation cooperation zones. These boundaries were subsequently mapped onto a 250m×250m grid covering Shenzhen, allowing for the possibility of multiple space types co-occurring within a single grid cell.

Mobile signaling data was then used to calculate the number of Hong Kong cross-border residents in each grid cell for May of each year. For shopping and consumption, leisure, and socio-cultural, grids cell were ranked by resident count, with the top 20% designated as hotspots. All grid cells corresponding to border checkpoint spaces identified via AOI data were classified as activity hotspots. Policy space hotspots were defined by the geographical extent of the Qianhai and Lok Ma Chau Loop cooperation zones.

Finally, an expert panel refined the hotspots selection through discussion, considering criteria such as representativeness, geographic proximity, and uniqueness. Specifically, for shopping and consumption, leisure, and socio-cultural spaces, three representative areas were selected from the top-ranked grids. Core locations within these areas were subsequently identified using AOI and Points of Interest (POI) data. For policy and border checkpoint spaces, the expert panel confirmed all previously identified hotspot grids. Overall, 15 key areas and 100 core locations were identified (locations shown in Figure. 1b.)

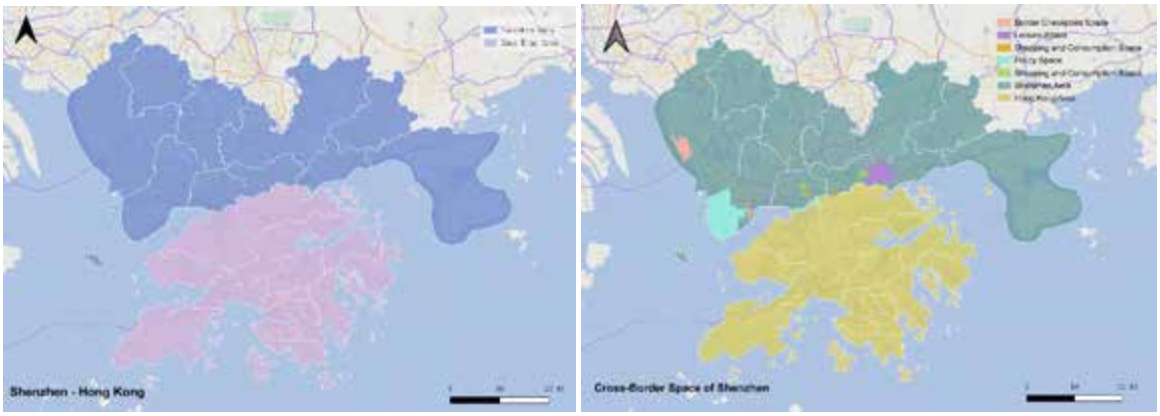

Figure. 1 a. Shenzhen-Hong Kong Map; b. Different types of cross-border space.

3.2 Cross-Border Spatial Social Media Text Data

Building upon the cross-border spatial areas defined above, we collected social media text data that either mentioned or was geo-located in those regions to construct a dataset for semantic analysis of cross-border spatial identity. Data was sourced from Weibo (www.weibo.com) and Xiaohongshu (www.xiaohongshu.com), selected based on platform activity level and data accessibility. As China's largest social media platform, Weibo reported 500 million daily active users in May 2020 (Kong et al., 2022). Xiaohongshu, an emerging platform integrating social networking, lifestyle sharing, and e-commerce, reached 200 million monthly active users in 2020, including a significant proportion of overseas users (He, 2024). Notably, with increasing engagement from Hong Kong users on mainland platforms, Xiaohongshu serves as a primary medium for accessing and sharing information related to mainland China (Digital Report, 2020). The dataset construction involved three steps: expansion of core location keywords, data collection, and filtering to isolate the Hong Kong cross-border population, as illustrated in Figure. 2.

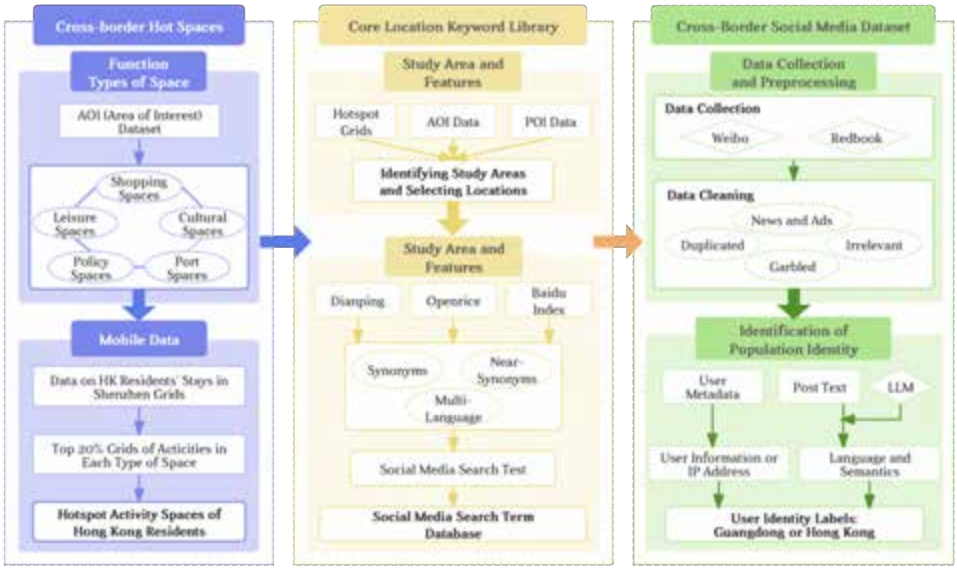

Figure. 2 Construction Process of the Cross-border Spatial Social Media Text Dataset

To ensure comprehensive data retrieval, the initially extracted core location keywords were expanded. Specifically, synonyms and related terms for each core location were generated by translating names into Simplified Chinese, Traditional Chinese, and English, accommodating Hong Kong residents' linguistic habits. Subsequently, the search functions of Weibo and Xiaohongshu were utilized to test and refine these keywords, identifying high-frequency terms and discarding low-quality ones. Tools such as Dianping, OpenRice, and Baidu Index were used to identify further high-frequency synonyms and phrases. Following an expert review to eliminate ineffective terms, a cross-border spatial location keyword bank comprising 405 search terms for the 100 core locations was established.

Using the keyword bank, we screened social media posts and location tags that mentioned relevant locations and collected 2.28 million original posts from January 1, 2018, to December 31, 2023. These posts include content, publication date, user ID, user type, follower count, IP location (since April-May 2022?), and location keywords. Since Weibo and Xiaohongshu began publicly sharing IP data in April-May 2022, we retained only content with IP addresses located in Guangdong and Hong Kong, while posts without IP data were reserved for later processing.

To enhance data quality, a systematic data cleaning process combining rule-based filtering and semantic analysis via LLMs was implemented. First, duplicate posts were removed by retaining only the earliest submission from each user in case of similar or identical post content. Second, special characters, irrelevant data fragments, and hyperlinks were removed to standardized text formatting. Third, a text length filter was applied, retaining posts containing between 20 and 1000 characters to ensure sufficient content relevance. Posts originating from official media or high-influence accounts were excluded to minimize promotional content bias. Finally, posts identified as advertising or news reports were removed using the ChatGLM, preserving only those reflecting genuine user opinions. This process resulted in 1.01 million valid posts, forming the analytical basis for the subsequent spatial identity assessments.

Based on this dataset, posts originating from the Hong Kong cross-border population were identified and extracted, considering metadata and semantic content, including Hong Kong-specific dialects, topics, and cultural factors. While existing research often relies on metadata (e.g., IP address, time zone, user profile data, social network data) and text analysis for population identification, this study employed a multi-level method combining post metadata, user profile data, and LLM-assisted content analysis to accurately capture posts from the target demographic.

Initially, posts were preliminarily identified based on metadata. Posts were classified as originating from the Hong Kong cross-border population if their associated IP address or user profile explicitly indicated a Hong Kong location. For posts lacking such definitive metadata, LLM was employed to analyze language style, writing patterns, and semantic content to infer the users' origin (see Figure. 3).

Step 1: Identifying Cantonese versus Mandarin Usage: This step focused on distinguishing between Cantonese and Mandarin text in the posts. First, an LLM prompt was developed, leveraging the distinct vocabulary and grammatical characteristics of Cantonese. The prompt design explicitly outlined the key differences between Cantonese and Mandarin and highlighted specific features indicative of Cantonese. Subsequently, few-shot learning examples representing both languages were provided. The LLM was then tasked with assigning a probability score indicating the likelihood that each post was written in either language (the probabilities sum to 1). Posts assigned a Cantonese probability exceeding 50% proceeded to Step2 for further refinement, while the remaining posts (classified as primarily Mandarin) were analyzed in Step3.

Step 2: Distinguishing Cantonese Variants (Guangdong and Hong Kong): Given that Cantonese spoken and written in Hong Kong exhibits differences from that used in Guangdong, particularly regarding character usage, vocabulary choices, frequency of English loanwords/transliterations, code-switching patterns, and grammatical structures. Posts identified as Cantonese in Step 1 underwent further examination. Recognition rules specific to Hong Kong Cantonese were established, focusing on the mentioned features. Manually identified social media examples illustrating these distinctions, along with discriminative criteria were provided to the LLM. Posts assessed as having a Hong Kong Cantonese probability exceeding 50% were classified as originating from Hong Kong users; otherwise, they are classified as originating from Guangdong users.

Step 3: Identifying Hong Kong Cross-border Semantics in Mandarin Posts: For posts identified as primarily Mandarin, semantic prompts were used to detect content indicative of a Hong Kong perspective. Indicators included phrases suggesting movement patterns typical of cross-border residents, such as "going to Shenzhen" (implying departure from Hong Kong) or "returning to Hong Kong" / "back to Kowloon" (implying residence in Hong Kong). Accordingly, the prompt design first introduced key features characterizing a Hong Kong perspective—including references to departure location, habitual residence, return destination, and expressions of belonging—along with culturally specific Hong Kong terms (e.g., "high tea," "OT," "taking the lift"). Next, manually curated examples demonstrating these features were provided. Explicit judgment rules were defined, instructing the LLM to assign a binary value (1 for Hong Kong perspective present, 0 otherwise). Consequently, posts assigned a value of 1 were classified as originating from Hong Kong residents, while the remainder were classified as likely originating from Guangdong residents.

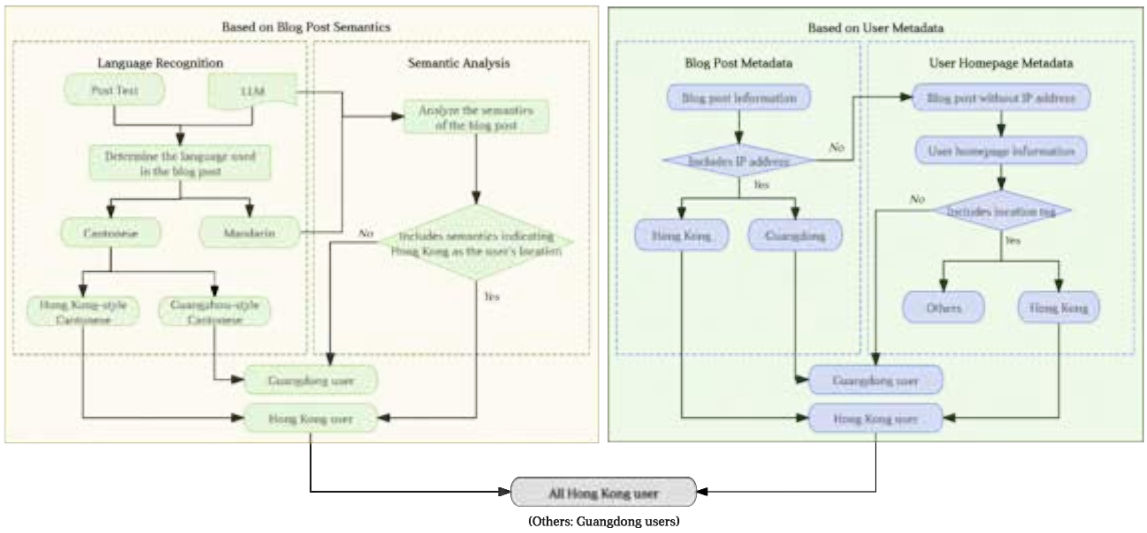

Figure 3: Crowd Identity Recognition Framework

To evaluate the performance of the developed LLM-based framework in differentiating user origins, we assessed its accuracy on distinct tasks. First, for differentiating Cantonese varieties (Steps 1 and 2), we compiled a test set comprising 100 samples each from the "Guangzhou Spoken Corpus" (representing Guangdong Cantonese) and the "Hong Kong MapTask Corpus" (representing Hong Kong Cantonese), supplemented by 200 Mandarin samples. The model (ChatGLM3) achieved 88% accuracy in distinguishing Cantonese from Mandarin, 100% accuracy in identifying Hong Kong Cantonese, and 74% accuracy for Guangdong Cantonese. Second, to evaluate the model's ability to identify a Hong Kong perspective in Mandarin text (Step 3), we addressed the absence of a suitable labeled corpus by generating synthetic data. Specifically, ChatGPT 4.0 was prompted to create 300 text samples exhibiting distinct Hong Kong-related semantic features; these samples were subsequently manually reviewed for quality and relevance. Evaluating the ChatGLM3 model against this curated, labeled dataset yielded a recognition accuracy of 81% for identifying the Hong Kong perspective. Overall, these results indicate that the proposed population identity recognition framework possesses robust discriminative capabilities. Following this validation, the framework was applied to classify the social media posts that initially lacked identifying metadata, assigning either a Hong Kong or Guangdong origin label to each. Finally, these newly classified posts were merged with the posts previously identified via metadata (IP address or user profile) to construct the final cross-border spatial social media text dataset. This comprehensive dataset serves as the foundation for the subsequent measurement of cross-border spatial identity.

4. Method

This study employed LLMs to assess cross-border spatial identity along three dimensions: spatial satisfaction, spatial imagery, and spatial sense of belonging. The methodology involved defining and labeling these dimensions, designing corresponding prompts for the LLM, computing identity scores for text data, and conducting attribution analysis (Figure. 4). After comparing models based on Chinese text analysis capabilities, response speed, and cost effectiveness, ChatGLM-3 was selected for implementation.

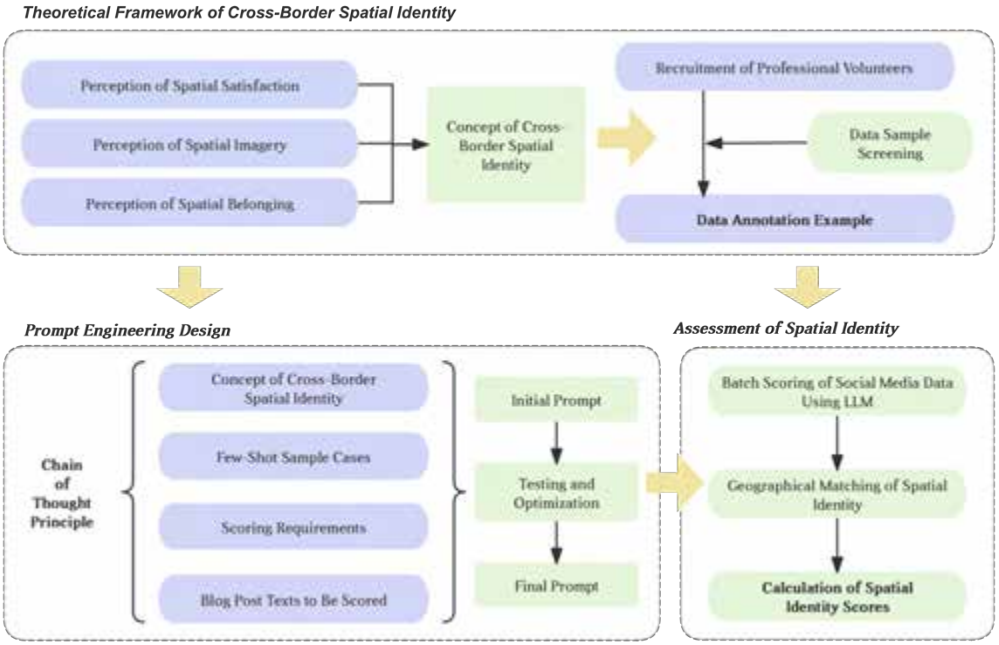

Figure. 4: Cross-Border Spatial Identity Recognition Framework

4.1 Definition and Labeling of Cross-Border Spatial Identity

Drawing on dynamic and hierarchical perspectives, this study proposes a framework comprising three dimensions to measure the cross-border spatial identity of Hong Kong residents concerning their activity spaces in Shenzhen (Casakin, Hernández and Ruiz, 2015).

1. Spatial Satisfaction: This dimension captures residents' evaluations of the quality and adequacy of the environment and facilities within the cross-border space, reflecting perceived convenience and suitability (Li et al., 2022). It assesses whether spatial functions meet individual needs, highlighting aspects significant for regional planning, such as public service provision, living convenience, and accessibility.

2. Spatial Imagery: This dimension relates to the residents' direct perceptual experiences of the cross-border space. It involves awareness of position and orientation, familiarity with spatial components and distinctive feature and the recalled events or memories associated with the space (Blajenkova, Kozhevnikov and Motes, 2006). Spatial imagery thus reflects the subjective impressions that shape the perceived character and image of a place.

3. Spatial Sense of Belonging: This dimension signifies the deep emotional attachment and loyalty residents develop towards the cross-border space. It manifests in behaviors such as willingness to engage in cross-border activities, protect the local environment, contribute to development, or make personal sacrifices for the place (Casakin, Hernández and Ruiz, 2015). This dimension underscores the planning objective of fostering inclusive and shared spatial environments.

Collectively, these dimensions represent a potential developmental trajectory where a strong sense of belonging emerges from cumulative positive spatial imagery and satisfaction. To quantify the perceived intensity for each dimension, this study employed an integer scale ranging from -3 (strong negative perception) to +3 (strong positive perception), with 0 indicating no discernible association. This approach frames the assessment of cross-border spatial identity as a three-dimensional multi-classification task, where each social media post is classified

according to the connotations expressed for each of the three dimensions.

To establish a benchmark for evaluating the LLM's performance, 10 volunteers with backgrounds in urban studies were recruited to manually annotate a sample of the social media data. These volunteers were provided with the definitions of the three cross-border spatial identity dimensions and asked to rate 500 randomly selected posts on the -3 to +3 scale for each dimension based on the text content. The resulting annotations were reviewed and refined by experts, establishing a reference standard for the abstract concept of cross-border spatial identity. This standard subsequently informed the design of few-shot learning prompts for the LLM and served as the basis for evaluating its measurement accuracy.

4.2 Prompt Engineering Design

Following the COT principle, the study designed a prompt engineering framework for scoring spatial identity using LLMs. The method guides the model's reasoning process step-by-step, thereby enhancing its ability to interpret complex semantic meanings in texts. Specifically, the framework comprises three steps: defining cross-border spatial identity, providing scoring examples, and iteratively refining the prompts.

Step 1: Definition. Cross-border spatial identity is defined in three dimensions: spatial satisfaction, spatial imagery, and spatial sense of belonging. This step clarifies the evaluation criteria and establishes a scoring range from -3 to 3, where negative values indicate negative identity, positive values indicate positive identity, and 0 denotes irrelevance.

Step 2: Scoring Examples. To instruct the model on the required logic and output format, the study present a small set of sample posts with corresponding scores and detailed reasoning for each emotional dimension. This step aids the model in accurately scoring spatial identity.

Step 3: Iterative Refinement. The effectiveness of the prompt design is evaluated through multiple rounds of testing, with continuous optimization based on model performance. Retry and backtracking principles are applied, requiring the model to review and correct its output (Yang et al., 2024). A self-consistency evaluation mechanism is also integrated to ensure the logical coherence and enhance result reliability (Wang et al., 2023). Additionally, the model is required to output its reasoning process and score explanations, thereby enhancing transparency. This approach has been shown to significantly enhance the reasoning capabilities of LLMs (Kojima et al., 2022).

Subsequently, the study employs the ChatGLM API, configured with the ChatGLM-3-turbo model, to assess the cross-border spatial identity of social media posts. Each post is individually embedded into the prompt and process to mitigate contextual interference. Posts are sequentially input into the model, which returns structured data. After sorting and cleaning, scores are assigned values of -3, -2, -1, 0, 1, 2, and 3, corresponding respectively to "Extremely Dissatisfied", "Dissatisfied", "Slightly Dissatisfied", "Unrelated to Spatial Identity", "Slightly Satisfied", "Satisfied", and "Extremely Satisfied". Posts scoring 0 were excluded (indicating irrelevance). Consequently, the final dataset comprises nearly 20,000 posts from Hong Kong and 687,000 posts from Guangdong, covering 15 spatial regions within Shenzhen. Each post is scored across the three defined dimensions.

4.3 Cross-Border Spatial Identity Scoring Model Evaluation

After computing the cross-border spatial identity scores, the study evaluates the LLM's performance. Precision and F1 score are adopted as evaluation metrics, as they are widely used in machine learning and have proven effective in sentiment analysis tasks. Precision is defined as the proportion of true positive instances (according to human annotations) correctly classified by the model. For example, in a post with a spatial sentiment score of 2, precision is the ratio of posts with a human-assigned score of 2 within the model's predicted category. The F1 score, calculated as the harmonic mean of precision and recall, provides a balanced evaluation of overall performance. The formulas are as follows:

$$Precision = \frac{|Correctly\ recognized|}{|All\ recognized|} \quad (1)$$

$$F_score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (2)$$

In this study, 500 posts were randomly selected from the cross-border social media dataset. Sentiment analysis tools (e.g., SnowNLP) and mainstream machine learning models (e.g., Support Vector Machines and Random Forests) were employed to score the spatial identity of these posts. These supervised models were trained using manually annotated spatial identity scores from Section 4.1, with the data partitioned into training, testing, and validation sets at ratios of 0.4, 0.4, and 0.3, respectively. Furthermore, since SnowNLP outputs continuous values between 0 and 1, the three-dimensional scores (spatial imagery, spatial satisfaction, and spatial belonging) from both the LLM and machine learning models were averaged and standardized to a range between 0 and 1 for comparison. Finally, using manual spatial identity scores from volunteers as benchmark labels, the models' performance was evaluated by calculating precision and F1 scores, thereby assessing the LLM's applicability in measuring cross-border spatial identity.

4.4 Cross-Border Spatial Scoring Indicators

Based on the cleaned scoring data, regional multidimensional spatial identity indicators were calculated for each region using the following formulas to quantify spatial imagery, satisfaction, and sense of belonging:

$$M_i = \frac{\sum_{j=1}^{N_i} p_{ij}}{N_i} \quad (3)$$

$$S_i = \frac{\sum_{j=1}^{N_i} q_{ij}}{N_i} \quad (4)$$

$$O_i = \frac{\sum_{j=1}^{N_i} t_{ij}}{N_i} \quad (5)$$

Where:

p_{ij} is the spatial imagery score of the j-th post related to region i;
q_{ij} is the spatial satisfaction score of the j-th post related to region i;
t_{ij} is the spatial sense of belonging score of the j-th post related to region I;
N_i is the total number of posts related to region i;
M_i is the average spatial imagery score for region i;

4.5 Attribution Analysis of Spatial Identity

LLMs can perform multi-dimensional evaluations of spatial identity on large-scale social media data and are capable of analyzing long texts and conducting inductive topic analysis (De Paoli, 2024). They can identify underlying meanings from sample annotations and qualitative data, thereby summarizing and generalizing vast amounts of qualitative text. In this study, the LLM analyzes social media data to uncover the driving factors behind spatial identity, akin to conducting semi-structured interviews (Dengel et al., 2023). The interview material comprises posts from platforms such as Xiaohongshu and Weibo, and the model's long-text analysis capabilities reveal core emotional features, enhancing the interpretability and credibility of the analysis. The process

involves the following steps:

1. Interview Guide Design: A semi-structured interview guide was developed for the LLM based on temporal and spatial influencing factors, spatial functions, changes in emotional identity.

2. Data Organization and Input: After obtaining the spatial identity scores for each region, social media posts were categorized into 90 groups based on five spatial types, three emotional dimensions, and six scoring outcomes. Each group was then summarized to form a database serving as the LLM's prior knowledge during the interview.

3. Model Inference and Interview: A semi-structured interview method was employed, using prompt engineering to guide the LLM in analyzing social media data and identifying spatial identity drivers. The prompts, designed in a role-playing format, instruct the LLM to act as a senior urban planning analyst to enhance its performance. Iterative questioning was applied to further probe underlying attributions when ambiguous or unexpected response emerged (Dengel et al., 2023).

4. Emotional Cause Induction: The LLM conducted an in-depth analysis of each text group, extracting underlying causes related to spatial identity and identifying potential influencing factors from the perspective of spatial function, along with providing targeted optimization suggestions.

Due to the ChatGLM's limitations in processing long texts, the Kimi Chat model was selected for further exploration. Through conversational prompts, attribution results for both positive and negative spatial identity across different spatial types were obtained. This approach combines quantitative and qualitative analyses, leveraging LLMs' strengths to offer a more comprehensive understanding of cross-border spatial identity.

5. Results

5.1 Measurement Results

This study evaluated the model's performance in scoring multi-dimensional cross-border spatial identity, comparing it against sentiment analysis tools (e.g., SnowNLP) and machine learning models (e.g., SVM) (Table 1). The LLM demonstrated superior performance, achieving 99% precision and an F1 score of 0.86, significantly exceeding the other models while closely aligning with human ratings.

Table 1. Comparison of cross-border spatial identity model assessments

	Precision	F1
LLM	0.99	0.86
SnowNLP	0.92	0.85
Random Forest	0.71	0.77
SVM	0.71	0.77
Logistic Regression	0.71	0.77
LightGBM	0.71	0.77

Table 2 presents the spatial identity perceptions of Shenzhen and Hong Kong residents. Guangdong residents consistently reported higher spatial identity than Hong Kong residents, consistent with literature indicating that local familiarity foster stronger place attachment (Hernández et al., 2007). Specifically, among the three dimensions, Hong Kong residents scored highest in spatial satisfaction (mean = 0.51) and lowest in spatial sense of belonging (mean = 0.34), with spatial imagery in between, indicating a more functional than emotional spatial identity toward Shenzhen. Similarly, Guangdong residents showed the lowest spatial sense of belonging, suggesting that robust emotional attachment and regional identity are more challenging to establish through short-term

cross-border interactions (Qian and Zhu, 2014).

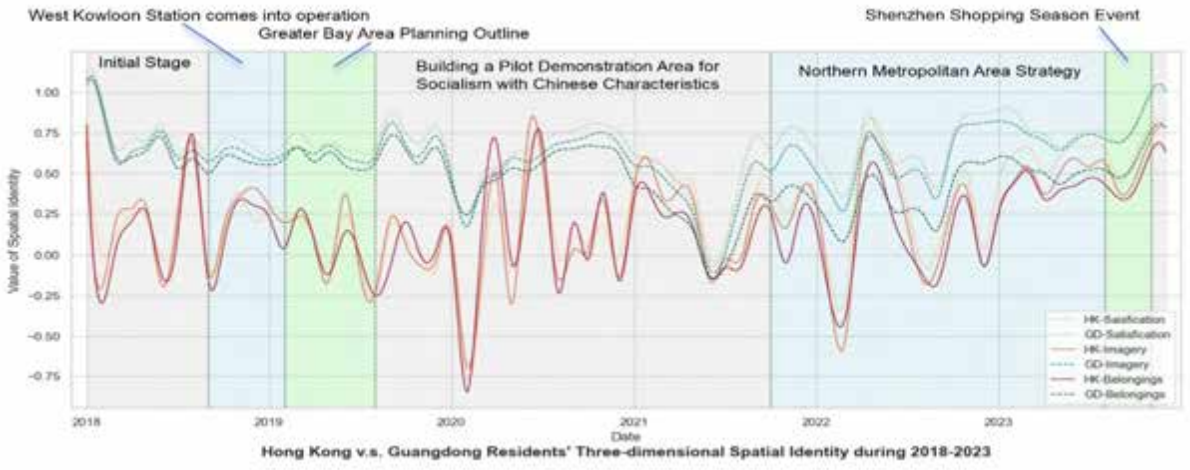
Despite a smaller sample size, Hong Kong residents exhibited greater variability in spatial identity perception than Guangdong residents. In contrast, Guangdong residents demonstrated more consistent spatial identity, likely reflecting more uniform spatial promotion and local culture in mainland China (Xie et al., 2020).

Table 2: Descriptive Statistics of Spatial Identity of Hong Kong and Guangdong Residents

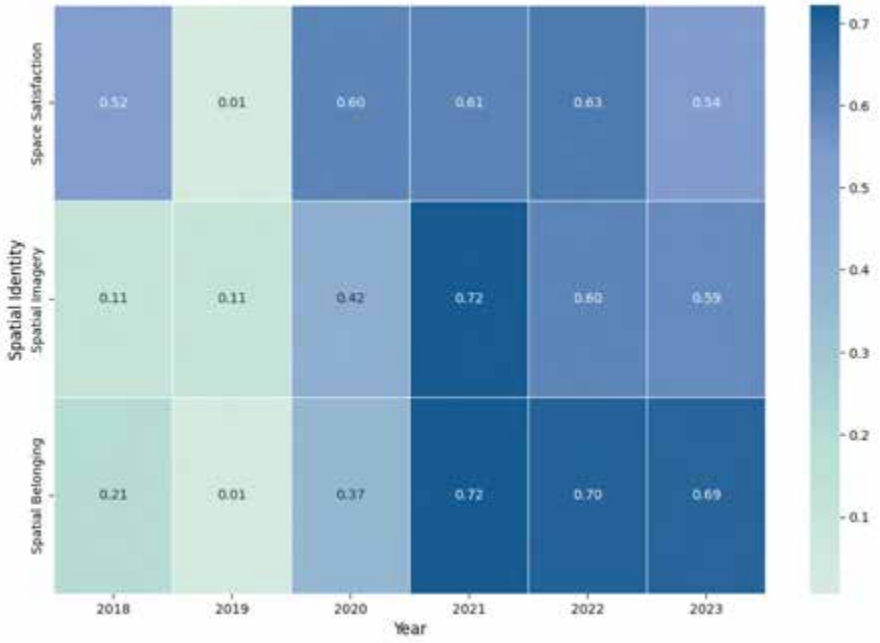
		Spatial Satisfaction	Spatial Imagery	Spatial sense of Belonging
Hong Kong	Mean	0.51	0.44	0.34
	SD	1.59	1.60	1.53
	observations	18374	17397	18421
Guangdong	Mean	0.71	0.70	0.47
	SD	1.55	1.57	1.44
	observations	664025	620594	669932

5.2 Temporal Heterogeneity

Figure. 5a illustrated the temporal evolution of cross-border spatial identity perceptions among Hong Kong and Guangdong residents, according to the timings of post publication. Cross-border spatial identity measured across three dimensions, fluctuated over time with alternating positive and negative values and consistent trends. For instance, in February 2020, Hong Kong residents' reached their lowest scores (satisfaction: -0.76; imagery: -0.69; belonging: -0.85), then experienced a brief peak in June-July 2020 (satisfaction: 0.68; imagery: 0.72; belongings: 0.70), followed by a rapid decline and recovery. Fluctuations intensified from 2021 to 2022, with the lowest scores in March 2022 (satisfaction: -0.24; imagery: -0.50; belongings: -0.37), and the highest in May 2022 (satisfaction: 0.76; imagery: 0.70; belongings: 0.55). After 2023, all dimensions gradually increased and stabilized. In contrast, Guangdong residents showed a more stable and consistently positive trend, with only minor fluctuations before 2020 and a slight decline in 2021 that recovered rapidly. Although the emotional disparity between the regions narrowed after 2021, the convergence reflects distinct regional dynamics in cross-border spatial identity.



a. Hong Kong v.s. Guangdong Residents' Three-dimensional Spatial Identity during 2018-2023



b. Correlation Matrix of Multidimensional Spatial Identity between Hong Kong and Guangdong Residents

Figure. 5a. Monthly Fluctuation Chart (Smoothed) b. Correlation Matrix of Multidimensional Spatial Identity between Hong Kong and Guangdong Residents

Fluctuations in Hong Kong residents' spatial identity were closely associated with key events in Hong Kong and Shenzhen, as well as regional integration policies. Significant shifts occurred during critical periods, such as the COVID-19 pandemic outbreak, the social unrest surrounding the extradition bill, the opening of West Kowloon Station, and the launch of the Greater Bay Area development plan. Specifically, between 2020 and 2023, the COVID-19 pandemic triggered marked declines in cross-border spatial identity, consistent with previous findings (Luo and Lam, 2020). Before the pandemic, gradual policy implementation maintained emotional connections; however, 2020's cross-border restrictions disrupted mobility and altered perceptions of Shenzhen. By 2023, as cross-border travel resumed, Hong Kong residents' spatial identity rebounded, with emotional intensity even surpassing pre-pandemic levels.

Similarly, sudden events such as the extradition bill protests might also affect Hong Kong residents' cross-border emotions. The protests in June 2019 led to a marked decline in cross-border spatial identity due to increased social tension and reduced mobility, while the 2020 National Security Law helped stabilize these fluctuations by boosting confidence in regional integration. (He et al., 2023). Although regional integration policies influence spatial identity, their net impact is moderated by key events and the pandemic, warranting further evaluation using econometric models.

Figure. 5a reveals significant differences in the trends and intensity of spatial identity dimensions between Hong Kong and Shenzhen residents. As shown in Figure. 5b, early in the study, the correlation between the regions' spatial identities was weak and divergent, with 2019 marking a clear trough when differences peaked. However, in 2020 and 2021, the correlation increased markedly, indicating reduced heterogeneity in spatial identity between the regions. This convergence likely reflects the progressive implementation of the Guangdong-Hong Kong-Macau Greater Bay Area development. The spatial satisfaction dimension consistently showed higher correlation, suggesting minimal heterogeneity, while spatial imagery and spatial sense of belonging initially showed more pronounced differences that diminished over time, particularly during 2020-2021. Overall, although some differences remain, the spatial identities of Hong Kong and Shenzhen residents are gradually converging under the

influence of policy initiatives and evolving cross-border dynamics.

5.3 Spatial Heterogeneity

The study categorized cross-border activity spaces into five types based on spatial functions: shopping and consumption, socio-cultural, leisure, border checkpoint, and policy spaces. Figure. 6a illustrates the geographical distribution of Hong Kong residents' cross-border spatial identity perceptions in Shenzhen, with colors denoting spatial types and bar heights representing identity strength. Evidently, Hong Kong residents' spatial identity varies with location types.

The study summarizes the spatial identity of Guangdong and Hong Kong residents across different spatial types. Hong Kong residents display distinct identity characteristics by function. In border checkpoint spaces, their spatial identity scores were low across all dimensions (0.1, 0.21, 0.05), significantly lower than in other spaces. This suggests that, although border checkpoint spaces are essential for cross-border movement, their limited facilities and services fail to fully meet cross-border needs. However, Hong Kong residents' spatial sense of belonging in these spaces was slightly higher than that of Guangdong residents, reflecting a stronger functional dependence. In contrast, shopping and consumption as well as socio-cultural spaces elicited the highest spatial identity scores among Hong Kong residents. In shopping and consumption spaces, scores peaked for spatial imagery (0.99), spatial satisfaction (1.33), and spatial sense of belonging (0.92), suggesting that these spaces best meet Hong Kong residents' needs for convenience and diverse facilities (Wang, 2004; Sharma, Chen and Luk, 2018). Shenzhen's advanced shopping services foster positive spatial imagery and, through routine activities, enhance emotional attachment and spatial belonging. Conversely, policy spaces received relatively lower identity scores, likely because their services primarily cater to mainland China.

Overall, Hong Kong residents demonstrate the strongest emotional attachment to shopping and cultural spaces, while their attachment to border and policy spaces is weaker. Guangdong residents demonstrate a similar trend. These findings marked significant spatial heterogeneity in cross-border spatial identity, suggesting service and facility imbalances that offer a comprehensive geographic perspective for policy development.

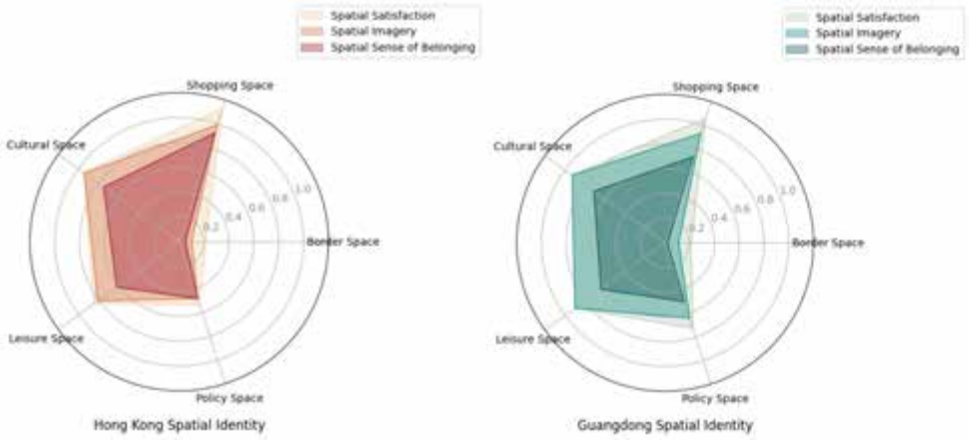
b. Geographic distribution of Guangdong spatial identities in various types of cross-border spaces



c. Hong Kong v.s. Guangdong Residents' Three-dimensional Spatial Identity during 2018-2023

Figure. 6 a. Geographic distribution of spatial identities in various types of cross-border spaces; b. Radar map of three-dimensional spatial identity perceptions of Hong Kong and Guangdong residents.

5.4 Qualitative Attribution Analysis

The study employed LLM's long-text mining and summarization capabilities to conduct an attribution analysis on blog posts with varying identity scores among Hong Kong residents. A semi-structured prompt process was established to investigate the drivers of spatial identity. The results indicate that although there some common factors significant differences emerge concerning spatial functions.

Negative spatial identity among Hong Kong residents was chiefly driven by functional deficiencies and inadequate management services. Specifically, issues such as traffic congestion, overcrowding, and poor spatial layouts were prevalent in border checkpoint, shopping and consumption, and leisure spaces (e.g., "Futian checkpoint is too crowded," "Shenzhen Bay Park... the long queues and traffic jams are exhausting," "The mall's layout is poor, I always get lost," "During National Day, I couldn't even get on the subway"). These factors diminished spatial identity perceptions. Moreover, each space type presented specific problems. For example, negative reviews of border checkpoint spaces cited problematic customs policies and poor transportation hub management, whereas critiques of shopping and leisure spaces focused on product quality and service attitudes (e.g., "The crabs bought in Shenzhen are half the price of those in Hong Kong").

In contrast, positive spatial identity was more consistent, driven by modern infrastructure, comprehensive services, diverse consumer experiences, and rich cultural activities. Improved facilities at some border checkpoint spaces enhanced spatial satisfaction ("Luo Hu station's free dedicated passage always has enthusiastic and polite staff"), and shopping and consumption spaces were praised for competitive pricing and products variety (e.g., "Prices are half of what they are in Hong Kong"). Similarly, leisure spaces were appreciated for natural scenery and outdoor activities, boosting both spatial imagery and satisfaction (e.g., "The beautiful view at Wutong Mountain helped me relax"). Socio-cultural spaces fostered a sense of participation and belonging (e.g., "The cultural atmosphere here makes me feel at home"), and policy spaces reinforced confidence in regional integration (e.g., "The future of the Lok Ma Chau Loop area will be prosperous!").

Additionally, the spatial drivers of three emotional evaluations reflect not only functional attributes but also subjective perceptual differences in cross-border activities. For example, the impact of border-crossing efficiency on spatial identity varies with time and crowd density, while evaluations of shopping spaces involved interactions among price, layout, and service quality. Cultural activities and natural landscapes uniquely contributed to positive identity formation.

Based on these findings, the study further validates the accuracy of the LLM's attribution extraction by analyzing original negative posts for the presence of identified factors. Frequency data in Table 3 supports the reliability of the text analysis; common factors such as traffic congestion, overcrowding, and disordered spatial layouts were frequently noted. Notably, in border checkpoint spaces, complex customs procedures (32.26%) and poor transportation hubs service (4.74%), were prominent. Similarly, issues of poor product quality and inadequate service in shopping and leisure spaces were substantiated. Overall, these results confirm the effectiveness of the LLM in long-text analysis and support the credibility of the spatial attribution analysis.

Table 3. Frequency of occurrence of spatial identity-driven elements in the original blog post

Space Type	Posts No.	Traffic congestion	Pedestrian congestion	Confused spatial layout	Poor quality of goods	Poor services
Political	1359	0.37%	2.87%	0.66%	1.25%	0.59%
Cultural	2061	0.92%	8.05%	1.36%	0.87%	0.63%
Leisure	2110	0.95%	6.59%	0.57%	1.09%	0.90%
Consumption	2191	0.27%	10.45%	1.14%	2.83%	1.51%
	No. Posts	Traffic congestion	Pedestrian congestion	Confused spatial layout	Cumbersome clearance policies	Poor services at transport hubs
Border	10078	4.20%	15.24%	1.88%	32.26%	4.74%

In conclusion, LLM-based long-text mining revealed the key spatial drivers of diverse perceptions of Shenzhen's cross-border spaces. Specifically, functional factors (border-crossing efficiency, transportation convenience, and facility layout) and experiential factors (cultural activities, consumer experiences, and natural landscapes) emerged as critical. Negative emotions were primarily linked to functional deficiencies, while positive emotions were correlated with high-quality spatial attributes and experiential benefits. Analyzing original blog posts further improved the interpretability and reliability of cross-border spatial identity, offering valuable insights for spatial planning and management.

6. Conclusion & Discussion

As a critical psychological mechanism underlying cross-border activities, cross-border spatial identity not only shapes residents' cross-border behaviors but also exerts a profound impact on the planning and construction of cross-border spaces and the process of regional integration. However, measuring it is challenging due to conceptual ambiguity, contextual complexity, data scarcity, and methodological limitations. The study develops a systematic, scalable, and data-driven approach to quantifying cross-border spatial identity, integrating social media data to capture the perspectives and emotions of cross-border residents while leveraging large language models (LLMs) to interpret spatial identity perceptions. We utilize the framework to examine its temporal evolution, spatial and demographic heterogeneity in Shenzhen-Hong Kong cross-border areas. The findings contribute to a deeper understanding of intra-regional connectivity and residents' sense of belonging, providing a theoretical foundation for cross-border spatial planning and development.

This study introduces a precise, efficient, and scalable framework for the long-term tracking and recognition of cross-border spatial identity, validating the effectiveness of LLMs in integrating quantitative and qualitative approaches for measuring the perception. Traditional methods like surveys are limited by small samples, high costs, low temporal resolution, and inability to capture dynamic evolution. Traditional machine learning models also struggle with the abstract nature of spatial identity, hindering precise identification and quantification. Moreover, they often neglect socio-cultural nuances, require language-specific retraining, and demand extensive labeled data, limiting scalability. In contrast, our LLM-based approach leverages zero-shot learning and advanced text comprehension to analyze complex semantics. First, by embedding a detailed definition of cross-border

spatial identity via prompt engineering, and using a multilingual LLM supporting both Chinese and English, we achieve unified text recognition across different languages. Subsequently, validation against expert annotations confirmed the LLM's effectiveness in analyzing complex spatial identity-related text and performing fine-grained sentiment classification. The findings underscore the substantial advantages of LLMs in analyzing complex emotions and multidimensional perceptual constructs, capturing nuanced emotional fluctuations and variations in identity. Particularly in cross-cultural and cross-regional sentiment analysis, LLMs have demonstrated unique potential, significantly enhancing the depth and breadth of cross-border spatial identity measurement.

Also, the study uses long-time-series social media data to reveal the dynamic evolution of cross-border spatial identity in the Shenzhen-Hong Kong cross-border areas. By analyzing residents' perceptions over the period from 2018 to 2023, the study captures shifts in cross-border social relations and regional integration. This longitudinal perspective enables identification of key regional events (e.g. the COVID-19 pandemic, the extradition bill protests, and major policy changes) influencing cross-border spatial identity, aligning closely with prior research (Guinjoan and Rodon, 2014; Borz, Brandenburg and Mendez, 2022). Unlike static cross-sectional studies, our longitudinal approach identifies cyclical patterns, sudden disruptions, and gradual transformations in cross-border spatial identity over time. By capturing the interplay between structural factors (e.g., policy shifts, infrastructure development) and individual experiences, this approach facilitates a deeper exploration of the causal mechanisms underlying changes in cross-border spatial identity.

Additionally, the study explores the differing cross-border spatial identity between Guangdong and Hong Kong residents. The findings indicate that Guangdong residents exhibit significantly higher spatial identity than Hong Kong counterparts. This dual-perspective analysis reveals distinct identity preferences and underscores the need to accommodate diverse demands in cross-border spatial planning. Addressing these variations requires a nuanced understanding of the unique socio-cultural characteristics of border regions for targeted and equitable policy interventions.

Furthermore, the study identifies significant heterogeneity in cross-border spatial identity across different functional spaces. For Hong Kong residents, border checkpoint areas exhibit the lowest levels, whereas shopping and consumption spaces generate the highest. These variations across spatial dimensions provide a deeper understanding of identity differentiation in Shenzhen's cross-border spaces and support empirically grounded optimization of spatial design and policy formulation. For example, areas with low spatial identity, such as border checkpoint spaces may require transportation infrastructure and efficiency improvements. At the same time, for specific groups (such as people with disabilities and business commuters), fast-track channels and convenient services should be added to improve travel experience. While areas with high spatial identity like socio-cultural and leisure spaces could benefit from optimizing spatial design and environmental quality, introducing more cultural integration elements, and diversifying activity forms. For shopping and consumption spaces, where spatial identity is stronger, it is important to maintain advantages in pricing, product quality, and services, while further exploring the diversity of spatial functions. For example, integrating dining, entertainment, and other functions to expand the consumption experience can enhance the overall attractiveness and impact of cross-border spaces. By tailoring interventions to specific functional space characteristics, overall spatial identity can be enhanced, promoting the integrated development of Shenzhen-Hong Kong cross-border spaces.

This study also has certain limitations that warrant further investigation. First, the proposed framework for cross-border spatial identity recognition may be affected by LLM hallucinations in text reasoning and generation, stemming from inherent stochastic processes in the LLM architecture. This variability could lead to inconsistencies in sentiment evaluation, so future studies should conduct comprehensive validation and performance assessments of LLMs to ensure their reliability, applicability, and robustness in spatial identity measurement. Secondly, the reliance on social media data, which predominantly represents younger demographics, may introduce bias due to limited participation from children and older adults (Marchi et al., 2022). To mitigate this, future studies should incorporate complementary data sources—such as surveys, interviews, and other additional textual datasets—to achieve a more comprehensive understanding of..... Finally, the linguistic similarities

between Cantonese and Mandarin mean that language distinctions have not been fully explored in this study. Consequently, the extent to which LLMs can effectively handle complex cross-linguistic variations remains insufficiently tested. Future research should expand the geographical scope to include multilingual and multicultural border regions, enabling a more rigorous evaluation of the applicability and robustness of LLM-based spatial identity measurement across diverse linguistic contexts.

Leveraging Digital Platforms for Circular Economy Implementation in the AECO Industry: Insights from Public-Private Partnerships

Abstract
Digital platforms are increasingly adopted in the built environment to advance circular economy goals, yet their capacity to align policy and technology remains unclear. This paper examines how platforms enable or obstruct alignment in Public-Private Partnership (PPP) projects. A mechanism-oriented systematic literature review (SLR) of 24 studies identifies three alignment failures: lifecycle misalignment, platform–governance decoupling, and mobility-driven flow disruption. A three-tier coding framework—covering lifecycle stages, governance roles, and data flows—supports the analysis. Rather than calling for more platforms, the paper argues that circular transformation requires viewing platforms as institutional infrastructures that coordinate actors, data, and policy. It concludes with a conceptual alignment model, inviting empirical validation and adaptation, especially in regions with limited capacity and fragmented governance.

Keywords: Digital Platforms, Circular Economy, Public-Private Partnerships (PPPs), Policy–Technology Alignment, Governance

1.Introduction

The building sector, as a major contributor to global carbon emissions and resource depletion, is facing mounting pressure to transition toward circular economy practices (D'Amico et al., 2022). While digital tools such as Building Information Modeling (BIM), the Internet of Things (IoT), and Digital Twins have proliferated across the Architecture, Engineering, Construction, and Operations (AECO) industry, their deployment remains fragmented—mostly concentrated in early lifecycle stages and lacking systemic integration across the full project timeline (Dervishaj and Gudmundsson, 2024). More recently, generative AI and parametric design systems have emerged to support scenario-based optimisation and lifecycle-informed circular strategies in the design phase, yet their integration into platform-level governance remains limited.

Public-Private Partnerships (PPPs), increasingly adopted for large-scale infrastructure delivery, offer institutional leverage and cross-sector governance potential (Hueskes, Verhoest and Block, 2017). However, much of the current literature treats digital tools and policy frameworks in isolation, overlooking how digital platforms—within which these tools operate—can function as integrative infrastructures. In this study, digital platforms are conceptualised as socio-technical systems that coordinate policies, actors, and data flows throughout the building lifecycle. Digital tools (e.g. BIM, IoT, parametric design software) are understood as operational components embedded within these platforms, enabling specific functions such as simulation, traceability, or design optimisation. Governance refers to the institutional arrangements (e.g. PPP contracts, procurement mandates) that shape how platforms distribute roles, authority, and accountability. Alignment denotes the functional coherence between policy intentions and technological execution. Rather than focusing on tool adoption alone, this study foregrounds the platform as the central mechanism through which policy–technology coordination is structured (Figure 1).

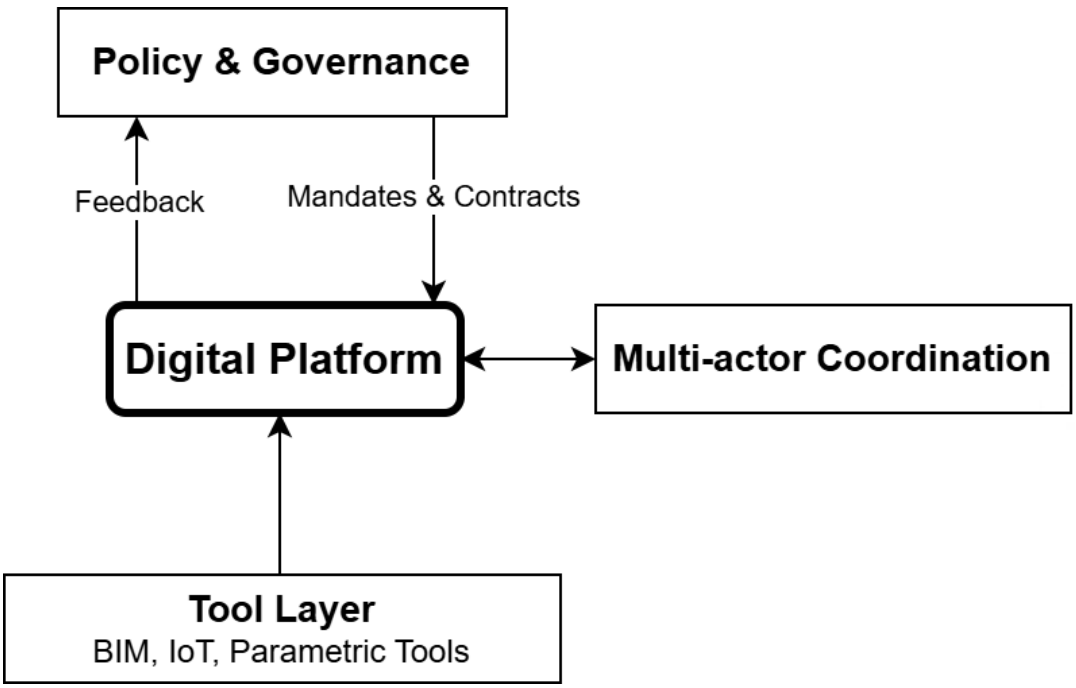

Figure 1. Platform–Tool–Policy Alignment Pathway

This paper introduces the concept of a Platform-enabled Policy–Technology Alignment Mechanism—a structural lens to examine how digital platforms mediate the interface between policy goals and technological interventions. It posits that structural misalignments between policy intentions, platform capabilities, and digital tool deployments are a key barrier to circular economy implementation in PPP-driven construction projects.

Drawing on a mechanism-oriented systematic literature review (SLR) (Pati and Lorusso, 2018), this study addresses the following questions: (1) how platform-embedded tools are distributed across different lifecycle stages in PPP contexts? (2) To what extent do platforms enable or constrain the alignment between policies and technologies? (3) What coordination bottlenecks and governance asymmetries emerge among stakeholders?

The findings provide a structured synthesis of alignment failures and coordination patterns, offering both a conceptual framework and actionable insights to support circular transformation in PPP-led AECO systems. This paper develops a policy–platform–technology alignment model to map structural mismatches and propose mechanisms for coordination in circular infrastructure governance.

2. Methodology: A Mechanism-Oriented Systematic Literature Review

This study adopts a mechanism-oriented systematic literature review (SLR) to explore how digital platforms mediate alignment between policy objectives and technological deployments in Public-Private Partnership (PPP) projects pursuing circularity in the AECO sector. Unlike traditional reviews that catalogue tools or trends, this approach focuses on identifying structural patterns of misalignment and coordination, with the aim of building a conceptual model of policy–platform–technology alignment.

2.1 Search Strategy and Screening Process

This study adopted a structured search strategy targeting the intersection of circularity practices, digital tools, lifecycle stages, and PPP governance frameworks. Four search strings were constructed (see Appendix A) to identify publications addressing either technological integration or collaborative mechanisms in the context of the built environment. The search was conducted across Web of Science, Scopus, and ScienceDirect, covering the

period 2014–2024. Only peer-reviewed journal articles and review papers in English were retained.

An initial pool of 184 articles was retrieved. After deduplication, title and abstract screening was conducted based on the following criteria: focus on the AECO sector, clear emphasis on circular economy practices (e.g., reuse, efficiency), mention of digital technologies (e.g., BIM, IoT, digital platforms), Reference to PPPs or multi-stakeholder coordination.

This stage resulted in 106 articles, which were further subjected to full-text screening. The final inclusion criteria required the study to: analyse digital tool deployment across lifecycle stages, discuss platform functions or governance roles, provide sufficient methodological and empirical detail to enable coding. After full-text assessment, 24 studies were retained for in-depth analysis and mechanism construction (see Figure 2).

2.2 Literature Screening Process

The review process followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) four-step model: identification, screening, eligibility, and inclusion (D'Amico et al., 2022). Full-text evaluation was conducted on 78 articles, leading to the selection of 24 core studies for detailed coding and mechanism abstraction.

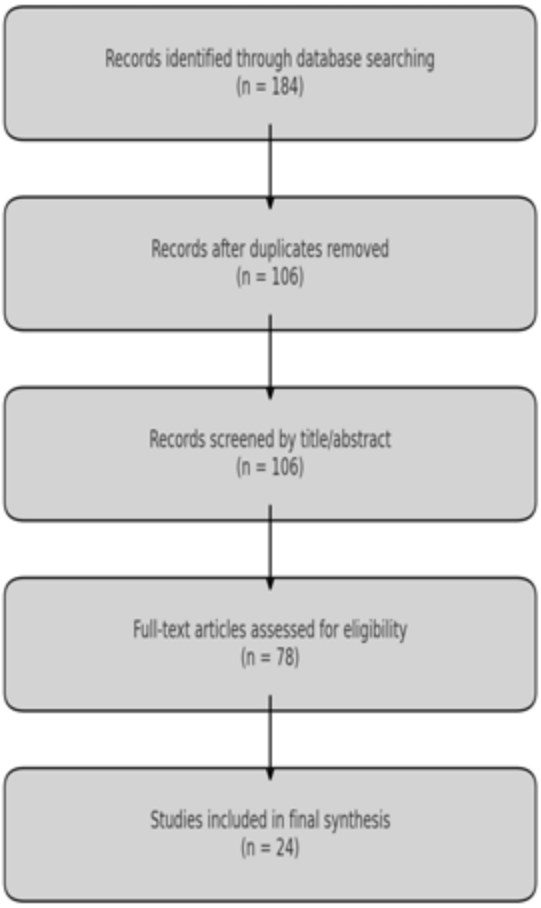

Figure 2. The PRISMA Flowchart

2.3 Data Extraction and Coding Framework

To go beyond static descriptions of digital tool usage, this study draws on Mobility Theory (Urry, 2007) as a conceptual lens to identify dynamic coordination mechanisms in PPP-based circular construction. Urry conceptualises modern systems as constituted by various forms of "flows"—including people, policies, materials, and information—which shape how institutions interact and evolve. In this context, platforms are not merely technical infrastructures but dynamic orchestrators of flow-based alignment across lifecycle stages and stakeholders.

Guided by this theoretical perspective, the coding framework integrates both structural and dynamic variables to capture how policy–platform–technology alignment is realised or constrained in practice. To capture both static structures and dynamic interactions underlying alignment processes, a three-tier coding framework was developed. Each retained study was analysed across the following dimensions (Table 1):

(1) System Structure Dimension — capturing technological deployment across the lifecycle;
(2) Platform Governance Dimension — capturing institutional design and platform functions;
(3) Mobility Flows Dimension — capturing dynamic flows of data, policy, and human coordination.

Table 1. Coding framework for analysing digital-platform-enabled alignment mechanisms

Dimension	Sub-Dimension	Examples
STRUCTURE	Lifecycle Stage	Design / Construction / Operation / Renovation / Demolition
	Digital Tool Type	BIM / IoT / Digital Twin / GIS / Blockchain
PLATFORM GOVERNANCE	Circular Economy Goal	Reuse / Efficiency / Emission Control
	PPP Model	Housing / Infrastructure / Public Works
	Platform Function	Monitoring / Coordination / Data Sharing
MOBILITY FLOWS	Policy Flows	Green Procurement / Policy Feedback / Regulatory Embedding
	Data Flows	Transparency / Traceability / Real-time Sensing via IoT
	Human Flows	Multi-stakeholder Collaboration / Cross-sector Teams / Role Integration

This coding framework enabled the abstraction of empirical patterns into a three-layer mechanism model: policy intentions, platform functions, tool deployments, which serves as the analytical structure for Section 3.

3. Results: Mechanism Construction from Literature Synthesis

This section presents the three core mechanisms derived from the systematic coding of 24 selected studies. Moving beyond thematic summaries, these mechanisms reflect structured patterns of alignment and misalignment between policy intentions, platform functions, and digital tool deployments in circular Public-Private Partnership (PPP) projects.

Based on the three-tier framework (Figure 3), the mechanisms are constructed through variable convergence across structural layers (e.g., tool type, lifecycle stage), governance design (e.g., PPP role, platform coordination), and flow dynamics (e.g., policy, data, and stakeholder mobility).

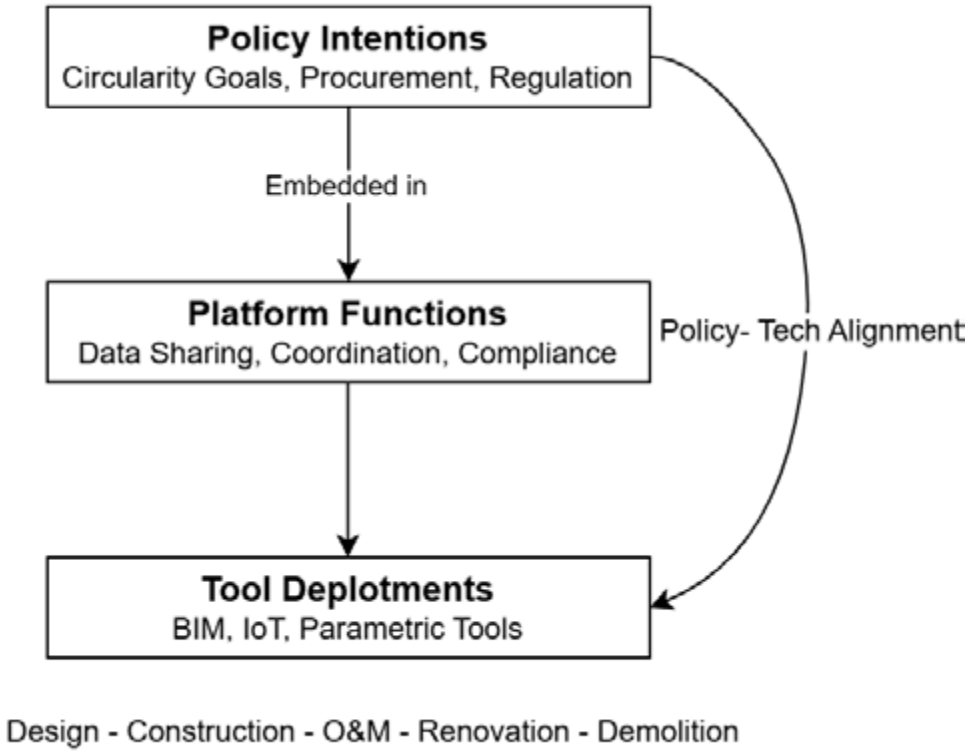

Figure 3. Platform-Enabled Alignment Model. This conceptual framework illustrates how digital platforms mediate structural alignment across policy intentions, technological tools, and governance mechanisms

Table 2. Mapping of extracted mechanisms to coding dimensions and empirical patterns in the literature

Mechanism	Key Misalignment / Enabler	Relevant Coding Dimensions	Empirical Support (n/24)
Lifecycle Misalignment	Tools heavily concentrated in early stages; renovation/demolition under-digitised	Lifecycle Stage, Digital Tool Type	20+ mention early-stage tools; <5 mention demolition/renovation
Platform–Governance Coupling	PPP structure and governance roles often unclear or missing	PPP Project, Governance Role, Policy-Tech Alignment	Only 4 explicitly focus on PPPs; 11 specify governance
Mobility-Driven Synchronisation	Policy, data, and human flows poorly integrated across lifecycle	Mobility: Policy Flows, Data Flows, Human Flows	Mobility flows rarely co-occur; dynamic feedback poorly explored

The mechanisms are summarised in Table 2. Together, these mechanisms illustrate that digital platforms are not merely technical infrastructures, but dynamic governance intermediaries that shape the success or failure of circular transformation in PPP settings. The details are elaborated in the following subsections.

3.1 Lifecycle Misalignment Mechanism

This mechanism captures the structural misalignment between digital tool deployment and the full building lifecycle in circular construction projects. While circularity principles advocate a closed-loop system across all lifecycle stages, from design to demolition, the analysis reveals a strong front-end concentration of technological interventions.

Based on the coding of 24 studies, over 80% mention tool applications in design, construction, or operation stages, while fewer than 5 papers explicitly reference refurbishment or demolition phases. Table 1 shows that tools such as BIM, IoT, and GIS dominate the early lifecycle, while end-of-life stages are largely under-digitised. This lifecycle asymmetry results in "digital blind spots", particularly where traceability and material recovery are critical to achieving circularity goals (Dervishaj and Gudmundsson, 2024).

For instance, although BIM is extensively used for planning and coordination during design and construction, very few studies explore its integration into disassembly modelling or deconstruction logistics. Similarly, Digital Twins—while theoretically suited for long-term lifecycle tracking—are rarely applied beyond building operation phases (Azcarate-Aguerre et al., 2022; Benedetti et al., 2022).

This misalignment is reinforced by two structural gaps: (1) a lack of regulatory mandates linking demolition data to material reuse policies, and (2) the absence of platform-level integration strategies that span the full lifecycle. As a result, even advanced digital platforms struggle to support closed-loop feedback, since critical end-of-life data never enters the system.

The Lifecycle Misalignment Mechanism thus reflects a fundamental weakness in circular PPPs: unless digital tools are embedded across the entire lifecycle—including post-use and reuse phases—policy objectives related to material recovery and traceability will remain aspirational and structurally unsupported.

3.2 Platform–Governance Coupling Mechanism

This mechanism highlights how the absence of robust governance structures within PPP projects weakens the ability of digital platforms to function as alignment mechanisms between policy objectives and tool deployments. While digital platforms are widely recognised for their technical capabilities, their actual performance in circular construction depends on how well they are embedded in the institutional and contractual fabric of PPP governance.

Among the 24 studies analysed, only 4 explicitly focus on PPP projects, and merely 11 provide any detail on the governance configuration (e.g., public-led, private-led, or joint arrangements). In many cases, the role of digital platforms is reduced to data repositories or coordination layers, with little attention to how they enforce contractual compliance, stakeholder incentives, or data sovereignty. As a result, platforms often fail to translate policy ambitions into enforceable lifecycle practices (Yu et al., 2023; Chartier and Pot, 2024)integrated information systems that are capable to identify, coordinate, and evaluate CE collaborations across heterogeneous projects are in demand. A digital collaborative hub, Circularity Information Platform (CIP. This is illustrated in Figure 4.

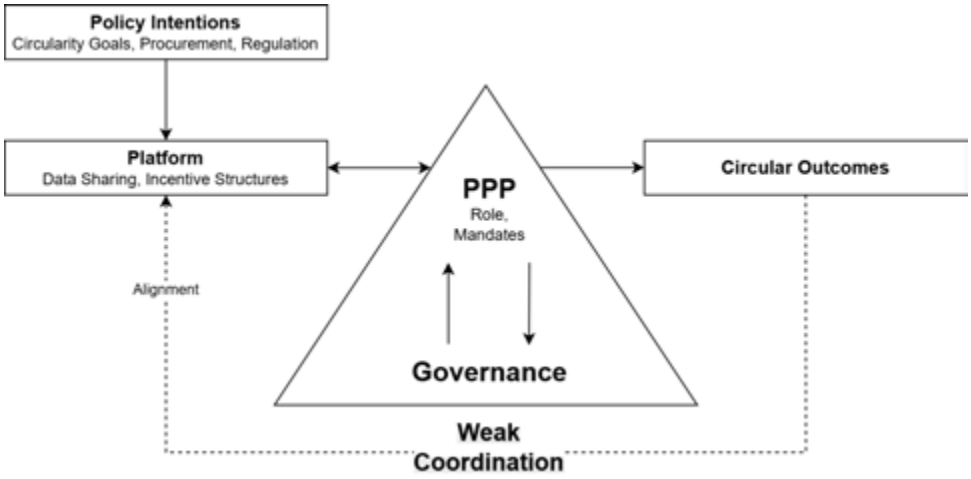

Figure 4. Platform–Governance Coupling Mechanism: illustrating weak contractual and institutional integration between platform, public authority, and private sector

For instance, Serrano (2022) show that platform efficacy in circular PPPs depends on contractual clauses that define responsibilities, access rights, and data transparency rules among actors. Without such governance scaffolding, platforms remain technically functional but politically inert. Similarly, Teigiserova and Schraven demonstrate that circularity outcomes in Dutch PPP housing projects were only achieved when platforms were backed by formal procurement mandates and institutional incentives (Teigiserova and Schraven, 2024).

The mechanism is further complicated by fragmentation between policy design and platform development. Many digital systems are developed by technology vendors or municipalities in silos, while policy makers and regulators are not involved in platform logic. This leads to implementation gaps—platforms that track data but lack authority, or policies that demand outcomes with no tool-based enforcement mechanism.

The Platform–Governance Coupling Mechanism thus reveals that alignment failure is not a technological problem, but a governance one. Without embedded authority, platforms cannot coordinate actors, distribute accountability, or translate circular goals into operational mandates.

3.3 Mobility-Driven Synchronisation Mechanism

3.3 Mobility-Driven Synchronisation Mechanism

This mechanism builds on Mobility Theory (Urry, 2007), which views modern systems as constituted through flows—of people, policies, information, and goods. In the context of circular PPPs, platform efficacy depends not only on structural deployment and institutional design, but also on the ability to synchronise multiple flows across the lifecycle and actor network.

However, the analysis reveals significant flow decoupling in the literature. Although 18 studies mention policy–technology alignment in some form, very few articulate how policy updates are operationalised through platforms, or how real-time data is used for feedback into regulatory processes. Furthermore, only a minority of studies (Yu et al., 2023; Teigiserova and Schraven, 2024) discuss cross-organisational collaboration as an embedded feature of platform logic.

For instance, in the Dutch "Circular Information Platform" case, Yu et al (2023) describe how material databases, LCA tools, and design software were interconnected, while the system relied on external incentives rather than integrated flow coordination. Similarly, Chartier & Pot observed that while policy dashboards existed in Nijme-

gen's PPP platform, there was little integration of citizen feedback or inter-departmental data exchange (Chartier and Pot, 2024).

Urry's framework helps explain why platforms often fail despite high technical capacity: these coordination breakdowns are illustrated in Figure 5, where policy, data, and human flows are depicted as interdependent but weakly synchronised. Solid arrows indicate desired coordination pathways (e.g., data flows enabling policy feedback), while dashed lines represent fragmentation. For instance, data from BIM/IoT platforms is often not fed back into procurement criteria (policy flow), and human collaboration across design, regulatory, and contracting units lacks institutional support (human flow). This weak synchronisation undermines the platform's potential to enable adaptive and circular outcomes.

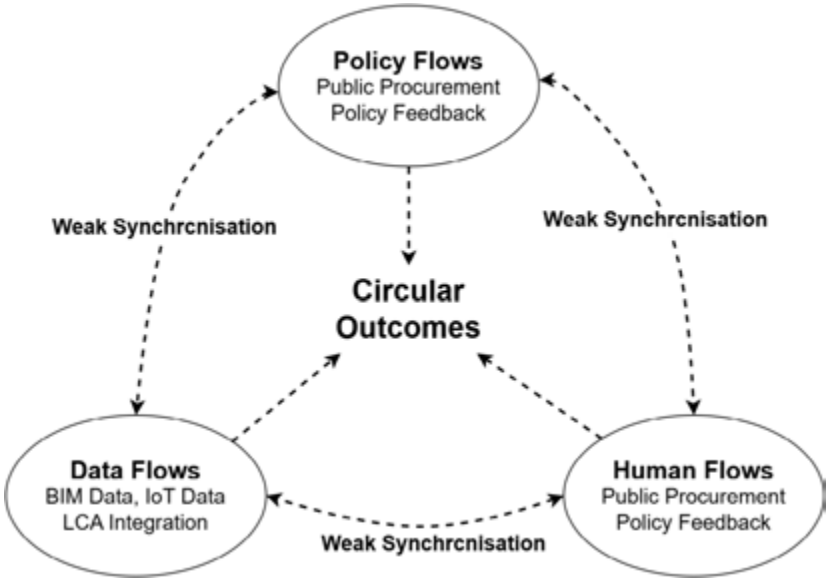

Figure 5. Mobility-Driven Synchronisation Mechanism. The diagram illustrates how circular outcomes depend on the effective synchronisation of policy flows, data flows, and human collaboration via digital platforms

The Mobility-Driven Synchronisation Mechanism therefore captures a dynamic misalignment: unless platforms are designed as multi-flow synchronisation infrastructures—connecting policy intentions, real-time data, and actor actions—they will fail to deliver system-wide circularity, regardless of governance or tool sophistication.

These three mechanisms collectively reveal that platform-based circularity in PPPs cannot be achieved through technical deployment alone. Structural coverage, institutional anchoring, and dynamic flow synchronisation are all necessary conditions for meaningful alignment between policy ambitions and material outcomes.

4. Discussion: Toward Mechanism-Informed Circular Governance

4.1 Translating Alignment Mechanisms into Design Challenges

This study identifies three systemic misalignments—lifecycle concentration, governance fragmentation, and flow decoupling—that collectively limit the capacity of digital platforms to support circular outcomes in PPP contexts. Each mechanism signals a distinct but interdependent research challenge:

(1) Lifecycle misalignment: The concentration of digital interventions in early building phases leaves end-of-life

stages under-digitised. Research should explore platform functionalities that support downstream activities, such as design-for-disassembly, demolition-data feedback, and reuse tracking.

(2) Platform–governance decoupling: Platforms often lack formal authority, operating as passive repositories rather than active coordinators. Future work should investigate how PPP contracts, institutional mandates, and platform governance roles can be re-designed to embed platform authority.

(3) Mobility-driven flow disruption: Digital platforms rarely synchronise the dynamic flows of policy, data, and people across lifecycle stages. Platform design must evolve to support cross-department data exchange, real-time feedback mechanisms, and contractual incentives for collaboration.

Together, these challenges call for a shift from platform deployment to platform architecture design—not just what platforms do, but how they govern, integrate, and learn across time and scale. Moreover, the three mechanisms do not operate in isolation—lifecycle gaps amplify governance ambiguities, while both undermine the potential for flow synchronisation. Understanding these interdependencies is key to platform redesign.

4.2 Regional and Conceptual Research Gaps

Despite the growing attention to circular platforms, the literature remains skewed toward Western European case studies, often situated in digitally mature, policy-rich contexts. These insights require adaptation to regions where PPPs face limited digital infrastructure, fragmented governance, or weaker enforcement environments.

Conceptually, terms like “integration” or “participation” are used rhetorically without institutional detail, and “digital tools” are often assumed to support circularity without tracing their role in material recovery or end-of-life planning. Future research should clarify the conceptual boundaries between sustainability and circularity, and explicitly link platform functionality to measurable circular outcomes. Moreover, most existing studies lack methodological frameworks capable of linking platform design choices to traceable circular performance outcomes. Addressing this gap should be a key priority for future empirical research.

4.3 From Diagnosis to Research Design: A Mechanism-Oriented Agenda

Based on the misalignments identified, this study proposes three strategic research directions. First, there is a need for cross-contextual validation to understand the conditions under which alignment mechanisms succeed or fail. Comparative research across different policy environments, contractual models, and lifecycle stages can reveal how asymmetries and disconnections in material and information flows manifest across various PPP regimes. Second, digital platforms should be prototyped not merely as coordination tools, but as flow-oriented infrastructures that synchronize policy feedback, enable traceable data exchanges, and distribute responsibilities across actors. Such prototypes can help bridge gaps between high-level circular ambitions and operational realities. Third, the integration of AI into platform governance presents both opportunities and risks. While AI can enhance predictive capabilities and dynamic alignment, it should be embedded within accountable and inclusive frameworks. Governance sandboxes or contractually bounded testbeds may offer controlled environments to evaluate AI’s performance not only in terms of efficiency but also in terms of equity and transparency. Ultimately, achieving alignment in circular PPPs is not solely a technical challenge—it is a matter of thoughtful design and responsible governance.

4.4 Visualising Alignment Architecture

To synthesise these findings, this paper proposes an Alignment Mechanism Model (Figure 6), mapping how misalignments across lifecycle, governance, and flows intersect to obstruct circular goals in PPPs. Rather than

treating platforms as neutral infrastructures, the model reframes them as governance-intensive systems whose performance depends on their institutional embedding, temporal continuity, and functional coherence. As such, the model offers both a diagnostic lens and a design heuristic—guiding empirical validation and informing future platform architectures tailored to circular goals.

Figure 6 synthesises these dimensions into a unified model, illustrating how circular governance failures emerge from the intersection of lifecycle asymmetry, governance fragmentation, and unsynchronised flows. At the core of the model is platform-based circular governance, which acts as a mediating mechanism between structural lifecycle phases and the need for flow-based coordination. Lifecycle misalignment is associated with coordination failures across different project stages, while mobility-driven synchronisation highlights the importance of aligning material and data flows across actors and timeframes. The figure underscores the importance of embedding authority within platforms to mitigate fragmentation and enable synchronised, circular outcomes.

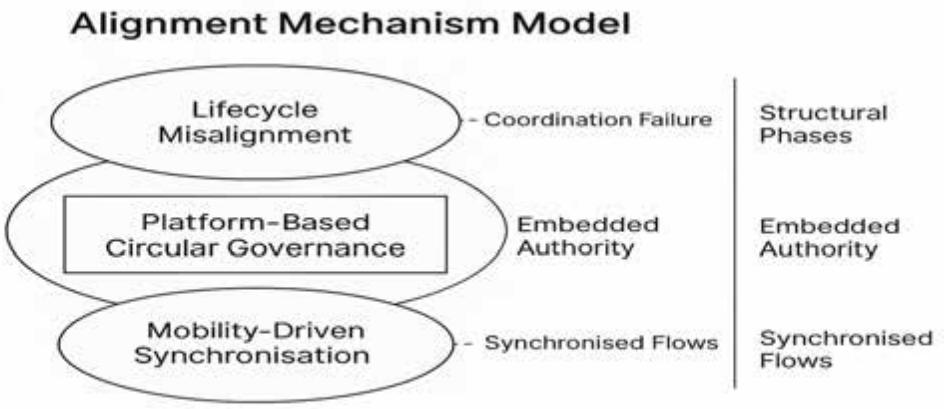

Figure 6. Alignment Mechanism Model

5. Conclusion and Policy Implications

This study set out to investigate how digital platforms mediate the alignment between policy goals and technological interventions in circular Public-Private Partnership (PPP) projects. Through a mechanism-oriented systematic literature review (SLR) of 24 core studies, it identified three interdependent misalignments, which are lifecycle asymmetry, governance fragmentation, and flow disruption, that collectively constrain the systemic capacity of platforms to enable circular outcomes. These findings suggest that digital circularity is not merely a matter of tool adoption, but a governance challenge that demands institutional integration, lifecycle coherence, and flow-based coordination.

Looking forward, platform-enabled circularity requires a shift from tool cataloguing to mechanism construction. Future research should validate the three mechanisms across diverse PPP contexts by examining how alignment breakdowns manifest under varying governance maturity, policy enforcement capacity, and infrastructural conditions. Experimental prototypes of digital platforms should be developed not just for integration, but also for synchronisation by embedding features such as real-time policy feedback, traceable data architectures, and incentive-compatible actor coordination. Equally important is the investigation of platform performance across scales: how effectively can platforms translate national circularity mandates into localised, lifecycle-informed interventions?

Ultimately, alignment is not a technical state. It is a design and governance achievement. As AI-enhanced platforms gain prominence, future studies must critically examine how algorithmic coordination tools can be embedded in transparent, inclusive, and adaptable institutional frameworks. Only through such systems-oriented experimentation can platform-based circularity advance from conceptual promise to operational transformation.

Appendix A. Search Strings Used in the Systematic Review

Search Focus	Search String
Part 1: Identifying Digital Technology	(circularity) AND (public spaces OR community spaces OR urban infrastructure OR built environment) AND (digital tools OR smart technology OR digital twin OR BIM OR IoT OR decision support tool*)
Part 2: Governance and Participation in PPPs	(circularity) AND (public spaces OR community spaces OR urban infrastructure OR built environment) AND (public-private partnership OR PPP)
Part 3: Resource and Material Management	(circularity) AND (material reuse OR waste management OR resource efficiency) AND (built environment) AND (digital tools OR BIM OR IoT OR digital twin)
Part 4: Intersectional Integration	(circularity) AND (built environment) AND (digital tools OR smart technology OR BIM OR IoT) AND (material reuse OR waste management OR resource efficiency) AND (PPP)

Databases: Web of Science, Scopus, ScienceDirect

Time span: 2014–2024
Language: English
Document Type: Peer-reviewed articles and review papers

Appendix B. Inclusion and Exclusion Criteria

B1. Abstract Screening Criteria

Inclusion	Exclusion
Mentions the **AECO sector** (architecture, engineering, construction, operations)	Focuses on unrelated domains (e.g., agriculture, generic urban policy)
Refers to **circular economy practices** (e.g., reuse, efficiency, low-carbon)	Only discusses sustainability in broad or undefined terms
Includes **digital tools or platforms** (e.g., BIM, IoT, Digital Twin, DSS)	Lacks any mention of digitalisation or technological intervention

B2. Full-Text Evaluation Criteria

Inclusion	Exclusion
Provides **empirical or analytical detail** enabling coding of mechanisms	Theoretical papers without clear empirical basis or methodological transparency
Discusses **digital tool deployment** across one or more lifecycle stages	Describes tools in abstract without lifecycle integration
Addresses **platform functions** (e.g., coordination, traceability, monitoring)	Mentions tools but omits platform-level architecture or governance discussion

Inclusion	Exclusion
Contains reference to **PPPs or multi-actor collaboration or governance mechanisms**	No indication of stakeholder interaction, public-private dynamics, or PPPs or governance dimension or stakeholder role specification

Appendix C. Coding Framework Variables

Dimension	Sub-Dimension	Examples
STRUCTURE	Lifecycle Stage	Design, Construction, Operation, Renovation, Demolition
	Digital Tool Type	BIM, IoT, Digital Twin, GIS, Blockchain
	Circular Goal	Reuse, Efficiency, Emission Control
PLATFORM & GOVERNANCE	PPP Model	Housing, Infrastructure, Public Works
	Platform Function	Monitoring, Coordination, Data Sharing
MOBILITY FLOWS	Policy Flows	Green Procurement, Policy Feedback, Regulatory Embedding
	Data Flows	Transparency, Traceability, IoT-based Monitoring
	Human Flows	Multi-Stakeholder Collaboration, Cross-Sector Teams

(Refer to Table 1 in the main text for operationalisation.)

Abstract
Public space is in a constant state of evolution, continuously reshaped by its sociocultural context, technological advancements, and the shifting needs of urban life. This research aims to investigate the role of phygital spaces in transforming public space by transcending physical limitations. It intends to help rethink public space and phygital public spaces' potential to revitalise underutilised urban spaces. Using expert interviews and thematic and framework analysis, the research identifies key themes such as social interaction, space activation, governance and design. The research argues for a reconceptualisation of public space that embraces digital integration, offering an alternative framework relevant to urban planners, designers, and policymakers addressing contemporary spatial challenges.

Keywords: Phygital Space, Public Space, Underutilised Spaces, Spatial Digitalisation

Introduction

Space is a dynamic product of social relations (Lefebvre, 1991). These social relations are especially prominent in public space since it is the stage of communal life (Carr et al., 1992). With digital technologies improving and being incorporated into our daily lives every day, there is also a transition in social life in the context of urban public space with this change in contemporary society's needs, demands and perception towards space (Castells, 2004). People use public space relatively less than they did in the past for various reasons (Cybriwsky 1999; de Freitas, 2010; Bazzanella et al., 2014; Akkar Ercan, 2016; Lee, 2020; Badel & López Baeza, 2021; Del Vecchio et al., 2023).

Reconceptualising public space in this sense can be an alternative design approach towards new placemaking to encourage people to use public space more. Phygital spaces can be exemplified as an alternative due to their emphasis on user experience and flexibility in terms of physical limitations. This approach can be used in underutilised urban spaces to activate these spaces, and this way reintegrate them into the urban fabric.
To further investigate the potential of phygital spaces especially as a way to transform underutilised urban spaces, the following research questions are posed:

- What is the potential for phygital space to transform public space socially and spatially?
- How can they be used to enhance the value and functionality of underutilised public areas?
- How do individuals perceive public spaces that integrate physical and digital elements?

Phygital Space

Phygital spaces represent the intersection and interweave of digital and physical realms where the boundaries of these two realms are blurred (Mele et al., 2022). The term "phygital" was first introduced by a marketing company that created it as a conceptual idea of branding that contained "immersive real-world experience" (Nofal et al., 2017, p. 220). In terms of urban planning, digital tools are used to enhance the physical space and thus user's experience enriching the way they interact with their environment and sometimes with each other (Bazzanella et al., 2014; Brusaporic&Maiezza, 2021).

The idea is simply capturing each realms' best features and eliminating bad ones, strengthening both (Nofal et al., 2017; Mele, 2022; Sui & Shaw, 2022). They are immersive and mostly interactive. They have a promising potential for both storytelling since they are a great and mostly fun way to transfer information, and for engagement

and co-design with the potential of gathering opinions from citizens and actually analyse and evaluate their behaviour in these spaces. Through both of these potentials the crucial part is they can be conversation starters, social interaction points, collaborative and collective experiences because they can be attractive and interesting for many people (Bazzanella et al. 2014; Andrade & Dias, 2020; Cevallos Andrade & Del Blanco García, 2025). As Del Vecchio et al. (2023) underlines, people are both passive users and creators of the meaning of new public places in urban phygital environments, which serve as a foundation for new intentional or unintentional community sharing.

Additionally, they are placeless and adaptive, meaning they can be inside/outside, a façade/ big open space/ small room, in the urban periphery/centre. They are independent of many laws because they are not fixed, changeable, removable, flexible.

Space Activation through a Phygital Approach for Reclaiming Underutilised Spaces

Space activation can be achieved through daily use or attachment to the place, so feeling a sense of belonging, identity. To be able to attach a place -and since it is a public space in the first place-, it needs to be accessible and inclusive. All these elements are tied to people's perceptions of space and that is in the hands of urban planners and designers that "make place". The concept of placemaking is creating shared memories through different social groups and improving quality of life (Chen et al., 2022; Pavlaki, 2021). Digital placemaking is augmenting physical places with digital services to improve the quality of these spaces thus attracting people and enhancing social, cultural, environmental and economic value of places (Morrison, 2018). Therefore, if these spaces can be made places through digital interventions (phygital approach), they can be used as a technique to revitalise and reclaim underutilised spaces by activating them the same way as well.

Underutilised urban spaces are a byproduct of growth in every city mostly as a cause of losing or reducing value (i.e. the meaning and use) due to lack of planning or one that didn't anticipate some certain consequences leading to areas that are unwanted (Lynch, 1960; Trancik, 1986; Di Giovanni, 2018; Hwang& Lee, 2019). They create disconnectivity and discontinuities in urban fabric and become something in between with no clear purpose especially in heavily populated cities (Trancik, 1986; Sameeh et al., 2019; Azhar et al., 2020). Beyond only being empty or vacant, there are other types of underutilised spaces such as mono functional spaces which are limited to a part of the day or only some events. Reusing and revitalising these spaces are a great way to create cohesive and interconnected urban fabric spatially and socially (Di Giovanni, 2018; Sameeh et al., 2019).

There are many possibilities and potentials on how to achieve this activation such as creating safer environments, more greenery, better accessibility. Along with these approaches, the research proposes another opportunity that is focused on digital interventions. By taking advantage of digital tools and technologies, these spaces that are often neglected and/or overlooked can be integrated into the broader urban and functional system in a novel way.

Case Studies

A wide spectrum of case studies from around the world are explained for a more concrete and better understanding of phygital spaces varying in temporality (temporary vs. permanent), interactivity (interactive vs. non-interactive), thematic orientation (heritage and culture-focused vs. entertainment- or infrastructure-driven) and public accessibility (open public spaces vs. controlled environments) (Table 1).

Table 1: Comparison of case studies.

Case Study	Urban Context	Technological Approach	Cultural Dimension	Financial Accessibility	Location
Basel Cathedral	Enhancing cultural heritage	Projection mapping	Cultural heritage preservation and narrative	Free	Indoor exhibition in public space
Rel:attiva Presenza	Narrating local neighbourhood history	Projection mapping	Explanation of the identity of a neighbourhood	Free	Indoor exhibition in public space
Luminous Pathway	Promoting social interaction	Interactive Lighting	Everyday urbanism with artistic approaches	Free	Square
Hagia-Sophia H&E Museum	Enhancing cultural heritage	3D animations immersive environment	Cultural heritage preservation and narrative	Paid entrance	Indoor museum
The Sphere	Transforming the silhouette	High-res LED immersive environment	Futuristic entertainment	Paid entrance	Indoors venue

Krypta unter der Vierung in Basel Cathedral is a permanent and immersive installation in the basement of Basel Switzerland's main cathedral. The cathedral is crucial to the city and its image since it is over 1000 years old and has had many different phases. There is a narrative explaining the history of Basel through these phases with animations, lights and projections over the oldest Roman ruins in the cathedral (Figure 1). It exemplifies how digital technological interfaces can mediate between the past and present, enabling cities to reinterpret underused or hidden spatial layers through cultural heritage (Bernasconi et al., 2019).

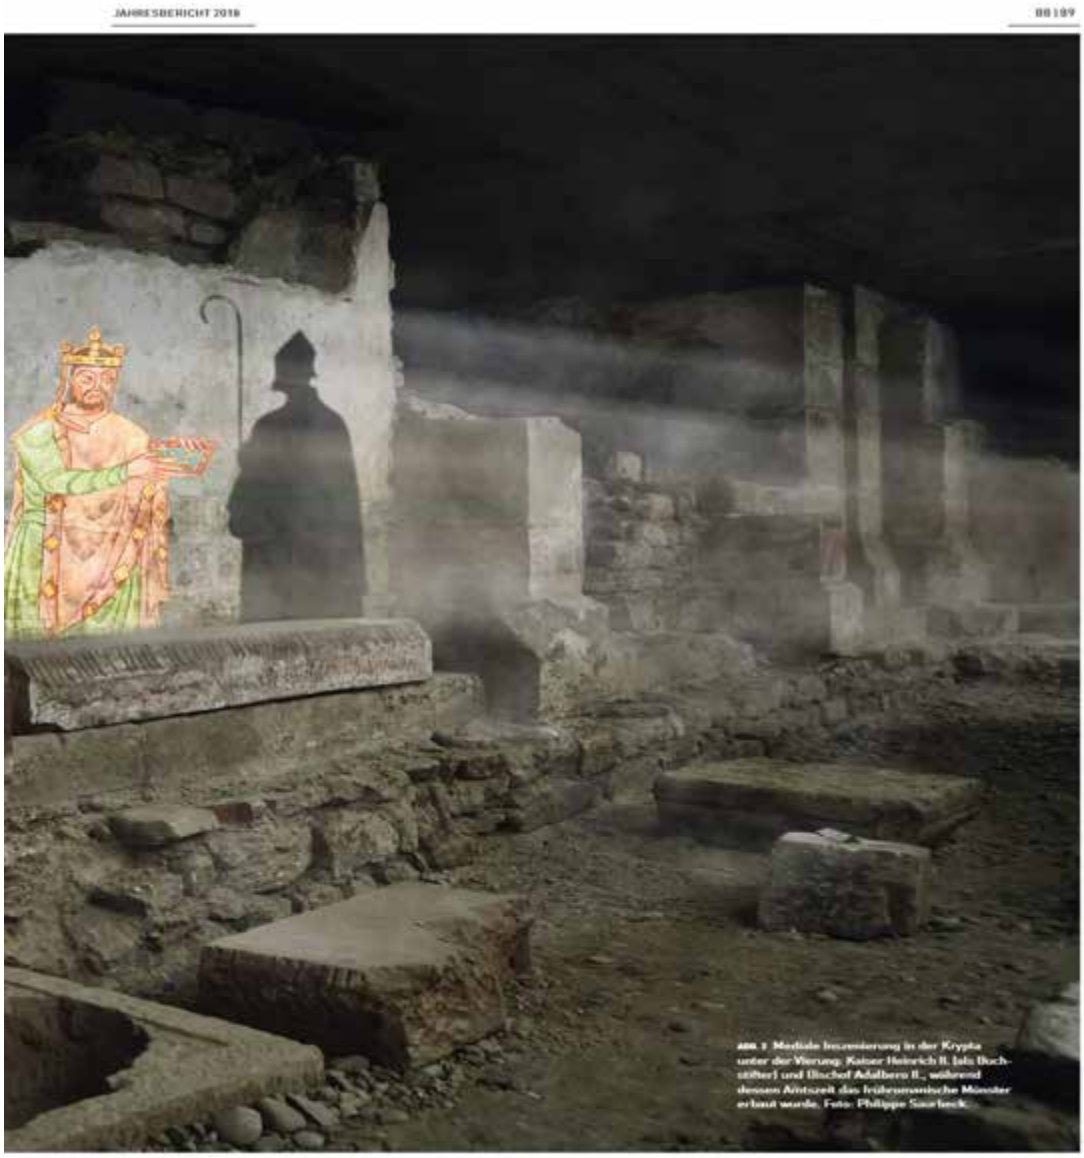

Figure 1: A part of the exhibition (Bernasconi et al., 2019, p88-89).

Rel:attiva Presenza was a temporary and immersive installation made in 2008 with projection mapping and sound environment in Mexico. The purpose was to describe the mutation of Coyoacán neighbourhood through time to create a narrative of the culture which is a historical and very important neighbourhood in Mexico City (Figure 2). The designated users were also the residents that had lived through these different forms of the neighbourhood, and this acted as the archive of perceptions, experiences and narrative of those people enabling them to reinterpret their environment with heritage (Iaconesi & Persico, 2013).

Figure 2: A part of the exhibition (AOS, 2008).

Luminous Pathway is a visionary media architecture and urban design project in Montréal, Canada in Quartier des Spectacles (QDS) which is the city's vibrant cultural district. The whole space covers 8 public spaces and 80 venues that change content and context (Figure 3). It is permanent as urban projection sites and temporary as luminous installations. The aim of the design is to attract people's interest, motivate them to engage, amaze, entertain, and provoke thought. It serves as a benchmark for experimental urbanism and media architecture where light acts as a spatial setting to change the perception and use of public space creating a sense of belonging. (Quartier des Spectacles, 2015; Quartier des Spectacles, n.d.)

Figure 3: Quartier des spectacles in 2023 (Quartier des spectacles, n.d.).

Hagia Sophia History and Experience Museum in İstanbul, Türkiye is an immersive and interactive museum with a historical narrative that blends digital technologies and cultural heritage again through a very crucial and iconic

building. Visitors are guided through a chronological journey from a pagan temple to a Byzantine cathedral and to an Ottoman Mosque including the stories of all 3 versions of rebuilding Hagia Sophia and with it İstanbul in different time spans (Figure 4). It has an urban memory and an urban perception in it that comes with such an important structure that shapes people's perception of the area after the visit of this phygital space adding another layer of importance and emotion on the visitor's eyes (Çelik &Kahraman, 2024).

Figure 4: The collapse of the dome of Hagia Sophia in past remodeled (Dem Museums, 2024, 7:19)

The Sphere is an immersive entertainment venue in Las Vegas, USA that is quite unique in terms of immersive architecture and experimental design (Figure 5). Very high technological equipment is used to achieve that level of immersive experience for many people which also brings high costs and sustainability issues (Nisa, 2023).

Figure 5: The inner design of The Sphere (Florian, 2023).

Methodology & Data Collection

The research used a qualitative method mixing thematic and framework analysis based on **in-depth interviews** with experts selected through purposive sampling. 10 experts participated in the research and experts were chosen based on their experience on intersecting themes of public space and digital transformation. There were urban planners, architects, interior and landscape architects and digital technology experts that have contributed to the research. While the sample size may appear limited from a quantitative standpoint, the aim was not statistical generalization but rather the extraction of rich, contextual insights.

The data of expert opinions was collected via semi-structured interviews based on 10 questions prepared with the light of research questions, objectives, literature review and case studies. There were 4 main themes in the questionnaire; general definitions and conceptual framework of phygital spaces, transformation of public spaces and digitalisation, transforming unused spaces and reconceptualising public space, future trends and recommendations (please see Appendices for the full interview form). The reason for the semi-structured design was to allow flexibility to the experts to engage in further conversation related to their expertise or newer topics that might be related to the topic.

Questionnaire for the interviews are presented below:
1. How do you evaluate the impact of merging physical and digital environments on public spaces?
2. What are the main advantages and disadvantages of phygital public spaces compared to traditional public spaces? Tip: Consider aspects such as accessibility, user engagement, privacy, economic opportunities, and over-reliance on technology.
3. Which urban challenges can be addressed through digitalization in public spaces? Tip: Some key challenges include overcrowding, rigid spatial configurations, lack of engagement in planning, inefficient land use, and public safety concerns.
4. What are the key drivers accelerating digitalization in cities? Tips: Factors may include urbanization, technological advancements, smart service demands, digital governance, sustainability goals, and citizen engagement.
5. What aspects of digitalization contribute most to user experience and satisfaction in public spaces? Tip: Think about factors like education, entertainment, personalization, and engagement.
6. Do you think phygital public spaces are effective in enhancing social interaction? Under what conditions are they more effective? Tip: Social engagement could be influenced by factors like design, ease of use, or cultural acceptance of technology.
7. What are your thoughts on transforming unused or underutilized urban spaces through phygital approaches considering limitations of size, capacity, and location? Tip: Examples include turning abandoned lots into interactive parks or using projection mapping to revitalize historical sites.
8. In your opinion, can the integration of digital technologies provide a sustainable solution for revitalizing underutilized spaces? Tip: Consider environmental, economic, and social sustainability in your response.
9. Do you think phygital public spaces can help create more attractive, functional, and sustainable urban environments? If so, how? What are the biggest barriers to implementation, and how can they be addressed?
10. Do you have any additional insights or perspectives on phygital public spaces?

The answers of the expert's insights were analysed through a combination of thematic analysis; identifying and analysing themes within qualitative data and framework analysis; systematically organising and interpreting this data through a structured matrix of themes and subthemes to identify patterns, relationships, and meaning. (Braun & Clarke, 2006; Ritchie & Spencer, 1994). Themes were created from the interviews based on the frequency and relevancy of the answers and later matrixes were created from summarised answers of interviews to have a holistic understanding of all experts' contributions for the topic.

Results

From the combination of literature, case studies and experts' answers and insights, a thematic and framework analysis has been conducted (Figure 6). Firstly, all interviews were transcribed and familiarised. Then, 6 themes have been created from codes in consideration with literature and case studies. Then the interviews were in-

dexed with the determined themes and matrixes were created with the summarised data from the indexing to be able to compare experts' opinions on the themes and interpret.

Figure 6: Word cloud from expert answers for each question.

The first theme is Blending of Digital and Physical Experiences in Public Spaces with 2 sub-themes: their evaluation of phygital spaces and the comparison to traditional public space (Table 2). Generally positive comments predominate in terms of the basics of phygital spaces.

Table 2: Blending of Digital and Physical Experiences in Public Spaces

Experts	Their evaluation	Comparison to traditional space	Keyword
A	Integration of these is quite seamless nowadays but digital is an augmentation that always reflects the precise moment where it is used in physical space.	Traditional public space is the inevitable goal and digital is an addition to it.	Integrated, Layer
B	It is more of a digital infrastructure, sensors and service in public space	People don't see traditional and enhanced space the same so they don't try to act like it but to immerse themselves in the digital parts more individually.	Amenity

C	There are many aspects to it like sensors, the environment and an interface level with people.	Digital enhancements create an alternative to a permanent physical infrastructure, maybe creating simpler solutions.	Diverse, Alternative
D	-	Users of merged digital and physical spaces can only compare the two with answering what value it brings	Layer
E	They could be both a bad experience that disconnects people from space with personal devices and also good one with a design that utilises digital tools well.	As the experience enriches the space, it might be a way of getting people's attention more.	Potential
F	There is a new type of physicality created through digitality which is a new cross-section.	It changes the perception of public space maybe by creating awareness for the existing space.	Enhanced
G	The integration depends on the users and their interest and background.	-	Dependent
H	As of now, such a discourse of integration or blending of digital and physical spaces is too bold.	-	Unrealistic
I	The boundaries of such a distinction of digital and physical space no longer exist.	-	Integrated
J	The integration of these spaces is positive because of an information layer that doesn't need effort.	With new layers like visuals, narratives and information, our experience in space changes than the traditional space (which is a different and still valuable experience as is)	Innovative

The second theme is Social Dynamics with 3 sub-themes: interaction, participation and engagement/co-design (Table 3). While some experts argue that social issues should be dealt with mostly basic design principles and several think that digital additions have a positive effect.

Table 3: Social Dynamics

Experts	Interaction	Participation	Engagement/ Co-design	Keyword
A	Digital enhancements don't necessarily improve social interaction.	Allows to have more ideas of the residents	-	Irrelevant
B	It generates different types of interactions but that might not be the result of digital technology.	Might create better outcomes because it is used to get data	-	Diverse interaction
C	Pointing at things together is the core of interaction and digital enhancements could create many things to point at with people.	Adding a digital layer makes it possible for a lot of people to participate in the imagination of what a public space can be.	They can be used to show a preview of space while being designed to make decisions on it with the people.	Convenient
D	A digital layer must be designed in a way that would enhance interaction than diminishing it.	Personal devices must not be the approach to create a suitable environment for participation.	-	Dependent on design
E	They help the creation of an arbitrary collective formed by users	The interactive nature makes participation and engagement to space easier and more effective maybe.		Easier
F	People are attracted to space through digital tools and meet in physical spaces enhancing interaction that makes them spend more time there than usual.		Adding digital layers to design processes is much more meaningful than seeing it as a billboard.	Communication
G	Social interaction is crucial in phygital spaces which is what is aimed.	Working with different types of people is beneficial for participation such as age	-	Goal
H	Interaction is encounters of people and aesthetic experience is individual not social.	Community engagement and participation cannot be discussed through these digital enhancements because there is very little material to talk about.		Irrelevant
I	It can increase interaction.	It could be used to get data about the demand.	There is not yet a bottom-up approach on these spaces.	Method for design

J	It is an effective way to increase interaction.	-	Gamification of spaces can be a great way to co-design and engage people.	Effective

The third theme is Governance, Ethics and Regulation of Phygital Spaces with 3 sub-themes: ownership, accessibility and inclusivity (Table 4). All experts gave great importance to the issue and highlighted the importance of these to create an equitable public space for all.

Table 4: Governance, Ethics and Regulation of Phygital Spaces

Experts	Ownership	Accessibility	Inclusivity	Keyword
A	Digital enhancement of any kind requires a budget, even through a public entity it will have a profit-driven or controlling approach that needs a digital conduct to be developed.	-	People who are disadvantaged such as homeless people might not be welcomed in these spaces.	Controlling
B	They create a controlled space either by a private or government. There should be implications and more research on the effects.	-	Might create inclusivity issues	Controlling
C	Ethical barriers like privacy or publicness of space are difficult problems.	It must be made sure that public space is still truly public and available and free for everyone. Digital additions might only serve privileged groups if not community oriented.		Inclusivity
D	A digital layer means controlled and regulated which can be both good and bad so there must be a balance of openness and security.	Space can be more accessible through a digital layer in terms of time of the use.	-	Reachable
E	-	Accessibility and inclusivity are about the basic design principles so the physical part not the digital one.		Irrelevant
F	The borders and level of digitality must be determined to decide on what should be regulated and controlled.	-	-	Prepared
G	-	Public space must be accessible and inclusive in any case, here the difference can be to determine who demands the digital additions.		Irrelevant

H	The digital space is controlled and limits the publicness of space.	Digitalisation is a tool of inequality now, there is a serious difference between societies that can access digital technology and those that cannot.	Because of the high possibility that these spaces are private and for a fee, it is semi-public so not entirely inclusive.	Controlling
I	-	The accessibility of digital technology might be limited because of infrastructure but will be overcomed with time.	-	Promising
J	-	-	-	-

The fourth theme is Revitalisation and Sustainability of Underutilised Spaces (Table 5). Some experts thought that phygital spaces would be an excellent match for the goal whereas others state that for a full transformation there must be something permanent that can fit into a daily routine, and they don't see digital interventions as such. Almost all experts underlined that physical basic design principles must be a part of the transformation and most thought that it is spatially, socially and economically sustainable as it is refunctioning a space.

Table 5: Revitalisation and Sustainability of Underutilised Spaces

Experts		Keyword
A	The biggest advantage of digital advancements is an opportunity to gain attention for certain underused and unrecognised spaces. It is sustainable socially and spatially.	Intriguing
B	Integration of digital technologies can provide a sustainable solution for revitalising underutilised spaces under circumstances, they can support the process, but they aren't transforming space by themselves.	Secondary
C	Digital could be few steps ahead of physical but ultimately physical investment must happen to really revitalise the space, it could be used as a drive to engagement and investment that would result with the aimed physical redevelopment.	Temporal
D	It is a good way to activate space in a flexible and temporary way without physical investment needed. But, there needs to be supporting reasons to use a particular underutilised space, digital things aren't enough by itself. The reason behind why this space isn't used must be investigated and connected to a supply demand approach.	Temporal
E	A well-designed physical space is needed for revitalisation, digital technology or digital tools are an addition of support.	Secondary

F	It is a great opportunity to revitalise the underutilised spaces from big parks to facades which would be very sustainable spatially.	Potential
G	There is a potential of revitalisation that would direct people into these areas providing economic, social and spatial sustainability but it is important to decide the reasoning behind it. If it is profit-driven, it might as well stay as it is.	Potential
H	There is a temporary possibility of transformation of underutilised spaces but just because there aren't many examples yet, it is not likely that a low-quality space is transformed with increased user experience. And sustainability shouldn't be searched with digitalisation.	Temporal
I	It has a great potential for especially monofunctional spaces with an existing infrastructure to integrate them into the urban fabric.	Potential
J	Underutilised spaces must be transformed without digitalisation first and be in a routine, after that it can be an addition.	Secondary

The fifth theme is Space Activation with Digital Tools with sub-themes; Enhancement of Sensation/Perception, Emotion, Memory, Experience and Urban narrative (Table 6). Many experts agreed that sensation, perception and experience would be enhanced through digital additions and several experts thought that this would add to the memory and emotions felt in this space creating room for sense of belonging and identity. Additionally, some experts pointed out that urban narrative would change in a way that people are more aware of their surroundings and open to information. However, some experts thought that this would be an unnatural way of experiencing space thus wouldn't be successful enough to activate space.

Table 6: Space Activation with Digital Tools

	Enhancement of...HN					
Experts	**Sensation/ Perception**	**Emotion**	**Memory**	**Experience**	**Urban Narrative**	**Keyword**
A	Digitalisation has a chance to synchronise the perceived space with inhabitants in public space.	-	-	It might bring a collective experience for people in an existing physical public space	-	Collective
B	They affect how we perceive space	-	-	-	They affect how we navigate space.	Minor difference
C	-	Telling the story of a space that includes curiosity, and playfulness adds emotion and memory to everyday spaces		-	Digital storytelling tools enhance attachment to places through layered historical or cultural narratives.	Identity

D	The triggers of space are the basics like senses to make a place.	-	-	Adds an experience to traditional space which makes it multifunctional and interactive.	Sensations could be integrated with the digital and physical application that is projected onto urban space	Novel experience
E	They stimulate the senses and load information triggering perception and thus emotion and changing the meaning of space.		Has an impact on collective memory, its construction and the creation of a culture.	Creates a new type of reality within physical space, changing the experience of the space and activate sensory ones.	Gives the possibility of space design even on a blank canvas that can be changed constantly	Adaptable, Identity
F	It changes the whole perception of public space.	-	-	Additions of experiences and playful interactivity can boost a sense of belonging.	People can participate more in the physical public space with digital additions, which makes it used more actively, effectively, for longer, activating the physical space.	Activating
G	-	-	-	The experience should be mild enough to blend in with the physical environment.	When the identity of cities and their physical reality don't create a need for interaction, digital technology may not be necessary.	Irrelevant
H	This can give a different form to the processes of sensing, feeling and mutual learning.		It wouldn't create memory because it is not organic.	It has the potential to transform the organic experience, into another form that is created with predefined content. We cannot anticipate the outcomes yet.	-	Cautious

I	It gives a new perspective and perception of the space at the same location and time especially when supported with senses.	-	-	It multiplies the experience by inverting the relationship of the user and space with being impressive and immersive.	It provides new ways of urban historical narrative that could be very informative.	Impressive
J	The spatial perception can be enhanced with digital tools.	-	The aim should be to create a memorable environment	It would create a new type of learning experience.	It can increase the awareness of an urban space with seamless information	Expansion of understanding

The sixth and final theme is Context Specific Design and Local Adaptation (Table 7). All experts highlighted the importance of context by content, culture, scale, location, existing situation of the physical environment, users and many more. They all agreed that without a context of specific space the evaluation of the phygital space is impossible since the context might vary vastly especially in different cultures but also in the same city or even the same neighbourhood. They stated that it depends on the people's existing perception of that space to be able to assess the change.

Table 7: Context Specific Design and Local Adaptation

Experts		Keyword
A	A context-oriented design approach is needed to have a certain observation and outcome with an emphasis on where the digital enhancement is done, by whom and how it could impact the public space.	Consequence
B	Technologies aren't the fast and easy solution; purposeful implementation is needed depending on the context. Social innovation, political will and change in public administration processes are needed.	Dependent on policy
C	Digital technologies are tools, not solutions. A sustainable integration must be adapted to local social, cultural and political contexts and must match people's needs rather than just being aesthetic or entertainment functions.	Need-driven
D	The design can never be disconnected from the context and the people.	Dependent on design
E	It depends on the place, scale, need and context. It might not be possible in every culture or urban environment.	Conditional

F	Design has an important role here. Digital additions can be integrated according to its scale, context, need, demand, user profile and usage patterns.	Dependent on design
G	The concept of phygital depends on the design, location and situation such as ease of use or cultural acceptance.	Acceptance
H	It is necessary to create a discourse of meta-digitalisation formed by associating the typologies of different types and contexts with how the experts evaluate them through a feedback mechanism.	Open to correction
I	The most important aspect is to integrate culture and locality into these spaces that would spark the interaction and participation.	Integration
J	The local adaptation and harmony of the space is very important for people to accept it.	Acceptance

Overall, it can be said that majority of the experts see phygital spaces as an opportunity for promising space activation and enhancement but without forgetting the essentials for proper design and planning structures and principles. They see it is an added value to a space, and that public space should already be of high-quality, accessible for all, inviting and welcoming both physically and by digital content including as an approach for revitalising an underutilised space. But most experts state that space can be activated through digital tools, and it is most of the time more effective or easier than physical investments.

There is a tie in terms of if social interaction could be achieved in phygital spaces mostly because of digital technologies' way of personalisation and individualism depending on who initiates this space which is why there should be regulations to make this space more accessible and simply available.

Finally, all the experts stated that phygital spaces depend on the context and can be successful only if it matches the physical, cultural, social and political sphere of the designated space.

Findings & Discussion

The general results of the expert interviews revealed that there is a consensus on change of user's perception and experience of space with the integration of digital technologies into public spaces. All experts investigated WH- questions for almost every question and have expended the questions and their insights mostly depending on their own expertise.

Integration of physical and digital spaces: Majority of experts agreed that the blending of digital and physical spaces is already underway. They emphasized that that digital layers should complement rather than replace physical space. According to them improvements in spatial conditions must first adhere to effective and well-established physical design principles, which should then be enhanced through thoughtful digital augmentation.

Sensory experience and memory: Most of the experts viewed phygital spaces as a challenge to traditional public space. They stressed the importance of existing public environments and the sensory experiences they offer in daily life—such as sounds of people and animals, or the smell of coffee. After establishing this, about half of the experts acknowledged that in certain contexts, phygital enhancements could enrich these experiences by making them more interactive and immersive, potentially encouraging the creation of new memories. Many

emphasized that the information that phygital interfaces provide is much more memorable and integrated than traditional space resulting in more awareness of surroundings. Because of this they can be a great way to create a collective memory and reinforce participation and local identity with urban narratives, digital storytelling, gamification through spaces that have historical and cultural value.

Practical benefits and data utilization: Majority of experts agreed that digitalisation can create innovative solutions for practical issues like communication between users and stakeholders especially due to the responsiveness potential of it. Several experts added that these spaces can be as platforms for collecting data from users—such as through speech input, surveys, co-design activities, or urban analytics—which can inform future design processes.

Temporality, flexibility and revitalization: Almost half of the experts thought that digital approaches are a great way to overcome rigid spatial configurations or investment hardships in congested urban areas due to phygital space's temporality opportunity and flexibility in terms of space and context. Especially in this sense, it was seen as a good opportunity for revitalising underutilised spaces without physical limits like size, capacity and location. Yet almost all experts emphasized that for this revitalisation to last basic design principles must be prioritised.

Critical perspective, ethics and governance: Nevertheless, several experts also pointed out that they are mostly controlled environments and thus there is an immense importance of content and context. All experts have underlined the importance and need of thoughtful design, ethical frameworks and governance models that pay attention to equity and long-term spatial justice.

With the light of these insights and previous literature and case studies, it can be said that phygital spaces are an alternative of space activation, and they can be used to reintegrate underutilised spaces to the broader city scape.

Expert opinions were a great match to the fragmented insights from different researchs in the literature review, even though the term phygital was new to many experts which is why there aren't many relevant comparisons to its definition in their eyes and the literature. Key themes from literature such as digital placemaking and space activation through digital interventions, adaptability, interactivity, immersivity were mentioned by almost all experts in a positive way complying with each other. Especially the cultural values and leisure time activities in public spaces that were very visible in many of the case studies were mentioned by the experts as enhanced experience, perception, sensation, emotion, and thus identity.

As also the patterns and inconsistencies of consensuses and conflicts show the nature of the topic to be polarising, and that individual experiences or perspectives might play a bigger part. This is why while experts' backgrounds were influential in terms of the results, all occupation groups' ideas were quite sharply divided in all questions. For each of the ten questions, responses were typically split, with around five experts expressing a positive view on phygital approaches and five a critical one, though the individuals in each group varied across questions. Nevertheless, there were many aspects that experts brought themselves up and agreed upon due to the general approach and favour of basic design principles. These aspects were a result of the cautiousness on the potential power that the designer institution holds in these spaces to the context and content.

In general, phygital spaces seem to bring more awareness and knowledge with them that could create an individual or collective identity. Nonetheless, this doesn't mean that urban challenges can be fixed entirely with digital additions. For permanent and just solutions to them, basic design principles that care about human centred, high-quality spaces that prioritise citizens' well-being are critical. Phygital space that centre users experience as their nature are a notable alternative when issues such as governance, ethics, context and content are secured.

Conclusion

The research explored the evolving nature of public spaces in the digital era through phygital spaces and their potential of revitalising underutilised spaces through space activation and engagement. It tried to explain the remarks for these spaces as a way to reconceptualise public space overcoming conventional limitations.

The findings and inferences from literature review, case studies and analyses showed that phygital space can be an alternative design approach for future public spaces. This is because it adds value to the existing space in a unique way that allows for freer applications than traditional implications. This freedom brings flexibility and adaptation possibilities to space which makes it applicable to many scopes taking the local context into consideration while doing so as exemplified with the case studies. Lifting the burden of conventional limitations like size, capacity and location physically and rigid construction codes legally enables this freedom which creates new opportunities for underutilised spaces that range from abandoned and neglected to monofunctional spaces.

Additionally, the change of perception and experience of space triggers a series of events that would make people see space differently, as a place. Cultural, locational and content specific examples can be great ways to revitalise any urban space, adding new experiences especially for leisure time in public spaces. This should be supported by basic design principles to create a holistic design approach for the space to be attractive and inviting and to be able to reintegrate into the urban fabric successfully and permanently. Through this process, regulations are vital to ensure an equal and ethical public space that fosters a responsive, adaptive and interesting nature.

Limitations of this research were reliance on limited sources and case studies due to the novelty of the topic, limited sample size of experts, no direct user comments or public data and subjective judgements about the topic due to the researchers' urban planning background.

Future research can further fill the gaps through large scale surveys, sensor-based research that really examines behavioural shifts of users; context-based research that focuses on the differences of culture and content in phygital spaces; focus on different types of digital technologies and their effect; political aspect of phygital spaces in terms of content and inclusivity.

EXPERT INTERVIEW FORM

Research Title: Digitalization and Phygital Public Spaces: Transforming Unused Urban Spaces

Researchers: Berna Gürkan & Prof. Dr. Fatih Terzi

Research Subject: This research explores the concept of Phygital Public Spaces, examining how the perception and function of public space evolve when integrating a spatial perspective of digitalization. The study aims to understand the implications of phygital environments on urban spaces and their potential benefits, particularly in activating underutilized areas.

Individual Consent for Participation: Your participation in this study is entirely voluntary. You have the right to withdraw at any stage without providing a reason. By agreeing to participate, you confirm that you have been informed about the study and consent to your responses being used for research purposes.

Estimated Duration of Participation: The interview is expected to last approximately one hour.

Publication of Information: The information you provide with the personal information you've given below will be included in the research findings and published as part of the master's thesis. The study adheres to academic and ethical guidelines, ensuring responsible use of all collected data.

Data Recording Consent: Audio and video recording will be conducted during the interview process.

Researcher:
Interview Date:
Expert's Name:
Profession/Field of Expertise:
Institution:
Years of Experience in the Field:

SECTION 1: GENERAL DEFINITIONS AND CONCEPTUAL FRAMEWORK
Guidance: The term phygital public spaces refer to the blending of physical and digital elements in urban environments. This integration can take various forms, such as smart infrastructure, augmented reality, or interactive digital features in public spaces. In this section, we aim to understand how experts define this concept and their perspectives on its role in urban transformation.
1. How do you evaluate the impact of merging physical and digital environments on public spaces?
2. What are the main advantages and disadvantages of phygital public spaces compared to traditional public spaces?
Tip: Consider aspects such as accessibility, user engagement, privacy, economic opportunities, and overreliance on technology.

SECTION 2: TRANSFORMATION OF PUBLIC SPACES AND DIGITALIZATION
Guidance: Digitalization is changing the way people interact with public spaces and each other. Smart cities, interactive installations, and digital governance tools are reshaping how these spaces function. This section explores the evolving role of public spaces in the digital era and benefits, and challenges of integrating digital technologies into public spaces.

3. Which urban challenges can be addressed through digitalization in public spaces?
Tip: Some key challenges include overcrowding, rigid spatial configurations, lack of engagement in planning, inefficient land use, and public safety concerns.
4. What are the key drivers accelerating digitalization in cities?
Tips: Factors may include urbanization, technological advancements, smart service demands, digital governance, sustainability goals, and citizen engagement.
5. What aspects of digitalization contribute most to user experience and satisfaction in public spaces?
Tip: Think about factors like education, entertainment, personalization, and engagement.
6. Do you think phygital public spaces are effective in enhancing social interaction? Under what conditions are they more effective?
Tip: Social engagement could be influenced by factors like design, ease of use, or cultural acceptance of technology.

SECTION 3: TRANSFORMING UNUSED SPACES

Guidance: Many urban areas contain underutilized or abandoned spaces that could be revitalized through digital technologies. Phygital approaches may provide opportunities to reimagine these spaces for cultural, social, or economic purposes.

7. What are your thoughts on transforming unused or underutilized urban spaces through phygital approaches considering limitations of size, capacity, and location?

Tip: Examples include turning abandoned lots into interactive parks or using projection mapping to revitalize historical sites.

8. In your opinion, can the integration of digital technologies provide a sustainable solution for revitalizing underutilized spaces?

Tip: Consider environmental, economic, and social sustainability in your response.

SECTION 4: RECONCEPTUALIZING PUBLIC SPACE & FUTURE TRENDS AND RECOMMENDATIONS

Guidance: As technology evolves, so do our expectations of public spaces. This section explores future trends and emerging technologies that may shape public spaces in the coming decades and aims to collect additional expert insights, potential research gaps, and practical challenges for future implementation.

9. Do you think phygital public spaces can help create more attractive, functional, and sustainable urban environments? If so, how? What are the biggest barriers to implementation, and how can they be addressed?

10. Do you have any additional insights or perspectives on phygital public spaces?

Abstract
The relationship between urban spaces, cultural structures and social interactions are being thoroughly transformed by the digital age. Social processes and new forms of interaction are restructuring urban space within the framework of different developments and paving the way for the emergence of a new society that produces cultural practices outside the conventional realities. These changes have transcended the traditional physical use of urban space, shifting our activities to digital environments and reshaping urban life through digital platforms. Therefore, this study aims to analyse the impact of digital technologies on the reconfiguration of urban and public spaces as well as cultural practices. It examines the hybridization of physical and digital environments in shaping urban dynamics and evaluates their potential to address future urban challenges. The research uses a "design fiction scenario-based survey" technique to model the potential impacts of digitalization on urban spaces.

Keywords: Digitalization, Urban Space, Culture, Virtual/Hybrid Space, Scenario-Based Research

1. Introduction

The dichotomy between 'reality' and 'virtual reality' dates back to ancient times in human history. The distinction between reality and virtuality has affected social norms in different historical periods. For example, in medieval society, where religion and art were at the forefront, the 'virtual' was at the forefront, while in the industrial age, the 'material' and 'tangible' came to the fore (Floridi, 2014; Levin & Mamlok, 2021). With the introduction of digital environments into our lives, the perception of the duality of real and virtual began to change, the relationship between humans and the artificial products provided by digital integration blurred and a process of transition from information scarcity to information abundance began (Batty, 1997; Floridi, 2015).

Digitalization has had a transformative impact on individuals and their relationships with their environment, adding a new dimension to the dialectical relationship between space, time and social structure. In this context, it has become increasingly important to understand the potential of social processes to shape space, as well as the potential of space and time to transform social habits. The transformations caused by digitalization in many areas of life have radically affected urban living practices and the ways of using urban space (Matsuda, 2010). The relationship established with space has transcended the physical dimension and has become reconstructed in the virtual dimension.

In this process, traditional forms of urban use are being transcended; many activities that take place in the physical environment are being transferred to digital platforms, creating new forms of urban life. Thanks to the rapid development of technology, the increasing prevalence of telecommunication systems affects the relationships between people's work, socialization, entertainment and all other activities and changes the character of their activities (Moss & Townsend, 2000). The fact that new technologies give us access to a new "place" raises the issue of how humans relate to space and place in relation to territorial life (Graham, 1998). It is thought that especially developed capitalist societies will be liberated from spatial, temporal and distance constraints and that these elements will cease to be a constraint on social, economic and cultural life (Graham, 1998; Graham & Marvin, 2002).

Urban space use culture is a dynamic structure that includes behavioural patterns, social norms and cultural practices related to how individuals use public and semi-public spaces in the city. This structure is transforming with the impact of digitalization; individuals' preferences for physical, virtual and hybrid spaces are being re-shaped. How this change is shaped according to socio-demographic characteristics remains important. In this context, examining the effects of virtual spaces and digital forms of interaction on the future culture of urban space use is critical for the transformation of today's cities and the re-functionalization of urban spaces.

Therefore, with a scenario-based approach, this study provides a comprehensive framework on how urban life will be reshaped in the process of digitalization by examining space preferences in future fictions together with socio-demographic characteristics and seeks answers to the following research questions:

1- With the development of digital technologies, how will individuals' preferences between physical, virtual and hybrid spaces change in the next 20 years in the context of their different needs?

2- How do demographic factors influence individuals' preferences for physical, virtual, and hybrid environments?

2. Interaction of Digitalization, Social Structure and Urban Space

Although the development of digital technologies was initially considered only as a tool for scientific advances and innovative approaches, it has led to radical transformations in social, cultural and economic structures over time (Batty, 1997). The foundations of digitalization were laid with the binary coding system developed by Leibniz in 1689, followed by Shannon's work on digital logic in 1938, and digital technologies became a concrete part of life with the production of the first computer in 1946 (Shannon, 1938; Castells, 2000; Jandrić, 2019). The establishment of computer-to-computer networks marked an important stage in the evolution of digital communication; today, this process has been intensively integrated into all aspects of life in areas such as big data, social media and artificial intelligence (Ilie et al., 2017).

One of the most critical turning points in the digitalization process was the creation of the World Wide Web (WWW) infrastructure. This technological development, combined with the widespread use of portable devices, paved the way for the elimination of spatial and temporal limitations; internet access became possible at any time and under any circumstances. This digital transformation, with its increasingly globalized structure, has led to the blurring of the boundaries between the real and the virtual and to radical changes in the perceptions of individuals. In this process, the concept of distance, which forms the basis of the idea of "community", has lost its importance and the forms of interaction between city dwellers have been redefined (Webber, 2013; Kellerman, 2014; Mahajan et al., 2024).

The new social structure conceptualized as information society, network society or post-industrial society, regardless of its name, is characterized by a new era in cultural structure (Bell, 1976; Castells, 2000; Webster, 1995; Uzelac, 2008). Digital technologies, which permeate almost every aspect of our lives, have led to changes not only in the use of new tools but also in our daily life practices, ways of thinking, social relations, production and consumption patterns. Therefore, digitalization should be considered not only as the development of technology but also as transformations in social and cultural structures (Hand, 2016).

Webber (2013) believes that society will eventually break away from physical proximity and integrate into social communities. In opposition to this view, Nie and Erbrig (2002) argue that online networks further strengthen communication between individuals who are part of a community, while Tayebi (2013) argues that communities still exist based on physical space, but with the advances in information and communication technologies, this has become more widespread. Floridi (2015) argues that the development and widespread use of digital tools has

had a significant impact on people and society and even argues that technology should not only be considered as digital tools but also as environmental forces that have become part of our lives.

The nature of digital technologies is changing people's habits with a disruptive effect while providing opportunities (Levin and Mamlok, 2021). Innovations in the way people experience their environment and daily activities are part of the cultural changes in the digital age. The new "networked" consciousness of society creates a new reality that we can call digital culture and all these changes deeply affect the value system and life practices of society. This change has led to a significant dissolution of the traditional social structure, which was more closely tied to physical space; the connection between place and people has weakened, while virtual communities have become more visible (Goodspeed, 2017). However, this is not only a rupture, but also the construction of a new form of spatial consciousness (Goodspeed, 2017). While digitalization weakens the relationship between place and community, it actually creates a new form of individual belonging to many places. While commuting to work, school, or home, people can check traffic updates on their phones, socialize through apps like Facebook and Instagram, order food or shop online. These services provided by digital tools are transforming urban life by disconnecting our daily life activities from physical space (Goodspeed, 2017).

The new social norms created by digital technologies have profoundly affected the way individuals use space and the effects of information and communication technologies on urban space have long been a topic of debate. The subject has paved the way for the emergence of different views. Webber (1968) argues that even when technological developments are not yet very active, physical space can be substituted and the city centre will lose its importance, Marvin (1988) argues that space will lose its value as time constraints are overcome and Pawley (1995), with his "cities without space" approach, states that developing technologies will create a need for high-capacity digital tools instead of a place for people to spend time.

Hall (1998) states that during the transition from the industrial age to the information age, skyscrapers rising in urban centres caused the urban fabric to change. Moss (1987), on the other hand, sees telecommunications itself, rather than a part of society such as white-collar workers, as influencing the growth or decline of future cities. Although Castells (2000) thinks that the telecommuting culture, which has entered our lives with the development of digital technologies, may lead to the spread of urban centres to the suburbs and consequently to decentralization and urban decentralization, Nilles (1998) and Huws et al. (1990) argue the opposite and think that the impact of the telecommuting model on urban space cannot reach advanced levels. Gottmann (1983) argues that the economic, social and cultural integration of digitalization in cities does not substitute the function of urban space but rather enables new ways of doing things in urban space that were done before digitalization. Abler (1995) supports Gottmann's (1983) view and argues that virtual spaces, which emerged as an alternative to physical space with digitalization, cannot be a substitute for real space. Virtuality would only enrich the reality of physical space and make it more layered. At this point, the idea emerges that physical spaces will be supported by digital tools and transformed into hybrid spaces.

In general, these studies address the effects of digitalization on urban space and social structure from different points of view and reveal its importance in shaping both spatial and social relations of the future. Social processes and new forms of interaction restructure urban space within the framework of different developments.

3. Case Study: The Effects of Digitalization on Urban Use Culture

In this study, an online survey method was used to understand the interaction between digitalization, urban use culture and urban space. The questionnaire was designed to test the relationship between socio-demographic characteristics and space preference and was statistically tested with the Multiple Correspondence Analysis (MCA) method.

3.1. Scenario Based Approach

In rapidly changing and transforming cities, the inadequacy of traditional planning methods to produce solutions to urban problems has encouraged researchers to use different tools. Scenario-based practices are one of them. Scenarios, which consist of stories about the future, encourage new ways of thinking among planners and participants, questioning the future effects of current policies and revealing alternative future visions and expectations for urban spaces (Chakraborty and McMillan, 2015).

According to Schwartz (1997), the concept of scenario is a way of thinking about what tomorrow might be like, discovering the changing aspects of our current lives and creating stories about the future so that we can adapt to this change. In this context, "scenario" can be defined as "A tool for organizing one's perceptions of alternative future environments" (Schwartz, 1997, p. 4). Godet (2000) mentions 5 benefits of these strategic forward-looking approaches that we can characterize as scenarios. These are: Reducing inconsistencies, stimulating imagination, creating a common language, creating a collective way of thinking and ensuring its adoption by decision makers (Godet, 2000:8). Scenarios are a way of thinking and can help people make better decisions (Schwartz, 1997). The future thinking endeavour, also defined as "la prospective", aims to create a hypothetical idea of the future by basing decisions as far into the future as possible and to find the important trends of society (Godet and Roubelat, 1996, p. 2).

Scenario-based studies can be divided into qualitative and quantitative. However, the approach coming from recent international scenario studies is that we do not need to choose between qualitative and quantitative scenarios. On the contrary, the combination of qualitative and quantitative studies gives more reliable results in analysing scenario outputs (Alcamo, 2008). The scenarios created within the scope of this study were also prepared with a qualitative approach using a storyline and presented to the participants. However, the analysis of the scenario outputs allowed the future expectations that emerged as a result of the participants' directing the scenario to be analysed with analytical methods. The prominent feature of this method is that it obtains more realistic results by blending normative information with analytical information (Goodspeed, 2017).

The scenario was created with a design fiction approach. Design fiction generates data that is used to assess the impact on lifestyles of services that do not yet exist but have the potential to exist or that exist but are not widespread (Harwood et al., 2020). The functionality of possible future technologies is explored when creating new and alternative future scenarios (Tanenbaum, 2014). By presenting possibilities that can affect society while shaping the future, the approach enables the participant to activate their imagination, suspend negative attitudes and imagine the future by blurring the boundary between fiction and reality (Bleecker, 2022).

The transformation of cities at an uncontrollable pace and the emergence of new types of spaces with the development of technology have paved the way for the use of the scenario technique as a tool in developing assumptions about the future of urban and public space (Blythe, 2014). This process helps us generate ideas that will shape the future and analyse the social impacts of current technologies. This study presents virtual and hybrid spaces that exist today, that do not yet exist, or that exist but have not yet become widespread, to the participants' preference, taking into account the developments in information and communication technologies with a scenario-based design fiction approach. In order to analyse the participants' approaches to their future physical, virtual and hybrid space preferences, 3 different scenarios were created for their lifestyles after 20 years. The scenarios were structured in three different categories for the spatial preferences of working individuals, students and non-working/retired individuals. Participants participated in the evaluation by choosing the most appropriate scenario for themselves. The scenario includes a set of activities related to daily life within the context of a story and the participants indicate the spaces (physical-virtual-hybrid) through which they would like to perform each of the activities they are asked in between the stories. These activities are grocery shopping, sports activities, travel organization, language course, museum visit, dinner and socializing.

3.2. Sample Selection

Purposive (monographic) sampling method and snowball sampling method, which are among the qualitative research sampling methods, were used to determine the participants to represent the research population.

The population of the research consists of individuals across Turkey. However, due to the practical limitations of the application such as time, resources and accessibility, a subset that is considered to have sufficient representation in terms of technology and urban space use was selected. Therefore, in order to ensure the validity and reliability of the study, the top 5 cities with the highest population in Turkey (Istanbul, Ankara, Izmir, Bursa and Antalya) were selected as the sample group in line with a structure that has high demographic and socio-economic diversity, has sufficient representation in terms of digital access and technology use, and includes sectoral differences.

The survey started with one person from each city accessing the survey link and being asked to forward it to individuals aged 18 and over in their city of residence. It was emphasized that the survey should be delivered to individuals with different demographics. In addition, the survey was also shared on social media platforms. In this respect, it can be said that convenience sampling method was also used in sample selection.

3.3. Sample Size

The confidence level in sample determination can be 99% or 95%, and the acceptable margin of error can vary between 1% and 5%. In this study, 95% confidence level and 5% margin of error assumptions are accepted. On March 15-2025, the population of Istanbul, Ankara, Izmir, Bursa and Antalya for the year 2024, which is the most recent data, was accessed through TurkStat (Turkish Statistical Institute) and only the group aged 18 and over was included in the population. The population of the 5 cities for the year 2024 aged 18 years and over is Istanbul 11.986.847, Ankara 4.531.181, Izmir 3.562.064, Bursa 2.453.932 and Antalya 2.078.804, totalling 24.612.828 people selected according to the criteria (URL-1). In order to calculate the sample size, the sampling equation in which the number of individuals in the population is known and the frequencies of discontinuous data can be measured was applied:

$$n = \frac{N.Z^2.p(1-p)}{(N-1).e^2 + Z^2.p(1-p)}$$

n: Number of samples required
N: Population size
Z: Z value corresponding to the confidence level (95%)
p: Variance ratio (0.5)
e: Margin of error (5% / 0.05)

When the required data are added to the formula, a sample size of approximately 384 people is determined with a 95% confidence level and a 5% margin of error. In the study, a sample size of 391 people was reached.

3.4. Socio-Demographic Structure of Participants

The data on the demographic characteristics of the participants obtained through the survey applied within the scope of this research play a critical role in analysing the preferences of different demographic characteristics regarding digitalization and the use of urban space. In the study, demographic data were collected and evaluated in 4 groups: gender, age, education level and employment status.

When gender distribution was analysed, 69.1% of the participants were female and 30.9% were male. The distribution according to age groups was grouped into 5 categories and 44.25% were between the ages of 18-27, 29.41% between 28-37, 15.09% between 38-47, 7.42% between 48-57 and 3.84% between 58-65. When the educational status of the participants is examined, there are no illiterate and only literate participants; 1% have primary education, 1% have secondary education, 12% have high school, 7.2% have associate's degree, 60.9% have bachelor's degree and 17.9% have graduate or doctorate level education. The majority of the participants are employed with a rate of 62.66%, 19.18% are students, 13.8% are not working and 4.35% are retired (Table 1).

Table 1: Socio-demographic structure of participants.

Demographic Characteristics		Category	Number of Participants	Distribution (%)
Gender		Female	270	69.1
		Male	121	30.9
		Total	**391**	**100**
Age		18-27	173	44.25
		28-37	115	29.41
		38-47	59	15.09
		48-57	29	7.42
		58-65	15	3.84
		Total	**391**	**100**
Educational Status		Illiterate	0	0
		Literate	0	0
		Primary Education	4	1
		Secondary Education	4	1
		High School	47	12
		Associate degree	28	7.2
		Bachelor's Degree	238	60.9
		Graduate/Doctoral Degree	70	17.9
		Total	**391**	**100**
Employment Status		Unemployed	54	13.8
		Student	75	19.18
		Retired	17	4.35
		Employed	245	62.66
		Total	**391**	**100**

3.5. Multiple Correspondence Analysis (MCA)

Multiple Correspondence Analysis (MCA) was conducted to determine the demographic characteristics of the participants. As a first step in determining demographic characteristics, the responses obtained from 391 participants were evaluated as raw data. Data on "gender", "age", "education level" and "employment status" were used to identify prominent socio-demographic groups (Table 2).

According to the results obtained, 4 basic socio-demographic profiles emerge. Student, female, respondents aged 18-27 with a bachelor's degree (Group A); working, male, respondents aged 28-37 or 38-47 with a graduate/doctoral degree (Group B); respondents with primary and secondary education (Group C); and non-working respondents aged 48-57 with a high school or associate's degree (Group D). Most of the retired participants are aged 58 and over (Figure 1.)

Table 2: Multiple correspondence analysis model summary.

		Variance Accounted For		
Dimension	**Cronbach's Alpha**	**Total (Eigenvalue)**	**Inertia**	**% of Variance**
1	.625	1.881	.470	47.026
2	.490	1.581	.395	39.525
Total		3.462	.866	
Mean	**.563**[a]	1.731	.433	43.275

a. Mean Cronbach's Alpha is based on the mean Eigenvalue

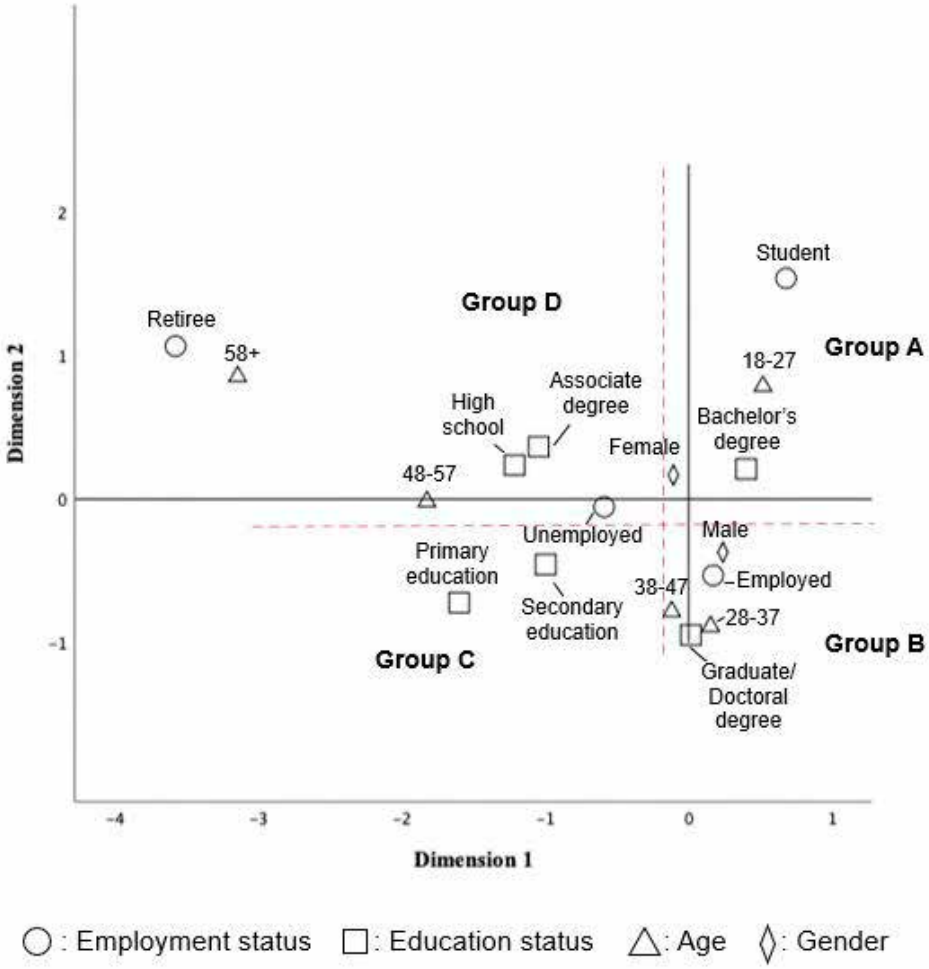

Figure 1: Socio-demographic profiles of participants.

After defining 4 socio-demographic profiles, the groups' preferences for virtual space, hybrid space and physical space in different activities related to daily life were investigated in the scenario-based survey section based on the design fiction. At this stage, "gender", "age", "educational status" and "employment status" were considered as independent variables, while the preference for virtual, hybrid or physical space according to different activity types was determined as the dependent variable.

In Figure 2, survey participants' preferences for virtual, hybrid or physical locations for grocery shopping are analysed together with socio-demographic groups. Respondents belonging to group A are highly represented by the option "Using a mobile application without leaving home". It is seen that hybrid space preference is predominant in this group. Participants belonging to group B are represented by the options "Connecting to the virtual market with VR glasses without leaving home" and "Physically going to the market but using augmented reality technology". In this group, it is seen that the preference for virtual space and hybrid space is predominant. This situation reveals that working male participants with a high level of education, between the ages of 28-47, want to experience digital technologies as well as experiencing the space and shows that they are individuals who are open to innovation and interested in digital systems. For the participants belonging to group C, there was no specific clustering feature on the choice of place for grocery shopping. Participants belonging to group D prefer the option of "physically going to the market". It is seen that participants aged 48-57, with high school or associ-

ate degree education level and not working are distant from virtual and hybrid spaces in shopping activities and prefer to shop physically.

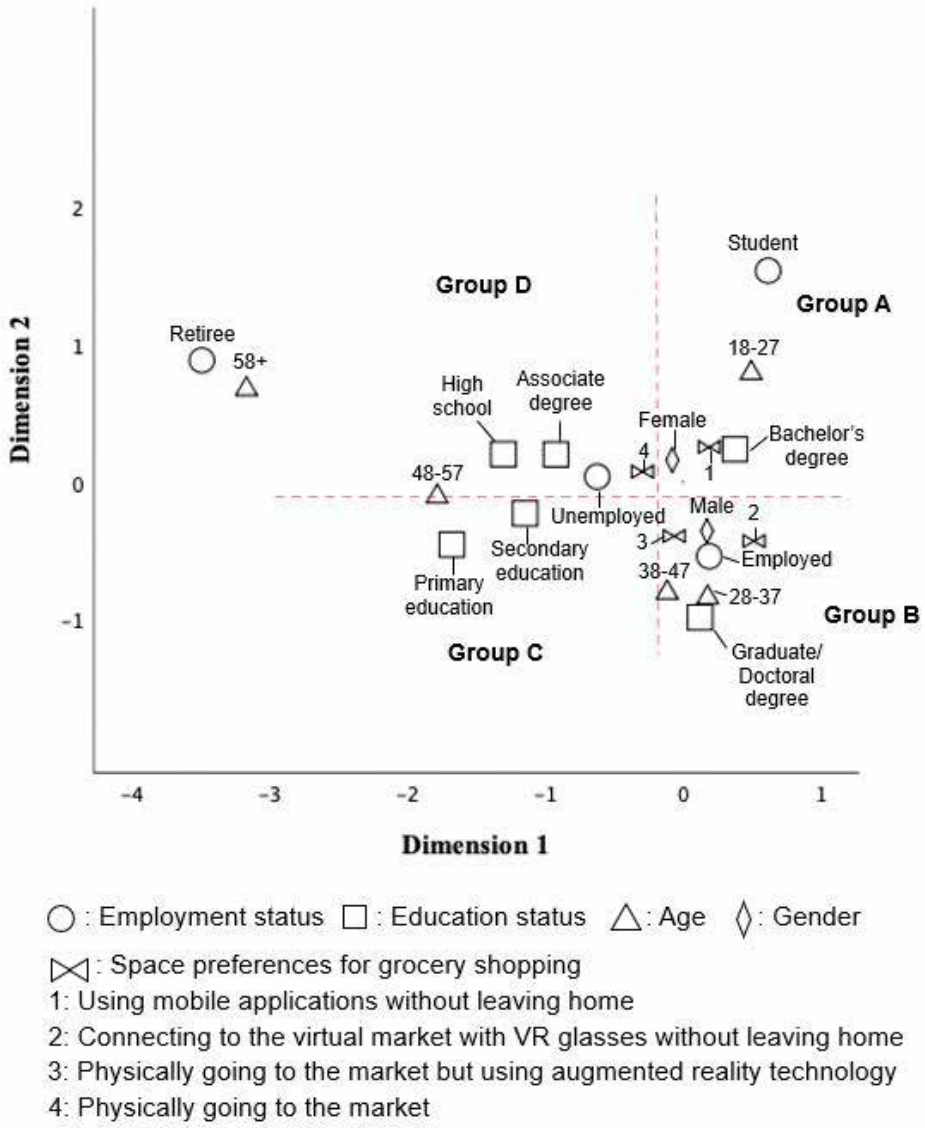

Figure 2: Socio-demographic characteristics of survey participants based on space preferences (Grocery shopping).

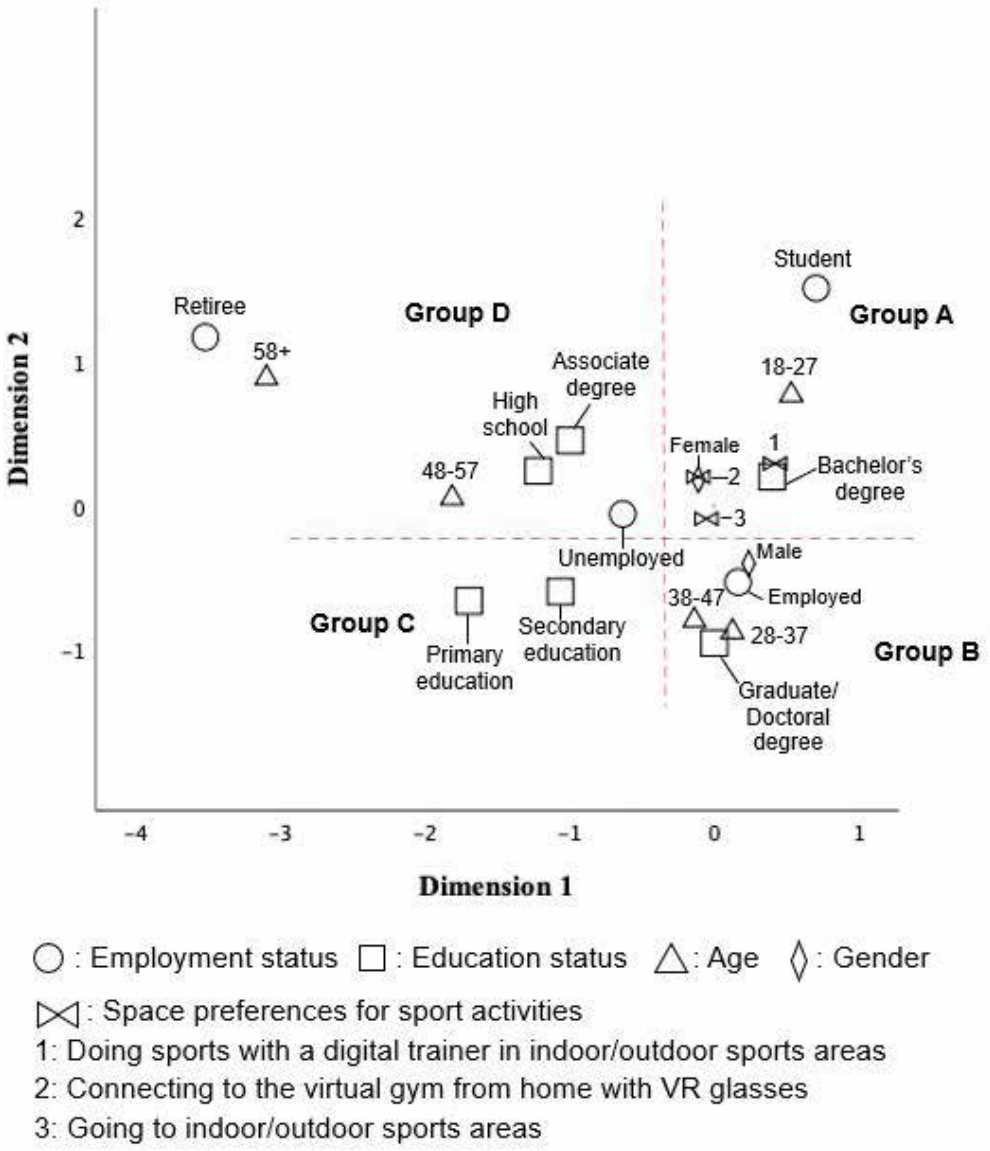

Figure 3: Socio-demographic characteristics of survey participants based on space preferences (Sports activities).

In Figure 3, survey participants' preferences for virtual, hybrid and physical spaces for sports activities are analysed together with socio-demographic groups. Participants belonging to groups B, C and D did not show any clustering in the choice of spaces for sports activities. Participants in group A are represented by all 3 space preferences: virtual, hybrid and physical. However, there is intense clustering between certain demographic characteristics and space preferences. For example, while individuals with a bachelor's degree are mostly represented by the option of "doing sports with a digital trainer in indoor/outdoor sports areas", almost all of the female participants prefer the option of "connecting to the virtual gym from home with VR glasses". This situation reveals that the participants at the undergraduate education level want to explore this space through digital tools as well as physically experiencing the space in sports activities. While female participants do not prefer outdoor spaces for sports activities, they want to experience digital tools at home and realize their activities through virtual spaces.

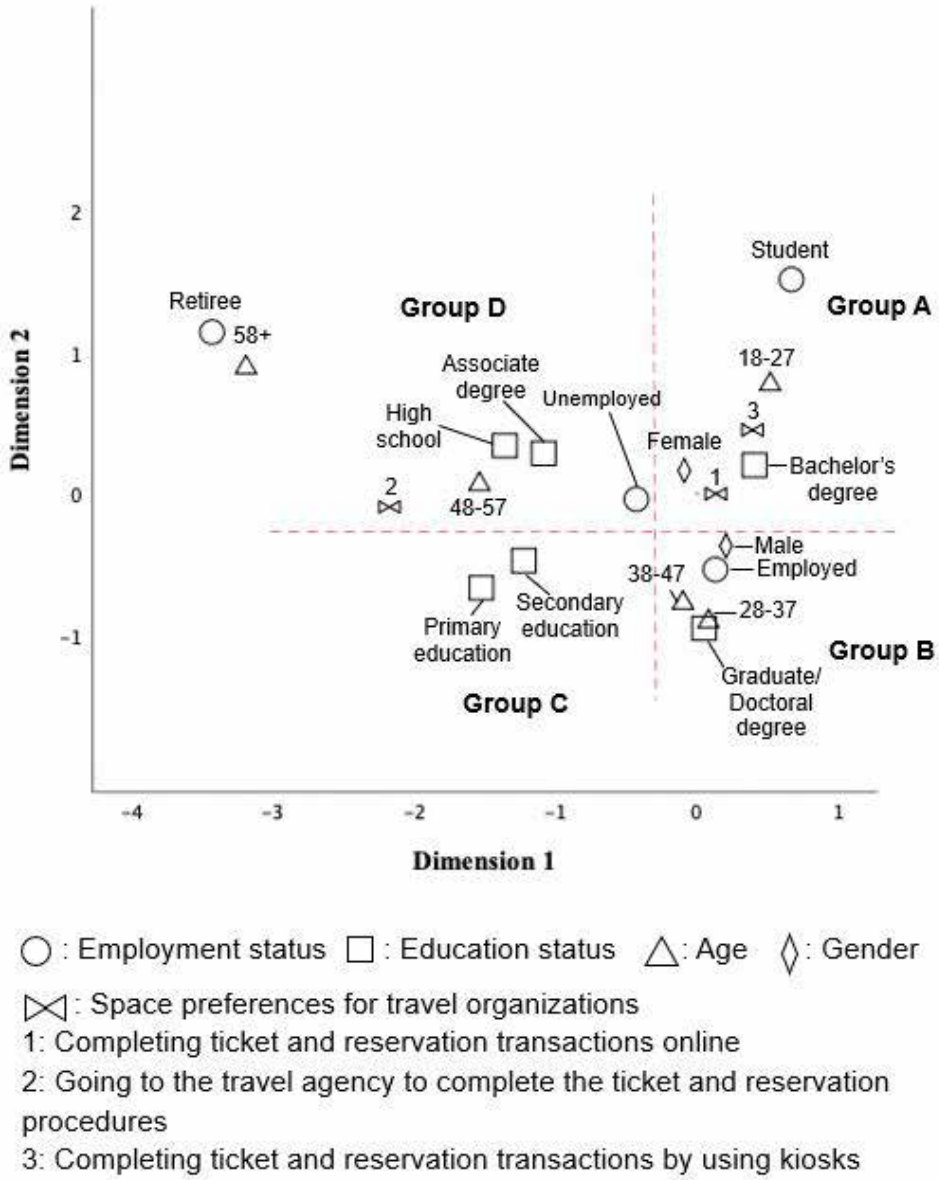

Figure 4: Socio-demographic characteristics of survey participants based on space preferences (Travel organization).

In Figure 4, survey participants' preferences for virtual space, hybrid space and physical space for travel organization are examined together with demographic groups. The answers "Completing ticket and reservation transactions online" and "Completing ticket and reservation transactions by using kiosks" stand out among the respondents belonging to group A. While it is seen that student participants at the young age group tend to prefer virtual and hybrid spaces for travel organizations, it also reveals the predisposition of this group to digital technologies. Although the answer "completing ticket and reservation transactions online" was prominent among the participants in group B, no clustering was found to characterize this group. No clustering feature was observed in the location preferences of the participants belonging to group C for travel organizations. The prominence of the answer "Going to the travel agency to complete the ticket and reservation procedures" among the participants belonging to group D reveals that the participants exhibit a tendency towards physical space preference. It is seen that the participants who belong to the middle-upper age group, have high school or associate's degree education and are not employed are distant from virtual and hybrid spaces for travel organizations

and want to complete their transactions physically.

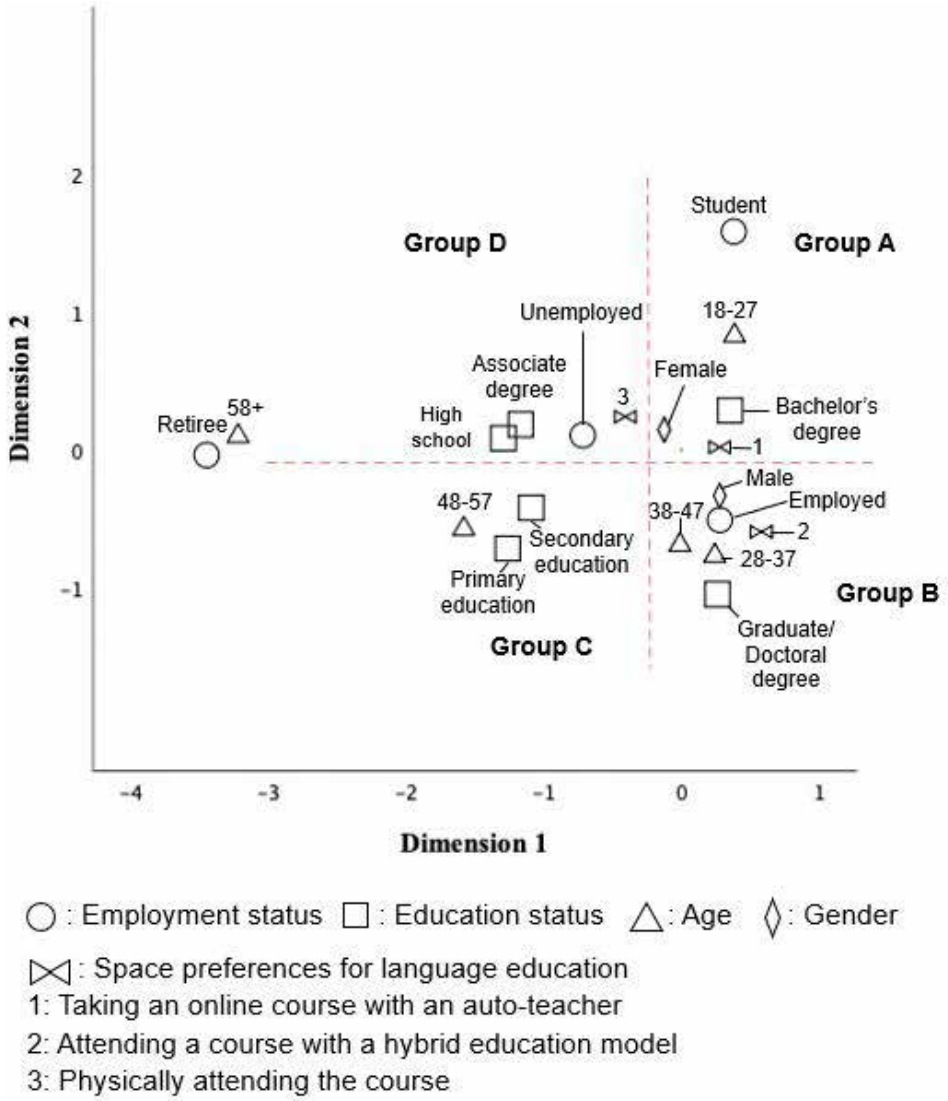

Figure 5: Socio-demographic characteristics of survey participants based on space preferences (Language education).

In Figure 5, survey participants' preferences for virtual, hybrid and physical spaces for language education are analysed together with socio-demographic groups. The answer "Taking an online course with an auto-teacher" stands out among the respondents belonging to group A. The fact that educated and student women prefer virtual spaces in the field of education is open to be associated with the fact that they have online education experiences with the effect of the Covid-19 pandemic due to their age group. Not being dependent on a place offered by online courses instead of physically going to a course for education provides a preferable environment for this group. Participants in group B show a clustering feature with the answer "Attending a course with a hybrid education model". Participants between the ages of 28-47, consisting of educated and working men, prefer an educational environment where they can both participate virtually and physically go whenever they want. When this situation is interpreted from the perspective of the working age group of these participants, it shows that a flexible understanding of space is important. Group A participants showed a tendency towards virtual space

preference and Group B participants showed a tendency towards hybrid space preference. Participants belonging to group C did not exhibit any clustering feature for the preference of location in language education. For the participants belonging to group D, the answer "physically attending the course" stands out. As a similar result with the previous questions on location preference, it is revealed that participants with high school and associate's degree education and who are not working prefer physical locations for education and want to experience the location directly without interacting with digital tools.

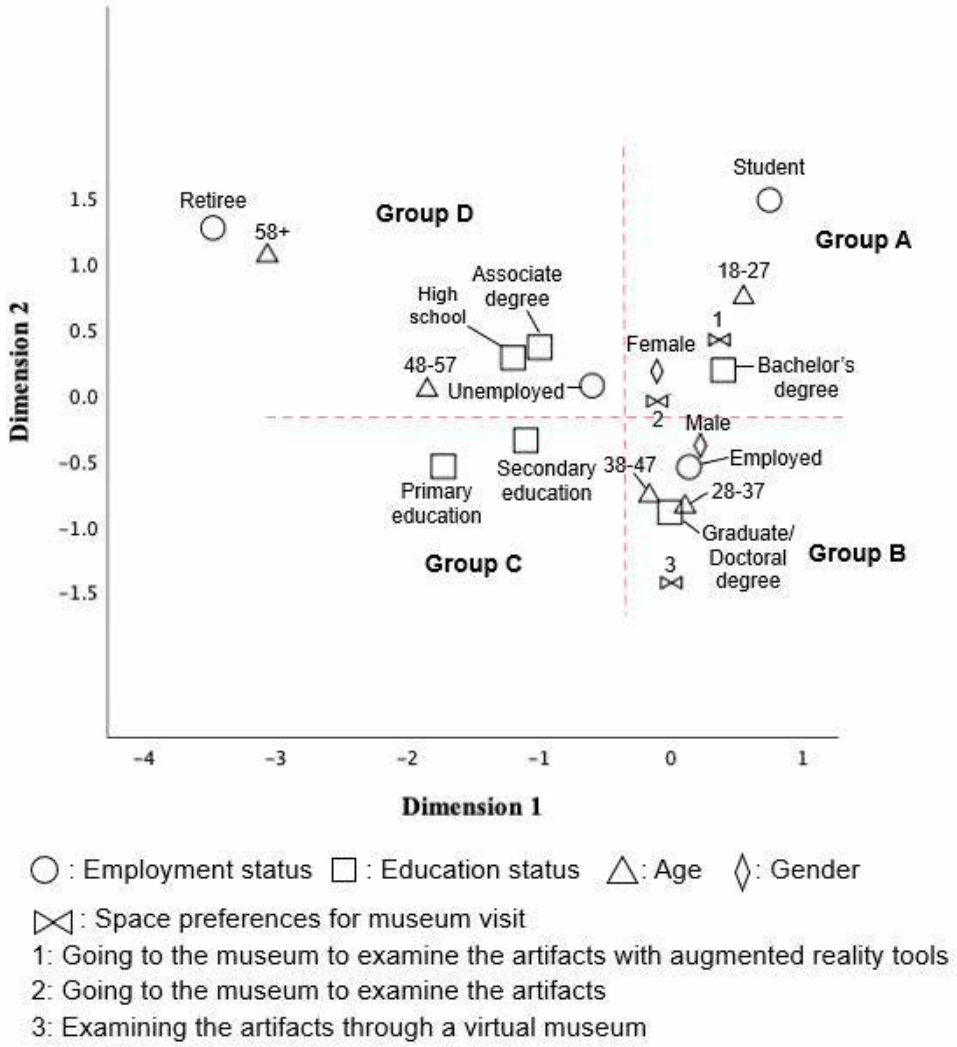

Figure 6: Socio-demographic characteristics of survey participants based on space preferences (Museum visit).

In Figure 6, the virtual space, hybrid space and physical space preferences of the survey participants for museum visits are analysed together with socio-demographic groups. The responses "Going to the museum to examine the artifacts with augmented reality tools" and "Going to the museum to examine the artifacts" show a clustering feature, especially among the participants of group A. It is noteworthy that participants between the ages of 18-27, with undergraduate education level and students attach importance to being physically present in the place in question for museum visits. However, while some of this group of participants would like to experience the artifacts in the physical space with digital tools, some of them do not prefer this. Participants in group B are represented by the response "Examining the artifacts through a virtual museum.". This reveals that 28-47 years old, educated and working men are a group of participants who are open to experiencing digital systems and innovations, as in the previous questions, and they want to realize their museum visits through virtual museum visits without the need for a physical space.

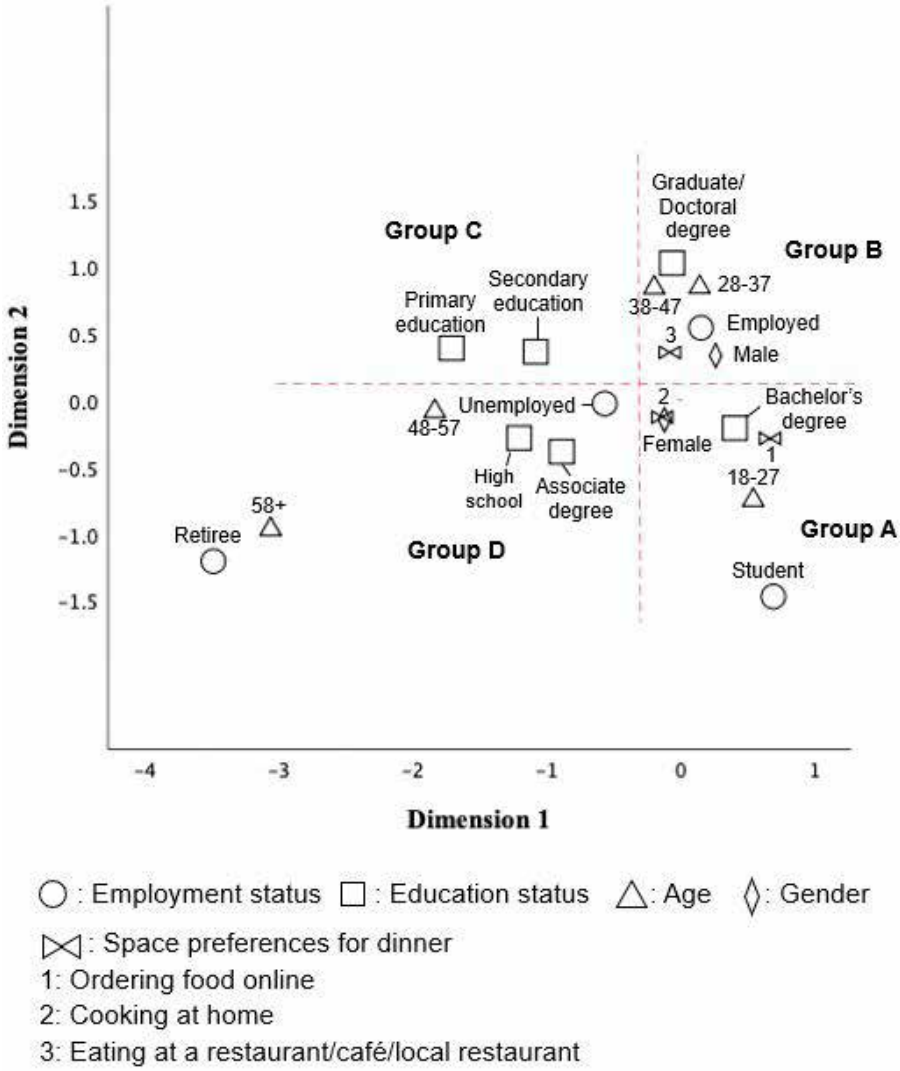

Figure 7: Socio-demographic characteristics of survey participants based on space preferences (Dinner).

In Figure 7, survey participants' preferences for virtual and physical spaces for dinner are analysed together with socio-demographic groups. The options "Ordering food online" and "Cooking at home" tend to cluster for respondents in group A. However, there is a strong correlation between certain demographic characteristics and space preferences. However, there is an intense relationship between certain demographic characteristics and space preferences. For example, almost all of the female respondents in group A prefer to cook at home, while the majority of respondents with a bachelor's degree prefer to order food online. Participants in group B, on the other hand, tend to cluster with the option of "Eating at a restaurant/café/local restaurant" for dinner. In this case, it can be said that 28-47 years old, educated and working male participants prefer out-of-home space for dinner. Participants with socio-demographic characteristics representing groups C and D did not show any clustering in their dinner preferences.

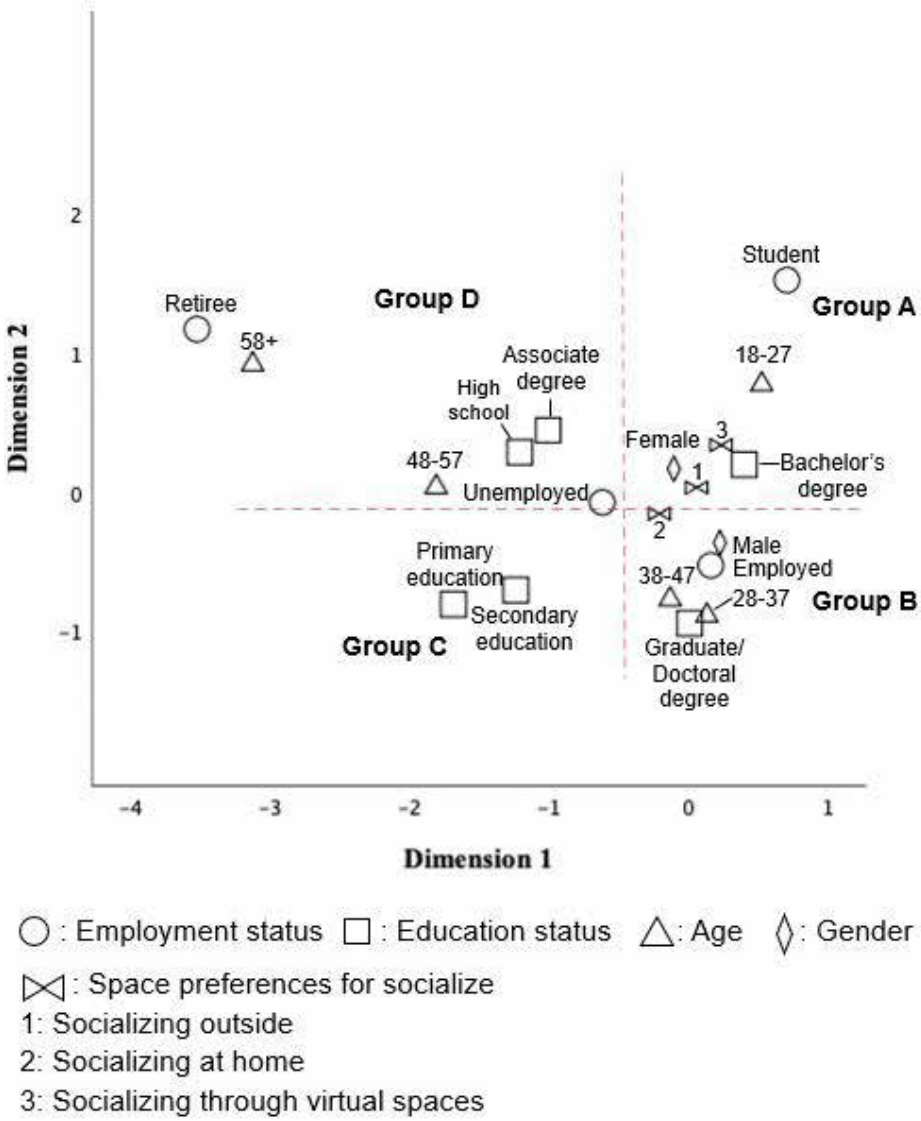

Figure 8: Socio-demographic characteristics of survey participants based on space preferences (To socialize).

In Figure 8, survey participants' preferences for virtual and physical spaces for socializing are examined together with socio-demographic groups. While the answers "Socializing through virtual spaces" and "Socializing outside" stand out among the participants in group A, the answer "Socializing at home" stands out among the participants in group B. Participants in group A preferred virtual spaces and physical spaces outside the home for socializing, while female participants generally preferred socializing outside and participants with a bachelor's degree preferred socializing through virtual spaces. Participants in groups C and D did not show any tendency characteristics in the options offered for socializing.

4. **Conclusion and Discussion**

This study aims to explore trends in the intersection of physical and virtual space in the future through a speculative approach while examining the impact of digital technologies on cultural dynamics and their potential to reconfigure urban space.

The scenario created with a design fiction approach was analysed in the context of its relationship with the future spatial preferences of the participants in line with their socio-demographic characteristics. The participants

were asked about their spatial preferences for several activities in daily life such as grocery shopping, sports activities, travel organization, language education, museum visits, dinner and socializing preferences. Multiple Correspondence Analysis was used to discover whether the socio-demographic characteristics of the participants showed a clustering feature. As a result of the test, 4 main groups emerged. These are: Female participants between the ages of 18-27, with a bachelor's degree, who are students; male participants between the ages of 28-47, with a graduate/doctorate degree, who are working; participants with primary or secondary education; and finally, participants between the ages of 48-57, with a high school or associate's degree, who are not working. Different socio-demographic groups showed certain variations in their preferences for spaces for different activities.

Student participants between the ages of 18-27, with a bachelor's degree, prefer virtual or hybrid spaces in almost all activities. This socio-demographic group prefers mobile applications for grocery shopping, digital coaches and virtual gym for sports activities, online booking or kiosks for travel organizations, auto-teachers for language education, augmented reality technologies and physical participation for museum visits, online ordering or home cooking for dinner and virtual spaces or out-of-home environments for socializing. Considering the space preference tendencies of this socio-demographic group in general, they can be called "digital natives" as defined by Marc Prensky (Prensky, 2001). As Souza e Silva (2006) points out, this group, due to the age range it represents, was born into the digital age or has been interacting with digital tools for a very long period of its life. For this reason, they prefer to perform many of their daily activities through virtual or hybrid spaces rather than interactively experiencing physical space.

Another socio-demographic group that shows clustering characteristics is the 28-47 years old, working, male participants with a graduate/doctoral degree. This group prefers to do grocery shopping through VR glasses or by using augmented reality technologies in the market, to visit artifacts through virtual museums and to use hybrid space for language education, while they prefer to go to outdoor environments such as cafes or restaurants for dinner and to be at home for socializing. When the virtual space preferences of this participant group are analysed, it is seen that they are interested in technologies that are not yet widely used but are expected to become widespread in the future and they want to experience the space together with technology. These characteristics, which Lengsfeld defines as "digital enthusiast", are represented by an intense interest in new digital technologies and an active participation in digital transformation (URL-2).

Another socio-demographic group that shows a prominent tendency in terms of location preference in the context of different activities is the participants between the ages of 48-57, with a high school or associate's degree and not working. This group prefers to go to the market for shopping, organize their travels through agencies and physically attend a course for education. Participants who prefer to experience the urban space firsthand in their daily life activities attach importance to face-to-face interaction even in the types of activities where technological applications are widely used today. It is seen that the behavioural norms brought by the digital age, which can be considered among the basic elements of cultural values, do not cause dramatic changes in the participants with the socio-demographic characteristics in question. This behaviour pattern, which tends to preserve the habits of the past, uses the Internet as a second option to access information, and which Marc Prensky calls "digital immigrants", would be an accurate approach to define the participant group in question (Prensky, 2001).

As the last noteworthy finding of the study, the expectations of different socio-demographic groups regarding their preferences for the use of urban space in the context of urban life in 20 years show different characteristics. Basically, 3 different approaches emerge: those who embrace the adopted urban use values, those who continue this tradition by being born into an already existing digital world and those who are open to the idea of experiencing urban space with digital tools. The results show that digitalization brings along various approaches in

the culture of urban space use in the context of different socio-demographic groups, thus creating the need to rethink the future of urban space.

Abstract
Topic modelling and extraction is not a new field in synthesis-research, but with the current advancements in LLMs and Transformer-based models, such processes can as well be advanced with better accuracy and efficiency. In this paper, we explore the application of Transformer based methods, firstly to validate the domain experts based manual identification of topics and secondly, to create a benchmark method for machine-based extraction of Topics and Themes related to sustainable urban development. The research uses a corpus of documents, including Project proposals and Project profiles, from ten projects in the field of Sustainable Development. The process builds upon established methodology whereby the tokenized text is used to create embeddings with BERT (Bidirectional Encoder Representations from Transformers) to create a vector space. As part of the new proposed architecture, the embeddings are then clustered and labelled according to their cosine similarity with domain expert themes, which allows a comprehensive view of themes/topics and sub-topics.

Keywords: Topic modelling, BERT based transformers, Sustainable development, Semantic clustering, Thematic clustering

1. Introduction

1.1. Background

Sustainable urban development policies are essential to address global challenges such as climate change, rapid urbanization, and population growth. Cities, housing over half of the world's population, contribute approximately 70% of global carbon emissions and 60% of resource consumption (United nations, 2019). With urban populations projected to increase by 2.5 billion by 2050, primarily in Asia and Africa (UN-Habitat, 2020), the strain on resources and ecosystems will intensify, necessitating effective sustainable policies. Sustainable urban policies aim to mitigate environmental impacts while enhancing quality of life, resilience, and inclusivity. Climate change exacerbates extreme weather events in urban areas, posing risks to infrastructure and populations (IPCC, 2021). Effective policies must incorporate adaptation and mitigation strategies, such as green infrastructure and renewable energy, to reduce risks and vulnerability.

Furthermore, sustainable development addresses socio-economic disparities by promoting equitable access to resources and green spaces in densely populated areas (OECD, 2020). Policies encouraging resource efficiency and pollution control are pivotal for urban resilience and long-term viability. Trend analysis is critical for monitoring policy changes and literature themes in sustainable urban development. It detects patterns to identify significant shifts and emerging priorities, providing insights into policy evolution in response to societal needs and environmental pressures (Olawumi and Chan, 2018). Advancements in Artificial Intelligence (AI), particularly Natural Language Processing (NLP) and Large Language Models (LLMs), have enhanced trend analysis by automating data extraction from vast textual datasets. These tools enable real-time analyses, improving the relevance of policy insights (Levitt, 2018; Kashi and Shah, 2023). Thus, trend analysis is invaluable in navigating the complexities of sustainable urban development and ensuring that policies remain responsive and adaptive.

1.2. Rationale

Qualitative trend analysis offers significant advantages by enabling policymakers to detect shifts in priorities, assess policy impacts, and anticipate future needs. It captures nuanced changes that quantitative methods may overlook, such as emerging themes in resilience, social equity, and environmental sustainability within urban policies. As cities adopt sustainability-focused frameworks, qualitative trend analysis reveals the evolution of policy goals in response to societal and environmental demands, supporting more adaptive policymaking (Olawumi

and Chan, 2018). It also provides insights into the long-term efficacy of sustainable development policies. However, sustainable urban development involves complex interactions between social, environmental, and economic systems. Rapid urbanization and climate change present challenges not easily captured by numerical data. Moreover, the growing volume of grey and academic literature—such as sustainability reports, policy frameworks, and research papers—creates information overload, hindering decision-making. Addressing these challenges, this paper reports on the experiment undertaken to explore the application of Trend analysis in Sustainable Urban Development. The experiment aims to bring for the methodology and adaptation employed for extracting Topics from texts and converting them to themes for trend monitoring.

The paper begins with a comprehensive literature review of the scope of Topic modelling, followed by the experiment conducted with a modified version of the Transformer based models. The research is conducted within the context of the SURE Facilitation and Synthesis Research project, focusing on sustainable urban development in Southeast Asia and China.

2. Literature review

2.1. Evolution of Topic modelling

Topic modelling is a popular technique used for text analysis that provides an automatic approach for coding a collection of documents into a set of meaningful categories, known as topics (Thompson and Mimno, 2020; Lore, Harten and Boeing, 2024; El-Gayar et al., 2024). It is considered an unsupervised machine learning technique primarily used to uncover hidden patterns and structures from large sets of unstructured data (El-Gayar et al., 2024). The goal of topic modelling is to organize, search, and summarize unstructured data, making it a valuable tool in various fields (El-Gayar et al., 2024). Topic models aim to identify hidden topical patterns within a collection of texts (Egger and Yu, 2022).

Different techniques and approaches have been used to extract topics using topic modelling (El-Gayar et al., 2024). Among the most established and frequently adopted techniques is Latent Dirichlet Allocation (LDA) (Egger and Yu, 2022; El-Gayar et al., 2024). Introduced by Blei et al., LDA is a probabilistic generative model (Churchill and Singh, 2022; Egger and Yu, 2022; El-Gayar et al., 2024) that aims to discover the topics in a document based on the words it contains. It views each document as a mixture of topics, and each topic as a distribution over words (Churchill and Singh, 2022; Lore, Harten and Boeing, 2024; Kapoor et al., 2024). LDA became a widely used algorithm for extracting meaningful topics from various types of text data (Churchill and Singh, 2022; Egger and Yu, 2022; El-Gayar et al., 2024). It is often considered a classic or traditional approach to topic modelling (Mu et al., 2024; Kapoor et al., 2024).

2.2. The promise of Transformer based models

Transformer based Large Language Models (LLMs) offer a significant promise for the field of topic modelling, presenting a compelling alternative to traditional methods like Latent Dirichlet Allocation (LDA) (Mu et al., 2024). The promise of these models for topic modelling stems from their advanced language understanding capabilities and flexible application (Mu et al., 2024). Classic topic modelling approaches, such as LDA, may lack semantic understanding and struggle to capture nuanced semantics and contextual understanding (Mu et al., 2024; Kapoor et al., 2024). LLMs, on the other hand, leverage deep neural networks to learn rich, contextual representations (Kapoor et al., 2024) and can capture subtle semantic, pragmatic features, nuances, and subtle thematic undertones in language (Mu et al., 2024; Kapoor et al., 2024). This enables a richer and more detailed categorization of topics (Egger and Yu, 2022; Mu et al., 2024).

LLM-based models can generate more cohesive and interpretable topics compared to LDA (El-Gayar et al., 2024).

BERTopic and RoBERTa, representing Transformer-based models, generated more cohesive topics in a case study, where associated words were closely related thematically (El-Gayar et al., 2024). This increased cohesiveness makes the topic labelling process easier and faster compared to topics generated by LDA, which often contain a large number of focused words. While LDA may achieve a higher labelling rate, the process is more challenging due to the word count and potential overlapping labels (El-Gayar et al., 2024). As opposed to the traditional approach, LLMs or Transformer based models can produce topics with superior clustering and improved semantic coherence.

Unlike traditional methods that often require text preprocessing (like stemming and lemmatization) and post-processing like manual topic labelling and interpretation, LLMs can also aid in reducing the need for human involvement (Mu et al., 2024). They can automatically extract (or generate) topics and provide human-understandable explanations. LLMs can also be used off the shelf to automatically assess the coherence of topic word collections and their ratings have shown to highly correlate with human annotations (Mu et al., 2024). Studies have shown that using LLM-extracted key phrases for clustering can reduce noise, avoid manual data cleaning, and result in semantically concentrated clusters (Kapoor et al., 2024).

2.3. Semantic clustering

Transformer based models, such as BERT (Bidirectional Encoder Representations from Transformers) and RoBERTa (Robustly Optimized BERT Pre-training Approach), utilize contextualized word representations (Thompson and Mimno, 2020; Churchill and Singh, 2022). Unlike earlier models that assigned a single vector to each word regardless of its usage, BERT generates embeddings that capture the dynamic meaning of words in their specific context (Thompson and Mimno, 2020; Churchill and Singh, 2022; Lore, Harten and Boeing, 2024; El-Gayar et al., 2024). This capability allows BERT to understand nuanced phrases and word relationships by considering the surrounding sentence (Thompson and Mimno, 2020; Lore, Harten and Boeing, 2024). These contextual embeddings provide a better representation and performance compared to traditional word embedding techniques, especially when working with large sparse matrices in NLP (El-Gayar et al., 2024).

One significant application of these contextual embeddings is in semantic clustering. This involves grouping textual data (like words, tokens, or documents) based on their meaning or semantic similarity, as captured by the embeddings (Thompson and Mimno, 2020). Clustering token-level contextualized word representations can produce output that shares many similarities with traditional topic models (Thompson and Mimno, 2020; Churchill and Singh, 2022). Since each word type is modelled as a single vector in vocabulary-level embeddings, those methods cannot easily account for polysemy (words with multiple meanings) or leverage local context for disambiguation (Thompson and Mimno, 2020). In contrast, token-level clustering, grounded in specific documents, supports a wide range of analysis techniques (Thompson and Mimno, 2020).

A key example of a BERT-based model implementing semantic clustering for topic extraction is BERTopic (Egger and Yu, 2022; Sy et al., 2024; El-Gayar et al., 2024). BERTopic uses BERT embeddings and a technique called class-based TF-IDF (c-TF-IDF) to generate dense clusters of documents and extract topic representations (Egger and Yu, 2022; Sy et al., 2024; El-Gayar et al., 2024). The process begins by representing each document as a set of numerical values using BERT embeddings and these embeddings capture contextual information about words (Sy et al., 2024). After obtaining the high-dimensional embeddings, dimensionality reduction techniques like UMAP can be applied to transform them into a lower-dimensional space, which helps in data visualization and clustering (Egger and Yu, 2022; Sy et al., 2024). Clustering algorithms, such as HDBSCAN, are then applied to the lower-dimensional space to identify dense clusters of data points, effectively grouping documents into topics (Egger and Yu, 2022; Sy et al., 2024).

Other approaches also leverage BERT embeddings for clustering. For instance, clustering tokens based on their contextual vectors drawn from BERT using k-means clustering has been proposed as a method to produce topics (Thompson and Mimno, 2020; Churchill and Singh, 2022). Clustering vocabulary-level embeddings has been shown to produce semantically related word clusters (Thompson and Mimno, 2020). Furthermore, hybrid techniques combine manual labelling with BERT-based models, using manually created labels as training data to fine-tune a pre-trained BERT model for sequence classification tasks to identify topics (Lore, Harten and Boeing, 2024). LLMs, including BERT-based ones, combined with clustering techniques can provide a scalable approach to identifying themes and patterns in unstructured text data by leveraging LLMs' semantic understanding and clustering algorithms' ability to group similar responses (Kapoor et al., 2024). BERT-based models provide rich, contextual embeddings of text, enabling semantic clustering approaches that group words, tokens, or documents based on their context-aware meaning (Thompson and Mimno, 2020; Sy et al., 2024).

2.4. Thematic Analysis

The rise of machine-based Topic modelling and analysis of text documents has provided immense help in understanding the semantic dimensions of text. This, however, is limited in some respects especially when compared with a more abstract level organization or classification of the said text. Such higher-level abstraction is where the Domain Expertise of humans becomes more valuable. Added to this, are the questions of traceability, reproducibility of knowledge and recognition of patterns over time that have been some of the obvious limitations of Machine based topic – modelling.

At the same time, Qualitative researchers have always focused upon the Thematic Analysis of texts as a qualitative analytic method (Clarke and Braun, 2017). Thematic analysis is defined as a method for identifying, analysing and interpreting patterns of meaning ('themes') within large text data (Clarke and Braun, 2017). According to Boyatzis (Boyatzis, 1998), such thematic analysis minimally organises and describes the text data in detail, but frequently goes further to interpret various aspects of the topic. Although it is one of the foundational method for qualitative analysis, there is no clear agreement about what thematic analysis is and how you go about conducting it (Braun and Clarke, 2006). Different fields of study, have approached the process of qualitative the-

matic analysis differently, but for the purposes of this research, we lean heavily on the fundamental work done by Braun & Clarke since the early 2000's (Braun and Clarke, 2006; Clarke and Braun, 2017; Braun and Clarke, 2021).

A simplistic structure proposed by (Clarke and Braun, 2017) for conducting a Thematic Analysis, involves Six main phases: Familiarising with data, generating/ extracting initial codes, searching for themes, reviewing themes, defining and labelling themes and lastly, reporting on the themes. In such a process, the researcher is not a passive participant but rather actively directs the identification of what's relevant in the text and what's not. As Braun and Clarke also argue that the notion that Themes are "Emerging" or "discovered", as a passive account of the process of analysis, denies such a role of the researcher. If anything, they conclude, Themes reside in our heads from our thinking about our data and creating links as we understand them (Braun and Clarke, 2006). There are usually two approaches to identifying themes as discussed below

2.4.1. Inductive versus Theoretical approach to Thematic analysis

In an Inductive approach, the themes are identified in a bottom-up way and are strongly linked to the text data under study. They do not necessarily need to reflect the researcher's theoretical interest in the subject (Braun and Clarke, 2006). Such an analysis involves coding or extracting key phrases from the text without any preconceptions of the researcher nor a pre-existing coding framework. As one can imagine, the Theoretical approach is driven by a researcher's analytical interest in the subject matter. The approach aligns with coding for a specific research question which is decided prior to the analysis (Braun and Clarke, 2006). In the context of Urban Development, this would be, for example, extracting phrases or coding the text on themes related to Ecosystem Services which deals with nature-based solutions.

Thematic analysis has however remained a rarely acknowledged method owing to its lack of transparency and lengthy ritual of execution. The flexibility of Thematic Analyses also allows for its drawbacks when compared to other qualitative approaches like Grounded Theory and Discourse analyses which could be considered 'Off- the -Shelf' methodologies.

2.5. Research Design

In qualitative research, a "trend" refers to a recurring pattern or tendency within data that reveals shifts over time, particularly in themes, priorities, or policy directions. A "trend signal" represents specific indicators or events that mark the emergence of these trends, such as policy revisions, increased funding in certain areas, or shifts in public discourse (Olawumi and Chan, 2018). These signals are vital as they enable researchers to identify the early stages of a trend, offering foresight into possible future developments. Key elements of trend analysis include "trend extrapolation" where researchers project current trends into the future to hypothesize potential directions (Sneegas et al., 2021). "Trend impact analysis" involves assessing the likely effects of these trends on a field, such as the impact of urban sustainability policies on climate resilience (Zhang et al., 2019). These components make trend analysis a comprehensive tool for understanding complex, qualitative data, facilitating a forward-looking perspective essential for adaptive and informed policy development.

For the purposes of our experiment, we derive the methodology for the first step of extracting "trend signals" and ascribe it the terminology of "topic extraction" which is often used in the topic modelling literature. We shall, use a modified BERT based methodology to extract semantic topics from the texts from ten projects under the SURE (Sustainable Urban Regions) funding. As we shall see, and is also advocated by (Braun and Clarke, 2006), themes do not just emerge from text but requires a certain view. Hence, we supplement the usual BERT based topic modelling architecture with a Theme mapping architecture as shown in Figure 2. Thereby, we propose a methodology for converting Semantic topics into Thematic topics.

3. Methodology

3.1. Project Data

The methodology outlines the approach used to review and analyse documents of ten research projects conducted under the Sustainable Urban Regions (SURE) initiative. The documents collected cover various phases of the projects, including the initial project proposals, the research and development phases, and the final reports. Each of these sources provides a comprehensive view of the projects, offering detailed insights into the participating institutions and collaborators, project funding structures, research objectives, identified problems, and the policy impacts. They also elaborate on the work packages, including the internal structure of the project and the distribution of tasks among partners. In addition, they contain project timelines, planning documents, academic profiles of team members, relevant references, and the academic literature that supports the research design and implementation.

Exclusion Criteria:

In order to ensure data confidentiality and maintain a focus on information directly relevant to the analysis, several categories of data were deliberately excluded from the review. First, the academic and professional curricula vitae of project partners were omitted, as they primarily contain personal backgrounds and qualifications that are not central to the scope of this analysis. Second, any personal contact information—such as email addresses, telephone numbers, or mailing addresses—was excluded in order to protect the privacy of the participants. Third, all financial documentation was removed from the analysis. This includes detailed funding information, cost breakdowns, and budgets.

Included Information:

The analysis focuses specifically on information that contributes directly to understanding the structure, aims, and scholarly contributions of each project. This includes general overviews and summaries that contextualize the research within broader goals, as well as detailed descriptions of the objectives, methodological frameworks, and policy relevance. In addition, the documents' descriptions of how work is divided through structured work packages, the scheduling and sequencing of tasks across timelines, and the incorporation of key academic references were all central to the analytical process. By narrowing the scope of the review to these components, this methodological approach ensures that sensitive personal and financial data are excluded, while allowing a comprehensive understanding of how the SURE projects contribute to sustainable urban regions´ development.

3.2. Focus Topics / Research Themes

In the initial stages of the project SURE, the team of qualitative researchers from the Synthesis team, had conceptualised 6 areas of Focus called Focus Topics. These are the research themes that each of the projects would fall under depending on their project proposal and expertise of research. The application of this methodology at the early stages of the project mandated that a limited number of documents were used for the manual thematic analysis. The documents used in this instance were the ones that we also use for the current experiment i.e, the project proposals and the shorter project profiles.

A systematic review was conducted to extract and identify the central themes from these documents. This process was complemented by open coding, a qualitative data analysis technique, to ensure an exhaustive identification of key topics. Following the coding process, thematic analysis was employed to group related topics, enabling the identification of overarching themes and priority areas. Table 1 shows the results of the initial experiment to derive the Research themes / Focus topics and their lower-order representations driven by domain expertise of the researchers involved.

Table 1 Overarching Themes or Focus Topics devised by domain expertise

Themes / Focus Topics	Lower-order Abstraction	Extracted from Documents
Integrated planning and development	Land use and urban development; Infrastructure and services	Strategic planning and governance tools; Build back better strategies; Integrated urban development; Integrated urban neighbourhood development; Co-development and decision support planning tools; Participatory urban development; Efficient municipal services of general interest; Reliable drinking water and sanitation supply; Integrated urban development
Urban Rural Nexus	Integrated territorial development	Urban-regional cooperation; Sustainable urban-rural development
Resource Efficiency and Mitigation	Strengthening circular development; Sustainable supply and waste infrastructure; Increase of indoor comfort; Energy and resource-efficient building	Urban -rural material flows
Risk management and Risk reduction	Concepts of multiple risk prevention; Strategic risk reduction; Risk transfer; Securing of critical infrastructure	Culturally adapted risk prevention; Informal settlements; Flood risk reduction; Improving (reduction) socio-economic vulnerability
Sustainable Behaviour and Practices	Migration; Environmentally friendly behaviour and sustainable living; Social and environmentally sustainable technologies; Sustainable utilization concepts for historic wooden houses; Environmentally friendly behaviour and sustainable lifestyles;	
Ecosystem Services and nature-based solutions	Blue and green infrastructures; Adaptation to flood risk	Sustainable water management; Strategic planning of green infrastructure; Modelling of nature-based solutions and blue-green infrastructure; Heat adaptation through green infrastructure and air quality improvement; Promotion of Urban Greening and Urban Climate; Improve of Air Quality

3.3. Proposed Architecture

Our proposed architecture for the experiment involves leveraging the original BERT workflow and integrating an additional flow that allows us to map the Semantic clusters on to a Thematic Analysis. Figure 2 shows the structure of the Integrated workflow, where the top part synthesizes all the Project documents like proposals and profiles, while the lower part synthesizes the Focus topic or Theme texts employing the same algorithms. We discuss each of these sections and the steps in the next section.

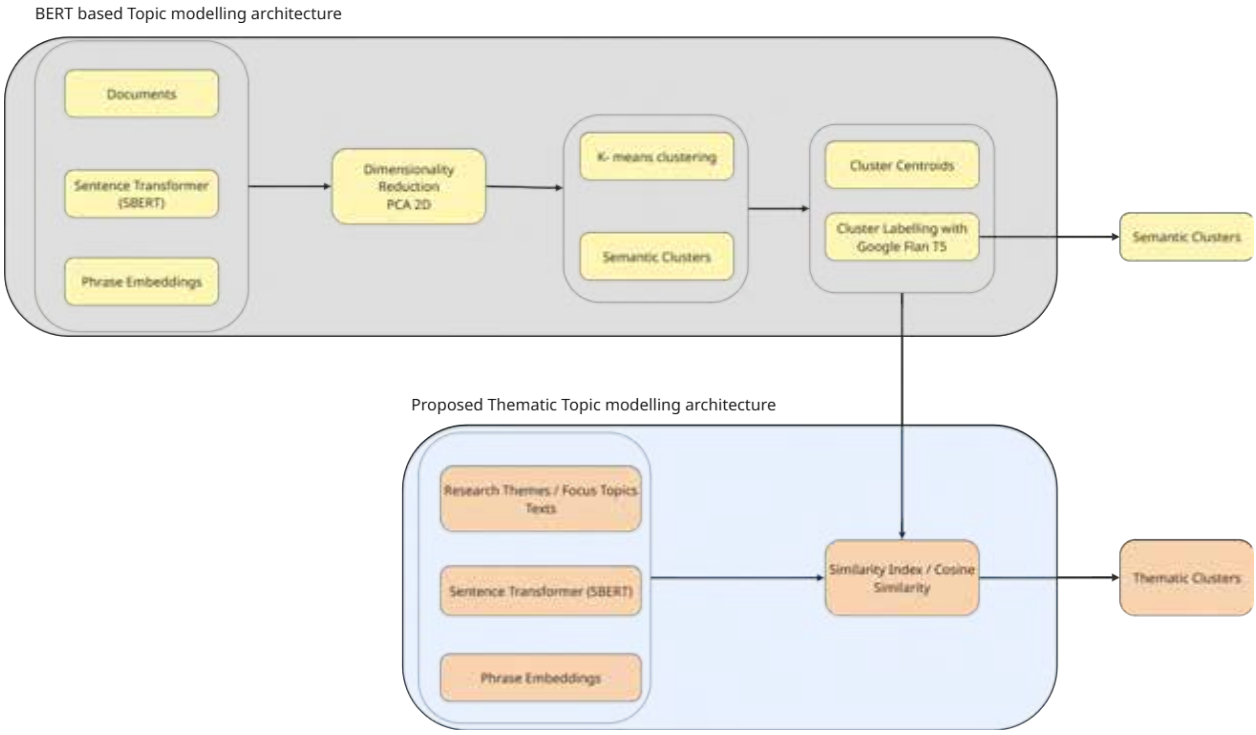

Figure 2 Proposed Architecture for Thematic clustering

4. Analysis

4.1. Phrase extraction

SBERT or Sentence BERT is a modification of the original BERT architecture, specifically designed to produce semantically meaningful phrase embeddings in a computationally efficient way. SBERT employs a Siamese Network structure map, which we shall not go into the details of in this paper, to map sentences into a vector space where semantically similar phrases lie close together and dissimilar ones far apart. As is evident form the study of (Cheng et al., 2023), SBERT's embeddings have been shown to align much better with human judgements of similarity and work effectively in downstream unsupervised tasks like clustering and topic modelling (Cheng et al., 2023).

We use the all-MiniLM-L6-v2 which is part of the SBERT family and used for its efficiency and small relative size. A total of 96,232 tokens were processed from the Project documents and these embeddings were saved with their metadata onto a ChromaDB vector database.

4.2. Dimensionality Reduction and Clustering

We use the PCA (Principal Component analysis) for transforming higher dimensional vector embeddings to 2D vectors to capture the highest variance. Here, as shown in Figure 3, the X-axis represents the highest variance and is the most important feature direction. The Y-axis represents the second highest variance in the data and together they aim to represent the highest possible variance in the data. This allows us to cluster the data in a more efficient way by using the standard k-means approach.

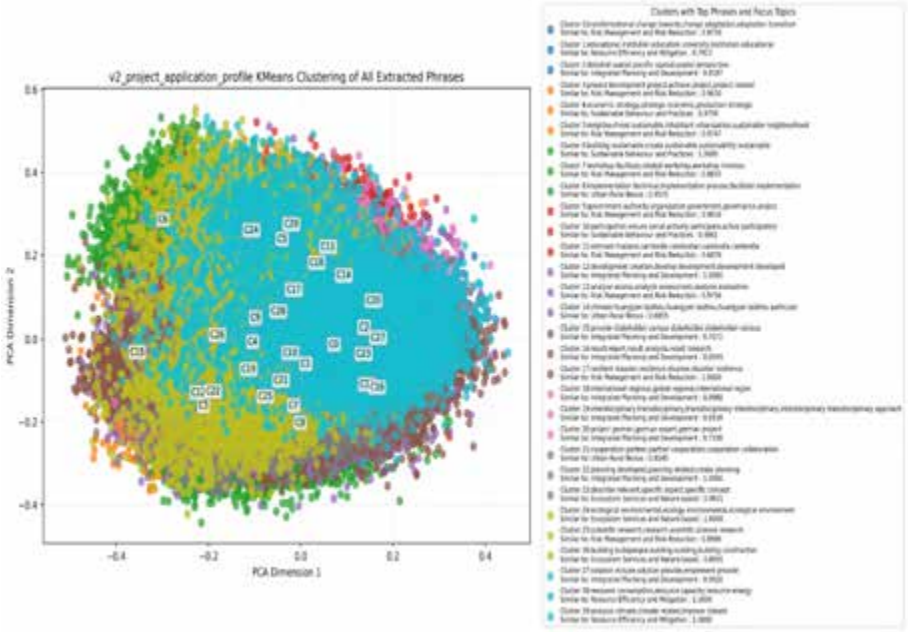

Figure 3 K-means Clustering of embeddings after PCA

Using K-means for clustering, our goal is simply to partition n data points into k clusters so that points within each cluster are as semantically similar as possible, and the clusters themselves are as distinct as possible. The challenge, however, is finding the optimal k for such large number of embeddings. We employ a heuristic approach of, what is commonly referred to as the 'Elbow Curve', where we plot for a loss function against every value (integer) of k iteratively until the change in the loss function is

minimal or stagnant. We use the function Inertia which is the total Within-Cluster Sum of Squared distances between each data point and iterate it over k.

$$Inertia = \sum_{i=1}^{k} \sum_{x \in C_i} \|x - \mu_i\|^2$$

To understand intuitively, a lower Inertia represents tighter clusters which means that the data points are closer to the cluster centroids. The eventual aim of the curve is to find the highest k for which the Inertia is the smallest and further reduction is not significant. Figure 5 shows the curve as applied in our experiment resulting in an optimal value of k = 30.

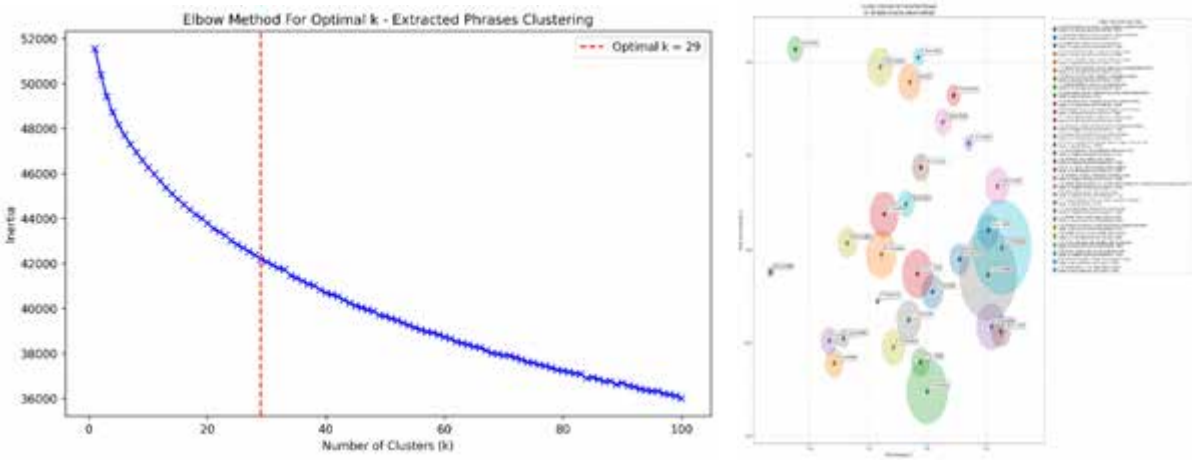

Figure 4 Deriving optimal K clusters
Figure 5 Clusters represented with their Centroids

A simpler visualisation of the resulting clusters is offered in Figure 5 which highlights the clusters, their sizes by the amount of data points they contain and their centroids. Table 2 shows some of the clusters and the data points or phrases extracted from the text.

In order to make these clusters human readable, we apply an open source LLM Google flan-t5-large, on the top 50 phrases in every clusters. This results in a stricter semantic topic creation, especially for larger clusters. Table 2 shows some sample clusters, the embedded phrases it contains and the LLM labelling of the semantic topic.

Table 2 Sample Cluster data points and their LLM labels

Cluster	Top 10 Phrases	Google flan-t5-large labelling
Cluster 0	transformational change towards; change adaptation; adaptation transition; transformational change; transformative change; transformation process towards; transformation process toward; change transformation process; adaptation transformation; transformative change towards	Transformational change and towards adaptation
Cluster 2	detailed spatial; specific spatial; spatial perspective; spatial structure; spatial mapping; spatial typology; spatial aspect; spatial perception; realistic spatial; investigates spatial	Spatial representations of a realism
Cluster 10	participation ensure social; actively participate; active participatory; analysis participatory; establishes participatory; realize participatory; involves participatory; effective participatory; community participation; approach participatory	Participatory analysis and the role of participation in social change

4.3. Converting Semantic Clusters into Thematic clusters

As is clearly seen from Table 2, the clusters have a significant semantic similarity whereby phrases with similar meaning or structure have been clustered efficiently. Yet, this erodes the thematic understanding of a 'topic' from the text while focusing only on parts of language as topics. To circumvent this issue, we propose the addition of the second part of our proposed architecture as shown in Figure 2 where we map our BERT based seman-

tic clusters onto the Thematic clusters derived by domain experts.

We follow the same methodology as used for the project documents, now with the Focus Topics/Themes that were devised by domain expertise as shown in Table 1. Each of the Focus topic has a short text that conveys the theoretical background and the current research directions in that theme. These texts are processed with all-MiniLM-L6-v2 and the embeddings for each theme are stored separately in a ChromaDB vector database. The number of key-phrases identified under each focus topic is shown in Table 3.

Table 3 number of Phrase embeddings in Focus Topics

Focus Topic / Theme	Number of key-phrases extracted
Integrated planning and development	146
Urban Rural Nexus	98
Resource Efficiency and Mitigation	167
Risk management and Risk reduction	147
Sustainable Behaviour and Practices	149
Ecosystem Services and nature-based solutions	168

We then undertook a cosine similarity to check the similarity of all the clusters obtained from the project documents with each of the six themes separately. Thus, we map each cluster from Figure 5 onto the theme embeddings and assign a cosine similarity score between 0 and 1, where 0 is no similarity to 1 is complete similarity with embeddings within the themes.

We noticed, that many a cluster would be less relevant to a certain theme and hence needed human intervention to design a threshold of similarity for inclusion. This was done manually based on the domain expertise and fixed at 0.75 which means that the clusters under the 0.75 score threshold were not considered relevant for the theme. Figures 6 – 11 show the different clusters belonging to each theme or Focus topic.

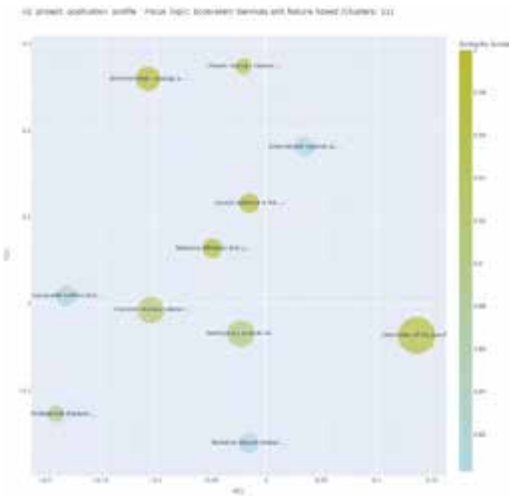

Figure 6 Ecosystem Services

5. Conclusion

5.1. Results

Our experiment focussed on generating thematic clusters from semantic clusters with the help of transformer-based models. The figures 6 – 11 show the details of thematic belonging of semantic clusters of our text data. To simplify our understanding, Figure 12 shows a Sankey chart referring to the relationship between semantic topics and their thematic focus.

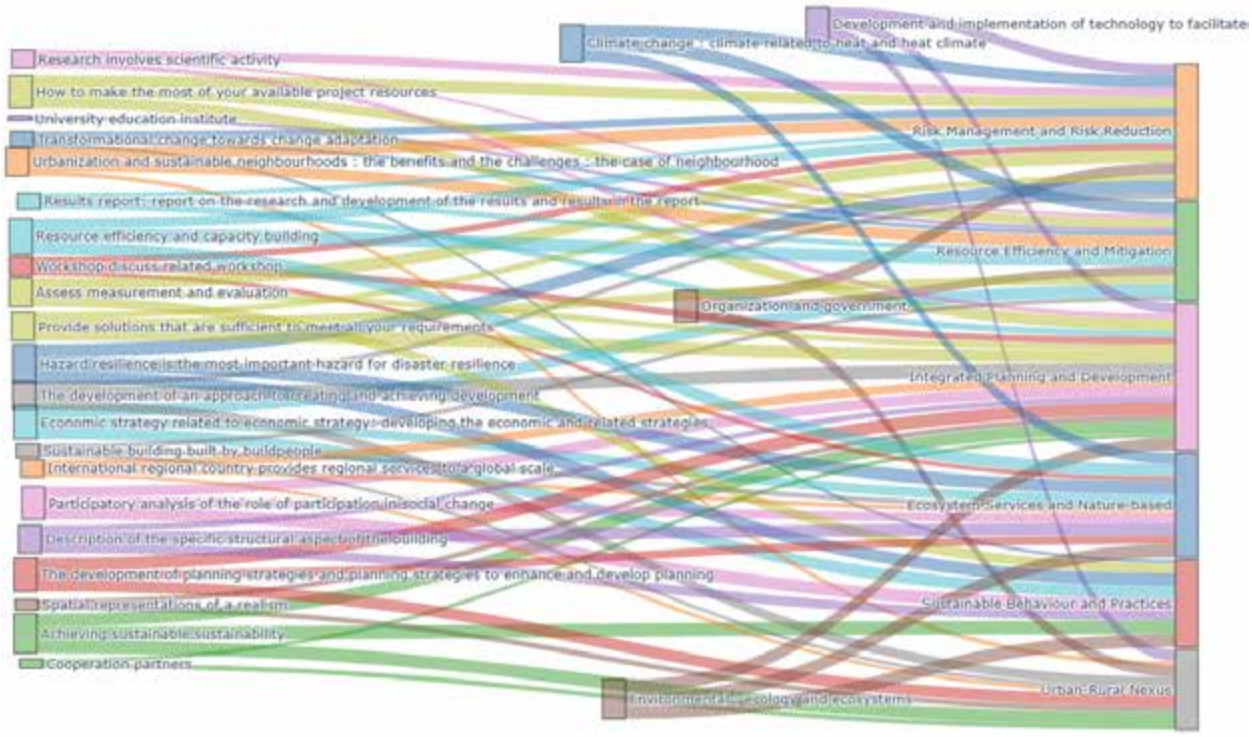

Figure 12 Sankey chart for understanding the links between Thematic and Semantic clusters

Some of the topics generated from the clusters, for example, 'Climate change related to heat stress mitigation' belongs to three different thematic groups viz. Risk Management and Risk Reduction, Resource Efficiency and Mitigation and Ecosystem Services and Nature-based solutions in varying proportions indicating its importance under these themes. In a similar vein, the topic 'Environmental: ecology and ecosystems' belongs in almost equal proportions to Integrated Planning and Development, Ecosystem Services and Nature based solutions and Sustainable behaviour and Practices. Yet, the accuracy overall can be argued to be a bit nuanced as it may not be entirely clear why a certain cluster should belong to a certain theme without the domain expertise present at our disposal.

5.2. Future pathways

This experiment was conducted as part of the Synthesis research project which aims to establish a sustainable contribution to the emerging field of knowledge management in the field of Sustainable Urban Development. It deals with a part of the larger question of monitoring trends in Urban Development research. As is our position, a topic is a subset of a Theme which mapped over time becomes a Trend, we aim to further this experiment with a larger corpus of structured Thematic texts onto which to map more documents and research and to monitor the consistent themes as trends.

5.3. Limitations

The experiment here is limited by the nature and sensitivity of the documents involved in within the larger SURE project. Thus far we have not used publicly available datasets like research papers, for our analysis and hence the architecture remains a proof of concept. Additionally, the text for the Focus topics or Themes devised by domain expertise is nimble and should be expanded to include more depth and breadth around a certain theme for better analysis.

Abstract
This study presents a closed-loop AI framework for assessing and enhancing "healthy streets," applied to downtown Haining City, China. First, semantic segmentation of street-view images yields eight quantitative indicators (e.g., greenery, enclosure, openness). Second, an Elo-based pairwise survey combined with Random Forest and CNN models reveals how these indicators predict perceived street healthiness. Third, we use a Low-Rank Adaptation model(Lora) in Stable Diffusion generator to optimise low-scoring scenes by adding health-supportive elements. Results indicate that (1) the eight indicators capture key environmental qualities; (2) Elo-scoring aligns with machine-learning feature importances—especially greenery, human-scale enclosure, and visual diversity; and (3) the generative model improves predicted health scores by enhancing greenery and openness. This iterative approach offers planners a rapid tool for healthy-street design.

Keywords: Healthy streets; Street view imagery; Semantic segmentation; Machine learning; Generative AI

1 Introduction

The idea of the Healthy City has put citizens' physical and mental well-being at the centre of urban planning since the late twentieth century. Among all public spaces, streets—the city's "capillaries"—shape daily activity, social contact, and psychological comfort more than any other setting. When they are walkable, human-scale, green, and orderly, streets foster exercise, lower stress, and lift overall happiness. Empirical evidence underscores this link. Ulrich's controlled experiments showed that simply viewing greenery or water restores positive mood, whereas scenes dominated by bare concrete increase sadness and anger (Ulrich, 1979). In urban design and public-health scholarship, such environments are now labelled healthy streets: places that invite walking and conversation, provide safety and comfort, and deliver a pleasing sensory experience (Chen et al., 2020; Xu & Hu, 2020). Creating and promoting healthy streets has therefore become a core objective of livable-city strategies.

Rapid urbanisation and motorisation have left many streets marred by poor pedestrian conditions, sparse greenery, excessive enclosure, visual clutter, and traffic hazards—factors that undermine public health and well-being(Chen, Zhang & Long, 2020). To address these deficits, researchers increasingly rely on quantitative evaluations that can steer evidence-based upgrades. The explosion of street-view imagery and advances in computer vision now make city-wide, objective assessments possible (Long & Tang, 2019; Ye et al., 2019). A seminal example is MIT Media Lab's Place Pulse, which crowdsourced judgements by asking online participants which of two street scenes appeared safer, livelier, and so forth. The resulting perception dataset underpinned StreetScore, a model that predicts perceived safety and vibrancy directly from images, enabling block-by-block comparisons across entire cities(Quintana, Gu & Biljecki, 2024). Subsequent deep-learning work has generalised these mappings worldwide, showing that AI can "read" visual cues—building massing, tree cover, human presence—and infer how people are likely to feel in those spaces. Such image-based analytics now offer planners a scalable lens on the everyday quality of urban life.

However, most current research is confined to measurement and prediction, with limited attention to how AI could improve street design. A notable exception is Wijnands et al. (2019), who trained a generative adversarial network (GAN) to rewrite street-view images and then estimated the health-related perception shifts caused by those edits. Their experiments showed that GAN-based style transfer can faithfully render "greener" versus "grey" streetscapes, yielding a virtual test bed for design interventions. This pivot from assessment to interven-

tion points to a new frontier: harnessing generative AI to prototype and appraise street-design options before a single curb is moved.

Recently, researchers have made significant progress in two key areas. First, researchers have refined the measurement of objective streetscape features. Long & Tang (2019) showed that computer vision now enables city-wide appraisals with unprecedented scope and precision. Based on this, Ye et al. (2019) extracted fine-grained indicators—greenery cover, spatial openness, façade articulation—from street-view imagery to produce block-level quality maps. Second, studies have demonstrated how these features are translated into health-related outcomes. From a public-health stance, Chen, Zhang & Long (2020) argued that elevating a street's "spatial order"—reducing clutter, improving pedestrian continuity—directly enhances its health performance by removing discomfort factors such as noise, pollution, or disorganised furniture. Complementing this point, Xu & Hu (2020) proposed a "healing streets" model grounded in therapeutic-landscape theory, calling for generous greenery, water features, public art, and accessible open space to help residents relax and recover from stress.

Although existing work supplies robust theories and metrics for healthy-street assessment, three gaps remain. First, the link between objective spatial indicators and subjective well-being is only weakly understood; we still lack models that clarify how quantified image features translate into lived health benefits. Second, most intervention studies are theoretical—design prescriptions are seldom tested on real streetscapes. Third, this field lacks a closed loop that cycles from diagnosis to intervention and back to evaluation. We address these gaps by building an AI-enabled workflow that (i) diagnoses street health, (ii) generates targeted design alternatives, and (iii) iteratively verifies their predicted influence. By fusing multi-sourced imagery with complementary AI models, our approach shifts the agenda from data-driven perception to AI-assisted design, giving planners a scalable toolkit for healthy-street regeneration.

2 Study Area, Data and Methods

2.1 Study area

Haining, a county-level city in Zhejiang Province's Yangtze River Delta, serves as our case study. Nestled between Hangzhou and Shanghai, it hosts about 800 000 residents and an economically active urban core. We focus on four central sub-districts—Xiashi, Haizhou, Haichang, and Maqiao—which together span the historic downtown and its surrounding neighbourhoods. Within this zone, narrow heritage alleys, protected preservation blocks, modern commercial corridors, residential streets, and major arterials coexist. The resulting spectrum—from centuries-old lanes to newly built boulevards—mirrors the diversity found in many medium-sized Chinese cities, making Haining a fitting proxy for comparable contexts.

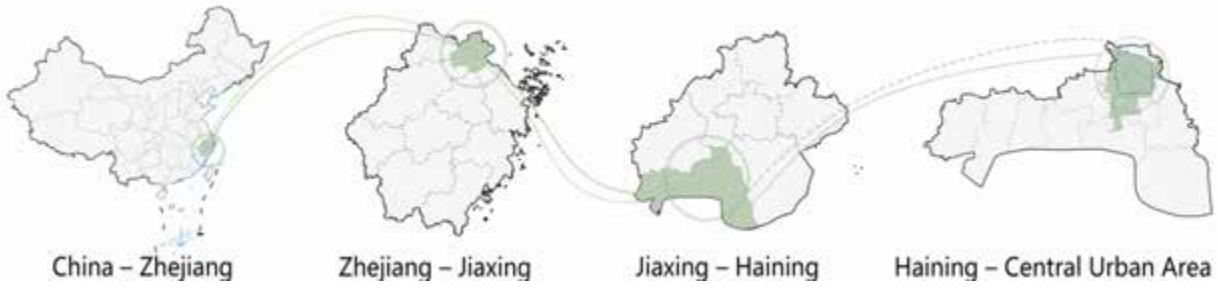

Figure 1. Study area: location and urban layout of Haining City

2.2 Data sources

Our analysis draws on four complementary datasets: geospatial vectors, street-view imagery, human-perception scores, and open-source generative-AI models.

·Geospatial vectors. Street-centreline geometries for the four sub-districts were downloaded from OpenStreetMap and cross-checked against Haining planning documents and statistical yearbooks to ensure coverage of all major land-use zones.

·Street-view imagery. Using the Baidu Street View API, we placed sampling points every 200 m along the network. At each of the 1077 points we captured the panorama and clipped two opposing perspectives aligned with the road axis, yielding 2154 images (1024 × 768 pixels). Shots were taken at pedestrian eye-level in fair daytime conditions during 2021–2022, spanning commercial cores, residential streets, park edges, and a few peril-urban roads (locations without imagery were excluded).

·Perception survey. To obtain subjective "street-health" scores, 50 participants (planners, public-health experts, and volunteers) performed Elo-style pairwise comparisons of randomly drawn image pairs (see section 5.1). The resulting crowd-sourced ratings provided training labels for our predictive models.

·Generative-AI toolkit. For the optimisation stage we employed Stable Diffusion 1.5 enhanced with Low-Rank Adaptation (LoRA) and ControlNet guidance. Pre-trained weights, open-source scripts, and a curated prompt library supplied the basis for domain-specific fine-tuning.

Figure 2 Road network and streetscape observation points in the study area

2.3 Methodological framework

Our study follows a three-stage, closed-loop workflow—Perception, Evaluation, and Optimisation.First perception, we run semantic segmentation on every street-view image to delineate key urban elements and compute objective visual indicators.Second evaluation, an Elo-style pairwise survey first yields subjective "street-health"

scores. These labels feed two predictive models: a Random Forest regressor trained on the indicator set and a convolutional neural network (CNN) trained on raw pixels. Together they explain how specific features shape perceived health and allow city-wide scoring. Finally optimisation, low-scoring scenes are redrawn with Stable Diffusion 1.5, fine-tuned via Low-Rank Adaptation (LoRA) and guided by ControlNet. The generator injects health-supportive cues—extra greenery, broader sky views, livelier façades—and the edited images are re-scored by the RF/CNN models (and inspected by eye). If gains fall short, the edit-evaluate cycle repeats until the target threshold is met.

By chaining computer vision, predictive modelling, and generative design, the framework moves seamlessly from diagnosis to intervention and back, offering planners a virtual test bench for healthy-street retrofits. The next sections unpack each stage in detail.

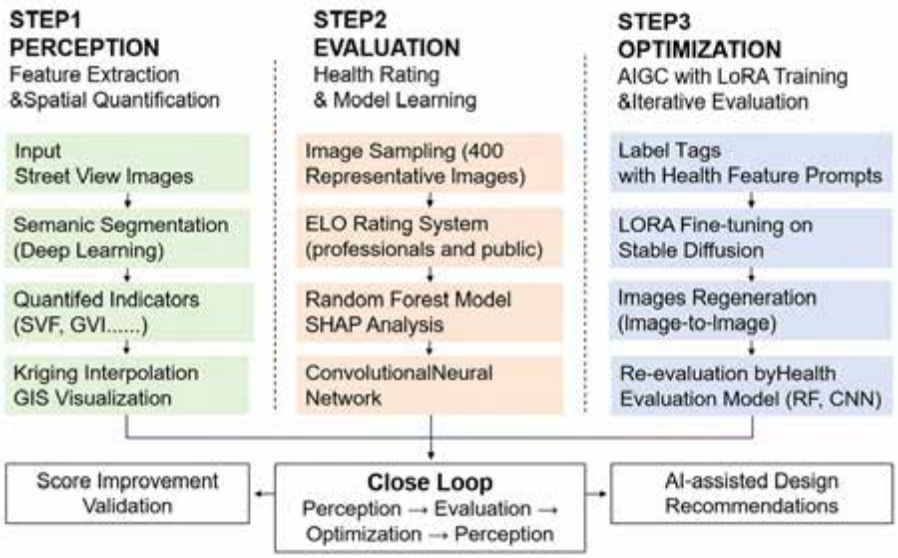

Figure 3 Flow chart of the overall methodological framework of the study

3 Perception: Visual-Indicator Extraction and Analysis

3.1 Semantic segmentation of street-view imagery

We applied semantic segmentation to all 2154 street-view photographs to convert raw pixels into meaningful urban elements. Using DeepLab-v3+ with a ResNet backbone—pre-trained on the Cityscapes corpus and lightly fine-tuned on 200 hand-labelled Haining scenes. Class masks were then aggregated into eight quantitative indicators aligned with four perceptual dimensions:

The eight visual indicators fall into four perceptual dimensions: Vibrancy, represented by Facade Diversity (FD) and Colour Richness (CR), captures the heterogeneity and chromatic variety of street façades; Comfort, measured by Building Enclosure (BE) and Height–Width Ratio (H/W), reflects spatial enclosure and human-scale proportion; Naturalness, via Sky View Factor (SVF) and Green View Index (GVI), assesses visual access to open sky and vegetation; and Safety, defined by Relative Walking Width (RWW) and Traffic-Facility Proportion (TFP), quantifies pedestrian space and the presence of traffic-management elements

To sum up, these metrics furnish a compact, interpretable synopsis of each streetscape's physical affordances for health. Table 1 details indicator formulas and class mappings, while Figure 4 illustrates a typical segmentation output.

Table 1 Definitions and calculation methods for the eight spatial indicators

Category	Indicator Name	Calculation Formula
Vitality	Facade Diversity	H = -∑(p_i * ln p_i),
Vitality	Color Richness	Entropy of HSV hue channel / $\log_2 36$, normalized to [0,1]
Comfort	Building Enclosure	Proportion of building elements
Comfort	Height-Width Ratio	(Building + Wall) / Road Elements
Nature	Sky View Factor	Proportion of sky pixels
Nature	Green View Index	Proportion of vegetation pixels
Safety	Relative Walking Width	Sidewalk / (Driveway + Trail)
Safety	Traffic Facilities	Proportion of traffic-related elements

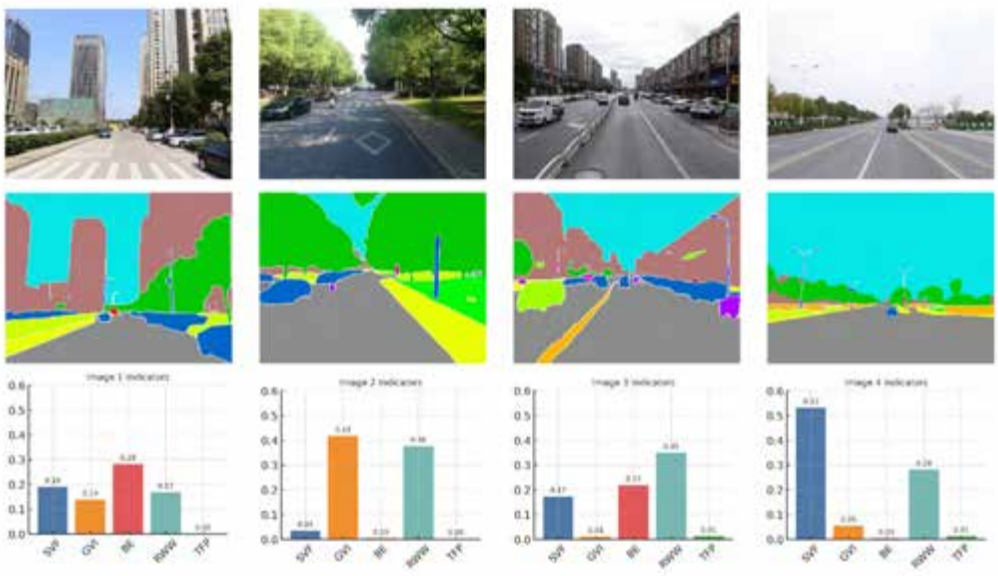

Figure 4 Street view image with semantic segmentation results

3.2 Indicator distribution and inter-relationships

After computing the eight indicators for all 2154 images, we examined their statistical profiles and pairwise links. Figure 5 plots the histograms, and Figure 6 shows the correlation heat-map.

The eight semantic indicators exhibit considerable variation across the dataset, capturing differences in vegetation, enclosure, openness, visual diversity, and pedestrian space. Some indicators, such as green view index and sky view factor, span a wide numerical range, while others, like traffic facility proportion, remain low but meaningful. These metrics provide a comprehensive quantitative basis for analyzing spatial patterns of perceived street healthiness.

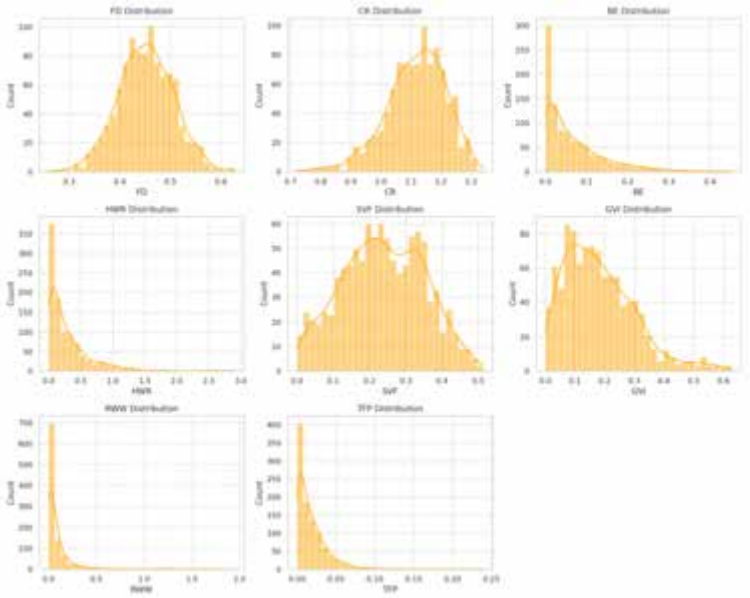

Figure 5 Histogram data distribution by indicator

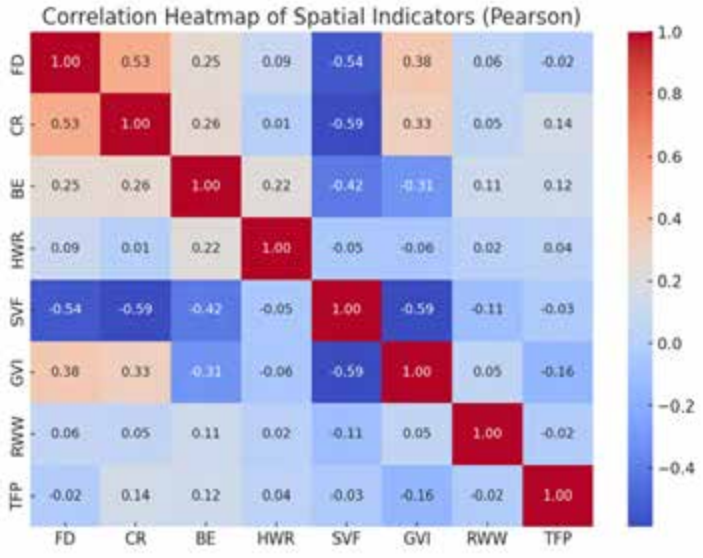

Figure 6 Heatmap of indicator correlations($p < 0.05$)

To read the eight indicators as coherent street profiles, we ran k-means clustering with k = 4. The feature set comprised the five most salient indicators—selected by variance and preliminary importance tests—which retained > 92 % of total information. Table 2 lists the centroid scores, Table 3 sketches the corresponding spatial traits, and Figure 7 plots the four centroids on a radar graph. The clusters form a clear typology. This four-way classification distils Haining's diverse streetscape morphologies into interpretable groups that anchor the subsequent evaluation stage.

Table 2 Clustering means

Cluster	Sky Openness	Green View Index	Building Enclosure	Road Width	Traffic Facilities
0	0.1343	0.1026	0.238	0.3027	0.0166
1	0.1394	0.3405	0.0385	0.2718	0.011
2	0.2283	0.1564	0.0726	0.2676	0.0766
3	0.3275	0.1187	0.0353	0.3296	0.0116

Table 3 Introduction to clustering types

Cluster	Street Type	Feature Keywords	Spatial Interpretation
0	Medium Road, High Enclosure	High enclosure (0.238), Medium road width (0.30)	Dense buildings on both sides, limited view, low greenery and sky, typical urban main road.
1	Open Green Type	Highest GVI (0.3405), Low enclosure & traffic facility	Rich vegetation, open and comfortable, few buildings, suitable for residential or park-side streets.
2	Infrastructure Enhanced	Most facilities (0.0766), Moderate enclosure, Mid-level openness	Strong infrastructure presence, visually active, functional streets or commercial corridors.
3	Wide Open Arterial Road	Highest openness (0.3275), Widest road (0.33), Few buildings	Extremely open, low architectural presence, likely highways or suburban roads.

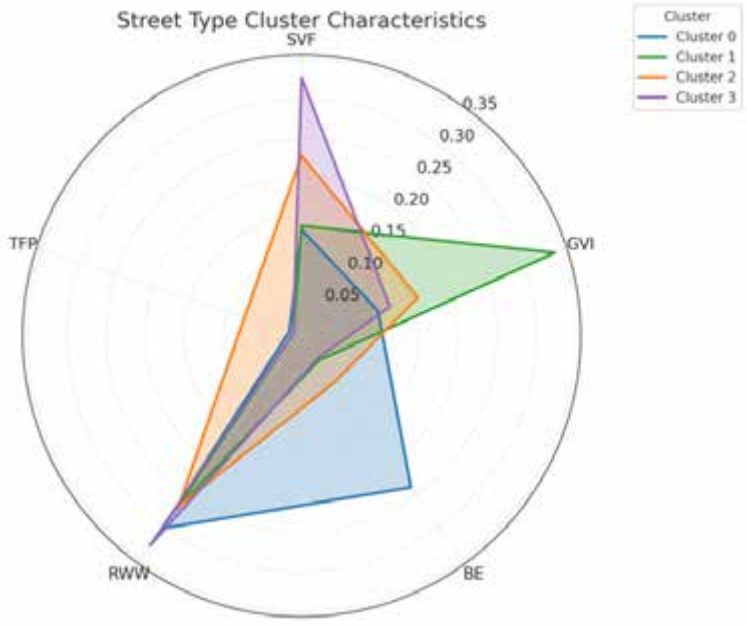

Figure 7 Radar diagram of clustering features

3 .3 Spatial distribution of street indicators

To locate where healthy-street attributes wax and wane across Haining, we interpolated each indicator from the 1 077 sampling points onto a continuous surface and rendered heatmaps (Figure 8).

·GVI ranges from less than 5% to over 60%, with a mean around 25%. Vegetation is heavily concentrated along the northern and northeastern river corridors, where greenways and linear parks flank the water. In contrast, the

dense downtown and the industrial southwest show severe vegetation deficits, making them visually "grey" and in need of greening.

·SVF averages approximately 30%, but varies widely. High SVF values are found in southeast and fringe areas with fewer vertical obstructions, while low values occur in historic quarters where mid-rise blocks obstruct sky views and create enclosed street canyons.

·BE inverts the GVI trend. Traditional urban cores such as Haizhou and Haichang have high enclosure due to tightly built, narrow street networks. Newer districts like Maqiao, with wider setbacks and open cross-sections, register low enclosure values, contributing to a more open spatial feel.

·H/W is strongly correlated with BE. Peaks occur along older corridors like Renmin and Yucai Roads, forming deep urban canyons with narrow view corridors. These areas may feel intimate, but risk reduced comfort under extreme conditions.

·CR and FD rise in commercial and mixed-use zones featuring varied signage, shopfronts, and building types. Uniform residential blocks and industrial areas score lower. These two indicators show a moderate positive correlation, as both are enhanced by land-use diversity and design articulation.

Taken together, the heatmaps reveal a stark spatial contrast in street environments—green, pedestrian-friendly corridors stand in sharp contrast to vegetation-poor, car-oriented zones in the historic core and industrial fringe. These disparities highlight priority areas for intervention, such as adding greenery, widening sidewalks, or improving traffic safety, and set the stage for the perceptual evaluation presented in the next section.

4 Evaluation: Street-Health Evaluation via Machine Learning

4.1 Elo-based collection of perceived-health scores

Because "healthy streets" are ultimately judged by people, we first needed a robust measure of perceived healthiness for each scene. We therefore adopted an Elo-style pairwise comparison, a method popular in online gaming and mirrored in the Place Pulse project, to translate thousands of binary choices into a continuous rating scale. A stratified sample of 400 images—drawn evenly from the four clusters described in § 3.3—served as the test set. An online survey then showed planners, public-health scholars, and lay volunteers random image pairs and asked, Which street looks healthier? Respondents judged greenery, openness, comfort, safety, and overall aesthetics; after each "match" the Elo algorithm updated both images' scores. Ratings stabilised after 10000 comparisons, yielding a scale from about 800 to 1 300. Inter-rater agreement was high (Kendall's W > 0.80), confirming that the scores capture a shared perception of street health. These Elo values can be used as basic truth labels for the predictive models to be presented below.

Figure 9 ELO evaluation system interface

4.2 Random-Forest regression and feature importance

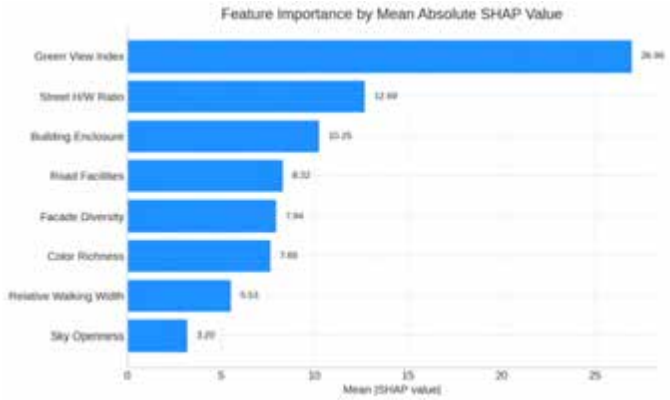
With Elo scores established for 400 street-view scenes, we next linked those subjective ratings to the eight objective indicators. A Random Forest (RF) regressor—well suited to modest sample sizes and non-linear feature interactions—served as the workhorse.

Model set-up. The images were split 80 / 20 into training (n = 320) and test (n = 80) folds. Input features were the eight indicators introduced in § 3.1; the target was the Elo score. A grid search with five-fold cross-validation tuned hyper-parameters. The best configuration—300 trees, maximum depth = 6, minimum samples per leaf = 2, delivered an out-of-sample $R^2 \approx 0.38$. Given the inherently subjective target, this indicates that the indicator set explains a substantial share of perceived street health, while leaving room for latent factors such as noise, smell, or social cues.

To unpack the model's decisions we applied Shapley Additive Explanations (SHAP). Figure 10 ranks features by their mean absolute SHAP value, and Figure 11 plots the full SHAP summary. Three findings stand out:

·GVI dominates the ranking, confirming greenery as the strongest visual cue of street health.
·BE and H/W follow, showing that human-scale enclosure matters, but only up to a point—very high values depress scores.
·CR and FD contribute positively, whereas TFP exerts only a minor influence, perhaps because safety cues are subtle in static imagery.

The RF model quantifies key design principles—more greenery, balanced enclosure, pedestrian-friendly features, and lively façades all contribute to higher perceived street health. These insights validate the indicator set and guide the optimisation stage by highlighting which attributes most efficiently lift perceived health.



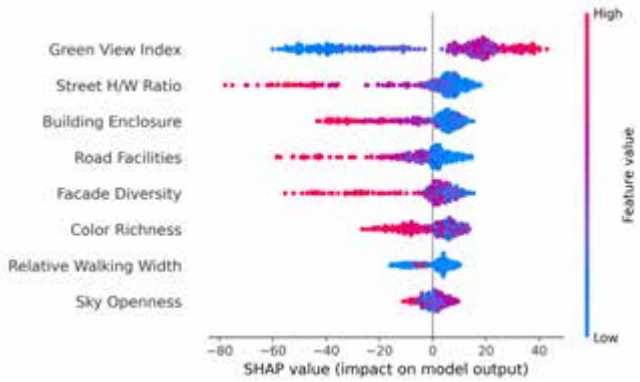


Figure 10 SHAP Importance Score (left)
Figure 11 SHAP Scatter Plot Analysis(right)

4.3 Convolutional Neural Network Prediction

To assess whether a deep model can learn health-related cues without predefined indicators, we trained a ResNet-50 convolutional neural network (with ImageNet weights) to directly regress Elo scores from street-view imagery, using the same 400 labelled images as in the Random Forest model.

The dataset was stratified 80/20 into training (n = 320) and validation (n = 80) sets. Each image was resized to 256 × 256 pixels, with any empty space padded with black pixels to preserve full scene content. The model was trained to minimise mean squared error, with early stopping applied once validation loss plateaued.er the small sample size.The model achieved an R^2 of approximately 0.48 and a mean absolute error of 72 Elo points, slightly outperforming the Random Forest, despite receiving no structured input features. High-scoring predictions consistently aligned with green, bright, and tidy scenes, while grey, empty, or car-dominated streets scored lower—paralleling SHAP findings from § 4.2. This confirms the CNN's capacity to autonomously extract relevant perceptual cues.

Table 4 Demonstration of RF model parameters

Parameter / Metric	Value
Model Type	Random Forest Regressor
Best n_estimators	300
Best max_depth	15
Best min_samples_leaf	2
Best max_features	sqrt
R^2 on Test Set	0.381
MSE on Test Set	≈ 1350

Table 5 Demonstration of CNN model parameters

Model	EfficientNet-B0
Input Size	224x224
Batch Size	32
Epochs	25
Learning Rate	1e-4
Optimizer	Adam

Loss Function	MSE (weighted)
Train Loss (final)	0.0023
Val Loss (final)	0.0172
MSE	7336.57
MAE	71.81
R^2	0.4792

Across the full 1,754-image dataset, the CNN's predictions correlated moderately with RF results (r ≈ 0.64), with both models identifying consistent high and low performers. Divergences likely reflect finer-grained visual textures perceived by the CNN but not captured by the indicator set, such as ground paving and street tidiness. Together, the two models offer complementary insights: strong agreement reinforces key design priorities (like greenery and human-scale proportion), while their differences point to additional visual nuances—some of which will be explored through generative enhancement in section 5.

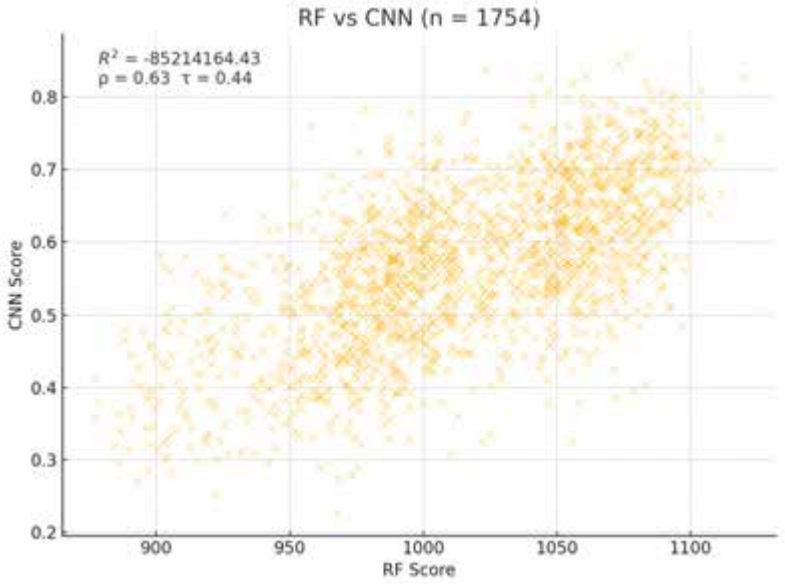

Figure 12 RF and CNN model prediction score correlation

5 Optimization: AI-Based Streetscape Optimisation and Iterative Validation

5.1 LoRA-fine-tuned image generation for healthy streets

With the key health features defined, we shifted from evaluation to visual intervention. To simulate healthier versions of low-scoring streets, we adopted an image-to-image generation approach using Stable Diffusion, and fine-tuned it via LoRA. This allowed the model to learn and apply health-promoting visual styles—while preserving the core structure of the original image.

(1)From Indicator Scores to Labels

The fine-tuning pipeline began with the 400 Elo-scored scenes. Each image was placed into one of three perceptual tiers—high, medium, or low health—defined by the upper, middle, and lower quartiles of the score distribution. Rather than feed the model cryptic numerical features, we distilled the eight indicators into short, human-readable phrases that echoed how survey participants had talked about the scenes. A frame with GVI ≈ 0.05 became "no trees"; GVI ≈ 0.25, "some street trees"; GVI > 0.40, "lush trees on both sides." Streets with BE and H/W at historic-core levels were tagged "narrow, tall buildings," whereas wide suburban corridors read "broad and open." Colour palettes and façade variety were rendered as "dull grey" or "bright and colourful." These textual

summaries were paired with the source images so that the generator learned not only which elements depressed a scene's health rating, but also how a healthier variant should look.Table 6 documents how to route from metric scores to specific labels, and Figure 13 illustrates the labels for a typical street map.

Table 6 Metrics and Labeling Transformation Logic

Indicator	Value Range	Level	Tags
facade diversity	≤ 0.3301	Low	plain building walls
facade diversity	0.3301 – 0.4905	Medium	simple facades with some variation
facade diversity	> 0.4905	High	street-level shops and balconies
color richness	≤ 0.9007	Low	gray and monotonous facades
color richness	0.9007 – 1.1294	Medium	some colored elements
color richness	> 1.1294	High	colorful signs and painted walls
building enclosure	≤ 0.2336	Low	buildings far apart
building enclosure	0.2336 – 0.4673	Medium	moderate space between buildings
building enclosure	> 0.4673	High	buildings tightly packed
street height width ratio	≤ 0.0198	Low	wide street with low-rise buildings
street height width ratio	0.0198 – 0.4810	Medium	balanced street scale
street height width ratio	> 0.4810	High	narrow road with tall buildings
sky openness	≤ 0.1904	Low	sky mostly blocked by buildings
sky openness	0.1904 – 0.3808	Medium	partial sky between buildings
sky openness	> 0.3808	High	open sky over wide street
green view index	≤ 0.2357	Low	no visible trees
green view index	0.2357 – 0.4714	Medium	scattered trees
green view index	> 0.4714	High	trees along both sides
relative walking width	≤ 0.0140	Low	narrow pedestrian strip
relative walking width	0.0140 – 0.0670	Medium	standard pedestrian space
relative walking width	> 0.0670	High	wide sidewalk with benches
road facilities	≤ 0.1395	Low	no visible traffic equipment
road facilities	0.1395 – 0.2791	Medium	some road markings
road facilities	> 0.2791	High	traffic lights and street signs
street health	≤ 850	Low	unhealthy street
street health	850 – 1075	Medium	average street
street health	> 1075	High	healthy street

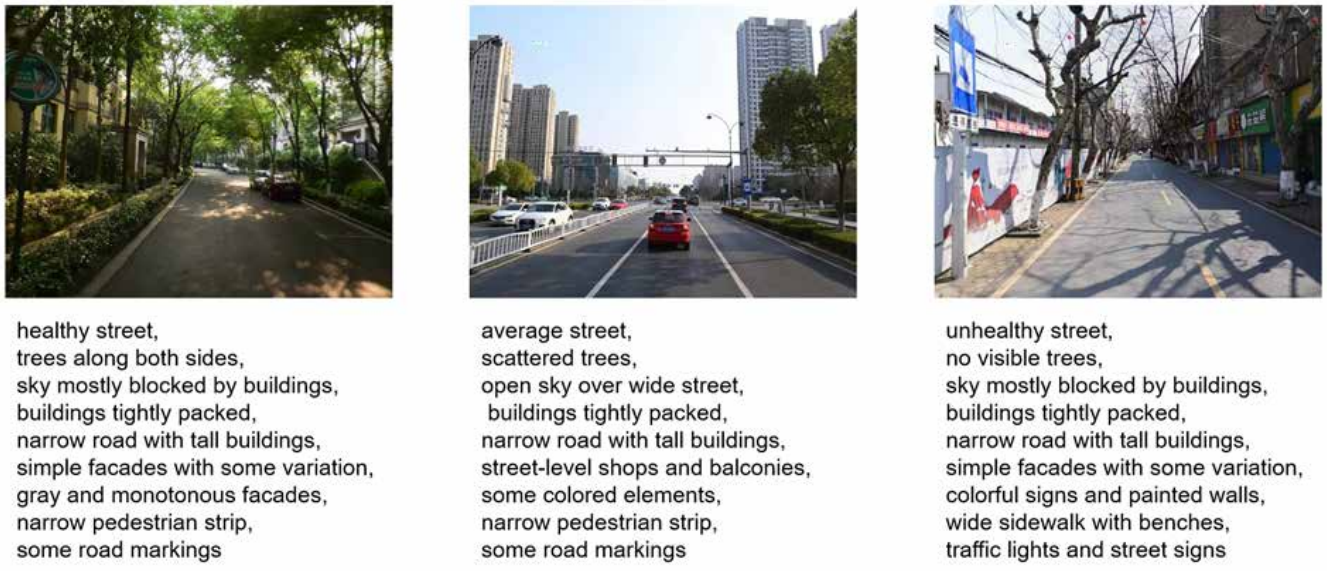

Figure 13 Representing the labeling results for Street View

(2)Lora Model Training
To enable health-aware generation, we fine-tuned the latent diffusion model AWPortrait_v1.4 using Low-Rank Adaptation. This lightweight approach inserts a small set of trainable matrices into the frozen UNet backbone, allowing the model to adapt to the new task—enhancing streetscapes for visual health—without updating the full network.

We used the same 400 Elo-scored images as in earlier models, resizing each to 512 × 512 pixels. Each image was paired with a prompt from the previously constructed label dataset, which provided explicit guidance on how healthy street features are visually expressed.

Training ran for approximately 16000 steps, with a learning rate of 1×10^{-4} and batch size of 4. We adopted an L1 loss function to guide the model towards stylistic enhancement without distorting structural geometry. As shown in Figure 14, the average training loss decreased from 0.30 to below 0.14, with key inflection points around steps 5000, 11000, and 14500. This indicates that the model successfully internalized the stylistic cues of healthier streets—such as greener vegetation, warmer colors, and cleaner appearances.

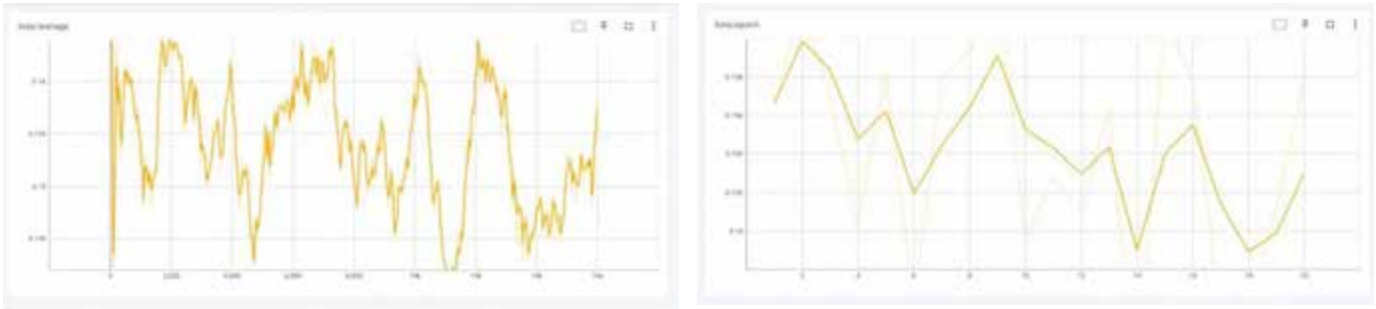

Figure 14 Variation of loss values for Lora model training

(3)Image-to-Image Regeneration
After fine-tuning, the LoRA-enhanced model was used to upgrade low-health street views via an image-to-image approach. Each original image was paired with a descriptive prompt that conveyed its intended transformation (e.g., “add lush trees,” “widen sidewalks,” “brighten facades”), and mild Gaussian noise was introduced to trigger generative variation.

To preserve spatial consistency, we incorporated ControlNet during inference. The model was switched to a large-scale base model (“Urban Streetview”), and semantic segmentation masks—obtained from previous analysis—were used as ControlNet input. This anchored the spatial structure of key elements such as roads, buildings, sky, and trees, ensuring layout fidelity while allowing stylistic transformation through the LoRA weights.

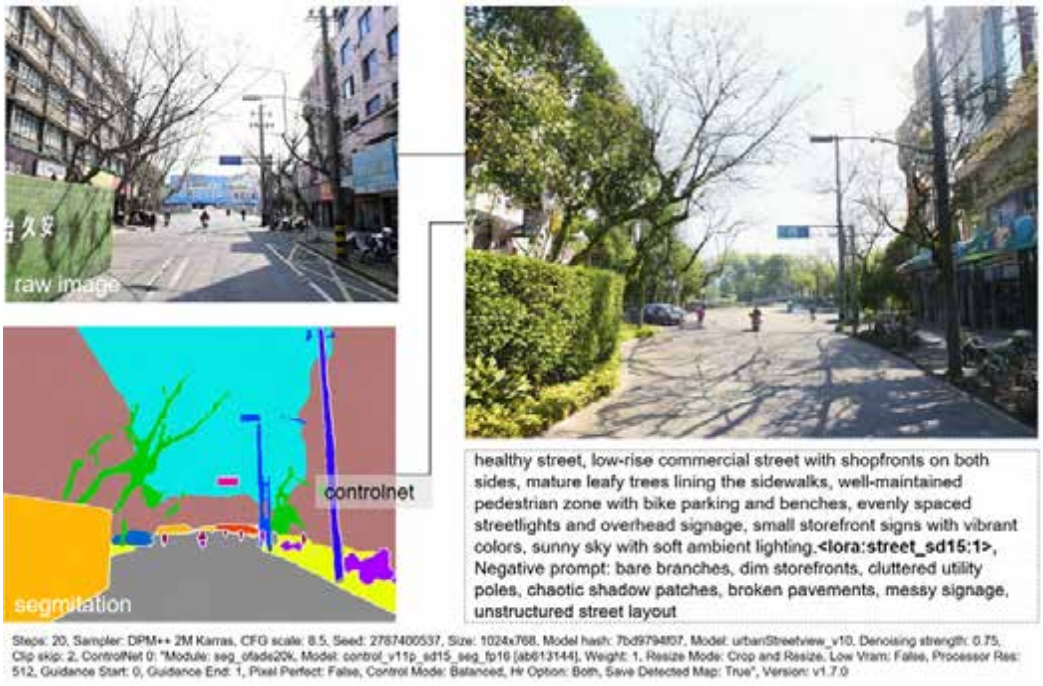

Figure 15 Typical street streetscape optimization process, sample 1

Figure 15 (Commercial Block Transformation) illustrates a typical result. The original scene shows a dull commercial street with gray façades and sparse vegetation. The generated version retains the layout but adds mature street trees, warm color tones, and new signage—creating a livelier and more inviting atmosphere.

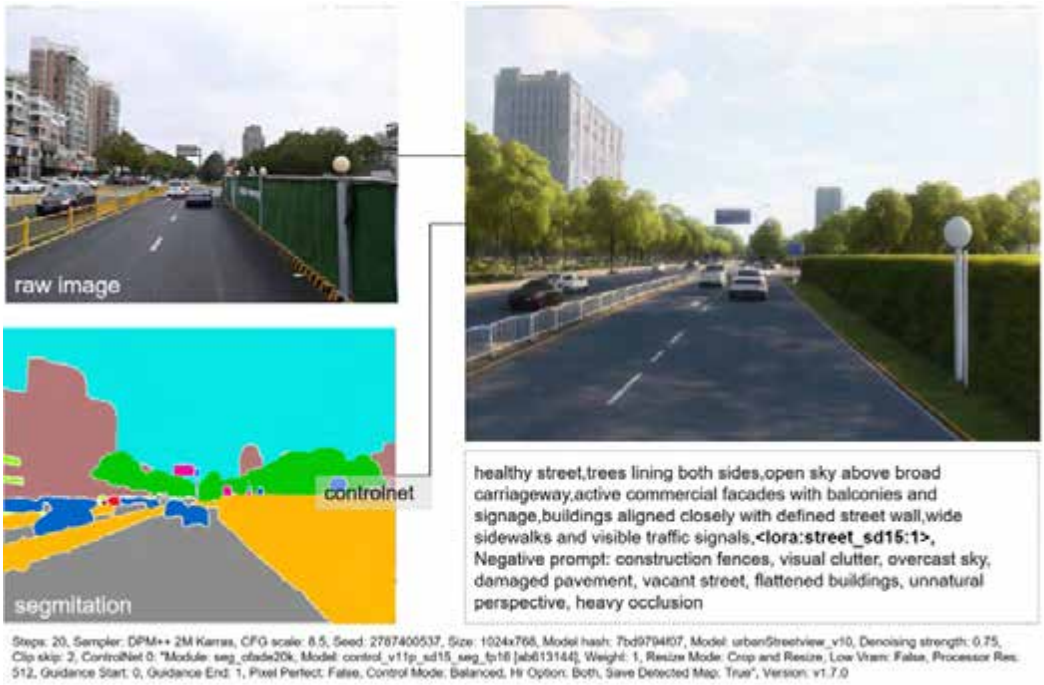

Figure 16 Typical street streetscape optimization process, sample 2

Figure 16 (Arterial Road Renewal) presents a congested urban road flanked by mid-rise buildings. The optimized output introduces planting strips, a brighter sky, and softened tones, improving the spatial feel while keeping the building envelope intact.

These examples confirm that the model has learned a coherent "visual grammar" of healthy streets. With only a semantic layout and a prompt, it can inject greenery, vibrancy, and visual order—offering a rapid, automated method for visual upgrading of urban streetscapes.

5 .2 Batch enhancement: results and evaluation

Encouraged by the single-scene trials, we ran the LoRA-adapted Stable Diffusion model on the remaining 1754 street views—every image outside the Elo survey. Using an NVIDIA RTX 4060, the image-to-image pipeline rendered the entire set in roughly one hour, underscoring the practicality of city-scale, AI-assisted retrofitting.

Figure 17 Batch optimization of Street View images

Figure 17 samples the outcomes. Across commercial corridors, residential lanes, and arterial roads, the AI generator consistently inserted or intensified health-supportive cues—canopy trees, brighter façades, tidier shopfronts, clearer skies—while retaining each street's geometry and landmarks. The resulting portfolio reads as recognisably Haining, yet palpably more verdant, colourful, and inviting.

To judge whether these cosmetic upgrades translate into a higher perception of street health, we re-scored every "before" and "after" image with RF and CNN models introduced in valuation section.

·RF Model: Predicted Elo scores rose by an average of +18.7 points, with a median gain of +26.5. Three-quarters of the images improved by more than +20 points. Only a handful of streets near the original ceiling showed little change, indicating that the model's headroom, not a failure of the generator, limited further gains.

·CNN Model: On the CNN's 0–1 scale, scores increased by ≈ 0.18 on average and ≈ 0.20 at the median. Many streets jumped by 0.4–0.5—an improvement large enough to shift them from the lower to the upper half of the distribution. A few scenes remained flat, typically where the generator's edits fell short of adding sufficient greenery or light.

Table 7 Score improvement under RF and CNN model scoring

Metric	RF Prediction Gain	CNN Prediction Gain
Sample Size	1754	1754
Mean Score Gain	41.89	0.065
Standard Deviation	40.3	0.086
Median Gain	37.59	0.059
Minimum Gain	-104.31	-0.205
Maximum Gain	202.88	0.43
Interquartile Range (25%–75%)	14.07 – 66.12	0.007 – 0.119

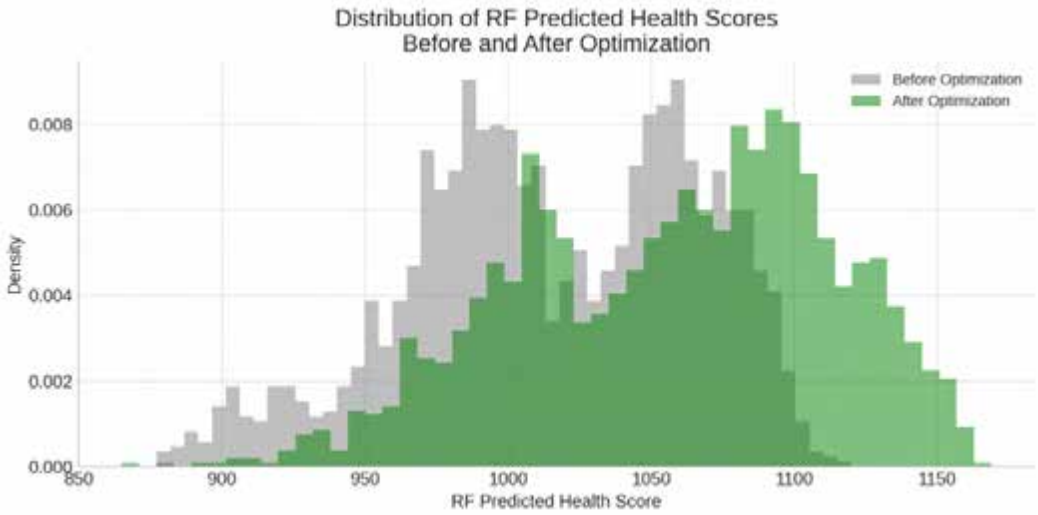

Figure 18 Histogram of RF and CNN model score changes

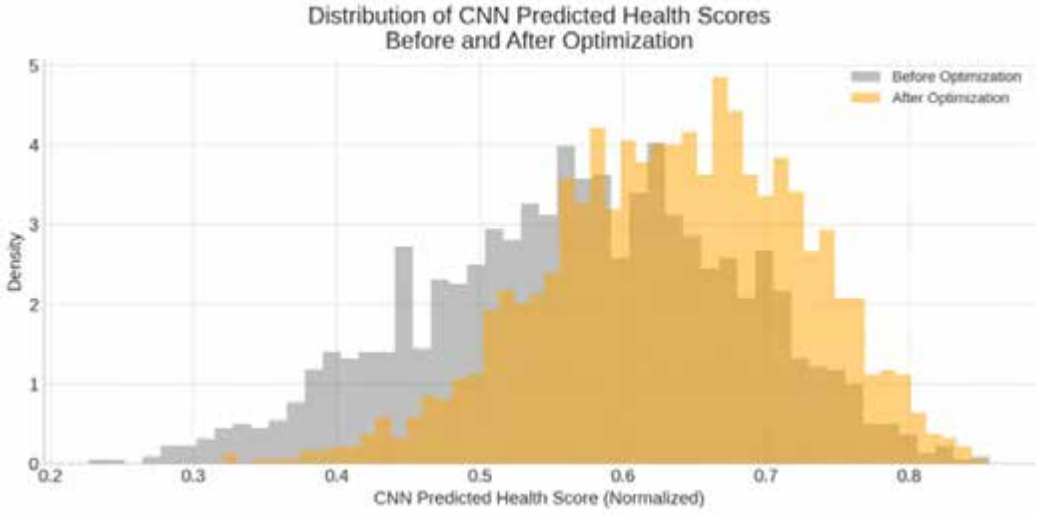

Figure 19 Histogram of RF and CNN model score changes

Taken together, the dual-model evaluation confirms that the AI intervention not only beautifies images but also measurably lifts the predicted healthiness of streets at scale. This quantitative uplift, combined with the rapid run-time, positions the workflow as a practical tool for planners seeking quick, evidence-based previews of healthy-street retrofits.

6 Conclusion

This study introduces an AI-driven workflow that links perception, evaluation and optimisation in a single, self-updating loop, and tests it on the streets of Haining. Deep-learning segmentation translated raw street-view imagery into eight visual indicators—greenness, enclosure, sky exposure, façade colour diversity and so on—whose city-wide maps expose where healthy-street qualities thrive and where they are scarce. Machine-learning models, trained on crowd-sourced Elo judgements, then bridged those objective metrics with subjective well-being: the Random Forest revealed that canopy trees, human-scale proportions, pedestrian infrastructure and visual vibrancy are the strongest predictors of health, while a convolutional network, working directly from pixels, echoed the same hierarchy. Finally, a Stable Diffusion generator, fine-tuned with Lora and anchored by ControlNet

masks, recast low-scoring scenes as greener, brighter and tidier streetscapes; re-scoring with the predictive models showed a clear, quantitative uplift. In short, the pipeline moves seamlessly from diagnosis to design suggestion and back to diagnosis, delivering a rapid, evidence-based aid for street retrofits.

This study introduces two major innovations that set it apart from prior work on street environment evaluation and design:
(1)A closed-loop methodology bridging perception, valuation, and intervention.Where many previous studies focus only on visual diagnosis or abstract design ideas, our research establishes a full-cycle framework that integrates objective spatial analysis, subjective well-being evaluation, and AI-based visual enhancement. By building a consistent pipeline—from semantic indicators to perception models to targeted visual regeneration—we enable not just problem identification, but also evidence-based solution generation and feedback verification.

(2) Deep integration of AI across the workflow, including pioneering use of generative models.We leverage state-of-the-art AI technologies throughout the process: deep-learning segmentation for semantic features, machine learning and CNNs for health score prediction, and—most notably—a fine-tuned generative diffusion model (via LoRA) for street-level transformation. Unlike typical AIGC applications focused on artistic or entertainment content, we demonstrate its use for purposeful, rule-informed urban design. By teaching the model to understand and apply the visual logic of healthy streets, we show that AI can not only see and evaluate cities but also reshape them—offering planners a novel and scalable tool for visual experimentation and public engagement.

But this study remains an initial probe. Haining is a medium-sized city with a mid-rise fabric; megacity canyons or small-town main streets may challenge the models in unforeseen ways, so cross-city replication is essential. Our indicator set is intentionally visual, yet everyday street health also hinges on sound, air quality and micro-climate; coupling image analysis with sensor feeds would yield a fuller diagnosis. In addition, the perceptual ground truth comes from a one-off survey. Embedding the system in an online platform where residents can iteratively rate—or even tweak—virtual street views would create a living feedback loop that refines both the evaluators and the generator while deepening civic participation.

Artificial-intelligence tools now let us see, evaluate and redesign the public realm in a single, accelerated workflow. By uniting quantitative perception analysis with generative design, the framework sketched here moves urban practice towards an interactive, evidence-based craft—a step, we hope, toward streets and cities that are not only smarter, but tangibly healthier and more delightful for those who use them.

The Study on the Measurement and Enhancement Strategies of Urban Street Space Quality Based on Street View Images: A Case Study of Streets in the Central Urban Area of Xi'an

Tianxin Zhang & Mengde Zheng

Abstract
Identifying the spatial quality characteristics of urban streets is crucial for achieving scientific planning and effective management. This provides a basis for optimizing urban spatial layouts and promotes the intelligent and sustainable development of cities. However, most previous studies have been limited to specific neighborhoods, lacking a systematic analysis of street quality across large urban areas. Therefore, this study integrates spatial pattern data and street landscape image data from the main urban area of Xi 'an, constructing a quantitative database for street spatial quality. It establishes a measurement system from both objective physical space and subjective perception. The system covers four primary dimensions: safety, comfort, richness, and convenience, with fourteen evaluation indicators. The system uses the entropy value method to assign weights and completes a large-scale quantitative assessment of street spatial quality. The study results indicate: (1) The spatial quality of streets in the main urban area of Xi' an generally shows a 'high in the center, low in the periphery' layered distribution pattern. The central urban area has significant advantages in street interfaces, visual environments, and traffic organization, while the peripheral new districts face issues such as insufficient greenery, enclosed spaces, and single-function configurations. (2) Through K-means clustering, this study identifies four types of street spatial qualities: safety-oriented, ecological comfort, interface vitality, and pedestrian convenience. It further analyzes the causes and mechanisms of these types from four aspects: location conditions, land use, planning policies, and historical evolution. (3) The study also used the Cohen's s Kappa coefficient to test the consistency between model outputs and subjective perception levels. The results showed that the integrated model outperformed the single objective index model in terms of recognition accuracy, confirming the necessity of incorporating perception dimensions. (4) Enhancing the spatial quality of streets requires a multi-dimensional collaborative strategy, including enriching street interfaces, enhancing road surveillance and lighting design, and improving green spaces and pedestrian facilities. The framework for measuring street spatial quality proposed in this paper is highly scalable and adaptable, both methodologically and practically. It not only provides a basis for targeted measures to improve the quality of streets in Xi' an's main urban area but also offers a feasible path and technical support for other cities to advance the refined governance and human-centric optimization of public spaces.

Key words: street space quality; street scene image; subjective and objective fusion; cluster analysis

1. Introduction

As urbanization accelerates and urban governance concepts evolve, enhancing the quality of urban public spaces has become a critical support for achieving livable, resilient, and sustainable cities. Streets, being the most human-centric urban units, not only serve as basic traffic corridors but also play a vital role in connecting diverse urban activities, fostering social interactions, and shaping the city's image. The quality of street spaces directly impacts residents' daily experiences, travel preferences, and the overall vitality of the city, making it a core issue in urban planning and governance (Xuan & Zhao, 2022).

Traditionally, the assessment of street space quality has primarily focused on the physical environment, emphasizing 'visible structure' indicators such as road section design, greenery layout, and the continuity of street interfaces (Wan, Lu, & Sun, 2022). However, this method, which emphasizes structural objectivity, often overlooks the subjective feelings and emotional responses of space users, making it difficult to fully capture the comprehensive impact of street spaces on residents 'psychological and behavioral aspects. In the current trend of urban governance that increasingly emphasizes' people-oriented 'and' perception-focused 'approaches, there is an urgent need to develop a multi-dimensional evaluation system that integrates subjective experience with objective measurement, breaking through the limitations of existing theories and methods (L. Zhang, Ye, Zeng, & Chiaradia, 2019). Meanwhile, with the rapid advancement of street image technology and computer vision algorithms, the recognition of urban street space characteristics is becoming more automated and refined (Ye, Zeng, Shen, Zhang, & Lu, 2019). Street images, as spatial data that approximate the human eye's perspective, offer the advantage of high-frequency, low-cost acquisition of street visual landscape features. By integrating deep learning and perception modeling technologies, these images can achieve quantitative analysis of street spaces in terms of safety, livability, and aesthetics, significantly expanding the depth and breadth of evaluation metrics (Tang & Long, 2019; Yu, Zhang, & Zeng, 2019). Therefore, the data-driven measurement framework based on street view images has become a key development direction in the current research on urban spatial quality.

However, existing research still has several shortcomings: Firstly, most studies focus on typical street segments

with small sample sizes, lacking systematic coverage of large-scale urban areas, which makes it difficult to reveal the overall distribution and spatial heterogeneity of street space quality. Secondly, discussions on the integration of subjective and objective factors are mostly theoretical, without a mature and stable empirical approach. Thirdly, there is currently a lack of a comprehensive research chain that effectively links measurement results to the identification of street space types, the analysis of formation mechanisms, and the formulation of subsequent optimization strategies, which affects its practical application in urban governance.

This paper selects the main urban area of Xi'an City, China, as the research area and proposes a framework for evaluating street spatial quality that integrates street scene image recognition, subjective perception modeling, and the measurement of street physical characteristics. The framework systematically analyzes the distribution pattern, type characteristics, and formation mechanisms of street space. The main innovations of this study include: first, integrating street scene images with GIS spatial data to construct a multi-level indicator system that encompasses both subjective and objective dimensions, thereby enhancing the accuracy of street spatial quality assessment; second, using the K-means clustering method to identify different types of street space, revealing the combined differences in safety, comfort, interface vitality, and functional accessibility among these types; third, based on multiple factors such as location characteristics, land use, policy orientation, and historical culture, the study deeply analyzes the formation mechanism of street spatial quality and proposes practical optimization paths and spatial zoning suggestions.

2. Literature review

In recent years, with the advancement of big data and automated analysis technologies, the measurement of urban street space quality has shifted from traditional subjective surveys and manual observations to a quantitative evaluation method based on multi-source data integration. As a vital part of urban public spaces, streets not only influence travel behavior but also directly impact urban vitality and residents 'quality of life. Early theories, proposed by Lynch, Jacobs, and others, focused on the linear continuity, human scale, and visual appearance of streets. Today's research leverages deep learning, street view imagery, and GIS technology to automate the measurement of various elements of streets, including greenery, building facades, skylines, and pedestrian activities (Harvey & Aultman-Hall, 2016).

Traditional evaluation methods primarily rely on questionnaires and on-site observations to capture the perceived environment and visual effects of streets. While these methods can directly reflect user experiences, their limited sample sizes and subjective assessments make them unsuitable for large-scale application. To address this issue, researchers have developed automated evaluation methods based on street view images and geospatial data in recent years. These methods use deep learning and computer vision to segment street view images semantically, automatically extracting indicators such as green visibility, road width, building proportions, and sky perspective factors, forming a quantitative physical measurement system (Biljecki & Ito, 2021; Tang & Long, 2019). In contrast, other studies focus on integrating physical indicators with pedestrian perceptions, validating the accuracy of automatic measurements through expert ratings, questionnaires, or social media sentiment analysis (Du & Huang, 2022). Additionally, research based on indicator systems often draws from the 5D framework, which includes density (Density), diversity (Diversity), design (Design), destination accessibility (Destination Accessibility), and transportation distance (Distance to transit), and has been expanded to include dimensions such as social, safety, and cultural aspects, such as the 5D+3S model (Wan et al., 2022; L. Zhang et al., 2019).

Despite progress in quantifying street space quality, current research often focuses on measuring physical space in a single dimension, particularly on extracting and analyzing structural features such as green coverage, building density, and street interfaces. However, incorporating residents' subjective perceptions has lagged behind, facing issues such as insufficiently systematic indicator construction, inadequate coupling between dimensions, and limited validation methods (Han, Wang, Seo, He, & Jung, 2022). Even studies that attempt to integrate subjective and objective elements are often confined to specific street segments or small experimental areas, lacking systematic and standardized analysis for larger-scale urban spaces. Moreover, the current methods

for collecting subjective perception data still heavily rely on costly manual surveys or limited sampling, which cannot meet the demands for high-frequency, dynamic, and extensive street assessments (Ogawa, Oki, Zhao, Sekimoto, & Shimizu, 2024). Therefore, there is an urgent need to develop a street space quality measurement system that balances physical characteristics with subjective experiences, is scalable, and practical. This would not only enhance the precision of urban governance but also provide robust data support and decision-making for smart city development and public space optimization. Based on this background, this paper intends to carry out a systematic study integrating intelligent analysis and perception verification mechanism of street view images, focusing on filling the deficiencies of existing research in the construction of multi-dimensional index system, spatial heterogeneity identification and strategy optimization path, which has important theoretical significance and practical value.

3. Study areas and data sets

3.1 Research area

This study selects Xi 'an City in China as the subject of empirical analysis. Located in the middle of the Guanzhong Plain, Xi' an is situated between 107°24'00"E and 109°29'24"E, and 33°25'12"N and 34°27'00"N. It borders the Wei River to the north and the Qinling Mountains to the south, forming the heart of the 800-li Qin Plain. Known as the 'ancient capital of thirteen dynasties,' Xi 'an has a city-building history of over 3,100 years and a capital-building history of over 1,100 years. Thirteen dynasties, including the Western Zhou, Qin, Han, Sui, and Tang, have established their capitals here. This study focuses on the main urban area of Xi' an, which includes six administrative districts: Xincheng, Beilin, Baqiao, Yanta, Lianhu, and Weiyang (Figure 2). The district comprises 55 sub-districts and covers a total area of 836.02 square kilometers (Lin, Xiping, Junyi, Yongyong, & Zhiyuan, 2025).

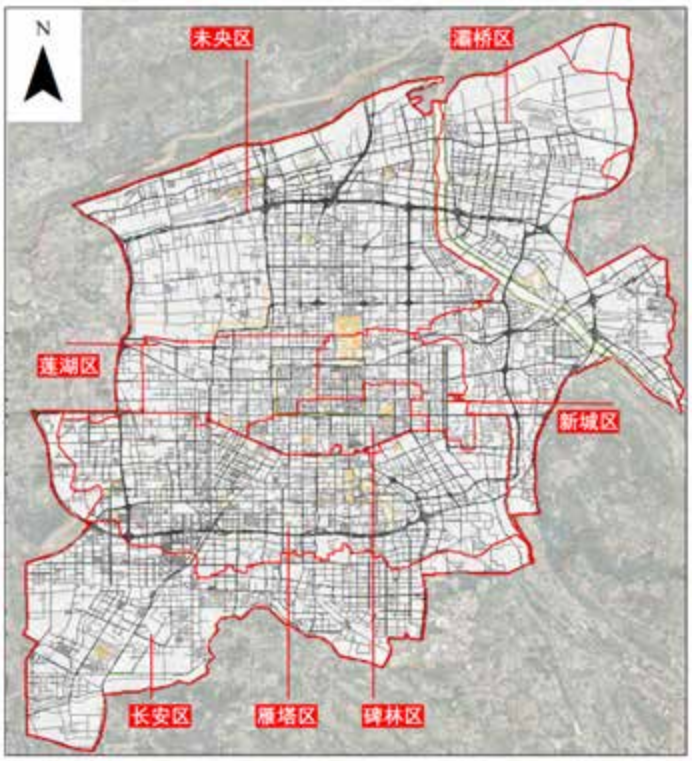

Figure 1. Scope of the study

3.2. Data sets and variables

The institute's data encompasses a variety of sources, including basic road information, spatial quality assessments, and administrative divisions. The basic road information is sourced from the 2021 updated OSM

platform (https://openstreetmap.org/). POI data are collected via Python 3.8 from Baidu and AutoNavi Maps, and have been corrected. Street view images are primarily sourced from Baidu Panorama Map, with 360 Maps providing supplementary data for missing areas. Sampling points are set at intervals of 100 m, capturing human-viewed images from 90°,180°,270°, and 360° angles (1024×512 resolution). Image semantic segmentation tools are used to extract the proportions of building interfaces, sky, and greenery. Administrative division base maps are sourced from the National Basic Geographic Information Public Service Platform and are uniformly projected into a consistent coordinate system using ArcGIS 10.7.

Table 1 Multi-source, multi-scale data types, sources and processing

data name	data sources	acquisition time	data handling
Road network data	Open Street Map	December 2024	After the road centerline is simplified and extracted by manual, the topology is checked and verified with reference to the Gaode satellite image
Street View data	Baidu Open Street View Map platform	December 2024	The Baidu Street View API was called to collect 289,664 static panoramic images with a spacing of 50 m, and the image size was 1024x512 pixels. Then the Mask2Former semantic segmentation model was used to segment the street view images.
Interest point (Point of Interest, POI) data	Baidu Map	December 2024	The geographic information interest point (POI) data was obtained from Baidu Map API. According to the research needs, 18 kinds of POI data such as food, hotel and shopping were obtained within the research scope and its surrounding area. The data contained industry categories, names, addresses, administrative areas and other information.
MIT Place Pulse Data set	MIT Media Lab Developed Place Pulse projects	December 2024	The Microsoft Trueskill algorithm was used to calculate the corresponding perception scores of six dimensions, and the model was trained to predict the scores of six perception dimensions on the streets in the central urban area of Xi 'an.

4. Research methods

4.1 Subjective perception score acquisition

In this study, to more accurately capture residents' subjective perceptions of the street space environment, the Place Pulse 2.0 dataset and its accompanying subjective perception model, developed by MIT Media Lab, were introduced as the core tool for generating perception scores. Place Pulse constructed a street scene perception evaluation system covering six dimensions—safety, security, livability, vitality, wealth, and sociality—by conducting paired comparisons and scoring global street scenes. The scoring results were then quantified and ranked using the Microsoft Trueskill algorithm (L. Wang, Han, He, & Jung, 2022).

In the implementation of this study, street view images from the main urban area of Xi 'an were selected as input data. Using a pre-trained Place Pulse perception model, scores were assigned to each image across multiple perceptual dimensions. To enhance the model's performance in localized applications, the model was fine-tuned and refined based on a small amount of manual scoring results. For each sampling point, four street view images were collected from four directions (90°,180°,270°,360°). Scores were assigned to each image and a weighted average was calculated to obtain the overall subjective perception score for that sampling point.

Subsequently, the study utilized GIS tools to map the scoring results onto street grid units, achieving a spatial visualization of scene perception. Ultimately, by calculating the weighted average of the scores from multiple

sampling points on each street, the study derived the representative subjective evaluation of that street. This scoring system not only provides a clear reflection of residents' overall impressions of the street environment but also offers crucial data and theoretical support for future analyses that integrate with objective physical indicators.

4.2 Objective perception score acquisition

The objective perception scoring system proposed by this institute primarily relies on semantic segmentation analysis of street view images and geospatial data processing. It aims to achieve automated and standardized quantitative evaluation of the physical characteristics of urban street spaces. The research team first used the Baidu Street View Open Platform API to set up sampling points at intervals of 50 meters in the main urban area of Xi'an City. They collected static street view images from four directions (90°,180°,270°,360°), with a uniform image size of 1024×512 pixels, to ensure data consistency and improve subsequent processing efficiency.

Subsequently, using the deep learning model Mask2Former, pixel-level semantic segmentation was performed on the images to automatically identify the proportions of greenery, sky, buildings, roads, and motor vehicles (Cheng et al., 2021). Based on this proportion information, a quantitative index system reflecting the spatial characteristics of streets was constructed, including dimensions such as road accessibility, motor vehicle interference intensity, visibility of greenery and sky, and street interface morphology (W. Zhang, Chen, & Tian, 2025). The image analysis results were matched with the road space network, and using GIS analysis tools, the measurement values were mapped to each street segment. An objective perception score at the street scale was formed based on the weighted average of the sampling points in each street segment.

To enhance the robustness and representativeness of the index system, the study integrates POI data to supplement the identification of street safety facilities (such as surveillance cameras) and functional interfaces (such as ground-floor openness). It also considers factors such as building openness, material diversity, and pedestrian accessibility, thereby constructing a more comprehensive framework for evaluating street physical characteristics (Miaoyi, Zhonghao, & Feng, 2021). The final scoring results not only reflect both structural and functional aspects but also lay a solid foundation for the integration of subjective perception results in subsequent analyses. This further supports the multi-dimensional modeling of street spatial quality and the identification of regional differences.

4.3 Construction of street quality index system

In constructing an evaluation system for assessing the quality of street spaces, this paper adheres to the urban design philosophy of 'people-oriented,' balancing practicality and interpretability. It integrates the objective attributes of physical space with residents' subjective perceptions, forming a diverse and systematic evaluation framework. This system primarily relies on street scene images, spatial data, and perception models as core information sources, aiming to comprehensively reflect the overall performance of street spaces from multiple perspectives, including function, environment, and experience.

On the objective level, the evaluation system focuses on the structural characteristics and functional environment of streets, covering key indicators such as spatial openness, traffic interference, green space ratio, street interface complexity, and pedestrian accessibility. It emphasizes the physical safety, comfort, and connectivity of streets (R. Wang, Huang, & Ye, 2024). On the subjective level, the system incorporates Place Pulse's perception scores, focusing on psychological dimensions like security, livability, vitality, and social interaction. This approach addresses the individual experience differences that traditional physical measurements often overlook, reflecting the environmental impact on residents' emotions and behaviors.

To achieve the organic integration of two dimensions, this paper uses a unified street segment spatial unit as the foundation and standardizes both subjective and objective indicators through Z-score normalization, enabling the comparison and analysis of indicators with different scales within the same system. By integrating the results of principal component analysis and correlation tests, the eight core indicators are categorized into three

primary dimensions: spatial efficiency, visual environment, and user experience, forming a hierarchical model for measuring street quality. This model not only highlights the multi-level characteristics of street space but also lays the theoretical groundwork for subsequent cluster analysis and spatial difference studies.

By integrating multi-source data and constructing a dual-dimensional framework, this paper transforms the spatial structure from 'visible' to 'felt' life experiences, advancing street quality research from a single physical measurement to a more comprehensive evaluation method. This approach provides practical pathways and assessment tools for creating urban spaces with a focus on humanistic care and refined governance (Wei, Tingting, & Jie, 2024). To validate the effectiveness of integrating subjective and objective dimensions in measuring street spatial quality, the paper further calculated the consistency between the fusion model and the single objective model in terms of street classification levels and subjective perception levels. The results showed that, based on Cohen's Kappa coefficient, the consistency between the single objective index model and subjective perception was -0.092, while the consistency between the subjective perception and the fusion model was -0.074 (Blackman & Koval, 2000; Warrens, 2015). Although neither model achieved a high level of consistency, the fusion model demonstrated better matching, confirming the importance of incorporating the subjective perception dimension in enhancing model accuracy and aligning with residents' experiences.

Table 2 Construction environment indicators and calculation methods

dimension	metric	computational method	weight	direction
safety	Vehicle interference	The degree of influence of motor vehicle traffic on pedestrian activity is measured by the number of vehicles in the unit.	0.0015	-
	Road surveillance	Assess the safety of a street, known as the "eyes on the street," by counting the number of surveillance facilities or pedestrians and shops on either side of the street.	0.1814	+
	sense of security	Based on the Place Pulse model, the "safety" dimension of street view images is scored, and the weighted average of multi-angle image scores is obtained to obtain the perceived safety score of street segments.	0.0138	+
degree of comfort	Visibility in the sky	The proportion of the visible part of the sky in the street space is calculated to reflect the degree of visual openness. The proportion of the sky in the total pixels is calculated through the analysis of street view images.	0.1663	+
	High ratings	The proportion of green vegetation in the street view is calculated to reflect the greening degree of the street. The proportion of green pixels in the total pixels is calculated through street view image analysis.	0.0792	+
	Sense of oppression	Based on the negative score results of "livability" and "safety" dimensions of Place Pulse model, the weighted calculation was carried out, and the lower the value, the stronger the sense of depression.	0.0162	-
	aesthetic feeling	The perception score of "aesthetics" dimension of Place Pulse model reflects residents' subjective evaluation on the visual image of the street, and the higher the score is, the stronger the aesthetic sense is.	0.0082	+

	Interface transparency	Measures the transparency of the facade of buildings on both sides of the street, i.e. the proportion of transparent or translucent parts (such as Windows, porches). Through street view image analysis, the proportion of transparent area to total facade area is calculated.	0.2699	+
rich	Interface richness	Evaluate the detail and diversity of the facade of buildings on both sides of the street. This can be measured by calculating the types and numbers of facade elements, such as decoration, material changes, etc.	0.0881	+
	Liveliness	The "activity" dimension of Place Pulse model is used to score the perception, which reflects residents' subjective evaluation on the visual image of the street. The higher the score, the higher the activity.	0.0264	+
	Boredom	The perception score of the "boredom" dimension of Place Pulse model reflects residents' subjective evaluation on the visual image of the street. The higher the score is, the higher the boredom degree is, which is a negative factor.	0.0096	-
convenience	Walkable accessibility	Measures how easily pedestrians can get from the street to various facilities (such as stores, public transport stops). It is usually calculated by calculating the number and distance of various facilities within a certain range around the street, combined with the street connectivity index.	0.1320	+
	Function mixing	The diversity of land use around the street is evaluated. The information entropy formula is usually used to calculate the proportion and distribution of different functions (such as residential, commercial, office, etc.) of land use around the street.	0.0013	+
	A sense of affluence	Based on the "sense of wealth" dimension score of Place Pulse model, the building material, facade decoration complexity and high-end commercial POI density are taken as auxiliary factors for comprehensive calculation.	0.0060	+

5.Results and analysis

5.1 Street quality identification results

To more deeply uncover the regional differences in the spatial quality of different streets within Xi 'an's main urban area, this study uses administrative districts as the basic analysis units. It employs the entropy value method to calculate comprehensive evaluation scores, conducting a systematic quantitative statistical analysis of the street quality in the five core urban districts: Xincheng District, Lianhu District, Beilin District, Weiyang District, and Yanta District. The study reveals that there are significant differences in street spatial quality among these five districts, reflecting a typical 'layer differentiation' spatial structure where the central urban area outperforms the peripheral new districts.

In terms of overall performance, the street space quality scores of Xincheng District and Lianhu District rank at the top, with average comprehensive scores of 10.39 and 10.38, respectively. Both districts have scores that are

close to each other and significantly outperform other administrative regions. This indicates that the central urban area has a clear advantage in street space interface design, environmental openness, greening levels, and pedestrian infrastructure construction, reflecting the long-term efforts of historical urban areas in refined urban management and planning. Additionally, the score standard deviations for the two districts are 2.69 and 2.96, respectively, indicating a high degree of balance in street space quality within the region, without significant polarization. The overall quality is maintaining a stable and balanced development trend.

The Beilin District, an old district with a rich historical and cultural heritage, also excels in street space quality, scoring an average of 10.00, ranking it among the top districts. The standard deviation of its score is 2.53, lower than that of Lianhu District, indicating relatively minor internal differences in street quality. However, the district's highest score of 26.58 significantly surpasses other districts, highlighting the outstanding performance of some historically significant and culturally rich streets in terms of visual appeal, environmental comfort, and interface diversity, showcasing the unique advantages of cultural streets. However, the lowest score in the district is only 5.77, significantly below the average of other districts, suggesting an uneven distribution of street quality within the district. The disparity in spatial quality between historical protection areas and ordinary streets warrants close attention during urban renewal efforts.

As key areas of urban expansion in Xi'an City in recent years, Weiyang District and Yanta District have an average street space quality score of 9.57 and 9.23, respectively, which is significantly lower than that of traditional central urban areas. While some streets in these districts have high scores, with the highest score exceeding 22 points, indicating a relatively good level of construction in certain areas, the overall standard deviation of street scores in these two new districts is relatively low, at 2.49 and 2.21, respectively, suggesting a noticeable trend towards homogenization in the design and construction style of street spaces. Notably, the lowest scores in Weiyang District and Yanta District are 4.60 and 4.69, respectively, far below the lowest scores in other administrative regions. These low scores are primarily concentrated in the urban fringe areas, highlighting issues such as strong motor vehicle interference, insufficiently transparent street interfaces, and inadequate green coverage, which require targeted improvements in future urban renewal efforts.

Further analysis of the distribution of street quality scores across different administrative districts reveals that high-quality streets are widely distributed in Xincheng District and Lianhu District, with generally superior spatial environments. In contrast, Weiyang District and Yanta District exhibit a dense concentration of medium to low-quality streets. This significant differentiation in spatial quality is closely linked to differences in urban development history, functional positioning, and policy resources, reflecting distinct development strategies in street spatial structure, land use methods, and functional layout across districts.

In summary, this study uses a comprehensive evaluation method to conduct a quantitative comparative analysis of the spatial quality of streets in various administrative districts of Xi 'an's main urban area. It highlights significant differences in spatial quality between traditional urban areas and emerging new districts. When formulating policies for future street quality improvements, it is essential to fully respect and integrate the specific development characteristics of each district. The central urban area should continue to enhance the optimization of interface details and the diversity of landscapes. For the peripheral new districts, the focus should be on increasing environmental openness, reducing traffic disturbances, and improving overall spatial comfort. This approach aims to promote the gradual coordinated development of street spatial quality across different regions, achieving balanced optimization and sustainable progress in the urban spatial environment.

Figure 2 Street quality identification results

Table 3 Street quality by district

canton	average value	standard deviation	maximum value	low
new city zone	10.39	2.69	24.83	5.22
Lianhu District	10.38	2.96	25.76	5.20
Beilin District	10.00	2.53	26.58	5.77
Weiyang District	9.57	2.49	22.45	4.60
Yanta District	9.23	2.21	23.12	4.69
Baqiao District	9.22	2.33	23.84	4.65
Chang'an District	8.83	1.77	24.38	4.46

5.2 Identification and characteristic analysis of street quality space types

In exploring the internal structural characteristics of street space quality in Xi 'an's main urban area, this paper uses the four core dimensions —— safety, comfort, richness, and convenience, established in the street space quality evaluation system, to classify the street spaces within the study area using the K-means clustering analysis method. Based on the performance differences of various streets across these dimensions, they are categorized into four types: 'safety-oriented streets,' 'ecological comfort streets,' 'interface vitality streets,' and 'pedestrian convenience streets.' The specific features of each type of street are as follows:

(1) Safety-oriented streets

These streets excel in safety, typically equipped with comprehensive road surveillance systems, offering a strong sense of security and relatively low motor vehicle interference. They are commonly found in densely populated or commercially active areas, providing robust public security. However, they fall short in terms of visual transparency (such as sky views) and green coverage, with room for improvement in the transparency and diversity of street interfaces. Therefore, future planning for these streets should focus on enhancing safety facilities while also improving ecological landscapes and visual quality.

(2) Ecological comfortable streets
These streets excel in green ecological indicators and visual environmental quality, featuring high green plant coverage, wide-open views, and a pleasant overall spatial experience. They are generally well-received by residents and are commonly found around green corridors, parks, and ecological scenic boulevards. However, they fall short in terms of pedestrian accessibility and mixed-use functionality, with insufficient interaction at street interfaces. Future urban renewal efforts should focus on enhancing functional complementarity and improving the pedestrian system to boost spatial vitality and usage efficiency.

(3) Interface dynamic street
Interface dynamic streets are renowned for their transparency, richness, and spatial vibrancy. They feature diverse building facades and strong visual appeal, creating a highly interactive and vibrant street environment. These streets are typically found in core commercial districts, historical and cultural areas, or tourist hotspots, making them ideal venues for cultural, commercial, and entertainment activities. However, high traffic volumes and a certain level of environmental pressure can also negatively impact the quality of experience. Therefore, while maintaining the vitality of the interface, enhancing traffic order and spatial transparency will be key areas for future optimization.

(4) Pedestrian-friendly streets
This type of street excels in pedestrian accessibility, mixed land use, and facility configuration. It features a well-planned spatial layout that is highly pedestrian-friendly, making it an essential part of daily commuting and living activities. Such streets are commonly found around urban commercial centers, transportation hubs, and comprehensive service areas. However, they generally lack visual appeal and greenery, with the street interface's attractiveness and visual comfort needing improvement. Future improvements should focus on enhancing visual experiences and ecological environments to comprehensively improve the quality and appeal of street spaces.

5.3 Analysis of the formation mechanism of street space quality types
The quality of street space is a key indicator for assessing the overall quality of urban public spaces, and its development is influenced by multiple factors. Based on the classification of street space types in Xi 'an's main urban area, this paper further explores the underlying mechanisms behind the differences in street quality from four perspectives: spatial location, land use, planning policies, and historical context.

(1) Differences in spatial location and endowment
The quality of street spaces is often closely tied to their location. Traditional central urban areas, such as Xincheng District, Lianhu District, and Beilin District, boast well-developed street systems and comprehensive commercial services and public facilities, offering superior location advantages. These factors naturally enhance the street vitality and pedestrian-friendliness of these areas. Moreover, early investment in public safety infrastructure has led to a dense distribution of 'safety-oriented streets' in central urban areas. In contrast, peripheral areas like Yanta District and Weiyang District, due to their later urban expansion, have less developed infrastructure, and the development of street safety and vitality is still in its early stages.

(2) Characteristics of land use mode and functional layout
The formation of different types of street spaces is closely linked to the intensity of land use and functional configurations. Pedestrian-friendly streets are typically found in commercial nodes, transportation hubs, and public service areas, where the land use is highly mixed, facilities are densely packed, and the focus is on enhancing pedestrian experience. Ecological comfort streets are mainly located around parks, green spaces, ecological axes, and new residential areas, characterized by low land density, high green coverage, and an open visual environment. Interface vitality streets, which rely on cultural and commercial land, feature interactive and visually diverse building facades, making the spatial interfaces highly attractive.

(3) Urban planning policy and governance orientation
In recent years, Xi 'an's planning policies have increasingly emphasized the quality of public spaces and the

refinement of urban governance. This has led to the updating of street safety facilities, the enhancement of interface images, and the optimization of pedestrian systems in the central urban area, resulting in a significant and stable improvement in overall spatial quality. Although the new urban areas initially focused on ecological space construction and created some ecologically comfortable streets, the lack of effective supporting policies has led to lagging development in other areas, resulting in a noticeable quality gap. In the future, it is necessary to enhance the vitality of the new district interfaces and pedestrian convenience through policy measures, promoting the coordinated development of the city's overall spatial layout.

(4) Historical development background and spatial heritage inheritance
The quality of street space is significantly influenced by the city's historical development and cultural heritage. Traditional urban areas, such as Beilin District and Lianhu District, are rich in cultural resources and humanistic landscapes. The streets in these areas have evolved over time, with highly dynamic spatial interfaces, making them an essential part of the urban landscape. In contrast, new urban areas lack historical and cultural support, and their street space design relies more on modern planning concepts, resulting in relatively weak visual and interface performance. Therefore, the renewal of street spaces should aim to protect historical and cultural heritage while integrating modern functional optimization, achieving an organic blend of tradition and modernity.

The formation of the spatial quality types of main urban streets in Xi'an City is essentially the result of the combined effects of various factors, including spatial location, land use, policy guidance, and historical and cultural elements. The location characteristics provide a foundation for development, land use enhances spatial functions, planning policies drive quality improvements, and historical heritage enriches the cultural significance of the spaces. Future urban street governance should, based on an understanding of these mechanisms, develop a multi-dimensional and balanced optimization strategy to promote the continuous improvement and coordinated development of urban public space quality.

6.Conclusion
This study, using the main urban area of Xi'an as a case, developed a framework for measuring urban street spatial quality that integrates intelligent recognition and perception scoring mechanisms of street scenes. It systematically integrates physical environmental elements with subjective perception factors, conducting a comprehensive and systematic analysis from the construction of evaluation indicators, data processing, spatial type identification to the analysis of formation mechanisms. Based on this framework, the study has reached the following key conclusions:

The subjective and objective integration evaluation system proposed in this paper has achieved significant breakthroughs in both theory and methodology for measuring the quality of street space. In terms of indicators, it expands the traditional measurement centered on physical structure to a multi-dimensional system that includes residents' perceptions. Technically, it leverages street view images and machine learning models to construct a large-scale, automated evaluation process, significantly enhancing the accuracy and applicability of street space quality analysis. By using Z-score standardization and entropy value weighting, a scientific, systematic, and hierarchical comprehensive index of street quality has been developed, providing a stable and reusable technical framework for spatial quality research.

(2) The spatial quality of the main urban area's streets generally follows a' high in the center, low on the periphery 'pattern. Traditional central areas, such as the new district and Lianhu District, excel in safety, interface diversity, green coverage, and pedestrian accessibility, with significantly higher average scores compared to peripheral new districts like Weiyang District and Yanta District. These structural differences are closely linked to the city's development stage, resource allocation, and policy priorities, highlighting the uneven distribution of urban spatial quality.

Through cluster analysis, four typical street types were identified: 'safety-oriented streets,' 'ecological comfort streets,' 'interface vitality streets,' and 'pedestrian convenience streets.' Each type of street excels in different

aspects, such as the completeness of safety facilities, the openness of visual landscapes, the vibrancy of interface interactions, and the integration and accessibility of functions. This classification highlights the diverse development paths of urban street spaces in terms of composite functions, structural forms, and service performance. The results provide a clear direction for future district governance and differentiated improvements.

(4) The classification and distribution of street spatial quality are influenced by multiple mechanisms, including location conditions, land use patterns, urban planning policies, and historical and cultural heritage. The spatial location determines the level of street infrastructure and the layout of supporting facilities. The structure of land use enhances the expression of spatial attributes, policy support accelerates the pace of quality improvement, and historical heritage profoundly influences the formation of street interfaces and forms. Urban street space optimization should be based on these factors, adopting comprehensive measures to achieve dynamic integration between planning logic and spatial practice.

(5) To evaluate the model's effectiveness, the study used Cohen's s Kappa coefficient to compare the consistency between different models and subjective perception levels. The results showed that the consistency between the single objective index model and subjective perception was -0.092, while the consistency between the integrated subjective-objective model and subjective perception improved to -0.074. Although the overall consistency level still needs improvement, the integrated model performed better, further confirming the positive impact of incorporating subjective perception factors in enhancing the explanatory power and accuracy of measurement models. This finding underscores the importance of a 'people-oriented' and 'perception-led' approach in future urban spatial quality assessments.

7.Discussion

This study introduces a street space quality measurement system that integrates subjective and objective perspectives. It overcomes the limitations of traditional urban space evaluation models in both theory and methodology, significantly enhancing the ability to identify the interaction between human perception and the spatial environment. By integrating street view images, subjective perception models, and multi-dimensional evaluation indicators, the study not only achieves a broad and high-precision assessment of urban street space quality but also demonstrates the positive impact of incorporating subjective factors on improving evaluation accuracy. Compared to a single objective model, the Kappa coefficient between the subjective level and the subjective-objective integration model is superior, although overall consistency has not yet reached a significant level, it shows potential for improving recognition accuracy. Additionally, the results of street type identification reveal the diverse patterns of urban street space functions and environmental characteristics, providing practical guidance for urban zoning governance and detailed updates.

Despite achieving some success, the research still has several shortcomings. Firstly, the quality of street view images is affected by shooting time, occlusion factors, and update frequency, leading to unclear or incomplete images in some areas. Secondly, subjective perception data primarily relies on the Place Pulse model, which has strong cultural biases in its training samples, making it difficult to fully reflect the actual perceptions of urban residents in China. Thirdly, the current method of integrating subjective and objective scores uses a simple averaging approach, lacking more robust weight optimization or structural modeling strategies. Lastly, while the classification of street spatial types has some application value in policy-making, it has not yet been effectively linked with land use, socio-economic characteristics, and governance units, resulting in a certain degree of disconnection between measurement and governance. Therefore, future research should enhance the model's adaptability to local conditions, expand the sources of diverse data, introduce mechanisms for behavioral responses and logic for matching governance scenarios, and promote the evolution of street spatial quality research from technical tools to governance mechanisms.

Abstract
Tourism plays an important role in the German economy, especially in hotspots in the northern coastal areas and the Alpine regions in the south, where up to 10% of the workforce is employed in tourism-related occupations. Like the broader labour market, these jobs are also affected by digitalisation trends and, as the analysis shows, they may be even more susceptible to certain aspects of it. This article maps digitalisation indicators to occupations and labour market statistics and defines digitalisation profiles that explain how digitalisation shapes employment in the tourism sector and where regional differences in susceptibility may occur.

Keywords: labour market, tourism, artificial intelligence, digitalisation, computerisation

1. Introduction

According to the United Nations World Tourism Organization (UNWTO, 2025), Germany ranked 8th among the world's top 10 most visited countries in 2024, recording 37.5 million international arrivals, an increase of 7.8% compared to 2023. The tourism industry is considered an important pillar of Germany's economy, significantly contributing to both the economy and employment. The World Travel and Tourism Council (WTTC) is forecasting that the sector could grow its annual GDP contribution to nearly € 554 billion by 2034, representing just over 12% of the German economy, and could potentially employ almost 6.5 million people across the country (WTTC, 2024).

Tourism data is sourced from the INKAR database (INKAR, 2024), maintained by the Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR). While cities such as Berlin, Munich and Hamburg attract the most tourists on absolute terms, the relative size of this economic sector is much larger in smaller, less-densely populated regions. Analysis on the level of districts and district-free cities ("Kreise" & "Kreisfreie Städte") shows large disparities in the importance of tourism, illustrated by the three maps on accommodation capacity, demand intensity, and tourism-related employment (Figure 1).

Focusing on the number of tourist beds per 1,000 inhabitants the analysis reveals high concentrations in the northern coastal areas (Baltic Sea and North Sea), the southern Alpine regions, and selected major cities such as Berlin, Munich, and Hamburg.

Tourism-related jobs are concentrated similarly, however some regions with high tourist accommodation capacities exhibit a relatively low share of tourism employment, for example some districts in Rhineland-Palatinate in the southwest of the country. This can result from factors such as reliance on external seasonal labour or a concentration of jobs in other sectors. The analysis of tourism demand, measured by overnight stays per inhabitant, shows some inconsistencies: regions with high accommodation capacity do not always exhibit equally high tourism demand, suggesting an under-utilization of facilities or stronger seasonality.

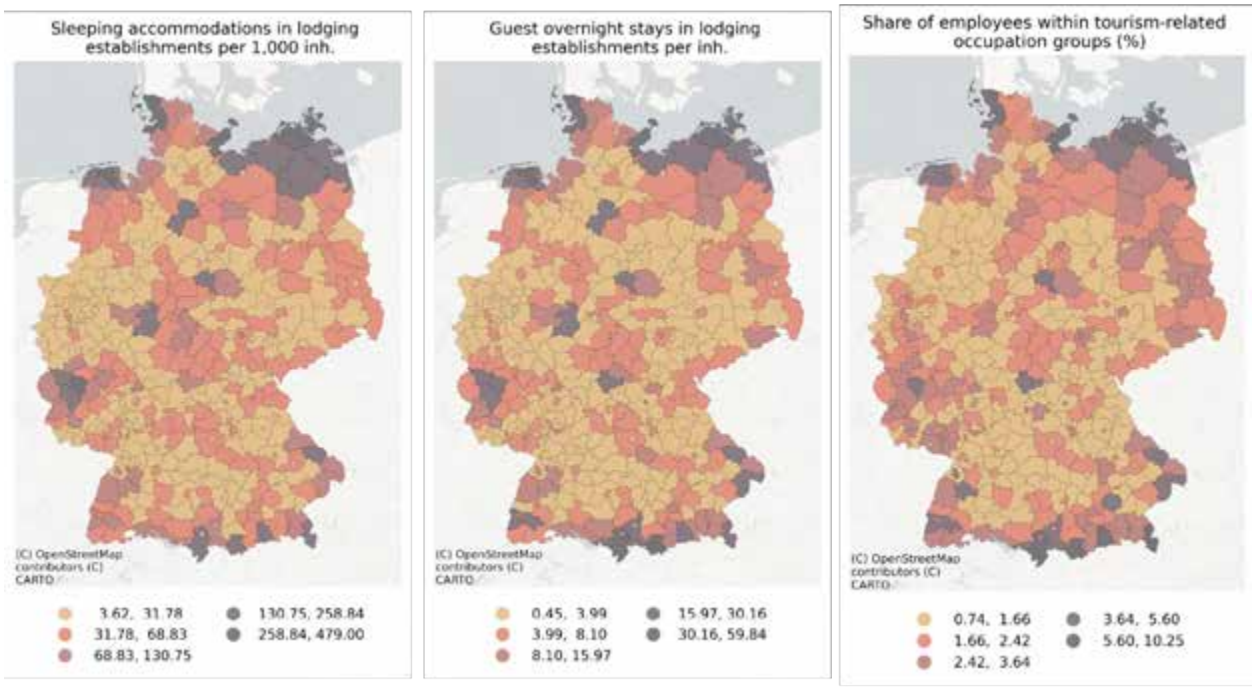

Figure 1. Regional variation in tourism intensity across Germany.

Tourism areas in Germany are not only leisure destinations but also important economic hubs, where tourism contributes to employment, income generation, and regional development. As a cross-sectional industry, tourism intersects with multiple sectors, ranging from transport and accommodation to gastronomy, culture, and business services, making it challenging to assess ongoing trends both statistically and spatially.

In a country where tourism plays a vital economic and cultural role, spanning urban, rural, and natural destinations, there is a growing need for a more integrated and comprehensive understanding of the sector. This article explores the structure, spatial distribution, workforce employments, and technological transformations shaping employment in the tourism sector in Germany.

2. Methods

2.1 Labour Market Information

To quantify and analyse the impact of digitalisation on the tourism sector, labour market data is queried from the employment statistics database (Bundesagentur für Arbeit, 2022) of the German Federal Employment Agency (Bundesagentur für Arbeit). This database consists of a structured list of occupations, occupation groups and sectors, as well as employment numbers per group and geographic entity.

Occupations are organised in a hierarchical system, which is described in the KldB 2010 structure. This occupational taxonomy distinguishes between 36 main occupational groups identified by 2-digit codes (e.g. 63 - Occupations in tourism, hotels and restaurants), which is split up into 140 occupational groups at the 3-digit level (e.g. 631 - Occupations in tourism and the sports (and fitness) industry), and 698 occupational subgroups at the 4-digit level (e.g. 6311 - Management assistants in tourism). On the lowest level in the hierarchy there are 1300 occupations with a 5-digit code (e.g. 63112 - Management assistants in tourism-skilled tasks). The Federal Employment Agency also provides with a list of job titles (with 18,838 entries) that can be linked to these occupations (e.g. jobs linked to occupation 63112 can have titles such as “travel agency assistant”, “economic assistant for tourism and foreign languages” or “tourism assistant”).

The data used within this research correspond to the reference date of 31 December 2022. Employment numbers

are available down to the occupational subgroup (4-digit) level on the federal scale and are differentiated by characteristics such as gender, nationality, age groups, and employment type (full-time, part-time, or marginal employment). At the regional level, data are only available at the level of occupational groups (3-digit), with a differentiation by employment type. This analysis builds up on data of full-time workers who are subject to social security contributions.

The regional breakdown follows the German system of districts and district-free cities (Kreise und kreisfreie Städte), corresponding to the NUTS-3 classification. There are a total of 400 districts and district-free cities, with a median population of 157,406 (INKAR, 2024). Due to data protection rules, occupational groups with fewer than 40 employees are masked in the regional statistics. There are 109 districts with masked data for more than 50 of occupational groups. For these groups, random numbers between 0 and 39 were assigned.

2.2 Data Constraints

A major challenge within this analysis results from the lack of availability of high-quality and disaggregated data, especially in labour market statistics. For instance, the occupational group 631, classified as "Tourism and Sport", includes up to 90 different job titles, ranging from tour guides and alpine guides to managers of travel agencies and graduates with an MBA in tourism economics. These job titles often differ in their qualification requirements, work environments, and digitalisation exposure. This complicates interpreting the impact of digitalisation on the level of occupational groups.

Furthermore, the regional units used in the analysis to obtain the number of workers in a given occupation group are relatively large and often internally diverse. This means that variation in the structure and relevance of the tourism sector may exist within a single district (Sarrión-Gavilán et al., 2015), which cannot necessarily be captured at the available level of resolution. In addition, tourism activities can be expected to produce spillover effects that extend beyond administrative boundaries. These spatial interactions are not reflected in the available data and should be kept in mind when interpreting the results.

2.3 Defining tourism jobs

Tourism is not a closed economic sector and involves a wide range of interactions with other industries. However, the structured and hierarchical nature of available labour market data cannot fully reflect these interdependencies (Liu and Wall, 2006). As a result, certain forms of economic activity are often underrepresented or misclassified, which can lead to a narrower depiction of the tourism sector, as it has been shown in an example in agrotourism (Guizzardi & Costa, 2023).

The classification of workers involved in the tourism sector in Germany by the broader framework of Tourism Satellite Accounts (TSA) is based on tourism-characteristic products and services. These classifications help determine which economic activities are directly or indirectly linked to tourism and, by extension, which types of employment are considered part of the tourism sector. Key tourism characteristic sectors in Germany include accommodation and food and beverage services as primary employers, along with various modes of passenger transport, travel agencies, and cultural, recreational, and sports services, while country-specific products such as health services, food, and fuel reflect additional tourist spending, and other products capture goods and services indirectly linked to tourism consumption (DeStatis, 2024).

Another way to delineate the sector is through activity-based definitions. For example, Melián-González (2025) suggests "accommodation activities; food and beverage service activities; travel agency, tour operator, and related activities" being representative of the tourism sector. Following a more pragmatic distinction, the scope of tourism employment can be interpreted using two complementary concepts: employment in tourism industries and tourism employment (Meis, 2014). The former includes all workers employed in industries that serve both tourists and non-tourists, while the latter focuses on jobs that would not exist, or would exist to a much lesser extent without tourism.

The KldB classification features three occupational categories that match the narrower definition of tourism:

- 631: Tourism and Sport
- 632: Hotel Business (Hotellerie)
- 633: Gastronomy

In order to test whether these three groups can reliably depict occupations in tourism in the narrower sense, the occupational classification was tested with two different methods.

2.3.1. Method 1: Keyword Search in Job Titles
Using the list of 18,838 official job titles, a keyword search was conducted to identify tourism-related occupations. Following keywords were used:

- tour
- hotel
- gast (guest)
- restaurant
- freizeit (recreation)
- camping
- unterkunft (accomodation)
- reise (travel)

Every job title that had one of these (sub-)strings was selected for being related to the tourism industry and was manually checked to exclude misleading results (e.g. "gastroenterology" containing "gast").

This approach identified 197 job titles, with the following distribution across occupational groups:

- 632 (Occupations in hotels): 62 job titles
- 631 (Occupations in tourism and the sports (and fitness) industry): 47 job titles
- 633 (Gastronomy occupations): 40 job titles
- 293 (Cooking occupations): 7 job titles
- 845 (Driving, flying and sports instructors at educational institutions other than schools): 5 job titles

This analysis shows that a vast majority of tourism employment is adequately captured within the three main occupational groups. Other occupational groups might contain individual occupations, though they are grouped along a large number of other jobs that do not belong to the sector. For example, group 845 includes both recreational sports teachers, but also occupations such as driving instructors. Due to the lack of data granularity, the inclusion of such occupations might lead to skewed results.

2.3.2. Method 2: Correlation Analysis with Core Tourism Groups
In a second method, a statistical correlation analysis was performed to identify occupational groups that consistently co-occur with the three tourism-related occupation groups across districts. The aim was to detect shared patterns that might indicate a functional relationship to tourism.

Occupational groups with correlation coefficients higher than 0.7 were considered relevant. The results are shown in the correlation in Table 1.

Table 1: correlation matrix of tourism-related occupational groups

Occupation group code (Kldb – level 3)	293	631	632	633
293 - Cooking occupations	1.00	0.28	0.53	0.89
631 - Occupations in tourism and the sports (and fitness) industry	0.28	1.00	0.57	0.47
632 - Occupations in hotels	0.53	0.57	1.00	0.70
633 - Gastronomy occupations	0.89	0.47	0.70	1.00

While group 293 (Cooking occupations) shows a relatively strong correlation with group 633, its weaker correlation with the other two groups suggests that it is not consistently aligned with core tourism employment patterns. Therefore, the final definition used in this study includes only occupations from groups 631, 632 and 633.

Although this excludes the broader landscape of tourism employment, it offers a focused and consistent basis for analysing tourism-related labour market structures using the available data.

2.4 Definition of digitalisation scores

The evolution of the labour market has been closely linked with technological advancements for centuries. Since the advent of the internet in the 1990s, digitalisation has played an important role in shaping labour market dynamics. Especially in the late nineties and early 2000s, technologies were expected to reduce the importance of physical space, which was signified through concepts such as "death of distance" (Cairncross, 1997). However, the internet and emerging technologies led more to a hybridisation of space (Frith, 2012) instead of a complete relocation of our activities to the virtual world.

The tourism sector is a good example for these hybrid places, with a high importance of physical interaction and real experience at its core, but with an integration of digital tools into related activities. The adoption of modern information and communication technologies (ICT) has significantly enhanced competitiveness and accessibility within the sector, enabling more efficient trip planning and booking, particularly for international travel and among younger age groups (Banescu et al., 2021), but has also been a contributing factor for challenges resulting from the adoption of short-term rental platforms (Bei and Celata, 2023). Immersive technologies such as Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (MR) can be used as marketing tools (Bogicevic et al., 2019; Tussyadiah et al., 2018) or enhance tourist experience. However, tourism is a sector where the importance of the human context and authentic experiences remain an important factor during the adoption of new technologies (Pencarelli, 2020).

Digitalisation in the workforce within the tourism and hospitality industry can affect the whole guest cycle and has already been adapted by the industry, most for example in the form of social hubs, chatbots, travel assistants or robots (Lukanova and Ilieva, 2019), Currently, technologies are mostly used as a complementary to human labour (Melián-González and and Bulchand-Gidumal, 2025), as automation can also lead to negative reaction from customers, for example in the gastronomy sector (Pancer et al., 2025).

Quantifying the impact of these digitalisation trends and predicting potential future outcomes is currently an unattainable task, even when just focusing a clearly defined set of occupations within a given industry. Public discourse often centres on automation and the anticipated displacement of workers, but these processes are more complex than a simple narrative of job loss. Labour market outcomes are shaped by institutional, organisational, legal, and political contexts (Degryse, 2016; Gordon and Gunkel, 2024). Digitalisation has many different facets and goes beyond a replacement of workers through computers (Acemoglu and Restrepo, 2018; Arntz et al.,

2019), which is also true for the tourism sector (Ivanov, 2020).

We can imagine job losses (e.g. through automatic check-in counters in hotels instead of human agents), but potentially alongside with a reorganisation of the content or importance of tasks (e.g. management of bookings on third-party booking platforms before the quests even arrive), the creation of new tasks (e.g. content creation for social media) or even the creation of new jobs (e.g. through an increased need of data analysts in the sector). However, research also finds evidence for a polarisation through automation in the hospitality industry (Yuan and Liu, 2025).

For this reason, measuring the impact of a broad trend such as digitalisation on the labour market is challenging, especially if the aim is to create quantifiable or spatial results. A widely used approach in approximating the effects of this trend is to compare skills or tasks linked to occupation groups towards certain aspects of digitalisation and then depicted as a numeric score. Such scores can be consequently aggregated on the occupational level and linked to labour market statistics. Such methods have been used to assess the effect of digitalisation based on routinisation (Autor et al., 2003), machine learning abilities (Brynjolfsson et al., 2018), teleworkablitiy (Dingel and Neiman, 2020) and (especially more recently) Artificial Intelligence (Colombo et al., 2024; Eloundou et al., 2023; Georgieff and Hyee, 2022).

This paper draws on three such indicators:

- "Artificial Intelligence Occupational Exposure" (AIOE) (Felten et al., 2021)
- "Potential Risk of Computerisation" (PRoC) (Frey and Osborne, 2017), and
- "Digital Competencies Indicator" (DCI) (Lennon et al., 2023),

These indices are described in more detail below.

2.4.1. Artificial Intelligence Occupational Exposure (AIOE)
Artificial Intelligence (AI) is a currently actively discussed topic within the context of labour market transformation. Tools for text and image generation, which were introduced in recent years, have already altered how certain tasks are carried out within occupations. While it remains difficult to quantify the labour market effects of AI or to determine what role AI might play in the future (replacement or reinstatement effects), its significance can be approximated through the AI Occupational Exposure score (Felten et al., 2021). This measure compares the skills associated with occupations in the SOC/O*NET framework to areas of recent AI progress, as tracked by the Electronic Frontier Foundation (EFF).

The EFF dataset identifies advances in specific AI capabilities (e.g. "image recognition", "language translation"), which are then linked to occupations based on the overlap between these AI capabilities and the human skills required for the job. The AIOE score indicates how exposed an occupation is to AI, based on the similarity between AI capabilities and occupational skill requirements. It is constructed as a relative metric, normalised using the standard deviation of AI-related skill importance and prevalence across occupations. Scores range from -2.67 for dancers to +1.53 for genetic counsellors.

2.4.2. Potential Risk of Computerisation (PRoC)
Another widely debated aspect of labour market digitalisation is the potential replacement of human workers through automation. The probably most well-known attempt to quantify this risk was made in "The Future of Employment" report (Frey and Osborne, 2013, 2017) which assigns a probability of computerisation to specific occupations based on expert assessments on computational bottlenecks. These inputs were used as training data for a machine learning model that estimated scores on an occupational level.
The resulting scores range from 0 to 1, with higher values indicating a greater susceptibility to computerisation. At the low end of the spectrum are occupations such as recreational therapists (score: 0.0028), which consist of

tasks that are hardly automatable. Conversely, 11 occupations, such as telemarketers, data entry keyers, and cargo and freight agents, receive scores of 0.99, indicating a high potential susceptibility to automation. It is however important to note that these numbers can best be interpreted as the highest level of computerisation that is technically possible (Coelli and Borland, 2019; Frey, 2021), without taking the organisational, legal or societal context into account.

2.4.3. Digital Competencies Indicator (DCI)

A third aspect of digitalisation can be identified through the requirements for digital skills for workers within their occupations. Lennon et al. (2023) developed a digital skills indicator using the ESCO database, which links skills to occupations. The indicator builds on an adapted version of the Revealed Comparative Advantage (RCA) statistic, measuring the relative concentration of digital skills within an occupation compared to all others. The analysis distinguishes between essential and optional skills, as well as between narrower and broader definitions of digital skills. Whether a skill is defined to be digital is based on the original ESCO classification (narrower definition), or also through a text analysis of their descriptions (broader definition).

For this study, we use the Digital Competencies Indicator (DCI) based on essential digital skills as defined in the broader sense (Option 3 in the original paper). This avoids overestimating the relevance of digital skills through optional attributes and allows the inclusion of skills not explicitly labelled as digital in the original ESCO taxonomy.

Indicators obtained through this method define 1,269 (42.20%) of the 3,007 occupations requiring no digital skills. The highest scores are defined for database integrators (11.98), digital forensics experts (11.46) and data quality specialists (11.35).

2.5 Indicator matching

While the indicators presented previously provide structured information about certain aspects of digitalisation, they were developed based on a specific occupational statistic and taxonomy with unique definitions of occupation groups and their hierarchical organisation. Germany uses the Klassifikation der Berufe (KldB) system, while the PRoC and AIOE scores are based on the SOC/O*NET taxonomy of the US Department of Labour. The DCI score is linked to the ESCO classification of the European Union.

Although the general structure and logic of these taxonomies are comparable, they define occupation groups differently and also differ in how occupations are grouped hierarchically. During mapping these indicators to geographic statistics, the lack of high-quality regional data is a second issue in the case of this research. Figures are available only on the level of occupational groups (KldB 3-digit level), while the digitalisation indicators are associated with more detailed categories, especially in the case of DCI (3,007 scores need to be mapped to only 140 occupations). As a result, multiple matches are possible between the taxonomies, and direct one-to-one translation is in general not feasible.

To harmonise these systems, crosswalk tables are provided by the maintainers of these taxonomies. In the case case of this study, two conversion tables had to be used, one for matching between the SOC/O*NET and the ESCO taxonomy (Bundesagentur für Arbeit, 2021) and a second one to link the ESCO and the KldB taxonomies (European Commission, Directorate General for Employment, Social Affairs and Inclusion, 2022). This means, the assignment of digitalisation scores is based on a multistep mapping, with in many cases multiple possible linkages.

The classification problem has been discussed in depth in a study of transferring PRoC scores to the German labour market (Bonin et al., 2015), which describes the “equal distribution” approach. Aggregating potential digitalisation scores to a simple number (e.g. taking the average of all potential scores) can result in a gravitation towards the average and masking potentially extreme (but relevant) values. The equal distribution takes all possible scores across a certain occupation group and then divides the number of workers based on the number of potential matches, which enables a better estimation of digitalisation scores, even if data is available only on an aggregated level (Cserpes, 2024).

As the selected indicators use different scales of measurement, the weighted median of these scores were defined to help orientation and relative comparability, following the approach in Fossen and Sorgner (2019). The weighted median across all employees within the employment database (Bundesagentur für Arbeit, 2022) was calculated to be at 0.09 for the AIOE, at 0.66 for the PROoC and at 0.54 for the DCI indicator. Jobs with scores below these thresholds were defined as having low digitalisation scores, and those above as high.

3. Results

3.1. AIOE Scores

Figure 2 displays the AIOE (AI Occupational Exposure) scores for the tourism-related occupational groups. Within the "tourism and sport" group (631), scores tend to be located around the median or above, indicating an overlap between the skills required in these occupations and areas in which AI has made significant progress. An exception in this group is fitness trainers and aerobics instructors, whose low exposure is likely due to the physical and interpersonal nature of their work. This group is included here due to the classification under sport. In contrast, managerial and supervisory roles in tourism show high exposure, suggesting that while customer-facing tasks may remain stable, AI may increasingly support or transform planning, coordination, and back-office functions. Occupations such as tour guides and escorts or event planners fall into a moderate exposure range, indicating partial transformation rather than replacement.

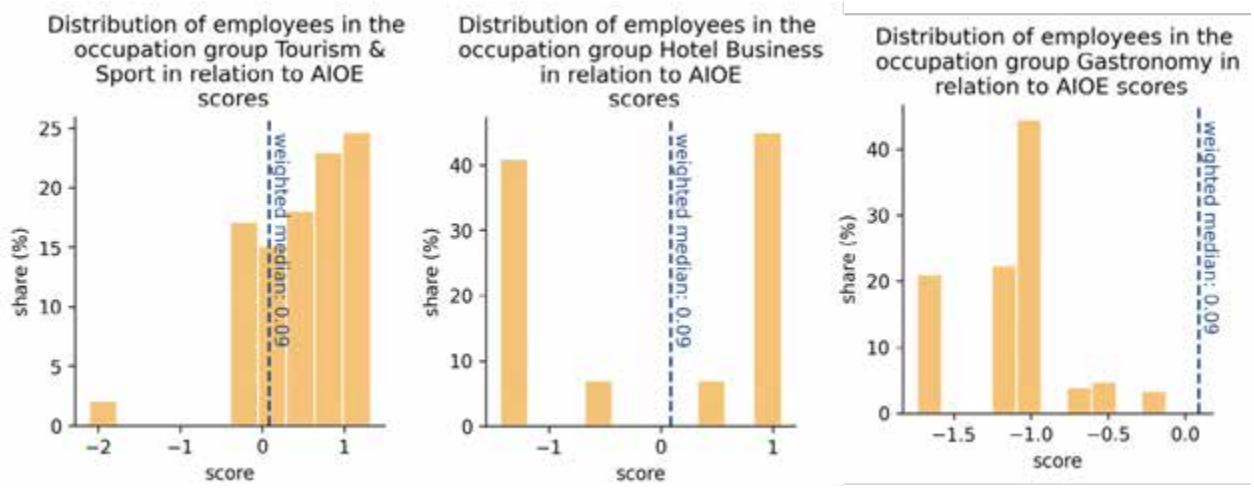

Figure 2. AIOE scores for tourism-related occupations

The hotel business occupational group presents a distribution of AIOE scores on both ends of the spectrum. On the lower end are jobs such as first-line supervisors and janitors, which involve significant managerial oversight or physical labour in areas where application of AI tools is unlikely. Conversely, a substantial portion of workers in this group are in high-exposure roles such as receptionists, administrative clerks, and secretaries who support managerial functions. This suggests that while the core structure of hotels may remain unchanged, the way administrative and support tasks are performed are likely to change due to AI adoption.

In the gastronomy sector, AIOE scores are clearly low, with only a few exceptions (such as food service managers) showing moderate exposure. This implies that, at present, AI is not expected to play a major role in reshaping most gastronomy jobs, which remain heavily reliant on physical presence and interpersonal service.

In summary, the level of AI exposure varies across tourism-related occupations. While workers in the general tourism sector exhibit higher AIOE scores (especially in managerial and planning roles) the hotel business shows a clear divide between supervisory and support roles. Meanwhile, the gastronomy sector appears largely unaffected by AI, at least in the near term.

3.2. PRoC Scores

Figure 3 presents histograms of the Potential for Replacement by Computerisation (PRoC) scores on the national level in Germany. The results indicate a heterogeneous distribution of susceptibility towards computerisation within the occupational group tourism and sport (group 631). Around two-third of the workers in this category can be assigned low susceptibility scores. These include managerial and supervisory positions, as well as occupations such as teachers, instructors, travel agents, and event planners. At the same time, around one-third of employees within this group show higher scores, such as hosts, tour guides and escorts or sales representatives.

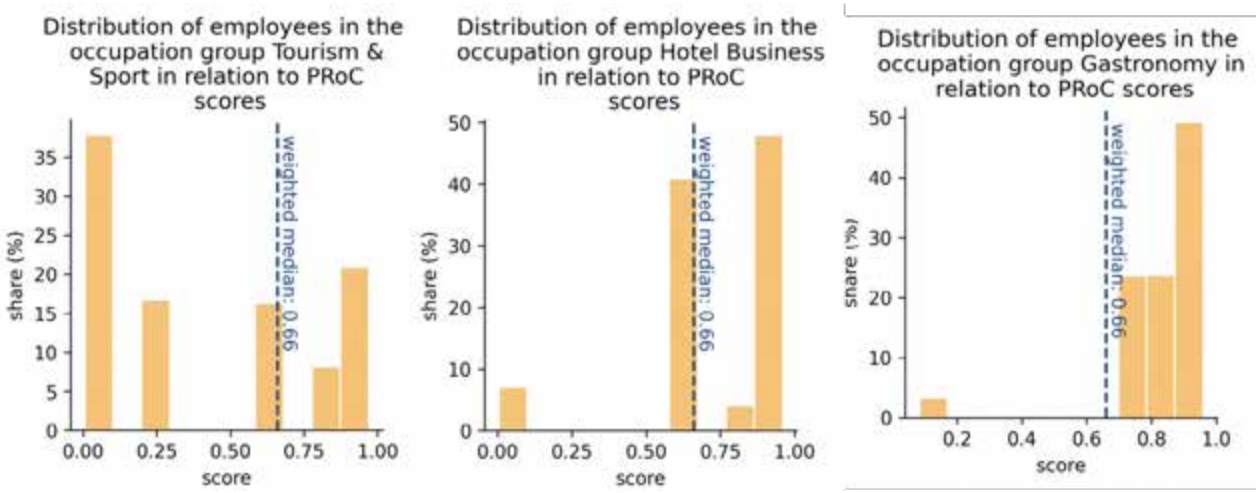

Figure 3. PRoC scores for tourism-related occupations

These findings highlight a central characteristic of task-based indicators such as the PRoC score: they are based on the technical feasibility of automating specific tasks. As such, they reflect the upper bound of automation potential but do not account for factors such as human oversight, social interaction, or customer expectations, which may limit the practical implementation of automation.

In the hotel business occupational group (632), the distribution of scores is more clearly skewed toward a susceptibility level at the median or above. Most jobs in this category, such as receptionists and administrative assistants, conduct tasks that are relatively straightforward to automate. An exception within this group are lodging managers, whose tasks tend to be less automatable due to their complexity and decision-making requirements. This pattern mirrors broader trends, such as the shift from traditional hotels to platforms like Airbnb, where check-in and service functions are largely automated, leaving only maintenance and cleaning staff physically required.

A similar picture emerges in the gastronomy occupational group. Here too, most occupations (such as food preparation workers, waiters, waitresses, and food servers) exhibit high computerisation potentials. Food service managers remain an exception with lower scores. However, despite the technical feasibility, the sector has not fully implemented automation.

In summary, occupations within the tourism sector tend to show different theoretical automation potentials, with higher tendencies within the hotel-business and gastronomy-related roles. However, this potential is not yet fully realised in practice, especially in the gastronomy sector, where human labour continues to play a central role despite the availability of automating technologies.

3.3. DCI Scores

In contrast to the PRoC and AIOE scores, the DCI data is originally available at a more granular occupational level (scores are assigned to 3,007 occupations), allowing for a more precise allocation of scores across occupation

groups (Figure 4). Despite this increased level of detail, distinct patterns in the distribution of digital skill intensity still emerge clearly.

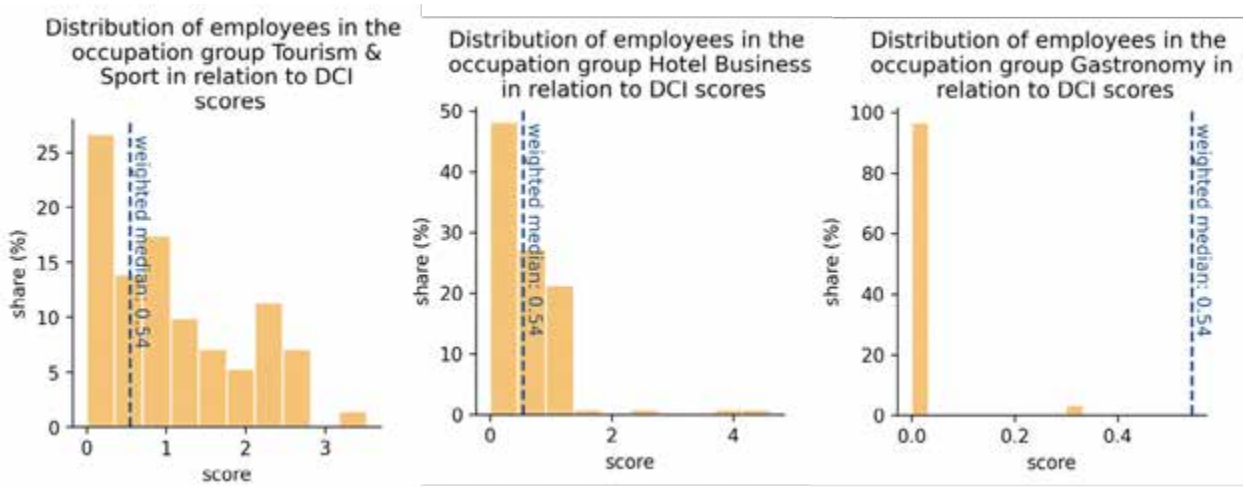

Figure 4: DCI scores for tourism-related occupations

The "tourism and sport" occupational group tends to showcase the largest proportion of workers above the median DCI score. These digital scores are primarily associated with jobs more closely tied to the business and organisational aspects of tourism (such as pricing specialists or customer experience managers). In contrast, roles like travel consultants, tour guides and (somewhat unexpectedly) clerks demonstrate low digital skill levels.

In the hotel business group, the concentration of low DCI scores is even more clear. Exceptions are limited to positions such as administrative assistants and executive assistants, likely due to their involvement in managerial and organisational responsibilities. As expected, occupations such as cleaners and helpers reflect minimal digital skill demands.

Interestingly, even accommodation managers register a DCI score of zero. This can be attributed to the methodology of the DCI, which focuses on essential core skills: in this case, the digital components are outweighed by other core, non-digital skills, suggesting that while digital skills may be present, they are not characteristic to the occupation's core requirements.

The gastronomy sector shows the clearest trend: aside from restaurant managers, nearly all occupations in this group exhibit practically no digital skills according to the DCI.

In conclusion, the findings confirm that the tourism sector is characterised by a contrast in digital skills requirements. There is a clear divide between customer-facing or operational roles and managerial positions, with the latter more likely to involve digital competencies.

3.4. Tourism Digitalisation Susceptibility Score

The selected three digitalisation scores highlight three distinct aspects of this trend, but to provide an overall estimation these indicators need to be analysed in combination. Such combinatory analysis has been applied to analyse AIOE scores per occupation and AI's potential complementarity (Pizzinelli et al., 2023), or through the mapping of occupations based on their PRoC and AIOE scores (Fossen and Sorgner, 2019) and relating them with spatial statistics (Cserpes, 2024). The methodology of this latter study is applied and enhanced in our analysis through the DCI-score as an additional dimension. Every occupation is matched with all possible scores for each of these three digitalisation indicators, then for each occupation the score of high or low is assigned, based on weighted medians of the scores as thresholds.

As an example, the occupation of barkeepers (KldB 6332) can be assigned the AIOE score of -0.62 (below the weighted median), the PRoC score of 0.77 (above) and the DCI score of 0 (below). This leads to the occupational digitalisation profile of low-high-low.

Three digitalisation profiles are particularly relevant for interpretation:

• High across all scores: Occupations with significant digital skill demands, high AI exposure, and high automation potential, likely to transform through digitalisation rather than be replaced (e.g. management assistants in tourism).
• Low AIOE, high PRoC, low DCI: Occupations that are technically automatable but neither heavily exposed to AI nor dependent on digital skills. These represent jobs that could, in theory, be automated but are not currently subject to strong digital transformation pressures (e.g. occupations in system catering).
• Low across all scores: Jobs with minimal digitalisation exposure, usually manual or service-oriented roles. These show limited susceptibility to technological change (e.g. occupations in hotel service).

Table 2 displays the distribution of German workforce across the digitalisation profiles in the whole labour market and within tourism-related occupations. Approximately 20% of all employees within the German labour market work in the low-high-low category, 11% in the high-all group, and another 11% in the low-all group.

Table 2. Overview of digitalisation metrics in tourism vs. the general labour market

AIOE	PRoC	DCI	Share in DE Employment (%)	Share in 631 (Tourism & Sport) (%)	Share in 632 (Hotel business) (%)	Share in 633 (Gastronomy) (%)	Share in all Tourism Occupations (%)
high	high	high	10.59	5.72	24.54	-	6.58
high	high	low	4.51	8.74	-	-	0.79
high	low	low	15.40	29.67	8.44	-	4.76
low	high	low	20.42	2.62	5.63	98.02	66.57
high	low	high	17.31	41.56	-	-	3.75
low	low	high	9.54	0.96	-	-	0.09
low	high	high	11.43	7.86	-	-	0.71
low	low	low	10.81	2.88	61.39	1.98	16.75

When looking at the tourism sector, this distribution is more skewed:

• Around 66% of workers in the tourism sector (especially in gastronomy) are working in an occupation with a low-high-low-profile, indicating technical automatability without current AI relevance or digital competence needs.
• 17% of tourism roles fall into the low-low-low category, including many in hotel maintenance and cleaning, where digitalisation plays a negligible role.

• A small segment (approximately 4%) scores high on all three indicators, mostly administrative or managerial roles in the hotel business, which are not easily replaced but are expected to change through digital processes.

3.5 Geographic distribution

Besides comparing these scores between occupational groups on the national level, understanding their geographic distribution can be a relevant question.

The low-low-low-group (displayed in Figure 5) shows a higher share within the tourism sector than in the general labour market, especially in the districts with high tourism activity in the southern part of the country at the Baltic and Northern Sea coast. This suggests that tourism-intensive regions are currently less strongly affected by digitalisation trends and a large share of their tourism workforce will experience little differences in how they conduct their jobs in future.

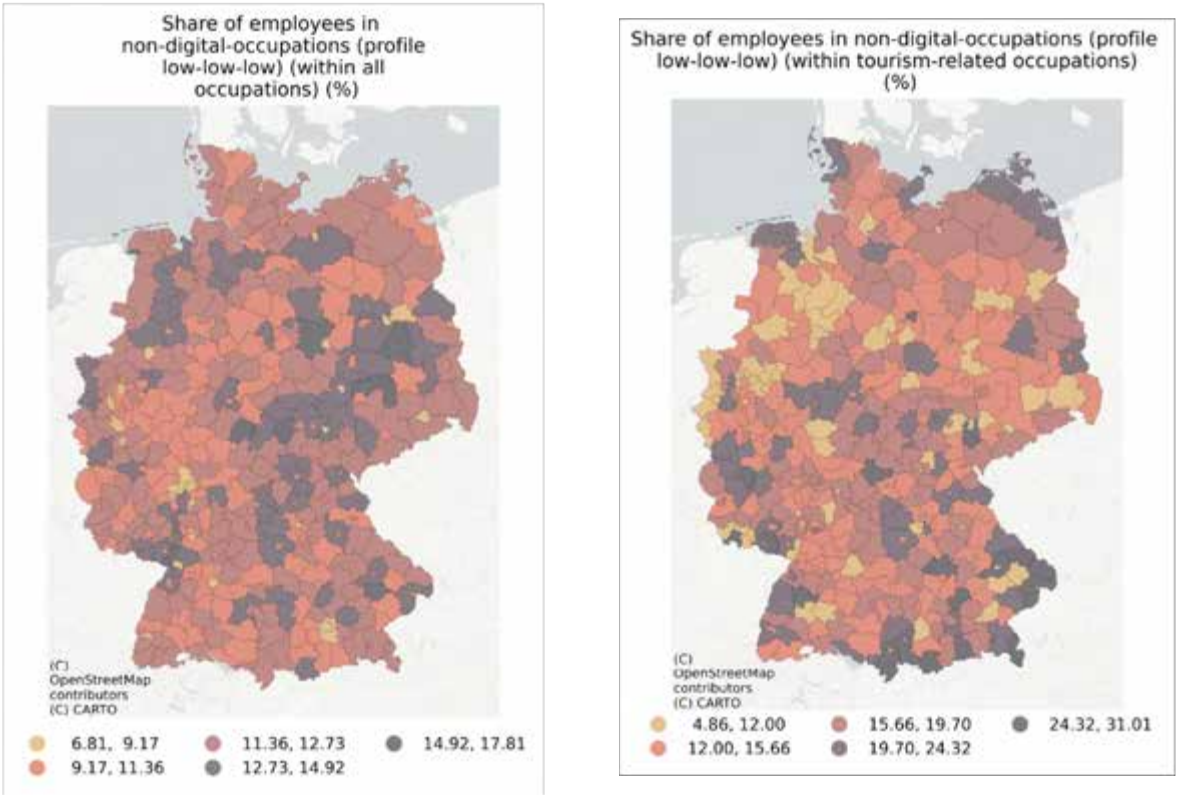

Figure 5. Spatial distribution of the low-low-low group across districts.

At the national level, the high-low-high-group (Figure 6) is the most prevalent, though the overall distribution of categories remains relatively balanced across districts, with some tendencies of urban areas showing lower shares of employees in this category. Within the tourism sector, this category becomes even more dominant. Besides a few exceptions, more than half of the tourism-related workforce has a share of more than 50% within this category, with some regions featuring shares of well above 70%, especially in regions that feature less tourism activity. However, no clear spatial pattern emerges for this category across the country, which suggests that these concentrations reflect local labour market and economic structures rather than broader regional trends or spatial typologies.

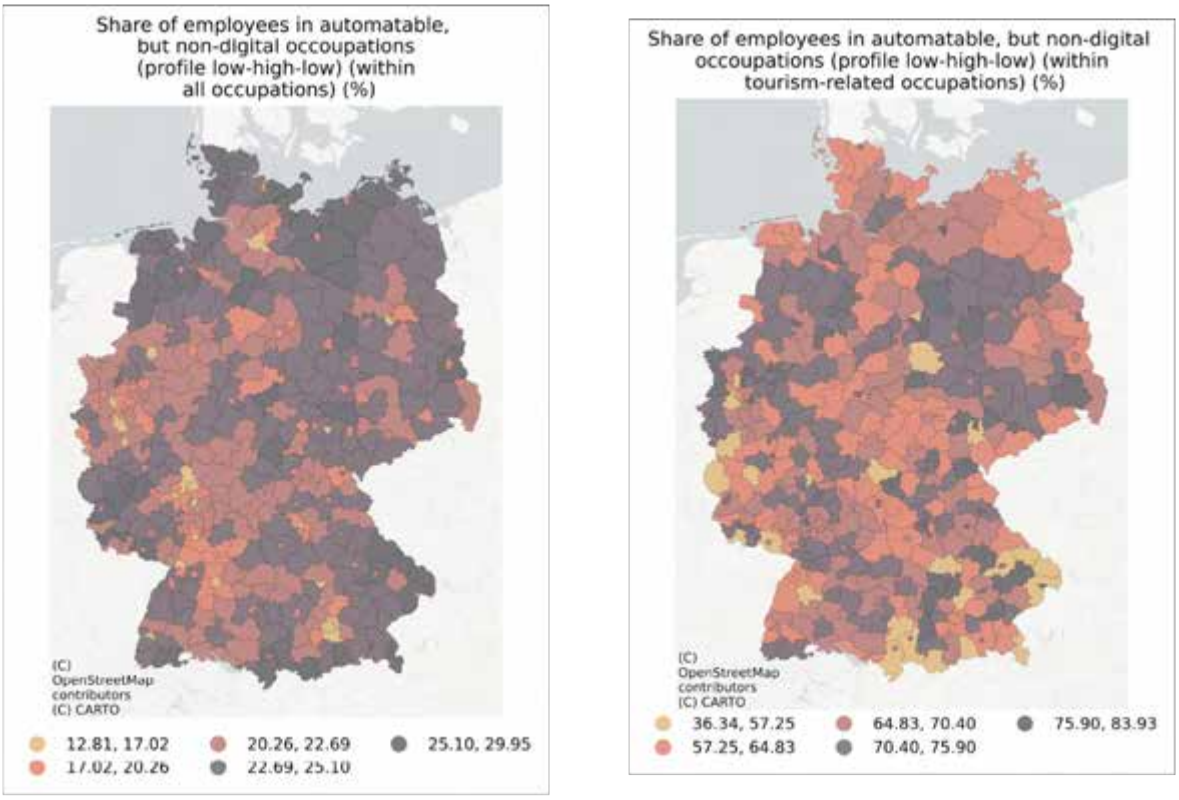

Figure 6. Spatial distribution of the high-low-high group across districts.

Meanwhile, the high-high-high-category (Figure 7) is more concentrated in urban areas, where both general employment and tourism sectors show a stronger presence of digital roles. Although this category is less prominent within tourism occupations compared to the general labour market, the difference is not as clear as with the other two categories. This indicates that digital transformation is affecting some tourism-related roles in a way comparable to broader national trends, particularly in cities.

Overall, the analysis shows that while large parts of the tourism sector remain less digitalised, certain urban areas are seeing a convergence with national trends in digitalisation, particularly in managerial and administrative roles.

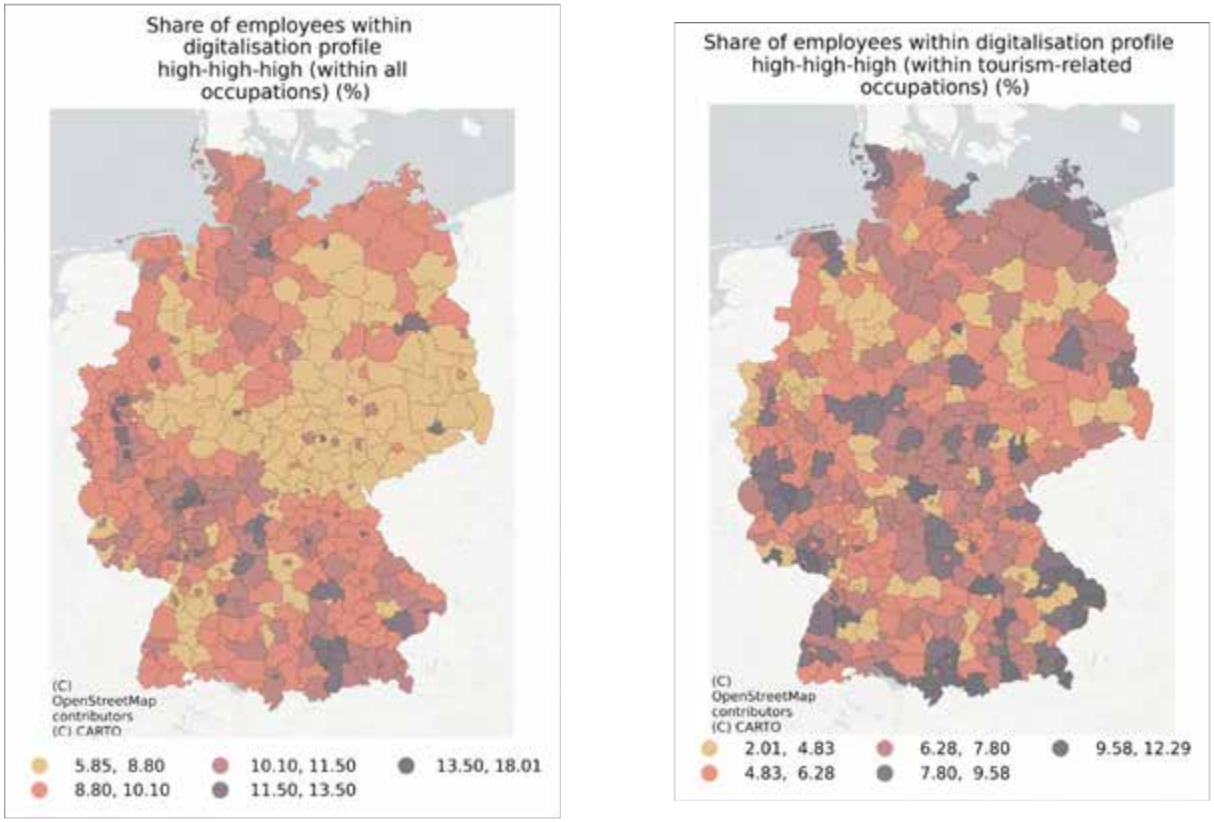

Figure 7. Spatial distribution of the high-high-high group across districts.

3.6. Discussion and outlook

Results of this research show that linking digitalisation indicators to labour market statistics offers a practical way to assess spatial exposure to technological trends. This approach enables a broad, comprehensible overview on both a sectoral (in this case tourism) and spatial level. However, the simplifications involved within this approach come with important limitations that need to be addressed.

The PRoC score, derived from the widely cited "Future of Employment" report, exemplifies both the potential and pitfalls of using quantitative digitalisation indicators. Although this score is useful for identifying technical automation potential, its reliance on expert judgments has been criticised for overestimating susceptibility to automation (Coelli and Borland, 2019; Frey, 2021). The sector of tourism serves as a good example, the occupational group of waiters was assigned a score of 0.94 (meaning high computerisation potential), despite the importance of human interaction in the everyday context (Pancer et al., 2025), which still characterised this occupation. Therefore, the scores presented here should be interpreted with caution, as the highest possible digitalisation potentials technically feasible, without taking the organisational, societal, political or legal context into account.

By incorporating the indicators AIOE and DCI, the composite approach helps to balance some of these overestimations. Nonetheless, each indicator is shaped by the assumptions of its original methodology, and thus still reflects inherent biases. Alternatives such as survey-based data, like PIAAC, can better reflect real-world work contexts, including actual tasks and skills (Georgieff and Hyee, 2021; Nedelkoska and Quintini, 2018). Such survey-based approaches however also come with trade-offs, especially when scaled to broader labour market estimates. Nevertheless, these indicators are only snapshots depicting the current situation and work context and cannot simply be used for future predictions.

For this study, two limitations need to be specifically addressed: the translation across occupational taxonomies and the quality and granularity of available labour market data. Two of the indicators (PRoC and AIOE) originate

from a U.S. classification system, which introduces potential mismatches when mapped to the German context. Though crosswalks and weighted distributions help mitigate this, a one-to-one mapping of occupations is hardly possible. More accurate results could potentially be achieved by either reconstructing the indicators using German-specific task or survey data (Bonin et al., 2015; Coelli and Borland, 2019; Georgieff and Hyee, 2021), or by applying the U.S.-based indicators within their original context. However, the occupational-level linkage of indicators remains robust when comparing the relative scores of occupational groups within a single national context (Bonin et al., 2015; Cserpes, 2024).

Second, Germany's regional labour market data is only available at an aggregated level, especially when conducting analysis related to geography. As a result, regional analyses in this paper offer general trends rather than precise local patterns, and should be interpreted accordingly. Finer-grained insights into regional impacts of digitalisation would require alternative data sources, such as targeted surveys or more qualitative elaboration.

From a territorial perspective, a limitation of this study is linked to the spatial resolution of the analysis in terms of referring to functional spatial realities of tourism areas generally overcoming statistical administrative boundaries and addressing analysis to especially in contexts commuting patterns, inter-municipal networks of tourism supply, or mixed economies (Batista e Silva et al., 2018; Li et al., 2018).

Future research should follow a more integrated spatial approach to tourism labour markets. It should focus on the relationship between local economic structures and digital vulnerability. Incorporating variables such as digital infrastructure, smart tourism investments, and public service quality in touristic areas could help to map a geography of tourism resilience, which would be useful for regional planning and targeted policy-making.

Additionally, the perspective to base the analysis on functional tourism networks that transcend administrative boundaries may un-disclose connections between local tourism supply chains and regional patterns of seasonal workers in tourism sector. This approach would enhance the overall understanding of the spatial logic of tourism employment beyond static territorial units.

Abstract
Humankind is currently living in a hyper-dynamic and constant transforming environment- in the so-called convergence era and 4th industrial revolution. This level of development requires a complexity-led approach and transformations of our political, societal, economic and technological framework: the way we are living and being educated, creating new jobs and generating sustainable growth, providing security, managing hyper mobility, as well as other development aspects related with our living quality and human values. This paper elaborates a specific model named UBT "SMART City" (Small Scale Smart Sustain System) which represents a concept of Entrepreneurial Innovation Ecosystem which could also be used as a Test-Bed for Future and Innovative Urban Planning with a particular focus in education, future planning concepts and emerging technologies.

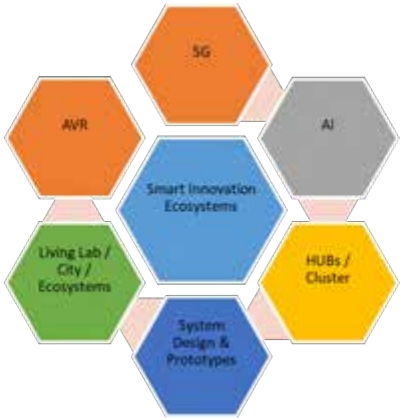
Keywords: *Smart Cities; Emerging Technologies; Transformative Urban Planning; Sustainable Development; Innovation Ecosystem*

Introduction and Background

The fourth industrial revolution is characterized by numerous emerging and disruptive technologies while technology is reshaping business practices, leading to improved market opportunities that also demand education and skills for innovation. AI, for instance, is currently used to fill a growing number of professional positions, and thus, the gig economy is booming. Ajah et al (2019) emphasizes that exponentially growing fourth revolution is characterized by the convergence of technologies that eradicate traditional boundaries across the physical, digital, and biological realms. Despite the fact that there are numerous opinions regarding the actual dates of beginning of the Fourth Industrial Revolution ((Ciulli, 2019) it is widely accepted that the term "Industrie 4.0" was firstly introduced at the Hannover Fair in Germany in 2011, and from this, the term "Industry 4.0" was derived, and it represents the Fourth Industrial Revolution. While the fourth industrial revolution (4IR) is gradually gaining momentum in a wide range- and as it gathers pace, innovations are becoming faster- many believe that the technologies that have been developed recently will allow organizations to enter a new computerized era to manufacture and manage large systems that were too complex to be integrated, monitored, and controlled before the advent of Industry 4.0 (Krajewski et al, 2022)....". On the other hand; since its beginnings UBT has always followed the current technological and socio-economic trends and developments, while in certain situations it has taken the leading roal towards future oriented solutions and forward-looking initiatives. In these terms, UBT now bases its scientific, research, teaching and innovation activities on the UNIVERSITY 4.0 Concept, by integrating Fully Digitalized Research and Education Process, CLASSROOM 3.0, Augmented and Virtual Reality (AVR) and 5G Telecommunication Network in its main Innovative and Scientific Campus in Lipjan/Kosovo and its other campuses and premises around Kosovo. The campus has been designed and developed around the small-scale smart city concept by covering all fields of life occurring in an open campus.

Driven by current technological development, innovative initiatives and its forward-looking vision, UBT has achieved a fully digitalized education and research process, mainly based on Augmented and Virtual Reality (AVR) technology offered by EON REALITY platform. In this regard, our institution has been recently implementing 2 important projects in Virtual and Augmented Reality technology. This platform allows all faculties (both students and staff) to contribute to the simplifying and enriching everyday life in terms of research and study.

UBT Model for Smart Ecosystem University can be illustrated as below:



This model fully integrates the Smart Systems, Resilience and Sustainability also the Society 5.0. Thus, we consider it one of the first small scales Systems Design globally.

In addition to previous initiatives, projects and innovations, UBT has recently established two institutes and laboratories in the fields of Artificial Intelligence and Cyber Security (CERT). This is in line with our strategic orientation and commitment to create and maintain a creative and innovative ecosystem which is based on integrative and transdisciplinary approaches in line with Convergence Revolution. This ecosystem should deliver all required resources to help others to fully realize one's potential- based on belief that human potential is unlimited. An important part on the digital transformation is as well the cyber security issues in the technological infrastructure. Thus, UBT has established the necessary tools, techniques and standards through which we ensure that all the assets including logical and physical are well protected and in compliance with industry standards. In these terms, UBT will focus their cyber crisis management on two main parts, namely Readiness and Response and these are detailly described below.

As per Augmented and Virtual Reality Platform; UBT has been recently implementing 2 milestone projects in Virtual and Augmented Reality technology (Prishtina, XK - EON Reality). This platform allows all faculties (both students and staff) to contribute to the simplifying and enriching everyday life in terms of research and study. Currently, the platform has over 1.8 million 3D, 2D and 360 Degree assets, while up to 40 thausands new assets are being created and added to the platform in each semester. Consequently, the implementation strategy for AVR and the connection of education with the industry occurs as following:

Each faculty contributes to the advancement of ICT in the industry using VR and AR industrial projects. *The Faculty of Management, Business and Economy (MBE), for instance, uses* the assets of this platform to change and transform the Marketing sector in the industry, creating assets for companies to promote their values using virtual interactivity. *The Faculty of Architecture and Spatial Planning* deals with the promotion of Tourism and historical values by turning this industry into VR and AR by digitizing the whole process of tourism promotion and virtual visits in historical sites and monuments. *The Faculty of Mechatronics* helps the manufacturing industry and all robotics industries to animate the work process for employees and management staff so that they can animate any process before starting the investment and as such it ensures time and cost efficiency in each company. *The Faculty of Design* uses VR and AR to help fields like Medicine, Manufacturing Industry, Marketing, Transport etc. on designing different tools and assets for their needs and purposes. *The Faculty of Computer Sciences* uses the VR and AR platform for enabling the creation of interactive games for education as well as enabling the heath

education in the field of medicine.

As per 5G Technology, 5G Hub and Test-bed; among many innovative and future based projects UBT has launched its 5G Hub which will be used for domestic needs (research, testing, experimentation) and also will help the industry to test their products and test them in a technology of the future as there is still no such network in Kosovo.

As per fully digitalization; driven by current technological development, innovative innitiatives and its forward-looking vision, UBT has achieved a fully digitalized education and research process, mainly based on Augmented and Virtual Reality (AVR) technology offered by EON REALITY platform and other supportive tools. The new digital forms enable students to access lectures 24/7 giving them the opportunity to study according to the schedule that was adjusted. Also through digital platforms students will have the opportunity to access new technologies through which they will receive faster information about national and global scientific developments in various scientific fields. The use of digital transformation will have a singular impact in improved accessibility and access, personalized learning approaches, access to Augmented Reality & Virtual Reality, Cloud-based learning opportunities, Incorporating the Internet of Things into the school environment, Security across digital devices, Big Data etc. Additionally to other initiatives and innovations that are presented previously, UBT has established two institutes and laboratories in the fields of Artificial Intelligence and Cyber Security System, which lays on Institution's CERT (Computer Emergency Response Team). Furtherly, UBT has recently established UBT VR/AVR Hub, UBT Knowledge Hub, as well as Sports, E-Sport & Art Hub. All of these developments and concrete actions are in line with Institution's strategic orientation and commitment to create and maintain a creative and innovative ecosystem which is based on integrative and transdisciplinary approaches in line with Convergence Revolution. This ecosystem should deliver all required resources to help others to fully realize one's potential- based on belief that human potential is unlimited, and thus is also in line with Institution's commitment to implement the 4th Industrialization advancements continually and with consistency.

Artificial Intelligence (AI) and Cyber Security System (CERT)
Both the institute and center aim to contribute to society as well as help the government, the army, the police and many other stakeholders. The institute that carries with it the laboratory of artificial intelligence with a data center with a supercomputer will be able to help many fields and faculties abroad, as described below:

The Faculty of Management, Business and Economy (MBE) will use the possibility of supercomputers for Business to enable banks and institutions to increase the quality of services by making predictions for the future thanks to artificial intelligence and supercomputers with their data. Also, the institute for security will enable all government institutions to increase the cyber security capacities of this institute and also to do the necessary tests in the CERT laboratory. *The Faculty of Architecture and Spatial Planning* will be supported through artificial intelligence to create the possibility for drones to take 3D images in real time and process those images for various purposes in the industry of virtual reality design, animations, etc. *The Faculty of Mechatronics* will use artificial intelligence in many fields and the testing of production machines in our laboratories, also supercomputers are used for testing algorithms for the image process in intelligent drones, and many new industries that use AI etc. *The Faculty of Computer Sciences* may use supercomputers for testing algorithms in various fields in medicine, the automotive industry, and all fields related to artificial intelligence. *The Faculty of Agriculture will* use supercomputers and artificial intelligence to calculate changes in drone scanning of the fertile area and the possibility for scientific research in the field of agriculture.

When it is combined with previously promoted initiatives and innovations, as such as UNIVERSITY 4.0 Concept, Fully Digitalized Research and Education Process, CLASSROOM 3.0, Augmented and Virtual Reality (AVR) and 5G Telecommunication Network, it will let our institution to further develop its research infrastructure in order to get research and its outputs more easy, fast, effective and more visible.

UBT VR/AVR Hub

Even though VR and AR are still largely in the developmental stage, these concepts are no longer science fiction. Considering the pace of the technological development, as well as consumer and industry demands, researchers have put an emphasis on producing technology through which we solve problems and interact with our world. From UBT's point of view, hosting the EON-XR Cluster Center and bringing EON-XR to campus comes with the opportunity to distinguish even further. By utilizing the interconnected self-service platform and the **Classroom 3.0 Model**, the world-class school is able to improve the interactivity and retention in lessons while also preparing students for the future by teaching them the technology that many leading industries and businesses are already using.

UBT Sports, E-Sport & Art Hub

UBT Sports, E-Sport & Art Hub is the newest center for the development of young talents in the field of sports and movement sciences. Through this center, young people have the opportunity to gain new knowledge in the field of sports and movement sciences, from the expertise of professional staff and to further develop their sports skills and talents. Among others, it integrates digital tools, software, and advanced technologies and application to help smart sport health managements, performance measurement and tracking, as well as managing the healthy nutrition processes.

Readiness and Response

UBT has established the necessary tools, techniques and standards through which we ensure that all the assets including logical and physical are well protected and in compliance with industry standards. In these terms, UBT will focus their cyber crisis management on two main parts, namely Readiness and Response, Readiness equates not only to vigilance, for example in the form of 24/7 Monitoring, but also to readiness of resources. A well prepared, multifunctional team will be poised to deal with all aspects of an incident or crisis. In addition, crisis simulation and war gaming enable management to understand what can happen, which steps to take, and whether the organization is truly prepared. On the other hand; Management's response can either contain or escalate an incident; indeed, a poor response can even create a crisis. Vigorous, coordinated responses to incidents limit lost time, money, and customers, as well as damage to reputation and the costs of recovery. Management must be prepared to communicate, as needed, across all media, including social media, in ways that assure stakeholders that the organization's response is equal to the situation.

Human Capital and Financial Resources

All given projects, initiatives and platforms require well prepared and professional staff/human and professional capital to maintain them and to assure that all services are being provided to people using them. UBT is able to cover, and is covering, all human requirements needed. These professionals are in charge to lead initiatives, projects, institutes, labs, centers and platforms, as well as to deliver tasks properly and to put other human resources in place whenever and wherever is needed. Furtherly, establishing and maintaining these structures, as well as assuring a proper service delivery of them require certain financial investments and maintain costs. However, based on its commitment to fully and effectively fulfill its 3rd mission towards society, UBT is also committed to, and is currently covering the all costs related to given structures. In parallel, AVR Platform is established and thus financed in partnership with EON Reality. When it comes to technological aspects of advanced smart applications, all Software, Online Platforms, Test Beds, Web-pages, PC Labs, Virtual Reality System tools and equipment, co-working areas, conference rooms, visualization and marketing means needed for the given structures are operating and being managed by UBT. The institution is covering all costs as an expression of commitment to fulfill its 3rd Mission in a fully and effective way.

1. Theoretical and Conceptual Framework of Smart Cities and Smart Development

By 2050, it is estimated that roughly 70% of the world's population will live in cities. With more citizens to serve, and a climate that is rapidly degrading, public service efficiency and effective resource-usage are becoming pressing issues for cities. In this context, ensuring sustainable development and quality of life in complex social ecosystems of cities and urban areas are important concerns. Cities are increasingly aware of the concept of "smart city" and are actively developing strategies towards the goal of becoming "smart" and manage city resources more efficiently while addressing development and inclusion challenges. To understand the concept of smart city, we begin with understanding the conceptual relatives of the model. Although limited in scope, they set the theoretical framework for the holistic notion of the smart city currently understood by the urban planning sphere. The notion of smart city is established from the combination of the knowledge society and digital city. It is defined as a "multi-layer territorial system of innovation" made up of digital networks, individual intellectual capital, and the social capital of the city, which together constitute collective intelligence (Komninos, 2008). Economic competitiveness and innovation achieved through the knowledge-based economy marks a city as intelligent, allowing it to generate a "spatial competitive advantage" through industrial districts, regions, and learning clusters that produce sophisticated R&D and are supported by digital networks and artificial intelligence (Komninos 2008). Based on the exploration of a wide and extensive array of literature from various disciplinary areas, the identified factors– Social, Management, Economy, Environment, Technology, Sustainability, (SMEETS) forms the basis of an integrative framework. This comprehensiveness is the distinguishing factor of the smart city, which integrates a number of physical, institutional, and digital components to create a holistic definition of what smart planning would look like.

1.1. Pillars of Smart City

At its core, a smart city framework leverages from the existing legal, economic and technical environment and impacts the social and management aspects in a sustainable manner[1]. Setting a smart municipality vision and effectively moving towards it with a systems-based approach is imperative to ensure optimum resource efficiency and security, along with preserving socially inclusive growth. Thus, the 5 pillars or factors of Smart Municipality are: (1) Smart Governance (Management), (2) Smart Public Infrastructure Services (3) Smart Transportation (4) Smart Economy, (5) Smart Environment, (6) Smart People & Smart Living.

Smart Governance[2]: "Smart Government" is about strengthening the connections and interactions between the government and all stakeholders - citizens, businesses and other organizations of the civil society - within a municipality. A municipal government following a smart city strategy is uniquely positioned to reconsider the quality, scale, and scope of services for citizens and businesses that it offers. Following a "city as a service" model can help to increase efficiency and effectiveness as well as transparency and trust. In this regard, smart public services, also known as digital public services or eGovernment, refer to the use of technology to provide services to citizens at local, regional and national levels. They bring many opportunities to both citizens and businesses: students can apply to study abroad, citizens can open bank accounts online, and workers can file taxes with the click of a button.

Smart Water Management: In simplest of words, a **smart water management system** is a concept that utilizes electronic and computerized engineering to increase information collection and analytics. Bigdata acquired from the system is used to maintain practical choices and upsurge the competence of water reserves[3]. As same as other smart infrastructure systems, Smart Water Management (SWM) uses Information and Communication

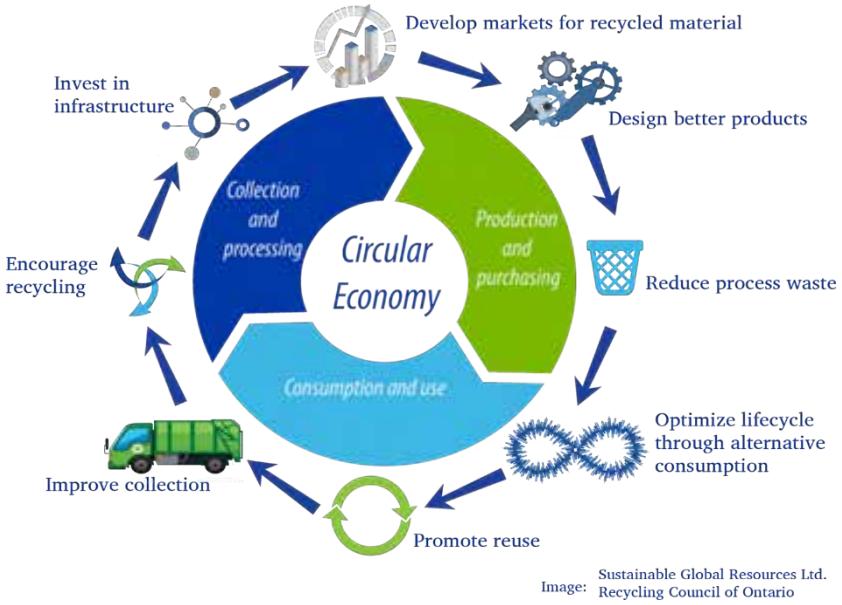
1 Moosavi, M.S., 2018. The Smart City; Challenges and Opportunities in Developing Countries. Iranian Online Journal of Urban Research, 3(1), pp.1-5.

2 The text used in this chapter is mainly based on two following sources: Smart City Indicators: Six Fields of Action for Success (beesmart.city) and Digital public services | Shaping Europe's digital future (europa.eu).

3 Smart Water Management: What You Need To Know | RPMANetworks

Technology (ICT) and real-time data and responses as an integral part of the solution for water management challenges. The potential application of smart systems in water management is wide and includes solutions for water quality, water quantity, efficient irrigation, leaks, pressure and flow, floods, droughts and much more. By applying SWM infrastructure such as sensors, smart meters, monitors, GIS and satellite mapping, and other data sharing tools to water management, real-time solutions can be implemented and broader networks can work together to reduce current water management challenges.

Smart Waste Management System[4] and Circual Economy[5]: Smart Waste Management (SWM) discusses the waste management process for different types of waste while introducing an intelligent approach to controlling the amount of waste. Thus; A smart waste management system, as a component of a broader "Smart Environment" initiative, should effectively integrate technology, data collection, and sustainable practices to optimize waste handling and enhance urban livability. This system is based on the following pillars: Advanced Data Collection; Automated and Optimized Routing; Recycling and Waste Segregation; Public Engagement and Education; Energy Recovery and Waste-to-Energy Solutions; Regulatory Compliance and Reporting. By implementing these features, municipalities can create a smart waste management system that not only efficiently manages urban waste but also contributes to the overall sustainability and resilience of the community, reducing environmental impact and improving the quality of life for all citizens. On the other hand; the **Circular Economy[6][7]** is a sustainable development strategy that aims to redefine growth, focusing on positive society-wide benefits. It entails gradually decoupling economic activity from the consumption of finite resources, and designing waste out of the system. Unlike a traditional linear economy, which has a 'take, make, dispose' model of production, a circular economy is based on three core principles: design out waste and pollution, keep products and materials in use, and regenerate natural systems. In a circular economy, the lifecycle of materials is maximized, meaning that products are designed and optimized for a cycle of disassembly and reuse. This systemic shift keeps resources in use for as long as possible, extracts the maximum value from them whilst in use, and then recovers and regenerates products and materials at the end of each service life.



The role of Industry 4.0 (I4.0) on 3Rs (Reduce, Reuse and Recycle)

4 https://www.sciencedirect.com/science/article/pii/S0956053X23005573
5 https://climatepromise.undp.org/news-and-stories/what-is-circular-economy-and-how-it-helps-fight-climate-change
6 https://www.researchgate.net/publication/306924920_Smart_Economy_in_Smart_Cities
7 https://www.oecd.org/cfe/regionaldevelopment/Ekins-2019-Circular-Economy-What-Why-How-Where.pdf

The role of Industry 4.0 (I4.0) technologies, particularly the Internet of Things (IoT), in waste management emphasizes enhancing the Reduce, Reuse, and Recycle (3Rs) approaches through advanced digital solutions.

Reduce: IoT technologies are instrumental in reducing waste by enhancing resource efficiency in various sectors. For instance, IoT-enabled smart fridge architectures help minimize food waste by monitoring expiry dates and consumption patterns, thus prompting more mindful consumption and purchase decisions.

Reuse and Repurpose: IoT also facilitates the reuse and repurposing of materials. Innovative uses of IoT include transforming agricultural waste into valuable products like compost or liquid fertilizer through smart processing technologies. Digital platforms can connect local retailers to promote the reuse of food products that might otherwise go to waste, exemplifying how IoT aids in creating circular economies at local scales.

Recycle: In terms of recycling, IoT enhances the efficiency and effectiveness of waste management systems. Smart bins equipped with sensors can classify waste more accurately, which improves recycling rates. Technologies like blockchain and AI integrated with IoT further refine the recycling process by automating sorting and enhancing the traceability of waste materials. This technological integration ensures that waste is handled more efficiently, reducing contamination and improving recycling outcomes.

Smart Energy Management[8]*: With the growth in world's population and the increasing global demand for energy, one of the greatest challenges of humanity is to ensure the balance between the environment and energy. As a result, using fossil fuels is no longer an alternative neither in terms of environmental protection nor in the construction of smart cities, so a handy solution to meet the energy demand is to use renewable resources such as solar, wind, hydropower and biofuels. Furtherly; all 6 of the main variables of Smart Municipalities need energy in different forms and modes, making it the key to sustainable development. Smart Energy involves more professional approaches that focus on adopting solutions based on an integrated approach to energy issues as crucial aspects in the sustainable development. Thus; Smart Energy Management (SEM) systems are crucial in optimizing energy use, enhancing sustainability, and reducing costs. These systems utilize Internet of Things (IoT) technologies to monitor and control the energy consumption of buildings and homes in real-time. For example, the Honeywell Building Management Systems offer solutions that integrate energy measurement tools with automated controls to enhance energy efficiency across various facilities*[9]*.*

Smart Mobility: Smart Mobility focuses on increasing the efficiency and service quality of urban transportation to enhance the use and adoption of new mobility solutions as well as to increase people mobility through efficient mobility management and targeted infrastructure investments. It also means achieving cheaper, faster, and environmentally friendly mobility as well as integrated multi-modal transportation.[10] Smart Mobility leverages the available technologies to gather and provide information to users, planners and transport managers, allowing the reshaping of urban mobility patterns, of planning mechanisms and the enhancement of multimodality by improving the coordination and integration of different transportation modes. **Intelligent Transportation System (ITS)** is often related to smart transportation. An intelligent transportation system is a technology, application or platform, that improves the quality of transportation or achieves other outcomes based on applications that monitor, manage or enhance transportation systems. Intelligent Transportation System relies heavily on data collection and its analysis.[11] Once the system is built to collect data and analyze it, the results are then used

Smart Mobility: The Main Drivers for Increasing the Intelligence of Urban Mobility. Sustainability. 2020; 12(24):10675. https://doi.org/10.3390/su122410675

11 https://www.aindralabs.com/what-is-intelligent-transportation-system-its-applications-and-examples/

control, manage and plan transportation. Sensors play an important role in data collection. Since there is an inseparable conceptual bond between Sustainable Transportation Systems and Smart Transportation, below are mentioned various components of Sustainable Transportation Systems that work together to reduce environmental impacts, enhance mobility, and improve the quality of life: **Accessibility**; **Park and Ride Integrated Multi-Modal Transport Systems; Green Vehicles**; **EcoMobility; Organic Transportation etc.**

Smart Cultural Heritage Management

Vattano (2014) asserts that the integration of a city's historical elements into its modern reality is a significant factor towards the advancement of its urban intelligence. The specific benefits of including cultural heritage in smart initiatives derive from big data management and augmented reality (AR). Big data management allow to store and administer great amounts of data, beneficial for the preservation of cultural heritage, and the sustainable monitoring of its life cycle conservation[12]. Meanwhile, optimizing technological use in cultural heritage management leads to cost reduction in terms of maintenance. Further, Municipalities through smart initiatives could advance cultural heritage ontologies with AR characteristics allowing both citizens and visitors to readily access their historical value. **There are two main tools municipalities can use for Smart Cultural Heritage Management**, namely a) **Digital Interactive Map of Cultural Heritage and b) Virtual Museums.**

Digital Interactive Map of Cultural Heritage is another important tool of smart management of cultural heritage. It is a web application that combines online maps, digital archives and multimedia. This map focuses on research, digital preservation and visualization of cultural heritage, both tangible and intangible. It aims at allowing users to explore and better understand cultural heritage. Provides an opportunity for citizens to interact with cultural heritage in an easily accessible and stimulating format, while also enabling spatial analysis related to cultural heritage. This map also enables data collection and analysis of the spatial distribution of cultural heritage- both tangible and intangible in the territory of municipality.

On the other hand; **Virtual Museum** is among the main tools that Municipalities can use in their way of adopting smart management system approaches towards their heritage. It is a digital entity that draws on the characteristics of a museum, in order to complement, enhance, or augment the museum experience through personalization, interactivity and richness of content[13]. It's a collection of digitally recorded images, sound files, text documents, and other data of historical, scientific, or cultural interest that are accessed through electronic media[14]. The goal of the virtual museum is not to compete with or replace traditional museum visits, but to enhance, complement, and augment the museum experience by offering a level of personalization, interactivity, and richness of content that is impossible to bring in the real world. Thus, they need to be seen as a coequal to traditional museums[15].

Smart Economy

Smart economy is an economy that is based on technological innovation, resource efficiency, sustainability and high social welfare as engines for success. It adopts innovation, new entrepreneurial initiatives, increases productivity and competitiveness with the overall goal of improving the quality of life of all citizens[16]. Smart economy is expected to generate more products and services with less energy and pollution, and create social benefits. Smart economy should result from improvement of education and promotion of innovation[17]. **Smart**

17 Digital Social Innovation for Better Connected Government: The Case of Republic of Macedonia: Government & Law Book Chapter | IGI Global (igi-global.com)

Economy describes all actions aimed at transforming and strengthening a city's economy, including improving the overall business climate, a city's attractiveness for start-ups, investors, businesses, and new (highly qualified) talent as well as growing the economy in an innovative and sustainable way to increase competitiveness. To achieve the desired objectives of Smart Economy, cities should focus on the following areas[18]:

AREA 1: Entrepreneurship | Productivity | Competitiveness: urban organization that fosters new entrepreneurial initiatives, an increase of competitiveness and high productivity in communities with the aim of improving the quality of life. In these terms, a smart municipality highly values creativity and welcomes new ideas, as well as enlightens entrepreneurial leadership.

AREA 2: R & D | Urban Labs: offer a solution which can be adopted by other universities or cities, and thus obtain a return on investment (ROI are its acronym in English) through the creation of innovative services and urban laboratories. In these terms, municipalities should be driven by innovation and supported by universities that focus on cutting-edge research, not only for science, industry, and business but also for cultural heritage, architecture, planning, development, and the like.

AREA 3: Tourist attraction and internationalization: Brandings which will provide a national and international perspective for the tourist promotion both social and economic. In these terms, a smart city is a destination that people want to visit (tourism).

AREA 4: Trainings and Life Long Learning | Smart Labor Force involves multiple components aimed at enhancing community engagement, personal development, and career progression through innovative educational technologies and customized training programs. These include actively assessing community training needs, integrating advanced educational tools such as AI and VR, and creating age-appropriate, inclusive learning modules for all demographics. Additionally, developing partnerships with industry ensures the relevance of training programs and provides practical experience, while strategies for attracting and developing local talent contribute to the region's attractiveness as a business location.

AREA 5: Smart Industry | Industry 4.0 or commonly known as the industrial internet of things (IIoT), describes the application of internet of things technologies in industrial processes and manufacturing. By implementing solutions/ concepts related to big data, machine learning, digital twin, artificial intelligence, predictive analytics etc., manufacturers aim to achieve the optimal level of responsiveness, adaptiveness and fully connected processes of a smart factory.

AREA 6: Smart Work Management | as per private sector, Smart Working means a new flexible working method. It is a new way of approaching work that gets rid of inflexibility and predetermined patterns in favor of focusing on what is relevant: ideas, projects and people.

Smart Environment

Smart Environment uses data collection from utility networks, users, and air, water, and other city resources in order to establish main areas of action in urban planning and city infrastructure planning as well as to inform urban services managers to achieve a more efficient and sustainable urban environment while improving the citizens' quality of life. The sustainable and smart territory leads reflections on the use and production of green and renewable energies, on more sustainable methods of food production or on the use of new technologies in order to optimize the management of resources (energy, air, water, waste, etc.). Urban agriculture, for example, is at the crossroads of these major issues. Thus, water management, waste management, emission reduction and smart air pollution monitoring are among topics to be considered in this context.

18 Smart Economy: Economía Inteligente. UA Smart University

Smart Air Pollution Monitoring
Smart Air Pollution Monitoring is a very important component of Smart Environment. Smarter Technologies' smart air quality monitoring solution is able to detect carbon dioxide levels, noxious gases and pollutants, sending real-time data to a central management dashboard. It provides enhanced visibility, improved situational awareness and earlier indications of pollution hotspots. The prime objective is to provide cost-effective access to air quality data to every citizen of the city, integrated with an accountable solution-mapping ability. Power and communication will lay the foundation of the monitoring network. The citizens of a smart city shall remain informed and engaged about the air quality via a dense network of monitors lodged with high-efficiency micro-sensors. A centralized dashboard will make this data extremely accessible.

3. UBT "SMART City" Overview / Transformative Planning Principles and Spatial Systems adopted by UBT Campuses

We are living in the times of convergence revolution which represents a very highly dynamic and complex environment. This dramatic transformation including using AI and other advanced technologies creates opportunities, but also new requirements for new competencies and skills. Traditional education is not enough today to provide the required future skills including skills adaptability, problem-solving, and collaboration. This requires a new solution for education, with highly complex and very dynamic-oriented models and systems. To support this causa, UBT – University for Business and Technology has created its model called UBT 5S – Small Scale Smart Selfsustained System or short UBT Smart City.UBT Smart City represents now an Entrepreneurial Smart and Sustainable Innovation Ecosystem. This model represents a dynamic complex system and is created to be used as a test bad system for smart and self-sustained solutions for education, innovation, and development. Made from different components for life and different technologies UBT Smart City creates a great opportunity to use Advanced and Innovation Technologies for Education, Training, Research and Development. Cases of using AI and XR Technologies in Education and their Impacts are presented to see the opportunities which is provided by UBT Smart City Ecosystem (Classroom 4.0). Classroom 4.0 provides many benefits, including an AI-powered immersive learning platform, the ability to quickly create courses for new types of job skills, cost-effectiveness, flexibility, real-time updates, accessibility, and inclusive retraining opportunities.

To support its mission of advancing and fully implementing smart systems in its everyday activities and processes, UBT has developed its Institutional Strategy and Action Plan for Green, Carbon-Neutral and Smart Campus. The Strategy and Action Plan focuses on nine key Initiatives, namely: Clean Energy, Building green, Getting around, Sustainable water management, Good food, Zero plastics, Smart technologies, Sustainable landscape, and Print responsibly. The given Initiatives-directly linked with certain SDGs- and related actions & project are briefly summarized below:

Clean Energy / Switch to Renewables: We'll transition to clean energy sources, reduce the campus's carbon footprint, and support sustainability by conducting an energy audit, installing solar panels, encouraging energy conservation, and exploring other renewable options.

Building Green/Green Building: Sustainable construction and ongoing green practices will reduce environmental impact and ensure long-term eco-friendliness through sustainable design, eco-friendly materials, energy-efficient systems, renewable energy integration, and ongoing maintenance.

Getting Around / Biking and Walking: Promoting non-motorized transportation options will reduce carbon emissions and foster a healthier lifestyle by developing a campus Master Plan, installing bike racks, implementing a bike share program, promoting biking and walking events, and integrating with public transport.

Never Waste a Drop / Sustainable Water Management: Efficient use, conservation, and recycling of water resources will conserve water, reduce costs, and minimize environmental impact through water audits, water-efficient fixtures, rainwater harvesting, improved irrigation practices, and community engagement.

Good Food, Healthy Planet / Zero Food Waste Campus: Sustainable food practices and reducing food waste will contribute to a healthier environment and carbon neutrality by implementing a sustainable sourcing policy, portion control, food recovery programs, composting, community education, and monitoring food waste.

Zero Plastics, Zero Waste/Single-Use Plastic Free Campus and Minimization of Disposable Items: Eliminating single-use plastics and minimizing waste generation will promote sustainability and environmental friendliness through a ban on single-use plastics, reusable items promotion, recycling and composting stations, waste reduction programs, and community education.

Adopting Smart Technologies/AVR: Integration of smart technologies will enhance efficiency, sustainability, and learning experiences by integrating smart building systems, incorporating AVR technologies, implementing IoT solutions, promoting remote learning, and developing smart campus initiatives.

Sustainable Landscape / Open and Green Areas: Creating and maintaining sustainable outdoor spaces will enhance the quality of life and promote biodiversity by using native plants, implementing water-efficient irrigation systems, creating multi-functional spaces, and engaging the community.

Print Responsibly/Save the Planet: Reducing paper consumption and minimizing the environmental impact of printing will conserve resources and promote sustainability through a print management system, digital document management, recycled paper and eco-friendly inks, a paperless initiative, and community education.

3.1. Embedded Emerging Technologies

UBT has embraced the **UNIVERSITY 4.0 Concept** as the foundation for its scientific, research, teaching, and innovation endeavors. This concept is actively implemented through a **Fully Digitalized Research and Education Process**, **CLASSROOM 3.0**, **Augmented and Virtual Reality (AVR)**, and the integration of a **5G Telecommunication Network**. These technologies are embedded within UBT's **Innovative and Scientific Campus in Lipjan/Kosovo**, as well as across its other campuses and facilities throughout the country. The campus itself is designed around the **small-scale smart city** concept, encompassing all spheres of life in an open and interactive environment. Fueled by technological advancements, innovative vision, and ongoing strategic initiatives, UBT has successfully transitioned to a **fully digitalized educational and research model**, prominently utilizing AVR technologies powered by the **EON Reality platform**. In this context, UBT is currently implementing **two major projects** centered on Virtual and Augmented Reality. The platform empowers both faculty and students across all disciplines to contribute toward simplifying and enriching everyday academic and research experiences.

The **UBT Smart Ecosystem University Model** integrates core principles of **Smart Systems, Resilience, Sustainability**, and **Society 5.0**, making it a globally relevant example of small-scale systems design. In alignment with its strategic direction and past achievements, UBT has recently established two pioneering institutes and laboratories in the fields of **Artificial Intelligence (AI)** and **Cybersecurity (CERT)**. These institutions reflect UBT's mission to foster an **integrative, creative, and transdisciplinary innovation ecosystem**, consistent with the **Convergence Revolution**. This environment is designed to unlock human potential—anchored in the belief that such potential is limitless. Moreover, cybersecurity plays a critical role in UBT's digital transformation agenda. The institution has established comprehensive **cybersecurity standards, tools, and protocols** to protect both digital and physical assets, in full compliance with international norms. UBT's **Cyber Crisis Management** approach is structured around two key components: **Readiness** and **Response**, both of which are outlined in detail.

Augmented and Virtual Reality (AVR) Platform: UBT is currently implementing two strategic projects focused on Virtual and Augmented Reality technologies in cooperation with **EON Reality (Prishtina, XK)**. This platform allows every faculty—students and staff alike—to actively develop, share, and apply educational and research-based content. Currently, the platform hosts over **1.8 million digital assets (2D, 3D, and 360°)**, with **approximately 40,000 new assets** added each semester.

5G Technology: UBT 5G Hub and Test-bed: UBT has launched a cutting-edge **5G Hub**, serving both internal (academic/research) and external (industrial) needs. As Kosovo currently lacks a 5G infrastructure, this hub is critical for future-oriented experimentation. Key capabilities include:

- Testing integration from **4G to 5G** networks for Internet Service Providers.
- Exploring **real-time communication** for **autonomous vehicles**.
- Facilitating **telemedicine** and **remote surgical simulations**.
- Testing **smart city solutions** for municipalities before full-scale implementation.
- Enhancing public/private transport systems through digital communication tools.
- Supporting **crisis communication networks** for national emergencies (medical, military, law enforcement, government, and media).
- Boosting service delivery by **centralizing servers** (Google, Facebook, Microsoft, etc.) and improving access speed by up to **300%**.

Fully Digitalized Education and Research: UBT's digitalization efforts, led by innovations such as AVR and supported by other smart technologies, have created a seamless 24/7 learning environment. Students benefit from real-time access to global scientific content, flexible study schedules, and personalized learning paths. This digital transformation enhances Accessibility and inclusion, Custom-tailored education**,** Access to AVR content**,** Cloud-based learning platforms**,** Internet of Things integration**,** Secure digital infrastructure, Big data analytics.

Strategic Institutes and Labs: In addition to previously outlined innovations, UBT has established the following hubs and institutes **Artificial Intelligence Institute and Laboratory; Cyber Security CERT Lab; UBT VR/AVR Hub; UBT Knowledge Hub; UBT Sports, E-Sports & Arts Hub.**

These are designed to reinforce UBT's commitment to the **4th Industrial Revolution** and the broader **Convergence Revolution**—enabling cross-sectoral, creative, and knowledge-based ecosystems for innovation.

Artificial Intelligence (AI) and Cybersecurity (CERT): These centers support both public and private stakeholders, including government bodies, military, and academia. Notable applications include:

- **Faculty of MBE**: Utilizes supercomputing for forecasting and service enhancement in the banking and finance sector; supports national cybersecurity efforts via the CERT lab.
- **Faculty of Architecture and Spatial Planning**: Leverages AI and drones for real-time 3D mapping and VR animation design.
- **Faculty of Mechatronics**: Applies AI to robotics, machine learning, and intelligent drone algorithm testing.
- **Faculty of Computer Science**: Develops AI applications for medicine, automotive, and technology sectors.
- **Faculty of Agriculture**: Uses AI and drones for soil fertility mapping and agricultural research.
- **UBT Stats Office**: Employs AI to refine and interpret large datasets for informed decision-making.

UBT VR/AVR Hub: Although still an emerging technology, VR and AR are no longer futuristic concepts. They are being actively used at UBT to solve practical problems and enhance interaction with the real world. As one of

EON Reality's top international centers, UBT has produced over **20,000 AVR lessons** across **20 different academic programs**, many of which are now part of featured global curricula.

This comprehensive approach underscores UBT's leadership in higher education digitalization and innovation—not only in the Western Balkans but also across Europe—further solidifying its role as a model for the Smart Ecosystem University of the future.

4. Challenges, Opportunities, and Transferability

Despite the integrative strengths of the UBT campus model, several challenges must be addressed to ensure long-term success and replicability. First; the **management of systemic complexity** poses difficulties in coordinating cross-domain data streams, infrastructure components, and stakeholder engagement. As Batty (2013) notes, cities—and by extension, campuses—are complex adaptive systems requiring non-linear and iterative governance models. Second; the governance of data, including issues of privacy, security, and interoperability, remains a significant barrier to fully operationalizing smart infrastructure (Kitchin, 2014). The challenge of **scaling** pilot innovations and interventions to whole campus area or regional implementation (always considering community's needs and expectations) requires institutional readiness, funding continuity, and administrative integration (Evans et al., 2019). Third; **digital inclusion** emerges as a critical issue, as emphasized by van Dijk (2020), since the benefits of smart systems must be equitably distributed among all campus users to avoid reinforcing socio-digital divides. Conversely, the UBT model presents valuable **opportunities** for innovation and policy learning. University campuses serve as ideal sites for **experimentation in urban resilience**, where modular, adaptive, and data-informed planning can be deployed and transferred (Karvonen, Evans & van Heur, 2014). The cross-sectoral nature of UBT's projects—engaging public institutions, tech providers, businesses, civil society, and local communities—supports collaborative innovation ecosystems, as core component of the process. Furthermore, the campus functions as a real-world interface for **policy prototyping**, facilitating agile testing of regulatory and planning frameworks in energy, mobility, and land-use systems.

Regarding **transferability**, the UBT framework offers a model adaptable to both local and global contexts. Its emphasis on tactical urbanism, integrated land-use, and community participation (although limited only to university community) aligns with principles of New Urban Agenda (UN-Habitat, 2016) and the EU's mission on Climate-Neutral and Smart Cities (European Commission, 2020). Thus, it is to emphasize that such university-based innovation ecosystems can be instrumental in supporting **institutional policy making in smart concepts and innovation strategies**, providing a scalable pathway for transitioning toward sustainable and inclusive urban futures.

5. Conclusion and Future Outlook

The UBT "SMART City" model represents a pioneering approach in integrating adaptive urbanism, circular economy principles, and smart infrastructure systems into a cohesive spatial and institutional ecosystem. As a transformative model, it redefines the role of university campuses from static educational environments to regenerative urban microcosms capable of responding dynamically to environmental, technological, and social shifts. Through its adoption of dynamic land-use modeling (Batty, 2009; Waddell, 2002), UBT has created a campus framework that enables continuous spatial adaptability and responsiveness to emerging demands, aligning with long-term sustainability goals. One of the key contributions of the UBT model lies in its operationalization of circular economy principles across campus infrastructures, drawing on theories of closed-loop systems to reduce waste and enhance resource efficiency (Ellen MacArthur Foundation, 2015). This has been translated into concrete actions in energy, water, food, waste, and material management, fostering synergies between environmental sustainability and everyday campus operations. Moreover, smart infrastructure deployments—including IoT-based environmental monitoring, smart building management, and integrated mobility systems—illustrate how technology can enhance campus resilience, optimize resource flows, and improve quality of life for all users (Batty et al., 2012; Neirotti et al., 2014). For planners, the UBT model offers a practical demonstration of multi-

functionality and scalability in spatial systems. By designing hybrid-use environments that support education, housing, innovation, and public interaction, the campus becomes a living lab for spatial experimentation and an ideal ground for testing forward-looking planning strategies (Gehl, 2010; Sharifi, 2016). Technologists can leverage the model's integration of smart systems to explore new configurations of energy management, sensor networks, and data-driven service delivery, while simultaneously addressing challenges of interoperability, data governance, and inclusion (Kitchin, 2014; van Dijk, 2020). For educators, UBT offers a context where pedagogy is embedded within the physical and operational fabric of the campus itself—an experiential learning environment where sustainability, technology, and design converge. Policymakers are presented with a platform for policy prototyping and institutional experimentation. The UBT campus has demonstrated how regulatory frameworks in sustainability, transport, and land use can be tested at a micro-scale before being scaled regionally or nationally (Karvonen, Evans & van Heur, 2014). Its alignment with broader agendas such as the EU's Climate-Neutral and Smart Cities mission and the UN-Habitat's New Urban Agenda positions UBT as both a local innovator and a globally relevant actor (European Commission, 2020; UN-Habitat, 2016). Looking ahead, UBT's future development plan, encapsulated in its Strategic and Action Plan "Towards a Smart, Green and Carbon-Neutral Campus," provides a structured roadmap for deepening these innovations. Priorities include further integration of clean energy solutions, digitization of learning environments, expansion of green infrastructure, and institutionalization of sustainability governance mechanisms. Importantly, UBT envisions broader global engagement through knowledge transfer, cross-border collaboration, and participation in international research and innovation networks. As such, the UBT "SMART City" model is not only a physical manifestation of adaptive and intelligent planning but also a replicable and scalable framework that can inform future city-making processes. It illustrates how academic institutions can be reimagined as leading agents of spatial transformation, social innovation, and environmental stewardship in the era of climate change and digital transition.

Harnessing Smart Technologies in Real Estate: A New Paradigm for Spatial Planning and Urban Development

Tarek Al-Rimawi*, Michael Nadler
Affiliation: Chair Real Estate Development, Faculty of Spatial Planning, Technical University Dortmund,
August-Schmidt-Street 6, 44227 Dortmund, Germany
Email: tarek.al-rimawi@tu-dortmund.de

Abstract
This paper presents a dual-tool system to support the assessment and development of smart cities and smart real estate. The first tool is a comprehensive evaluation framework that independently and jointly measures the smartness of urban systems and real estate projects across seven strategic categories. The second is a smart technology utilization map that identifies the added value of specific technologies across different phases of the real estate lifecycle—from land acquisition to post-operation. Together, these tools enable stakeholders—such as city authorities, developers, and investors—to identify performance gaps, prioritize improvements, and plan smarter, more integrated developments. The study also outlines the role of public and private actors in enabling smart infrastructure and encourages coordinated, data-driven decision-making to advance urban sustainability, efficiency, and resilience.

Keywords smart city, smart real estate, smart technologies, urban planning

1. Introduction

Urbanization is accelerating faster than ever before, with the United Nations estimating that 68% of the global population will be living in cities by 2050 (UN-Habitat, 2022). This trend puts significant pressure on urban infrastructure, urban governance, and real estate markets.

Simultaneously, smart technologies (for example, the Internet of Things (IoT), artificial intelligence (AI), and geographic information systems (GIS)) are altering urban systems, and cities are beginning to adopt these technologies to respond to these pressures (Batty *et al.*, 2012; Ahmed *et al.*, 2017).

Real estate development, as a fundamental urban development component, provides a major opportunity for technological convergence. However, at present existing models do not provide a reliable framework to identify smart technology interventions through the real estate development space. Most smart city (SC) models also do not appropriately integrate real estate or treat it as a small part of the overall model (Albino, Berardi and Dangelico, 2015; Allam and Newman, 2018) Therefore, there is a need for a hierarchy system that assesses the smartness of developments, identifies the smartness gap, and matches the better innovation and technology intervention to the necessary development stages.

This paper will help fill that gap by offering a practical roadmap for stakeholders (i.e. municipalities, real estate developers, investors, and decision-makers) to determine and improve the assessment of SC systems and smart real estate (SRE) development. The paper proposes two primary tool components that stakeholders can utilize or adjust to their urban and project contexts:

1. An Evaluation Framework: This assessment instrument compares and evaluates the level of 'smartness' of both city and real estate levels, provides a diagnosis for current inadequacies, and identifies objectives for governance, infrastructure, people, environment, building, and technology, and identifies the gaps in each level (Al-Rimawi and Nadler, 2023).
2. A Smart Technology Utilization Map: This component identifies the added value of smart technologies along the real estate life cycle and identifies when and where to use technologies. Utilizing recent integrative reviews (Al-Rimawi and Nadler, 2025)It identifies which technologies, such as GIS, BIM, AI, IoT, VR/AR, and digital twins, are most impactful during specific phases of the real estate life cycle, from land development, development, operation, and redevelopment.

These tools provide strategic purpose and meaningful insights both across and up and down the hierarchy. The

framework supplies coordinated planning and a policy context, while the technology map indicates investments that can be made in smart systems that drive more operational efficiency, sustainability, and value over time. The study addresses this need for collaborative integration rather than fragmentation and contributes to a stream of research recognizing the importance of collaboration across sectors and interoperable planning processes. While no case studies are present, illustrative examples are provided to demonstrate how these tools can be applied in practice.

2.Theoretical Foundations and Literature Review

2.1 Defining Smart Cities and Smart Real Estate

The concept of the SC has been developing since the early 1990s, starting the knowledge-based city, which emphasized the importance of knowledge-based urban development (Šiurytė, 2015). Among the key hindrances to both the development and actualization of the SC concept is the lack of a shared definition. This lack results in definitional ambiguity, which weakens conceptual clarity for smart cities and could jeopardize their practical value. The variation in definitions is due to the fact that the SC is an interdisciplinary concept with several fields such as urban planning, information technology, environmental sustainability, and real estate being involved. Scholars and practitioners thus define SC based on their respective areas of specialization.

In response to this challenge, Al-Rimawi and Nadler (2025) propose a comprehensive and inclusive definition that that captures the key dimensions of smart cities and brings together the key elements of SC. Where it is the city that utilizes smart technologies to render its interlinked sectors and essential elements, including city administration, citizens, energy, infrastructure, property, technologies, information, and nature more intelligent, sustainable, integrated, and efficient. This perspective positions smartness as a two-pronged change—technological and strategic—with profound consequences for governance, infrastructure, and the quality of urban life. To avoid what could be termed smart washing—the superficial or misleading application of the term—the SC must move beyond definitions. It must become a tangible and measurable reality, grounded in practical implementations, data-driven evaluation, and meaningful impact across its various systems and stakeholders.

SRE is a similar but distinct concept. It refers to the integration of smart technologies into the property development, operation, and management sectors in order to achieve operational efficiency, user-centered functionality, and sustainable performance throughout the real estate life cycle. In contrast to smart buildings, which focus primarily on building automation and system efficiency (e.g., HVAC, lighting, security) smart real estate permeates the whole property life cycle. These include the land development stage, project development, operational stage, and post-operation activities (Ullah, Sepasgozar and Wang, 2018; Al-Rimawi and Nadler, 2025). In each phase, decision-making, design optimization, predictive maintenance, and user engagement are facilitated by technologies such as IoT, GIS, AI, and big data analytics (Yigitcanlar, 2021; Al-Rimawi and Nadler, 2025).

SRE cannot be an isolated category; rather, it is inherently integrated into the framework of the SC. The interaction between the built environment and urban infrastructure—such as energy networks, transportation systems, and information platforms—allows a synergistic interaction. SRE initiatives are part of essential elements producing and reacting to information at the city level, assuming their position in reinforcing urban efficiency and sustainability goals (Albino, Berardi and Dangelico, 2015; Apanaviciene and Shahrabani, 2023). This integration underscores the need for comprehensive frameworks that evaluate smartness across both scales—urban and real estate—ensuring coordinated innovation, data interoperability, and systemic impact.

2.2 Smart Cities and Smart Real Estate Integration

Integrating SRE within smart cities is critical to the success of efficient, resilient, and sustainable urban systems. SRE, especially smart buildings, constitutes a fundamental element of the overall urban infrastructure, facilitating contributions toward energy management, automation, and adaptive technologies (Al-rimawi and Nadler, 2023). Successful integration, however, requires an integrated approach at three levels: physical (e.g., accessibility to urban infrastructure and utilities), data (interoperable platforms for real-time exchange), and functional (integration with urban goals like energy efficiency and well-being of the citizens) (Apanaviciene and Shahrabani, 2023).

Strategies for SRE integration differ according to technological capability and developer goals. Al-Rimawi and Nadler (2023) discern three principal strategies: leading, in which RE establishes the standard for nearby smart developments; following, in which RE conforms to existing smart standards; and waiting, whereby selective and piecemeal introduction of isolated smart features is undertaken without strategic planning. Every strategy demonstrates disparities in smartness levels and likely influence, underlining the necessity for diligent coordination between real estate developments and city-wide systems. Ultimately, proper integration allows for mutual gains—maximized utilization of resources, improved urban development, and augmented environmental and social returns cementing the position of renewable energy as a core facilitator in SC frameworks.

2.3 Smart Technologies

Smart technologies are the enabling infrastructure, or foundation, for both smart cities and SRE, enabling a digitally transformed built environment and urban space. These technologies facilitate functionality, efficiency, and sustainability across the entire life cycle of city and real estate development and delivery processes. These are the core technologies that enable intelligent decision-making and enable automation and integration within urban contexts and built environmental systems. Figure 1 represents the different smart technologies groups based on their main function and utilization.

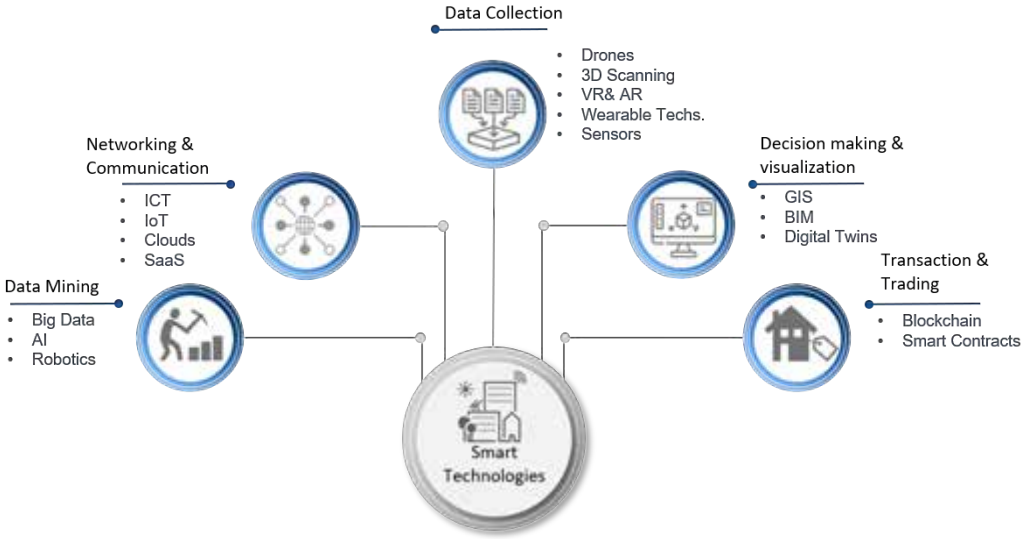

Figure 1 Smart city technologies that impact smart real estate (Al-Rimawi and Nadler, 2025, p. 04)

Data Mining & Intelligence Tools: Technologies such as big data analytics and AI serve a central role in the analysis of complex data sets, to help inform predictive analytics in models of traffic, energy, and operations of building management systems (Kitchin *et al.*, 2015). In assisting in a variety of project marketing processes, as well as maintenance projections and user behavior, AI will improve operational efficiencies and with enhanced service personalization (Ullah, Sepasgozar and Wang, 2018; Al-Rimawi and Nadler, 2025). Networking and Communication Tools: Information and communication technologies (ICT), the Internet of Things (IoT), cloud computing, and software as a service (SaaS) are part of the digital nervous system of smart cities and are the fundamental tools used to facilitate interoperability and communication between all buildings, infrastructure, and user devices (Boulos and Al-shorbaji, 2014).

Data Collection Technologies: Tools such as drones, 3D scanning, wearable devices, virtual reality (VR), and augmented reality (AR) facilitate real-time monitoring, visualization, and augmented experience for users, and are particularly influential in project marketing, design and refurbishment aspects of real estate (Naeem, Rana and Nasir, 2023; Al-Rimawi and Nadler, 2025) Decision-Making & Visualization Platforms: Geographic Information Systems (GIS), Building Information Modeling (BIM), and Digital Twins (DT) can facilitate, support, and contribute

towards the urban planning, real estate design, simulating, and lifecycle management processes. GIS has had a strong impact in land development and land selection, while BIM and DT can support integrated design and operations (Bronckers, 2024); (Malik *et al.*, 2021); (Karan, Irizarry and Haymaker, 2016; Arcuri *et al.*, 2020).

Transaction and Governance Tools: Blockchain and smart contracts provide transparent and tamper-resistant systems for land registration services, lease agreements, and real estate trading, which can improve trust and increase efficiency in ownership transfer processes (Ullah and Al-Turjman, 2023).

A recent integrative review (Al-Rimawi and Nadler, 2025) conducted an analysis of how these technologies are contributing to the real estate life cycle. The study discovered that the greatest added value through these technologies was experienced during project acquisition, conception, and operation, with GIS contributing the greatest value during site selection and land development processes. GIS and BIM also dominated during the conception stage, while BIM was the most visible during the realization and construction stage. For promoting marketing a product, either AI, Virtual Reality or Augmented Reality tools assist in portraying the property with simulation and visualizations that attract end-users and experience more traction during this stage of the real estate life cycle.

Emerging technologies like AI, the IoT, wearables, DT, and BIM were key technologies during the operation and maintenance phases, facilitating performance, user interface, and energy consumption improvements. BIM and 3D scanning facilitated refurbishment, however, a transition from vacancy and demolition proved more challenging with limited outcomes. Operational enhancements were generally noted with enhancements in emergent technologies manifested as better decision-making, reduced errors, better resource management, and reductions in operational tasks. Integrating the emergent technologies improves value propositions as they create synergies that lead to new uses and efficiencies. Although the emergent technologies offer transformative potential, there will be challenges to implementation including financial capacity, institutional inertia, and the issue of interoperability with data. However, with some strategic planning, these emerging technologies can be a more useful tool and can cater to urban and real estate development (Ullah, Sepasgozar and Wang, 2018; Al-Rimawi and Nadler, 2025).

3. Materials and Methods

3.1 Research Design

The study takes a conceptual and systems-design approach to create an integrated assessment and enhancement system for SCs and SRE. The research is based on the author's two previous frameworks ((Al-Rimawi and Nadler, 2023, 2025)) that outlined:

1. A comprehensive evaluation framework for determining and measuring the smartness of cities and real estate.
2. A structured model for identifying the added value of SC technologies throughout

This paper presents a framework that is open for use generally and practically, based on academic references and supplemented with examples that demonstrate the inaugural use of the original system in practice. Prioritize smart upgrades in terms of strategic impact and feasibility.

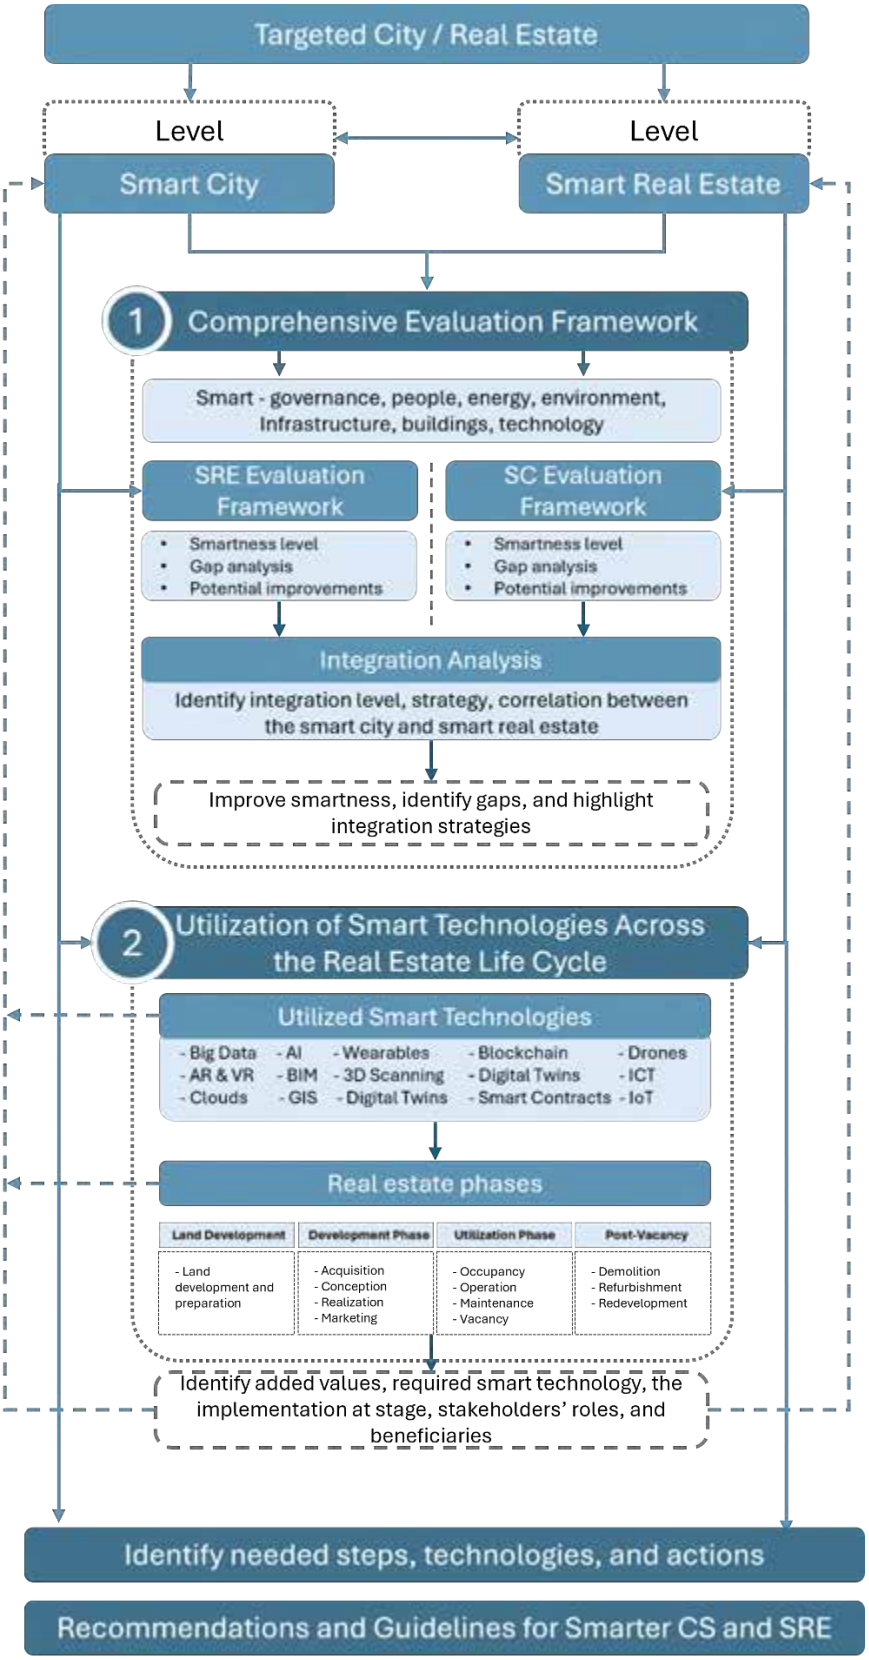

Figure 2 . *Research methodology. Source: Author, 2025.*

4. Roadmap and Tools for Smartness Improvement

The road map proceeds in the following steps:

4.1 Step 1 - Comprehensive Evaluation Framework

Smartness Determination and Assessment

The smartness of both the city and the real estate sector are assessed separately following the evaluative frameworks developed by (Al-Rimawi and Nadler, 2023). This assessment includes:

- Verifying whether the city or real estate qualifies as "smart" based on indicator thresholds.
- Evaluating performance across seven smart dimensions: governance, environment, economy, people, mobility, living, and real estate.
- Assigning scores to each dimension for comparative and developmental analysis.

The comprehensive Evaluation Framework is designed to assess and guide the development of SCs and SRE. It identifies current performance, highlights gaps, and suggests improvements, with a focus on interoperability and future adaptability. The flexible structure allows for the integration of emerging technologies and indicators. This tool supports municipalities, developers, contractors, and investors in planning, evaluating, and enhancing smart initiatives. It is applicable for both assessing existing developments and providing a roadmap for future ones.

The framework is structured around seven shared categories: smart governance, people, infrastructure, energy, environment, technology, and real estate development (RED) status. Each category includes sub-categories and indicators derived from academic research, established indexes, and regulatory frameworks.

For SCs, key references include the Smart City Index (2021), City in Motion Index (2020), EU Taxonomy (2020), and studies by (Kaluarachchi, 2022) and (Shari, 2020). For SRE, indicators were informed by SBISC (Apanaviciene, Vanagas and Fokaides, 2020), Jain's evaluation system (Jain, 2019), and Ullah et al.'s Big 9 study (Ullah, Sepasgozar and Wang, 2018), alongside certification schemes like LEED, BREEAM, and the EU Smart Readiness Indicator (SRI).

Each indicator is scored based on relevance and importance, using three methods:

- Published indexes: Weighted according to indicator significance.
- Quantitative data: Based on figures or percentages within defined ranges.
- Multi-source elements: Scores are compiled from several components, each contributing to the overall value.

4.1.1 Step 1.1- Evaluation Framework City level

The SC evaluation framework includes 28 sub-categories and 85 indicators. Each indicator is assigned a weighted score of 4, 6, 8, or 10 points, based on its relevance and importance. The total possible score is 560 points, evenly distributed across the seven main categories (80 points each). Figure 3 provides a simplified overview of the SC-level framework, as developed by (Al-Rimawi and Nadler, 2023). It outlines the primary categories, their sub-categories, the number of indicators, and the scoring structure—offering a quick snapshot of the framework's scope and focus areas.

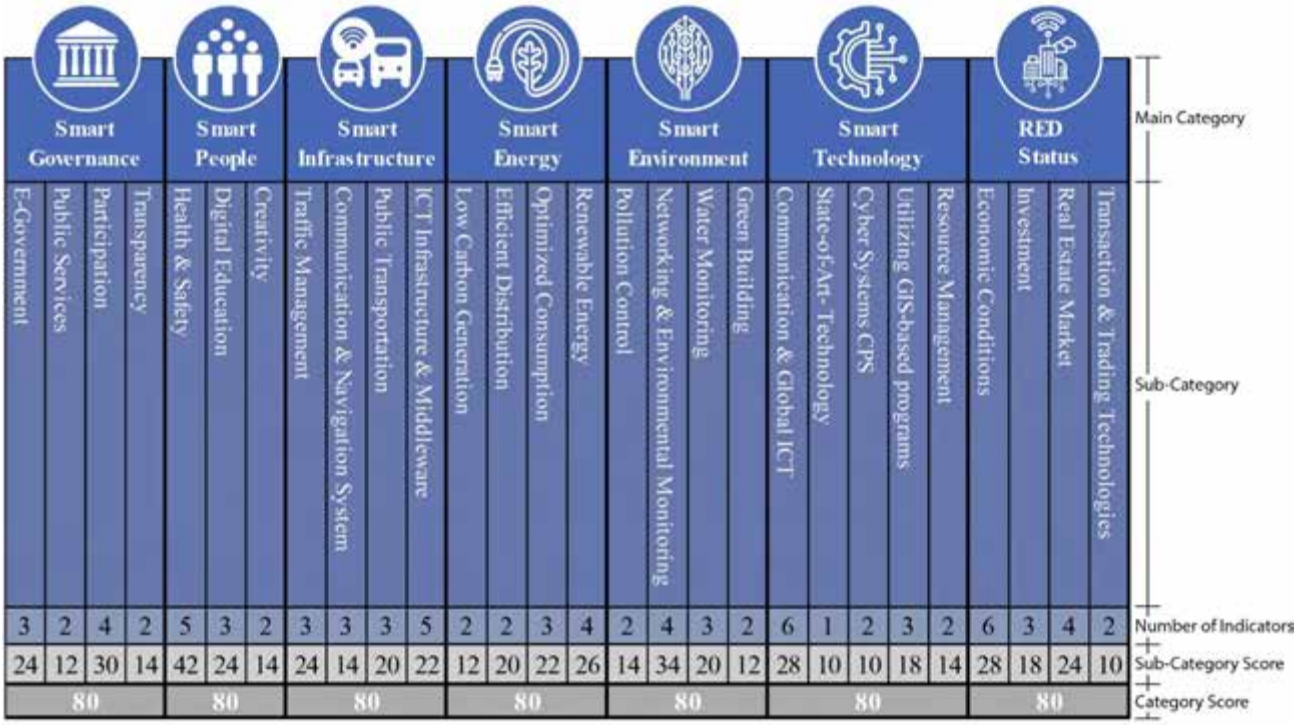

Figure 3 *Smart City Level Simplified Evaluation Framework, Author, 2025.Based on (Al-Rimawi & Nadler, 2023)*

4.1.2 Step 1.2- Real Estate (Project) Level Evaluation

The SRE project evaluation includes 90 indicators grouped into 28 sub-categories, with a total possible score of 255 points. Scores are allocated based on each category's relevance to SRE. Smart technologies, being the core of SRE, received the highest share (60 points), followed by smart energy and environment (40 points each). Smart infrastructure and real estate development (RED) status were allocated 35 points each, while smart people and governance—less directly linked—received 30 and 15 points, respectively.

Each indicator was scored on a 1–5 point scale, weighted according to its importance. Unlike the city-level framework, which uses higher point ranges, the project-level framework focuses on finer evaluation granularity. Although the maximum score per indicator is lower, results are calculated as percentages to maintain comparability and simplify evaluation across different cases. The framework follows the same process and steps as the SC, with different subcategories and indicators.

4.1.3 Step 1.3- Gap Analysis

Following the smartness assessment, the framework provides a gap detection mechanism to:

- Identify underperforming indicators and dimensions;
- Reveal areas with potential for enhancement in smart technologies, policies, or strategies;

To validate the developed evaluation frameworks, in the publication (Al-Rimawi and Nadler, 2023) the evaluation frameworks were applied to seven selected benchmarks, at both levels of SC and SRE. This practical application enabled a comparative analysis across various indicators, revealing performance gaps and opportunities for improvement. These gaps highlight where interventions or strategic enhancements are needed at both the city and project levels.

Figure 4 presents the average performance scores of the selected benchmarks, visualizing the relative impact, utilization, and importance of each indicator. Some indicators demonstrated consistently strong performance across all cities, suggesting they are already well-integrated and can be considered critical success factors for SC development. Conversely, underperforming indicators indicate areas where cities and developers can prioritize future improvements to enhance smartness, efficiency, and integration.

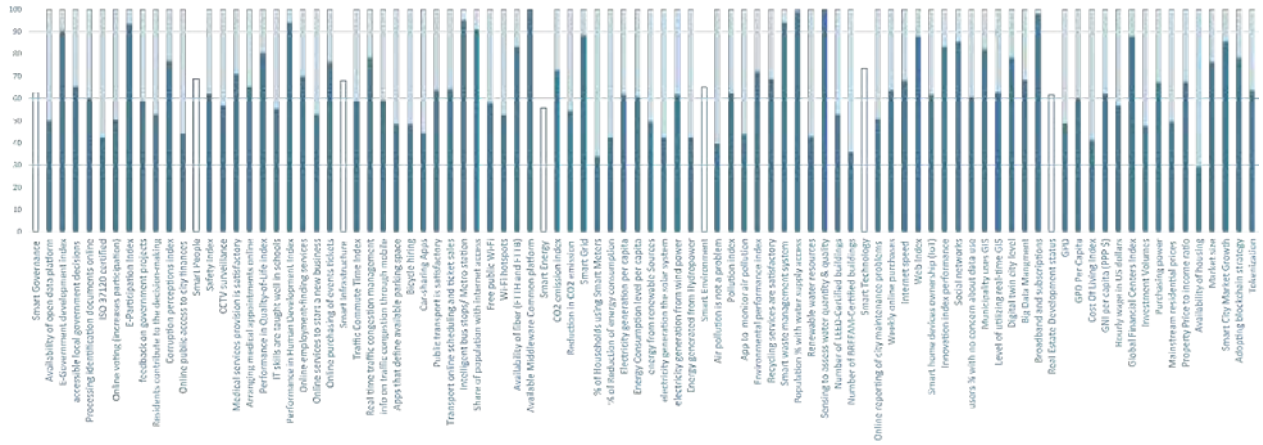

Figure 4 *Average performance and gap analysis example. Based on the case* (Al-Rimawi and Nadler, 2023)

4.1.4 Step 1.3- Integration Level Analysis

Integration between the city and real estate is analyzed using a dual-scope structure:

- Intra-scale integration: Assessing alignment and interconnectivity within the city or the real estate sector at three levels—indicator-to-indicator, sub-category-to-sub-category, and main category-to-main category.
- Cross-scale integration: Assessing the relationship and interdependence between city systems and real estate systems at the same three levels.
- This multi-level analysis will support the identification of ways in which the real estate sector supports or integrates with broader city-level smart strategies.

Several elements represent the integration analysis, Figure 5 represents a cross-sectional analysis, that represents SC and SRE performance.

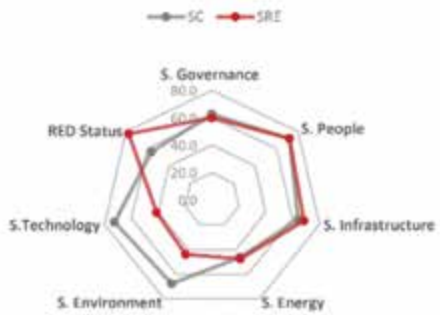

Figure 5 *Example of Sectional analysis, Smart Real Estate integration into Smart Cities and the performance. Author, 2025*

In order to capture the level of impact and correlation at all the levels SPSS (Statistical Product and Service Solutions) software is used on both SC and SRE levels and their integration. The analysis tests the three classifications: main categories, subcategories, and indicators.

4.2 Step 2- Added Value Analysis of Smart Technologies

After evaluating the smartness level, identifying gaps, and integration level, the next step would be implementing technologies to fill these gaps and improve the smartness level of the city or the real estate. The Publication (Al-Rimawi and Nadler, 2025) provides a tool that represents 16 technologies (represented in Figure 1) utilized at both levels, that have been investigated. The research followed an integrative review methodology; the review is based on 168 publications. The compiled results based on metadata analysis displayed the state of each technology's added values and usage in both scales. A total of 131 added values were identified.

4.2.1 Step 2.1 - Identification of Real Estate Life Cycle Phases

It determines how SC technologies provide value throughout a real estate lifecycle as represented in Figure 6. Real estate phases, sub-phases, and processes. (Al-Rimawi and Nadler, 2025) Across the four main phases, and their subphases:

1. Land Development
2. Project Development (Acquisition, Conception, Realization, Marketing)
3. Operation (Occupancy, Operation, Maintenance, Vacancy)
4. Post-Operation (Project Demolition, Refurbishment, Redevelopment)

Figure 6. *Real estate phases, sub-phases, and processes.* (Al-Rimawi and Nadler, 2025)

4.2.2 Step 2.2 - Identification of Added Values and Critical Elements

Each technology is evaluated in terms of:

- Functional benefits (e.g., efficiency, automation, environmental performance);
- Strategic contributions to SC goals;
- Relevance and feasibility across the lifecycle phases.
- Provider and beneficiaries

Main Phase	Sub Phase	Process/Task	Added Value *	Technologies	Provider **	User
Land Development		Land Surveying	Enhance boundary and detailed topographic mapping with integrated spatial analysis	GIS, Drones	Municipal authorities (urban planners, surveyors)	Real estate developers, municipal authorities
		Zoning and Planning	Enhance analysis of zoning and land-use data and simulate various scenarios	GIS, BIM	Municipal authorities (urban planners)	Real estate developers, municipal authorities, investors
			Improve communication with zoning and permitting authorities	ICT	Municipal authorities, technology providers	Real estate developers, municipal authorities
		Site Preparation	Improve site conditions and constraints analysis	Big Data, GIS	Municipal authorities (urban planners, architects, surveyors)	Real estate developers, municipal authorities
			Coordinate and manage site preparation activities	ICT, GIS, BIM	Municipal authorities, construction managers	Real estate developers, municipal authorities
			Facilitate and enhance site clearing and grading	Drones, 3D Scanning, GIS	Construction managers, surveyors	Real estate developers, municipal authorities
		Infrastructure Development	Improve Infrastructure network management and planning	ICT, IoT, VR and AR, GIS	Municipal authorities (urban planners), technology providers	Real estate developers, municipal authorities, investors
			Coordinate infrastructure development activities	GIS, BIM	Municipal authorities, construction managers, technology providers	Real estate developers, municipal authorities
			Develop and create e-government infrastructure	ICT, Blockchain and Smart Contracts	Municipal authorities, technology providers	Real estate developers, investors, citizens
			Optimize municipal systems and provide geodata	ICT, GIS	Municipal authorities, technology providers	Real estate developers
			Improve essential data access and transparency	Big Data, ICT, Clouds, and SaaS	Municipal authorities, technology providers	Real estate developers, investors
		Environmental Impact Assessment	Provide a simulation of environmental impacts and help mitigate hazards	VR and AR, GIS, BIM, DT	Municipal authorities (environmental scientists, urban planners)	Real estate developers, municipal authorities, investors
		Community Impact Assessment	Increase participation	ICT, IoT	Municipal authorities	Real estate developers, investors, citizens
			Facilitate communication with the stakeholders	ICT	Municipal authorities (urban planners)	Real estate developers, municipal authorities, investors,

* These results are based on metadata analysis, highlighting the technologies that significantly achieve that added value. These technologies can contribute to other added values and have different abilities. The responsibility is not only for the highlighted stakeholders, but those are the key ones, and their significant role is in the scope of smart cities and smart real estate. This applies to Tables 3–6. ** The provider, the stakeholder responsible for activating these added values, can delegate the responsibility to an external expert to activate these added values highlighted between brackets. This applies to Tables 3–6.

Figure 7 *Screenshot of the technology utilization analysis*, (Al-Rimawi and Nadler, 2025)

4.2.3 Step 2.3 - Stakeholder Roles and Technology Utilization

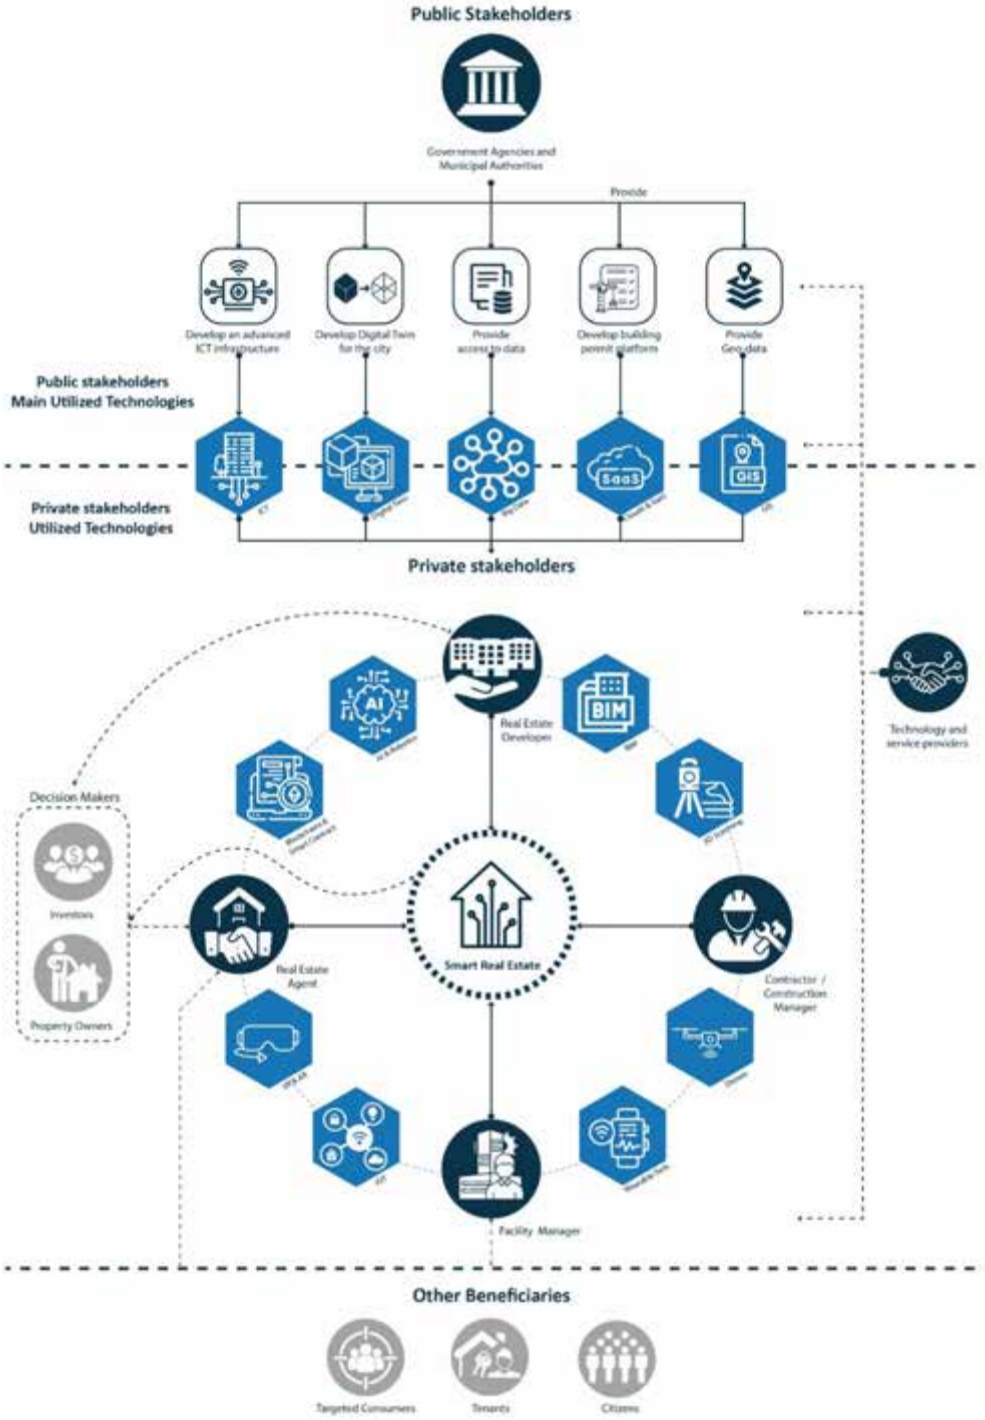

Figure 8 *Public and private stakeholders' relationships and their utilized technologies.* (Al-Rimawi and Nadler, 2025)

SC and SRE development relies on coordinated efforts between public and private stakeholders, each utilizing different technologies at various stages of the development cycle represented in Figure 8 (Al-Rimawi and Nadler, 2025).

Public stakeholders such as municipalities and government agencies—lay the foundation by upgrading digital infrastructure, deploying IoT networks, and creating centralized platforms for data integration. They invest in open geospatial and big data systems, enabling advanced analytics through AI. Technologies like GIS, ICT, and Big Data are commonly used, with a growing influence on AI adoption. Additionally, they support automation in permitting and planning through cloud-based tools and help build digital twins to support urban management. These actions directly enhance land development and early real estate phases, encouraging smarter private sector involvement.

Private stakeholders, including developers, contractors, agents, and facility managers, adopt a broader range of smart technologies. Developers use GIS, BIM, Big Data, and AI for acquisition, design, and planning. Contractors rely on BIM, AI, and wearable tech for safety, coordination, and resource optimization during construction. Agents leverage VR, AR, drones, and blockchain for immersive marketing and secure transactions. Facility managers use BIM, digital twins, AI, and IoT for real-time operations and predictive maintenance during occupancy and operation phases.

Together, both sectors drive smarter, more connected urban and real estate ecosystems by leveraging the right technologies at the right development stages.

4.3 Step 3 - Strategic Implementation and Action Planning

Now that gaps, strengths, and opportunities are identified through the evaluation and technology mapping, the attention should shift to implementing a strategic plan. This step involves:

4.3.1 Step 3.1 - Prioritizing Improvements

- Rank areas with the largest performance gaps or with indicators of high impact.
- Identify quick wins (e.g., tech already available but underutilized) vs. long-term investments.

4.3.2 Step 3.2 - Developing a Roadmap

- Outline short-, medium-, and long-term actions in consideration of stakeholder capacity and goals of the city/ real estate.
- Assign responsibilities among public and private actors.
- Define timelines, budgets, and measurable targets.

4.3.3 Step 3.3 - Integration and Collaboration Mechanisms

- Propose ways to **align public and private efforts**, such as:
  - Data-sharing protocols
  - Public-private partnerships (PPPs)
  - Joint investment strategies

4.3.4 Step 3.4 - Monitoring and Feedback Loops

- Establish mechanisms to **track progress** and update the framework as technologies evolve.
- Identify KPIs associated with each indicator to measure ongoing performance.

5. Discussion

The evaluation framework and technology utilization analysis presented in this study offer a structured approach to understanding the smartness of cities and real estate developments. This dual-tool methodology revealed significant insights into the performance status, technological gaps, and opportunities for enhancement across

both city-wide and project-level developments.

5.1 Smart Cities and Smart Real Estate Dependence
The evidence presented provides further support for the idea that smart cities and SRE are dependent on one another, one cannot advance fully without the other. Smart cities ultimately provide the foundation of policies and infrastructure whereas SRE projects can offer innovation and scale at the project level. The evaluation framework revealed that categories such as smart governance or smart people tend to lag in privately led projects whereas smart technologies and smart infrastructure are more developed for commercially driven real estate projects. This can mean that a greater emphasis on collaboration between public and private actors is ideally required to ensure appropriate development across all smartness pillars.

5.2 Technological Readiness and Strategic Timing
Differences in technology adoption were evident in the utilization analysis of the lifecycle. Technologies, such as GIS, BIM, IoT, and AI, are performing strongly in the cradle phases of conception, construction, and operation, respectively, and underperforming in transition sub-phases (e.g., vacancy, and demolition). These differences in readiness speak to the importance of strategic timing this includes not only knowing what technology you are going to use but also when and where you are going to utilize that technology relative to its value.

5.3 Stakeholder Roles and Gaps
The review found that public and private stakeholders both had instrumental roles to play. Public entities likely have the foundational enablers - high-speed communication, open data platforms, digital governance tools- while private stakeholders tend to more easily adopt new private innovation technologies (e.g., AR/VR, wearable tech, blockchain), especially around marketing and customer engagement.

However, these efforts remain fragmented without coordinated strategies/research. This reinforces the need for coordinated approaches, including integrated plans, joint data-sharing frameworks, and clear incentives for coordination between public and private stakeholders.

5.4 From Assessment to Action
The gap assessment in the evaluation framework is, diagnostic and directional in orientation. It shows where cities and projects exist today and where to act next (the next step). The next step should focus on:

- Customized action plans to develop high-impact indicators/outcomes.
- Cross-sector partnerships to leverage shared data and infrastructure.
- Capacity-building and awareness programs to ready stakeholders, specifically municipalities and smaller developers.

5.5 Limitations and Future Work
Although comprehensive, the framework is not a complete evaluation process. It has been reflective of the state of the literature and technologies available today, and updates will need to be conducted as urban challenges evolve and technologies emerge. Additionally, this study does not contain primary case studies and, therefore lacks empirical verification. Future work can utilize this methodology in specific urbanities to validate and improve the overall practical value of the evaluation framework.

It was also observed that certain technologies – e.g., Digital Twins, predictive tools with AI – yielded the most value during the utilization and maintenance phases, suggesting that investment priorities are shifting beyond construction whereby optimizing lifecycle use is the highest value proposition for these technologies.

6. Conclusion and Future Directions
This paper presented a dual-tool approach to support the assessment and development of smart cities (SC)

and smart real estate (SRE). The first tool a comprehensive evaluation framework was designed to measure the "smartness" of urban areas and real estate projects based on seven key categories and a set of weighted indicators. The second tool analyzed the added value of smart technologies across the real estate lifecycle, identifying when and where each technology could contribute to the real estate development cycle, as well as when and how each technology should fit in the real estate development life cycle (which stage, when, and where in the development cycle) order to maximize value-added performance.

Together, these tools provide a practical roadmap for municipalities, developers, investors, and policymakers. They enable informed decision-making by identifying performance gaps, prioritizing technology integration, and aligning stakeholder efforts. The results emphasize the interconnectedness of SC and SRE, showing that both public infrastructure and private development must advance in tandem to achieve holistic urban innovation.

While the paper does not conduct empirical case studies, it offers a structured methodology and insights that can guide future implementations and research. As technologies evolve and cities continue to grow, the framework is flexible and adaptive, capable of incorporating new indicators and innovations to remain relevant.

In conclusion, advancing smart cities and smart real estate requires strategic planning, coordinated efforts, and the intelligent use of technology. The tools developed in this study offer a foundation for such advancement—helping cities and developments transition from traditional models to smarter, more resilient, and more sustainable futures.

Abstract
Cross-domain knowledge integration is crucial for complex urban and architectural decision-making, with ontology engineering playing a foundational role. To address limited automation and low interpretability in ontology alignment, this study proposes an LLM-powered agent framework to support ontology reuse across built environment domains. The performance of four LLMs and three prompt strategies is explored in alignment tasks. Three specialised agents, for context generation, expert validation, and explanation synthesis, are proposed and integrated with retrieval and mapping agents. Together they form a closed-loop framework linking automatic alignment, expert review, and explanatory feedback. This agent-enhanced architecture improves the traceability and interpretability of alignment results and facilitates expert involvement and iterative refinement, offering a solid foundation for managing and reusing ontologies in complex urban-scale contexts.

Keywords: Large Language Modelling (LLM), ontology alignment, knowledge integration, semantic interoperability

1 Introduction

Complex decision-making in the built environment increasingly relies on multi-source and heterogeneous data across domains (Li et al., 2022; Fadhel et al., 2024). Semantic data modelling has emerged as a key strategy to explicitly represent domain knowledge in a machine-interpretable and human-comprehensible format (Gruber, 1993; Alexopoulos, 2020). Among various representation techniques, ontologies—formalized schemas of domain entities and their relationships—serve as the backbone of semantic integration. Powered by Semantic Web technologies (Berners-Lee, Hendler and Lassila, 2001), ontologies enable structured knowledge from different systems to be unified, queried, and reasoned over, bridging disciplinary boundaries.

Extensive efforts have been made to develop ontologies that capture different layers of spatial, physical, and operational semantics across the built environment. These efforts span diverse areas including infrastructure systems (Nandini and Shahi, 2019; Du et al., 2023), smart city development (Qamar et al., 2019), healthy city planning (Pietra, De Lotto and Bahshwan, 2021), urban disaster response (Dutta and Sinha, 2023), building performance optimization (Utkucu and Sacks, 2025), facility operation and maintenance (F.H et al., 2025).

While numerous ontologies have emerged across domains, their independent and purpose-specific development has led to persistent semantic heterogeneity and limited interoperability. Ontology alignment remains a critical role in enabling scalable knowledge integration and system-level semantic reasoning, especially in large-scale built environment systems like integrated digital twins and urban energy platforms. Ontology alignment, or matching, is the first step toward resolving semantic heterogeneity by generating correspondences between entities such as concepts, properties, or instances (Shvaiko and Euzenat, 2013; Algeria et al., 2015). By comparison, ontology mapping denotes the structured expression of alignment results, often stored as external documents or internal annotations.

Ontology alignment in practice remains heavily dependent on manual efforts (Elshani et al., 2025). It often requires significant cross-domain expertise to interpret conceptual differences, resolve ambiguities, and validate alignment decisions—making the process both time-consuming and difficult to scale. Moreover, the lack of

systematic validation and explanation mechanisms undermines the reliability and reuse of alignment results. Despite its critical role, alignment is rarely treated as a first-class concern in ontology engineering workflows. Mappings are often missing, informal, or undocumented, especially in domain-specific ontologies developed for isolated use (Ma et al., 2024).

These issues severely restrict semantic interoperability across domains and impede the evolution of shared knowledge infrastructures in the built environment. Recent advances in LLMs have opened new possibilities for automation in various phases of ontology engineering (Li, Garijo and Poveda-Villalón, 2025). With their powerful capabilities in semantic understanding, contextual reasoning, and cross-domain generalization, LLMs have shown promising results in a range of ontology-related tasks, including ontology learning (Babaei Giglou, D'Souza and Auer, 2023) ontology generation (Doumanas et al., 2025), terminology annotation and entity completion (Norouzi et al., 2025), ontology evaluation (Tsaneva, Vasic and Sabou, 2024) , among others. However, their potential for application in ontology engineering of the built environment remains largely unexplored and unvalidated.

To address the persistent challenges of low automation, missing alignment modules and mappings and limited interpretability in ontology alignment, this study aims to explore the potential of LLMs to enhance ontology alignment processes in the built environment domain. Specifically, it explores how different LLM types and prompting strategies perform in alignment tasks. Furthermore, this study proposes a dedicated LLM-powered agent framework to improve the interpretability, traceability, and reusability of alignment process and results.

This study presents the first empirical exploration of using LLMs to support cross-domain ontology alignment in the built environment. It fills key gaps in existing frameworks by introducing verification and documentation capabilities, and pioneers a paradigm shift in ontology alignment—from mere result generation to semantic asset construction. Furthermore, it provides an agent-based toolchain that enables ontology experts to generate interpretable alignment comments and reusable documentation.

This paper is structured as follows. Section 2 reviews key challenges in built environment ontologies, the evolution of ontology alignment methods, the integration of LLMs for semantic modelling and alignment, and recent advances in LLM-enhanced documentation generation and interpretability. Section 3 presents a systematic evaluation of four representative LLMs and five prompting strategies across six ontology alignment datasets, highlighting their strengths and limitations under varying semantic complexities. Section 4 analyses the experimental results. Section 5 introduces an enhanced agent-based framework that integrates semantic context construction, human-in-the-loop validation and explanation generation. Section 6 summarizes key findings and outlines future directions for extending ontology alignment as a traceable and interpretable semantic infrastructure.

2. Related Work

2.1 Ontological Engineering Challenges and FAIR Bottlenecks in the Built Environment

Although a large number of urban and architectural ontologies have been proposed, their overall performance across the four dimensions of the FAIR principles, Findability, Accessibility, Interoperability, Reusability, which remains suboptimal. For instance, Mazimwe et al. (2021) evaluated 69 disaster management ontologies and identified significant deficiencies, particularly in interoperability and reusability. Specifically, the average FAIR score was only 19.54%, with 'findability' (or discoverability) scoring as low as 1.8%. Even urban ontologies constructed in recent years, such as city infrastructure ontologies (Du et al., 2023)the ground, roads, and buried pipes, Urban District Sustainability Assessment Ontology (Kuster, Hippolyte and Rezgui, 2020)factoring in environmental, social and economic requirements. However, the current assessment schemes are (a, and Smart City Services Ontology (Qamar et al., 2019)interconnected and intelligent. However, absence of a centralized system produces many

troubles for its stakeholders i.e. citizens and administration in order to perform their day-to-day actions. Semantic web technologies, and in particular linked open data is a tool which allows sharing and merging of data of different systems. Consequently, this paper aims to propose a Smart City Services Ontology (SCSO, generally lack standardized alignment documents and readable annotation structures. While it is widely acknowledged that publishing an ontology should be accompanied by detailed documentation of its concepts and relationships, to reduce the prevalent tendency of researchers to create new ontologies rather than reuse existing ones (Farghaly, Soman and Zhou, 2023), this best practice is rarely implemented in practice. In addition, the resulting mappings are often difficult to interpret, making it challenging for non-ontology experts to understand their semantic intent and the boundaries of their applicability (Mazimwe, Hammouda and Gidudu, 2021).

In recent years, several studies have explored automated and even semi-automated ontology alignment in the built environment (Schneider, 2019; Schlenger et al., 2025). However, no research to date has investigated the use of large language models (LLMs) for ontology alignment within the built environment.

2.2 Extending the Semantic Capabilities of LLMs in Built Environments

With the breakthrough of LLMs in natural language understanding and generation, increasing researchers are trying to introduce them into semantic modelling tasks in built environments. Feng et al. proposed the CityGPT framework, which significantly improves the LLM performance in spatial cognition, path planning, and instruction comprehension by constructing an urban task dataset and an evaluation benchmark (Feng et al., 2024). Li et al. (2025)operation and maintenance (O&M further mapped the mapping relationship between urban tasks and language modelling capabilities, pointing out that it has a high potential for interfacing with urban perception, prediction, and interactive reasoning.

In the context of building systems, Zhang et al (2025) constructed a chain of LLM-based energy simulation agents capable of directly transforming natural language descriptions into EnergyPlus model files. In addition, a control interpretation module incorporating the Shapley mechanism has been preliminarily validated to enhance the transparency of LLM in the field of semantic control of buildings (Zhang, Chen and Ford, 2024). The Shapley mechanism, originally developed in cooperative game theory, assigns credit to input features by quantifying their marginal contribution to a model's output—thus making the decision logic of black-box models more interpretable (Lundberg and Lee, 2017).

However, most of the above studies focus on mid-level tasks, such as information extraction, semantic questions and answers, or operation execution, and there is still a lack of in-depth exploration of semantic alignment at the structural level.

2.3 Evolution of Ontology Alignment Techniques and Trends in LLM Integration

Ontology alignment, as a key link to support ontology reuse, heterogeneous system integration and cross-domain semantic interoperability, has undergone three major stages in recent years. The first stage is represented by rule-based systems such as AML (Faria et al., 2013) and LogMap (Jiménez-Ruiz and Cuenca Grau, 2011), which mainly rely on manually set structural mapping rules with strong logical consistency but lack self-adaptation, which makes it difficult to apply to scenarios with variable contexts. The second stage introduces deep semantic embedding, such as BERTMap (He et al., 2022), which improves the alignment accuracy by word vector training, but requires large training sets and the generalisation ability is limited, which makes it difficult to cover the semantic migration between multiple domains. The third phase is the current key trend: generative alignment methods centred on LLMs. Such approaches achieve zero/few-shot alignment through prompt engineering, with low sample dependency, high generality, and strong semantic generalisation (Hertling and Paulheim, 2023).

Early studies on LLM-based ontology alignment primarily relied on prompt engineering to explore zero-shot and few-shot capabilities, often evaluated on benchmark datasets like Ontology Alignment Evaluation Initiative (OAEI) (Hertling and Paulheim, 2023; Norouzi, Mahdavinejad and Hitzler, 2023). These methods showed promise in terms of recall and generative flexibility, enabling the discovery of novel candidate alignments. However, they also revealed persistent limitations: low precision, unstable outputs, and poor structural consistency. Consequently, LLMs were often positioned as semi-automated tools requiring manual filtering by experts, rather than end-to-end alignment systems.

In addition, LLMs research has gradually shifted focus from early-stage prompt engineering to the development of more autonomous and modular LLM agents. As illustrated in Figure 1, the core of an LLM agent lies in its planning module, which enables the decomposition of complex tasks and iterative improvement through self-reflection. It leverages modular tools (e.g., domain-specific software) to perform both internal reasoning and external actions, and employs short-term and long-term memory to retain contextual knowledge and enhance decision-making (L. Zhang et al., 2025). In contrast to traditional prompt-based LLM usage, which is often inefficient, stateless, and hard to control when handling complex tasks such as ontology matching, Agent-OM exemplifies a paradigm shift: transforming LLMs from reactive generators into proactive decision-makers equipped with planning, memory, and tool-use capabilities. Qiang, Wang and Taylor (2025) introduced the Agent-OM framework, where LLM-based agents are equipped with planning, memory, and tool-use capabilities to modularly execute retrieval and matching workflows. The framework demonstrated competitive performance with state-of-the-art systems in simple tasks and outperformed most baselines in complex and few-shot ontology alignment scenarios, showing particular strengths in handling domain-specific and cross-domain alignment tasks. It slightly underperformed only against a few deep learning systems such as Matcha.

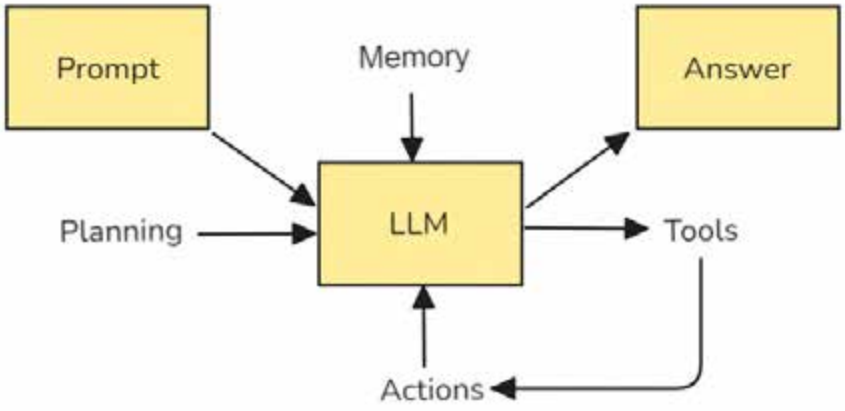

Figure 1. Architecture of an LLM-powered Agent with Prompt, Memory, and Tool Modules

Meanwhile, integration attempts between LLMs and traditional algorithms are also emerging. Taboada et al. (2025)but it remains challenging due to the need for large training datasets and limited vocabulary processing in machine learning approaches. Recently, methods based on Large Language Model (LLMs proposed the MILA framework, which incorporates a Prioritized Depth-First Search (PDFS) strategy to optimize LLM-driven ontology matching. This method significantly reduced the number of LLM queries required for complex alignment tasks. In multiple OAEI tracks, MILA outperformed existing unsupervised and some supervised systems without requiring fine-tuning. Sampels, Efeoglu, and Schimmler (2024) presented a hybrid approach that combines graph-based search algorithms (random walk and tree traversal) with prompt engineering. Their method extracts local

contextual information of candidate entities and verbalizes it into natural language prompts. This approach achieved an F1-score of 0.7147, outperforming zero-shot methods such as GPT and OLaLa, and highlighted the effectiveness of contextualization and verbalization in improving both precision and recall.

2.4 Documentation Generation and LLM-enhanced Interpretability

Recent advances in ontology engineering highlight a growing emphasis on human-readability and interpretability, particularly through documentation generation. While LLMs have demonstrated initial potential in generating ontology-related texts, this area remains underexplored. Only a few studies have addressed ontology publication via documentation generation (Li, Garijo and Poveda-Villalón, 2025). Existing work primarily focuses on generating Competency Questions (CQs) (Rebboud et al., 2024, 2025) and transforming ontology structures into user-facing documentation. In biomedical domains—often more mature than the built environment, researchers have developed specialized tools to enhance accessibility. For example, Giri et al. (2024)Gene Ontology (GO proposed GO2Sum, a model that converts complex lists of Gene Ontology (GO) terms into human-readable functional summaries, improving both usability and interpretability. Complementing this, Norouzi et al. (2023) introduced alignment explanation generation as a novel use of LLMs, enabling experts to provide feedback that informs model refinement through prompt tuning or few-shot updates. These approaches collectively point toward the future of ontology systems that are not only machine-readable but also meaningfully explainable to human users.

3. Performance Comparison of LLMs and Prompting Strategies in Ontology Matching

To explore the adaptability of existing LLM-powered ontology alignment in the context of architectural and urban ontologies, we designed two complementary experiments. Experiment 1 isolates the effect of model version by keeping the prompt fixed, examining whether newer or instruction-tuned models improve semantic alignment. Experiment 2 fixes the model and varies the prompt strategy, evaluating the influence of prompt design on alignment performance. The experimental protocol is presented in Table 1.

Table 1. Overview of Experimental Design

	Objective	Variable Tested
Experiment 1	Explore impact of different LLMs on ontology alignment tasks	Type of LLMs
Experiment 2	Explore impact of different prompt strategies on complex alignment tasks	Type of prompt strategies

Most existing experiments utilize large-sample OAEI datasets and primarily focus on exploring equivalence relationships between ontology entities. However, in real-world engineering applications, subclass and superclass relationships are more prevalent. Therefore, this experiment centres on non-equivalent inclusion relationships, covering the types summarized in Table 2. These relationship types are used to classify semantic mappings in ontology alignment tasks, especially when identifying non-equivalent inclusion relationships.

Table 2 Semantic Relationship Types Between Ontology Entities

Symbolic Form	Description
a ≡ b	a is equivalent to b
a ⊑ b	a is a subclass or subproperty of b

Symbolic Form	Description
a ⊒ b	b is a subclass or subproperty of a
a ⊥ b	a and b are unrelated or disjoint

Note: a refers to entity1, and b refers to entity2

3.1 The Selection of LLMs and Prompting Strategies

To systematically compare LLMs for ontology alignment, we selected four models based on two criteria: (1) demonstrated performance in recent studies on semantic alignment and reasoning, and (2) diversity across commercial and open-source paradigms. Prior work has evaluated models including GPT-3.5/4, LLaMA, BLOOMZ, FLAN-T5, and Falcon-7B (Hertling and Paulheim, 2023; Li, Garijo and Poveda-Villalón, 2025). Among these, the latest high-performing models from the GPT series have achieved state-of-the-art results in zero- and few-shot alignment tasks involving complex semantics (Macilenti, Stellato and Fiorelli, 2024; Qiang et al., 2025)Stellato and Fiorelli, 2024; Qiang {\\i{}et al.}, 2025. GPT-4.1—the most capable publicly available model in the GPT series during the study period—was selected for its semantic reasoning strength and reliable performance. Claude Sonnet 4, a commercial model from the Claude family, was selected for its balanced trade-off between semantic performance and response latency. LLaMA3.1–8B served as a widely adopted open-source baseline, while DeepSeek-R1 was chosen for its emerging benchmark strength and reasoning-oriented design. Table 3 summarizes all model configurations. The four models were evaluated under a unified prompt and task setup in Experiment 1.

Table 3. Test model version and base information

Model Name	Version	Type	Source / API Access
GPT-4.1	gpt-4.1-2025-04-14	Commercial	OpenAI
Claude Sonnet 4	claude-sonnet-4-20250514	Commercial	Anthropic
Deepseek	deepseek-ai/DeepSeek-R1	Open source	Siliconflow
llama3.1	llama3.1:8b	Open source	Local Deployment

In Experiment 2, we designed five prompt types with progressively increasing levels of contextual and semantic richness, as summarized in Table 4. This categorization was developed with reference to recent classification schemes in prompt engineering research (Macilenti, Stellato and Fiorelli, 2024; Amini et al., 2025; Dang et al., 2025), aiming to evaluate model behaviour under varying degrees of input complexity. Prompt 1 served as a minimal baseline, using only basic instructions to assess the model's default generalization ability. Prompt 2 introduced ontology-level background information, such as the ontology's name, domain, and intended purpose. Prompt 3 incorporated few-shot examples to provide more explicit behavioural guidance. Prompt 4 added syntactic and semantic attributes—including domain and range—to test the model's ability to leverage structured information. Finally, Prompt 5 further enriched the input by integrating lexical features extracted from the ontology's entity structure, namely the comment, definition, and example fields, to support fine-grained semantic reasoning and enhance robustness under potentially adversarial conditions.

Table 4. Overview of Prompt Types Used in Experiment 2

Prompt Type	Description
Prompt 1	Minimal instructions to test default generalization
Prompt 2	Adds ontology background (name, domain, purpose)
Prompt 3	Includes few-shot examples to guide model behaviour
Prompt 4	Combines syntactic cues (e.g., labels) with semantic attributes (e.g., domain, range)
Prompt 5	Further enriches input with lexical features (comment, definition, example) for fine-grained semantic understanding

3.2 Experiment Data

This study employs two types of cross-domain ontology alignment datasets: a series of author-curated alignment modules cantered on the Occupant Feedback Ontology (OFO) (Donkers, de Vries and Yang, 2024); and a set of alignment cases derived from Building Topology Ontology (BOT). The former refers to the alignments between the Occupant Feedback Ontology (OFO) and several external ontologies, including the Building Performance Ontology (BOP), Friend of a Friend Ontology (FOAF), Smart Appliances REFerence ontology for Wearables (SAREF4WEAR), Ontology for Property Management (OPM), and the Semantic Sensor Network Ontology (SOSA/SSN) (Donkers et al., 2021). The latter refers to the alignments between the Building Topology Ontology (BOT) and both the Industry Foundation Classes (IFC) and the Brick ontology.

To introduce varied levels of alignment difficulty, we selected entity pairs from the database where the source and target names are non-equivalent and grouped them into distinct subsets according to their semantic complexity.

Table 5 provides a comparative overview of all alignment datasets used in this study. Among them, OFO-BPO represents the most challenging set, especially due to its inclusion of abstract and dynamic concepts related to communication and sensing. Similar levels of complexity are observed in the OFO-SAREF4WEAR and OFO-SOSA/SSN subsets, which also involve cross-domain and behaviour-oriented semantics. BOT-BRICK and OFO-OPM are categorized as medium-difficulty datasets. These alignments remain largely within the architectural domain and do not exhibit substantial conceptual shifts across domains, though they still involve structural and functional abstraction. Finally, the BOT-IFC dataset is considered the easiest. In this set, many target entity names contain the source entity name as a substring (e.g., IfcBuildingStorey vs. Storey), without being strictly equal. These name-based cues make the alignment more straightforward compared to the others.

Table 5. Ontology Alignment Datasets Overview

Dataset	Classes	Properties	Example Pair
OFO-BOP	0	4	monitors Feedback ↔ performs Execution
OFO-SOSA/SSN	1	2	Wearable ↔ System
OFO-SAREF-4WEAR	2	2	Result ↔ Measurement
OFO-OPM	1	0	Result ↔ Property State

BOT-IFC	5	0	Space ↔ IfcSpace
BOT-BRICK	2	3	contains Zone ↔ has Part

Note: The numbers of Classes and Properties refer to aligned pairs

3.3 Experiment Procedure

The experiment consists of three main stages: (1) environment setup and configuration, (2) data preparation and gold-standard alignment generation, and (3) ontology matching execution. All experiments were conducted in an Anaconda virtual environment. Model variants and prompt strategies were specified via the configuration file, and necessary API keys (e.g., OpenAI) were securely initialized.

This study partially adopts the retrieval module and configuration setup from Agent-OM by Qiang et al. (2025), particularly for extracting syntactic, lexical, and semantic features. To address the high semantic heterogeneity across ontologies and the limited number of reference alignments, we implemented a full-retrieval strategy that exhaustively generates all possible candidate pairs and evaluates them individually to ensure comprehensive coverage. On top of this, we customized the prompt templates and extended the explanation module to support more interpretable and task-specific alignment outputs.

Each experiment run relied on three input files: the source ontology, the target ontology, and a reference alignment file. The ontologies were retrieved from publicly accessible repositories and provided in RDF/XML format. Reference alignments, originally authored by ontology developers, were standardized into Alignment API-compliant XML files and subsequently parsed to generate gold-standard alignment pairs, from which subclass and superproperty mappings were explicitly extracted. We began by applying a baseline prompt (Prompt 1) to evaluate the ontology alignment performance of four representative LLMs. Based on the results, GPT-4.1 demonstrated the most favourable trade-off among accuracy, efficiency, and cost, and was therefore selected for downstream experiments. Subsequently, we conducted a systematic evaluation of five distinct prompt types across six benchmark datasets, allowing for a fine-grained analysis of how prompt design impacts ontology matching performance.

4. Results

This section presents the results of two ontology alignment experiments and discusses the comparative performance of different LLMs and prompting strategies.

4.1 Performance Comparison of Different Models

Across all alignment tasks, GPT-4.1 consistently outperformed other models in terms of F1 score, demonstrating superior robustness in both semantic generalization and relation directionality detection. Claude exhibited comparable precision to GPT yet suffered from reduced recall in structurally divergent pairs such as OFO-OPM and OFO-SOSA. DeepSeek-R1, while capable of identifying general subclass relations, frequently hallucinated symmetric alignments, especially in BOT-IFC and OFO-SAREF4WEAR, where it confused $\sqsubseteq$ with $\equiv$. LLaMA, though lightweight, showed competitive recall in BOT-BRICK, but struggled in abstract property mappings across OFO-centric scenarios.

Notably, precision-recall trade-offs were observed across all models. For instance, Claude exhibited high precision on BOT-BRICK but missed multiple legitimate subclass mappings, leading to low recall. Conversely, DeepSeek's aggressive recall yielded inflated false positives, lowering precision. The OFO-BOP and OFO-OPM tasks proved most challenging, as they required semantic bridging across distinct conceptual layers, such as subjective feedback and operational control, which many models failed to capture reliably. These findings indicate that

current LLMs remain sensitive to ontology lexical divergence and relation asymmetry, and highlight the need for context-augmented, agent-based refinement to achieve consistent alignment performance in multi-domain ontology ecosystems.

4.2 Comparison of Prompting Strategies

To investigate how prompting strategies affect the performance of large language models in ontology alignment tasks, we compared GPT's outputs across six ontology pairs using three prompt types: Prompt 1, Prompt 2, and Prompt 3. Figure 2 illustrates that prompt formulation significantly influences alignment quality, especially in scenarios with structural complexity or abstract semantics. For relatively straightforward alignment tasks, Prompt 1 often led to high recall, retrieving a large number of candidate alignments. However, this came at the cost of reduced precision, particularly due to overgeneration of subsumption and equivalence relations. This trend is evident in ontology pairs such as BOT-IFC, where many predicted matches reflected broad semantic overlaps but lacked precise correspondence.

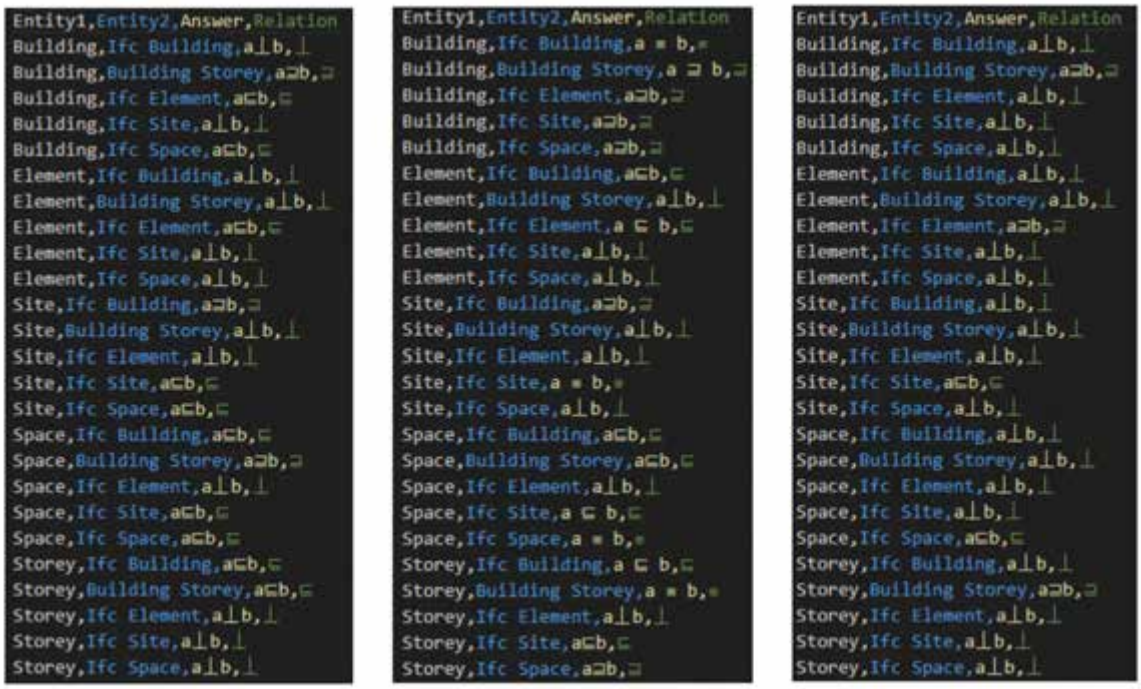

Figure 2. Alignment Outputs under Three Prompting Strategies (Prompt 1 → Prompt 2 → Prompt 3, from left to right)

In contrast, Few-shot prompting improved precision, especially for subclass and part-of relationships. This indicates that GPT was able to effectively learn from curated examples, producing more selective and accurate matches. Nonetheless, minor directional errors were observed in some subsumption cases, suggesting sensitivity to example framing. When Context-enhanced prompts were used, the output pattern resembled that of the Simple prompts: high recall with a large number of inferred equivalence and subsumption relationships. This suggests that while additional ontology context enriches the semantic field, it may also amplify GPT's tendency to generate broader relational assertions, potentially at the expense of specificity.

Overall, Few-shot prompting yielded better balance in precision-recall trade-off for structurally simple align-

ments, while Context-enhanced prompts were more effective in hierarchical or nested ontologies, such as BOT-BRICK and OFO-OPM, where semantic context is essential for interpreting complex relations. These findings highlight the nuanced effects of prompt design and support the inclusion of tailored prompting strategies in ontology alignment systems.

Prompt 1, Prompt 4, and Prompt 5 were compared to evaluate the impact of different types of semantic information on ontology alignment performance. Among them, Prompt 4, which integrates structural and contextual information (e.g., domain, range, hierarchical roles), consistently achieved the highest balanced F1-score, demonstrating its necessity for reliable prediction. In terms of prompt design, Prompt 4 significantly outperformed Prompt 5, particularly in alignment tasks of moderate difficulty within the built environment domain. While Prompt 5 introduces additional annotations and ontology-specific details (e.g., comments, URIs), this extra information occasionally misleads the model, causing it to infer inclusion or equivalence relationships even when entities are only loosely or indirectly related.

As illustrated in Figure 3, entity pairs such as contains Element and is Location Of were correctly judged as unrelated under Prompt 4. However, under Prompt 5, GPT tended to generate false positive relations, interpreting such pairs as semantically connected due to the presence of shared terms in the textual context. Moreover, in moderate alignment tasks, entity pairs often exhibit partial or ambiguous overlap, making it easy for the model to avoid predicting "unrelated." This behaviour inflates recall but comes at the cost of reduced precision, particularly when weak semantic signals are amplified by prompt structure.

5. Discussions and extended framework for enhanced ontology alignment

5.1 Discussions

The adoption of agent-based design in ontology alignment is not merely beneficial but increasingly necessary. As the complexity of alignment tasks and the scale of ontological data continue to grow, agent architectures offer critical advantages—most notably in modularity, scalability, integration with external reasoning tools, contextual management, and expert-in-the-loop support.

The Agent-OM framework proposed by Qiang, Wang, and Taylor (2025) provides an important starting point by introducing LLM agents for retrieval and matching. However, it lacks a dedicated mechanism for generating alignment context, which limits its ability to capture precise domain semantics and background knowledge. In addition, the capabilities of large language models remain constrained, particularly when addressing abstract or structurally complex concepts. Despite ongoing efforts to enhance automation, human-in-the-loop verification remains indispensable, especially in cross-domain ontology alignment tasks within the built environment. Current approaches still lack robust mechanisms for error correction, result validation, and for ensuring interpretability and traceability throughout the alignment process. As Doumanas et al. (2024) emphasize, while LLMs can significantly accelerate ontology development, expert oversight remains essential to guarantee alignment quality, transparency, and reliability. Bridging this gap calls for standardized benchmarks and hybrid workflows that combine automated alignment with structured expert feedback (Li, Garijo and Poveda-Villalón, 2025).

Finally, although the original Agent-OM architecture supports multi-layer parsing and semantic-syntactic feature extraction, the direct feedback from LLMs tends to be verbose and lacks clarity. It does not generate concise, high-quality explanatory documentation necessary for human interpretation and downstream reuse. Our preliminary experiments using JSON-formatted outputs confirmed the difficulty of interpreting LLM errors in the absence of structured rationale. These findings highlight the need for enhanced tool integration for structured reasoning, tighter expert–LLM interaction loops, and more interpretable output formats.

5.2 An LLM-powered agent framework for enhanced ontology alignment

To address the above, we propose an LLM-powered agent framework for enhanced ontology alignment. The overall architecture and workflow are presented in Figure 4. Building on the architecture of Agent-OM, our extended framework integrates Retrieval and Matching Agents into a centralized planning loop and introduces three additional agents: the Context Agent, which constructs structured semantic context; the Expert Review Agent, which enables multi-level human validation for complex relations such as containment and subclassing; and the Explanation Agent, which generates interpretable alignment rationales and enhanced OWL/XML annotations.

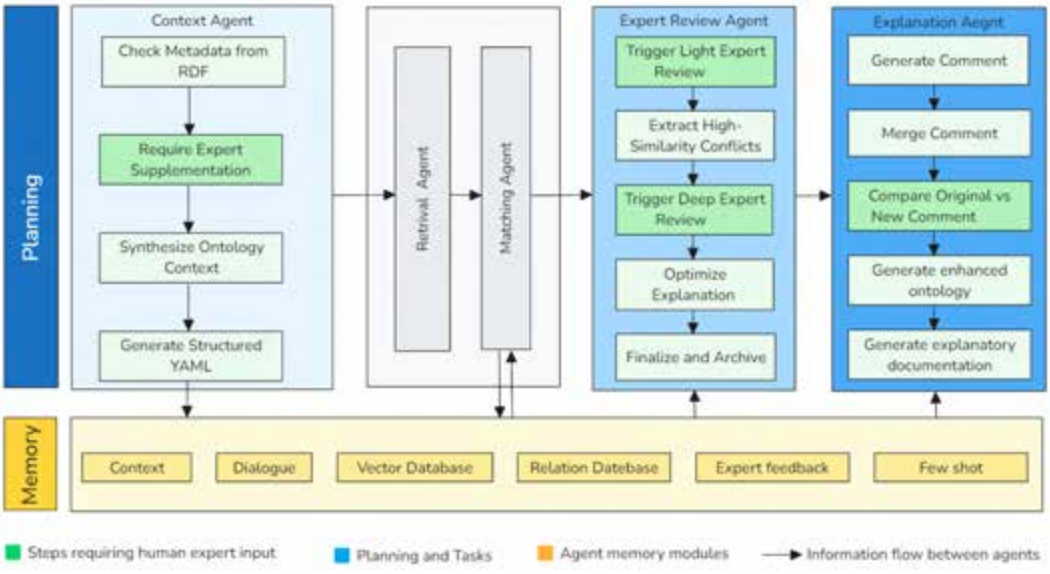

Figure 4. Explainable ontology alignment agent architecture

Note: The system consists of four agent modules: a Context Agent that synthesizes ontology background knowledge, a Retrieval Agent and Matching Agent for candidate generation, an Expert Review Agent for human-in-the-loop validation, and an Explanation Agent that produces revised comments and final documentation.

The Context Agent constructs a complete semantic context to support ontology alignment. It begins by extracting RDF metadata from the source ontology and, if necessary, performing supplementary web searches to enrich missing descriptions. When critical context fields are absent, expert-driven supplementation is triggered. Experts provide additional inputs, including the expected application domain of the target ontology, representative use cases for both ontologies, and the rationale for alignment—that is, why specific components of the source ontology should be aligned to parts of the target ontology. The resulting metadata is stored both in the central database and in the Context Agent's internal memory module, enabling reuse across future alignment sessions and improving contextual continuity.

The Expert Review Agent supports interactive human-in-the-loop validation, including not only equivalence but also complex structures such as containment and subclassing. It conducts both light and deep review stages: the light review focuses on quickly confirming high confidence matches and identifying potential misclassifications, while the deep review targets ambiguous or structurally complex entity pairs. Experts annotate each decision with structured justifications. These justifications are further refined by the LLM to ensure clarity, consistency, and future reusability. Finally, all verified results are archived for use by the Explanation Agent to generate comprehensive alignment rationales. Expert feedback is also stored as potential few-shot exemplars to guide future alignment tasks.

The Explanation Agent transforms validated alignment rationales into structured, human-readable documentation. It first processes the verified results from the Expert Review Agent to generate semantic alignment justifications, which are then merged with existing ontology comments. Experts may review and confirm whether the new comments should overwrite the originals. Finalized annotations are written back into the ontology, resulting in an enhanced OWL/XML version with improved interpretability and traceability. In parallel, the agent compiles an external explanation document, serving as both a human-readable rationale archive and a resource for ontology reuse and future alignment transparency.

5.3. Limitations and future work

Several limitations in the current study warrant further investigation. First, although multiple LLMs were evaluated, the analysis did not encompass some of the most recent models—such as Claude 4 and LLama 4—whose advanced architectures may offer advantages in particular alignment scenarios. Second, the evaluation datasets used in this study primarily basic containment relations. However, ontologies in the built environment often embody more complex semantic structures, including hierarchical constraints, compositional dependencies, and semantic overlaps. Expanding benchmark coverage to include such relation types is necessary to fully validate the utility of the experimental results. Third, additional algorithmic and empirical efforts are needed to determine optimal few-shot configurations and prompt engineering strategies that can improve LLM-based ontological reasoning. The interaction between prompt design, context granularity, and relation types remains insufficiently explored, yet is likely to significantly impact the robustness and generalizability of alignment performance across domains. Furthermore, based on the present framework, we are developing an LLM-powered agent system that operationalizes enhanced ontology alignment through modular planning, expert feedback integration, and explainable output generation.

6. Conclusion

This study investigates the potential of LLMs to support ontology alignment across built environment domains and proposes an agent-based enhancement to address observed limitations. We first conducted systematic experiments comparing four LLMs and five prompting strategies across ontology alignment tasks. The results show that GPT-4.1 achieves a favorable balance between performance and cost, and that prompting strategies significantly influence alignment quality depending on the semantic complexity and structural characteristics of ontology pairs. However, the experiments also reveal that relying solely on prompt engineering is insufficient—particularly for handling complex, ambiguous, or hierarchical relations. In response, we propose an enhanced LLM-powered agent framework that builds on the initial pipeline and introduces three additional agents: a Context Agent for semantic grounding, an Expert Review Agent for human-in-the-loop validation, and an Explanation Agent for generating interpretable alignment rationales. These enhancements improve the interpretability, traceability, and reusability of the alignment process and outputs. Rather than treating alignment as a static, one-time task, the proposed framework supports iterative expert involvement and positions ontology alignment as an evolving semantic asset in complex, multi-domain settings. Rather than treating alignment as a static, one-time task, the proposed framework supports iterative expert involvement and positions ontology alignment as an evolving semantic asset in complex, multi-domain settings.

Abstract
Spatial planning integrates policies to enhance people's well-being globally, yet its effectiveness is constrained in China's flood detention areas (FDAs) balancing flood control and development. Vertically, policy priorities, synergies, and coherence deviate across planning levels. Horizontally, jurisdictional overlaps exist with other management systems. This study employs a comparative approach in China's Huaihe River Basin, analyzing territorial spatial plans across provincial, municipal, and county levels covering nine key FDAs, alongside multi-tiered construction management policies. In-depth fieldwork including resident interviews was conducted in one area. We scrutinize interactions between flood management and spatial planning systems, revealing policy framework characteristics and goal orientation similarities/differences. The research provides insights for optimizing spatial planning and improving well-being in these critical zones.

Keywords: Flood detention areas; Territorial spatial planning; Policy comparison; livelihood

1 Background

1.1 Flood detention areas in China

China's Flood Detention Areas (FDAs) are specialized low-lying zones within river basins designed to mitigate flood losses and redistribute floodwater temporospatial patterns (Yu et al., 2022). They serve dual roles in flood storage and residential livelihood. China's seven major river basins host 98 FDAs (National Revised Directory, 2010). Pre-2000, FDA management was fragmented, with inadequate flood-control infrastructure, emergency response, and post-disaster compensation. Since 2000, integrated policies on flood engineering, population control, and economic compensation have been implemented.

Nevertheless, FDA development faces persistent challenges, notably in the **Huaihe River Basin**. Constrained by frequent flooding and environmental limits, it is a "double-depression" in geographic and socioeconomic terms (Wang, 2018), exhibiting the highest economic/population density yet the lowest urbanization level among China's major basins (Song, 2023). Human-flood land competition is acute. Rural hollowing intensifies yearly, exacerbated by weak transport, substandard infrastructure, and low resource efficiency. These issues accelerate village hollowing, degrade public space resilience, and amplify social vulnerability through population loss. Targeted research and interventions for livelihood security in Huaihe's FDAs are urgently needed.

Spatial planning is a technical and policy instrument for coordinating spatial development and integrating objectives (Xu et al., 2017), functioning as a political governance process (Qian & Luo, 2011) and a mediator of human-environment relations (Zhao et al., 2024). China's spatial planning system, reformed through integrating multiple plans (e.g., land use, urban-rural), now adopts a "five-tier vertical structure (national to township) and three-category horizontal framework (master/specialized/detailed plans)" for territorial spatial planning (Li et al., 2025). This system coordinates socio-economic activities, ecological supervision, and cross-regional infrastructure.

Nevertheless, implementation challenges persist in vertical policy transmission and horizontal coordination, including fragmented departmental oversight, disconnected regulatory tools, and unaligned land-use control procedures (Li et al., 2025). FDAs in the Huaihe River Basin epitomize these issues. As critical flood regulation zones subject to dual planning systems (flood control and spatial planning) (Dong et al., 2016), FDAs bear dual mandates of disaster prevention and regional development, necessitating focused assessment of their planning objectives and outcomes.

1.3 Research focus

Existing studies on China's FDAs predominantly adopt engineering perspectives—covering hydraulic infrastructure, disaster compensation, resident relocation (Bi & Pan, 2024; Wang et al., 2020), land use patterns, social networks, and resilience assessments (Zhang, 2021; Du, 2023)—yet lack systematic analysis of territorial spatial planning. This study fills this gap through a comparative approach: vertically examining FDA management systems, and horizontally comparing multi-level spatial plans across 9 key FDAs in the Huaihe River Basin. The research analyzes similarities and differences in planning priorities, spatial structures, and policy instruments, integrating qualitative policy assessment with quantitative metrics. An in-depth case study of Mengwa FDA—the basin's primary flood buffer—evaluates policy implementation outcomes and resident interactions. Findings inform spatial planning optimizations for people's well-being in FDAs.

The study comprises four sections:

1) Vertical Analysis of the FDAs management system;
2) Horizontal Comparative Analysis of provincial, municipal, and county-level spatial plans for key FDAs;
3) In-depth Case Study of the Mengwa FDA integrating fieldwork findings;
4) Synthesis of Challenges in current management frameworks and proposed optimization strategies.

2.Research Methods

Data were sourced from official portals at multiple governmental levels, including policy documents, technical standards, spatial planning reports, and implementation records. Supplementary data came from interviews with water-resource officials and FDAs residents, focusing on policy implementation dynamics.

The policy analysis employed a comparative framework:

1)Vertically: Examining policy transmission characteristics across administrative tiers;
2)Horizontally: Contrasting goal alignment, priority focus, and content coherence among peer-level policies.

A two-day field campaign in the Mengwa FDA involved structured workshops and semi-structured interviews with local officials and 30 residents. Interview protocols and questionnaires were designed a priori, with follow-up interviews conducted for data triangulation and depth validation.

3. Institutional Framework for FDAs in China

China's FDAs cluster in low-lying plains of seven major river basins. Their management follows a three-tier vertical hierarchy: national - basin/provincial - municipal/county levels, operating through government-led, ministry-coordinated, multi-agency collaboration. Flood control infrastructure is planned, constructed, and managed via categorized, zoned, and tiered approaches under legal statutes and specialized planning instruments (Figure 1).

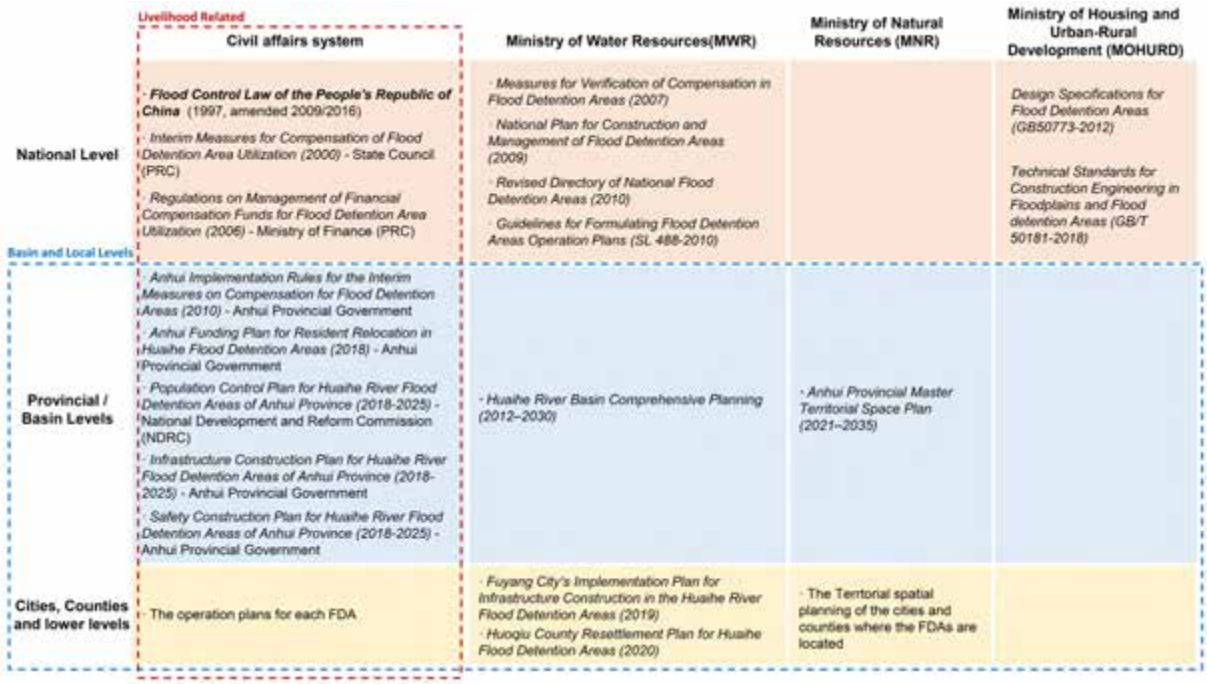

Fig.1 Institutional framework for FDAs in China (Anhui section of the Huaihe River Basin)

3.1 National Policy Framework by Agencies

3.1.1 Supreme Legislation

The Flood Control Law of the People's Republic of China (1997, amended 2009/2016) establishes a three-tier flood planning system (major river basins/other basins or regions/urban flood control), mandating safety infrastructure planning, population growth control, and organized resettlement in FDAs.

3.1.2 Ministry of Water Resources (MWR)

1) National Plan for Construction and Management of Flood Detention Areas (2009): Synthesizes basin-level and provincial plans, with thematic studies on safety construction models, economic development frameworks, and management systems; systematically evaluates flood risk objectives.
2) Guidelines for Formulating Flood Detention Area Operation Plans (SL 488-2010): Specifies requirements for organizational safeguards, early-warning systems, evacuation protocols, and engineering operations.
3) Measures for Verification of Compensation in Flood Detention Areas (2007): Audits compensation procedure compliance, loss data authenticity, and compensation standard rationality.
4) Revised Directory of National Flood Detention Areas (2010): Designates 98 FDAs based on flood risk assessment.

3.1.3 State Council & Ministry of Finance (MOF)

1) State Council: Interim Measures for Compensation of Flood Detention Area Utilization (2000): Defines compensation recipients, scope, and criteria; announces first 97 national Flood Detention Areas.
2) MOF: Regulations on Management of Financial Compensation Funds for Flood Detention Area Utilization (2006): Standardizes fund usage targets, coverage, criteria, and application/approval procedures.

3.1.4 Ministry of Housing and Urban-Rural Development (MOHURD)

1) Design Code for Flood Detention Areas (GB 50773-2012): Requires flood-control works to comply with integrated basin planning and flood control plans, with designs categorized by FDA types and risk levels.

2) Technical Standard for Buildings in Floodplains and Flood Detention Areas (GB/T 50181-2018): Regulates technical requirements for foundations, masonry structures, and reinforced concrete frame buildings.

3.2 Provincial Policy Framework (Anhui Section of the Huaihe River Basin)

3.2.1 Ministry of Water Resources

Huaihe River Basin Comprehensive Planning (2012–2030): Coordinates flood regulation, development governance, and environmental protection to guide construction and management of basin-scale flood control projects.

3.2.2 Civil affairs system

1) Anhui Implementation Rules for the Interim Measures on Compensation for Flood Detention Areas (2010): Issued by Anhui Provincial Government, refines compliance audits, loss verification, and fund supervision procedures for compensation disbursement.
2) Anhui Funding Plan for Resident Relocation in Huaihe Flood Detention Areas (2018): Issued by Anhui Provincial Government, establishes diversified funding mechanisms and implementation pathways for resettlement initiatives.
3) Population Control Plan for Huaihe River Flood Detention Areas of Anhui Province (2018-2025): Issued by National Development and Reform Commission (NDRC), implements population management, resettlement programs, diversified relocation, and supporting infrastructure in 16 designated FDAs along the Huaihe River.
4) Infrastructure Construction Plan for Huaihe River Flood Detention Areas of Anhui Province (2018-2025): Issued by Anhui Provincial Government, standardizes construction tasks, technical criteria, funding allocation, and implementation responsibilities for transportation, power grids, potable water, and telecommunications systems.
5) Safety Construction Plan for Huaihe River Flood Detention Areas of Anhui Province (2018-2025): Issued by Anhui Provincial Government, specifies technical requirements for resident relocation, flood-resistant shelter construction, relocation subsidies, and operational modifications of detention basins.

3.2.3 Provincial Department of Natural Resources

Anhui Provincial Territorial Space Master Plan (2021–2035): Mandates spatial control measures for FDAs within urban-rural coordination frameworks, emphasizing disaster resilience and ecological conservation.

3.3 Local Implementation

Operational plans for FDAs are developed by city/county water resources departments with multi-level government input. Natural resources bureaus formulate territorial spatial plans for localized land-use control. Selected governments enact resettlement plans, e.g.: Fuyang City's Implementation Plan for Infrastructure Construction in the Huaihe River Flood Detention Areas (2019), Huoqiu County Resettlement Plan for Huaihe FDAs (2020), specifying relocation principles, scope, and compensation.

3.4 Systemic Challenges in Flood Detention Governance

China's flood management centers on the Flood Control Law of the People's Republic of China, with national policies coordinating standards and compensation. Local implementations exhibit critical gaps:

1) Regulatory Hierarchy Deficits
The Flood Control Law establishes statutory principles for area operation and safety.
Supplementary regulations (e.g., Interim Measures) lack binding force (Wang et al., 2022).
Poor articulation between basin and spatial plans persists.
2) Fragmented Management Conflicts
Divergent departmental objectives lead to Interest conflicts; Cross-sectoral/regional complexities lead to Coordination failures; Disparate low relocation standards across basins (Table 1).

Table 1 Management Responsibilities and Departments

Management Responsibility	Responsible Authority
Engineering Planning	Basin Agencies + Water Administrators
Flood Operation & Safety Plans	Flood Control Headquarters + Governments
Socioeconomic Management	Local Governments
Spatial Planning	Natural Resources Bureaus + Local Governments

4. Comparative Study of Territorial Spatial Planning

The Huaihe River Basin's 9 critical FDAs are all located in Anhui Province (selected from its 16 total basins), spanning 5 cities and 9 counties (Figure 2 and Figure 3). Divergent planning objectives and priorities emerge from geographical, resource, and disaster exposure variations. This study conducts a comparative analysis of municipal/county plans (Table 2), examining key aspects including livelihood security, disaster resilience, "Three Zones and Three Lines," and agricultural/ecological layouts to identify systemic challenges in spatial planning frameworks and propose targeted optimization strategies.

Fig.2 The 9 key FDAs in the Huaihe River Basin within Anhui Province

Chuzhou-Mingguang		Mingguang Master Territorial Space Plan (2021-2035)	

4.1 Provincial Spatial Planning

1) Three Zones and Three Lines: "Three Zones" refer to Agricultural Space, Ecological Space and Urban Space; "Three Lines" refer to Permanent Basic Farmland Protection Line, Ecological Conservation Red Lines and Urban Development Boundaries. Delineate flood risk control zones incorporating FDAs and riparian lands;

2) Ecological Restoration: Designate Huaihe River ecological recovery zones (Fuyang, Huainan, Bengbu, Chuzhou, Lu'an), enforce riparian flood-control standards, phase out development threatening flood safety, and enhance flood regulation;
3) Settlement Relocation: Relocate high-risk villages;
4) Infrastructure: Expand water storage capacity through basin adjustments, resident relocation, and channel dredging;
5) Regional Coordination: Implement integrated governance aligned with rural revitalization;
6) Heritage Conservation: Strictly protect hydraulic engineering heritage sites.

4.2 Comparative Analysis of Municipal Planning

Municipal planning, as the operational implementation of provincial-level strategies, serves as the foundational basis for county and township-level spatial planning and development activities. The comparative analysis reveals systematic deployment across five dimensions: "Three Zones and Three Lines" spatial patterns, ecological function optimization, agricultural development, infrastructure improvement, and regional coordination.

4.2.1 Three Zones and Three Lines Spatial Layout

Uniform designation of flood risk control lines with strict restrictions on non-flood control construction. Fuyang

and Chuzhou adopt zonal control mechanisms to prohibit irrelevant development, implementing a dual-track approach (dike reinforcement + wetland restoration).

Fuyang and Lu'an emphasize integrated population resettlement and spatial layout optimization, while Huainan innovatively proposes proactive avoidance of high-risk zones in urban development boundaries, reflecting resilience-oriented spatial governance.

4.2.2 Ecological Restoration and Governance
Watershed-based ecological restoration focuses on rehabilitating Huai River wetland systems. Bengbu establishes an "Ecological and Healthy Water Network System," enabling integrated governance of flood storage areas with river-lake-wetland complexes.

Huainan innovates by converting coal mining subsidence areas into flood regulation reservoirs, creating a "subsidence remediation-space expansion" composite model; Fuyang develops watershed-partitioned restoration units to refine systematic governance frameworks.

4.2.3 Disaster Prevention and Infrastructure Support
Standardized flood control and drainage systems are implemented, with Fuyang and Lu'an prioritizing urban-rural resilience through Baizhuangwei construction. Huainan explores integration of mining subsidence remediation with disaster prevention systems.

Bengbu establishes specialized heritage site protection mechanisms, balancing cultural conservation with flood control demands.

4.2.4 Regional Coordination
Optimization of upstream-downstream flood control systems in the Huai River Basin is universally adopted. Fuyang and Huainan construct cross-regional disaster prevention networks to enhance emergency response capabilities; Bengbu and Chuzhou integrate with the Yangtze River Delta urban agglomeration, advancing transportation and economic synergy.

Lu'an innovates inter-regional population resettlement and ecological land ratio optimization mechanisms, offering institutional innovation for regional coordinated development.

4.2.5 Short Summary of Municipal Planning
Municipalities align on flood risk management and ecological restoration objectives, adopting a watershed-based governance framework with rigorous risk zoning to reinforce dual "flood regulation + ecology" functions and promote regional coordination. However, divergent resource endowments and spatial strategies lead to differentiated approaches:

1) Functional Orientation:
Fuyang: Prioritizes flood storage integrity and emergency coordination.
Huainan/Lu'an: Integrates mining remediation with basin-scale ecological coordination.
Bengbu: Balances flood protection with heritage conservation.
Chuzhou: Aligns with Yangtze River Delta eco-economic integration.
2) Utilization Models:
Bengbu/Chuzhou: Focus on wetland restoration and biodiversity enhancement.
Fuyang/Huainan: Expand depression management and multifunctional flood regulation space.
Lu'an: Optimize population resettlement through territorial spatial planning.
3) Regional Coordination:
High-risk dense areas (Fuyang/Lu'an/Huainan): Establish cross-regional flood control networks.

Yangtze River Delta-linked areas (Bengbu/Chuzhou): Promote Huaihe River ecological corridor integration with regional development.

4.3 County-level Spatial Planning

County-level planning refines provincial/municipal territorial spatial strategies, focusing on "Three Zones and Three Lines" patterns, ecological protection, agriculture, infrastructure, and regional coordination in flood storage zones, with most plans emphasizing safety resilience. Panji District, integrated into Huainan City after administrative reorganization, follows municipal planning; Fengyang and Mingguang jointly cover the Huayuanhu FDA, where draft plans remain incomplete and strategies are consolidated at the municipal level.

4.3.1 Three Zones and Three Lines Spatial Layout

Counties integrate along-Huaihe FDAs, rivers, and lowlands into flood control lines under the "Three Zones and Three Lines" framework, enforcing strict regulations and optimizing flood prevention. Upper-middle reaches (Funan, Yingshang, Huoqiu) apply rigid constraints due to high pressure; middle-lower reaches (Shouxian County, Huaiyuan, Wuhu) prioritize ecological restoration with flood engineering.

4.3.2 Ecological Restoration and Governance

Ecological restoration focuses on key areas: Funan's Wangjiaba Wetland, Huoqiu's Chengdonghu / Chengxihu, and Wuhu's Huayuan Lake. Yingshang targets dynamic water balance ("inflow, flow, outflow"); Shou County divides ecosystems into "flood regulation and biodiversity zones"; Huoqiu balances ecology with tourism.

4.3.3 Agriculture Development

Agriculture emphasizes farmland protection: Funan values ecological functions, Huoqiu (grain base) addresses disaster risks, and Wuhu consolidates rural settlements for urban resource concentration.

4.3.4 Disaster Prevention and Infrastructure Support

Disaster resilience includes Funan's Mengwa drainage and irrigation, Yingshang's emergency command centers, Shou County's "sponge city," and Wuhu's integrated water transport-flood engineering.

4.3.5 Regional Coordination

Regional coordination involves Funan/Yingshang in spatial collaboration and Wuhu in Huaihe River eco-economic integration and rural revitalization.

4.3.6 Short Summary of County-level Planning

Counties adopt watershed-based flood-ecology integration, delineate flood risk control lines, and emphasize synergy between flood regulation and ecological restoration. Divergences arise from geographical positions and resource endowments:

1) Functional Priorities:
High-pressure areas (Funan, Yingshang, Huoqiu) focus on infrastructure and disaster resilience, supporting flood storage zone restoration and regional coordination; low-risk areas (Shou County, Huaiyuan, Wuhu) leverage resources for development.
Specific strategies: Funan enhances safety resilience, Huoqiu balances flood control and grain security, Shou County integrates flood prevention with tourism, Wuhu adjusts population/resource layouts.
2) Utilization Models:
Ecology-led (Yingshang, Shou County, Wuhu): Link FDAs with ecological functions via natural/historical resources;
Agriculture-composite (Funan, Huoqiu, Huaiyuan): Balance farmland protection with agricultural expansion.
3) Industrial Integration:
Huoqiu and Yingshang propose "mine remediation + flood regulation + ecological restoration" synergies.

4) Driving Factors:
Topography, resources, and spatial contexts shape strategies, reflecting "pressure-driven" and "resource-oriented" dual logics.

5. Critical Issues in Spatial Planning Systems

5.1 Deficiencies in Vertical Coordination

Provincial plans macroscopically coordinate regional positioning, standards, and resource allocation; municipal plans mesoscopically decompose watershed and FDA functions; county plans microscopically implement engineering solutions. However, three-tier planning faces coordination failures:

1) Insufficient vertical linkage: Cross-regional FDAs lack management division/compensation mechanisms with unstandardized emergency support;
2) Weak horizontal synergy: Provincial ecological restoration zones misalign with local endowments (e.g., no specialized plans for coal mining area restoration in Huainan City and Lu'an City);
3) Functional conflicts: Mengwa FDA simultaneously pursues flood storage and agricultural expansion, while Huoqiu County's grain production base contradicts flood control functions;
4) Priority ambiguity: Unclear hierarchy among ecological restoration, cultural preservation, and flood control.

5.2 Failure of Horizontal Coordination

1) Jurisdictional overlaps: Water authorities lead personnel transfers, but multi-agency responsibility boundaries remain blurred;
2) Data standard conflicts: Temporal gaps between spatial planning (2021–2035) and watershed plans (2018–2025) cause classification inconsistencies;
3) Implementation deviations: Potential policy conflicts during overlapping plan periods (2021–2025).

5.3 Conflicts in Development Goals and Functional Positioning

1) Goal-Implementation Gap:
While current municipal/county plans promote watershed eco-economic integration and safety resilience (e.g., coordinating Huaihe Ecological Economic Belt development, cross-basin water quality protection), critical deviations exist:
FDAs are still treated as monolithic risk sources (e.g., strict construction restrictions within "Three Zones and Three Lines"); Absence of livelihood-oriented policies for public service facilities and agricultural development;Inadequate support mechanisms for underdeveloped areas (e.g., homogenized facility standards in FDAs).
2) Hierarchical Misalignment:
Identical requirements are categorized differently across plans:
Fuyang City, Funan County, Yingshang County, Wuhe County classify flood risk control lines under "Three Zones and Three Lines"; Lu'an City, Huainan City, Huoqiu County, Shou County, Huaiyuan County categorize them as "basic support systems"; Wuhe County integrates rural settlement consolidation into agricultural planning.
3) Divergent Regional Coordination Priorities:
High-disaster areas (e.g., Funan County) emphasize inter-city disaster emergency coordination; Ecologically sensitive zones (e.g., Shou County, Yingshang County) prioritize ecological governance and flood regulation along the Huaihe, reflecting diverse governance needs.

6. Empirical Study of Mengwa FDAs, Huaihe River Basin

As the primary FDAs in the Huaihe Basin (180.4 km²), Mengwa exhibits chronic flood exposure due to topographical depression and high population density. Its operational protocol consists of three phases: 1) Gate opening for flood storage, 2) Months-long water retention, 3) Controlled discharge upon downstream water level reces-

sion. The registered population (2022: 184,900) is concentrated within 131 Zhuangtai (earthen platforms) and 6 Baozhuangwei (embanked settlements), with agricultural predominance. There 2 key questions:

1) Flood impacts: Complete inundation of low-lying farmlands/roads restricts transportation to dam-bridge networks.
2) Livelihood challenges: Structured interviews with 30 residents and governmental stakeholders identified critical gaps in resettlement compensation, employment, and public service delivery.

6.1 Demographic Structural Imbalance

Stringent migration policies promote out-migration while restricting return, with compensation via land exchange and housing support. Spatial planning data reveal:
1) Resident-to-registered population ratio <70% in Funan County (2020),
2) 12 townships exhibiting >40% hollowing rate,
3) 47% of surveyed residents aged ≥60 years, indicating accelerated aging.

6.2 Compensation Mechanism Failure

1) Housing disparity persists:
1960s/1980s resettlement housing remains overcrowded and structurally deficient. New housing projects, co-funded by residents and government based on registered/resident population quotas, achieve merely 28% occupancy (<30% adoption rate despite 62.3% relocation intent). And compensation standards fall significantly below Yellow River floodplain benchmarks.
2) Post-flood recovery deficit:
34.5% of households require structural reinforcement and 27.6% need interior rehabilitation, yet compensation prioritizes agricultural losses.

6.3 Employment-Agriculture Dilemma

1) Limited industrial absorption:
Labor-intensive factories (e.g., Hongliang Bag Factory in Wangjiaba Township: 160 jobs) provide marginal employment.
As for agricultural suppression, prohibition of large machinery (planters/harvesters) to prevent flood damage necessitates manual farming, reducing productivity by 35–40% (estimated).
2) Migration paradox:
While 80% of working-age youth engage in temporary migration, permanent relocation rates remain below 50% due to compensation insufficient to cover actual resettlement costs, and disincentives from forfeiting land revenue streams.

6.3 Public Service Delivery Gaps

1) Allocation inefficiency:
All townships in floodwater detention zones have established health facilities, elderly care centers, and schools per Territorial Space Planning mandates (allocated by administrative divisions or population proportion). However, Funan County's status as Fuyang's lowest public-budget jurisdiction results in: accessibility barriers, quantity-over-quality service provision, and significant service discontinuity between normal and flood periods (Table 2).

Table 3 Flood-Nonflood Service Disparity

Period	Education Access	15-min Medical Coverage
Non-flood	Off-village access required for 55%	56.2%
Flood	Partial school closures	49.2% (Δ=-7.0%)

2) Service accessibility degradation:
Infrastructure underutilization: 50% of nursing homes (3/6) operate on state subsidies. "Three Connections and One Leveling" infrastructure (sanitation/waste/water systems) experiences <40% utilization amid persistent depopulation.

7. Discussion

This study reveals that while China's spatial planning in Huaihe River Basin FDAs exhibits institutional resilience, its effectiveness is constrained by fragmented cross-level coordination, policy fragmentation, and disconnection from livelihood needs.

7.1 Planning Resilience Deficits

1) Vertical implementation gaps: Provincial macro-goals disconnect from municipal/county implementation. For instance, integrated flood regulation-coal mining subsidence restoration-water heritage conservation initiatives lack specialized planning, causing uneven resilience resource allocation.
2) Horizontal coordination failures: Overlapping responsibilities among water resources, planning, and civil affairs agencies reduce efficiency. Absence of standardized cross-city emergency mechanisms undermines disaster response resilience.

7.2 Multidimensional Livelihood Resilience Imbalance

1) Spatial-social resilience disjunction: Overreliance on rigid flood risk control lines neglects dynamic adaptation of public services to population outflow. As Mengwa demonstrates, high housing vacancy and degraded medical/educational services exacerbate social vulnerability.
2) Economic resilience deficiency: Ambiguous industrial positioning and uncoordinated agricultural-ecological functions (e.g., harvesters ban) suppress income growth.

7.3 Pathways for Planning Optimization

1) Strategic innovations:
Multi-scale resilience synergy: Establish a "watershed-administrative region" dual framework to integrate flood control, ecological, and industrial planning, ensuring vertical coherence and horizontal accountability (e.g., aligning spatial and population control planning timeframes).
Dynamic adaptation: Adopt resilience stress-testing tools for iterative planning evaluation.
Livelihood-oriented transition: Embed public service quality (e.g., 15-min medical coverage) and resettlement compensation equity into core assessment metrics.
2) Methodological advancements:
Integrated planning governance: Emulate the Dutch water resilience model (Lu et al., 2020) by coupling water management with spatial planning through multi-stakeholder collaboration.
Specialized livelihood planning: Develop zone-specific strategies for agricultural modernization and emerging industries.

8. Conclusions

Addressing the paucity of systematic research on spatial planning policies for FDAs, this study employed a comparative approach within the Huaihe River Basin. It systematically identified key characteristics and challenges

pertaining to vertical policy transmission and horizontal coordination across provincial, municipal, and county-level territorial spatial plans, contrasting these with the FDA construction and management system. Key findings indicate:

1) Institutional fragmentation, manifesting as vertical transmission gaps and weak horizontal coordination, characterizes China's spatial planning system for FDAs;
2) A predominant focus on disaster risk reduction within both frameworks contributes to multidimensional livelihood resilience deficits;
3) Inadequate integration between spatial planning and construction management systems constrains effective governance, necessitating enhanced institutional coordination with water resources management and flood risk management to advance multi-plan synergy.
From a resilience perspective, future territorial spatial planning must prioritize systematicity, dynamism, and equity. Integrated institutional reforms and technological innovation are essential to catalyze a paradigm shift from «passive flood control» to «proactive adaptation,» strengthening cross-system collaborative governance to achieve the tripartite resilience imperatives of flood safety, ecological restoration, and sustainable livelihoods.

Industry 5.0 as a Tool for Strenghtening Urban Resilience Against Disaster Risks

Abstract
Each Industrial Revolution throughout history has brought about significant economic, social, and spatial transformations, with cities serving as the primary arenas of these changes. This paper investigates how production paradigms shaped by Industry 5.0 in the 21st century may transform urban metabolic systems and contribute to enhancing urban resilience. Introduced by the European Commission in 2021, Industry 5.0 differs from previous industrial models by prioritizing human-centric, sustainable, and resilient production approaches. In this context, urban forms and metabolic structures aligned with Industry 5.0 are expected to offer new frameworks for developing resilient urban environments, particularly in response to crises such as climate change and natural disasters. Through a comprehensive review of the literature on Industry 5.0, urban resilience, and urban metabolism, this study outlines the fundamental characteristics of an Industry 5.0-oriented urban environment and proposes a conceptual model to guide planning and design practices.

Keywords: Industry 5.0, Urban Resilience, Urban Crises, City Planning

1. Introduction

Natural disasters such as floods and earthquakes, which have disrupted economies, ecosystems, and cities worldwide, have been significantly intensified by human-induced environmental degradation. In particular, the growing number of warnings about anthropogenic climate change suggest that humanity may be approaching the sixth mass extinction of life on Earth. In this context, the transition from the "Age of Progress" to the "Age of Resilience" marks a profound philosophical and psychological restructuring in how humanity perceives nature and its place within it (Rifkin, 2022).

The Age of Resilience is characterized by a shift from efficiency to adaptability, from productivity to renewability, from seller-buyer markets to provider-user networks, from centralized supply chains to distributed ones, from corporate conglomerates to high-tech SMEs, from globalization to localization, and from negative externalities to circular systems. In this transformative process, the fact that more than half of the global population now resides in urban areas positions cities as critical actors in shaping this new paradigm.

Industry 5.0 is increasingly considered a key driver in this transformation. This thesis assumes that integrating Industry 5.0—a new phase in industrial development—into urban metabolic processes can enhance urban resilience against disasters.

2. Problem Definition

"Cities are spaces that enable the coexistence, interaction, and integrated functioning of individuals, networks, organizations, and various infrastructure components." (Eraydın, 2022, p.50). With the Industrial Revolution, cities underwent radical changes in scale, and these transformations brought by industrialization became the main driving force of change in the 19th century. As a result, they created the most degenerated urban environments the world had ever seen; cities became overcrowded and unhealthy spaces (Mumford, 1961/2007).

Since then, cities have become both amplifiers of disasters and the places most affected by them. One-third of the world's topsoil has been degraded since the 19th century, and studies suggest that only 60 years of arable soil remain to feed the global population. Moreover, the planet's oxygen levels are depleting at a rate not seen in two billion years. One of the most critical reasons for this is that emissions resulting from global climate change have increased ocean temperatures, leading to the destruction of phytoplankton — one of the planet's primary oxygen sources (Rifkin, 2022).

As emissions driven by climate change continue to raise the Earth's temperature, the frequency of disasters such as floods, hurricanes, and droughts is also increasing. These disasters — whether climate-induced or natural events like earthquakes — affect the sustainability of urban systems and bring the issue of urban resilience to the forefront. The planning approach that Jane Jacobs referred to as "orthodox city planning," which remains in effect today — one that divides cities into distinct functional zones — is considered inadequate in addressing such challenges. Instead, the transformation emerging around Industry 5.0 within urban metabolism is seen as a potential tool to strengthen urban resilience.

3. Disaster Risks

Disasters are defined as serious disruptions in the functioning of a community or society that result in widespread human, material, economic, or environmental losses. These disruptions often exceed the affected community's or society's ability to cope using its own resources. Disaster risk, on the other hand, refers to the potential for such losses to occur in the future, within a given time period and among a specific population. It is shaped by the interplay between natural or human-induced hazards and the vulnerability of the exposed elements (Şenol Balaban, 2017).

In the contemporary era, the majority of the world's population resides in urban areas—a trend that is projected to accelerate in the coming decades. This urban concentration amplifies exposure to hazards, making cities critical arenas for both disaster risk and resilience. Urban areas are increasingly affected not only by acute, high-impact events such as earthquakes or floods but also by slow-onset and cumulative stresses, including heatwaves, water scarcity, and land degradation, which are exacerbated by climate change (Rifkin, 2022).

Moreover, anthropogenic pressures—such as uncontrolled urban sprawl, excessive resource consumption, pollution, and ecological degradation—further erode the resilience of urban systems. These pressures often stem from unsustainable development practices and inadequate planning frameworks. Consequently, cities become more vulnerable to cascading risks, where one disruption (e.g., a heatwave) may trigger or exacerbate others (e.g., energy shortages, health crises) (Gencer et al., 2018).

In this context, enhancing urban resilience requires a shift toward integrative and anticipatory planning approaches that not only mitigate risks but also address the underlying causes of vulnerability. This includes investing in adaptive infrastructure, promoting inclusive governance, strengthening social safety nets, and preserving and restoring urban ecosystems.

An Industry 5.0-oriented urbanization model and production relations—innovative, sustainable, human-centric, and resilient—can serve as a strategic tool in strengthening cities' capacity to cope with crises.

4. Urban Resilience

With the ongoing and intensifying effects of urban crises such as global climate change, it is expected that the world will undergo radical transformations, and that existing ecosystems and settlements will be exposed to these changes. To cope with various shocks that cities may experience—particularly those caused by climate change—the concept of urban resilience has been introduced. To better understand urban resilience, it is helpful to first discuss the broader concept of resilience. The term "resilience" originates from the Latin word resilio, which means "to bounce back" (Klein, Nichols, Thomalla, 2003; as cited in Meerow, Newell, Stults, 2016). In line with this definition, resilient systems are described as structures that maintain functionality in the face of shocks and can rapidly restore systems after disruptions or breakdowns (Bruneau et al., 2003; O'Rourke, 2007; McBain, Wilkes, Ritter, 2010; as cited in Tyler, Moench, 2012). Resilience increases the capacity to cope with encountered challenges and is therefore often considered the opposite of vulnerability (Adger, 2000). The concept of resilience has been adopted by various disciplines. Originally rooted in physics, it was defined as the ability of materials to withstand external forces and maintain elasticity under pressure (Gordon, 1978; as cited in Galderisi, 2014). Later, the term gained prominence in fields such as psychology and ecology. The modern understanding of resilience is often traced back to Holling's work in 1973 (Meerow, Newell, Stults, 2016). Holling's perspective emerged as a critique

of the traditional ecological paradigm put forth by Clements (1936), which claimed that ecosystems possessed a static structure. A review of the resilience literature reveals that different types of resilience have been identified, generally distinguished based on the concept of equilibrium. These include engineering resilience, which is based on a single equilibrium state; ecological resilience, which allows for multiple equilibrium states; and approaches focused on dynamic non-equilibrium (Holling, 1996; Folke, 2006; Davoudi, 2012; as cited in Meerow, Newell, Stults, 2016).

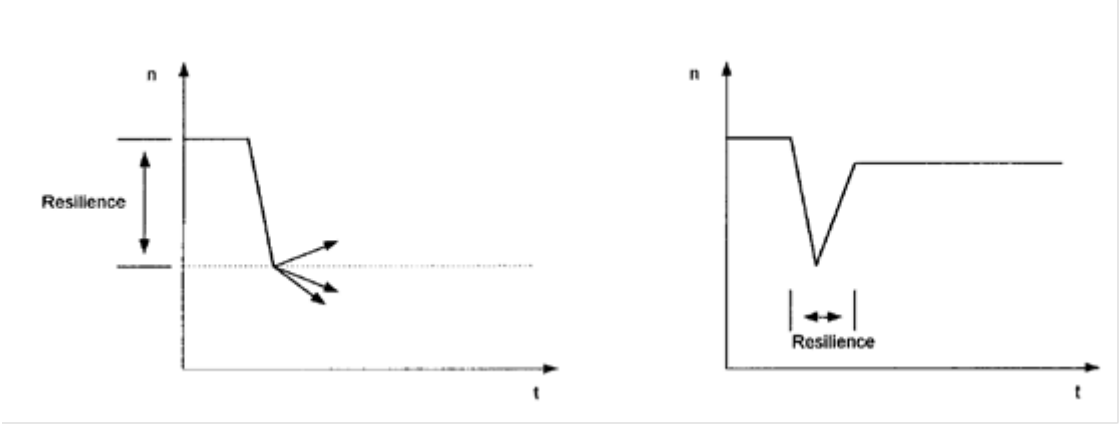

Figure 1 "Resilience Types Based on Different Equilibrium Conditions: Ecological (Left) vs. Engineering (Right) (Adger, 2000)"

As shown in Figure 1, engineering resilience depicted on the right side of the diagram refers to a single-state equilibrium. This understanding of resilience defines the capacity of a system to return to its original or near-original state after a shock or disruption (Holling, 1996; as cited in Meerow, Newell, Stults, 2016). The engineering resilience approach is commonly used in fields such as disaster management, psychology, and economics (Pendall et al., 2010; as cited in Meerow, Newell, Stults, 2016). In this context, resilience is defined as the rate at which a system recovers from disruption (Adger, 2000).

In contrast, the ecological resilience approach argues that systems can have more than one stable equilibrium. According to this view, systems may shift from one stability state to another in response to disturbances (Holling, 1996; as cited in Meerow, Newell, Stults, 2016). Rather than emphasizing the ability to return to a previous state, ecological resilience focuses on understanding how complex, nonlinear, and self-organizing systems respond to change (Berkes et al., 1998; Holling, 2001; Walker et al., 2004; Bankoff et al., 2004; as cited in Galderisi, 2014). Holling (1996) emphasized that while the traditional understanding of resilience in engineering disciplines is based on stability, efficiency, and predictability, ecological resilience refers to a system's capacity to absorb change and continue functioning (Holling, 1973, 1996; Galderisi, 2014; as cited in Meerow, Newell, Stults, 2016).

Beyond these two approaches, the more recent dynamic non-equilibrium perspective suggests that systems do not have a fixed balance and are in a constant state of change (Pickett, Cadenasso, Grove, 2004; as cited in Meerow, Newell, Stults, 2016). In this framework, the concept of resilience moves away from simply "bouncing back" and instead focuses on the capacity of a system to manage change (Matyas, Pelling, 2014; as cited in Meerow, Newell, Stults, 2016).

Based on these dynamic approaches, Holling (1973) developed the concept of resilience to explain the sustainability of ecosystems in the face of events such as fires, droughts, and floods (Marcus, Colding, 2014). In socio-ecological systems, resilience is defined by three core attributes:

- The ability of a system to maintain control over its structure and function despite disturbances,
- The capacity for self-organization,
- The ability to learn and adapt.

• Additionally, other attributes associated with resilience include:
• Maintaining core functions or developing new methods to fulfill them,
• Having backup capacities to meet demands under extreme stress,
• The ability to absorb shocks and disruptive changes (Tyler, Moench, 2012; Marcus, Colding, 2014).

Within this framework, resilience has increasingly been viewed as a strategic response to the impacts of global climate change on both natural and human systems. Resilient systems maintain functionality not through the strength of individual components, but through strengthening and diversifying the functional relationships between them (Tyler, Moench, 2012).

The increasing impact of climate change and other shocks on cities in recent years has affected millions of people and necessitated the development of risk reduction and adaptation policies. As a result, the concept of resilience has entered the urban planning discourse, giving rise to the broader concept of urban resilience, which encompasses issues from infrastructure to basic services (UN-HABITAT, DIMSUR, 2020). Urban resilience is defined as the capacity of especially low-income, marginalized, and excluded populations to survive and thrive amid urban risks (ARUP & Rockefeller Foundation City Resilience Index, 2014). This approach does not solely focus on minimizing losses due to disasters but seeks to enhance system performance against multiple threats. Approaches developed to assess urban resilience can be grouped into four categories (ARUP & Rockefeller Foundation, 2014):

Asset-based approaches: Focus on physical assets (infrastructure, buildings, etc.), but may overlook abstract values (social networks, culture, knowledge, etc.).

System-based approaches: Consider the city as a meta-system composed of social, economic, and physical subsystems, emphasizing inter-systemic and holistic thinking.

Sector-based approaches: Focus on the resilience of sub-systems such as transportation, health, or energy, rather than overall urban resilience.

Performance-based approaches: Emphasize the city's capacity to maintain core functions. This approach evaluates performance as a combination of systems, actors, and practices, while addressing interdependencies across different scales.

According to ARUP (2014), resilient urban systems should possess the following attributes:

Reflectiveness: The capacity to accept uncertainty and change by learning from the past and integrating it into decision-making processes.

Robustness: Well-designed and well-managed structures that can withstand hazardous events without severe damage or loss of function.

Redundancy: The presence of alternative options and backup capacities to ensure functional continuity.

Flexibility: The ability to adapt to changing conditions. This attribute is especially associated with decentralized and modular infrastructure approaches.

5. Industrial Revolutions and Cities

The relationship between the city and production has been inextricably intertwined. The extensive history of the city from the Industrial Revolution to the present can be traced through the changing role of industry within it—from being a driver of growth to becoming a source of political and social upheaval (Lane & Rappaport, 2020). Throughout history, production has constituted a fundamental function of cities and, as such, has consistently

been attributed a privileged position within the urban context. This centrality is also reflected in mythological narratives. For instance, in Greek mythology, the story of Prometheus giving fire to humanity after stealing it from the gods is interpreted not merely as the transfer of a physical element, but as the symbolic transmission of knowledge, technology, and civilization. The gifting of fire represents a significant turning point in human history, enabling people to protect themselves from the cold, cook food, and develop more complex tools and production techniques. In a similar vein, the Industrial Revolutions marked critical historical junctures that radically transformed modes of production and, consequently, had profound effects on urban structures, societal organization, and everyday life. This section examines how the five historical Industrial Revolutions have reshaped production processes and, in turn, reconfigured urban systems.

5.1 Cities Before Industrial Revolutions

Before the emergence of the First Industrial Revolution in the 19th century, cities were essentially small-scale settlements based on a trade economy and a rigid social order inherited from the tradition of feudalism. Sjoberg (1960) presented an idealized model of the social geography of the pre-industrial city. At its core, this model reflects the spatial expression of the division of the pre-industrial city into a small elite and much larger lower classes and marginalized groups (Knox & Pinch, 2010).

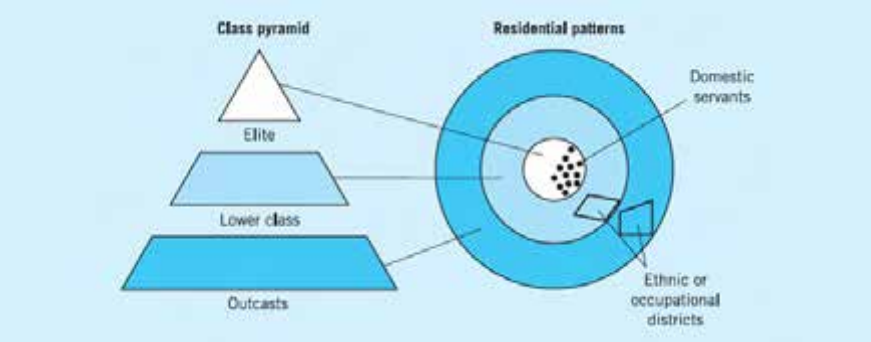

Figure 2 Sjoberg's idealized model of the social and geographical structure of the preindustrial city. (Radford, 1979; akt. Knox ve Pinch, 2010)

As shown in Figure 2, in the pre-industrial city, the elite generally lived around a pleasant and calm central area, while the lower classes and marginalized groups resided in poorly built and waste-filled surroundings. According to Sjoberg, the elite consisted of groups that managed and controlled the city's religious, political, administrative, and social functions (Sjoberg, 1960; cited in Knox & Pinch, 2010).

Although there was no highly diversified population beyond the core area inhabited by the upper classes, lower-class populations did exist. Distinct socio-economic clusters emerged as a result of the spatial coexistence of different types of artisans, and these were reinforced by social organizations such as guilds, which encouraged the spatial clustering of guild members. Poorer, less organized groups within the city — such as ethnic and religious minorities — found themselves in the outer neighborhoods, in expansive yet densely populated areas characterized by substandard and unhealthy housing areas (Knox & Pinch, 2010).

In each occupational district, housing, workshops, and storage spaces were arranged not horizontally, but vertically. Workshops were located on the ground floor, the living quarters of the master's family occupied the floor above, and the uppermost levels housed workers and storage rooms. This model of the city, in which spatial differentiation was dominated by a mosaic of occupational areas, contributed to a second dimension of class and status stratification that was more vertical than horizontal. The pre-industrial city has often been portrayed as a pedestrian city in which everything was physical and the distance between home and workplace was tightly constrained by the patriarchal and familial organization of labor (Knox and Pinch, 2010). In general, pre-industrial cities based on mercantilist production were characterized by a close relationship between workshops

and housing areas. However, with the advent of the Industrial Revolution in the 19th century, urban form began to shift: production areas were organized on the inner periphery of the rapidly expanding city, strategically connected to steam-powered railways and maritime transport systems (Çalışkan & Çağlar, 2023).

5.2 First Industrial Revolution (Industry 1.0)

Revolutions can be defined as major milestones in history. A revolution is a turbulent and transformative event—and a series of actions—that seeks to change a nation, a region, or a society, including its production processes and, more recently, its business world (Groumpos, 2021). The First Industrial Revolution (Industry 1.0) took place in the second half of the 18th century and the early 19th century. It caused profound transformations in production processes, initially in England and then worldwide, significantly affecting economic and social systems (Mohajan, 2019). In England, James Watt invented the first steam engine in 1776, and in the years that followed, the steam engine became a transformative phenomenon across Europe and America (Rifkin, 2022). This transformation is considered the starting point of the Industrial Revolution. With Watt's steam engine being used as the primary source of power, the revolution included the shift from manual to machine-based production, the development of new chemicals, the use of steam and water as main energy sources, the emergence of machinery, and the rise of mechanized factory systems (Groumpos, 2021). Economic historians argue that the onset of Industry 1.0 was one of the most significant developments in human history since the domestication of animals and plants and the beginning of agriculture (Weightman, 2010; as cited in Groumpos, 2021). The innovations brought by Industry 1.0 affected almost every aspect of people's daily lives. For example, by the end of the 18th century, with the dissolution of feudalism in Europe, waves of peasants without land ownership began migrating to cities where industrial production took place. This long-term migration movement gave birth to the urban working class (Koca, 2020). Along with these migrations, agricultural production was pushed into the background, while industrial production came to the fore. The importance of capital and labor in wealth creation was emphasized, and the resulting changes marked a transition from an agricultural and feudal society to an industrial and capitalist one (Rifkin, 2022; Prisceru, 2016; as cited in Kılıç, 2023).

The development of industry and the accompanying migration waves led to profound qualitative and quantitative changes in urban systems, especially in Europe (Benevolo, 1993/2006). For instance, London's population, which was around 1 million at the end of the 18th century, rose to 2.5 million by 1851; Manchester's population, which was around 12,000 in the 1760s, reached approximately 450,000 by the mid-19th century (Benevolo, 1993/2006). However, this rapid urbanization and population growth negatively impacted quality of life; low-income groups and workers were condemned to live in unhealthy and inadequate conditions, while everyday life became dominated by issues such as social inequality, poverty, and social instability (Kılıç, 2023).

When examining the spatial effects of Industry 1.0 on urban areas, it becomes clear that industrialization—the dominant force of the 19th century—created the most degraded urban environment ever seen up to that point (Mumford, 2007). The political foundation of this new type of urban clustering was built on three pillars: the abolition of guilds and thus the dismantling of traditional labor organization, the establishment of an open competitive market for labor and goods, and the acquisition of overseas colonies to supply raw materials and serve as markets ready to absorb the surplus products of mechanized industry (Mumford, 2007). The economic foundations of the new industry in cities were based on the exploitation of coal mines, iron, and the introduction of steam power (Mumford, 2007). Industrial facilities were established in cities close to ports and railway stations, which facilitated access to markets and raw materials, turning them into major destinations for intense rural migration. With innovations in transportation, the movement of people and goods became easier (Sharma and Singhi, 2020). Factories were typically built along rivers or near rail lines leading to rivers, and there was no planning principle aimed at keeping noisy or health-damaging industrial activities away from residential areas (Mumford, 2007).

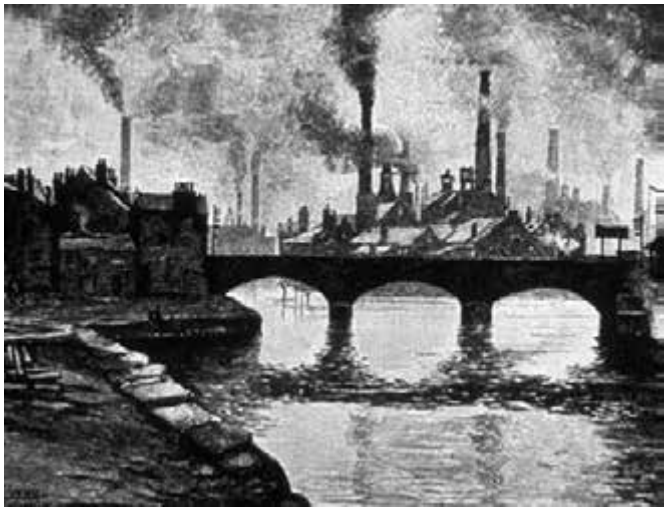

Figure 3 Industrial towns contained many polluting factories [URL 1]

As illustrated in the figüre 3, the placement of production zones in city centers led to inefficient land use, contributing to urban sprawl and traffic congestion. Basic municipal services were often absent in these new industrial towns. A general lack of hygiene prevailed. Deficiencies in access to sunlight, clean water, fresh air, and food were so widespread that they caused significant health and sanitation problems for large segments of the population (Mumford, 2007).

5.3 Second Industrial Revolution (Industry 2.0)

Due to the slow adoption of the original innovations of Industry 1.0—such as mechanized spinning and weaving—and the saturation of markets, an economic stagnation was experienced from the late 1830s to the mid-1840s (Donovan, 1997; cited in Groumpos, 2021). The Second Industrial Revolution (Industry 2.0) began in the 19th century with the discovery of electricity and the development of the assembly line through the use of new technologies (Groumpos, 2021). The United Kingdom, which played the leading role during Industry 1.0, began to give way to countries such as Germany and the United States (Koca, 2020).

Industry 2.0 marks a period during which industrial products developed significantly in terms of both quantity and diversity. The technological innovations of this period include electricity, electronics, mechanical devices, and automobiles (Kılıç, 2023). During this era, the steam engine was replaced by petroleum-based electric vehicles, a defining feature of Industry 2.0 (Koca, 2020). One of the major intellectual architects of this revolution was Frederick W. Taylor. In his book The Principles of Scientific Management, Taylor aimed to place efficiency in production at the center of modern civilization. His ideas, later systematized under the name Taylorism, were based on separating management and planning from the execution of tasks in the production department and subdividing the general production process into simpler parts to increase productivity. This method emphasized the coordination of each subtask and the separation of intellectual and manual labor.

To achieve this, Taylor advocated for the standardization of all worker actions within a work environment in which laborers were not distinguished from the machines they operated, essentially treating workers as an extension of the production apparatus (Koca, 2020; Rifkin, 2022). As a result, a vertically rigid division of labor and hierarchy emerged, leading to a high degree of differentiation in tasks and positions. This allowed for the execution of work by unskilled or semi-skilled labor, reducing businesses' dependency on skilled workers (Koca, 2020).

Two innovators, Henry Ford and Taiichi Ohno, adopted and expanded upon Taylor's theory. Ford pioneered the use of moving assembly lines to meet rising demand, while Ohno, the architect of the Toyota Production System, emphasized product variety by focusing on customer needs (Yin et al., 2018; cited in Çelik, 2023). In the Fordist

system, based on Ford's production technique, a fixed relationship was established between unskilled labor and machinery. The moving assembly line standardized production, increased the number of products per worker, and created economies of scale, ultimately aiming to enhance productivity and profit (Tokol, 2000).

By the 1870s, the use of electricity had become widespread. Technological advancements in production also affected other industrial fields such as iron-steel, chemical, transportation, and other manufacturing sectors (Kılıç, 2023). The significance of electricity grew steadily, beginning with the invention of the electric motor in 1821 and the dynamo in 1831, followed by the telegraph, arc lamp, and ring dynamo. Later innovations such as electric railways, electric blankets and stoves, electric trams, the modern lightbulb, multiphase electric motors, and transformers solidified electricity's critical role (Çelik, 2023).

In the realm of transportation, railways became faster, safer, and more comfortable during the Second Industrial Revolution. After 1870, ships began to be constructed increasingly from steel, enabling the building of larger, stronger, and faster vessels. The invention of the steam turbine in 1884 and subsequent advancements triggered a major revolution in maritime transport. The emergence of interchangeable parts and mass production at the end of the 19th century spurred the development of the automobile industry. By 1914, Henry Ford was selling nearly a quarter-million Model T cars annually. The development of the airplane further expanded the scale of transportation (Çelik, 2023).

With Industry 2.0, advancements in production technology facilitated the widespread adoption of various technological systems, including telegraph and railway networks that had previously been concentrated in a few industrial cities, as well as infrastructure for gas and water supply and sewage systems (Groumpos, 2021). Along with increasing urbanization, devices such as electric lighting, radio, and the telephone transformed how people lived and communicated. These innovations have led to the perception that the modern world was realized through Industry 2.0 (Groumpos, 2021).

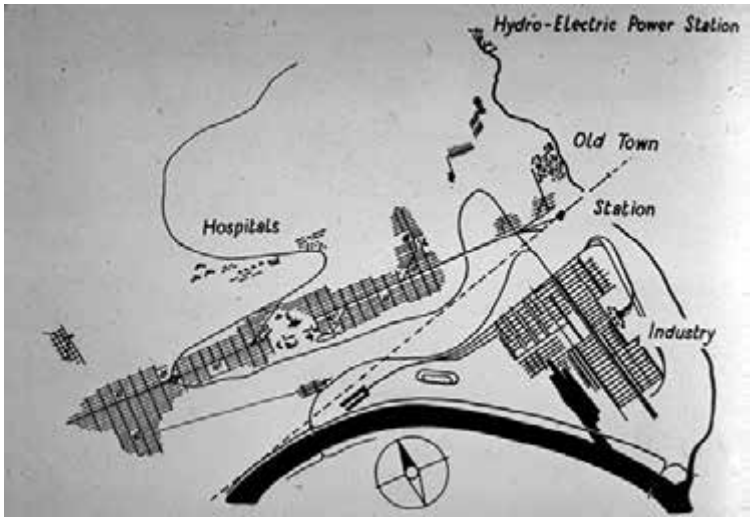

Figure 4 Tony Garnier's La Cite Industrielle Model [URL 2]

The urban planning approach that emerged during this period primarily aimed to respond to the urban problems caused by the First Industrial Revolution and to enhance production efficiency (Eraydın, 2022). As illustrated in the model developed by Tony Garnier—La Cité Industrielle—a city designed between 1899 and 1904 envisioned a settlement for 35,000 inhabitants. In this city, four essential functions were designated: living, working, recreation, and health, which were reflected in designated residential areas, industrial buildings, train stations, and other necessary public facilities. The model emphasized the physical integration of these functions through pedestrian pathways and transport systems, while ensuring industrial facilities were located close to energy sources and transportation infrastructure as a core principle (Eraydın, 2022).

Following the 1929 economic crisis, serial/Fordist production necessitated a redefinition of the urban-industry relationship. During this period, the Keynesian theories introduced by John Maynard Keynes also influenced the approach to the city. Contrary to the classical economists like Adam Smith—who dominated the previous era and emphasized the primacy of individual interests over societal ones—Keynes advocated for a greater role and function of the state in the national economy. He argued that the state should play an active role in ensuring efficient resource allocation, promoting economic development, maintaining price stability, achieving full employment, and establishing a more equitable income distribution (Yılmaz, 2009; Rifkin, 2022). These ideas also transformed perspectives on urbanism and planning.

Another urban approach related to the Second Industrial Revolution emerged through the CIAM (Congrès Internationaux d'Architecture Moderne) meetings held in the 20th century. The urban model discussed in CIAM was a response to the rapid urbanization, unhealthy housing environments, pollution, and congestion brought about by industrial society (Günay, 1988; cited in Eraydın, 2022). CIAM's most significant proposal was to define the city through four primary functions—dwelling, working, recreation, and transportation—and to spatially separate these functions into a distinct urban land use pattern. This approach claimed that by isolating industrial facilities from other urban functions, the environmental, transportation, and complexity-related problems could be mitigated (Eraydın, 2022).

5.4 Third Industrial Revolution (Industry 3.0)

It is acknowledged that the Third Industrial Revolution (Industry 3.0) emerged after the end of World War II, with the development of memory, programmable controls, and computer technology, leading to partial automation (Groumpos, 2021). Unlike Industry 1.0 and Industry 2.0 in terms of quality, the core components of Industry 3.0 include the internet, information and communication technologies, digital communication, and microelectronics, among others (Koca, 2020). Following the advancement of these technologies, the entire production process began to be automated without human assistance. For this reason, Industry 3.0 is also referred to as the automation and digital revolution (Groumpos, 2021; Kılıç, 2023).

The economic crisis of the 1970s marked a shift away from Fordist and Keynesian policies that had dominated the previous period, ushering in an era of neoliberal policies (Eraydın, 2023). Industry 3.0 represents the transition from an industrial society to an information society. During this period, flexible manufacturing systems were introduced to enable shorter production times, more personalized products, and quicker responses to consumer demands (Sharma, Singh, 2020). This process can also be described as a transition from economies of scale to economies of scope.

After the economic crisis of the 1970s, the new production order defining the global economy began to spatially fragment. Less developed countries became integrated into new production chains as subcontracted manufacturers, while deindustrialization processes started to occur in developed countries (Eraydın, 2023). During this time, many labor-intensive manufacturing units with outdated technologies shut down, and vast urban areas—especially those on the urban peripheries that hosted these industries—were abandoned (Eraydın, 2023). In the Industry 3.0 process, supply chains gradually acquired a global character, and no product was produced entirely in one single location anymore (Koca, 2020).

When examining the effects of Industry 3.0 on cities, a duality becomes apparent. In the Global North, considered developed, many large industrial units were shut down, and the number of people living in cities and working in industry significantly declined. To prevent deindustrialization, these cities attempted to create a production order based on knowledge and new technologies. During this period—characterized by the globalization of services and the growing dominance of new service sectors—reduced state intervention in the economy and a return to free market conditions defined a new accumulation regime. These processes led to problems such as rising income inequality, unemployment, and social fragmentation in cities (Eraydın, 2023).

Since the capacities of developing Global South countries were insufficient to fully implement new forms of

production, a dual structure emerged in both production and labor markets. In these countries, while there were mass-production factories and an organized workforce, there also emerged small-scale production enterprises and an informal labor market (Eraydın, 2023). Global South cities, which sought to become subcontracted production hubs in global markets, did not undergo a deindustrialization process; however, they became new playgrounds for capital focused on the real estate sector. During this period, the cities of Global South countries experienced major transformation and destruction due to a construction-led growth model. It is also observed that low-tech industries employing relatively cheap labor compared to developed countries were again located on the urban peripheries (Eraydın, 2023).

5.5 Fourth Industrial Revolution

The Fourth Industrial Revolution (Industry 4.0) was introduced at the 2011 Hannover Fair in Germany as a series of actions by the German government aimed at implementing its high-tech strategies (Xu et al., 2021; Kılıç, 2023). The primary objective of Industry 4.0 is to compete with manufacturing-centered countries such as India and China, and to prevent the outflow of wealth from developed countries like those in the European Union and the United States (Kılıç, 2023). To achieve this, Industry 4.0 is considered a stage that promotes and supports collaboration in production, transitions, and the integration of learning and knowledge flows among different types of manufacturers (Hatuka, Ben-Joseph, 2023).

There are two main reasons behind the emergence of Industry 4.0:

• First, it is the return of factories to their home countries. Following the 2008 economic crisis, many Western countries had shifted production to various countries—especially in the Far East—due to low labor and resource costs. Industry 4.0 represents the process of bringing this production back home.

• Second, the primary impact of globalization on the economy is the liberalization and mobilization of capital. With the liberalization of capital flows, capital tends to move toward countries where it can yield the highest profit (Koca, 2020).

The technological scope of Industry 4.0 is extensive and includes technologies such as cloud computing, the Internet of Things (IoT), artificial intelligence, autonomous robots, and blockchain, all aimed at creating smart factories (Barata, Kayser, 2023). Industry 4.0 has led to the development of cyber-physical production systems that integrate information technology and operational technology within enterprises and supply chains (Grabowska et al., 2022). The trends and impacts of this revolution can be observed across all macro and micro scales of the market.

The core principles of Industry 4.0 can be summarized as follows:

• Service-oriented reference architecture,
• Smart, self-organizing cyber-physical systems,
• Adaptability and flexibility to changing requirements,
• Optimization for overall equipment effectiveness,
• Data integration across disciplines and throughout the entire life cycle,
• Reliable and secure communication between enterprises (Xu et al., 2021).

The rapid increase in the application of Industry 4.0 technologies today and the tendency of businesses to remove human labor from production systems have raised concerns for workers, society, and governments. In Industry 4.0, the working environment is defined by integrated, advanced, and resilient production techniques equipped with sensors monitoring machines and advanced communication systems—rarely mentioning the role of existing workers (Grabowska et al., 2022). The main focus of Industry 4.0 policies is to withdraw human resources from production processes and replace them with autonomous and optimized industrial tools (Koca, 2020). The technologies of Industry 4.0 typically require more knowledge than what is available to engineers,

skilled manufacturers, or the traditionally low-skilled workforce (Rappaport, 2023).

When examining the relationship between Industry 4.0 and cities, it is based on the understanding of cities as innovation ecosystems. The speed and breadth with which cities adopt and distribute technology—supported by flexible policy frameworks—will determine their ability to compete in attracting talent. It is argued that having ultra-fast broadband, using digital technologies for transportation energy consumption and waste recycling, will make cities more livable and increase their competitiveness (Schwab, 2016). Cities can actively invest to create opportunities for digital transformation in order to attract entrepreneurs and investors to innovative ventures, and to encourage established businesses to align themselves with Industry 4.0 opportunities. According to the innovation organization NESTA, the five cities identified as having the most effective policy environments for promoting innovation are New York, London, Helsinki, Barcelona, and Amsterdam (Schwab, 2016).

In Industry 4.0-focused production, a dual structure can be observed in the relationship between cities and industry. The first of these structures refers to the attraction of small producers to urban areas. While large, vertically integrated companies dominated national production in previous industrial revolutions, today's production landscape consists of decentralized networks of small, specialized firms, largely operating in the United States (Rappaport, Lane, 2020). The other structure is characterized by large-scale areas containing standardized industrial buildings and surrounded by various boundaries. Autonomous industrial zones, usually located near infrastructure such as railways or airports, contribute to regional development, but may also compete with and weaken the economies of traditional industrial zones in nearby cities (Hatuka, Ben-Joseph, 2023).

Critics argue that Industry 4.0 aligns with long-term neoliberal capitalist models that emphasize profitability and prioritize shareholders, while intensifying several prevalent social and environmental concerns such as regional inequality, environmental degradation, and the fragility of the global economy (Javaid et al., 2020; cited in Ghobakloo et al., 2022). Automation may particularly have adverse effects on rapidly growing markets and developing countries, as these nations risk losing their comparative advantage in the production of labor-intensive goods and services (Schwab, 2016).

6. Emergence and Development of Indusry 5.0

The COVID-19 crisis that emerged in 2019 clearly demonstrated the need to reassess existing working methods and approaches. This crisis further deepened the vulnerabilities of industrial systems—such as fragile strategic value chains—and increased the necessity for both flexible and robust innovations to address these weaknesses (Breque et al., 2021).

6.1 The Emergence and Definition of Industry 5.0

In this context, the European Commission published a report in 2021 titled "Industry 5.0: Towards a Sustainable, Human-centric and Resilient European Industry" (Xu et al., 2021). Still in its early stages of development, Industry 5.0 has taken shape as a response to the challenges brought about by Industry 4.0, including unemployment, social inequality, and resistance to technological integration (Güdek, 2023). While Industry 4.0 primarily focused on production efficiency and digitalization, Industry 5.0 aims to establish production systems that are human-centric, sustainable, and resilient (Breque et al., 2021).

6.2 Human-Machine Collaboration and Value Proposition

One of the most distinctive features of Industry 5.0 is its emphasis on deeper collaboration between humans and advanced artificial intelligence systems (Nikolov, 2025). This collaboration aims to transform production processes into systems that are not only efficient, but also creative, fair, and capable of promoting long-term well-being (Huang et al., 2022). This vision involves the redesign of operations and supply chains based on principles of resilience, sustainability, and human-centricity (Grabowska et al., 2022; Ivanov, 2022).

6.3 Literature Analysis

As part of this study, a literature analysis was conducted on academic research related to Industry 5.0. A review of the annual distribution of studies reveals a notable increase in publications, particularly after 2020 (Figure 5).

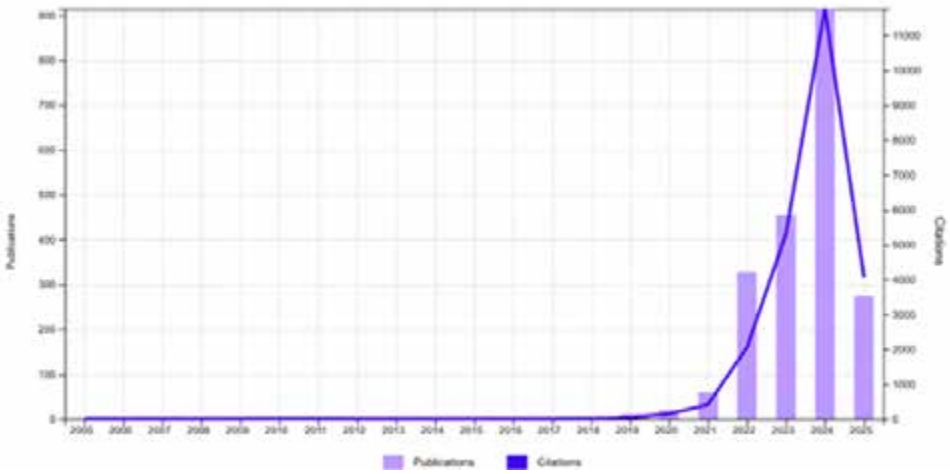

Figure 5 Distribution of Academic Studies on Industry 5.0 by Year (Obtained from Web of Science Data)

Keyword analysis highlights recurring themes such as smart manufacturing, sustainable development, digital transformation, Industry 4.0, and human-centricity (Figure 6).

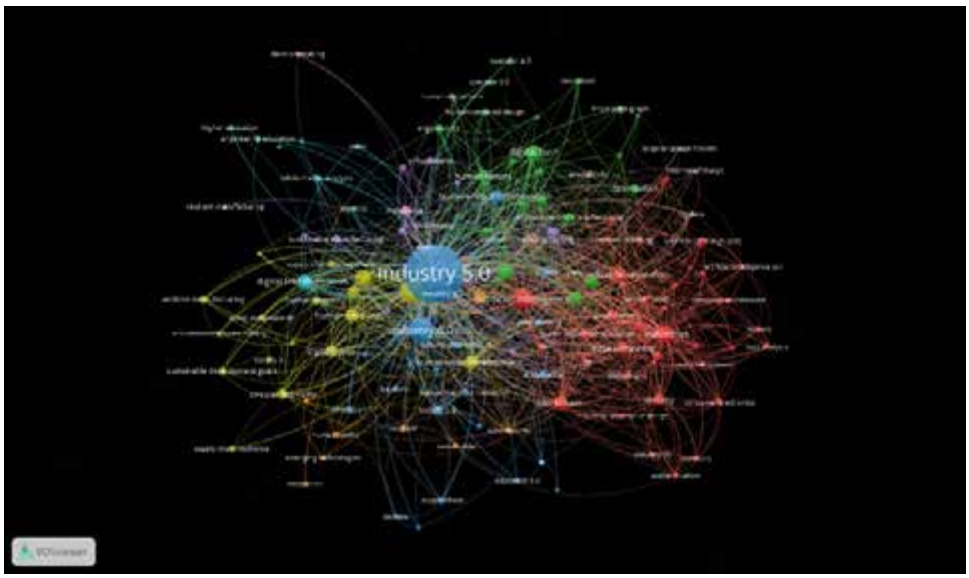

Figure 6 Distribution of Key Concepts Used in Studies on Industry 5.0 (Obtained from Web of Science)

When examining the relationship between these studies and the Sustainable Development Goals (SDGs), it is observed that the most commonly addressed goals are:
Goal 9: Industry, Innovation and Infrastructure
Goal 12: Responsible Consumption and Production
Goal 11: Sustainable Cities and Communities (Figure 7)

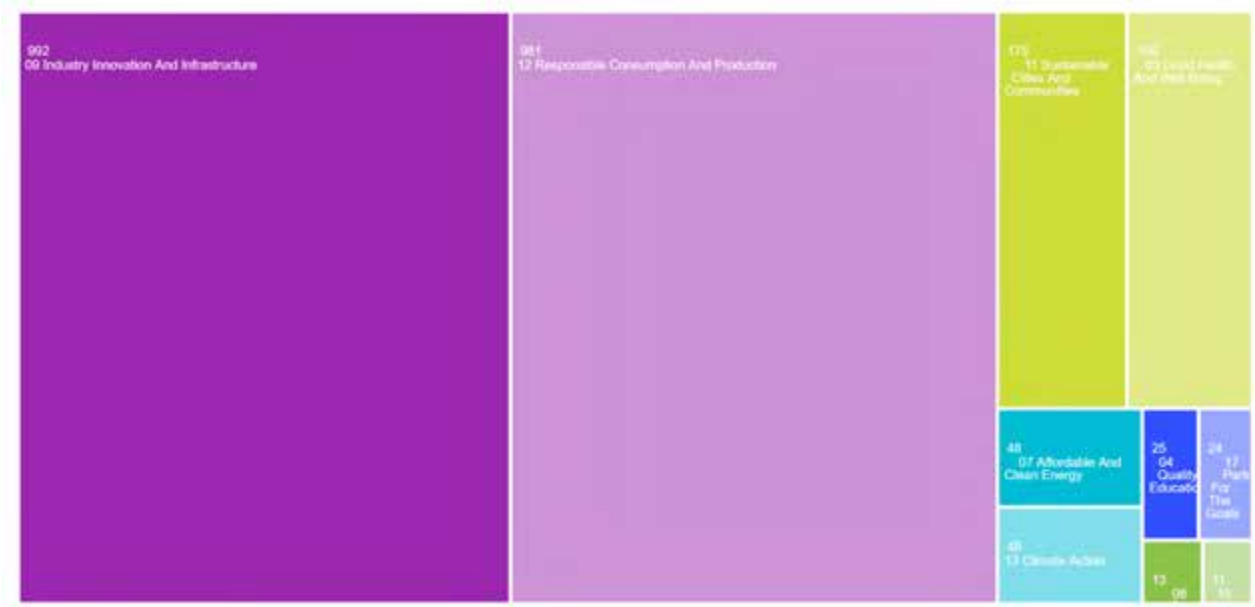

Figure 7 Sustainable Development Goals on Which Industry 5.0 Studies Concentrate (Obtained from Web of Science)

6.4 Relationship Between Industry 5.0 and Cities

The literature review revealed a lack of direct studies addressing the intersection of Industry 5.0 with urban planning and urban design. Therefore, the present study draws insights from existing research focusing on the core principles of Industry 5.0—human-centricity, resilience, and sustainability. Based on these principles, it can be argued that an Industry 5.0-oriented urban development model represents a paradigm shift from earlier urbanism approaches, emphasizing a form of urban circular symbiosis where industrial and urban systems are integrated.

This symbiotic approach particularly refers to the use of urban by-products (e.g., waste) as alternative raw materials or energy sources in industrial activities (Van Berkel et al., 2009). Through such an Industry 5.0-driven urban metabolism, the integration of residential, work, and industrial spaces is encouraged. This integrated model aims to regulate the transition between land uses, promote circularity and supply chain diversification enabled by new technologies, facilitate worker well-being in alignment with the principle of human-centricity, and foster spaces for social interaction (Eraydın, 2022).

In this context, the re-emergence of production activities within cities is gaining traction in novel forms such as maker spaces, innovation districts, vertical urban factories, and fab labs—highlighting emerging patterns of contemporary and future urban production (Lane & Rappaport, 2020). Historically, zoning regulations confined industrial activities to designated areas. However, Industry 5.0-compatible production activities—like 3D printing, laser cutting, small-scale prototyping, and media or film production—are not always compatible with traditional land-use regulations (Lane & Rappaport, 2020).

Therefore, the development of new planning and design strategies is required for spaces where Industry 5.0-based production can occur. These spaces should support fine-grained, mixed-use activities, maximize face-to-face interaction, and creatively resolve challenges related to material flow and building functionality (Lane & Rappaport, 2020). The identified urban design principles for such areas include:

• Street designs should support both the movement of goods and diverse modes of interaction between producers and non-producers.

• Open spaces should be flexible, vibrant, and active throughout the day.

• Edges of the zones should be well-defined yet permeable.

• Spatial configurations should accommodate new living-working relationships, ensuring gradual transitions between factories and adjacent neighborhoods in terms of scale and land use (Lane & Rappaport, 2020).

Elements of urban form—such as street and block networks, public spaces, edges, and adjacency of uses—play a crucial role in shaping the complex and flexible ecology of production (Lane & Rappaport, 2020). The design of Industry 5.0 production areas should ensure access to public transport, dining, and gathering facilities, thereby enhancing the quality of life for workers and realizing the human-centric vision (Lane, 2020).

In terms of resilience, such spaces should be conceptualized as ecosystems with diverse and interconnected supply chains. In times of crisis, flexible and adaptable production capacities can enhance systemic resilience (Ivanov, 2020; Kılıç, 2023). Furthermore, the transformation of production relations and urban systems through Industry 5.0—particularly aligned with the concept of urban symbiosis—points toward the development of circular systems that reuse, repurpose, and maximize resource efficiency, thus contributing directly to the principle of sustainability (Xu et al., 2021).

7. Conclusion

"The world has changed.
I see it in the water.
I feel it in the Earth.
I smell it in the air.

This passage from the beginning of Tolkien's The Lord of the Rings symbolically reflects the paradigm shift we are currently experiencing. Today, one of the most significant driving forces behind this transformation is the increasing frequency and severity of crises and disasters. Cities have become the primary sites where the most devastating impacts of these crises are felt. The fact that more than half of the world's population now lives in urban areas further complicates the issue. This study explores the potential of Industry 5.0 as a tool to enhance the resilience of cities against such crises, and examines the transformations it may bring to urban space. Within the framework of Industry 5.0's three core principles—human-centricity, sustainability, and resilience—it is anticipated that the resulting urban landscape will be more compact, mixed-use, and cyclical in nature.

Industry 5.0 seeks to merge technologies such as artificial intelligence and robotics with human creativity. Unlike previous industrial revolutions, it represents a shift toward placing not only economic growth but also social goals and a non-extractive view of nature at the center of production.Accordingly, in cities shaped by Industry 5.0, the reorganization of living, working, and production spaces is expected to integrate circularity and diversity into everyday life—thereby increasing urban resilience in the face of future crises.

Exploring the Feasibility of Sponge City Solutions for Flood Resilience in Gangnam, Seoul

Dayeon Shin, Taeyeong Kim, Dakota Aaron McCarty
George Maon University
dshin29@gmu.edu tkim68@gmu.edu dmccar6@gmu.edu

Abstract:
Gangnam District in Seoul faces increasing flood risks due to rapid urbanisation, aging drainage infrastructure, and intensified rainfall linked to climate change. This study assesses the feasibility of implementing Sponge City strategies—such as permeable pavements, bioswales, and rain gardens—alongside the Deep Tunnel Sewer System (DTSS) to build long-term urban resilience. Employing a mixed-methods approach, the research combines GIS-based spatial analysis, flood simulation modelling, SHAP-informed risk prediction, and stakeholder engagement through public surveys. Findings identify spatial hotspots for intervention, highlight strong public support for green infrastructure, and underscore institutional and regulatory barriers to implementation. The study proposes a hybrid green-grey infrastructure pathway tailored to Gangnam's urban fabric and contributes to broader debates on integrating nature-based solutions in high-density cities facing complex climate and development pressures.

Keywords: Sponge City; Urban Flooding; Green Infrastructure; GIS Analysis; Gangnam Seoul

1. Introduction

Cities globally face escalating risks from climate change, with urban flooding emerging as a critical threat to infrastructure, public safety, and socio-economic stability (IPCC, 2014). Gangnam District in Seoul, South Korea, exemplifies this challenge. As a dense, economically vital urban area, Gangnam is increasingly exposed to pluvial flooding driven by extreme rainfall events, low-lying topography, and impermeable urban surfaces. The severe inundation of 2022 revealed the district's vulnerability and exposed the limitations of its aging drainage infrastructure and insufficient green space.

While municipal authorities have implemented temporary or reactive responses, these have proven inadequate for long-term risk reduction. There is a growing need to adopt comprehensive, forward-looking approaches grounded in nature-based, adaptive urban planning. This paper explores the feasibility of implementing Sponge City principles—originally developed in China by Yu Kongjian—as an integrated solution for enhancing flood resilience in Gangnam. Specifically, the study investigates how green infrastructure (e.g., bioswales, rain gardens, permeable pavements) can complement grey systems like the Deep Tunnel Sewer System (DTSS), currently under construction and scheduled for completion in 2028.

By combining spatial analysis, simulation modelling, and stakeholder engagement, this research aims to generate actionable insights for sustainable flood mitigation in Gangnam and offer a replicable planning framework for other high-density cities navigating similar climate and development pressures.

2. Conceptual Framework:

This study is guided by a multi-dimensional conceptual framework that connects physical infrastructure with governance, equity, and long-term resilience planning. Drawing from urban environmental planning theory and contemporary practices in climate adaptation, five key pillars form the basis for evaluating Sponge City feasibility in Gangnam:

2.1. Sponge City and Nature-Based Solutions (NbS)

Originally developed in China by Yu Kongjian, the Sponge City concept reimagines urban areas as permeable, living systems that absorb, retain, and filter stormwater much like natural ecosystems (Yu, 2016). As a form of NbS, it incorporates green infrastructure elements—such as bioswales, rain gardens, permeable pavements, and constructed wetlands—to manage water close to its source. These strategies reduce runoff, improve water quality, and deliver co-benefits like biodiversity enhancement, heat mitigation, and improved urban aesthetics (Li et al., 2017). This paper treats Sponge City design not only as a technical solution, but as a new paradigm for ecologically embedded urbanism.

2.2. Hybrid Infrastructure Approaches

While nature-based solutions provide essential ecological functions, they may not suffice alone in compact and heavily built environments. In such contexts, a hybrid approach—combining green and blue systems with traditional grey infrastructure—is needed to provide a multi-layered defence against extreme weather events (Park et al., 2024). The Deep Tunnel Sewer System (DTSS), for example, addresses large-scale runoff and deep storage needs, while decentralised GI interventions help mitigate frequent, less intense rainfall. This dual strategy improves system redundancy and allows for both surface-level adaptation and sub-surface drainage enhancement.

2.3. Urban Resilience and Adaptive Planning

Urban resilience refers to a city's capacity to withstand, adapt to, and recover from climate-related shocks. It is grounded in long-term, systemic thinking and spatial planning that anticipates change rather than reacting to crises (IPCC, 2014). Resilient flood management includes zoning for permeable land uses, regulating impervious surface expansion, and integrating hydrological data into urban planning tools. In this study, resilience is operationalised through spatial flood vulnerability mapping, scenario-based simulations, and identification of adaptive pathways for Gangnam under various future rainfall regimes.

2.4. Stakeholder Engagement and Participatory Governance

Infrastructure interventions are rarely successful without community support and institutional coordination. Meaningful stakeholder engagement—including residents, municipal agencies, planners, and the private sector—can foster local ownership, improve design outcomes, and resolve land-use conflicts (Reed, 2008). Participatory planning helps address socio-political dimensions of urban adaptation and surfaces place-based knowledge that may not be captured by technical analysis alone. In Seoul, where governance complexity and jurisdictional fragmentation are challenges, participatory mechanisms are essential for coordinated Sponge City implementation.

2.5. Planning for Equity and Feasibility

Finally, for any resilience strategy to succeed, it must be socially equitable and practically implementable. Equity involves ensuring that green infrastructure is not disproportionately concentrated in affluent areas, but distributed to benefit vulnerable populations and historically underserved zones. Feasibility includes legal, financial, and administrative capacities to support intervention deployment at scale. In Gangnam, where land is highly contested and built-up, planning for Sponge City implementation requires careful negotiation of regulatory frameworks, financing models, and land-use incentives (Choi and Kim, 2022; Ro and Garfin, 2024).

3. Methodology

To assess the feasibility of Sponge City implementation in Gangnam, this study employed a mixed-methods approach integrating quantitative spatial analysis, flood simulation modeling, and qualitative stakeholder engagement. This approach enabled both predictive modeling of flood risk and an evaluation of institutional and public readiness for green infrastructure adoption.

3.1. Study Area: Gangnam and Seocho 2-dong District, Seoul

Gangnam is a dense and economically significant district in Seoul, characterised by high-rise development, extensive impervious surfaces, and a legacy of inadequate drainage. Its low-lying topography and rapid urbanisation have contributed to repeated pluvial flooding, most notably during the extreme rainfall event of August 2022. As a representative case of high-density Asian urbanism, Gangnam offers both logistical challenges and strategic opportunities for Sponge City interventions.

3.2. GIS-Based Spatial Analysis and Flood Vulnerability Mapping

A Geographic Information System (GIS) database was developed to identify spatial patterns of flood risk and to prioritise zones for intervention. The analysis incorporated the following spatial layers:

• Topography: Digital Elevation Models (DEM) were used to calculate slope, curvature, and flow accumulation.
• Land Use/Land Cover (LULC): Classified surfaces by imperviousness and vegetation cover (e.g., urban, forested, water).
• Hydrology: Existing drainage infrastructure and natural flow paths were mapped to identify hydrological bottlenecks.
• Urban Fabric: Road networks, building footprints, and population density were used to assess urban exposure.
• Flood Records: Spatial extents of the 2022 flood event were digitised and validated with field reports and media documentation.

The Seoul metropolitan area was tessellated using H3 hexagonal grid cells (resolution: ~100 meters per edge) to spatially aggregate and compare variables. Zonal statistics (mean, sum, distance to) were applied to extract attributes for each cell, allowing for flood risk mapping across the district.

3.3. Machine Learning and SHAP Analysis

To quantify the influence of spatial variables on flood vulnerability, a binary classification model was trained using PyCaret, an AutoML framework in Python. The target variable distinguished between cells intersecting 2022 flood extents and those that did not.

After model comparison, a Random Forest classifier was selected for its performance and interpretability. To improve transparency and inform planning decisions, SHAP (SHapley Additive exPlanations) was applied to rank the most influential predictors. Key features identified included:
• **Distance to road:** Higher risk near roads with poor drainage.
• **Building count:** Proxy for impervious surface concentration.
• **LULC_Urban:** Direct correlation with runoff volume.
• **Downstream topography:** Low elevation and slope predict pooling zones.

These results were later cross-referenced with flood simulation outcomes and community priorities to recommend site-specific interventions.

3.4. Flood Simulation Modeling

To evaluate the hydrological performance of proposed interventions, a two-stage simulation was conducted:
1. **Baseline Scenario:** Simulated surface runoff and inundation extent under current land use and infrastructure, using design storm events calibrated from Seoul's rainfall history.
2. **Intervention Scenarios:** Modeled the impact of:
   A. Increased permeable surfaces (via bioswales and pavements)
   B. Rain gardens and vegetated detention zones
   C. The planned Deep Tunnel Sewer System (DTSS)
   D. A hybrid scenario combining green infrastructure with DTSS

Simulations estimated reductions in peak flow, runoff volume, and flooded area for each intervention. These outputs informed feasibility rankings and spatial targeting.

3.5. Stakeholder Engagement and Policy Analysis

To assess institutional readiness and public acceptance, two qualitative methods were employed:
• Stakeholder Consultations: Semi-structured interviews with representatives from the Seoul Metropolitan Government, Gangnam District Office, and environmental NGOs explored regulatory, financial, and implementation constraints. Key themes included jurisdictional overlap, land-use policy gaps, and funding needs.
• Community Survey: A structured survey (n = 35) was administered to Gangnam residents and frequent visitors to assess:
   • Awareness of flood risk
   • Trust in current governance

- Support for Sponge City interventions
- Willingness to contribute financially (via taxes or fees)

Survey data were analysed descriptively and visualised using bar charts and heatmaps, identifying key areas of public support and skepticism.

3.6. Integration of Methods

The mixed-methods design allowed for iterative triangulation between technical and social data:

- GIS and SHAP outputs identified risk hotspots and their physical characteristics.
- Simulation models quantified the expected benefits of nature-based and engineered interventions.
- Survey and consultation findings contextualised the feasibility of implementing these interventions within current governance structures and public sentiment.

Together, these methods produced a robust, evidence-based assessment of where and how Sponge City strategies could be implemented most effectively in Gangnam.

4. Key Findings and Analysis

Empirical Insights on Urban Flood Risk, Mitigation Efficacy, and Public Perception in Gangnam

This section presents the outcomes of spatial flood risk mapping, machine learning interpretation, simulation modeling, and stakeholder engagement conducted in Gangnam District. The analysis highlights key predictors of flood vulnerability, evaluates the relative performance of grey and nature-based interventions, and assesses public support and institutional readiness for Sponge City implementation.

4.1. Spatial Patterns of Flood Vulnerability

Spatial analysis using GIS and H3 hexagonal grids revealed concentrated zones of flood risk in Gangnam, notably around Gangnam Station, Seocho 2-dong, and Yeoksam-dong. These areas are characterised by a combination of high-rise commercial development, minimal green space, and low-lying topography. The spatial overlay of building footprints, elevation data, and known flood extents from the 2022 event confirmed these sites as high-priority targets for intervention.

The vulnerability assessment was further supported by SHAP analysis, applied to a Random Forest classification model trained on spatial features. Among the most influential predictors of flood-prone areas were proximity to roads, building count, urban land cover, and downstream elevation. Areas with high building density and impervious surface coverage were consistently associated with elevated flood risk. Low elevation values in the flow direction also increased the likelihood of water accumulation, confirming field observations. These insights provide a robust empirical basis for targeting green infrastructure interventions and align with broader literature on urban impermeability and runoff generation.

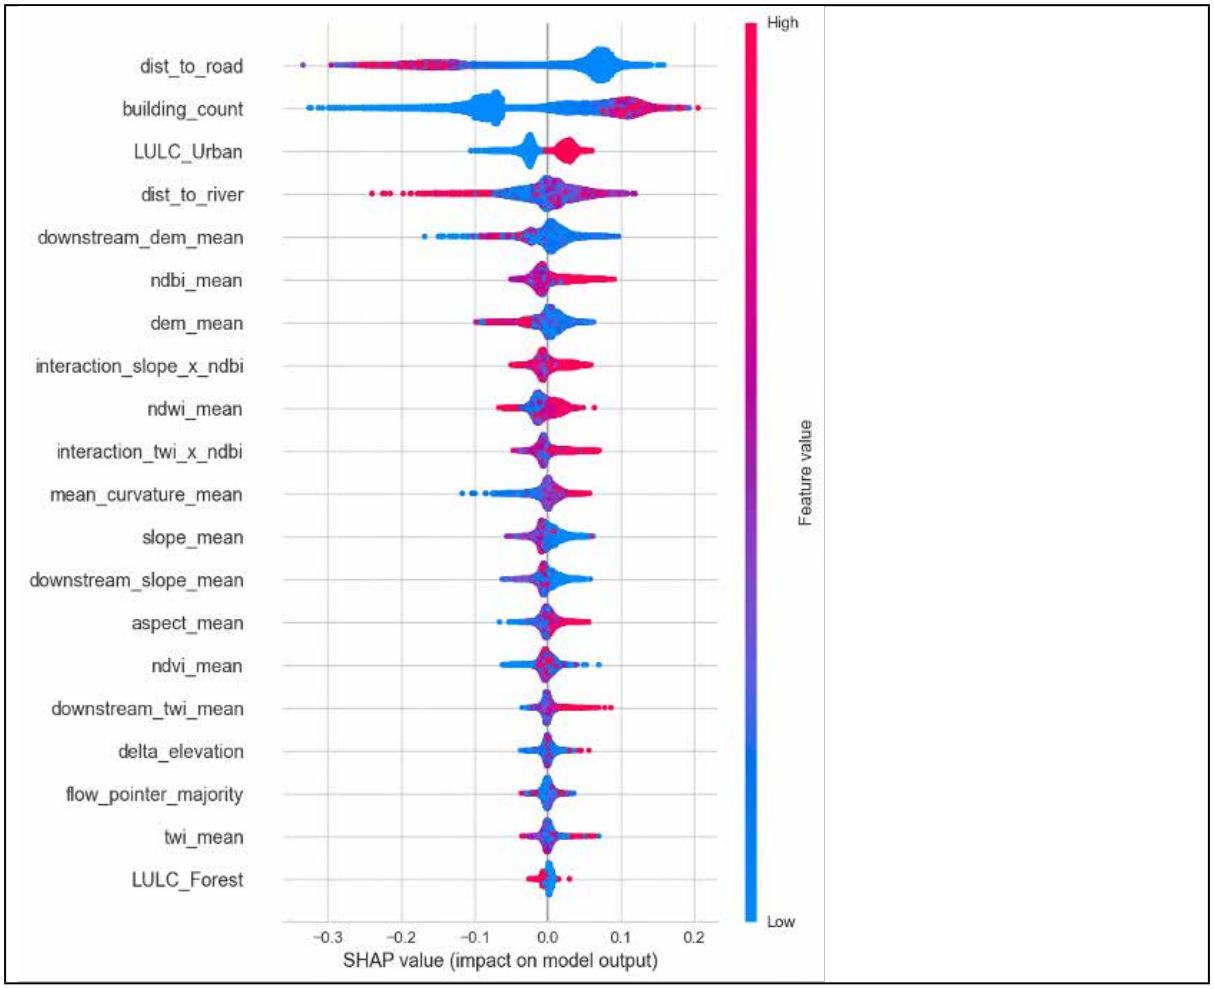

Figure X. SHAP feature importance plot

4.2. Hydrological Performance of Green and Grey Infrastructure

Flood simulation modeling was used to evaluate the projected effectiveness of various intervention strategies under both moderate and extreme rainfall scenarios. In the baseline model, current infrastructure conditions failed to prevent widespread pooling and surface runoff, particularly in low-lying commercial corridors.

Green infrastructure measures, including bioswales, permeable pavements, and rain gardens, were introduced into high-risk zones identified through GIS and SHAP analysis. These decentralized interventions reduced surface runoff volumes by approximately 18 to 25 percent and delayed peak discharge rates, especially during mid-intensity storms. However, their impact was limited in scenarios simulating high-intensity rainfall events.

By contrast, the Deep Tunnel Sewer System (DTSS)—a large-scale grey infrastructure project currently under construction—demonstrated substantial capacity to reduce overall flood extent during extreme events. While the DTSS did not significantly reduce nuisance-level flooding from frequent minor storms, its performance was critical in managing peak loads and preventing basin-scale inundation.

The most promising outcomes emerged from a hybrid scenario integrating Sponge City measures with the DTSS. In this configuration, green infrastructure absorbed and detained runoff at the surface level, reducing inflow pressure on sub-surface systems. This synergy led to a 30 to 35 percent reduction in total flooded area across storm categories. The results support recent scholarship advocating for polycentric, multi-layered flood defense systems in complex urban environments.

4.3. Public Perception and Support for Sponge City Implementation

To complement the technical analysis, a structured survey was conducted with 35 respondents, including both Gangnam residents and frequent visitors. Although only a minority had prior knowledge of the Sponge City concept, a substantial majority supported the general idea of using green infrastructure for flood mitigation once it was explained. Most respondents were aware of Gangnam's flood history, and over half expressed concern about increased flooding in the coming decade.

When asked to evaluate the current flood management system in Seoul, fewer than one in five respondents considered it effective. The most commonly cited shortcomings were insufficient drainage capacity, a lack of urban green space, and inadequate urban planning. In terms of proposed solutions, respondents prioritised expanding the drainage network, increasing green space provision, and adopting climate adaptation policies. Public education and preparedness training also ranked highly.

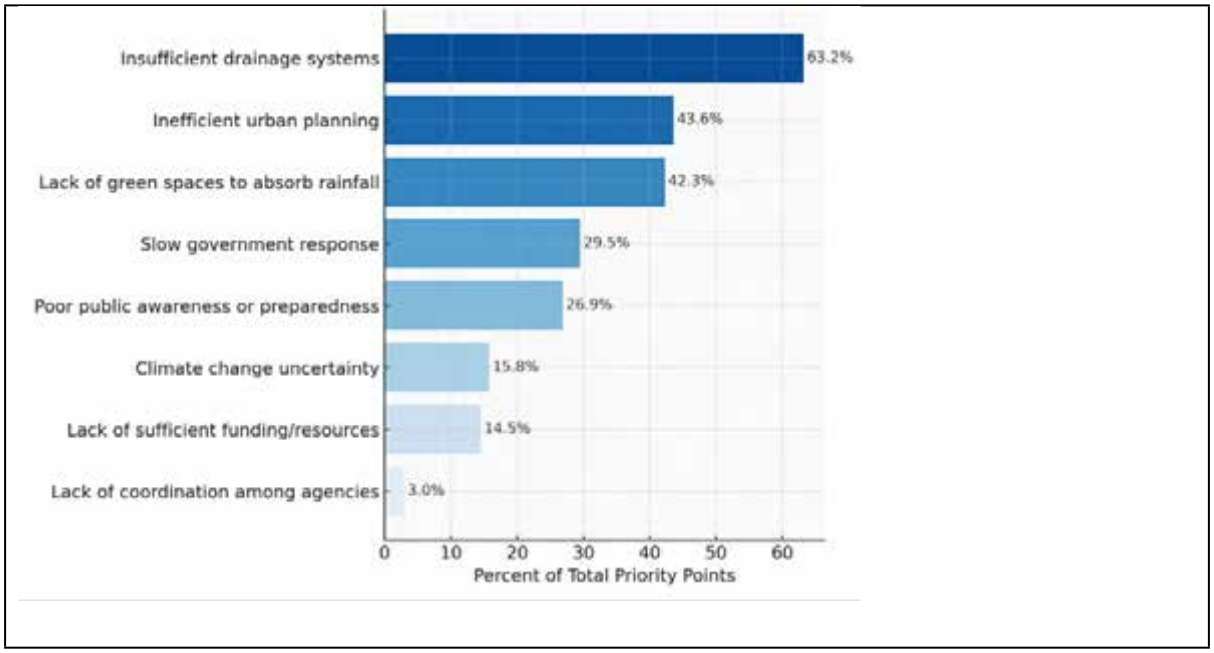

Figure X. Public ranking of top perceived flood management challenges

Crucially, the survey revealed a moderate willingness among residents to contribute financially to flood mitigation initiatives. Around 26 percent of respondents were willing to pay additional monthly taxes to support Sponge City measures, especially when the anticipated benefits were made transparent. However, many remained undecided, citing concerns about cost distribution and governmental accountability. These findings underscore the importance of transparent financing frameworks and communication strategies in securing long-term public support. Among all respondents, willing to pay or not, there was a strong agreeance for permeable payments, which while a strong sponge city intervention, does go against the researchers thinking that respondents would prefer green infrastructure developments. However, that said, as seen in Figure X below, the agreement does remain strong across all levels.

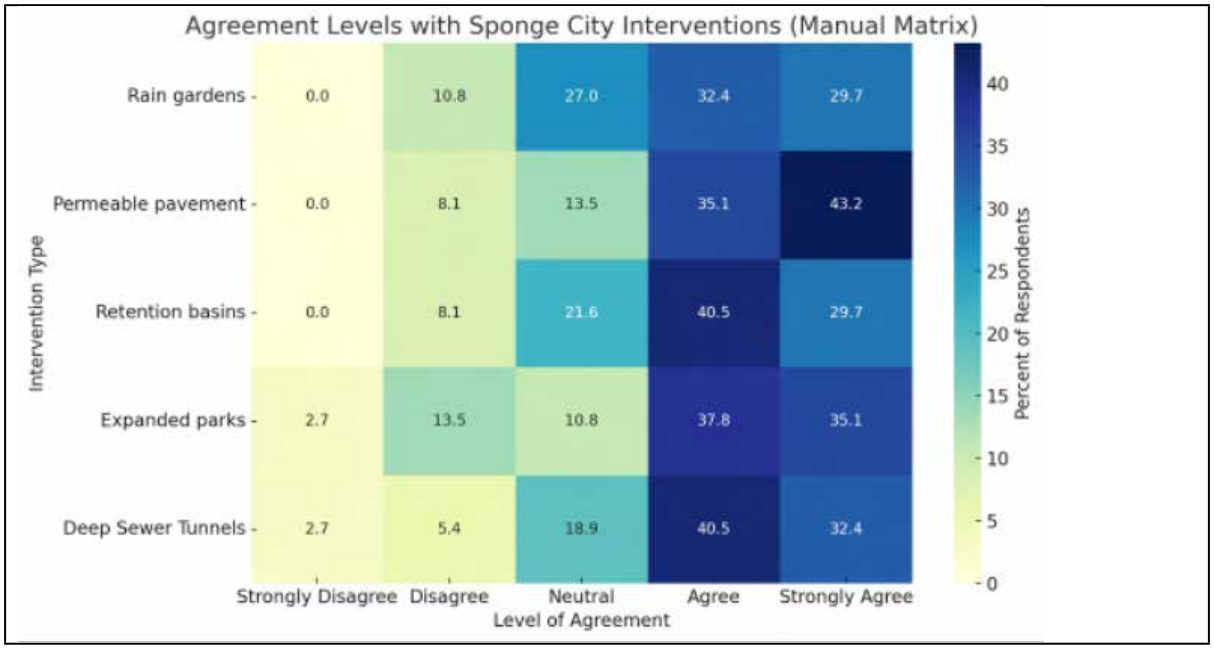

Figure X. Heatmap showing public support for specific Sponge City interventions

4.4. Institutional Readiness and Governance Barriers

Semi-structured consultations with municipal officials and planning practitioners highlighted both awareness of Gangnam's flood vulnerabilities and recognition of the limitations of existing governance structures. Participants cited fragmented responsibilities among departments, difficulties in retrofitting existing developments, and a lack of financial incentives for private developers as major constraints to Sponge City implementation.

While there is growing interest in adopting green infrastructure, current regulatory frameworks do not adequately incentivise or mandate its integration. Additionally, competition over limited urban space and jurisdictional overlaps between environmental and planning authorities present obstacles to coordinated action. Officials noted that without clearer national guidelines or earmarked funding, large-scale implementation of Sponge City strategies would be difficult to operationalise.

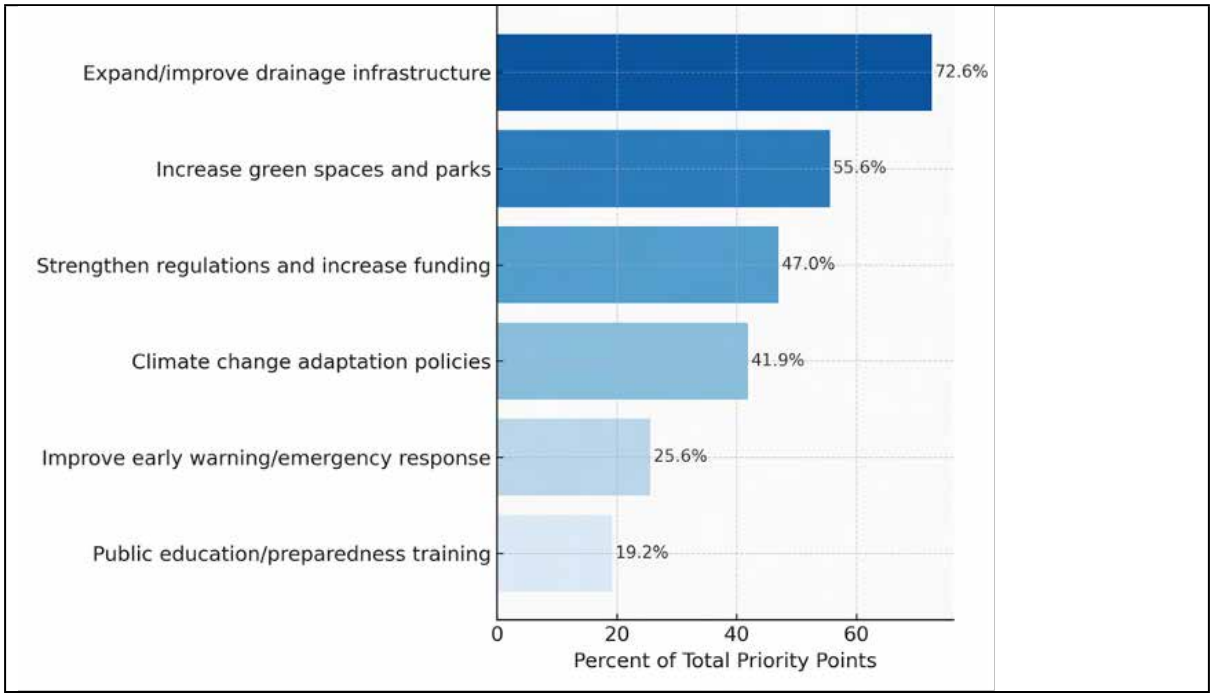

Figure X. Public preferences for improved flood resilience strategies

5. Discussion: Towards a Flood-Resilient and Sustainable Gangnam

The findings from this study provide compelling evidence that a hybrid flood mitigation strategy—integrating Sponge City principles with engineered drainage systems—can offer significant resilience benefits for Gangnam. Yet the success of such a transition is not solely dependent on technical efficacy. It requires coordinated planning, adaptive governance, and deliberate efforts to align infrastructure investment with public values and spatial equity.

5.1. Integrating Green and Grey Infrastructure in Urban Planning

The modeling results clearly demonstrate that neither green nor grey infrastructure alone is sufficient to address Gangnam's diverse flooding risks. While the DTSS is critical for managing large-volume storm events, it cannot address the more frequent, localised floods caused by everyday rainfall. Conversely, Sponge City interventions such as bioswales, permeable pavements, and detention areas are highly effective for mitigating surface runoff, but offer limited benefit during extreme events.

Urban planners should therefore prioritise a dual strategy: allocating large-scale investments toward the DTSS while simultaneously incorporating decentralised green infrastructure across the urban surface. This approach allows for tiered flood defense—absorbing, storing, and diverting water through multiple systems operating at different scales. Priority should be given to retrofitting high-risk corridors near transit hubs and commercial zones, using geospatial analysis to target interventions precisely, rather than implementing social and financing aspects of Sponge City concept uniformly due to Seoul's limited available area. In doing so, urban flood management should transition from a reactive drainage model to a proactive, spatially embedded strategy, to optimize resource allocation and maximize site-specific benefits.

5.2. Addressing Governance and Implementation Barriers

Despite technical feasibility, institutional inertia remains a key barrier to Sponge City adoption. The current division of responsibilities across Seoul's municipal agencies creates fragmentation in planning, budgeting, and execution. This is exacerbated by weak enforcement mechanisms, especially regarding the integration of green infrastructure into private developments.

Policy reform is essential. Urban planning regulations and building codes should be updated to mandate green infrastructure in both new developments and significant renovations. This can be facilitated through density bonuses, development incentives, or mandatory "greensurface ratios" that ensure minimum levels of permeability on each parcel. In dense districts like Gangnam, policies must also account for spatial constraints by allowing green infrastructure to be implemented creatively—e.g., through green alleys, parklets, rooftop gardens, and bioswales integrated into streetscapes.

In parallel, a coordinating body or task force should be established to unify efforts across planning, environment, and transportation departments. Such an entity would be responsible for standard-setting, monitoring, and managing cross-sector funding for hybrid infrastructure. Drawing lessons from European SuDS implementation and China's national Sponge City program, it is evident that without an institutional backbone, green infrastructure efforts tend to remain fragmented and underfunded.

5.3. Financing and Public Engagement as Cornerstones of Resilience

While a portion of Gangnam residents surveyed expressed the willingness to pay for Sponge City implementation, sustained financial support will depend on transparent, equitable, and accountable financing mechanisms. Public trust in local government was moderate at best, suggesting that confidence-building must precede any tax-based funding initiative. Urban planners and city governments must therefore adopt participatory budgeting strategies that involve residents in decision-making and clearly communicate how funds will be used and maintained over time.

Specifically, the external and internal incentives can be implemented by promoting nature-based infrastructure adoption among developers because the Gangnam and Seocho 2-dong district is composed of highly developed buildings. External incentives are divided into financial and non-financial incentives. Crispi and Abubakar (2022) claims that "Economic incentives that can facilitate uptake of adaptation activities include tax waivers, direct grants, municipal property tax rate reduction, tax abatements for infill development". Similarly, the non-financial incentives can be indicated that developers can receive it such as on their construction permission for higher buildings and increased density per land area in exchange for providing something beneficial to the public (Crispi and Abubakar 2022). On the other hand, internal incentives are motivated internally such as human well-being, market demand, and gratification related, which focus on internal motivations, not derived from external factors (Olubunmi et al., 2016).

Beyond financing, citizen engagement is crucial for long-term legitimacy. Planning processes should include mechanisms for co-designing interventions with communities, especially in areas where space is contested or perceived benefits are unclear. Equally, planners must recognise that green infrastructure provides not only environmental and hydraulic benefits but also contributes to public space quality, mental health, and environmental justice—co-benefits that should be integrated into cost-benefit analyses and planning narratives.

5.4. Spatial Equity and the Politics of Implementation

Finally, it is critical to address the unequal spatial distribution of both flood risk and mitigation resources. Green infrastructure should not be concentrated in affluent commercial zones or high-visibility flagship projects, but must be equitably distributed across residential areas, including vulnerable and under-resourced communities. This requires planners to develop spatial equity criteria that prioritise areas with limited existing green space, high exposure, and socio-economic vulnerability.

A resilience strategy that fails to address spatial justice risks reinforcing existing inequalities.The Sponge City framework, if implemented thoughtfully, offers an opportunity to reshape Gangnam's urban form toward a more just, inclusive, and ecologically resilient future.

Furthermore, inconsistency of politics in changing GI infrastructure policies lead to weak GI application. Enforcement policy is needed to enhance and emphasize the GI implementation in the highly urbanized city, Gangnam, offering more rapid and fast putting in GI.

6. Conclusion:

This study has demonstrated that the escalating risks of urban flooding in Gangnam, Seoul, cannot be addressed through conventional grey infrastructure alone. As the 2022 flood event illustrated, Gangnam's dense urban fabric, low-lying geography, and legacy drainage systems render it particularly vulnerable to climate-induced rainfall extremes. To mitigate these risks and build long-term resilience, an integrated approach is needed—one that blends engineered systems like the Deep Tunnel Sewer System (DTSS) with decentralised, nature-based interventions rooted in Sponge City principles.

Through a mixed-methods analysis combining spatial modeling, SHAP-informed feature interpretation, flood simulations, and stakeholder engagement, this research identified both the physical and institutional conditions necessary for effective implementation. Spatial analysis revealed that flood vulnerability clusters around areas of high building density, impervious land cover, and inadequate drainage. Simulation modeling showed that hybrid strategies significantly outperform single-mode interventions, reducing runoff and inundation under both frequent and extreme rainfall scenarios. Survey results and interviews further confirmed public interest in green infrastructure, though tempered by concerns over cost, trust in governance, and policy clarity.

These findings point to three key pathways forward. First, planning policy must mandate and incentivise green infrastructure, not as an aesthetic supplement, but as core urban infrastructure. Second, governance structures must be reformed to ensure inter-agency coordination, regulatory clarity, and implementation capacity. Third, meaningful public engagement and participatory planning processes must be embedded within infrastructure development to ensure legitimacy, equity, and long-term stewardship.

However, the high cost of real estate in Gangnam presents a significant barrier to Sponge City implementation, particularly in securing space for green infrastructure. Therefore, realistic budget analysis and land use strategies are encouraged to be combined. Future studies may include a scenario-based economic analysis that incorporates actual budget items for Gangnam-gu, public-private cost-sharing ratios, and average costs per LID unit installed.

The Gangnam case underscores a broader lesson applicable to many high-density cities across Asia and beyond: resilience is not merely a technical challenge, but a socio-spatial and governance imperative. Sponge City principles offer a powerful framework for rethinking the relationship between water, infrastructure, and urban space—but their success depends on more than design. It demands a planning paradigm shift toward preventative, adaptive, and community-supported systems.

Future research should continue to refine scenario-based planning tools that incorporate both quantitative and qualitative data, evaluate long-term maintenance and life-cycle costs of green infrastructure, and test co-production models that integrate citizens into the design and monitoring of urban resilience interventions. By advancing such interdisciplinary planning approaches, cities like Seoul can move beyond flood response toward transformation—designing not only to survive climate uncertainty, but to thrive within it.

Abstract
As climate change leads to increasingly frequent extreme rainfall events, the risk of urban flooding disasters is rising. Urban areas commonly adopt structural flood control measures to mitigate flood risks. However, this may create a "levee effect," giving residents a false sense of security and promoting development in high-risk areas, ultimately increasing long-term risks. This study takes Tainan City as an example, using a literature review and spatial analysis to identify potential areas affected by the levee effect. A stratified random sampling method is employed for a questionnaire survey, followed by cross-analysis to explore the differences in risk perception among different groups. The research aims to enhance risk awareness, promote practical response actions, and provide references for adaptation strategies and policy planning.

Keywords: Levee Effect, Risk Perception, Adaptive Strategies, Flood Risk Management, Cross-tabulation Analysis

1. Introduction

As climate change increases the frequency of extreme rainfall events, which are becoming increasingly normalized, urban flooding disasters are becoming more severe, directly threatening the safety of residents' lives and property. In response to the rising risk of flooding, urban areas tend to adopt structural flood control engineering facilities, aiming to effectively mitigate the impact during flood events and ensure that cities do not experience flooding.

However, research indicates that these flood-prone areas often create a false sense of security among people, as urban managers rely on structural measures that can show significant improvements in the short term. This leads to the misconception that flood control projects can provide absolute protection while failing to recognize that, in the context of long-term changes due to climate change, the protective standards of flood control projects and facilities have technical and cost limitations. The reliance on structural measures can shift people's perception of flood risk, potentially accelerating development in high-risk areas and ultimately increasing long-term risk. This contradictory phenomenon is referred to as the "levee effect" (Burby,2006; Collenteur et al., 2015).

The Intergovernmental Panel on Climate Change (IPCC) Sixth Assessment Report emphasizes that future adaptation efforts must shift from short-term disaster response and incremental adjustments to the current system to long-term transformative adaptation that can change the fundamental characteristics of social-ecological systems. This also signifies the importance of transitioning flood risk management from structural to non-structural measures. Risk perception, as a subjective assessment of the likelihood of threats and potential damages(Grothmann & Reusswig, 2006)and reduce the need for public risk management. But, research on the determinants of private households' prevention of damage by natural hazards is rare, especially in Germany. To answer the question of why some people take precautionary action while others do not, a socio-psychological model based on Protection Motivation Theory (PMT , is considered a core element in formulating effective flood management strategies (Kellens et al., 2011). Human dynamic behaviour plays a crucial role in flood risk management, and the dynamic changes in risk perception, attitudes, and adaptive behaviour are areas that current research urgently needs to deepen (Bubeck et al., 2012).

Although the concept of the levee effect has been widely discussed, the universality of its impact on changes in risk perception and whether it creates a similar "illusion" for everyone still requires further exploration. Individual differences in conditions, such as education level, age, socioeconomic background, and past disaster experienc-

es, have been shown to significantly influence personal risk assessment(Babcicky & Seebauer, 2017; Grothmann & Reusswig, 2006). In past discussions of the levee effect, it has often been directly concluded that flood control and disaster reduction measures lead to a decrease in risk perception, with less consideration given to how individual differences may play a moderating role in risk perception. As a result, the varying degrees to which flood control measures affect risk perception across different groups may have been overlooked, or it may not be the primary factor influencing their risk perception.

This study aims to re-examine the relationship between the levee effect and risk perception, considering individual differences in areas potentially affected by the levee effect. It explores the cognitive differences among various groups when facing flood risks to develop appropriate adaptive strategies for different groups. The empirical research will be conducted in Tainan, Taiwan. First, a systematic literature review will be carried out to organize relevant risk perceptions and risk measurement indicators from past flood management, which will inform the design of the questionnaire. Second, spatial analysis will be used to identify potential levee effect areas, and a stratified random sampling survey will be conducted in those areas. The survey results will be analysed through cross-analysis to compare the differences in risk perception and influencing factors among different groups. The goal is to promote more precise risk management and flood prevention behaviours in the future, enabling effective responses to flood risks. This can serve as a reference for adaptive management and planning policies, enhancing residents' awareness of flood risks.

2. Discussion on the levee effect and flood risk

2.1 Basic Concepts of Disaster Risk Management

This study takes "disaster risk and risk management" as the core perspective for exploring flood disasters. First, it follows the definitions provided by the United Nations Office for Disaster Risk Reduction (UNISDR, 2016) to define the core concepts.

Table 1: Definition of related terms

Disaster Risk	The potential loss of life, injury, or destroyed or damaged assets that could occur to a system, society, or a community in a specific period of time, determined probabilistically as a function of hazard, exposure, vulnerability, and capacity. 1. Hazard: A dangerous phenomenon, substance, human activity, or condition that may cause loss of life, injury, or other health impacts, property damage, loss of livelihoods and services, social and economic disruption, or environmental damage. 2. Vulnerability: The conditions determined by physical, social, economic, and environmental factors or processes that increase the susceptibility of an individual, a community, assets, or systems to the impacts of hazards. 3. Exposure: The situation of people, infrastructure, housing, production capacities, and other tangible human assets located in hazard-prone areas. Measures of exposure can include the number of people or types of assets in an area. 4. Capacity: The combination of all the strengths, attributes, and resources available within an organisation, community, or society to manage and reduce disaster risks and strengthen resilience. Capacity may include infrastructure, institutions, human knowledge and skills, and collective attributes such as social relationships, leadership and management.

Hazard	A process, phenomenon or human activity that may cause loss of life, injury or other health impacts, property damage, social and economic disruption or environmental degradation. The mere occurrence of a flood event (hazard) does not constitute a flood disaster; only when the flood causes actual damage to social or environmental systems, such as loss of life or property, can it be called a disaster.
Residual Risk	The disaster risk that remains in unmanaged form, even when effective disaster risk reduction measures are in place, and for which emergency response and recovery capacities must be maintained.
Disaster Risk Management	The application of disaster risk reduction policies and strategies to prevent new disaster risk, reduce existing disaster risk, and manage residual risk, contributing to the strengthening of resilience and reduction of disaster losses.
Disaster Risk Reduction, DRR	Disaster risk reduction is aimed at preventing new and reducing existing disaster risk and managing residual risk, all of which contribute to strengthening resilience and therefore to the achievement of sustainable development. Disaster risk reduction can be divided into structural, which includes the application of engineering techniques such as dams and levees, and non-structural, which includes building codes, land-use planning laws and their enforcement, research and assessment, information resources, and public awareness programmes.

2.2 The Levee Effect in Flood-Prone Areas

The "Levee Effect" is a phenomenon of concern in the field of flood management, originating from White's (1958) study on land use in the floodplains of the United States. White pointed out that while flood control projects reduce the frequency of flood disasters, they also create a false sense of security, which encourages urban development and the concentration of population and assets in floodplain areas, thereby forming new potential sources of risk (White, 1958). In the context of industrialization , the sense of security provided by flood control projects has led to the gradual neglect of the fact that "engineering measures have their limits, and residual risks always exist". Therefore, the continuous increase in flood damage is primarily not due to an increase in the frequency or intensity of floods, but rather because flood control projects enhance the value of floodplain locations, leading to urban expansion and increasing the exposure of assets and populations, which in turn raises long-term flood disaster risks(Deeming et al., 2012) .

The "false sense of security" created by flood control projects often stems from an overreliance on these engineering solutions, leading to accelerated land development and urbanization. Under this perception, originally protected areas gradually transformed into "safe" areas, resulting in increased population migration and more prosperous commercial activities (Burby, 2006). Parker and Tapsell (2009) describe this phenomenon as the "Escalator Effect," which means that while flood control measures can effectively manage high-frequency, low-intensity flood events, they may significantly increase disaster losses when low-frequency, high-intensity events occur. Burby (2006) uses Hurricane Katrina's devastating impact on New Orleans as an example, emphasizing that the government's structural disaster reduction strategies and insurance systems have facilitated the expansion of high-risk areas, creating the "Safe Development Paradox," which ultimately exacerbates the severity of disasters.

The levee effect is not limited to the levees themselves; any measures taken through flood control projects to reduce disaster risks may produce similar effects. This phenomenon is commonly observed in floodplains with a "lack of effective land use regulation" (Parker, 1995). Research by Kuo et al. (2015) shows that residents of Benhe Village in Kaohsiung, due to the effective flood reduction provided by a retention pond during Typhoon Morakot,

became complacent about subsequent disaster preparedness. As a result, they faced greater losses during Typhoon Fanapi, confirming that other types of structural flood control measures can also lead to similar outcomes.

In the context of extreme rainfall events caused by climate change, areas with high exposure may face catastrophic losses that exceed expectations when encountering extreme flood events that surpass the design standards of flood control. These areas may experience more severe socio-economic impacts and long-term population effects than unprotected regions.

Therefore, the core issue of the levee effect, in addition to the lack of appropriate and continuous land use management and spatial planning constraints, also highlights the complex dynamic relationship between human society and natural hydrological systems, referred to as "coupled human-water systems." However, existing flood risk assessments often overlook the interactions between human behaviour and hydrological systems, failing to capture the long-term impacts of policies on behaviour and risk dynamics (Kuhlicke et al., 2020)we argue that these changes represent a wider behavioral turn in flood risk management (FRM. Consequently, flood prevention strategies cannot solely rely on single structural measures. From a long-term perspective, contemporary flood risk management must go beyond engineering thinking and shift towards a more comprehensive understanding of risk and adaptive strategies.

2.3 Characteristics of Flood Risk Due to Levee Effects

2.3.1 Harm Reduction

Structural flood control measures primarily target the "harm" aspect of risk, directly reducing potential casualties, property losses, and socio-economic activities by decreasing flood events. As illustrated in Fig. 1, the Farmer's curve is used in disaster risk reduction research to illustrate the relationship between the frequency and intensity of disaster events, which follows a power law distribution and exhibits an inverse relationship. After the construction of flood control projects, the actual disasters that occur will be low-frequency but high-intensity, harmful events. Since such events occur less frequently, there will be a phenomenon of reduced flooding and improvement in the short term (Renaud et al., 2013).

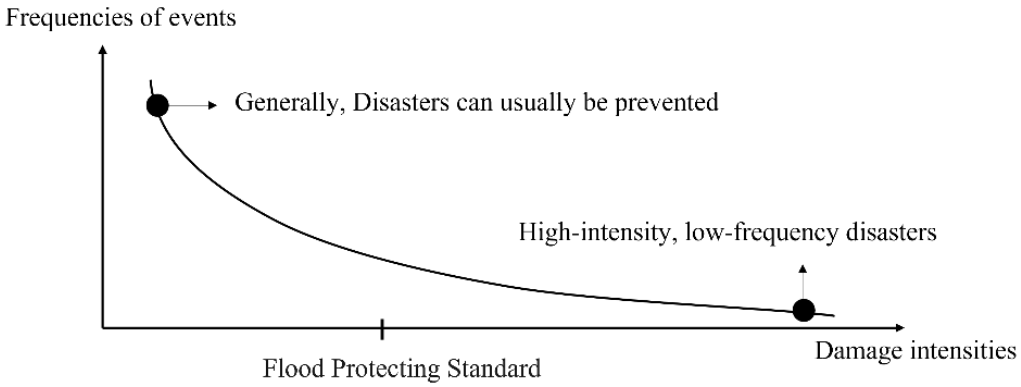

Fig. 1. The Relationship Between Farmer's Curve and Disaster Events

2.3.2 Spatial Concentration and Increased Residual Risk

As flood control infrastructure becomes more complete, floodplain areas may attract more population and development activities, leading to a concentration of risks and the emergence of residual risks. In disaster risk management, residual risk is defined as "the disaster risk that cannot be managed even after effective measures to reduce disaster risk have been taken" (UNISDR, 2016).

The causes of residual risk, based on its operational definition, can be divided into two perspectives: one is that "perfect engineering design and maintenance can eliminate the risks of flood control projects," and the other

is that "there are limits to engineering design standards, and residual risks will inevitably exist in flood control projects" (Chang & Hsu, 2021; Domeneghetti et al., 2015; Pinter et al., 2016)

There is still a lack of understanding and management research on addressing residual flood fronts in studies related to levee effects. However, in flood risk management, residual risks are still challenging to identify independently, which slows down the transfer of knowledge between cases(Wang et al., 2024).

2.3.3 Conceptual Framework and Influencing Factors of Flood Risk Perception
In the integrated flood risk management framework, public risk perception is a key factor in promoting effective disaster preparedness behaviours and enhancing community resilience. Risk perception is not merely a passive reception of objective disaster data; rather, it is a complex and subjective psychological construction process that involves individuals' interpretation and evaluation of the likelihood of a disaster occurring and its potential consequences (Kellens et al., 2011).

Individual flood risk perception is a dynamic and multifaceted process. Traditional approaches often fail to account for the interactions between physical and human systems (Fig. 2, top). They thus cannot fully capture the evolving human responses to and interactions with levee effects. Changes in flood risk should be understood as the result of coupled dynamics between hydrological and social systems, involving continuous interactions and feedback loops between society and the physical environment. The formation and evolution of this perception are influenced by a wide range of internal and external factors (Fig. 2, bottom)(Di Baldassarre et al., 2015), and the heterogeneity of these factors forms the basis of individual differences in flood risk perception(Bubeck et al., 2012; Lechowska, 2018).

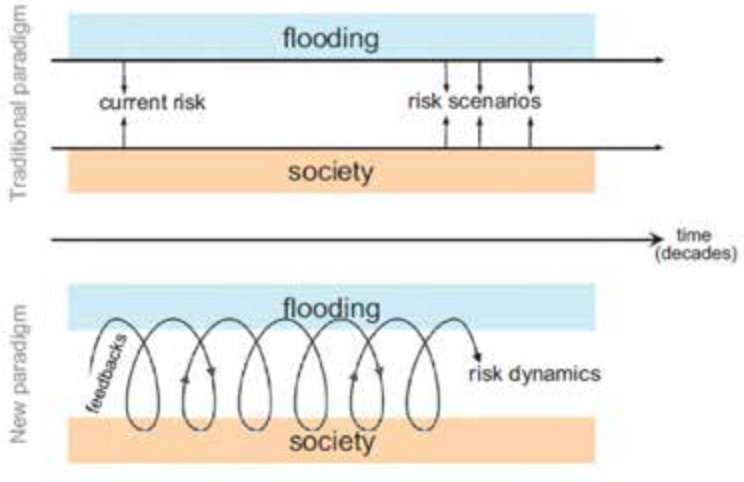

Fig. 2: Changes in Flood Risk
(Di Baldassarre et al., 2015)

Flood Risk Perception Influencing Factors :
a. Experiential Factors
An individual's direct or indirect experience with flooding is one of the most significant influences on risk perception. People who have experienced floods tend to perceive a higher level of threat, exhibit a stronger motivation to take adaptive actions, and consider themselves more vulnerable(Grothmann & Reusswig, 2006)and reduce the need for public risk management. But, research on the determinants of private households' prevention of damage by natural hazards is rare, especially in Germany. To answer the question of why some people take precautionary action while others do not, a socio-psychological model based on Protection Motivation Theory (PMT.

However, empirical studies also show that experience-based risk perception is not fixed—it tends to diminish over time, mainly when no subsequent disasters occur. Individuals may forget past impacts and underestimate future risks (Bubeck et al., 2012; Wachinger et al., 2013).

b. Socio-demographic Characteristics
Variables such as age, gender, education level, socioeconomic status (e.g., household income, occupation, property value), duration of residence, and place of household registration have all been widely shown to significantly influence personal risk assessments (Babcicky & Seebauer, 2017; Lechowska, 2022). For example, individuals with higher education levels are generally better at understanding complex risk information and the scientific basis of flood control infrastructure. Additionally, individuals from different socioeconomic backgrounds vary in vulnerability, resource access, and coping capacity.

c. Geographic and Environmental Exposure
The physical proximity of individuals to potential flood hazards, such as rivers or coastlines, the elevation of their location, and whether they live in officially designated floodplains or hazard-prone areas directly affect how exposed they perceive themselves to be (Ludy & Kondolf, 2012). These objective geographic features are transformed into subjective perceptions through everyday lived experience.

d. Knowledge and Information Access
An individual's knowledge of floods, understanding of the function and limitations of local flood control infrastructure, and awareness of official warnings and disaster preparedness information play a critical role in shaping risk perception. Effective risk communication must translate complex technical knowledge into accessible language for the public to reduce gaps in understanding (Kellens et al., 2011; Merz et al., 2009). Additionally, the credibility of information sources and the mode of dissemination (e.g., government, media, family and friends, or social media) significantly influence information acceptance and perception formation.

e. Social Influence and Social Capital
Social networks, community norms, trust in neighbors, and mutual assistance (i.e., social capital) indirectly influence individual risk perception by shaping how information is exchanged, how experiences are shared, and how collective behaviours form (Babcicky & Seebauer, 2017; De Dominicis et al., 2015). The perceptions of risk held by community members can reinforce each other and lead to collective interpretations.

f. Trust in Disaster Management Institutions
People tend to trust government agencies and experts perceived to possess disaster-related knowledge and to bear responsibility for reducing risk. However, the public often lacks a clear understanding of flood magnitudes and may not recognize the possibility of events exceeding infrastructure protection levels (Bradford et al., 2012). When land within protected areas is no longer officially recognized as flood-prone due to the presence of flood defenses, residents may continue living or working in such areas under the assumption that they are entirely safe. Governments, in turn, use tax revenue to protect these residents(Deeming et al., 2012). This mutually reinforcing relationship can increase public dependency on the government and reduce individual risk awareness.

These diverse and complex factors shape individuals' heterogeneous perceptions of flood risk. This subjectivity explains why the public's perception of risk often differs from the objective risk assessments made by experts based on scientific data(Glaus et al., 2020) . Research on the "risk perception paradox" indicates that people's judgments about risk are often influenced by intuition, emotions, and cognitive biases rather than being entirely rational; disaster risk perception is often composed of complex causal relationships and multiple intervening factors. For example, it is commonly believed that a higher perception of risk leads individuals to take protective actions. However, this is not necessarily true and still depends on various contextual factors, particularly personal memories of past losses or imaginations of disasters, which can influence individuals' actions.

At the same time, people's trust in managers also affects their risk perception (Wachinger et al., 2013). The study

by (Ludy & Kondolf, 2012) pointed out that even when most residents are well-educated professionals, new development projects in flood-prone areas can lead them to be unaware of the real flood risks they face, believing instead that a once-in-a-hundred-years levee can protect them from all floods. Therefore, the perception of flood risk is a complex process that requires a deep understanding of the interactions among these influencing factors.

3. Methodology

3.1 Research design-case study strategy

This study adopts a case study approach that integrates qualitative and quantitative methods, with Tainan City in Taiwan as the empirical study area. As one of the core metropolitan cities in southern Taiwan, Tainan has experienced rapid urbanization and has invested significantly in flood mitigation infrastructure, conditions that make it a likely context for the emergence of the levee effect. Given that the levels of urban development and flood vulnerability vary across districts in Tainan, the study focuses on areas that have experienced severe flood events and exhibit high degrees of urbanization and centrality.

The quantitative analysis aims to assess changes in residual flood risk over time. Spatial analysis techniques are employed to identify the clustering of flood-prone points and examine changes in their spatial distribution. Specifically, global Moran's I is first applied to determine whether spatial clustering of flood events exists within specific periods. This is followed by using Local Indicators of Spatial Association (LISA) to explore local variations in spatial patterns, identifying the spatial relationships between each unit and its neighboring areas. These analyses define the potential spatial scope of the levee effect, within which qualitative questionnaire surveys are subsequently conducted.

3.2 Background of the study area

After the major infrastructure works under Tainan City's 2006 "Flood-Prone Area Mitigation Project" were completed, significant changes in land use and urban development patterns were observed in certain areas, such as Yusheng Village in the East District and Sanjia Village in Rende District. These areas have since been identified as potential zones exhibiting the levee effect (Chang & Hsu, 2021).

In recent years, due to the increasing influence of extreme climate events, statistics from the Water Resources Bureau show that rainfall in 37 districts of Tainan has exceeded the design standards of local drainage systems, resulting in flooding. Moreover, compared to previous typhoon events, the cumulative rainfall over 1-hour, 3-hour, and 24-hour periods in flatland areas has surpassed the levels recorded during Typhoon Morakot—the most recent major flood disaster in Taiwan (see Table 1). This indicates that areas potentially affected by the levee effect also face residual flood risk issues.

Table 2. Accumulated Rainfall from Major Precipitation Events in Tainan (mm)

Maximum Accumulated Rainfall	2009 Typhoon Morakot		2018/08/23 Heavy Rain		2024 Typhoon Koinu	
	plain	Mountain area	plain	Mountain area	plain	Mountain area
1 hour	86.0	107.5	77	92.0	120.0	105.5
3 hour	159.0	286.0	173	195.0	205.0	191.0
6 hour	245.0	417.5	294	316.5	276.0	294.0
12 hour	391.5	692.5	438	458.0	370.5	535.0
24 hour	594.0	1089.5	735	843.5	567.5	919.0
Total Accumulated Rainfall	799.5	2316.0	827	923.5	881.0	1340.5

3.3 Data collection and analysis

3.3.1 Questionnaire Design

This study draws upon existing literature on flood risk perception to design a comprehensive questionnaire that integrates various dimensions of how the levee effect influences risk perception. The questionnaire is structured into five main sections (Table 3).

In addition, given that flood control infrastructure and flood-related adaptive measures significantly impact both the development and risk profiles of flood-prone urban areas, a mismatch between the expected outcomes of these measures and the adaptive behaviours of individuals may lead to what is referred to as the "adaptation gap" (Aerts et al., 2024). Therefore, this study incorporates the concept of adaptation constraints into the questionnaire to further explore the extent to which residents are willing to accept flood risks and how much effort they are prepared to invest in mitigating them. This approach allows for an in-depth examination of the potential factors that contribute to the emergence of adaptation gaps.

3.3.2 Sampling Method

The questionnaire survey will be conducted in areas identified through spatial analysis as potentially affected by the levee effect. This study adopts a stratified random sampling approach to ensure the representativeness of the responses and the generalizability of the findings. The sampling design aims to adequately include geographically distinct strata related to the levee effect, specifically, (1) areas where flooding has been alleviated but residual risk has increased, and (2) areas where both residual risk and flood severity remain high. At least 400 residents will be surveyed, with 200 respondents selected from each stratum, to ensure sufficient data coverage and diversity.

3.3.3 Data Analysis Method

This study employs cross-tabulation analysis as an initial exploratory tool to examine the distributional differences of key categorical variables across different spatial strata related to the levee effect. This analysis provides critical preliminary insights , enabling a more comprehensive understanding of how the levee effect influences residents' risk perceptions and adaptive behaviours.

Table 3. Questions and their justification

Category	Question	Purpose
Flood Experience	During your time living in this village, have you ever experienced flooding caused by typhoons or heavy rainfall?	To understand whether respondents have experienced flood disasters in the past, and how these experiences have influenced their daily life and perception of flood severity.
	Have these flood events caused inconvenience in your daily life (e.g., health or property damage, commuting disruptions)?	
	How long has it been since you last experienced a flood disaster?	
	In recent years, Tainan City has implemented several flood mitigation projects. How has the severity of flooding near your home changed?	
	To what extent has flooding impacted your quality of daily life?	

Perceived Impact of Flooding	To what extent do you think flooding affects your personal safety?	To assess the respondent's subjective perception of the potential impacts of flooding, especially its effects on personal safety, property, and quality of daily life.
	To what extent do you think flooding affects your personal property?	
	To what extent do you think flooding affects your quality of daily life?	
Flood Risk Perception	I am aware that I live in a flood-prone area.	To explore respondents' subjective assessment of flood risk, including awareness of flood-prone conditions, perceived future risk, the impact of flood defenses, and confidence in individual and public preparedness.
	I believe there is a high possibility of flooding in my residential area in the future.	
	I feel less worried about floods because of the presence of flood control measures (e.g., levees).	
	Since the construction of flood control measures (e.g., levees), I believe the likelihood of flooding in my area has decreased.	
	I understand the flood prevention actions I can take in advance.	
	I believe that preventive actions taken before a flood can reduce flood-related losses.	
	I believe the government has the capacity to effectively manage flood disasters.	
	I believe the government provides sufficient information about the flood risks in my residential area.	
	I believe the government will take all necessary measures to protect me from flooding.	
	I believe the government fully considers flood risks when approving new developments or planning land use.	

Flood Risk Acceptability	What level of flood risk do you personally find acceptable?	To assess the respondent's willingness to accept various levels of flood risk, how much they are willing to invest to reduce risk, and their sense of responsibility in managing flood risk.
	If your home is located in a flood-prone area, how much would you be willing to spend to reduce flood risk?	
	Do you believe individuals have a personal responsibility to take action to reduce flood risk?	
	Under what circumstances would you consider relocating from your current residence?	
Socio-demographic Characteristics	What is your age?	To collect basic demographic information for analyzing how individual heterogeneity influences flood risk perception and behaviour.
	What is your gender?	
	How long have you lived in this area?	
	What is your highest level of education?	
	What is your approximate monthly household income?	

Expected Results

4.1 Risk Perception Heterogeneity under the Levee Effect

This study anticipates that individual flood experience, socio-demographic characteristics, and the level of trust in government-led flood management measures will significantly influence perceived flood risk. Through stratified random sampling, the study distinguishes between two types of areas: those where flooding has been alleviated but residual risk has increased and those where both flood severity and residual risk remain high. By comparing different groups, the study seeks to identify variations in flood experience perception, trust in government, and overall risk perception levels. This serves as a preliminary response to the hypothesis that the impact of levee effects on risk perception is not uniformly consistent across all populations.

4.2 Preliminary Insights on "Adaptation Gap"

This study incorporates the concept of adaptation limits in the questionnaire design, aiming to explore the public's acceptable level of flood risk and their willingness to make efforts to mitigate that risk. It is anticipated that potential cognitive factors leading to the "adaptation gap" will be identified from the collected data. These factors may include, but are not limited to, overestimating the effectiveness of structural flood control measures, underestimating personal responsibility, or overly relying on government.

5. Conclusion

This study addresses the long-standing oversight of individual heterogeneity in flood risk management by re-examining the complex interplay between the levee effect and flood risk perception. The potential distinctions of the levee effect are categorized into two types: "flooding situations are mitigated, but residual risk increases, and "flooding situations remain severe while residual risk continues to rise. This categorization reflects the diverse impacts of levee construction on actual flood scenarios under varying circumstances and explores the heterogeneity in flood risk perception among residents living in these environments.

Through empirical investigation, this study aims to uncover how residents' flood experiences, socio-demographic characteristics, and levels of trust in government disaster prevention measures collectively influence their perception and assessment of flood risk across various risk environments shaped by structural flood control interventions. However, merely enhancing risk awareness may be inadequate; if residents have a high tolerance for risk, they may still hesitate to take action despite acknowledging the threat. Therefore, it is crucial to examine variations in risk tolerance to gain a deeper understanding of the formation of adaptation gaps.This research aims to identify the social, psychological, and cognitive mechanisms underlying these heterogeneities, moving beyond the limitations of traditional "one-size-fits-all" flood control strategies. The goal is to develop differentiated policy designs tailored to groups with varying characteristics in the future. This approach will facilitate more precise risk management and flood prevention behaviours, serving as a reference for adaptation management and planning strategies.

What Are the Obstacles in the Recovery Process Considering the Role of Actors? The Case of the Kahramanmaraş Earthquake in Turkey

Gözde İdil ÖZCAN
Affiliation: Istanbul Technical University
Email: gozdeidilozcan@gmail.com

Abstract
The earthquakes centred in Kahramanmaraş on 6 February 2023 revealed profound structural and institutional vulnerabilities in Turkey's disaster management system. This study explores the post-disaster recovery efforts in Hatay and Adıyaman, focusing on the difficulties encountered by central and local governments, NGOs, international organisations, and community-based actors. Employing qualitative content analysis, the research demonstrates that the highly centralised governance structure restricts local adaptability and participation, resulting in spatial injustices and widespread institutional distrust. The findings underscore that recovery must extend beyond technical reconstruction and be guided by inclusive, multi-actor, and transparent governance approaches. Strengthening local institutional capacity and ensuring the meaningful integration of civil society and diverse actors into the recovery process are essential for building long-term resilience.

Keywords: Recovery; earthquake; actors; institutional hierarchy; Turkey

Introduction

Earthquakes are disasters that not only cause physical destruction but also disrupt social, economic, and institutional systems. Due to its location on active fault lines, Turkey frequently experiences earthquakes, which continuously challenge its disaster management capacity and reconstruction processes. The two major earthquakes that struck on 6 February 2023, centred in Kahramanmaraş and directly affecting 11 provinces, brought about severe difficulties not only on a physical level but also at institutional and societal levels. This disaster affected approximately 13.5 million people, resulted in the displacement of around 3.3 million individuals, and caused an economic loss exceeding 87 billion USD (Turkish Enterprise and Business Confederation [TÜRKONFED], 2023).

The post-disaster recovery process entails not only the reconstruction of destroyed infrastructure but also the restoration of the social fabric, the revitalisation of economic activities, and the rebuilding of governance capacity (UNDRR, 2015). In this process, coordinated action among actors at different levels—central and local governments, civil society organisations, international aid agencies, and community-based structures—is essential for effective recovery. However, Turkey's disaster management system largely operates through centralised structures, often limiting the roles of local actors.

The primary aim of this study is to examine the roles of actors involved in the recovery process following the Kahramanmaraş earthquakes and to identify the main obstacles encountered during this process. In this context, the research focuses on the following question: What challenges did the actors involved in the post-earthquake recovery process face, and how did these challenges affect the effectiveness of the process?

The study adopts qualitative content analysis as its research method. Within this framework, academic publications, official reports, documents produced by local administrations and NGOs, and media content related to the aftermath of the earthquakes were examined. Through the analysis of discursive and thematic patterns, findings were obtained regarding the roles of various actors, the institutional and structural challenges they encountered, their positions in decision-making processes, and the forms of interaction between them.

The article consists of five main sections. First, the literature review will discuss post-disaster recovery processes and actor-based governance approaches. The second section will explain the research methodology based on

content analysis. The third section will address the heterogeneity of the regions affected by the Kahramanmaraş-centred earthquakes. The fourth section will present the contextual framework of the study by describing the socio-economic and spatial characteristics of the two most affected provinces. The fifth section will focus on the findings obtained through thematic analysis, highlighting the challenges faced and the roles of different actors. In the final section, an evaluation of the findings will be provided, along with policy recommendations for an actor-based and inclusive recovery process.

1. Theoretical Framework and Literature Review

Post-disaster recovery processes are generally addressed in the literature in two main phases: short-term and long-term recovery. While short-term recovery refers to response-oriented processes such as search and rescue, emergency aid, and temporary shelter, long-term recovery involves not only physical reconstruction but also the restoration or more resilient rebuilding of social and economic systems (UNDRR, 2015). The success of these processes depends not only on the optimal use of financial resources but also on the ability of institutions and communities to develop strategies that enhance post-disaster resilience.

At this point, the concepts of resilience and adaptation come to the forefront in evaluating post-disaster recovery processes. Resilience refers to the capacity of societies or systems to withstand crises and recover rapidly (Cutter et al., 2008), whereas adaptation highlights the ability of these systems to adjust to changing conditions following such crises (Adger et al., 2005). Considering the diversity and complexity of disaster impacts across different spatial contexts, it becomes essential to examine these two concepts together.

Recovery processes are shaped not only by theoretical principles but also by the roles of the actors involved. Disaster management is considered a multi-actor domain; the relationships among central governments, local administrations, civil society organisations (CSOs), international agencies, and local communities directly influence the success of recovery. In this regard, the literature emphasises the multi-actor governance model, which prioritises the participation and collaboration of diverse stakeholders in decision-making processes, based on the principles of transparency, inclusiveness, and accountability (Ansell & Gash, 2008). The effective implementation of this governance model is directly dependent on institutional capacity. Kapucu (2008) stresses that the capacities of institutions involved in disaster management are shaped by factors such as access to information, resource mobilisation, coordination ability, and decision-making skills during crises.

In the Turkish context, disaster management has long been structured through centralised mechanisms. This centralisation has limited the participation of local authorities in decision-making processes and exacerbated coordination problems in post-disaster interventions. The formation and operation of such centralised institutions and their structural limitations have been observed in Turkey's past disaster experiences. For instance, the 1999 Marmara Earthquake triggered a major transformation in Turkey's disaster management system; in its aftermath, new institutional structures such as AFAD were established, and response coordination was consolidated under a single central authority (Ergünay, 2001). However, similar coordination problems, as well as imbalances in temporary shelter and resource distribution, were also noted in the 2011 Van and 2020 Elazığ earthquakes. These examples indicate that although institutional transformation in Turkey's disaster management system has begun, the capacity for multi-actor governance remains underdeveloped.

While the disaster management literature broadly discusses governance models, institutional capacities, and inter-actor collaboration, it often fails to address in sufficient depth the spatially differentiated roles of actors and how these roles manifest on the ground—especially in disasters affecting extensive and diverse geographies. Existing studies tend to focus on institutional actors at the macro level, with limited attention to local implementation patterns, variations shaped by local needs, and disparities in the capacities of local actors. In large-scale disasters such as the 6 February 2023 Kahramanmaraş earthquakes, which occurred in a socio-economically and spatially heterogeneous region, such comparative analyses are particularly significant. Given Turkey's multi-centred structure, regional disparities, and administrative differences, it is evident that the recovery process unfolds differently across provinces and actors.

This study aims to contribute to the existing literature by analysing the coordination deficiencies, institutional and structural obstacles, and functioning of multi-actor governance mechanisms in recovery processes across different provinces following the Kahramanmaraş earthquakes. In doing so, it not only proposes an actor-focused framework but also offers a comparative assessment of recovery practices shaped by different regional contexts, providing a critical contribution to the understanding of post-disaster governance in Turkey.

2. Method

This study aims to analyse the division of responsibilities, institutional visibility, and levels of collaboration among actors involved in the recovery processes across various provinces affected by the Kahramanmaraş earthquakes of 6 February 2023. In this context, content analysis was chosen as the primary method for data interpretation.

Content analysis is a qualitative data analysis technique that enables the systematic and objective examination of written or verbal materials. Through this method, hidden structures, patterns, and themes within texts relating to social phenomena can be revealed (Sheydayi and Dadashpoor, 2023). The approach adopted in this study was preferred for its ability to reconstruct statements from diverse sources within a coherent thematic framework. Content analysis includes both the explicit meanings of texts and the latent meanings embedded between the lines.

During data collection, various types of textual documents related to the Kahramanmaraş earthquakes were utilised. These included official disaster reports from public institutions, statements by local administrations, evaluation reports from civil society organisations, and academic articles published in the aftermath. These sources reflect not only the interventions of central authorities but also those of local actors, volunteer groups, and international institutions.

Although all provinces affected by the Kahramanmaraş-centred earthquakes were considered within the analytical universe, Hatay and Adıyaman were selected as case studies for in-depth analysis. The selection was based on the severity of physical destruction and the challenges encountered during the recovery process. Hatay was among the most severely affected in terms of absolute destruction and population loss, while Adıyaman stood out due to its high rate of building collapse per unit and the impact on rural areas. Additionally, the administrative, spatial, and socio-economic differences between these two provinces enabled a comparative analysis. Thus, the study aims to evaluate the recovery process with sensitivity to regional contexts.

The data analysis was structured according to the four fundamental stages of content analysis: identification of meaning units, coding, categorisation, and thematic interpretation. Each document was first read in detail, and relevant passages were marked as “meaning units.” These units were then translated into explicit codes based on their conveyed messages. Codes were grouped by similarity to form subcategories and themes, allowing for a systematic identification of recurring structures and governance-related patterns in the recovery process.

To ensure the reliability of the study, the principle of transparency was observed during the analysis process. The coding process was carried out systematically by the researcher, and the resulting themes were compared with the existing literature to strengthen internal consistency. This approach aimed to reduce the potential subjectivity inherent in qualitative analysis, while maintaining a transparent and traceable research process.

Ethical use of data was also a key consideration throughout the research process. All textual sources were compiled from publicly available documents, and no personal data or confidential information was used. Additionally, all sources referenced in the study were properly cited.

In conclusion, this methodological approach offers a suitable analytical framework for understanding the multi-actor structures and regional differences in post-disaster recovery processes. In doing so, it enables a comprehensive evaluation of both social and institutional dynamics, and considers post-earthquake governance not

only from a technical but also from a socio-political perspective.

3. The Impact Area and Regional Heterogeneity of the Earthquake

The earthquakes centred in Kahramanmaraş on 6 February 2023 are regarded as among the most devastating disasters in the history of the Republic of Türkiye. The two major earthquakes, measuring 7.7 and 7.6 Mw, occurred in the districts of Pazarcık and Elbistan in Kahramanmaraş and directly affected 11 provinces, causing severe physical, social, and economic destruction across a vast area of 110,000 km² (Disaster and Emergency Management Authority [AFAD], 2023; EERI, 2023). As a result of the earthquakes, a total of 51,158 people lost their lives in these 11 provinces (Turkish Statistical Institute [TÜİK], 2023).

Hatay recorded the highest number of fatalities, with 19,795 deaths. It was followed by the epicentral province of Kahramanmaraş, where 11,828 individuals lost their lives. Among the 11 provinces, the lowest number of fatalities was recorded in Kilis, with 107 deaths. Although Hatay reported the highest absolute death toll, Adıyaman had the highest relative fatality rate, with deaths amounting to 1.34% of its 2022 population. Across all affected provinces, the average fatality rate was recorded at 0.35% (Turkish Statistical Institute [TÜİK], 2023).

Table 1 Number of Fatalities and Their Percentage to the 2022 Population in the 11 Earthquake-Affected Provinces (Turkish Statistical Institute [TÜİK], 2023)

Province	2022 Population	Number of Fatalities	Fatalities as a Percentage of the 2022 Population
Hatay	1 686 043	19795	%1,17
Kahramanmaraş	1 177 436	11828	%1,00
Adıyaman	635 169	8523	%1,34
Gaziantep	2 154 051	4309	%0,20
Adana	2 274 106	1756	%0,08
Malatya	812 580	1626	%0,20
Osmaniye	559 405	1080	%0,19
Diyarbakır	1 804 880	968	%0,05
Şanlıurfa	2 170 110	829	%0,04
Elazığ	591 497	337	%0,06
Kilis	559 405	107	%0,02
Total	**14424682**	**51158**	%0,35

In addition to the human losses, 518,809 residential buildings were either destroyed or severely damaged, while a further 131,577 suffered moderate damage (Ministry of Environment, Urbanisation and Climate Change [ÇŞİDB], 2023). The extent of the damage varied significantly between provinces. Hatay was the province with the highest number of damaged or destroyed residences, followed by Kahramanmaraş. When the number of damaged and destroyed residences is evaluated as a proportion of the total housing stock in each province, Hatay ranks first with 60.22%, followed by Adıyaman with 52.45%.

Among the 11 affected provinces, Kilis reported the lowest number of damaged residences. However, the provinces with the lowest ratio of damaged or destroyed residences to the total housing stock were Adana and Şanlıurfa (Strategy and Budget Office of the Presidency [SBB], 2023; Ministry of Environment, Urbanisation and Climate Change [ÇŞİDB], 2023)

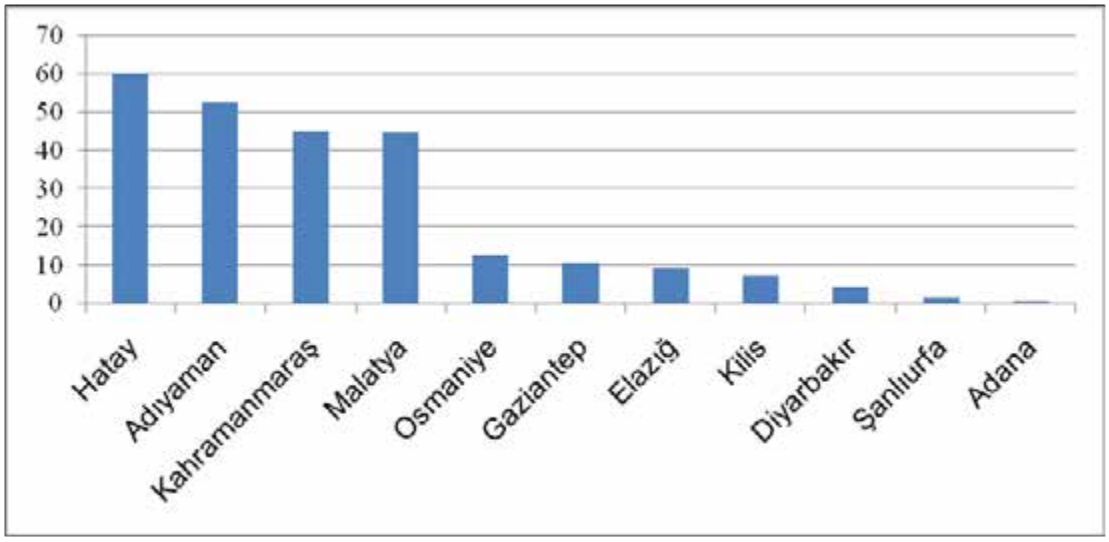

Figure 1 Percentage of Destroyed and Damaged Residential Buildings to the Total Housing Stock in the 11 Earthquake-Affected Provinces (Strategy and Budget Office of the Presidency [SBB], 2023; Ministry of Environment, Urbanisation and Climate Change [ÇŞİDB], 2023)

When examining the overall impact of the earthquake, it becomes evident that the extent of destruction across the affected provinces was not homogeneous. Significant differences emerged between provinces in terms of physical damage, loss of life, aid delivery processes, and reconstruction needs. This variation was shaped by a range of factors, including proximity to the earthquake's epicentre, soil conditions, the quality of the building stock, and the capacity for emergency response.

In this context, in order to enhance the analytical depth of the study and enable a comparative analysis, the research focuses on the two provinces that experienced the most severe disaster-related losses: Hatay and Adıyaman. Hatay was the most affected province in terms of total fatalities and infrastructure destruction, while Adıyaman recorded the highest relative fatality rate in proportion to its population. A comparative examination of these two provinces allows for a more concrete and multidimensional analysis of the structural and institutional challenges encountered during the post-disaster recovery process.

4. Regional Background and Socio-Spatial Characteristics

The pre-disaster structural, socio-economic, and spatial characteristics of Hatay and Adıyaman—the two provinces most severely affected by the Kahramanmaraş-centred earthquakes of 6 February 2023—largely explain the complexity of the subsequent recovery processes. These provinces, where societal, administrative, and spatial vulnerabilities intersect, proved more susceptible to external interventions during the crisis period, ultimately delaying the recovery process.

In terms of demography and social structure, Hatay had a population of approximately 1.7 million as of 2022, making it the 13th most populous province in Türkiye (Turkish Statistical Institute [TÜİK], 2023). With a population density of 258 people per km², Hatay comprises both densely populated urban centres such as Antakya, Defne, and İskenderun, and extensive rural areas. It is also characterised by a multicultural and multilingual social structure. The coexistence of diverse religious and ethnic groups has occasionally contributed to governance challenges and inequalities in resource distribution.

Adıyaman, by contrast, had a smaller population of around 635,000 in 2022 and a population density of 89 people per km². Despite its size, the province has a population growth rate above the national average and a significant-

ly high rural population; approximately 46% of its inhabitants reside in rural areas. The proportion of youth is high, while the elderly population remains below the national average (Turkish Statistical Institute [TÜİK], 2022). These demographic characteristics contributed to difficulties in accessing shelter, transportation, and emergency services during the earthquake. Furthermore, levels of education and income in Adıyaman are below the national average, increasing the province's overall vulnerability.

Prior to the earthquake, both provinces experienced both in- and out-migration. Hatay, due to its proximity to the Syrian border, hosted over 400,000 Syrians under temporary protection. In Adıyaman, mobility was mostly seasonal and based on agricultural labour, with temporary workers arriving from other regions during harvest periods.

The two provinces also differ significantly in their economic structures. Hatay was one of Türkiye's prominent industrial and port cities prior to the earthquake. It played a major role in iron and steel production, logistics, and agriculture. The Port of İskenderun was not only crucial for Hatay but also for foreign trade in Türkiye's eastern and southern regions (Eastern Mediterranean Development Agency, 2014). However, this economic potential turned into a major risk factor due to a lack of structural safeguards. The extensive damage to industrial infrastructure created a significant void in economic as well as physical recovery (Turkish Enterprise and Business Confederation [TÜRKONFED], 2023).

In contrast, Adıyaman's economy relies heavily on agriculture and small-scale industrial activities. The province is known for the production of tobacco, pistachios, and cotton, yet its industrial infrastructure remains weak (İpekyolu Development Agency, 2020). According to 2022 data from the Turkish Statistical Institute (TÜİK), Adıyaman ranks among the lowest provinces in terms of per capita income. This weak industrial base has constrained the ability of local economic dynamics to contribute to recovery. The province has low export capacity, a fragile production chain, and limited private sector investment.

In terms of the built environment, Hatay is marked by high urban density. The narrow street layouts and multi-storey buildings in districts such as Antakya and Defne were key factors that amplified the destructiveness of the earthquake. Much of the housing stock in these districts consists of old, structurally vulnerable buildings (World Bank, 2023). In Adıyaman, spatial vulnerabilities were more prominent in rural areas.

Due to their pre-disaster socio-spatial configurations, both Hatay and Adıyaman were among the provinces that faced the most severe challenges in the post-disaster recovery process. In both cases, physical vulnerabilities, limited economic capacity, and social inequalities exacerbated the impact of the earthquake.

5. Recovery Process: Actions, Challenges, and Governance

The previous section detailed the pre-disaster spatial, socio-economic, and administrative vulnerabilities of Hatay and Adıyaman, highlighting how these fragile structures intensified the impacts of the 6 February earthquakes. This background is critical not only for understanding the scale of destruction but also for explaining why the recovery process in these two provinces was particularly complex and delayed. This section focuses on the concrete actions taken during the post-disaster recovery process, the key challenges encountered, and the governance-based interactions among the actors involved.

In the literature, the recovery process is defined not merely as the reconstruction of physical infrastructure, but as a multi-layered endeavour shaped by the reorganisation of the social fabric, the establishment of institutional coordination, and the inclusion of local communities in decision-making (Smith & Wenger, 2007; Tierney, 2014). In analysing this multi-layered process, Hatay and Adıyaman are examined under two main subheadings. The first subheading presents post-disaster physical and administrative interventions and the problems encountered, based on thematic content analysis. The second subheading evaluates the governance relations among public institutions, local authorities, civil society organisations, and international actors, with a focus on the distribution of authority and contradictions in decision-making processes. Through this structure, the recovery process is revealed to be less a technical issue and more a matter of governance.

5.1. Recovery Actions and Challenges

The post-disaster recovery process initiated after the Kahramanmaraş-centred earthquakes of 6 February 2023 has raised numerous questions regarding its design and prioritisation. Analysis of the process reveals key challenges such as damaged infrastructure systems, reconstruction policies, centralised interventions, and inequalities in resource distribution.

Both Hatay and Adıyaman faced significant logistical infrastructure problems. These issues stem not only from earthquake-induced destruction but also from long-standing structural deficiencies. In Hatay, the collapse of urban transportation routes, the absence of alternative roads, and the disruption of port connections severely hindered search-and-rescue and aid delivery operations. Additionally, the fire and destruction at the Port of İskenderun interrupted the logistics chain (Şipal, 2023). In Adıyaman, the limited capacity and narrowness of the arterial roads connecting to the main highways caused significant delays in the delivery of aid to the region. Access problems in rural areas further exacerbated the situation. In Adıyaman's rural neighbourhoods, collapsed roads and landslide risks left many villages isolated for weeks. This not only restricted access to essential needs for the rural population but also delayed the provision of health, food, and temporary shelter services (Şipal, 2023). In Hatay, the dispersed settlement pattern in rural areas and the collapse of bridges also hindered emergency response teams from accessing certain zones.

Infrastructure deficiencies in temporary shelter areas also posed a major challenge to the recovery process. In both provinces, container and tent settlements were established without prior infrastructural preparation, and basic services such as water, sanitation, and electricity were either unavailable or provided at very low capacity in the initial days. In some tent areas in Hatay, safe drinking water, toilets, and showers could not be provided for several weeks (Erdoğan, 2023). These shortcomings not only increased public health risks but also contributed to social unrest and a growing sense of distrust. The lack of infrastructure reflects not only the limitations of local capacity but also the broader deficiencies of disaster management in preparedness and scenario planning.

A second and widely debated dimension of the recovery process concerns the centralised nature of reconstruction policies. The mass housing projects managed directly by the Housing Development Administration (TOKİ) under central authority bypassed local planning processes. In both Hatay and Adıyaman, these centrally implemented initiatives ignored local urban plans and zoning strategies, drawing serious criticism regarding their spatial integration, respect for historical context, and alignment with community needs (Bozkurt & Keleş, 2023).

Exclusion of local planning is not merely an administrative preference but also a governance issue. Decisions regarding the location, design, and social amenities of post-disaster housing were made by central actors, neglecting the needs and priorities of local residents. In Hatay, for instance, some TOKİ housing units were built in geologically controversial areas, which both violated scientific principles and undermined public trust.

Moreover, the implementation of standardised housing projects across different regions created issues in both spatial and social cohesion. Observations suggest that most TOKİ projects in Hatay and Adıyaman were constructed with similar scales, materials, and architectural styles, failing to adapt to the diverse cultural, climatic, and social contexts of the regions. While the needs of disaster victims varied greatly, the uniform solutions offered created a "one-size-fits-all" approach that contradicted the principle of equity.

This situation not only affects the physical environment but also undermines the sense of social belonging. Shelter is not merely the provision of a roof, but the reconstruction of a space where social relations are reorganised. Therefore, the rigid, standardised interventions of central institutions transform the recovery process from a purely technical effort into a matter of social cohesion. However, housing problems for earthquake survivors persist, and significant deficiencies remain in temporary accommodation areas. While the construction of new housing is being carried out predominantly by public authorities, the costs of repair and reinforcement have been left to homeowners, thereby exacerbating existing inequalities (Özüdoğru, 2023).

One of the most pressing difficulties encountered during post-disaster interventions and reconstruction was the inequitable distribution of resources at both spatial and institutional levels. In both Hatay and Adıyaman, serious disparities were reported in the allocation of in-kind aid and housing investments. In Hatay, for example, the concentration of aid in certain districts led to a sense of "invisibility" in others. In Adıyaman's northern rural villages, it was reported that aid had not reached some communities for several weeks (Özer, 2023). Furthermore, the involvement of political actors in the distribution of aid undermined the legitimacy of the entitlement system for disaster survivors.

Spatial injustice was not only about the volume of aid but also about the prioritisation of certain areas over others. In Hatay, despite the extreme devastation in central districts such as Antakya and Defne, some rural neighbourhoods did not see the initiation of housing projects for months. In Adıyaman, permanent housing construction began in specific zones, while other equally affected areas experienced no progress. This inequality was reflected not only in the physical landscape but also in demographic changes: 148,872 people reportedly migrated from Hatay due to the earthquake, while in Adıyaman, over 6% of the population relocated to other cities (Turkish Statistical Institute [TÜİK], 2023) (Table 2). These trends indicate that local-level assessments of both physical and social conditions were insufficiently incorporated into the recovery planning process.

Table 2 Migration Flows to and from the 11 Earthquake-Affected Provinces (Turkish Statistical Institute [TÜİK], 2023)

Disaster-Induced Migration Dynamics in Earthquake-Affected Provinces in 2023		
Province	**Out-Migration (Number of People)**	**InMigration (Number of People)**
Hatay	148 872	6 743
Malatya	93 895	8 382
Kahramanmaraş	71 709	8 565
Adıyaman	42 100	7 089
Gaziantep	30 987	22 172
Adana	28 546	17 028
Şanlıurfa	23 697	15 606
Diyarbakır	21 801	6 059
Osmaniye	12 643	9 690
Elazığ	6 399	14 470
Kilis	2 556	4 579
Total	**483 205**	**120 383**

The fact that permanent housing in some regions has yet to be completed illustrates the extent to which the recovery process has been shaped by regional inequalities. According to the most recent data published by the Disaster and Emergency Management Authority (AFAD) and the Housing Development Administration (TOKİ), the number of planned permanent housing units in Hatay exceeds 40,000; however, less than 15% of these units were completed within the first year. Similarly, in Adıyaman, only 17% of the approximately 25,000 planned housing units have been delivered (Table 3). Furthermore, when delivery performance is assessed as a percentage of documented urban housing needs, the disparities become even more pronounced. In Kilis, the number of delivered urban units (1,097) exceeds the identified need (733), reflecting a delivery rate of approximately 150%. In stark contrast, only 5% of the urban housing need has been met in Adıyaman (2,158 out of 41,171), and merely 3% in Hatay (6,572 out of 220,006). This contrast highlights significant inconsistencies in how provinces are prioritised within the recovery process.

The underlying causes of these delays are not purely technical; rather, they reflect political, bureaucratic, and capacity-based decisions embedded within the prioritisation mechanisms (Altay & Labonte, 2014). Thus, the recovery process must be analysed not only in terms of what has been implemented, but also in terms of what has not—or could not—be realised.

Table 3 Urban Housing Needs and Reported Number of Housing Units Ready for Delivery (Disaster and Emergency Management Authority [AFAD] and Housing Development Administration [TOKİ], 2024)

	Housing Development Administration [TOKİ], 2024			Disaster and Emergency Management Authority [AFAD], 2024	
Province	Urban Housing Need	Rural Housing Need	Commercial Space Need	Reported Number of Urban Units Ready for Delivery	Reported Number of Rural Units Ready for Delivery
Adıyaman	41171	23640	17392	2158	640
Hatay	220006	34129	55777	6572	703
Kahramanmaraş	82104	30310	34504	8122	716

Kilis	733	2628	697	967	136
Elazığ	20261	-	4528	2255	-
Total	**53672**	**165271**	**169000**	**39327**	**4574**

5.2. Actors and Governance in the Recovery Process

Following the earthquakes centred in Kahramanmaraş, the recovery process was shaped not only by technical and physical interventions but also by questions regarding who implemented these interventions, how, and at what level—questions which have become central to the discussion. Post-disaster governance entailed the involvement of multiple actors at various levels and with differing capacities; however, coordination among these actors was often fragile. The following thematic evaluations address this process through institutional structures, local administrations, civil society, international actors, and community-based organisations (Göver, 2023).

Neighbourhood volunteers played a prominent role in meeting fundamental needs such as aid distribution, the establishment of temporary shelter sites, and the support of vulnerable groups, particularly during the initial days. In certain neighbourhoods of Hatay and Adıyaman, where public institutions could not reach within the first 72 hours, neighbourhood volunteers took organised action to supply food and water and actively contributed to the physical setup of temporary accommodation areas.

Nevertheless, many of these structures were fragile due to a lack of both formal institutional recognition and financial resources. While they provided short-term solutions during the recovery phase, their inability to operate sustainably underscores the need for systematic recognition and support of these practices. Integrating local volunteer groups into formal frameworks would enhance capacity utilisation and reinforce a sense of belonging.

The research conducted in Hatay and Adıyaman indicates that, despite the theoretical presence of a multi-actor

structure in the recovery process, in practice, central government institutions were overwhelmingly dominant. Local authorities, civil society organisations (CSOs), and community-based structures were either marginalised or excluded from the process entirely. This governance model resulted in decision-making occurring behind closed doors, the exclusion of local knowledge and experience, and a deepening institutional distrust. The success of the recovery process is thus not solely dependent on technical capacity but is directly linked to how this capacity is mobilised through democratic, inclusive, and multi-actor mechanisms. Despite its strong central structure, Türkiye's current disaster management system suffers from severe limitations in terms of local adaptability and flexibility, hindering not only the pace but also the equity of post-disaster recovery.

One of the most striking issues during the recovery process in Hatay and Adıyaman was the multiplicity of institutional authorities and ambiguity in the distribution of responsibilities. The Disaster and Emergency Management Authority (AFAD), the Ministry of Environment, Urbanisation and Climate Change (ÇŞİDB), the Ministry of Interior, and the Housing Development Administration (TOKİ) operated independently of one another. At the provincial level, roles and responsibilities between the governor's office, metropolitan municipalities, and district municipalities were poorly defined (Göver, 2023). This fragmentation led to delays in decision-making and reduced the responsiveness of interventions to local needs.

The marginalisation of local governments posed a further serious issue. While local authorities in Türkiye possess limited disaster management capacity, they are known to be among the fastest-responding units with direct contact with the public during crises (Altay & Labonte, 2014). Nonetheless, in both Hatay and Adıyaman, municipalities were largely excluded from planning processes, resource allocation, and decision-making mechanisms. Instead, interventions were carried out directly through governorates, district governorships, and central government institutions. Municipalities were compelled to act on their own initiative due to a lack of official authorisation, which not only prevented the effective use of local knowledge and capacity but also weakened channels of communication with the public.

The centralised structure of The Disaster and Emergency Management Authority (AFAD) constituted the most critical aspect shaping the institutional framework of the process. Particularly in the early stages, The Disaster and Emergency Management Authority (AFAD) had full control over emergency response and shelter planning. In some cases, municipal settlement plans were disregarded and annulled by The Disaster and Emergency Management Authority (AFAD), pushing local actors into a subordinate role as mere implementers. This approach resulted in standardised intervention models being applied without consideration for the region's spatial, social, and economic diversity. In decisions ranging from the siting of container settlements in Hatay to the construction of permanent housing in Adıyaman, the exclusion of local dynamics was clearly evident.

This dominance of central government extended beyond decision-making to resource allocation and prioritisation of interventions. The distribution of aid, allocation of housing, and infrastructure investments often ignored local demands, damaging relationships between actors and leading to a lack of trust and cooperation on the ground. Such issues reflect not only governance shortcomings but also directly impact the effectiveness of the recovery process.

Civil society organisations (CSOs) played a crucial role in post-disaster recovery not only through service provision but also by contributing to social solidarity and the development of inclusive governance mechanisms. However, in the context of the earthquakes centred in Kahramanmaraş, CSOs were largely marginalised or rendered ineffective in Hatay and Adıyaman.

In the initial days following the earthquakes, CSOs were among the first actors to reach the affected areas, delivering critical assistance in areas such as shelter, food distribution, and psychosocial support. In Hatay, organisations such as Ahbap, along with local volunteer initiatives, provided essential services in regions where the state was unable to respond promptly. For instance, the Ahbap Association and its partner civil initiatives reportedly distributed over 4,000 containers across Hatay. In Defne, female volunteers established community kitchens with

their own resources, serving hot meals to thousands (Ahbap, 2023). In Adıyaman, small civil initiatives from neighbouring provinces organised tent distributions and similar relief efforts. However, many of these actions lacked a systematic coordination mechanism, and CSO representatives were frequently excluded from crisis coordination centres established under The Disaster and Emergency Management Authority (AFAD).

Moreover, central institutions predominantly portrayed relief operations in the media and public discourse as being driven solely by The Disaster and Emergency Management Authority (AFAD) and ministerial efforts. Yet, in many areas, it was in fact the work of CSOs that sustained living spaces, food supply chains, and emergency first aid points. This exclusionary approach not only created symbolic invisibility but also led to material constraints. Many CSOs faced difficulties obtaining permits to collect donations or were compelled to channel funds through AFAD, thereby limiting their operational autonomy.

Despite these challenges, some CSOs managed to maintain continuity in specific regions owing to their strong community ties and flexible organisational structures. Small-scale support efforts led by women's associations, youth initiatives, and neighbourhood forums effectively addressed the gaps left by central government agencies, particularly in rural areas. However, unless these contributions are integrated into a systematic governance structure, their scalability will remain limited.

The role of international actors in post-disaster recovery is particularly significant in terms of funding, technical assistance, and normative guidance. Following the 6 February 2023 earthquakes, Türkiye received financial and logistical aid from numerous international institutions. Nevertheless, how this support was translated on the ground and the extent of collaboration with local actors sparked considerable debate, especially in Hatay and Adıyaman.

Following the disaster, more than USD 1.6 billion in aid and credit was pledged by the World Bank, the European Union, the United Nations Development Programme (UNDP), and various international NGOs. Of this, USD 1 billion was allocated to Türkiye by the World Bank as an emergency credit package, channelled through central projects managed by The Disaster and Emergency Management Authority (AFAD) and the Ministry of Interior, and the Housing Development Administration (TOKİ). However, no information was shared regarding the provincial-level allocation of these resources. The European Commission's Directorate-General for European Civil Protection and Humanitarian Aid Operations (ECHO) provided EUR 25 million in direct funding for humanitarian aid efforts in Hatay and Adıyaman (World Bank, 2023; UNDP, 2023). Yet, these funds were distributed without the involvement of local authorities; in some neighbourhoods, interventions were unnecessary, while rural areas were entirely neglected. Most of these funds were allocated through the Disaster and Emergency Management Authority (AFAD) and relevant ministries. Public disclosure regarding the transparency of this aid, its distribution process, and provincial allocations remains significantly lacking. For instance, while some permanent housing projects in Hatay were reportedly financed through international aid, their visibility on the ground has been limited.

Transparency in the use of funds is not merely a technical administrative issue but also a key determinant of public trust in the process. In both Hatay and Adıyaman, there has been no publicly accessible reporting on the allocation of international aid, the criteria used to define regional priorities, or how decisions were made. This has fuelled perceptions that aid may have been guided by political or institutional preferences, eliciting backlash particularly from neglected rural communities.

Meanwhile, there have been limited efforts by institutions such as UNDP and the EU to promote local capacity-building through long-term technical support programmes. However, for these initiatives to expand and become sustainable at the local level, there is a need for clearer governance protocols and stronger partnerships with local actors.

In conclusion, the contribution of international actors to the recovery process has been largely mediated through central authorities, resulting in weak collaboration at the local scale. Yet, for recovery to be both effective and

equitable, it is not sufficient to ensure the flow of funds—these resources must be utilised in ways that are sensitive to the local context and involve active participation of local stakeholders.

Finally, it is essential to recognise that post-disaster recovery processes are not solely driven by institutional actors. On the contrary, informal community-led initiatives also played a critical role. Content analysis and field observations in Hatay and Adıyaman reveal that neighbourhood volunteers, local networks, and community-based organisations filled vital gaps in rebuilding life after the disaster.

6. Conclusion and Policy Recommendations

The earthquakes centred in Kahramanmaraş on 6 February 2023 marked a turning point in Turkey's disaster management history, leaving deep traces both physically and institutionally. The content analysis conducted within the scope of this study demonstrates that the post-disaster recovery process is not merely a technical reconstruction effort, but also a multi-actor and multi-level governance process. In-depth analyses of the provinces of Hatay and Adıyaman reveal that, due to their socio-spatial vulnerabilities, these two provinces faced more complex challenges in the recovery phase. The findings show that post-disaster interventions were spatially unequal and heavily centralised in terms of governance, with the roles of local governments, civil society organisations (CSOs), and international actors remaining limited.

In this context, regionally scaled policy recommendations are critically important for reducing the impact of disasters and accelerating recovery processes. First, the institutional capacity of local governments in high-risk areas must be strengthened. As evidenced in the cases of Hatay and Adıyaman, municipalities lacked both financial resources and planning authority, which hampered effective coordination on the ground. In order for local administrations to play an active role in disaster planning, their disaster management budgets should be increased, personnel training supported, and they should be structurally integrated into decision-making processes.

Second, institutional coordination mechanisms at both local and national levels must be restructured. One of the main issues encountered during the recovery process was the lack of clearly defined responsibilities and task allocations (Ergünay, 2001). Overlaps in authority between the Disaster and Emergency Management Authority (AFAD), the Ministry of Environment, Urbanisation and Climate Change (ÇŞİDB), the Housing Development Administration of Turkey (TOKİ), and local actors led to delays in the field and unjust distribution of resources. Therefore, task definitions for post-disaster interventions should be predetermined, and a clear coordination protocol ready for activation in times of crisis must be established.

Third, the integration of civil society organisations and volunteer structures into the process has become a necessity. The critical role played by the Ahbap Association and similar organisations in the initial days of the disaster ensured the continuity of essential services in areas unreachable by central institutions (Ahbap, 2023). However, the lack of visibility of these structures in the official process led not only to symbolic exclusion but also to material inequalities. CSOs should be subject to a pre-disaster certification and authorisation system; support-capable structures should be identified in advance and integrated accordingly. Furthermore, their operations should not be subordinated to the Disaster and Emergency Management Authority (AFAD)'s coordination, but rather conducted through horizontal collaborations and information-sharing platforms.

Fourth, international funding and technical assistance must be managed transparently. The provincial distribution of funds from institutions such as the World Bank, the European Union, and the United Nations Development Programme (UNDP) should be made public, and regular reports must be published detailing which projects these resources were allocated to, when, and according to which criteria. In Hatay and Adıyaman, the visibility of these funds remained particularly low in some areas, reinforcing perceptions that assistance was directed based on political or technical preferences. To counter this, transparent and accountable monitoring mechanisms that involve local actors in the allocation of international funds must be developed.

Finally, the long-term social impacts of the recovery process must be considered. Post-disaster migration, we-

akening of social belonging, and the erosion of trust have lasting effects not only on physical space but also on the social structure (Tierney, 2014). Given that more than 148,000 people migrated from Hatay and over 6% of Adıyaman's population relocated to other provinces (Turkish Statistical Institute [TÜİK], 2023), the recovery process must be supported not only through housing policies but also with community rebuilding programmes.

In conclusion, this study shows that Turkey's post-disaster recovery process has a highly complex and multi-actor nature; however, the current governance structure remains inadequate in addressing this complexity. For recovery efforts to be conducted effectively and equitably, central institutions must collaborate with local actors, strategies must be developed with sensitivity to social needs, and institutional capacity must be strengthened at every level. Implementing these recommendations is vital for building a more resilient society and governance structure in the face of future disasters in Turkey.

How the coastal cities are transforming? The disaster as catalysts of change

Francesca Paola Mondelli, Marta Rabazo Martin, Maria Grazia Cianci

Abstract:
In the current climate crisis, coastal cities face growing risks related to both water scarcity and flooding. Climate change, uncontrolled urbanization, and the inherent vulnerability of coastal areas call for a rethinking of planning strategies. This contribution presents part of the PRIN COSTA|Med research project, which collects international case studies where environmental crises have triggered innovative adaptation strategies. Focusing on two examples—the Dutch Delta Programme and the PATIVEL in Valencia—we explore how planning and design can respond jointly to complex challenges. The goal is to identify shared trajectories and outline integrated guidelines for resilient coastal management, with a focus on the Mediterranean, one of the regions most exposed to sea-level rise.

1. Introduction. Designing with Disasters — Rethinking Coastal Urbanism in the Age of Climate Crisis.

In the 21st century, climate change has ceased to be a distant scenario and has become a structuring force transforming how we live, plan, and imagine our cities. Coastal territories—liminal spaces between land and sea—are among the most affected. The combination of rapid demographic growth, increasing anthropization, and the expansion of urban settlements into ecologically fragile zones has significantly heightened the exposure of coastal cities to natural disasters. These are not merely episodes of exceptional violence, but manifestations of a systemic imbalance in the relationship between human development and natural systems.

Among the various elements at play, water emerges as the central agent of crisis. Its dual character—both scarcity and excess—makes it pivotal to many of the most disruptive phenomena of our time. Prolonged droughts, wildfires, and water shortages reveal the fragility of inland ecosystems, while excessive precipitation and storm surges destabilize cities and coastlines. In parallel, slow-onset phenomena such as sea level rise, salinization, and coastal erosion threaten the long-term viability of urban development along the coasts.

These dynamics compel us to critically reconsider the human-nature relationship. As Neil Smith (2006) famously stated, "there's no such thing as a natural disaster"—what we perceive as disasters are often consequences of political, social, and spatial decisions, such as the occupation of flood-prone areas, the sealing of soil, or the removal of natural buffers like wetlands and dunes. In this sense, disasters are not nature's intrusion into the urban realm, but the return of suppressed ecological processes in territories overbuilt and overregulated.

The relationship between city and nature has never been static—it has evolved through centuries of shifting paradigms, from domination and separation to a more integrated and dynamic vision. Historically, urbanization in coastal territories has exemplified the impulse to control nature: land was reclaimed, estuaries filled, shorelines fixed, and rivers canalized to serve industrial, logistical, and speculative purposes. This anthropocentric model, rooted in the Enlightenment ideal of nature as inert matter to be shaped by human will, has generated a brittle urban ecology incapable of responding to contemporary environmental challenges. As climate change accelerates, sea-level rise, storm surges, and saltwater intrusion are reclaiming spaces once artificially stabilized, exposing the fallacy of this dichotomy. Contemporary scholarship—from Haeckel's early ecology (1866) to Latour's political ecology (2018) and the systemic readings of urban metabolism (D'Arienzo & Younés, 2018)—has argued for a more relational approach, one that recognizes humans as part of, not separate from, ecological processes.

This shift reframes the role of design: cities, and particularly coastal cities, must be understood not as closed systems protected from nature, but as open, adaptive infrastructures embedded within it. The goal is no longer to resist natural dynamics through static barriers, but to accommodate, absorb, and even learn from them—by

shaping urban forms that respond to hydrological rhythms, sediment flows, and climatic variability. In this regard, aesthetics and engineering must converge to support both functional resilience and cultural imagination. As Diana Balmori succinctly states, "We must put the twenty-first-century city in nature rather than put nature in the city; to put a city in nature will mean using engineered systems that function as those in nature and deriving form from them" (Balmori, 2010). This reorientation calls for a fundamental transformation in how we conceive urban life at the edge of water—shifting from opposition to coexistence, from containment to collaboration.

Jeremy Rifkin (2019) highlights the deep incompatibility between carbon-intensive urban models and the planetary limits we now face, calling for a "Green New Deal" of infrastructure capable of decentralizing and decarbonizing urban life. Similarly, landscape architect Kate Orff (2016) argues for a new ecological imagination in urban design—one that moves beyond cosmetic greening toward "living infrastructure" systems that mimic, restore, or collaborate with natural processes. For Orff, resilience is not about resistance, but about dynamic adaptation, cohabitation, and repair.

Such perspectives mark a fundamental shift in how disasters can be understood. Rather than treating them as interruptions, this research proposes to interpret disasters as revelatory episodes—moments that expose systemic weaknesses but also generate possibilities for innovation. This approach advocates for a move away from superficial "greenwashing" toward engineering-informed strategies inspired by natural systems, including sediment cycles, wetland restoration, oyster reef cultivation, and dynamic floodplain design.

Cities such as New York—through the Rebuild by Design initiative (2012)—Mumbai, and Rotterdam have pioneered these ideas, implementing forward-looking strategies that embed risk management into the DNA of urban and coastal planning. Northern European countries have institutionalized long-term resilience policies, but in contrast, the Mediterranean remains one of the world's most vulnerable and underprepared regions. Despite early efforts such as the Barcelona Convention (UNEP/MAP, 1976), many Mediterranean countries still suffer from fragmented governance, lack of integrated planning tools, and reactive emergency management. The flooding event that struck the Valencian coast in October 2024 is a stark reminder of this fragility.

According to recent projections (EEA, 2024), sea levels in the Mediterranean under low-emissions scenarios could lead to extreme flooding events becoming ten times more frequent by 2050—transforming what were once centennial phenomena into regular occurrences. In this context, a crucial question emerges: how can we plan and design coastal territories in a way that is proactive, integrated, and resilient?

This essay responds by developing a multidisciplinary framework that brings together urban design, spatial planning, and environmental systems thinking. At its core lies a curated archive of global case studies documenting how cities have reacted to, learned from, and reimagined themselves through coastal crises. These experiences are not seen merely as emergencies but as generative events—catalysts for transforming the built environment, governance models, and the relationship between land and water.

By drawing lessons from diverse geographies while grounding the analysis in the unique socio-environmental conditions of the Mediterranean, the research aims to define a set of spatial and strategic guidelines. These will serve not only to mitigate risk but also to inspire new design cultures capable of co-evolving with the rhythms of nature. In reframing disasters as design tools, this study advocates for a paradigm of coastal planning rooted in resilience, reciprocity, and long-term thinking.

2. **International References**

In the United States, a series of major climate-related disasters over the past two decades have spurred significant innovation in the fields of urban planning, infrastructure design, and resilience thinking. Among these, Hurricane Katrina in 2005 stands out not only as the costliest natural disaster in the nation's history, but also as a turning point in how vulnerability, inequality, and risk are understood and addressed in urban contexts.

Hurricane Katrina, which struck the Gulf Coast in August 2005, brought winds reaching 175 mph and a storm surge that overwhelmed the levee system, causing catastrophic flooding in New Orleans (Fig.1). The disaster resulted in over 1,800 deaths and displaced more than a million people. The damages exceeded $160 billion, making it the most expensive natural disaster in U.S. history (Graumann et al., 2005). Yet beyond the sheer scale of destruction, Katrina exposed long-standing systemic failures: racial and economic inequalities, aging infrastructure, and institutional fragmentation. Entire neighborhoods—particularly the predominantly Black and low-income Lower Ninth Ward—were submerged for weeks, showing how climate events magnify social vulnerability.

Fig. 1: Aerial view showing a flooded neighborhood adjacent to the 12th Street levee in New Orleans. Source: Vincent Laforet/The New York Times/Redux

The failure of the levee system—long believed to offer adequate protection—was not just a technical collapse but a manifestation of decades of underinvestment, poor planning, and environmental mismanagement (Colten, 2006). The Army Corps of Engineers, which oversaw much of the levee construction, later acknowledged critical design and construction flaws. The emergency response, primarily led by FEMA, was widely criticized for being disorganized and inequitable. In this sense, Katrina was not merely a natural disaster, but a human and political one.

Recovery efforts were uneven. While various plans such as the Unified New Orleans Plan (2007) attempted to guide reconstruction, many were top-down and failed to involve the communities most affected. Some areas of New Orleans have rebounded, but others remain marked by vacancy, slow repopulation, and continued risk. As historian Andy Horowitz has argued (Horowitz, 2020), Katrina should not be seen as an isolated crisis but as part of a "century-long disaster" rooted in the complex intersection of geography, policy, and inequality.

Despite its failures, the Katrina experience catalyzed a national rethinking of resilience and urban design. It helped lay the conceptual and institutional foundations for subsequent initiatives—like Rebuild by Design—that seek to merge ecological insight with participatory governance and long-term planning.

Nevertheless, Katrina sparked national and international conversations on urban resilience, environmental justice, and the ethics of reconstruction. It laid the groundwork for later initiatives, such as Rebuild by Design, that attempt to address climate risks through collaborative, inclusive, and ecologically informed planning. The lessons from New Orleans underscore the importance of designing not just for physical protection, but for social resilience, institutional accountability, and historical memory

The Rebuild by Design program, initiated in response to Hurricane Sandy in 2012, introduced a new design methodology based on interdisciplinary competition, co-design with local communities, and resilient infrastructural strategies (Rebuild by Design, 2014; Gould & Lewis, 2016). One of the most emblematic cases is the intervention in the Hudson Bay area, where the project "The BIG U," proposed by the Bjarke Ingels Group team, envisioned a continuous coastal protection system for Manhattan. This multifunctional belt not only serves as a physical barrier against flooding but also incorporates public spaces, parks, bike paths, and ecological devices that enhance urban quality (BIG Team, 2014; Lang & Rothenberg, 2017). The project stands as a prototype of resilient planning that integrates infrastructural scale with the quality of urban space.

However, Rebuild by Design is not limited to a single intervention. The competition launched in 2013 led to the selection of ten finalist proposals, each addressing specific vulnerabilities along the New Jersey and New York State coasts. Among these, "Living with the Bay" for Long Island, "Hunts Point Lifelines" for the Bronx, and "New Meadowlands" in New Jersey reinterpret riverine and coastal territories with integrated approaches that combine ecology, green infrastructure, and community engagement (Rebuild by Design, 2014; Oppla, 2020; Sanderson et al., 2016). These proposals share a core principle: the goal is not to resist nature but to learn to live with its dynamics.

Rebuild by Design has highlighted the importance of understanding natural systems — watersheds, marine currents, coastal ecosystems — as the foundation for urban management. This awareness has enabled the development of design strategies that not only respond to emergencies but also rebuild the relationship between human settlements and landscapes, promoting a vision of resilience based on adaptability, equity, and co-design (de la Peña et al., 2014; Lang & Rothenberg, 2017).

Another significant methodological contribution comes from the Atlas of Disaster, published in 2021 by Rebuild by Design in collaboration with New Jersey Future (Rebuild by Design & NJ Future, 2021). This document gathers data and narratives on climate disasters that have affected the State of New Jersey, highlighting socioeconomic inequalities, systemic vulnerabilities, and the need for cooperative governance. The atlas serves as a knowledge base to strengthen integrated planning, promoting the use of visual and collaborative tools to engage citizens, administrations, and professionals in the creation of fairer and safer scenarios.

In India, the SOAK project, proposed by Anuradha Mathur and Dilip da Cunha for the metropolis of Mumbai, radically rethinks the relationship between the city and water by proposing a dispersed and capillary model of coexistence with moisture rather than containment. SOAK's approach is based on cartographic and phenomenological observation of the monsoon landscape, where water does not follow a clear line but forms an extended, changeable, and distributed zone. Mumbai is interpreted as an estuary rather than land to be defended: the central idea is not to build barriers against water, but to design spatial conditions to absorb, distribute, and celebrate it. Water is not seen as an enemy but as a generative urban substance (Mathur & da Cunha, 2009).

SOAK's design methodology is distinguished by its exploratory, situated, and phenomenological character, emphasizing graphic and cartographic representations (Fig.2) that merge environmental data, material culture, and design imagination. This is not an abstract theoretical exercise, but a systemic and design-oriented response to a context marked by recurrent disasters such as the monsoon floods that cyclically affect Mumbai. SOAK does not stem from a single catastrophic event but from a critical understanding of the hydrographic landscape and its urban dysfunctions, which are attributable to modern hydraulic management based on containment and channelization. Here, resilience strategies are framed as narrative and spatial scenarios capable of inspiring a

new urban mindset oriented toward coexistence with climate variability and the valorization of water as a generative element of space.

Fig. 2: Drawing from the exhibition SOAK, opened at the NGMA (National Gallery of Modern Art) in Mumbai on June 23, 2009. Source: https://www.mathurdacunha.com/soak

In contrast with Rebuild by Design, which operates in a concrete field made of public competitions, inter-institutional partnerships, and infrastructural implementations, SOAK proposes an exploratory and conceptual design approach. Both projects share the centrality of water as a subject of urban design but differ in methods and language: Rebuild uses masterplans and implementation budgets; SOAK works with mappings, visions, and new territorial grammars.

Far from being a contradiction, this dichotomy offers fertile ground for a theory of urban hydraulic design that combines technical competence, geographical understanding, and symbolic imagination.

3. Europe at Risk

In the global context, the United States and India represent two distinct yet extreme environmental and climatic scenarios. In both contexts, differing socio-economic models—each driving specific patterns of urban growth—have resulted in heightened exposure to climate-related risks, ultimately culminating in large-scale natural disasters.

In Europe, by contrast, despite operating within a smaller geographical and demographic framework, there is a wide range of environmental conditions that have led to varied historical approaches to the relationship between land and sea. Northern European countries—such as the Netherlands, Belgium, Denmark, and the UK—have long faced the challenges of flooding and the delicate balance between human activity and natural systems. In response, these countries have implemented both governance and design strategies aimed at enhancing urban resilience.

Conversely, although Mediterranean countries have a long-standing cultural heritage of living with water, they have been comparatively slower in developing effective climate adaptation strategies, despite some noteworthy examples of adaptation in specific cities and regions. Yet, the Mediterranean remains highly exposed to climate-related risks, particularly in deltaic areas across Italy, France, Spain, Greece, and Egypt (De Lucia et al. 2022). As highlighted by the European Environment Agency (2024), the Mediterranean basin is among the regions most vulnerable to sea-level rise—making it especially at risk of experiencing extreme high water levels up to ten times more frequently across much of Europe by 2050. Coastal areas in this region are increasingly affected by erosion, soil salinization, infrastructure degradation, and declining habitability.

In Europe, flooding events—triggered by a variety of factors—have long been frequent and widespread across the continent (Bevacqua et al., 2019; van de Wal et.al., 2024). The HANZE (Historical Analysis of Natural Hazards in Europe) database (Paprotny et al., 2018) provides an overview of extreme weather events and their impact on European territories between 1870 and 2020. As illustrated in the map (Fig. 3), the number of recorded flood events during this period is surprisingly higher along Mediterranean coastal regions—reaching peaks of up to 45 episodes in the Venetian Lagoon, 39 along the Catalan coast, and 23 in the Comunitat Valenciana—than in other flood-prone northern countries such as Belgium, the Netherlands, or Denmark, where the relationship with water has long shaped spatial planning and territorial governance.

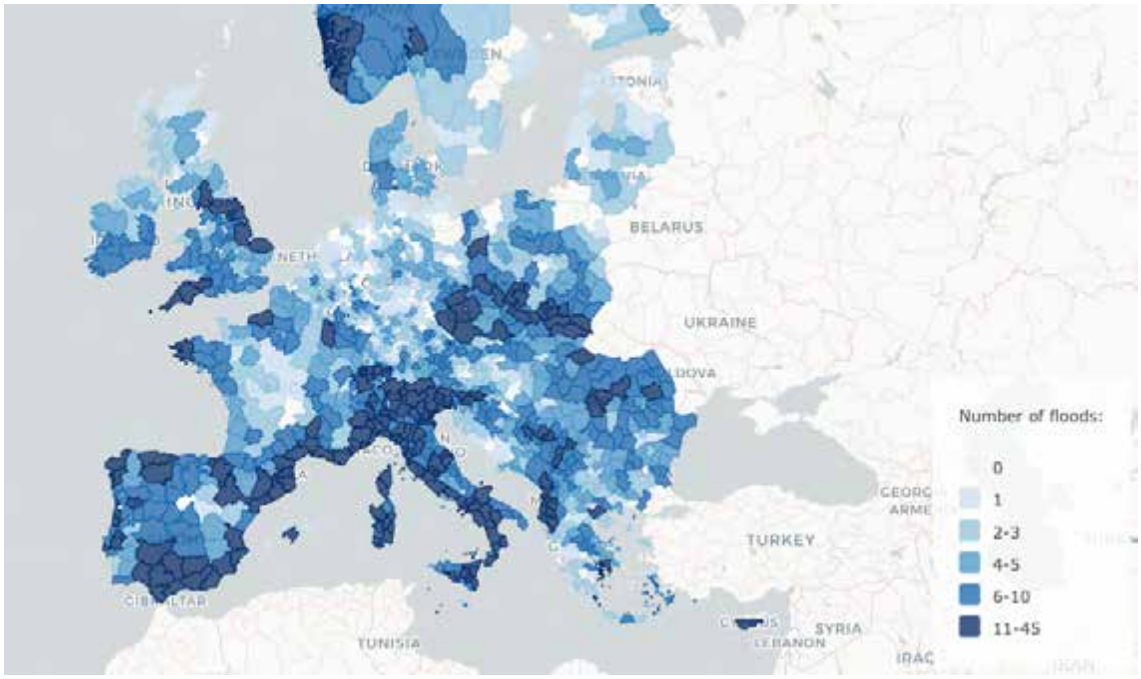

Fig. 3: number of recorded flood events in Europe between 1870-2020. Source: HANZE

However, it is important to note that both the frequency and the intensity of such events determine the actual level of risk for coastal territories. For example, areas like the Po Delta—despite recording a lower number of flood events—are among those most severely affected, with catastrophic impacts in terms of both human lives

and economic losses. This underlines the fact that, albeit with different patterns, the vast majority of European coastlines remain highly exposed to risk.

In territories that have experienced the most severe impacts, large-scale flood defense infrastructures have been implemented since the 20th century. In countries such as the Netherlands and the UK, extensive systems of movable barriers and beach nourishment programs have been deployed. These combined strategies have proven effective, particularly in semi-enclosed geographic contexts—such as bays and lagoons—where engineering solutions tend to have greater impact and efficiency. However, these systems come with high costs—not only for implementation but also for long-term maintenance (van de Wal et al., 2024). Moreover, as natural dynamics evolve—such as further sea-level rise or changes in tidal behavior—these infrastructures may become obsolete or inadequate. It is therefore increasingly evident that the paradigm must shift: rather than continuing to contain seas and rivers, it is human presence, with its settlement pressures and economic activities, that must adapt to natural processes.

Indeed, while climate change is clearly exacerbating existing vulnerabilities, flood events have always occurred across Europe. What has changed in recent decades is the growing urbanization of coastal areas—thereby increasing the exposure and risk to human populations—and the enhanced ability to record and analyze catastrophic events, which has led to a heightened awareness of the issue, including in the Mediterranean basin.

Europe presents a variety of approaches to coastal management and risk adaptation, with differences between northern and Mediterranean countries. While national strategies are more established in some northern contexts, southern regions are beginning to develop their own frameworks, often in response to specific environmental and social challenges. In many cases, it is only in the aftermath of a disaster that political and institutional momentum drives the development of long-term planning and strategic action. In this light, the two case studies presented in this paper—the Netherlands and the region of Valencia in Spain—illustrate parallel trajectories, where major flood events have triggered projects that later informed broader regional strategies.

3.1 Northern Europe: the Netherlands

Among the European countries most advanced in coastal zone management, the Netherlands stands out. The country's physical geography—characterized by the interweaving of the Rhine, Meuse, Scheldt, and Ems River deltas—exposes much of its territory to a constant risk of flooding, exacerbated by the ongoing rise in sea levels. These phenomena pose not only a threat to the resident population but also to the Dutch economy as a whole. As the world's eighteenth-largest economy (International Monetary Fund, 2018), any disruption in the Netherlands would have significant repercussions for the broader European and global economic balance.

This particular territorial condition led the Dutch government to develop flood risk protection strategies much earlier than many other European countries. Of particular interest is the Delta Programme—a modern evolution of the original Delta Plan, launched in response to the catastrophic North Sea flood of 1953, which devastated coastal areas of the Netherlands, the UK, Belgium, and Scotland.

In its initial phases, the Delta Plan focused on the construction of large-scale engineering works aimed at increasing the safety of the country's most low-lying and vulnerable areas. Specifically, the plan entailed the reinforcement of coastal dunes and the construction of a series of massive dams, including the renowned Oosterscheldekering (Eastern Scheldt storm surge barrier, Fig.4). These interventions were carried out between 1958 and 1997 and resulted in 14 major infrastructural works, including dams, sluices, and storm surge barriers. This first phase of the programme is emblematic of the engineering-driven approach typical of the second half of the twentieth century.

Fig. 4: Aerial photo of Oosterscheldekering flood barrier by Frans Lemmens

Today, however, with the increasing risks linked to climate change—coastal erosion, sea level rise, and the growing frequency of extreme weather events—there has been a marked shift toward a more adaptive and resilience-oriented strategy in the Netherlands' coastal management framework.

In 2007, the Dutch government established the Second Delta Commission (the first having been created in the 1950s), chaired by former Prime Minister Cees Veerman. The commission was tasked with assessing the potential impacts of climate change on the Netherlands and providing strategic recommendations for flood risk management. Its findings, compiled in an influential report, have guided national climate adaptation policy ever since.

The report contains twelve key recommendations, addressing a wide range of issues including:
- The structural integrity of dikes and flood defenses in the Netherlands;
- Urban development in areas with high flood risk;
- The administrative, organizational, and financial aspects of implementing flood prevention measures.

Following the adoption of these recommendations, the current Delta Programme was established through the Delta Act, which came into force on January 1, 2012. The Delta Act formally defines the roles of the Delta Commissioner (who manages the programme) and the Delta Fund (which provides its financing). The entire programme operates under the direct responsibility of the Ministry of Infrastructure and Water Management. The Act also mandates that the programme be updated annually, and it is financed through a dedicated annual budget of €1 billion from the Delta Fund.

The Delta Programme represents a long-term adaptation and resilience strategy for the Netherlands (Fig.5), operating across both national and regional levels. Its central goal is to align climate change management with socio-economic development needs. Operationally, this strategy is articulated through several key components: (i) Delta Decisions, which define the overarching national regulatory framework[1]; Delta Plans, which translate these

1 Between 2010 and 2014, five Delta Decisions were developed, forming the foundation for policy and planning over the next 35 years: 1. Delta Decision on Flood Risk Management; 2. Delta Decision on Freshwater Supply; 3. Delta Decision on Spatial

decisions into concrete implementation measures at both national and regional levels.[2]

Adaptive Delta Management
Since its establishment in 2009, the Delta Program has progressively evolved by adopting the so-called Adaptive Delta Management (ADM) approach—an adaptive strategy, capable of evolving in response to climate or socio-economic changes, and an integrated one, designed to address the various dimensions of water management in densely urbanized contexts (Bloemen, 2019).

Given its long-term perspective, the program's goals are intentionally broad to allow for adjustments and updates over time as priorities become clearer. The Delta Committee has proposed three distinct time horizons (scenarios) for achieving the program's objectives:
1. Concrete interventions through 2050;
2. A clear vision through 2100;
3. Long-term recommendations for beyond 2100.

The ADM methodology is critical to the success of the Delta Program:
«we look far ahead to the challenges facing us and, with this knowledge, we take the measures on time that are necessary and affordable at that point. In doing so, we ensure that we can always respond flexibly to new opportunities and new insights. For example by giving rivers more room step by step[3]. Or by strengthening the coast with sand nourishment operations that we can adjust easily when required: more or less nourishment, or in a different location»[4]

In pursuit of an efficient and adaptive model, the Delta Program relies on the Monitoring, Knowledge, Action cycle, which involves continuously assessing whether: (i) the program is on track with its implementation timeline; (ii) new developments or events necessitate updates to the roadmap; (iii) an integrated approach is being maintained; (iv) authorities, institutions, and stakeholders are being sufficiently engaged.

Based on this methodology, an annual assessment of the program is conducted, along with a comprehensive systemic review of the Delta Decisions and Preferred Strategies every six years.

Adaptation; 4. Delta Decision on the Rhine–Meuse Delta; 5. Delta Decision on the IJsselmeer Region

2 1. Delta Plan for Flood Risk Management; 2. Delta Plan for Freshwater Supply; 3. Delta Plan for Spatial Adaptation

3 The *Room for the River* project (lounched in 2007 and largely implemented by 2015) was a key precursor and pilot for the Delta Programme.

Decision Making

The experience of the Delta Program is particularly relevant when it comes to the decision-making process, that is, the sequence of events that led the Netherlands to formally adopt this national strategy. In the early 2000s, although political interest in climate adaptation was steadily growing, no concrete decision had yet been made regarding when and how to move forward with a new, forward-looking approach to climate-related risks.

Once again, it was an emotional and political response to a natural disaster—specifically, the devastation caused by Hurricane Katrina in the United States (see section 2. International References)—that provided the necessary momentum for change in the Netherlands.

The key milestones that led to the institutionalization of the Delta Program can be summarized as follows:

- March 2005: Senator Lemstra introduces a motion urging the government to invest in a proactive strategy to anticipate climate change and rising sea levels.
- May 2005: In response to this motion, the Ministry of Housing, Spatial Planning and the Environment launches the national program Climate Adaptation and Spatial Planning (ARK).
- August 2005: Hurricane Katrina strikes the U.S. Gulf Coast. The catastrophic impact of the storm serves as a wake-up call for the Dutch government, reinforcing the urgency of the ARK program.
- 2006: The Royal Netherlands Meteorological Institute conducts a study to assess the potential impact of sea level rise on Dutch territory.
- 2007: ARK publishes the first National Adaptation Strategy (NAS), identifying flood safety as one of the most pressing issues to address.
- June 2007: The Ministry of Transport, Public Works and Water Management releases the Water Vision report. Among its most important proposals is the establishment of a high-level, independent advisory committee dedicated to long-term planning and climate adaptation.
- September 2007: In line with the Water Vision, the Second Delta Commission is established.
- 2008: The Delta Commission publishes its final report.

• 2009: Climate adaptation policies are consolidated through the creation of the Delta Fund, providing dedicated financial resources.
• 2012: The Delta Act comes into effect, giving full legal authority to the Delta Program.

In the analysis of coastal governance models, the Dutch case is particularly significant as it exemplifies a comprehensive institutional commitment to adaptive and integrated territorial management. This demonstrates that coastal governance in the Netherlands is not confined to sector-specific planning nor delegated solely to local authorities; rather, it is embedded within a national strategy prioritized as essential for the governance of the entire country. From this overarching strategy, regional-level plans and programs subsequently cascade. Specifically, the financial resources allocated annually to the program by the Delta Fund—with a medium-term horizon of seven years, periodically extended—enable operational capacity that goes beyond planning, supporting projects and initiatives at multiple scales.

3.2 Mediterranean Basin: Valencia Region

The urban transformation of Valencia in response to water-related disasters exemplifies a critical shift toward ecological awareness and urban resilience. The pivotal moment came in 1957, when a catastrophic flood of the Turia River inundated the city, causing widespread destruction and significant loss of life. The disaster exposed the inadequacy of existing flood control measures and forced the city to confront its vulnerability to extreme weather events. In response, authorities implemented a monumental hydraulic intervention: the diversion of the river's course to the south of the city. Known as the Plan Sur, this redirection removed the watercourse from the densely populated urban core, significantly reducing the risk of future flooding. Although it followed the technocratic logic of mid-20th-century modernist planning — emphasizing infrastructure and control — it inadvertently created an unprecedented urban opportunity: the potential reuse of the abandoned riverbed within the heart of Valencia (Fig.6).

Fig. 6: Green Infrastructure in the metropolitan area of Valencia. Source: Muñoz Criado, A., 2009

In the aftermath of the diversion, the former riverbed lay dormant, a linear void threading through the city's fabric. Initial proposals envisioned the space as a transport corridor, complete with highways and rail links, aligned with the era's emphasis on motorization and urban expansion. However, these plans soon met with increasing public resistance. During the 1970s, a groundswell of civic activism emerged, mobilized around the idea that this central space should be reserved for public use rather than further sealed by asphalt. Environmental groups, cultural organizations, and ordinary citizens coalesced around the slogan "El río es nuestro y lo queremos verde" ("The river is ours and we want it green"), successfully halting the infrastructure project.

The outcome of this mobilization was the creation of the Turia River Park (Jardín del Turia), a linear urban park that redefined Valencia's relationship with its hydrographic and ecological heritage. Formalized in the local planning framework of the late 1970s, the project reclassified the old riverbed as public green space, with an emphasis on natural character and multifunctionality. From that point forward, the park evolved as a symbol of the city's capacity for adaptive reuse and democratic planning (Galán, 2011a).

Constructed in 18 sectors and stretching more than 8 kilometers from west to east, the Turia Park integrates a wide range of uses and functions. It acts as a major piece of urban green infrastructure, combining recreational spaces, ecological corridors, cultural institutions, sports facilities, and pedestrian and cycling routes (Galán, 2011b; Medina Piles et al., 2010). Its physical configuration is one of its most distinctive features: sunken approximately four meters below street level, it provides an uninterrupted, traffic-free environment that contrasts sharply with the surrounding cityscape.

This recessed design has a dual character. On one hand, it has contributed to some fragmentation, weakening transversal connections and making parts of the park feel visually and physically isolated from the adjacent neighborhoods. On the other hand, it has proven to be a vital asset during extreme meteorological events. The DANA (Depresión Aislada en Niveles Altos) storm of 2024 demonstrated the park's strategic hydrological role. Acting as a massive floodplain, the park absorbed significant volumes of stormwater runoff, mitigating the impact of the torrential rains that overwhelmed other urban and peri-urban drainage systems (Generalitat Valenciana, 2025). In this way, the Turia Park provided an emergency buffer zone and reaffirmed its value as a piece of resilient infrastructure in the face of climate uncertainty.

Beyond its flood mitigation capacity, the Turia Park stands as a landmark example of urban ecological retrofit. It exemplifies how cities can repurpose obsolete or hazardous infrastructures into multifunctional public spaces that promote environmental sustainability, public health, and social equity. The park's genesis and growth reveal the importance of civic participation, flexible planning instruments, and the willingness of institutions to revise earlier technocratic visions in light of evolving ecological and cultural values.

Nevertheless, the park's full potential has yet to be realized. Its integration into broader territorial systems remains an open project. Linkages with the Albufera Natural Park to the south, the Huerta de Valencia agricultural landscape, and the upstream Turia Natural Park are still fragmented or underdeveloped (Muñoz Criado, 2009). These connections are essential for establishing a coherent regional green infrastructure that promotes ecological continuity, habitat connectivity, and integrated mobility.

Ultimately, the Jardín del Turia illustrates how cities can turn crises into opportunities — how a site once defined by risk and destruction can be transformed into a symbol of resilience, community, and sustainable urbanism.

Building on the lessons learned from inland adaptive strategies such as the Turia River Park, the Valencian region has progressively extended its environmental planning efforts toward the coastline — a territory equally vulnerable to both anthropogenic pressure and climate-induced hazards. The Mediterranean littoral of the Comunitat Valenciana is characterized by a sharp juxtaposition between ecological richness and urban expansion, where natural systems such as wetlands, dune fields, and fertile agricultural lands coexist uneasily with tourism-driven development and infrastructural sprawl. Recognizing the critical role of the coast in territorial resilience, the Generalitat Valenciana approved in 2015 the Territorial Action Plan for the Green Infrastructure of the Litoral, commonly known as PATIVEL (Plan de Acción Territorial de la Infraestructura Verde del Litoral) (Jódar-Abellán & Molina Giménez, 2019).

PATIVEL (Fig.7) represents a paradigm shift in Spanish coastal governance. Unlike earlier regulatory tools focused on isolated protected areas, this plan introduces an integrated and supramunicipal perspective aimed at ensuring the continuity and functionality of the coastal green infrastructure system. It does so by defining a coastal protection strip extending 500 meters inland from the shoreline — a distance that can be expanded up to 2,000 meters where necessary to guarantee ecological connectivity with inland natural systems (Jódar-Abellán & Molina Giménez, 2019, pp. 715–716).

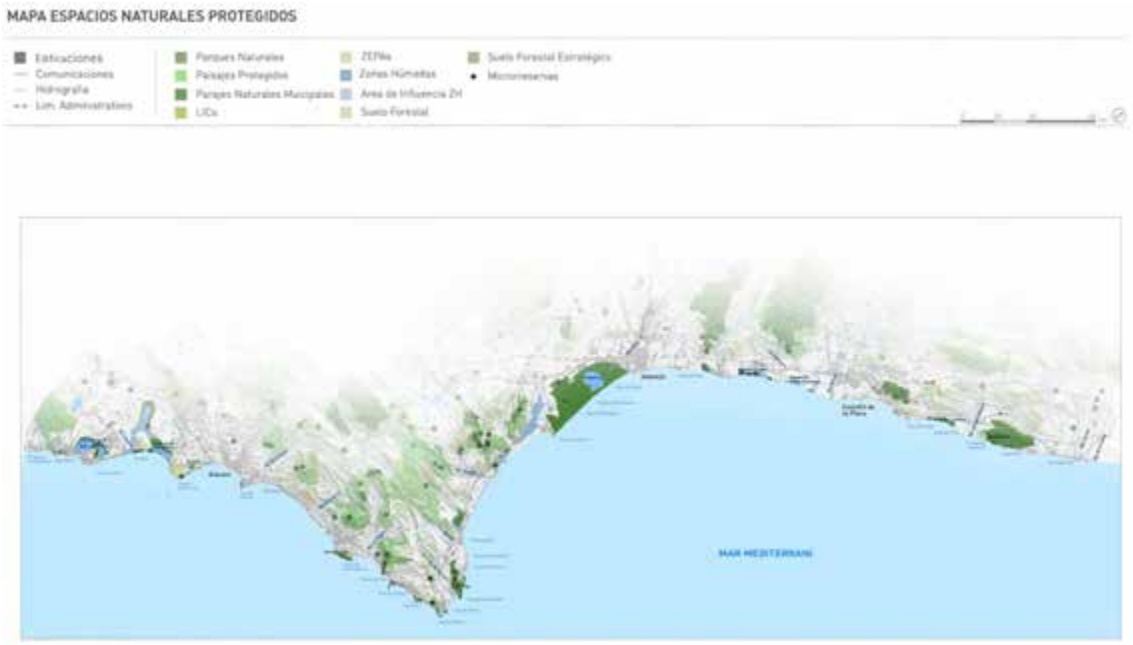

Fig. 7: Map of protected natural areas. Source: Pativel, 2018

This regulatory perimeter includes a wide range of environmental assets: wetlands of international importance (e.g., Albufera and El Hondo), coastal aquifers vital for water security, productive agricultural landscapes such as the Huerta de Valencia, and natural habitats listed under the EU Natura 2000 network. PATIVEL's guiding principle is that these assets should be preserved not only for their intrinsic ecological value but also for their contribution to public well-being, territorial permeability, and disaster risk reduction.

To operationalize this vision, PATIVEL defines five zoning categories based on environmental sensitivity and land-use constraints. These include non-developable coastal areas (ZRP-NA), ecological connectors (ZRC-AG1), regulatory buffers (ZRC-AG2), and areas of common agrarian interest (ZRC-AG3). Through this typological framework, the plan restricts new developments in high-risk or ecologically strategic areas and provides municipalities with a reference model for incorporating green infrastructure into their local planning instruments (Jódar-Abellán & Molina Giménez, 2019, pp. 717–719).

However, as with the Turia Park, the effectiveness of such territorial tools depends on institutional coordination, political commitment, and technical enforcement. One of PATIVEL's most innovative contributions is the creation of the Visor Cartográfico, a digital mapping platform that enables stakeholders — including public officials, professionals, and citizens — to interact with updated geospatial information regarding land classification, zoning restrictions, and environmental constraints. This platform enhances transparency and fosters a culture of participatory governance, echoing the role that civic engagement played in the creation of the Turia River Park (Galán, 2011a).

Despite these advances, the implementation of PATIVEL has faced substantial challenges. In the province of Alicante, for example, political pressures from landowners and local administrations led to a significant reduction — over 50% — of the initially proposed protected areas, raising concerns over potential rollbacks in environmental safeguards and exposing the administration to future claims of patrimonial responsibility for desclassified land (Jódar-Abellán & Molina Giménez, 2019, p. 721).

More importantly, recent events have demonstrated the urgency of PATIVEL's objectives. The DANA storm of October 2024, which caused the overflow of secondary watercourses such as the Poyo stream (Fig. 8) and devastated several peri-urban areas (Torrent, Paiporta, Picanya), illustrated the region's vulnerability not only along major river basins but also across minor drainage networks and urban margins. These territories, often excluded from

major hydrological plans, are precisely the types of zones PATIVEL seeks to regulate through ecological buffer zones and undeveloped corridors. In this sense, the plan functions not only as a regulatory document but as an adaptive framework — one that anticipates the multifunctional role of open spaces in risk mitigation, biodiversity conservation, and climate adaptation (Generalitat Valenciana, 2025).

Fig. 8: The Albufera area of Valencia, before and after the DANA. Source: ESA, Landsat-8 satellite, published by El Independiente

The coastal zone thus mirrors, on a regional scale, many of the tensions and possibilities observed in the case of the Turia Park: the friction between development pressure and landscape preservation; the necessity of cross-scalar governance; and the potential of green infrastructure to serve as both ecological and civic infrastructure. Just as the sunken corridor of the Turia River offered an unexpected but critical role during extreme rainfall events, the preservation of open coastal land — often undervalued — may prove essential in the face of sea-level rise, salinization, and hydrometeorological volatility.

In conclusion, PATIVEL represents a robust, if imperfect, attempt to shift coastal planning paradigms from reactive protection toward proactive resilience. Its integration with wider territorial plans — including the Plan de Acción Territorial del Paisaje, the regional wetland strategy, and local urban development plans — is crucial for its success. Like the Jardín del Turia, it reflects a broader redefinition of landscape not only as an aesthetic or natural element but as a strategic infrastructure for the future of Mediterranean cities.

4. Discussion: comparing pathways

Both the Dutch Delta Programme and the Valencian PATIVEL reflect how environmental disasters can act as pivotal catalysts in transforming spatial planning paradigms. The 1953 North Sea flood and the 1957 Turia River flood exposed systemic vulnerabilities and triggered immediate technical responses. Yet, rather than leading directly to comprehensive strategies, these events initiated a progressive trajectory—from emergency response to pilot projects, and eventually to the formulation of enduring territorial strategies.

The two case studies are particularly interesting to compare due to the temporal proximity of their trajectories, which both began in the 1950s. To facilitate comparison—both in terms of timing and in relation to governance structures and spatial scales—the main points are summarized in Table 1.

Table 1

Dimension	Delta Programme (Netherlands)	PATIVEL (Comunitat Valenciana, Spain)
Triggering Event	(i) **1953** North Sea flood disaster; (ii) renewed focus post **2005** with Hurricane Katrina	**1957** Turia River flood in Valencia; increasing coastal degradation
Precursor Projects	(i) 14 major infrastructural works including *Oosterscheldekering* (between 1958-1997), (ii) *Room for the River* (launched 2007) — spatial adaptation to flood risk	*Jardín del Túria* (post 1957) — river diversion and public park
Programme Launch	**2010** (official Delta Programme)	**2018** (official adoption of PATIVEL)
Key Objectives	Flood protection, freshwater security, climate change adaptation	Protect coastal green infrastructure, regulate urban expansion
Planning Philosophy	Adaptive Delta Management; "living with water"	Territorial ecological planning; limiting development
Geographic Scale	National (entire delta region); subdivided into regional sub-programmes	Regional: entire Valencian coastal strip (~500 km)
Governance Structure	Led by Delta Commissioner; multi-level collaboration (state, local, water boards)	Led by Generalitat Valenciana; coordination with municipalities
Public Participation	Strong participatory approach, co-creation, expert input	Formal consultations; more top-down approach
Legal and Planning Tools	Delta Act, Water Act, Environment and Planning Act; climate stress tests	PATIVEL as a binding Territorial Action Plan; land-use moratoria
Integration with Broader Policies	Linked with housing, agriculture, transport, and energy policies	Integrated with tourism, landscape, and sustainability frameworks
Focus Areas	River basins, coastal areas, urban settlements, agricultural zones	Ecological corridors, tourism zones, vulnerable coastal lands
Implementation Style	Long-term planning cycles (6 years); yearly updates	One-time plan with implementation oversight and revisions

In both contexts, it was the project—not the plan—that first redefined spatial and ecological possibilities. In the Netherlands, the Room for the River initiative (2007) marked a shift from purely technocratic flood defense to spatially integrated adaptation. Similarly, in Valencia, the creation of the Jardín del Túria transformed a flood-prone riverbed into a central green corridor, setting the stage for broader ecological thinking that would eventually underpin PATIVEL.

This trajectory underscores the value of concrete interventions—pilot projects capable of reshaping collective imaginaries and institutional approaches—as necessary precursors to robust, long-term strategies. In the Dutch case, this process was institutionalized through dedicated funding mechanisms like the Delta Fund and a multi-level governance framework. In contrast, PATIVEL's implementation faced fragmented authority and local resistance, particularly in areas like Alicante where political pressures halved the extent of proposed protections.

While the Netherlands and the Comunitat Valenciana differ in geographic, economic, and cultural contexts, they both illustrate a common pattern of adaptive transformation. This shared experience highlights the necessity of proactive planning, informed by past disasters but not dependent on future crises to spur action. As discussed in this paper, flooding has always been part of Europe's coastal and deltaic histories. The real challenge lies in moving from reactive responses to anticipatory governance, recognizing that all such territories remain inherently vulnerable under changing climatic conditions.

5. Conclusions

This contribution presents a section of the PRIN COSTA|Med research project, funded by the Next Generation EU initiative. The broader project focuses on collecting and analyzing international case studies (Fig.9) where climate

change adaptation and sea-level rise strategies have emerged in response to catastrophic events or situations of acute environmental, urban, and social vulnerability. The aim is to identify shared trajectories that can inform the development of guidelines for coastal zone management and adaptation across the Mediterranean—adopting an integrated perspective in which planning and design work together. Strategic visions must guide action, but strategies themselves are also shaped through concrete interventions.

Fig. 9: Location of the different global case studies considered in the PRIN COSTA|Med research project. In red, innovative territorial design initiatives; in blue, completed case studies.Source: Marta Rabazo Martin

The two case studies discussed—the Dutch Delta Programme and the PATIVEL in the Comunitat Valenciana—demonstrate this reciprocal relationship between strategy and project. These experiences are particularly relevant for other coastal territories, even those not yet severely affected by extreme events. As highlighted throughout this paper, the entire Mediterranean basin is exposed to a wide range of risks, with potential impacts on population, economic systems, agriculture, and cultural heritage.

Our intention here was to illustrate the methodological approach of our study and some of the key dimensions used to compare and analyze different experiences. In fact, our comparative research spans over [insert number] global case studies. COSTA|Med promotes a research by design approach—a methodology still relatively underdeveloped in Italy but clearly effective in many of the international contexts we have explored.

Furthermore, the project aims to broaden the focus of impact assessments: from analyzing consequences on populations and infrastructure to considering the vulnerability of cultural heritage and cultural ecosystem services. Raising awareness of these often-overlooked dimensions is essential to grasp the full scope of sea-level rise implications.

Finally, we may need to revise our understanding of what constitutes a "disaster." Rather than framing it solely as a sudden and disruptive event, we should also recognize the slower, progressive transformations of territorial practices and heritage uses—changes already underway in many places. Only by acknowledging these evolving dynamics can we begin to see this new form of "disaster" as a potential driver for change, adaptation, and forward-looking planning strategies.

Post-Disaster Population Mobility: Considerations for the February 2023 Earthquakes in Türkiye

Tuğba KÜTÜK[1], Cansu GÜLLER[2]
[1] Gazi University, Faculty of Architecture, Department of City and Regional Planning, Ankara, Türkiye, tugbakutuk@gazi.edu.tr
[2] Atatürk University, Faculty of Architecture and Design, Department of City and Regional Planning Erzurum, Türkiye, cansu.guller@atauni.edu.tr

Abstract
The February 6, 2023 earthquakes in Türkiye caused immense destruction, displacing millions and highlighting the importance of understanding post-disaster mobility. This study examines the socio-economic and environmental drivers of population flows after the disaster, using Geographically Weighted Regression (GWR) to analyse data from receiving cities. Key variables include GDP per capita, unemployment, education, population density, and climate conditions. Findings show that displaced populations mostly relocated to nearby, less-affected cities rather than distant western regions. This shift reveals the critical need for targeted policies addressing infrastructure, employment, and social integration. Unplanned relocation can worsen inequality and deepen socio-economic divides. The study underscores the importance of integrating mobility data into disaster recovery planning, emphasising equitable, long-term strategies that enhance resilience and reduce vulnerability in both affected and receiving areas.

Keywords: Post-disaster mobility, earthquakes, unplanned relocations, urban resilience, Türkiye

Introduction

The increase in the frequency, intensity and impact of natural disasters worldwide in recent years has made disaster management and recovery processes even more critical. Among natural disasters, earthquakes, with their devastating and unpredictable effects, cause great loss of life and property on a global scale. An analysis of nearly 100 major earthquakes that have occurred worldwide since 1900 shows that 93% of global deaths are caused by earthquakes (Daniell et. al., 2017). If urgent, fair and permanent solutions to the economic, ecological, psychological and social problems that occur after earthquakes are not produced, much more serious problems, including security, will come to the agenda (İrdem and Mert, 2023). Foremost among these problems is the earthquake-related phenomenon of forced migration. This makes post-disaster population mobility an important focus in understanding not only the physical but also the social and economic consequences of disasters.

This post-disaster population mobility is considered as a critical variable for the success of response and recovery plans. Wu et. al. (2021) state that understanding and predicting the direction and pattern of post-disaster migration is important for assessing the vulnerability levels and resilience capacities of communities. Similarly, it is stated that migration directly affects the demographic structure, labour market, social service provision and infrastructure, and therefore, post-disaster flows are not only temporary but may cause permanent social transformations. This situation forces city administrators to think about laws and practices that will make cities resilient especially in times of crisis.

Türkiye is one of the countries with a high earthquake risk, and the occurrence of two major earthquakes of magnitude 7.8 and 7.5 on 6 February 2023, nine hours apart, centred in Kahramanmaraş, was recorded as a first in history. More than 50 thousand people lost their lives as a result of the earthquake. Approximately 13.5 million people in 11 provinces including Kahramanmaraş, Hatay, Adana, Gaziantep, Kilis, Osmaniye, Adıyaman, Şanlıurfa, Malatya, Diyarbakır and Elazığ were affected and thousands of people had to leave their homes and migrate to other regions. This mass population mobility is not only a coping strategy, but also brings new problems at social, economic and spatial level for the receiving and giving cities. The critical role of population dynamics after the occurrence of disasters requires an in-depth study of this issue in order to draw useful conclusions for

post-disaster response and recovery plans. Understanding the direction, triggering factors and consequences of post-disaster population flows is of great importance in terms of both increasing the effectiveness of response processes and producing long-term resilience policies. At this point, earthquake, which is one of the natural disasters and has a significant impact especially considering the damage and loss of life it causes, also stands out in the legal framework in Türkiye and in making significant decisions on prevention and post-disaster response. In this context, the study aims to contribute to better management of the post-disaster process by addressing the spatial and socio-economic determinants of post-earthquake migration movements.

This article progresses in four sections after the introduction. In the second section, it examines the conceptual framework of post-disaster population mobility, the triggering factors behind post-disaster migration patterns, and the human movements that followed past earthquakes in Türkiye. In the third section, material and method used are explained. In the conclusion section, an evaluation of the results of the study conducted and understanding the direction, triggering factors, and consequences of post-disaster population movements are presented.

Literature Review

Disasters are multidimensional crises that create not only physical destruction but also social instability and vulnerability. Disasters have serious destabilising effects on individuals and societies. Management of these impacts is only possible through planned and multi-actor co-operation. In the literature, this process is generally handled within the framework of the concept of 'disaster management'. Disaster management deals with the pre-planning of natural or man-made disasters, minimisation of damages, effective response at the time of disaster and organisation of post-disaster recovery process (Duruel, 2023).

Population movements following disasters are expected occurrences (Myers, 2002). Especially the loss of life caused by earthquake, which is one of the types of natural disasters, the psychological effects that people experience as a result of the loss of their acquaintances, the destruction or damage of their houses, or the fear of earthquake again in the region where they live lead individuals to different coping strategies. Post-disaster human mobility is one of the main coping strategies adopted by individuals and households to respond to adverse conditions and recover their pre-disaster lifestyles (Dickinson, 2013). Following the devastating effects of earthquakes, individuals who have experienced the earthquake leave the place where they live and migrate to different cities where they feel safer after the disaster in order to meet the basic needs of the affected population such as shelter and safety. These movements may include temporary and permanent relocation, resettlement and return. Human mobility may cause long-term population changes that affect the economy and social structure of the country (Ting-Hsiang et. al., 2024). However, this situation has caused and is thought to continue to cause many problems both in the abandoned earthquake zone and in the settled provinces. While migrating individuals struggle with the effects of being cut off from social networks, adaptation difficulties and psychological traumas, migrating regions lose resources and resilience, and their economic and social structures are weakened (Ting-Hsiang et. al., 2024). Understanding the interaction between the recovery of infrastructure systems and population movement (displacement and return) after such large-scale disasters is essential for developing policies that can enable population return in communities and promote sustainable development in hazard-prone areas (Aerts et al., 2018). Therefore, it is vital to take preventive measures to reduce the possible destructive effects after an earthquake and eliminate risks as much as possible.

The direction and intensity of post-disaster population mobility may vary according to the socio-economic characteristics of the migrating individuals. After the earthquake, individuals show three different tendencies: migration to villages/rural areas where those affected by the earthquake think that they are relatively safer; migration to provinces not affected by the earthquake; and migration to large cities. Groen and Polivka's (2010) study on the aftermath of Hurricane Katrina revealed that households that suffered housing damage and were economically disadvantaged were less likely to return. On the other hand, it was observed that some households returned to their damaged houses in a short time due to financial inadequacies and difficulties in finding accommodation elsewhere (OCHA, 2023). There are similar dynamics in the case of Türkiye. After the 1999 Marmara Earthquake, the rate of migration from the region doubled compared to the previous year, while the rate of migration recei-

ved decreased (Peker and Şanlı, 2022). After the 2011 Van Earthquake, approximately 250,000 people temporarily migrated to metropolises such as Istanbul, Mersin, Antalya, Ankara, Bursa and Izmir (Tiryaki Yenilmez, 2023). On 6 February 2023, a similar picture emerged in the Kahramanmaraş earthquake. It was determined that 800,000 people took shelter in villages in the first month of the earthquake and 3.3 million people left the earthquake zone and migrated to other provinces (Sağıroğlu et. al., 2023).

Earthquakes not only displace individuals, but also lead to long-term demographic and economic changes at the country level. In Türkiye, the impact of disasters becomes more evident in the context of regional inequalities. The regional plans and urban plans prepared in Türkiye since the 1960s in order to reduce regional development disparities have not achieved the expected success. While regional plans were inadequate in practice, cities developed in an unplanned and risk-insensitive manner (Özgen, 2007). The post-1980 liberal economic policies led to the concentration of population and investments in the western metropolises and coastal regions located in the most risky seismic belts of Türkiye (Yoloğlu and Zorlu, 2024). This situation has led to the spatial concentration of disaster risks in certain regions and revealed the inadequacies of the planning system in managing these risks. At this point, it is possible to say that the spatial planning system implemented in Türkiye has failed both in reducing disaster risks and in the balanced distribution of population.

The phenomenon of migration has been at the centre of academic research for many years, and many theoretical approaches have been developed to explain the causes, scope and dynamics behind migration movements. One of these approaches, the neoclassical theory, explains migration by economic factors, especially interregional labour demand and wage differences (Rodríguez-Pose and Ketterer, 2012; Scott, 2010). According to this model, individuals tend to move from regions where job opportunities are limited and wages are low to regions where employment is more easily available and wages are high (Whisler et al., 2008). On the other hand, there are also approaches that argue that migration decisions are not limited to economic factors; environmental and social opportunities that affect the quality of life can also be determinant in individuals' relocation decisions. Individuals may prefer to move to regions where wages are lower but more attractive in terms of lifestyle, social environment or natural environment (Nelson and Ehrenfeucht, 2020). Discussions on such opportunities were first raised in the 1970s when Graves (1979) showed the influence of climate factors in migration patterns in the US (Li et. al., 2023). Over time, the concept of amenities has expanded to a wider range of factors that affect quality of life, such as social relations, cultural richness, recreational opportunities, and social tolerance (Scott, 2010; Whisler et al., 2008). However, there is no clear consensus in the literature on the relative weight of economic factors and such life opportunities in migration decisions (Buch et al., 2014; Nelson and Ehrenfeucht, 2020). These differences are thought to stem from the diversity in the social and economic structures of countries (Lee and Kim, 2019). In this context, it is thought that understanding the spatial and socio-economic triggers of post-disaster migration movements in Türkiye will form an important basis for urban managers, planners and stakeholders involved in the process in terms of disaster management.

Material and Method

In this study, a Geographically Weighted Regression (GWR) model was employed to analyze the factors influencing post-disaster migration flows, with a specific focus on spatial heterogeneity. Unlike conventional global regression models, GWR assumes that the relationships between dependent and independent variables may vary across geographic space. As highlighted in the literature (Fotheringham and Sachdeva, 2022; Fotheringham et al., 2009), the underlying mechanisms driving migration flows can differ spatially, and the factors that attract individuals to particular regions are often shaped by local contexts. Therefore, the socio-economic and environmental determinants of migration are expected to exhibit spatially non-stationary relationships (Rijnks et al., 2018; Wang et al., 2019; Szymanowski and Latocha, 2021). To account for these regional disparities, GWR was selected for this study, as it assigns spatially varying weights to each observation based on geographic proximity. The migration data utilised in this research are based on the 2023 records of the Turkish Statistical Institute (TURKSTAT). The dependent variable comprises the number of out-migrants from provinces directly affected by the earthquakes that occurred in February 2023. The independent variables were selected based on an extensive review of the literature and were grouped into three main categories: economic conditions, socio-demographic

structure, and environmental characteristics (Table 1). These variables were derived from 2022 data in order to reflect the pre-disaster context, thus capturing the underlying conditions that may have influenced subsequent migration decisions.

Table 1. Description of variables

Categories	Variable	Source
Economic conditions	Gross domestic product ($) per capita	TurkStat, 2022
	Rental value of a residential property (Unit Prices per m²)	Endeksa, 2022
	Sales value of a residential property (Unit Prices per m²)	Endeksa, 2022
	Unemployment rate (%)	TurkStat, 2022
	Number of enterprises in the agriculture, forestry, and fishing sector	TurkStat, 2022
	Number of enterprises in the manufacturing sector	TurkStat, 2022
	Number of enterprises in the construction sector	TurkStat, 2022
Socio-demographic status	Not finishing a school rate (%)	TurkStat, 2022
	Primary and secondary education rate (%)	TurkStat, 2022
	High school rate (%)	TurkStat, 2022
	Bachelor's degree rate (%)	TurkStat, 2022
	Postgraduate rate (%)	TurkStat, 2022
	Population ratio in the 0-14 age group	TurkStat, 2022
	Population ratio in the 15-64 age group	TurkStat, 2022
	Population ratio in the 65+ age group	TurkStat, 2022
	Population density (per square kilometer)	TurkStat, 2022
Environmental characteristics	Earthquake risk level	Disaster and Emergency Management Authority, 2022
	Distance from the earthquake zone	ArcGIS Pro Living Atlas of the World
	Erinç rainfall activity index	Meteorology General Directorate, 2022
	DeMartonne aridity index	Meteorology General Directorate, 2022
	Average air temperature	Meteorology General Directorate, 2022
	Total annual precipitation (mm)	Meteorology General Directorate, 2022

Economic, social, and environmental factors are considered as major pull determinants that shape individuals' decisions to relocate in the aftermath of a disaster (Görür and Yüzbaşı, 2024). These determinants contribute to differences in perceived utility, which in turn influence the direction and volume of migration. In the category of economic factors, key labour market indicators such as gross domestic product (GDP), unemployment rate, and entrepreneurial activity were considered (Buch et al., 2017; Lee and Kim, 2019; Li et al., 2023). Additionally, housing prices in the destination provinces were included in the model as an economic variable associated with local living conditions (Li et al., 2023). Recent research has shown that non-economic factors have become increasingly influential in shaping migration preferences, complementing traditional economic determinants (Buch et al., 2017; Wu et al., 2019). Accordingly, this study also incorporated socio-demographic indicators such as age distribution, educational attainment, and population density to evaluate the attractiveness of potential destinations. Given the proven relevance of climatic and geographical factors in migration behavior (Görür and Yüzbaşı, 2024), environmental variables such as seismic risk level, average temperature, and precipitation were also included in the analysis.

During the data analysis phase, all variables were first normalised using the min–max scaling method. To address potential multicollinearity, factor analysis was conducted to identify and exclude variables that could compromise the reliability of the model. Subsequently, variables free from multicollinearity were included in various model configurations, and model performance was evaluated using the Akaike Information Criterion (AIC), R^2, and Adjusted R^2 metrics. The spatially varying effects derived from the GWR model were then visualised through maps, enabling the interpretation of statistically significant spatial patterns in migration dynamics.

Empirical Results

Figure 1 illustrates the migration patterns originating from the earthquake-affected region. According to the results, the provinces with the highest out-migration are Hatay, Malatya, and Kahramanmaraş, while Elazığ and Osmaniye recorded the lowest migration figures.

Post-disaster migration flows predominantly occurred either within the vicinity of the affected region or toward western parts of Türkiye. Provinces that experienced substantial out-migration—such as Hatay, Adıyaman, Diyarbakır, Malatya, Adana, and Kahramanmaraş—sent large numbers of migrants to Türkiye's three major metropolitan areas: Istanbul, Ankara, and Izmir. In addition to neighboring provinces, Antalya and Mersin emerged as key destination cities. Notably, Hatay, one of the provinces most severely impacted by the earthquake and the highest source of migration, witnessed large-scale population movements to a wide range of provinces, particularly in western Türkiye. By contrast, provinces that suffered less severe damage primarily experienced migration to adjacent provinces or select major urban centres.

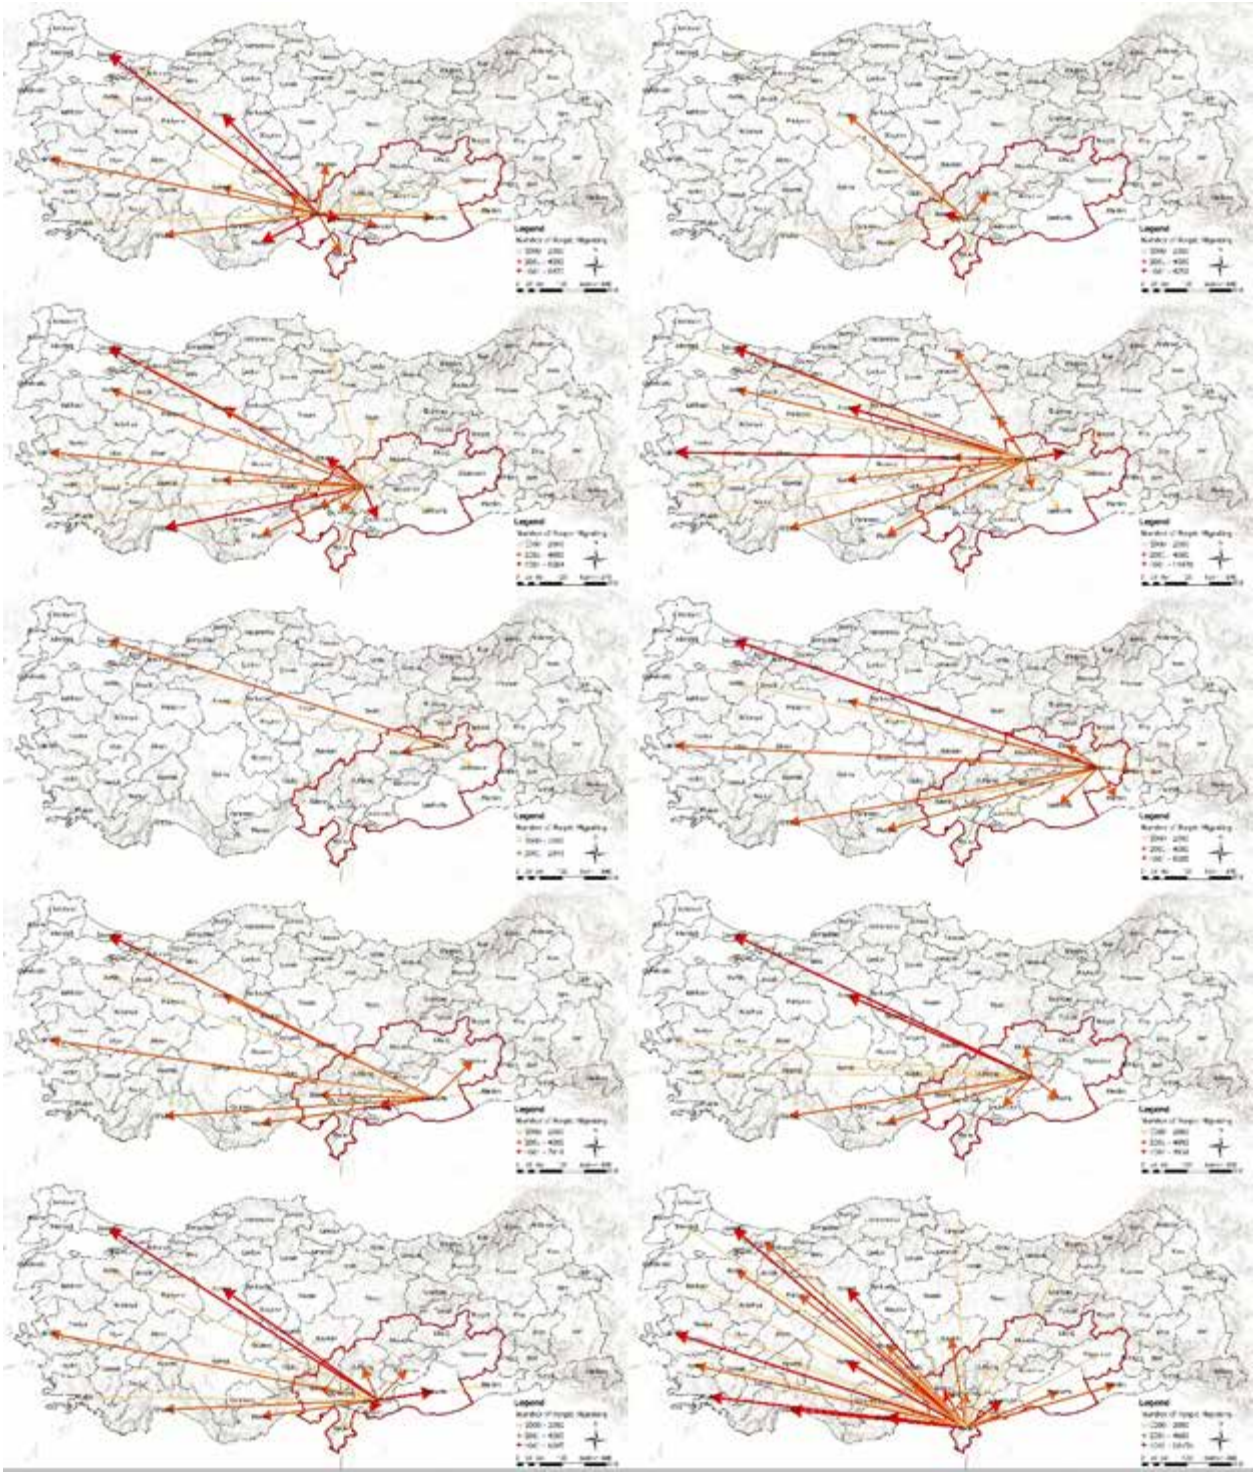

Figure 1. Spatial distribution of interprovincial migration density following the earthquake in Türkiye.

The results of the GWR analysis reveal how the effects of independent variables on the dependent variable vary across provinces, and these relationships are visualised through thematic maps. The figures include both the coefficient maps—which display the magnitude and direction of influence—and the statistical significance maps, which illustrate the spatial variability of effect strength.

Figure 2 presents the spatial relationship and significance levels between the number of migrants from the

earthquake-affected region (independent variable) and gross domestic product (GDP) per capita (dependent variable) across Turkish provinces. The coefficient distribution map indicates a strong negative relationship between GDP per capita and post-disaster in-migration in the coastal provinces of the Mediterranean region. In these areas, lower levels of GDP are associated with higher migration inflows following the earthquake. Conversely, in eastern Türkiye. a positive association was observed between GDP and migration inflows, although this relationship is not statistically significant. These findings reflect the spatial heterogeneity in economic attractiveness and the differentiated role of GDP in shaping post-disaster migration decisions across regions.

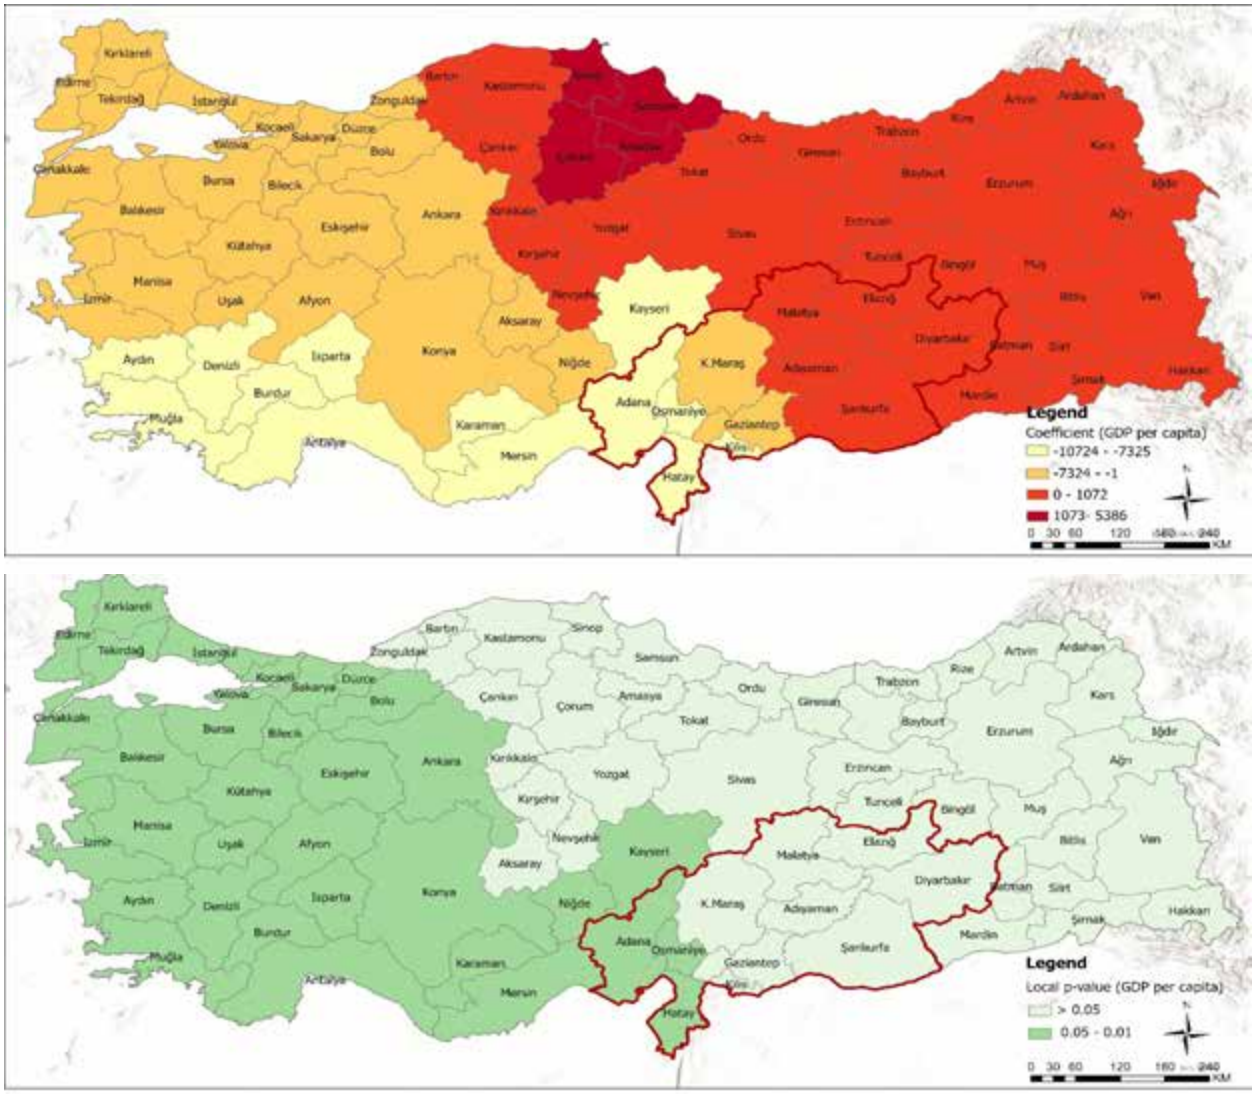

Figure 2. Distribution and significance of the relationship between GDP and post-disaster migration by province

Figure 3 demonstrates that the spatial effects of rental price levels on migration vary significantly across regions. In the northeastern provinces, increases in rental prices exert a negative impact on migration inflows, suggesting that rising housing costs act as a deterrent. In contrast, a positive association is observed in provinces located in Central Anatolia and western Türkiye, where higher rental levels are linked to increased migration inflows. This spatial divergence indicates that the influence of housing costs on migration decisions is not uniform across space. Notably, in western Türkiye, rental price increases do not appear to function as a deterrent, suggesting that post-disaster migration toward these regions is driven by factors other than affordability, and that housing costs are not a decisive factor in migration preferences in the western provinces.

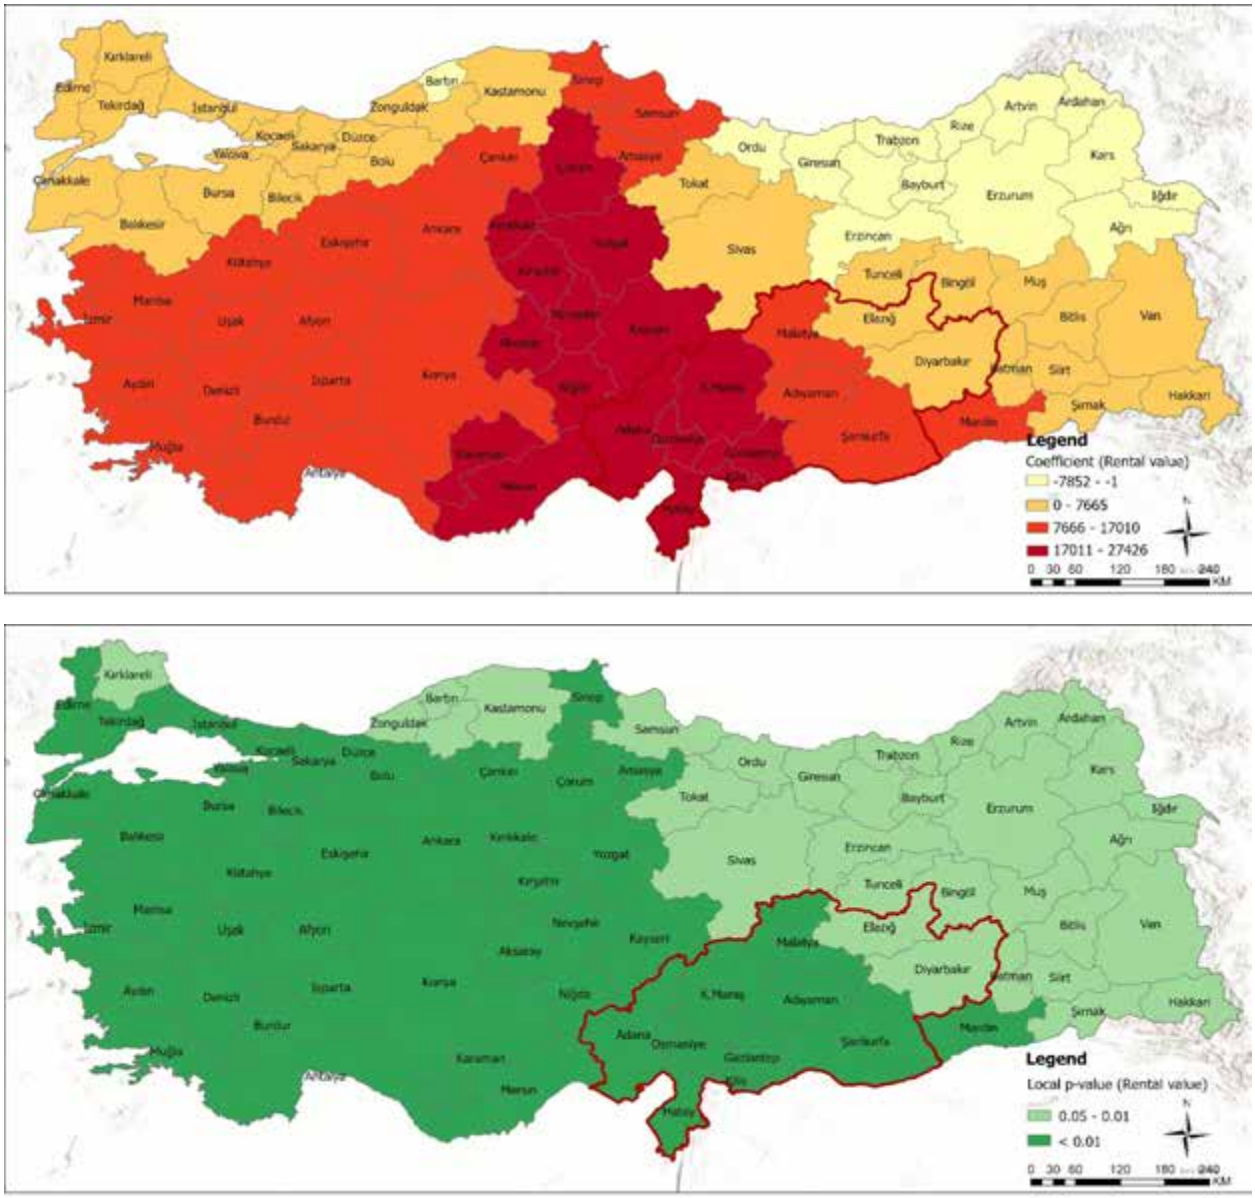

Figure 3. Distribution and significance of the relationship between rental value and post-disaster migration by province

Figure 4 reveals a positive relationship between the number of enterprises in the manufacturing sector and post-disaster migration across all provinces. This suggests that increases in the number of manufacturing enterprises are consistently associated with higher levels of in-migration from the earthquake-affected areas. The effect is particularly pronounced in the eastern regions of Türkiye, where industrial development remains in progress. These findings highlight that investment in the manufacturing sector exerts a significant positive influence on the migration attractiveness of less-developed provinces. In this context, the presence of industrial opportunities appears to act as a key pull factor, especially for populations relocating in the aftermath of the disaster.

Figure 4. Distribution and significance of the relationship between number of enterprises the manufacturing sector and post-disaster migration by province

Figure 5 illustrates the relationship between the proportion of the population holding a bachelor's degree and post-disaster migration. The results indicate a strong positive association between higher education attainment and in-migration in western Türkiye, suggesting that provinces with a higher share of university-educated residents attract more migrants from the earthquake-affected areas. In contrast, in eastern Türkiye, the relationship between the bachelor's degree rate and migration appears to be negative, meaning that increases in the proportion of educated residents are associated with lower levels of in-migration. However, this relationship is not statistically significant in the eastern region. These findings suggest that the higher concentration of educated populations in western Türkiye enhances the migration attractiveness of these provinces. This pattern can be linked to the more developed labour markets, diverse employment opportunities, and higher perceived quality of life in western regions, which collectively act as strong pull factors for disaster-induced migration.

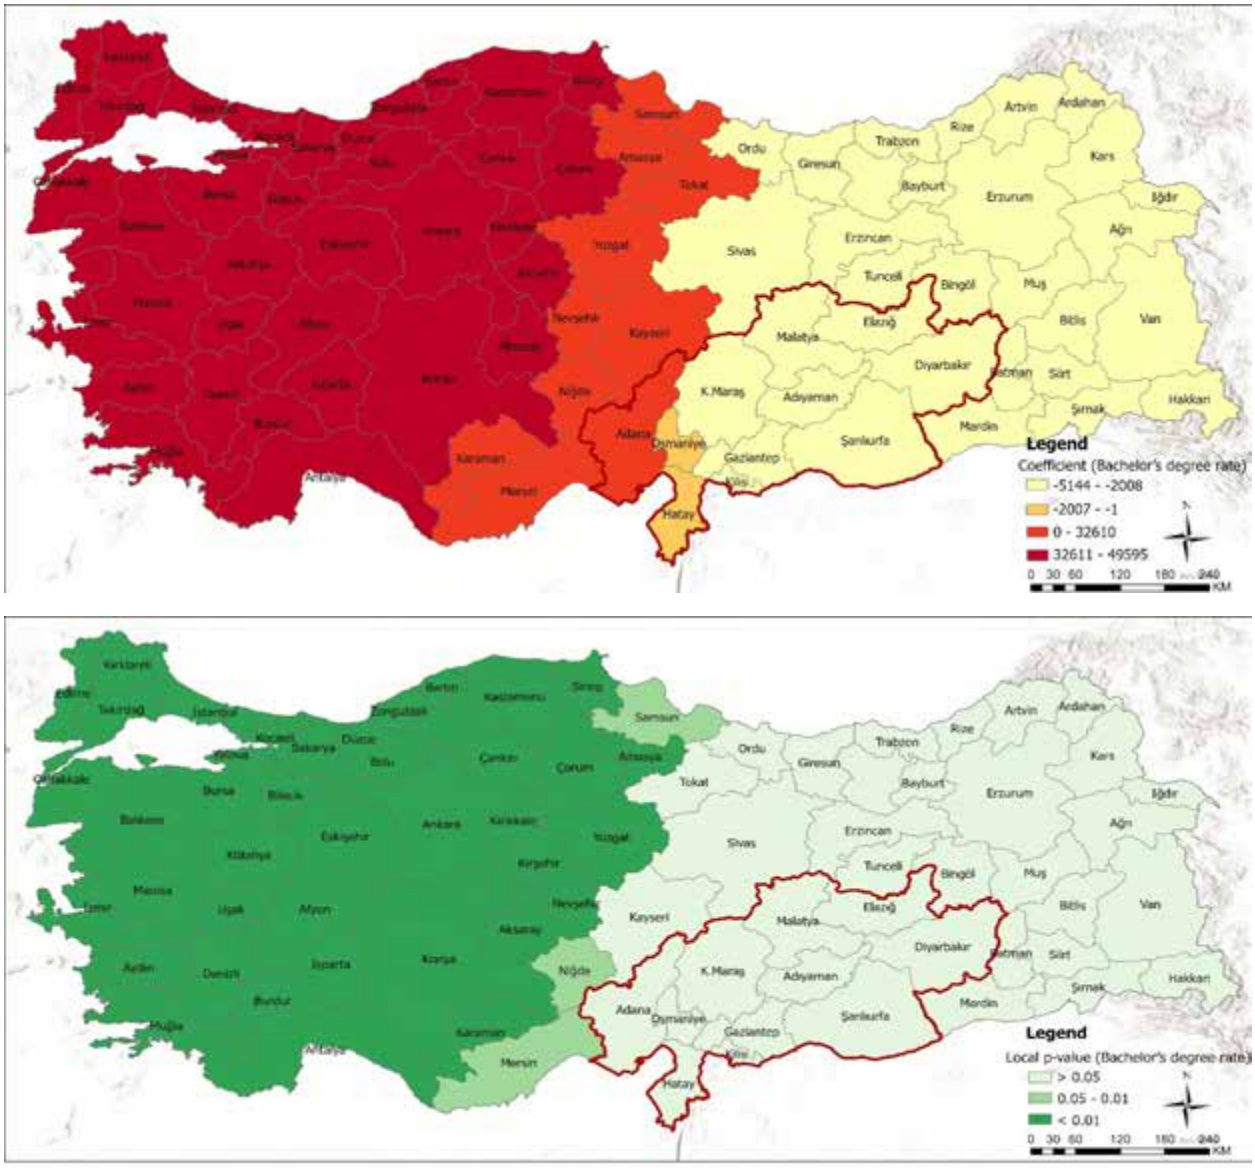

Figure 5. Distribution and significance of the relationship between Bachelor's degree rate and post-disaster migration by province

Figure 6 demonstrates the spatial variability in how provincial earthquake risk levels shape post-disaster migration patterns. In eastern Türkiye, higher seismic risk is significantly associated with reduced in-migration from the affected areas, suggesting that individuals are more likely to avoid relocating to high-risk zones in the aftermath of the disaster. In contrast, in western Türkiye elevated earthquake risk does not appear to discourage migration, indicating that risk perception exerts a less influential role in destination choices in these regions.

These findings highlight the geographically differentiated nature of risk perception in migration behavior. In particular, major western cities such as Istanbul and Izmir continue to attract significant post-disaster migration despite their high seismic vulnerability. This implies that the economic and social advantages offered by these urban centres, such as robust labour markets, higher quality of life, and strong institutional infrastructure, override concerns about earthquake risk, maintaining their appeal even in the face of elevated hazard exposure.

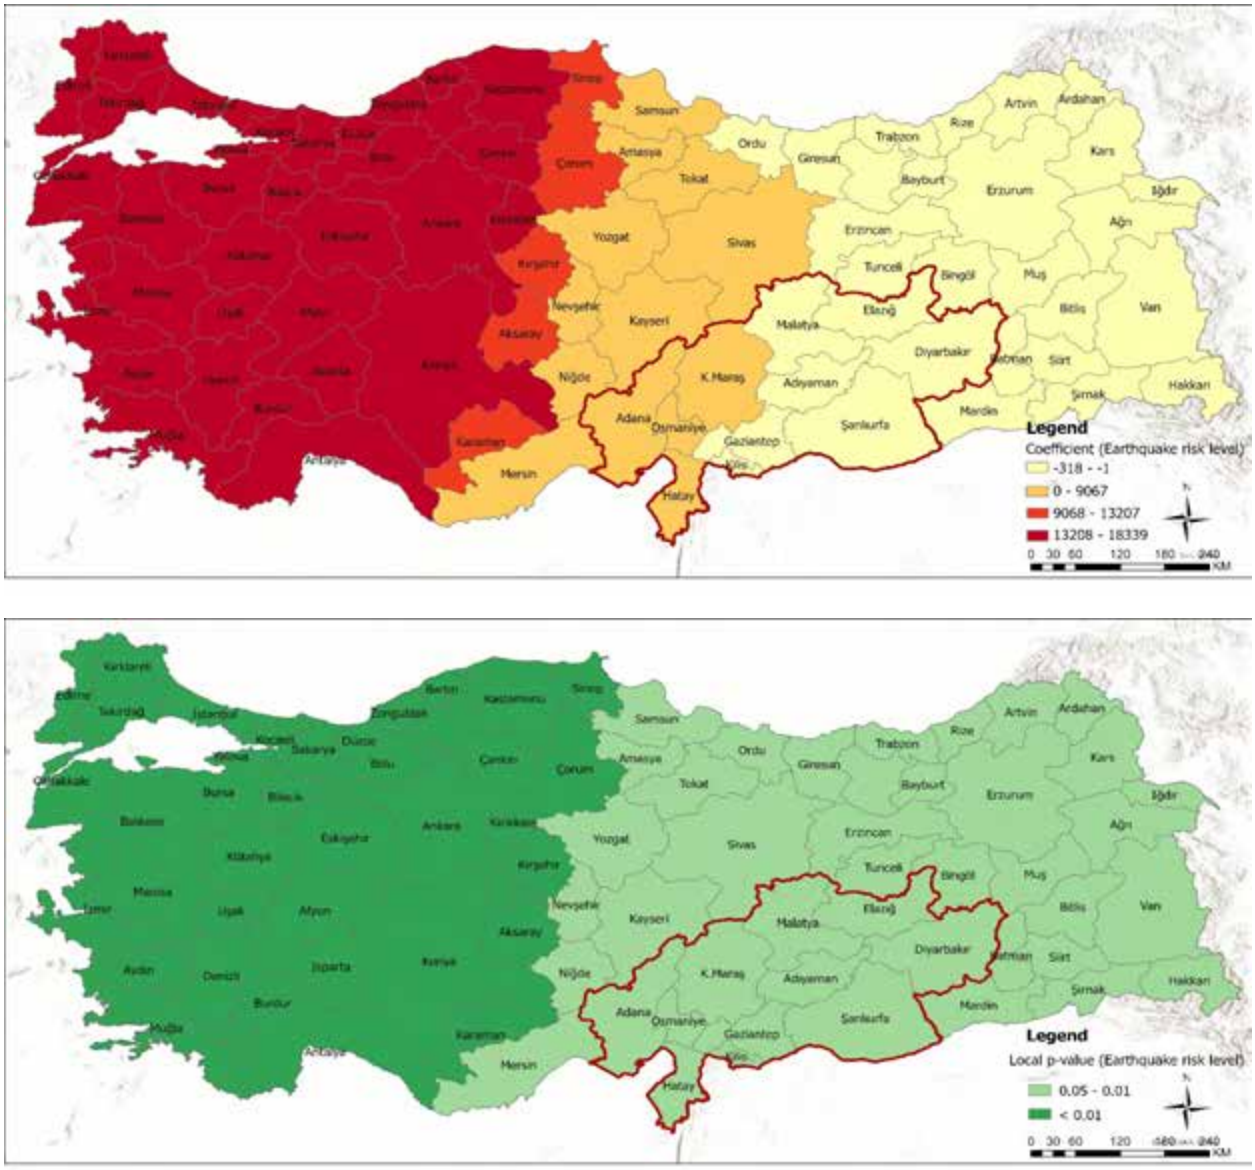

Figure 6. Distribution and significance of the relationship between Earthquake risk level and post-disaster migration by province

Figure 7 reveals the spatial relationship between the Erinç Rainfall Activity Index and post-disaster migration. The findings indicate that in eastern Türkiye, higher levels of rainfall activity are significantly associated with a decline in migration, suggesting that more intense and challenging climatic conditions may discourage displaced populations from relocating to these areas. This relationship was found to be statistically significant. In contrast, in western provinces, although an increase in the Erinç index shows a positive tendency to attract migration, this association does not reach statistical significance. This suggests that while greater climatic comfort may enhance migration appeal in the west, economic and social factors play a more decisive role in shaping post-disaster relocation preferences in those regions.

These results underscore the regionally differentiated impact of climate conditions on migration decisions. In the east, unfavorable weather patterns—despite potentially supporting agriculture-based livelihoods—may act

as a deterrent for disaster-affected individuals seeking resettlement. Conversely, in the west, the limited role of rainfall-related comfort highlights a greater dependence on structural and socio-economic advantages. Overall, the varying influence of the Erinç Rainfall Activity Index points to the non-uniform role of environmental factors in shaping post-disaster migration. Particularly in eastern provinces, climate-related constraints appear to exert a more pronounced effect, emphasising that disaster-induced mobility is not solely determined by economic considerations, but also by environmental conditions within the spatial context.

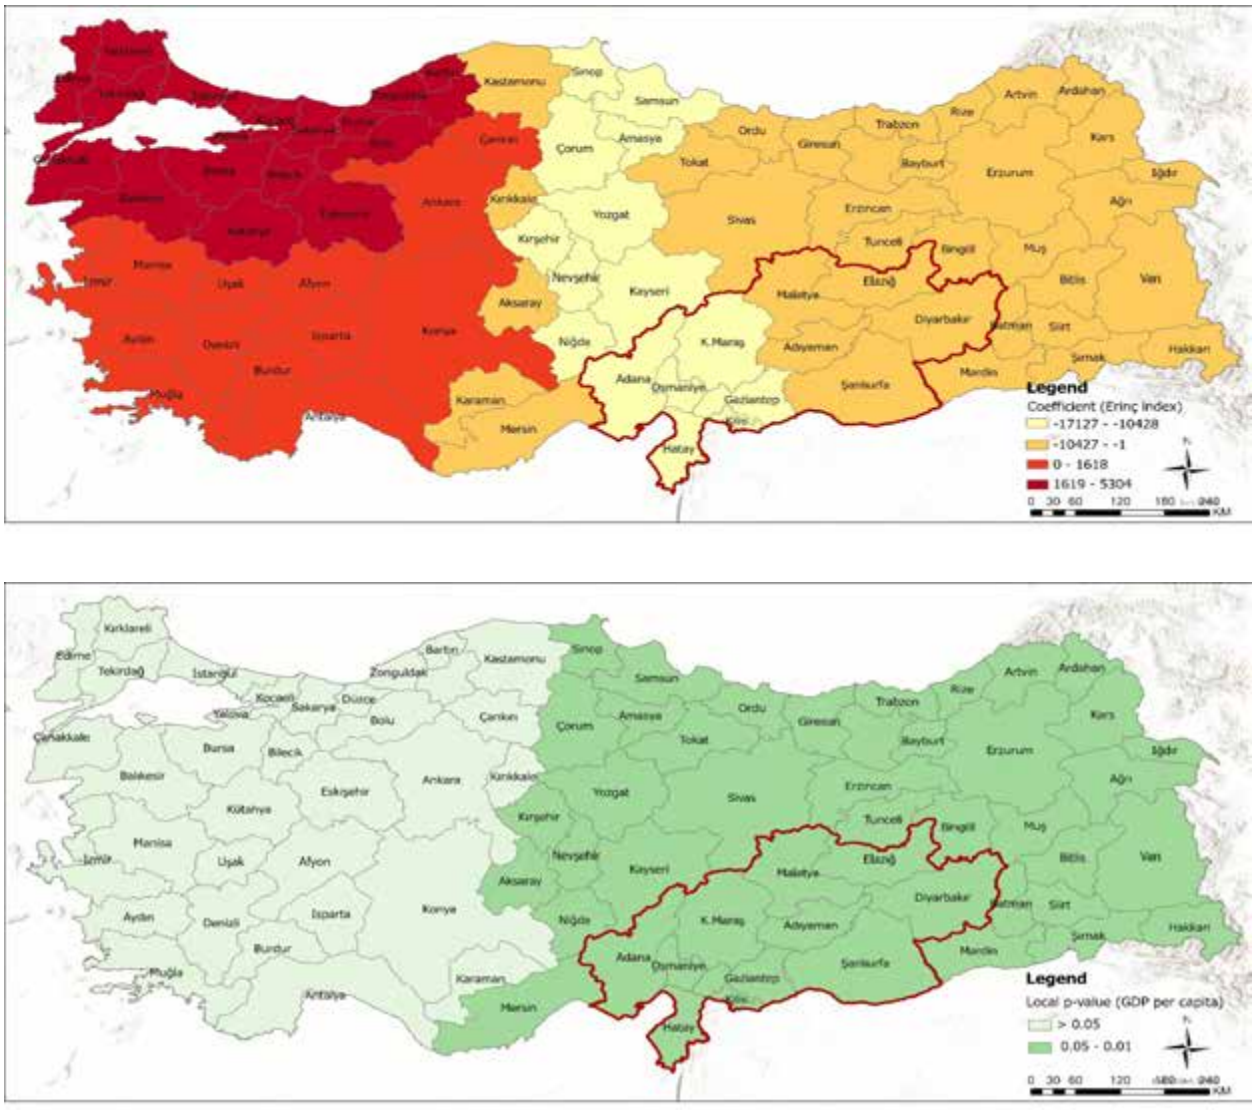

Figure 7. Distribution and significance of the relationship between Erinç rainfall activity index and post-disaster migration by province

Conclusion

This study demonstrates that post-disaster migration flows were disproportionately concentrated in the western regions of Türkiye—particularly in major metropolitan areas such as Ankara and Istanbul—compared to the eastern provinces. In the western regions, economic prosperity (as measured by GDP per capita) and higher education attainment emerged as primary pull factors driving migration. Conversely, in the eastern provinces, the expansion capacity of the manufacturing sector was identified as the most influential determinant shaping increased migration inflows.

On the other hand, factors such as seismic risk, rising housing costs, and adverse climatic conditions were found to suppress migration in eastern regions. Notably, these deterrent factors did not exhibit a significant impact on migration decisions in the west, where their influence appeared negligible.

These findings highlight that the spatial structure of post-disaster migration is shaped not only by economic opportunities but also by a complex interplay of environmental and socio-demographic factors. The fact that migration flows to the eastern regions are more sensitive to a broader range of variables suggests that these areas may be more vulnerable and volatile in terms of their migration dynamics. In this regard, the manufacturing sector's potential to attract migrants in the east holds strategic importance for the formulation of post-disaster population redistribution policies aimed at spatial balance.

Importantly, the study also reveals that post-disaster migration dynamics cannot be fully explained by economic indicators alone. In the eastern provinces, the increasing influence of environmental factors—particularly those linked to climate change—on migration decisions underscores the urgency of developing climate-adaptive settlement and development strategies. Therefore, effective governance of post-disaster migration requires the implementation of integrated policy frameworks that prioritise not only economic development but also environmental sustainability and regional resilience.

Abstract
Italian seismic risk management has traditionally prioritized post-disaster recovery instead of effective urban prevention strategies. This approach carries significant costs, and the speed of recovery plays a critical role in determining whether communities choose to rebuild or relocate permanently. To accelerate post-earthquake recovery and enhance urban resilience, effective disaster risk reduction policies centered on urban prevention strategies to safeguard territorial safety effectively, are needed.

In this work, we introduced the Early Recovery System (ERS) framework that identifies essential urban elements with potential for seismic retrofitting. Through the calculation of 18 indicators over different time intervals and across three hypothetical scenarios in the case study of L'Aquila post 2009 earthquake, we generated recovery curves that illustrate urban functionality loss and recovery trajectories, to establish the optimal prevention strategy to be adopted.

Keywords Seismic risk prevention; Early recovery; Urban functionality assessment

1. Introduction

Italy faces high seismic risk due to several factors, including a widespread seismic hazard, the high vulnerability of its built environment, and substantial exposure in terms of population density and historical-cultural heritage (Dolce et al., 2021). Since 1950, earthquakes have caused approximately 5,000 casualties and significant economic damage (Coviello and Somma, 2021).

Despite this evidence, the predominant approach to seismic risk management has focused mainly on emergency public actions and the physical restoration of individual assets rather than comprehensive urban prevention strategies. This "territorial compensation" approach entails very high costs in terms of financials and territorial equity (Balducci et al., 2021).

Catastrophic events can significantly impact local communities, and time plays a crucial role, as the speed of recovery is decisive in determining whether community members will decide to stay and rebuild or leave permanently (Arendt and Alesch, 2014). Recovery time, defined as the period needed to restore system functionality to the desired pre-earthquake level, is a variable with high uncertainty and typically depends on several complex factors: pre-event conditions, available resources, and governance (Terzic et al., 2021).

To accelerate post-earthquake recovery, policy initiatives such as the Sendai Framework for Disaster Risk Reduction (UNISDR, 2015) have emphasized the potential of stakeholders and communities to become more adaptable through practices and policies aimed at implementing Disaster Risk Reduction (DRR) programs and actions.

Since the 1980s, defining policies and actions for DRR has been the subject of intense technical and scientific experimentation throughout Italy. However, attention has often been limited to prevention interventions primarily implemented on individual buildings. However, protecting entire settlements is unrealistic due to the high costs of interventions, procedural complexity, and the long time required to achieve goals. The challenge, therefore, lies in identifying a minimum system of essential urban functions whose preventive safety measures could reduce urban vulnerability and enable recovery to begin.

The Italian approach to seismic risk prevention in urban areas began to take shape more concretely in this direction after the Abruzzo earthquake on April 6, 2009. Following the consequent massive urban damage, the Italian government introduced a significant funding program of approximately 1.2 billion euros to finance interventions for risk management in seismic-prone territories (Castenetto, 2024). Through the National Plan for Seismic Risk Prevention (PNPRS), the State embarked on an ambitious agenda of Seismic Microzonation investigations, Emergency Limit Condition (ELC) analysis, and structural interventions on buildings. Although the allocated finances represent a small fraction of the expected average annual cost of earthquake damages, the PNPRS is Italy's first national plan considering prevention from an urban planning perspective (Bramerini et al., 2013).

The ELC analysis, focused on validating the emergency management system defined in Civil Protection Plans, aims to verify the existence and consistency of strategic elements in the emergency management system, suggesting intervention priorities to administrators (Tomassoni et al., 2023). The ELC is significant because it represents a step towards reducing urban vulnerability by defining a minimum system of buildings, open spaces, and road networks to be safeguarded to maintain fundamental strategic functions for emergency management.

However, urban vulnerability is a multidimensional concept influenced by building features, functional systems (Braga et al., 2015), and socioeconomic factors (Blackwood and Cutter, 2023). It requires, therefore, a broader vision aimed at maintaining essential settlement functions (Fiore et al., 2018). Following this approach, the Urbisit Project (Cavinato, 2013) extended the concept of building limit states to urban settlements, formulating Urban Limit Conditions (ULCs) as a scale of prevention goals with increasing urban performance to guide seismic risk prevention policies (Bramerini et al., 2013; Basaglia et al., 2019).

In recent years, ULCs have been experimented at both local and national scales. Locally, the 'EQ-DIRECTION' procedure was developed to evaluate a specific ULC aiming to protect essential urban functions necessary for ensuring a rapid return to pre-earthquake conditions (Cattari, 2024). At the national scale, a methodology was proposed to map different ULCs for various earthquake scenarios, estimating the seismic resilience of large-scale communities (Anelli, 2023). Both methodologies, though valuable, have limitations: the first focuses on a specific case study and requires local political involvement, making it difficult to generalize nationally. The second considers only housing as a proxy for urban functionality.

Moreover, ULCs theory has difficulty quantifying performance levels, which range from the worst to the optimal condition—that is, the full recovery of the urban system. This complexity makes it challenging to translate the theory into actionable public policies.

Our work aims at contributing to the debate on urban seismic prevention by proposing i) a new planning prevention instrument for early recovery—the Early Recovery System (ERS)—inspired by ELC and a simplified conceptualization of ULCs, and ii) a methodology to introduce the concept of urban functional recovery assessment. This methodology compares the potential seismic retrofitting of different ERS configurations in a specific risk scenario and provides support for decision-makers.

In this paper, we present: the ERS instrument (Chapter 3) and a set of indicators to evaluate the best ERS configuration and visualize hypothetical post-event recovery trajectories (Chapter 4). We propose a counterfactual experimentation of our methodology on a pilot case study: the city of L'Aquila, severely affected by the 2009 earthquake (Chapter 5).

We want to demonstrate that seismic prevention from an urban planning perspective can guide decision-makers in assessing, a priori, the potential impact of prevention instruments on post-event urban functionality, helping to set intervention priorities and allocate financial resources towards territorial safety goals.

2. Switching paradigm: from building to urban functional recovery

Finding methods to reduce vulnerability and assess the capacity for post-disaster recovery over time is a key motivation for academics and policymakers in promoting community resilience and functional recovery concepts (Mayer, 2019; FEMA, 2021). Over the past few decades, community resilience has emerged as a compelling paradigm to advance DRR initiatives. Generally defined as the ability of a system to prepare for, respond to, and recover from disasters minimizing impacts and damage, the concept has been addressed in extensive literature through two predominant approaches: the socio-economic, focus on the characteristics of local communities (Cutter, 2014; Berke and Campanella, 2006) and the engineering centered on the physical properties of the built environment and its ability to restore functionality over time (Bruneau et al. 2003; Cimellaro, 2016). When applied to urban systems, the concept of resilience often extends beyond physical structures to include the capacity of social, cultural, and economic systems to recover and restore functionality after an earthquake (Burton, 2015; Zhang et al., 2021).

However, improving or building resilience is a process that requires comprehensive and long-term strategic planning. In recent years, the concept of functional recovery has gained attraction as a way to link resilience goals with the design, construction, and retrofitting of individual structures (EERI, 2019; FEMA, 2021). Functional recovery is defined as the post-earthquake state of a building or infrastructure in which its capacity is sufficiently maintained or restored to support pre-earthquake functionality (EERI, 2019). From a public policy perspective, functional recovery should serve as a mechanism for achieving broader community-wide goals. Recent studies (Zhang et al., 2021; Ren et al., 2021) have begun evaluating the functional recovery of building groups at the urban scale, considering both internal factors (building type, age, and function) and external factors (social systems). However, the literature notably lacks consideration of urban planning decisions and practices as a bridge between these internal and external factors.

The built environment plays a socio-spatial role in the urban space, embedded in the lives of local communities. Functional recovery at the urban scale should not be seen merely as the sum of individual buildings' post-disaster functionality. It must also take into account factors such as social networks, accessibility, and a certain level of urbanity, all of which encourage communities to remain in their territories after a disaster.

In this study, we extend the concept of functional recovery to the urban scale by considering an essential urban core of physical elements and their connections, which are necessary for recovery to begin. Given the limited financial resources available, one of the key priorities for decision-makers is identifying, through prevention plans, which buildings and infrastructure are critical for the very early stages of recovery. This selected urban core is treated as a minimum spatial unit to assess urban functionality, which we define as the ability of the urban system to maintain its pre-existing spatial, functional, and relational organization after a disaster. We do not focus on buildings' structural performance, allowing us to maintain a broader perspective on urban planning issues. We strongly believe that just as buildings have different functionality limit states, urban systems may also exhibit varying levels of functionality during recovery, indicating the system's capacity to function after an earthquake.

3. Towards an urban scale prevention instrument: the Early Recovery System (ERS)

Post-earthquake recovery is an evolving process, and while the end goals may be apparent, the path to achieving them is often uncertain. Much depends on how physical reconstruction is approached—whether as a collection of individual building restorations or as part of a comprehensive urban planning strategy. There is also a significant disconnection between response management, which is generally well codified, and the phases of the recovery process. The latter, from the construction of the so-called 'temporary city' to the beginning of recovery and the long-term reconstruction, is often the result of a complex system of decisions and actions, typically implemented on a case-by-case basis over a period ranging from the immediate aftermath to several years later (Coppola et al., 2021).

To bridge short-term response measures with medium- to long-term recovery programmes, the 'Early Recovery' (ER) paradigm (IASC, 2006; UNDP, 2008) was introduced. Although this concept has yet to be fully operationalized, it

primarily focuses on the humanitarian aspects of post-disaster situations, often neglecting the urban planning dimension (Noureddine Tag-Eldeen, 2017). However, without integrating planning expertise into the ER framework, there is a risk of disjointed actions across different post-disaster phases, creating imbalances that could hinder urban development.

Adopting the definition of ER as a multidimensional process that aims at generating self-sustaining, resilient processes for post-crisis recovery, encompassing the restoration of basic services, livelihoods, shelter, governance, the environment, and social dimensions, including the reintegration of displaced populations (IASC, 2006; Cluster Working Group in Early Recovery, 2008), we aim to enhance the ER concept by developing its spatial dimensions. We focused on identifying key services and infrastructures whose immediate usability after an earthquake could be strategic for minimizing common post-disaster effects, such as losses, displacement, and relocation. Observing post-earthquake experiences, and considering that disaster impacts are often more severe in areas with fragile infrastructure, the continuous functioning of basic services, such as healthcare facilities and schools, plays a vital role in strengthening the community's capacity to respond effectively in the aftermath of an event (Burton, 2015; FEMA, 2016; Mutch, 2018; Fontana et al., 2020).

Global campaigns like Hospitals Safe from Disasters (ISDR, WHO, and World Bank, 2009) emphasize the importance of maintaining the functionality, accessibility, and high quality of healthcare facilities after a disaster. These facilities are not only essential for monitoring community well-being (Achour et al., 2014), but communities with a high concentration of primary care facilities generally exhibit better overall physical and mental health, making them more resilient in absorbing and recovering from disasters (FEMA, 2016).

Similarly, integrating the educational sector into DRR strategies is crucial for minimizing a disaster's impact on younger populations, which directly affects the entire community (Tong et al., 2012). Structural improvements to school buildings, combined with enhancing administrators' capacity to maintain cohesion in the school community after a disaster, are key factors (Mutch, 2018). Schools, often centrally located, not only support the well-being of children and young people but also serve as hubs for local social cohesion. As a result, they play a significant role in all phases of the risk management cycle (UNISDR, 2007; ADPC, 2007; GADRRRES, 2022).

Therefore, maintaining pre-existing basic services in situ and preserving their relationship with the territory as part of an interconnected functional system—along with temporary housing plans that respect pre-disaster spatial organization and social networks—form the basis of the Early Recovery System (ERS) concept. Inspired by the ELC prevention instrument, ERS defines a minimum core of elements common to all territories, whose functionality must be preserved to reduce urban vulnerability (Fontana et al., 2024).

Specifically, it comprises i) strategic functions for rescue operations, ii) healthcare facilities, iii) schools, iv) areas for temporary housing, v) the road network that connects these functions, and vi) 'interfering buildings', whose collapse could interrupt system connections.

To define ERS, the first step is to identify the elements and their interconnections on the cartography (Figure 1, Step 1). Depending on the complexity of the road network, the selection of these elements can generate diverse ERS configurations (Step 2), which may change urban functionality levels. To evaluate the best ERS configuration, the different configurations must be assessed on specific risk scenarios (Step 3): for each configuration, the urban functionality loss and the possible recovery trajectory are calculated through a set of indicators (Steps 4). Hypothesizing and assessing different ERS configurations is a way to support policymakers in planning risk reduction strategies and developing intervention programs. While Steps 1, 2, and 4 are the focus of this paper, Step 3 will be explored further in the research process.

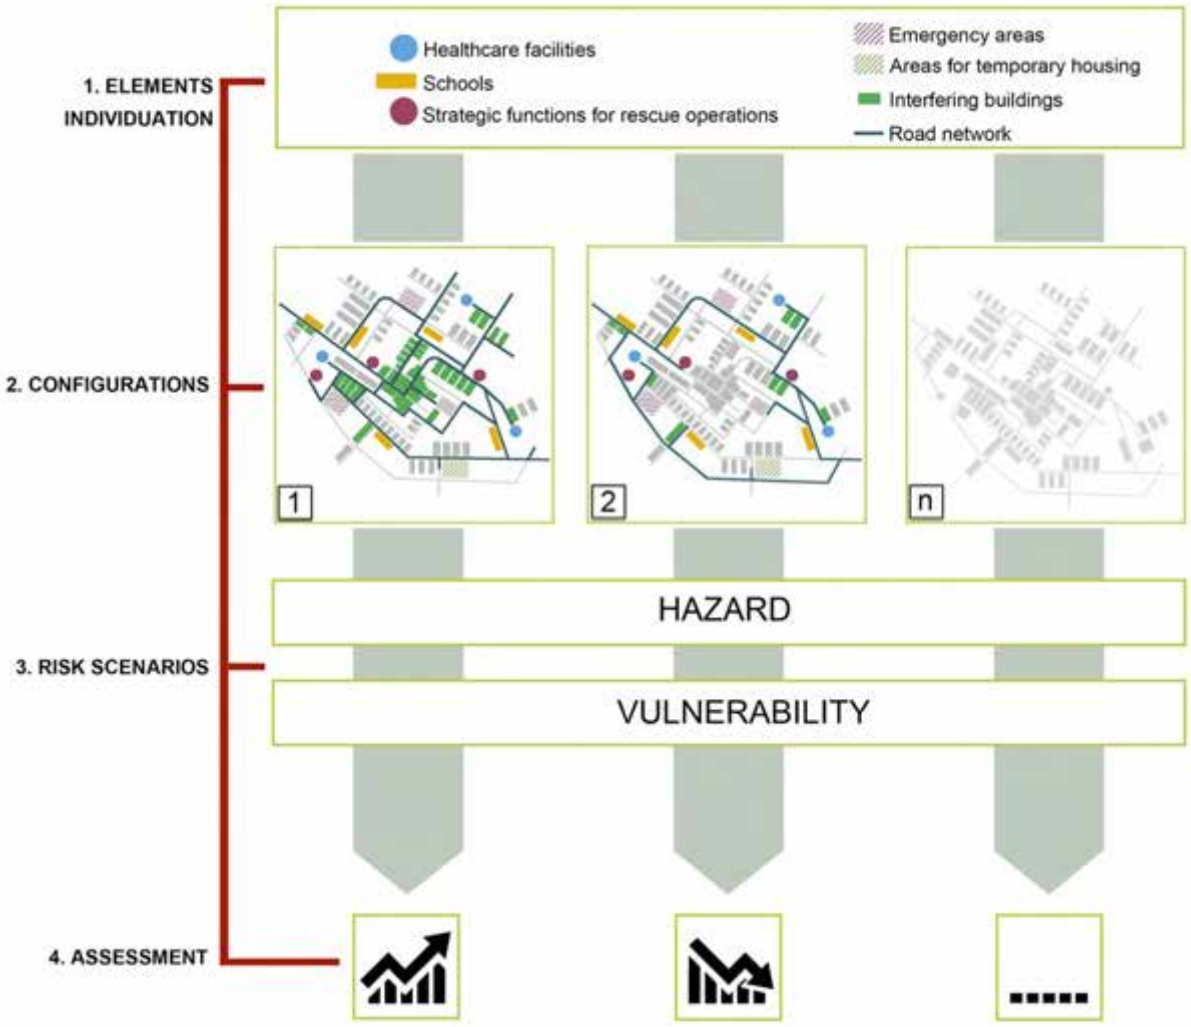

Figure 1. The four steps of ERS planning methodology.

4. A methodology to assess post-earthquake urban functionality

To analyze the urban system's capacity to respond to shocks, we divided it into different functional dimensions that reflect the complexity and multifaceted nature of society (Cutter et al., 2014; Singh-Peterson, 2014; Cimellaro, 2016; Kammouh et al., 2019; Fontana et al., 2020). We identified six dimensions: environmental, housing, school, healthcare, infrastructural, and socio-cultural. To assess the functionality of the urban system and its recovery trends over time, we developed a set of indicators.

According to us, these dimensions help identify the variables that have the most significant impact on the early recovery of a post-earthquake territory and can be directly (healthcare, school, housing, and infrastructural) or indirectly (environmental and socio-cultural) correlated with the ERS elements. To each dimension, we associated a specific urban damage proxy for the loss of functionality measured through 18 indicators (Table I).

For the environmental dimension, we measure the reduction of the environmental balance, a key aspect of the quality of life and human health. To calculate it, we consider two variables: 1) land consumption growth, amplified by the construction of temporary settlements and commercial and facilities areas, and 2) the volume of rubble produced over time from the collapse and/or demolition of buildings. Within the housing dimension, the loss of

functionality is intended as the displacement of households, measured through variables that show the changes in the urban spatial structure due to temporary housing settlements and the consequent relocation of people. This can lead to a loss of community sense and social networks, encouraging the permanent abandonment of places. The school dimension is linked to its usability decrease caused by both service interruption due to building damage and its relocation to a different area. Similarly, the healthcare dimension is linked to the reduction of its usability. In this case, however, it is important to consider not only service interruption and its possible relocation but also the potential post-earthquake performance downgrade or upgrade. For the infrastructure dimension, we measure the reduction in accessibility caused by damage to road infrastructure and the perimeter extension of the 'red zones. ' Finally, for the socio-cultural dimension, fundamental to maintaining and consolidating community identity and sense of belonging, we calculate variables related to the unavailability of cultural heritage and social spaces to measure the loss of socio-cultural networks.

Table I: Selected indicators to describe the loss of functionality in the six dimensions.

URBAN FUNCTIONAL DIMENSIONS	LOSS OF FUNCTIONALITY	INDICATOR	DESCRIPTION	EFFECT
Environmental	Reduction of environmental balance	**Land Consumption**	Expansion of built-up areas, using Corine Land Cover data (hectares)	-
		Volume of Rubble	Volume produced by the collapse of public and private buildings, the demolition of unsafe structures, and public and private building interventions (tons)	-
Housing	Displacement of households	**Displaced Population**	Homeless resident population on total population (%)	-
		Change in the City's Spatial Structure	Average distance of the temporary settlements from the pre-event inhabited areas (meters)	-
		Temporary Settlements Delivery	Temporary settlements delivered to the displaced population (%)	+
		Population Displaced in Hotels	Population displaced in hotels on total homeless residents, weighted based on the distance (%)	-
School	Decreased usability	**Unavailability of School Facilities**	Condemned schools (%)	-
		Repair of the School Function	Reactivated schools, including delocalization and temporary schools (%)	+
		Change of the School service Spatial Organization	Average distance of the new schools from the existing ones (meters)	-
Healthcare	Decreased usability	**Unavailability of Healthcare Facilities**	Condemned healthcare facilities (%)	-
		Repair of the Healthcare Function	Reactivated healthcare facilities, including delocalization (%)	+
		Displacement of Healthcare Facilities	Average distance of the new healthcare facilities from the existing ones (kilometers)	-
		Performance of Post-Earthquake Healthcare services	Value based on the post-earthquake performance of the healthcare service: 0 (no service); 0.2 (medical clinic, ASL); 0.4 (First aid point); 0.6 (Emergency Room); 0.8 (second-level Emergency Admission Department); 1 (first-level Emergency Admission Department)	+

Infrastructural	Accessibility reduction	**Level of Inaccessibility**	Interrupted access to inhabited areas, weighted on residents' number (%)	-
		Red Zone Extension	Ratio of forbidden 'red zone' extension to total urban settlement area	-
Socio-cultural	Socio-cultural relationships loss	**Unavailability of Cultural Heritage**	Condemned cultural building heritage (%)	-
		Unavailability of Sites dedicated to Culture and Social network	Condemned sites dedicated to culture and social network (%)	-
		Repair of Sites dedicated to Culture and Social network	Reactivated sites dedicated to culture and social network, including delocalization (%)	+

4.1 Data collection, aggregation, weighting, and calculation time

After the development of the pre-established risk scenario, all the indicators can be calculated using secondary data sources obtained from open-access databases, primarily from institutional sources. Additionally, information can be extracted from earth observation data to supplement the primary dataset. Each variable is assigned a maximum and minimum value based on the indicator measurement. The calculations for each variable are performed at the local municipal scale. To assess urban functionality, each variable is normalized using a Min-Max rescaling scheme, which allows for the comparison of values across different scenarios and various urban dimensions. This normalization process scales values between 0 and 1, with 0 representing the worst rank and 1 representing the pre-earthquake functionality.

After normalizing the variables, the values are aggregated for each dimension through a simple average. All variables are equally weighted. This decision is based on two main considerations, as argued by Cutter et al. (2010) and supported by the authors: 1) such a method of aggregation is transparent and easier for other potential users to understand and use, and 2) there is no theoretical justification for attributing a hierarchy of importance across indicators. Moreover, all indicators are considered relevant for measuring urban functionality only if observed from an equal and systemic perspective.

The indicators are then calculated over four different time intervals: t=1 (from the earthquake to 1 year after); t=2 (from 1 year to 2 years after); t=3 (from 2 to 3 years after), and t=10 (10 years after).

The first three intervals represent the early recovery period, while t=10 provides an overview of long-term recovery. Calculating recovery at different time points allows for the generation of a recovery curve (see Chapter 5 as an example).

5. L'Aquila after the 2009 earthquake: a counterfactual hypothesis with and without ERS interventions

To test the methodology and evaluate the sensitivity of the chosen indicators to variations in the urban system functionality, the case of L'Aquila, severely damaged after the 2009 earthquake, has been selected as a pilot case study.

With a population of roughly 69,000 inhabitants spread over 470 square kilometers, L'Aquila exhibits a highly fragmented and unbalanced spatial structure. Rebuilt numerous times following earthquakes, its spatial organization has historically centered around two primary systems: a historic center of significant social and cultural value and a vast network of smaller villages.

On April 6, 2009, a seismic event with a magnitude of Mw = 6.3 occurred with the epicenter located approximately 6 km away from the city of L'Aquila. The earthquake severely impacted it and 56 additional municipalities, resulting in 309 casualties and displacing 60,000 inhabitants. A total of 37,000 buildings were damaged, including 34,000 private houses, 1,000 public buildings, and 2,000 buildings of significant historical value (OECD, 2013).

L'Aquila's highly damaged historical center was immediately evacuated, declared 'red zone', and placed under

military control. Residents were rescued and relocated to camps managed by the Civil Protection body or to hotels along the coast. The reconstruction process of the historical center only started in 2012, three years after the earthquake. Consequently, many socio-economic and cultural activities were relocated, and people displaced into temporary settlements scattered and dispersed within the large municipality boundaries (Frisch, 2010).

In this context, we posed the question: To what extent could urban functionality have been preserved if ERS strategy had been implemented before the earthquake?

To address this complex question, we first calculated the indicators based on the current state, considering real damages. We then hypothesized to apply an ERS prevention strategy in a counterfactual manner and calculated the indicators for two hypothetical configurations:

1. ERS1 → connecting elements of the system through the historical town center and relocating temporary housing based on proximity criteria (compact system);
2. ERS2 → connecting elements of the system while minimizing or avoiding passage through the historic town center; temporary housing locations remain unchanged from reality (diffused system).

For each of these configurations and the generation of a recovery curve, we calculated the set of indicators across four different time intervals: t=1 from April 6th, 2009 to March 2010; t=2 from April 2010 to March 2011; t=3 from April 2011 to March 2012; t=10 from April 2019 to March 2020.

For the two hypothetical configurations, ERS1 and ERS2, we calculated the indicators for each interval by subtracting from the real available data the amount derived from the elements potentially retrofitted during the prevention phase to implement the ERS, assuming that the interventions were 100% effective and that there would therefore be no damages that could compromise the functioning of those elements.

For instance, the Red Zone Extension indicator was calculated by measuring the extent of the 'red zone' for each time interval, as defined in various municipal resolutions, in relation to the urbanized area. As the interventions for securing, demolition, and reconstruction proceeded, the boundaries of the restricted zones were updated over time. For the calculation of values in the two configurations (ERS1 and ERS2), the areas occupied by elements included in the ERS were subtracted from these surfaces, considering them as potential safe areas.

Individual values were then aggregated by urban functional dimension. The results for each dimension were visualized using linear graphs illustrating the initial loss of functionality due to the earthquake and potential recovery trajectories over time.

We are aware that the ERS is a complex system (i.e., a system of sub-systems) and that the aggregation of independently calculated indicators may be a forced approximation of reality. In any case, to compare the different configurations in the first instance, we considered ours to be an acceptable approximation.

5.1 Current state: no intervention

Figure 2 illustrates the repercussions of the L'Aquila earthquake on various urban dimensions. The socio-cultural dimension shows the most severe loss: in fact, the historical center, where all the social and cultural activities were concentrated, was completely evacuated and strictly controlled by the institution of the red zone. The historical center began reopening gradually only three years later, exacerbating the impact on social and cultural activities.

The school dimension shows a similar loss, having been heavily affected, with over half of the 36 public schools sustaining significant damage. Students were relocated to temporary school units, located outside the town center, scattered across the suburbs, and often distant from their original locations (on average 700 meters).

Additionally, the environmental dimension exhibits a notable negative trend between t2 and t3. This was primarily due to the extensive construction of the 'temporary city' and the relocation of businesses and services that increased land consumption. Moreover, the long-term physical reconstruction of the historical center resulted in a substantial accumulation of rubble.

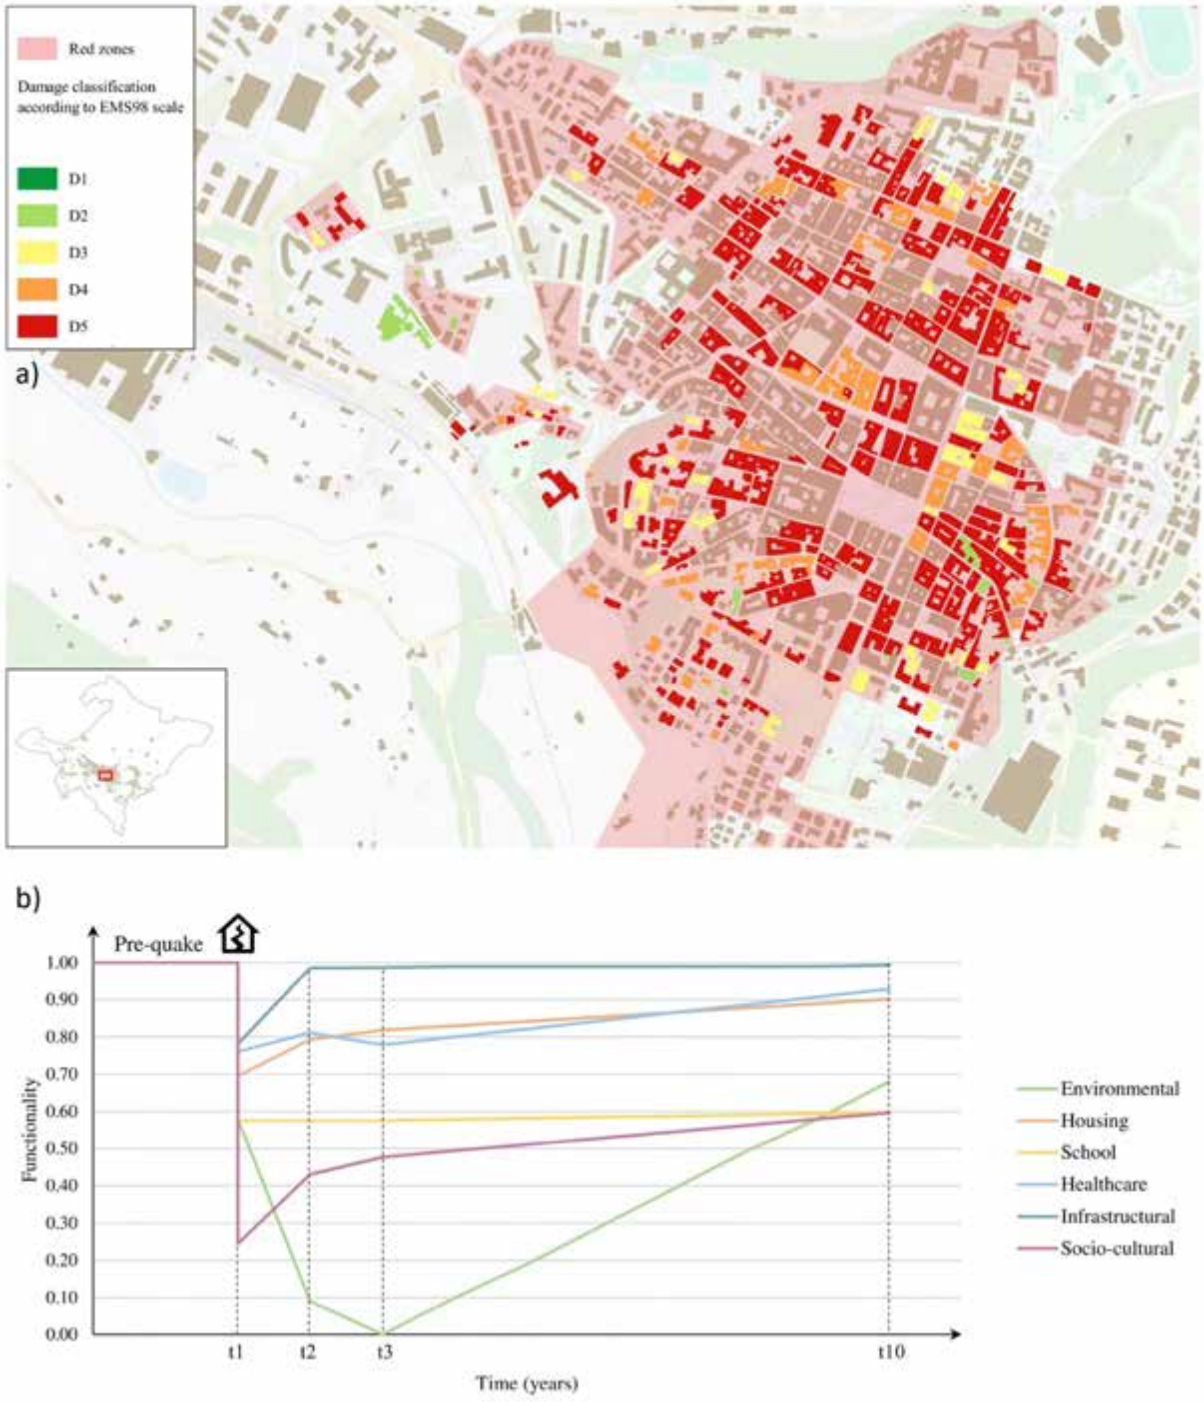

Fig. 2: Map of the damage of private buildings in the historical center of L'Aquila (a); Loss of urban functionality for the current state 'no intervention' (b).

5.2 Configuration 1: ERS1

The ERS1 configuration establishes a network of interconnected elements utilizing a road network through the town center. Figure 3 depicts an excerpt of ERS1, highlighting the elements classified by typologies and a revised demarcation of the 'red zone,' which considers the potential seismic retrofitting of buildings. Given the substantial number of historical buildings involved, implementing a similar intervention program will undoubtedly necessitate a comprehensive planning effort. However, this would promise significant community and financial benefits throughout the long process of post-earthquake reconstruction and recovery.

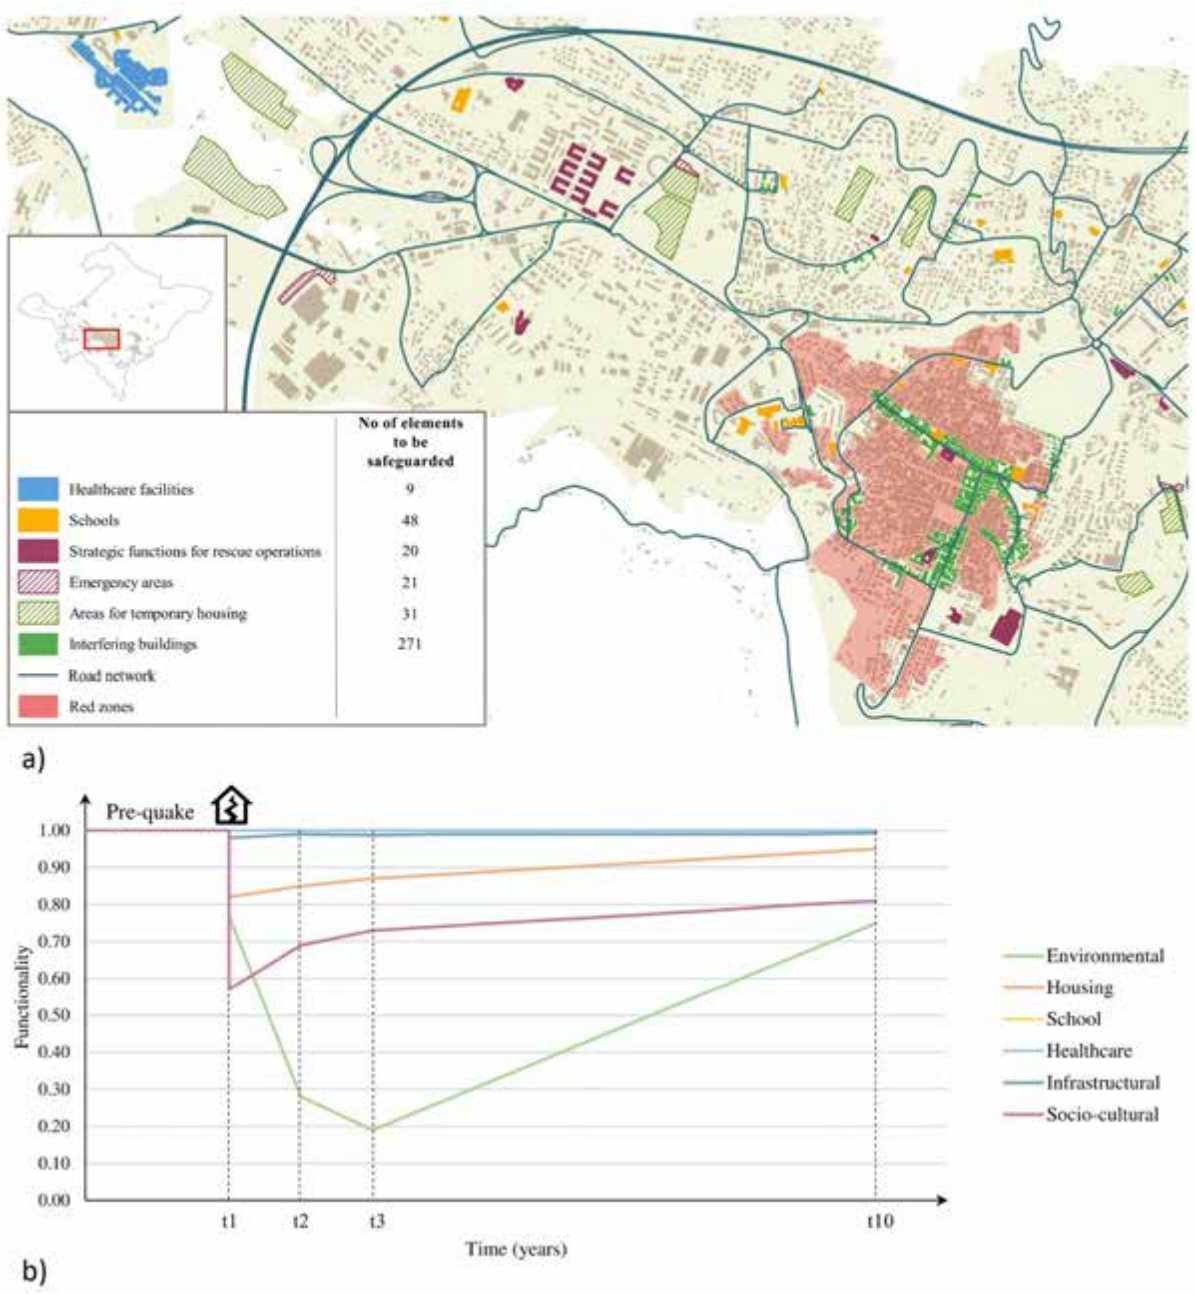

Fig. 3: ERS1. Excerpt of the historical center and surroundings (a); Loss of urban functionality for the ERS1 configuration (b).

During the prevention phase, the potential retrofitting of approximately 350 structural units (public and private buildings), 300 km of roads, and the identification of 31 suitable areas for temporary houses would have helped preserve a significant part of the spatial and relational urban organization. As illustrated in Figure 3, the school and healthcare dimensions would maintain their functionality, while the infrastructural dimension would experience only a minor loss of 0.02. The housing dimension shows a lighter loss compared to the current state (0.18 compared to 0.31) and demonstrates better recovery over 10 years (although the slope of the line remains relatively consistent). The socio-cultural dimension, which includes historical buildings and cultural and social venues, benefits from this configuration, reducing functionality loss from 0.76 to 0.43. The environmental dimension, despite still experiencing significant functionality loss, would also benefit from this configuration, particularly through fewer relocations due to the prevention planning of temporary locations and seismic retrofitting of schools.

5.3 Configuration 2: ERS2

The ERS2 configuration includes the same elements as ERS1, except for the relocation of two buildings for rescue operations outside the town and modified connections between elements outside the center (Figure 4). Additionally, the post-earthquake locations of temporary housing were maintained as determined by government decisions.

With this configuration, the number of potential seismic retrofitting interventions would be significantly reduced, decreasing from around 350 structural units in the previous configuration to approximately 270. The preservation of road infrastructures remains largely unchanged, except for those associated with the historic center.

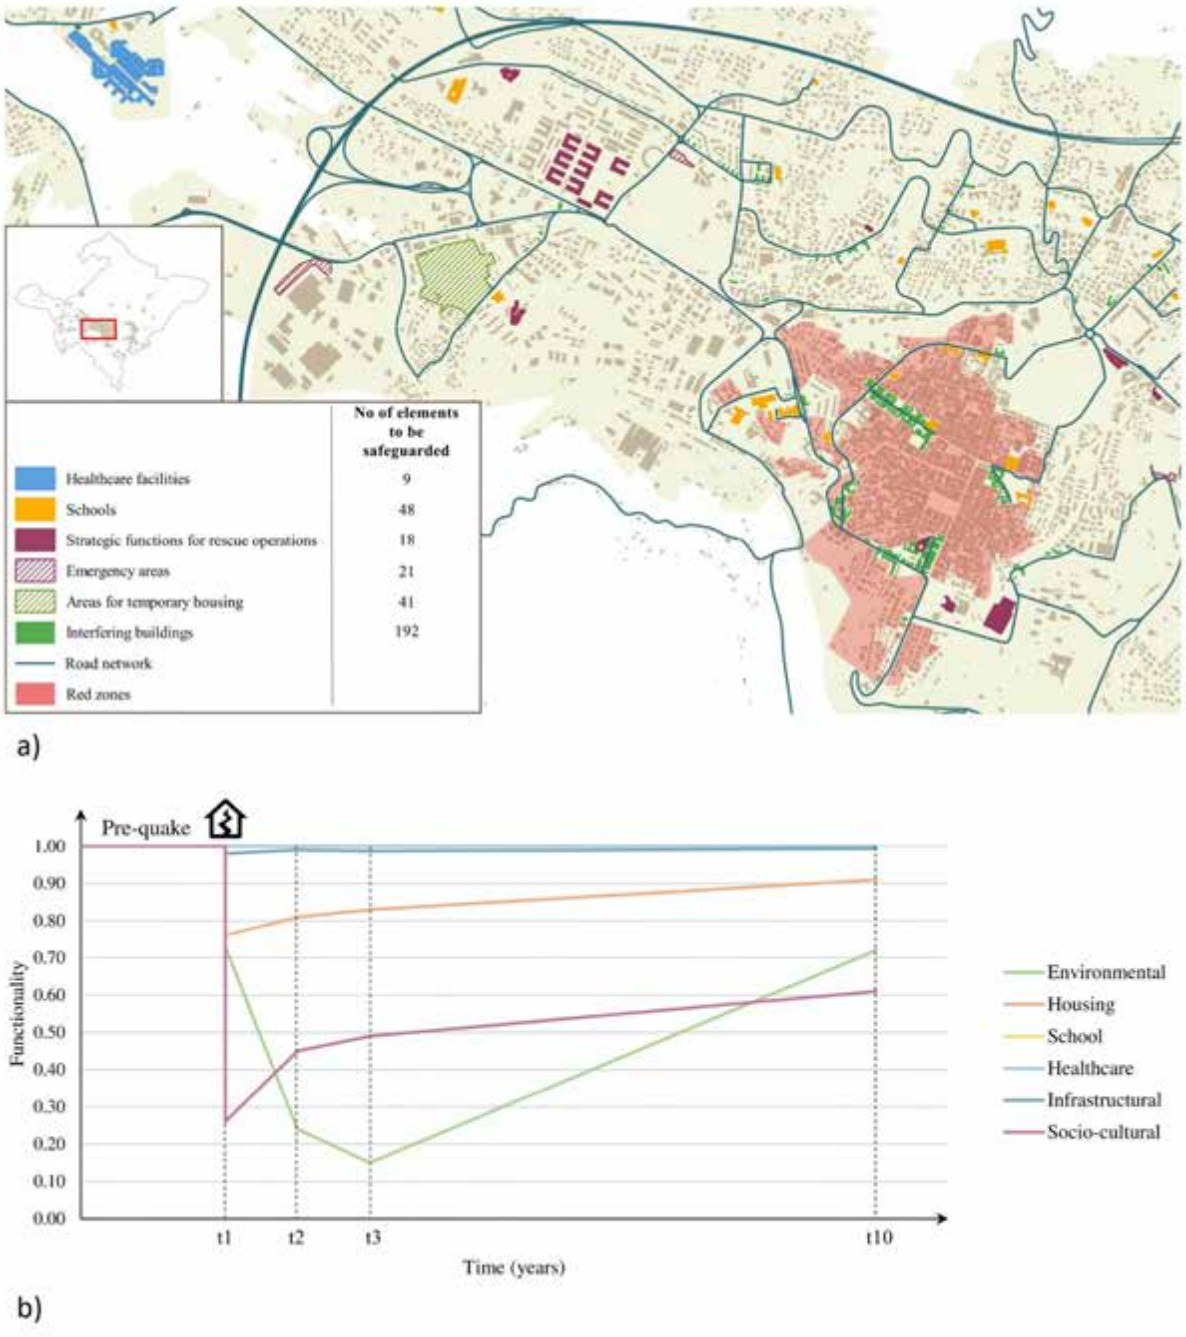

Fig.4: ERS2. Excerpt of the historical center and surroundings (a); Loss of urban functionality in the configuration ERS2 (b).

Like the ERS1 configuration, school, healthcare, and infrastructural dimensions would maintain their functionality in ERS2. However, there is a minor pejorative difference for the housing dimension compared to the previous configuration (functionality loss of 0.24 compared to 0.18). The most significant change occurs in the socio-cultural dimension. By not including the road network within the town center and thus not accounting for interfering buildings, many cultural and social venues would be excluded from ERS2. As depicted in Figure 4b, the socio-cultural functionality curve shows little difference from the current state (0.74 for ERS2 and 0.76 for current state).

5.4 Discussion

In summary, across both ERS configurations, the dimensions directly involved in the selection of system elements (school, healthcare, infrastructural) exhibit very little or no functionality loss. However, the ones indirectly involved still show some loss of functionality, albeit significantly less compared to the current state. Notably, the socio-cultural dimension continues to experience considerable functionality loss in the second configuration (ERS2) due to the absence of a road network within the historic center.

The effects of lacking seismic prevention urban strategies over time are supported by concrete facts. More than 15 years later, the region is still grappling with both physical and socio-economic recovery. L'Aquila's urban system has undergone profound changes in its functional and relational organization, and the overlap between the temporary city and long-term reconstruction has exacerbated socio-spatial imbalances. The reconstruction of public buildings has barely reached 50% of the planned interventions (USRA, 2023), resulting in a scarcity of socio-cultural spaces and the absence of schools within the historic town. The general spatial reorganization, which accelerated a depopulation process already underway before the earthquake, also had significant social impacts, generating collateral effects such as increased land consumption and traffic congestion.

Conversely, the ERS1 configuration suggests that implementing a seismic retrofitting program for the system's elements would have prevented significant damage to the school and healthcare sectors. Additionally, retrofitting the buildings within the historic center—many of which host important social and cultural spaces—would likely have mitigated the loss of functionality in the socio-cultural dimension. This approach would have allowed these functions to continue in situ, without disrupting the city's socio-spatial structure, and would have limited land consumption resulting from temporary relocations.

Regarding the loss of functionality in the housing dimension, since it is not feasible to secure all private residential properties, there is still an evident, albeit limited, loss. The real advantage, therefore, lies in the prevention planning for temporary housing areas, where the choice of locations for new settlements becomes a strategic issue to reduce abandonment processes and excessive new land consumption.

Experimentation on the specific case of L'Aquila post-2009 earthquake allowed us to highlight the strengths and weaknesses of the proposed methodology. Among the weaknesses is the difficulty in obtaining data for calculating the indicators, which did not allow us to detail the various functional dimensions equally and address all characteristic aspects. In addition, the lack of literature on indicators to measure urban functionality, as defined in this paper, made the choice of the indicator set highly experimental.

The absence of existing models in literature pushed us to test the methodology on a specific area already affected by an earthquake, with known effects on the short and long-term reconstruction and recovery processes, to validate the methodology and the set of indicators by comparing them with the state of the art. What emerged is that the proposed variables and the resulting recovery curves seem to reflect the recovery trajectory of L'Aquila. This result allows us to continue the research to abstract the methodology, applying it within a complex framework of risk scenario simulation to support public prevention policies.

6. Conclusions

In this article, we introduced a new prevention instrument for Early Recovery and a methodology to assess urban functionality by comparing different prevention spatial configurations, emphasizing the importance of viewing prevention from an urban planning perspective. Considering that retrofitting the entire urban settlement is unlikely, our approach aimed to identify a proto-system of essential functions, open spaces, and road networks to be preserved to guarantee a minimum level of urban vitality after a major event and foster recovery to begin. In

analogy and continuity with the general structure of the Emergency Limit Condition (ELC) analysis, we developed the Early Recovery System (ERS) instrument. As for the ELC, identifying specific essential elements allows the methodology to be consistently applied across all territories at the national scale.

Through the calculation of a set of 18 indicators, framed into 6 urban dimensions, across four time intervals– t1, t2, t3, and t10 – we generated and compared recovery curves for different ERS configurations (ERS1 and ERS2), providing a visual representation of functionality loss and potential recovery trajectories over time.

The lack of existing models in the literature to measure post-earthquake urban functional recovery from a planning perspective prompted us to conduct a counterfactual experiment using the proposed methodology on a case study that had already been affected by a major event: L'Aquila post-2009.

By comparing the current state with the best ERS configuration (ERS1), we demonstrated the severe long-term impacts on L'Aquila's functionality. In contrast, ERS1 showed potential for significantly preserving urban functionality and reducing long-term disruptions.

The experimentation in a specific area with known effects on short- and long-term recovery processes allowed us to highlight the strengths and weaknesses of the proposed methodology. Despite limitations, the resulting functionality curves reflected L'Aquila's recovery trajectory, validating the methodology's potential.

Now that the assessment methodology has been tested, we aim to further this research by applying it to other Italian territories during peacetime and within a complex risk scenario simulation framework. The ultimate goal is to design an effective urban prevention path to support decision-makers in planning interventions and setting priorities, thereby mitigating long-term urban imbalances in the wake of seismic events.

Investigation Of Earthquake Damage in Terms of Different Land Covers: 2023 Kahramanmaraş Earthquakes

Adem SAKARYA
Affiliation: Yildiz Technical University
Email: asakarya@yildiz.edu.tr

Abstract
On February 6, 2023, the Kahramanmaras earthquakes in Türkiye caused great loss of life and property. Studies on earthquake damage in the literature mostly focus on the built-up area, but studies on the land cover are limited. This study examines how earthquake damage differs in different land cover types. Land cover data and earthquake damage data are the main datasets. The areas with the highest damage rates are identified as bare ground, rangeland, and built-up area, respectively. Damage in agricultural and forest areas is lower. The findings show that damage is different for different land cover types. While assessments of earthquake damage are largely based on the built environment, this study reveals that earthquake damage is also important for different land cover types.

Keywords: Earthquake, Damage Proxy map, Land cover, Kahramanmaraş, Türkiye.

Introduction and Literature Review

On February 6, 2023, Türkiye was shaken by two major earthquakes 8 hours apart, with Kahramanmaraş as the epicenter. These earthquakes, with magnitudes of 7.7 and 7.6 respectively, directly affected 11 provinces, Kahramanmaraş in particular, resulting in the loss of more than 50,000 lives and the destruction of approximately 40,000 buildings. Described as the "disaster of the century, " this disaster caused loss of life and property and deeply affected all social, environmental, and spatial systems with its direct and indirect effects. A disaster of this scale reveals the necessity of a multidimensional examination of earthquake impacts and reassessment of existing disaster management approaches.

Earthquakes are important natural phenomena that affect both the physical and natural environment. In the literature, these impacts are mostly addressed on the built environment axis; analyzed through collapsed buildings, infrastructure losses, and human mobility. However, earthquakes can cause damage not only to the built-up area but also to different types of land cover. In this context, determining the damage to different land cover types such as forest, agriculture, rangeland, and bare ground, in addition to built-up areas, is of great importance for a more holistic understanding of the spatial effects of the disaster. This study aims to evaluate the impact area of the disaster from a broader perspective by analyzing the damage following the Kahramanmaraş earthquakes in terms of different land cover types. Relatedly, the question of the study is defined as "*does earthquake damage differ in different land cover types*?".

Studies on the built-up area in the analysis of earthquake damage are intensively included in the literature. These studies range from the building scale to the whole settlement. Studies focusing on the built environment associate earthquake damage with indicators of building height (Armaş et al., 2017), building floor area and building height (Doğan & Kalaylı, 2019), proximity of the building to the epicenter (Sangadji et al., 2023), and building material (Ruiz- Pinilla et al., 2016). In addition, some studies examine earthquake damage by associating natural structure with built environment factors (Sakarya et al., 2024).

Studies on the damage of natural disasters such as earthquakes on land cover other than the built-up area, consider this damage as earthquake environmental effects (Choudhury et al., 2016). Earthquake environmental effects are divided into primary and secondary. Primary effects are such surface ruptures or faulting; secondary effects are such landslides, liquefaction, tsunamis (Boulton et al., 2025; Bilir & İnci, 2024). This two-stage effect causes significant changes in land cover. Studies on the effects of earthquakes on land cover can be evaluated in two groups. While the studies in the first group examine the damage to different land covers after earthquakes

over specific sample areas, the studies in the second group examine the land cover change caused by the damage with long-term data.

Among the first group of studies, Bpulton et al. (2025) examine the damage caused by the Kahramanmaraş earthquakes and find that landslide occurs in forest areas and liquefaction occurs in agricultural areas. Koyanagi et al. (2020) analyze the 2016 Kumamoto earthquake damage to compare forest and grassland cover. According to the results of the study, the damage was high in the grassland. It is also a basic finding that slope is a determining factor in damage.

Among the second group of studies, Xiang et al. (2022) examine the impact of the 2008 China-Wenchuan earthquake at the scale of Sichuan Province. The study, which examines the land cover change between 2011- 2014- 2017- 2020 after the earthquake, finds that earthquake damage is higher where vegetation is high. Ishihara and Tadono (2017) examine the impact of the 2011 Japan earthquake at the Tohoku district scale. The study, which analyzes land cover data for the years 2006- 2011- 2013- 2015, states that earthquake damage differs according to different land covers. While the rice paddy ratio decreases due to the tsunami effect, it is found that the damage to bare land is high in the short term, but in the long term, bare land increases with losses in forest and agricultural land. Wang et al. (2022) examines the 2013 China-Lushan earthquake damage at the scale of Lushan country. In the study comparing land cover data from 2012 to 2020, it is determined that cropland, forest, built-up area, and bare area have changed significantly, and natural ecological restoration is stated as an important recommendation. Karadeniz and Sümbül (2023) compare the land cover in 1990 and 2000 in their study of the 1999 Düze earthquake in Turkey. According to the results of the study, forest and agricultural areas decreased, and built-up areas increased. Balamurugan and Aravind (2015) examine the impact of the 2001 India, Bhuj earthquake in Mundra, Kutch District of Gujarat region. Similar to the results of Karadeniz and Sümbül (2023), it is found that agricultural areas decreased and built-up areas increased in the process. DiCarlo et al. (2015), on the other hand, conduct such a study in the context of the 2015 Nepal earthquakes. Focusing on Dolakha district, the study finds that the agricultural crop pattern has changed.

This study, which examines the damage of the Kahramanmaraş earthquake on different land covers, is similar to the first group of studies mentioned above by examining the short-term post-earthquake data but differs from the studies in this group by analyzing the entire area where the earthquake damage occurred. This points to a gap in literature.

Data and Methods

Two data sets were used in the study. The first data set is land cover. Land cover data for the year 2022 was obtained through the Esri Living Atlas application. This data, created by the remote sensing method, consists of water, forest, flooded vegetation, crops, built area, bare ground, snow/ice, and rangeland land covers. In this study, as most damaged covers, forest area, agricultural area, built-up area, bare ground, and range land, are used. Water, snow / ice and clouds covers are not included

The second data set is the regional damage proxy map. It was produced by the National Aeronautics and Space Administration (NASA). This map detects the change in the surface by comparing the satellite images before and after the earthquake and shows these areas as damaged. The damage proxy map is used in many studies for rapid damage assessment after disasters. By damage proxy map, Agapiou (2020) analyzes the Beirut explosion, Romaniello et al. (2017) evaluate the Haiti earthquake damage, and Nur and Lee (2021) analyze the effects of the 2016, 2017 earthquakes in Korea.

These two datasets were superposed in geographic information system (GIS), and the earthquake damage rate was calculated for different land cover types.

The Kahramanmaraş earthquakes affected 11 provinces; Adana, Adıyaman, Diyarbakır, Elazığ, Gaziantep, Hatay, Kahramanmaraş, Kilis, Malatya, Osmaniye, and Şanlıurfa. The area is officially defined as a disaster region. The scope of the study was determined within the boundaries of the damage proxy map in this disaster region. This area is approximately 58 km² (Figure 1).

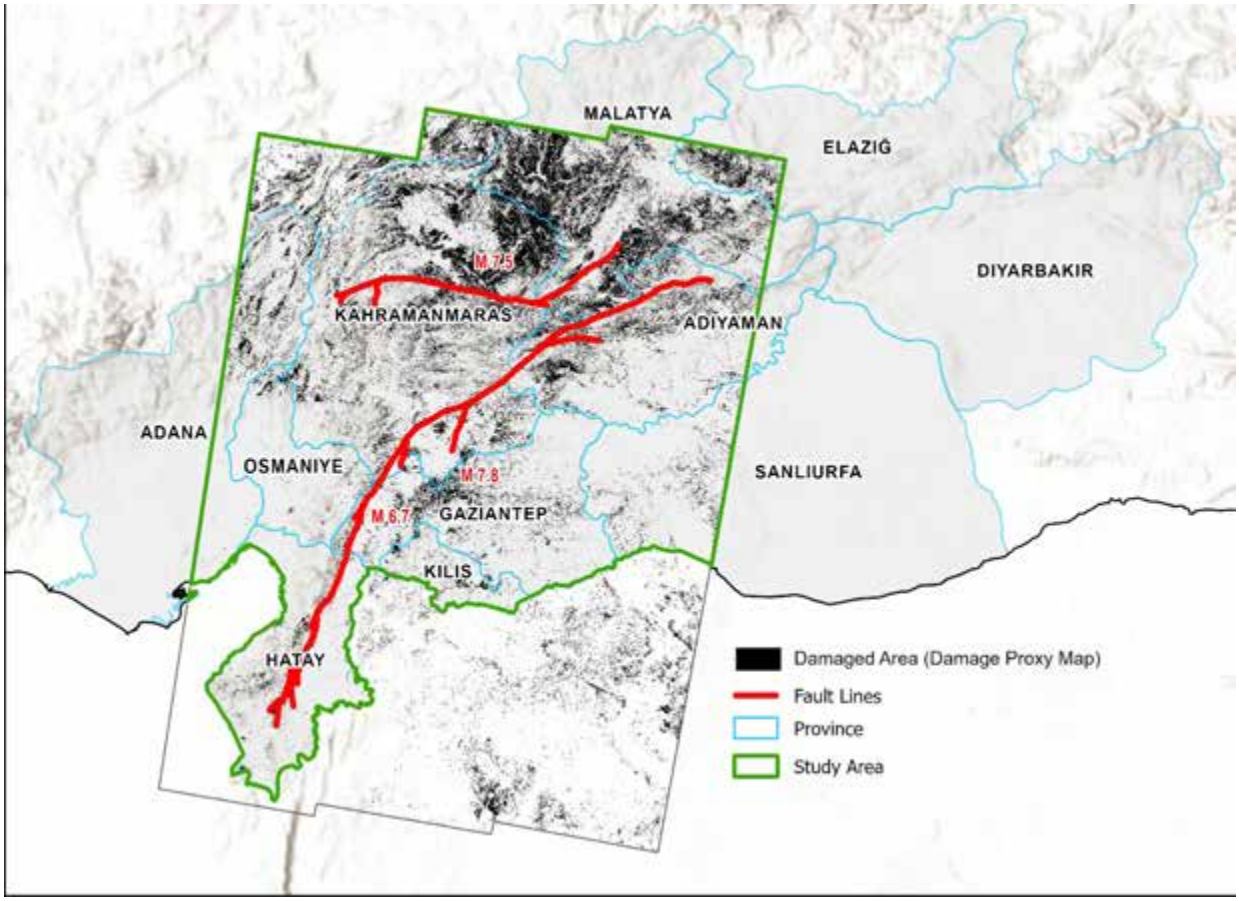

Figure 1: Study area

Findings

According to land cover in 2022, more than half of the area is rangeland. Rangelands are mostly concentrated in the east and north of the study area. The other land cover that has a significant size in the area is agriculture. Agricultural areas are especially dense in the south of the area. Forest areas are in the west of the area in the mountainous region between Hatay- Antakya, and Kahramanmaraş. The provincial centers of Hatay- Antakya, Kahramanmaraş, Gaziantep, and Malatya stand out with their built-up areas (Figure 2; Table 1).

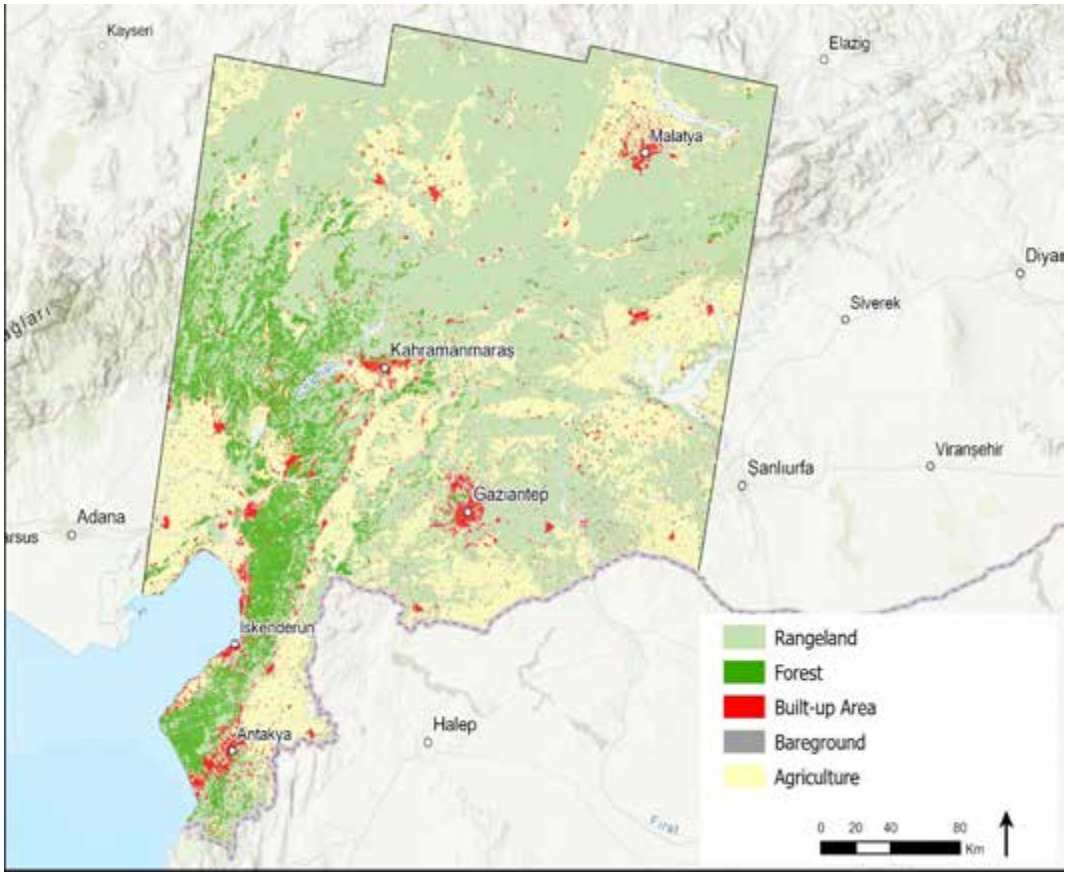

Figure 2: Land covers in the study area

Table 1: Land cover statistics

Land Cover	Area (ha)	Ratio
Rangeland	3.079.870	53%
Forest	595.460	10%
Built-up Area	290.792	5%
Bare Ground	41.453	1%
Agriculture	1.688.550	29%
Water- Snow/ Ice- Clouds	114.952	2%
Total	5.811.077	100%

The damage rate in the study averaged 18 % for the whole area. The land cover classes with the highest damage rates are bare ground, rangeland and built-up area, respectively. Especially in the north of the area where the slope is low, damaged rangeland areas are noteworthy in the region located in the west of Malatya. There are also damaged agricultural areas within these areas.

Damage in the built-up area is concentrated on the route between Hatay, Antakya and Kahramanmaraş, where the fault line also passes.

Damaged forest areas are also located in a limited area along the fault line. In this respect, the fact that the dam-

age is higher in the northern part where the slope is flatter indicates that slope is an important factor, as stated in Koyanagi et al. (2020) (Figure 3; Table 2).

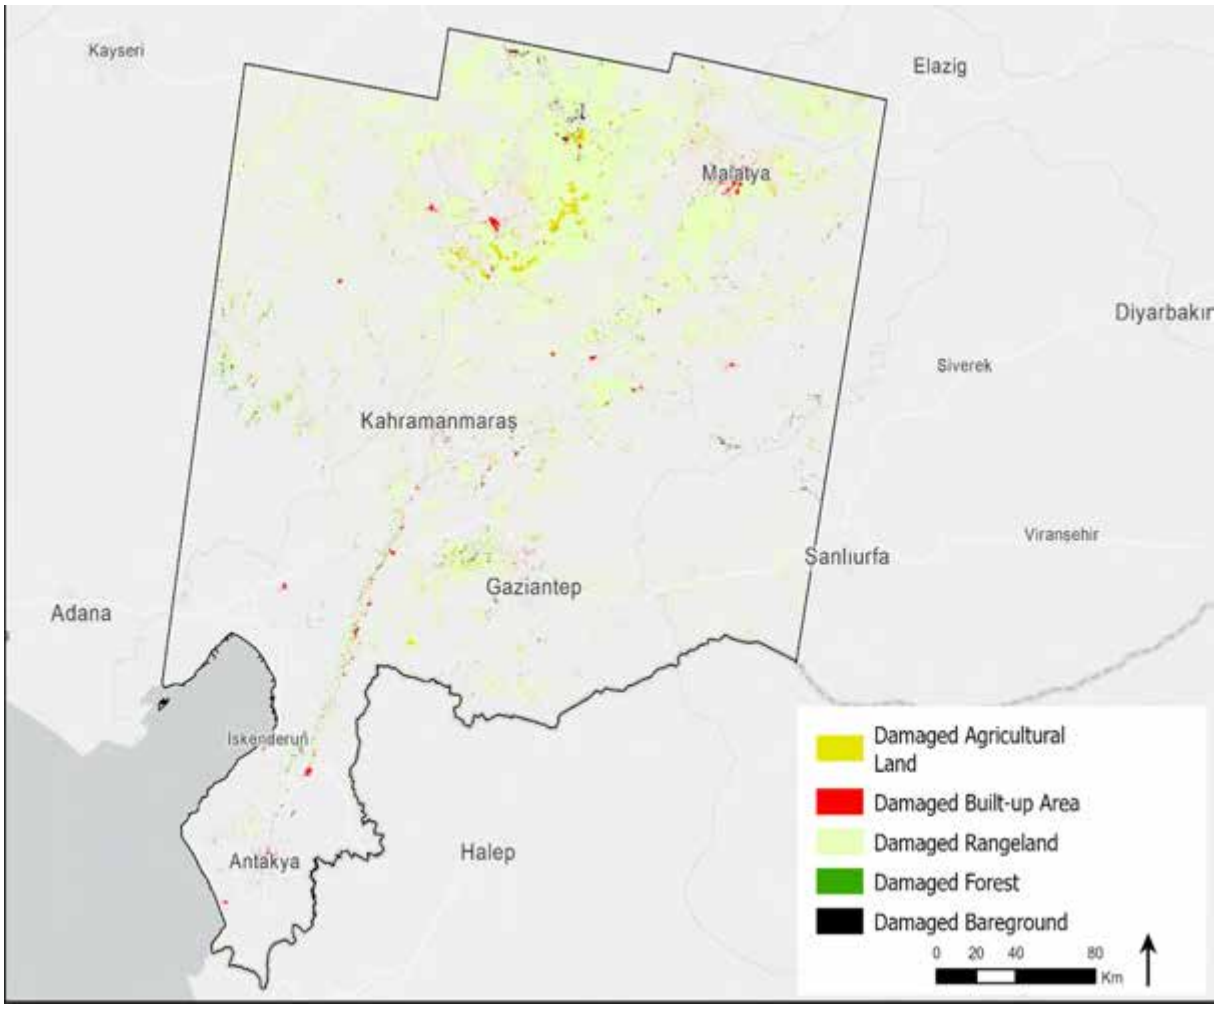

Figure 3: Damaged areas and land covers

Table 2: Damaged area land covers' statistics

Land Cover	Area (ha)	Damaged Area (ha)	Damaged Area Ratio
Forest	595.460	17.983	3%
Agriculture	1.688.550	77.101	5%
Built-up Area	290.792	40.075	14%
Bare Ground	41.453	14.256	34%
Rangeland	3.079.870	896.136	29%
Water- Snow/ Ice- Clouds	114.952		
Total	**5.811.077**	**1.045.551**	**18%**

Conclusion

This study aims to provide a holistic assessment of the spatial distribution of earthquake damages by analyzing the impact of the Kahramanmaraş-centered earthquakes that occurred on February 6, 2023 on different land cover types. The finding that earthquakes directly affect not only the built-up areas but also the natural environment reveals the necessity of considering natural land cover in post-disaster response and recovery strategies.

In the study, the analyses made by overlaying the land cover classes created using Esri Living Atlas data and the damage proxy map produced by NASA in the GIS, show that the highest damage occurs in bare ground, rangeland and built-up area, respectively.

This result indicates that damage varies across different land covers in relation to the research question identified by the study.

The findings reveal that significant damage occurred in rangeland and agricultural areas, especially in the northern parts where the slope is low, and emphasize the role of the morphological characteristics of the natural environment on the earthquake effect. Between Hatay-Antakya and Kahramanmaras, extensive damage was detected in built-up areas located along the fault line.

In the light of the data obtained, it is clear that land use decisions should be revised both in terms of the built-up area and the natural environment. With a disaster risk management perspective, integrating earthquake risk mitigation elements into land use plans can minimize not only loss of life and property but also loss of natural resources.

Damage to rangelands and agricultural areas is also critical for post-disaster food security and rural livelihoods. Therefore, developing policies to protect fragile natural areas will contribute to prevent post-disaster agricultural production losses. Likewise, the limited but strategically important damage to forest areas should be taken into account in terms of the continuity of ecosystem services. To increase the resilience of the natural environment in the face of disasters, more emphasis should be placed on ecological restoration and conservation-based approaches, as mentioned in Wang et al. (2022).

This study has some limitations as it is a short-term analysis with limited data. However, the assessment of damage to different land cover types at the scale of the whole study area differs from the examples in the literature in this respect and fills an important gap. For future studies, monitoring land cover changes using long-term satellite imagery will provide important findings in terms of the extent and significance of damage. For example, determining whether the increase in bare ground areas after the earthquake is related to construction or agricultural transformation in the following years will be of great importance in terms of guiding post-disaster spatial planning.

Furthermore, comparative studies with different types of disasters can reveal how the impacts of disasters on land cover differ from one another. Multidimensional analyses on how disasters such as floods, landslides and fires, as well as earthquakes, cause spatial changes in different cover types will contribute to the reshaping of both risk analyses and post-disaster response plans in a nature-sensitive manner. Such studies will serve as an important guide not only in the academic context but also for policy makers, local governments and disaster management institutions.

Critical Infrastructures and Their Role in Regional Resilience: Mapping EU Regions

Aydan Ege Güven*
Giulio Breglia
Marco Modica
Gran Sasso Science Institute
*aydanege.guven@gssi.it

Abstract
This study assesses the spatial distribution of critical infrastructure and its implications for regional resilience across EU NUTS-2 regions. The study develops a composite indicator for critical infrastructure stock using data on transport, energy, ICT, and public services, capturing both demographic and geographical accessibility. Findings reveal strong spatial disparities, with Central and Northern regions generally better equipped than Southern and Eastern counterparts. A median-split based typology to assess the sufficiency of CI Stock classifies regions into four categories, highlighting that only 9% exhibit high sufficiency across all sectors. Many regions show imbalanced critical infrastructure stock profiles, underscoring the need for multi-dimensional assessment. The study offers a quantitative framework for identifying vulnerabilities and guiding regional policies, stressing the importance of sufficient critical infrastructure, spatial equity, and integrated regional planning in strengthening regional adaptive capacity.

Keywords: Regional resilience; critical infrastructure stock; disaster prevention

1. Introduction

Regions are becoming increasingly interconnected through population mobility, economic flows, and infrastructure systems, forming complex webs of interdependencies that shape both their development trajectories and resilience. As these interregional linkages deepen, the capacity of regions to withstand and recover from disruptive events has emerged as a core concern for planners and policymakers. Within this context, critical infrastructures (CIs) including transport systems, electricity grids, digital networks, and water supply, play an essential role in maintaining societal and economic functioning. These infrastructures not only support the everyday routines of regional life but also underpin the capacity to absorb shocks and ensure continuity during times of disruption. However, their interconnectedness means that the failure of one component may trigger cascading effects across regions, exacerbating crises and magnifying risks (Shi et al., 2021).

Resilience, broadly understood as a system's ability to adapt to change and recover from disturbances (Boschma, 2015), is thus intimately linked to the structure, sufficiency, and interdependency of CIs in the regions. Inadequate backups, spatial inequalities, or an overdependence on single infrastructure hubs can transform localized hazards into systemic breakdowns. Studies highlight that resilience involves networks of linked adaptive capacities, making connectivity crucial as it provides alternative paths during disruptions (Reggiani et al., 2015). However, Reggiani (2022) highlights a key trade-off: highly connected hubs enhance efficiency but risk severe cascading failures when disrupted, whereas decentralized and redundant networks, although less efficient, enhance resilience. Redundancy, originating from ecological studies, refers to having multiple alternatives ensuring continued system function despite disruptions (Galland et al., 2020). For critical infrastructure, redundancy mitigates risks by providing alternative pathways, thus minimizing cascading effects from failures (Bauer et al., 2012; Sheffi, 2005; Akbarzadeh et al., 2017; Forcellini, 2023).

The conceptualisation of what is deemed "critical" infrastructure is not fixed. It is shaped by policy frameworks, academic interpretations, and societal needs. While energy, transport, and ICT are frequently emphasized in both academic and policy discourse, sectors such as education, housing, and healthcare, though vital, are often overlooked (Huddleston et al., 2022; DGAP, 2023). This reflects underlying epistemological and political commitments that determine which systems are prioritised for protection and investment.

This paper aims to address these complexities by mapping the stock of critical infrastructures across EU NUTS-2 regions and exploring their relationship with regional resilience. Instead of focusing on distinct infrastructure failures or individual case studies, we adopt a regional approach. We construct composite indicator of critical infrastructure stock based on availability, sufficiency, and distribution, and assess how these patterns vary across the EU.

By visualising the geography of CI stock and their potential insufficiencies, the study seeks to bridge the gap between theoretical studies and practical planning tools for resilience. Ultimately, this work contributes to emerging debates on how infrastructure systems can support regions in facing future uncertainties through enhancing robustness, improving recovery capacities, or enabling equitable access to essential services.

2. Conceptual Framework

2.1. Critical Infrastructure

Understanding the role of critical infrastructure in shaping regional resilience requires a careful conceptualisation of what these systems are, how they function, and why their presence or absence matters. Critical infrastructures are not just physical networks but systems that enable the delivery of essential services, support social and economic functioning, and influence a region's capacity to respond to disruptions (Deelstra and Bristow, 2023). Their criticality becomes most visible during crises (Steele et al., 2017), when breakdowns in infrastructure; such as electricity failures, blocked transport routes, or collapsed communication networks, can escalate the impacts of hazards and delay recovery (Thévenaz and Resodihardjo, 2010; Ke and Hsu, 2022).

There is no universally accepted definition of critical infrastructure. The term is used across academic disciplines and policy frameworks with varying scopes and emphases. In general, what distinguishes critical infrastructure from "basic" infrastructure is the severity of consequences associated with its disruption. As Burgess (2007) and Gallais and Filiol (2017) argue, infrastructure becomes "critical" when its failure transforms a disturbance into a broader crisis, threatening public safety, economic continuity, and the delivery of core services. The concept of criticality, in this sense, is relational and contingent on both societal needs and political priorities.

Larkin (2013) offers a foundational understanding of infrastructure as systems that enable the operation of other systems. He emphasises that infrastructures are not just technical objects but also social and relational structures. In the case of critical infrastructure, this means recognising the ways in which roads, hospitals, and power grids connect people, places, and institutions; not just materially, but functionally and politically. Infrastructures are embedded in everyday life and often remain invisible until they fail.

Policy definitions of critical infrastructure have evolved in response to changing threat perceptions and disruptive events. The United States was among the first to define and institutionalise the concept in the 1990s, particularly after the Oklahoma City bombing and later, following September 11 attacks, broadened its conception of CI (Moteff, 2007; Zebrowski and Sage, 2017; Collier and Lakoff, 2008). Since then, the list of sectors designated as critical has expanded significantly, including domains such as finance, emergency services, and digital infrastructure (Cybersecurity and Infrastructure Security Agency, 2025). While the U.S. provided one of the earliest formal definitions of critical infrastructure, policies on critical infrastructure in the EU date back to 2004, following key disruptive events such as the 2003 Italian blackout and the 2004 Madrid train bombings. These events prompted the launch of a strategic framework for critical infrastructure protection, which led to the establishment of the European Programme for Critical Infrastructure Protection (EPCIP) and the adoption of Directive 114/2008 aimed at strengthening infrastructure security which focused on transport and energy. However, the more recent CER Directive (2022/2557) reflects a broader view. It includes eleven sectors, such as public administration, healthcare, and the food supply chain, and introduces a shift from protection to resilience (Božović, 2023). The Directive on the Resilience of Critical Entities, effective from 16 January 2023, requires EU Member States to implement national legislation by 17 October 2024. It addresses eleven sectors: energy, transport, banking, financial market infrastructure, healthcare, drinking water, wastewater, digital infrastructure, public administration, space, and food

supply chains (European Commission, 2024). While each member state identifies and protects national critical infrastructures, the EU also promotes cooperative measures for transnational coordination.

Beyond the US and EU, modern definitions of critical infrastructure in various countries are largely similar in scope, most nations include infrastructure for energy, transportation, communications etc. as "critical". A 2023 study by the German Council on Foreign Relations (DGAP) analysing how 100 countries define and perceive critical infrastructure (CI) sectors is illustrating this well. According to the study, the most frequently cited sectors are energy, ICT, and transport, respectively, whereas sectors such as water, food, national security, and research & education are mentioned far less often.

What often differs is priority and emphasis, each state may prioritize certain sectors over others based on its unique needs and risk perceptions, which have the potential to obscure the distinction between infrastructure critical for basic societal survival and that which is deemed critical primarily for a nation state's interests (Newbill, 2019). Moreover, given that most CI systems are owned and operated by private entities, the influence of market and neoliberal governance cannot be overlooked (de Bruijne and van Eeten, 2007). Therefore, it is important to prioritize society's fundamental needs by focusing on a core set of universally critical infrastructures, which extend beyond national boundaries and can be narrower than those broadly defined by state interests (Newbill, 2019). As academic studies have highlighted, infrastructures that are not prioritised in formal frameworks such as housing, education, or childcare may still be essential for maintaining well-being and everyday functioning (Huddleston et al., 2022). The scope of what is considered critical thus reflects political, economic, and epistemological decisions, often influenced by prevailing governance models and private sector interests.

2.2. Regional Resilience and Critical Infrastructure

Resilience, while a debated and multidimensional concept, is broadly understood as the ability of socio-economic systems to adapt to both internal and external changes. Martin and Sunley (2015) conceptualise regional economic resilience as a process comprising four dimensions: vulnerability, resistance, robustness, and recoverability. Vulnerability reflects the extent of exposure to shocks, while resistance denotes a system's capacity to withstand them. Robustness refers to the ability to maintain core functions under stress, and recoverability measures how quickly and effectively a system returns to its prior trajectory. Other scholars, such as Sun et al. (2018), further highlight the role of redundancy and fast recovery mechanisms in building resilience.

Critical infrastructure plays a central role in supporting resilience by enabling continuity in essential services such as energy, transport, and healthcare. Although many studies focus on single sectors such as electricity (Afgan & Veziroglu, 2011), water (Sitzenfrei, 2011; Hwang, 2013), or digital networks (Boh et al, 2023), these analyses consistently demonstrate that infrastructure sufficiency enhances both robustness and recoverability. Some studies note that resilience is not only about infrastructure robustness but also about resourcefulness, and coordination between systems (Hickford et al., 2015). Other studies providing frameworks like the Resilience Measurement Index (Carlson et al., 2012) and spatial vulnerability models (Demirel et al., 2015) aim to quantify infrastructure resilience; yet, a gap remains in cross-sectoral evaluations for wider geographies.

Despite its conceptual richness, the empirical assessment of critical infrastructure (CI) and its contribution to regional resilience remains rather unexplored. Since, critical infrastructure is difficult to measure uniformly across regions, many studies focus on single sectors or isolated case studies which are limiting comparability and generalisability. While monetary values such as investment amounts are commonly used, scholars argue that physical indicators (like kilometres of roads or electricity capacity) provide more meaningful and comparable metrics across regions (Canning, 1998; Bröcker, 2009). However, these are not neutral; they are shaped by geography, urbanisation, and income levels. Data limitations, including the private ownership of many CI systems and security restrictions, further complicate standardised measurement.

A key methodological issue is endogeneity, whether critical infrastructure stock creates resilient regions or resilient regions attract infrastructure. Studies that are focusing on the relationship between regional development

and infrastructure attempt to address this challenge using historical infrastructure paths, planned routes, or inconsequential units approaches (natural experiments) (Redding & Turner, 2014), yet establishing causality remains difficult. Moreover, infrastructure often produces spatial spillovers, benefiting areas beyond their immediate location, and these functional interdependencies are rarely captured in standard models. Although methods like fault tree analysis, input-output models, agent-based simulations, and network modelling are increasingly applied (Chopra and Khanna, 2015; Pant et al., 2015), more comprehensive spatial assessments remain limited.

Building on this literature, this study approaches critical infrastructure as a system of interdependent networks that deliver essential services. Rather than focusing on disruptions or hazard events, the emphasis is placed on infrastructure sufficiency and spatial distribution, what we define as critical infrastructure stock. To this end, we develop a composite indicator for critical infrastructure stock at the NUTS-2 level for EU regions, where data availability and institutional coherence support meaningful cross-regional comparison.

3. Data and Methodology

3.1. Data

Data for this study were collected from a range of publicly available sources, with an emphasis on spatial precision and coverage. Most indicators were collected in georeferenced format and processed using QGIS software to enable spatial analysis and aggregation at the regional level.

- **Transport**: Road and railway networks, stations, and airports were obtained from EuroGlobalMap (2025) and Eurostat GISCO (2013).
- **Energy**: Power plant data (capacity and number) were sourced from the Global Energy Monitor (2024) and OpenStreetMap (2025) for infrastructure components such as powerlines and towers.
- **ICT**: Internet access data were retrieved from Eurostat (2024), expressed as the share of households with internet connection.
- **Public Services**: The number of hospitals and educational facilities was derived from OpenStreetMap (2025), and the surface area dedicated to sports and leisure activities was obtained from the CORINE Land Cover dataset (2018).

Table 1. Data Variables and Sources

CI Sectors	CI Stock Variables	Source	Year
Transport	1. Roads (line) 2. Railways (line) 3. Railway stations (node) 4. Airports (node)	1. EuroGlobalMap 2. EuroGlobalMap 3. EuroGlobalMap 4. Eurostat GISCO Airports 2013 dataset	1. 2025 2. 2025 3. 2025 4. 2013
Energy	1. Power plants (node) 2. Tower/mast (node) 3. Power lines (line)	1. Global Energy Monitor 2. OpenStreetMap 3. OpenStreetMap	1. 2024 2. 2025 3. 2025
ICT	1. Households that have access to internet (%)	1. Eurostat	1. 2024
Public Services	1. Health facilities (node) 2. Schools (node) 3. Sports/leisure activities (polygon)	1. OpenStreetMap 2. OpenStreetMap 3. CORINE Land Cover	1. 2025 2. 2025 3. 2018

The dataset covers 234 NUTS-2 regions. Due to the limitations in data availability and concerns of consistency, some regions that are predominantly islands or overseas territories were excluded from the analysis. These include Ciudad Autónoma de Ceuta and Ciudad Autónoma de Melilla in Spain; Canarias; the autonomous Portuguese regions of Açores and Madeira; and the French overseas territories of Guadeloupe, Martinique, Guyane, La Réunion and Mayotte.

3.2. Methodology

To comprehensively evaluate regional patterns in critical infrastructure (CI) stock, we employed a dual-method approach. The first method involved constructing a composite indicator that synthesizes sectoral CI stock scores (standardized by both population and land area) into a single metric, thereby enabling cross-regional comparison of overall infrastructure levels. The second method builds upon these composite scores by distinguishing between spatial coverage and infrastructure sufficiency relative to population. Through a typology-based classification using median splits, we assigned regions to distinct categories reflecting combinations of high or low spatial and demographic provision within each CI sector. This approach not only reveals underlying patterns of CI distribution but also addresses the key research question: Are there regions that perform strongly or weakly across all dimensions, or do certain regions exhibit mixed infrastructure profiles? For example, a region classified as high per capita and high per land area in transport can be considered both well-connected and accessible, while a region with low per capita but high per land area may possess extensive infrastructure coverage yet still lack adequate provision relative to its population, which an important distinction for assessing resilience. Similarly, in the energy sector, high numerosity but low capacity indicates redundancy but potential underpowering, whereas low numerosity with high capacity suggests robustness but limited redundancy. By integrating these two methods, our analysis aims to provides a more nuanced understanding of infrastructure sufficiency and distribution across regions.

3.2.1. Composite Indicator Construction

In the literature, studies developing datasets covering both geographical and sectoral breadth to enable comparisons across multiple regions and countries are limited. A similar motivation guided Canning (1998) in developing a worldwide infrastructure database. In his study, Canning examines infrastructure stock through physical indicators expressed per land area and per capita. He justifies the use of these physical indicators by highlighting that countries can vary significantly in infrastructure's per-unit costs due to differences in input prices and variations in public sector efficiency. Bröcker (2009) further adds that natural conditions, which may vary not only among but also within countries, can significantly affect infrastructure costs due to natural conditions for example. He provides examples of physical indicators useful for assessing infrastructure stock, such as road and railway length (km) and electricity supply capacity (megawatts).

A more recent study by Nirandjan et al. (2022) provides a global dataset of critical infrastructure (CI) derived from detailed OpenStreetMap (OSM) data, covering seven sectors: transport, energy, telecommunications, water, waste, education, and health. Similar to their Critical Infrastructure Spatial Index (CISI), which aggregates multiple standardized critical infrastructure indicators into composite spatial scores at varying resolutions to reveal hotspots of CI concentration at global scale, our approach involves combining infrastructure metrics standardized per capita and per land area through min-max normalization. In our study, these normalized indicators were further aggregated into a single composite indicator at regional scale, ensuring both demographic accessibility and geographic coverage are comprehensively reflected.

Based on these takeaways from the literature; in order to assess the availability and sufficiency of infrastructure, two standardised measures were calculated for each variable: per capita and per land area. These indicators were first computed individually, then normalised using min-max scaling. The two dimensions were averaged to capture both demographic reach and spatial coverage. For each sector, the standardised indicators were then summed and re-normalised to ensure comparability across regions.

In the case of energy infrastructure, the number of power plants (numerosity) and total installed capacity were evaluated separately by both population and land area. This distinction acknowledges that while large-capacity plants may enhance robustness, they can also introduce vulnerability due to over-reliance on a limited number of high-output facilities. A system dominated by a few large sources may lack the redundancy needed for resilience during disruptions.

For ICT, which consists of a single variable (the share of households with internet access), the indicator was directly standardised. Finally, the four sectoral scores transport, energy, ICT, and public services were combined with equal weights into a single composite index of critical infrastructure stock.

1. Density Calculation: For each indicator (e.g., kilometres of roads and railways, number of hospitals), we calculated values per capita and per square kilometre at the NUTS-2 level.

2. Min-Max Normalisation: Each per capita and per land value was normalised using min-max scaling:

$$x_{capita}^{norm} = \frac{x_{capita} - \min(x_{capita})}{\max(x_{capita}) - \min(x_{capita})}$$

$$x_{land}^{norm} = \frac{x_{land} - \min(x_{land})}{\max(x_{land}) - \min(x_{land})}$$

3. Averaging Spatial and Demographic Dimensions: The two standardised values (per capita and per land) were averaged to reflect both demographic accessibility and spatial coverage.

$$x_{avg} = \frac{x_{capita}^{norm} + x_{land}^{norm}}{2}$$

$$x_{avg}^{norm} = \frac{x_{avg} - \min(x_{avg})}{\max(x_{avg}) - \min(x_{avg})}$$

4. Re-normalisation: These average scores were standardised again to preserve comparability across indicators within the same sector.

5. Sectoral Aggregation: For transport, energy, and public services, the re-normalised values of each indicator were summed and standardised once more to produce a final **sectoral infrastructure score**. ICT, which includes only a single indicator, was directly standardised.

6. Composite CI Score: The four sectoral scores were then summed-up, assigning equal weight to each, and then standardised to form a **total critical infrastructure score** for each region

$$Total\ Score = Transport^{norm} + Energy^{norm} + ICT^{norm} + Public\ Services^{norm}$$

$$Normalized\ Total\ Score = \frac{CI - \min(CI)}{\max(CI) - \min(CI)}$$

3.2.2. CI Stock Classification and Median-Split Approach

As a second step, to interpret regional differences in critical infrastructure stock and identify broader patterns, we implemented a typology-based classification approach. This method aligns with other studies in the literature aiming to spatially classify infrastructure stocks using typological or cluster-based methods (Borgatti, 2008; Onda et al., 2014: Nirandjan et al. 2022).

Instead of relying on unsupervised, data-driven algorithms (such as hierarchical clustering or k-means), which are typically favoured for very large datasets (Xu et al., 2017), we opted to categorize continuous CI scores using a median-split approach. This technique, adopted in previous studies (e.g., Trojanowski et al., 2024; King et al., 2011), facilitates targeted comparison of infrastructure provision patterns across regions and sectors, supporting both spatial and cross-sectoral assessments. While some critiques exist regarding the potential for median splits to reduce statistical power and obscure underlying variation (DeCoster et al., 2011), this method enhances interpretability and is particularly valuable where clear typological distinctions are required and multicollinearity is limited (Iacobucci et al., 2015). Based on the idea that a manual median-split approach ensures results are trans-

parent, directly comparable, and easy to interpret making it particularly suited for policy-oriented assessments we applied median splits to categorize continuous variables for typology construction.

For each sector, we assessed regional infrastructure typologies using median splits of standardized indicators, considering combinations of per capita and per land measures or numerosity and capacity for energy (excluding powerlines and towers). Specifically, for Transport, Energy, and Public Services, regions were categorized into four typological groups (High-High, High-Low, Low-High, and Low-Low) based on these dual axes. For ICT, which relied on a single indicator (household internet access), a simple High vs. Low classification relative to the median was applied.

Subsequently, each region was assigned a score based on its typological classification within each sector: two points were allocated for the highest-performing typologies (e.g., High-High combinations), one point for intermediate typologies (High-Low or Low-High), and zero points for the least sufficient typologies (Low-Low or low ICT access). The sum of these points across all sectors yielded a total CI Stock Typology score for each region, ranging from 0 to 8, thereby quantifying overall infrastructure sufficiency with respect to both spatial and population coverage. Finally, regions were classified into four groups according to their total scores: Low Sufficiency (scores 0-2), Moderately Low Sufficiency (scores 3-4), Moderately High Sufficiency (scores 5-6), and High Sufficiency (scores 7-8).

Table 2. Typology Calculation

CI Stock Typologies per Sector	Points Assigned
High–High (Transport, Energy, Public Services), High (ICT)	2
High–Low or Low–High	1
Low–Low (Transport, Energy, Public Services), Low (ICT)	0

4. Findings

The composite indicator of critical infrastructure stock reveals notable spatial disparities across EU NUTS-2 regions. Regions in Central and Northern Europe, particularly parts of Germany, Scandinavia, and the Benelux countries, consistently show the highest composite CI stock scores, reflecting a combination of transport networks, energy supply, ICT and public service infrastructure. Contrarywise, much of Southern and Eastern Europe, including many regions in Spain, Portugal, Greece, and Eastern member states, appear in the lower ranges of the index. These areas are often characterized by sparser infrastructure networks and lower levels of service provision, especially in transport and public services.

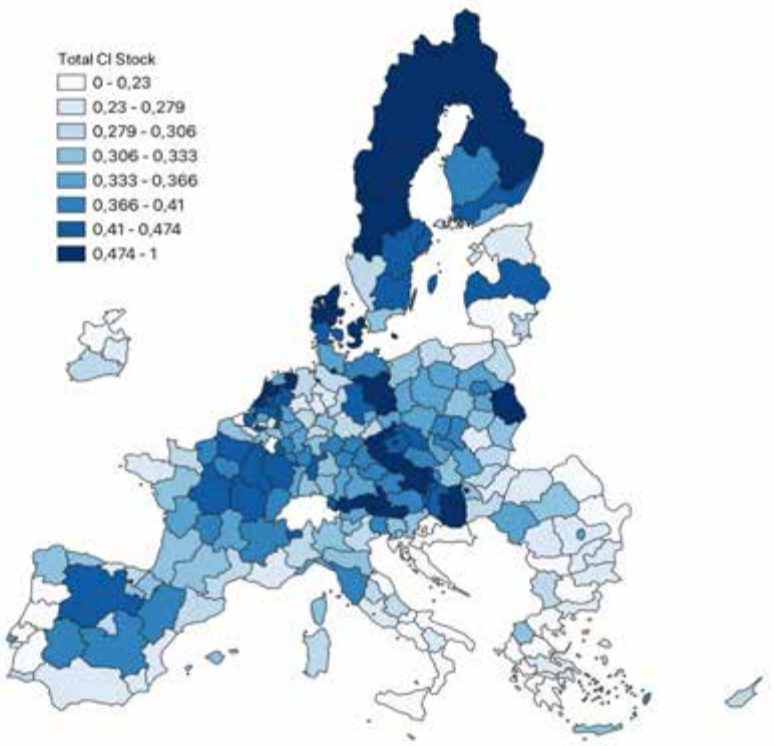

Figure 1. Total CI Stock Scores of NUTS 2 Level Regions in EU

The map further highlights that CI stock is not uniformly distributed even within countries. For instance, certain metropolitan or capital regions may achieve higher scores due to agglomeration effects and concentrated investments, whereas more peripheral or rural areas often lag behind.

Another important insight is that strong performance in one sector does not necessarily correlate with strength in others. For example, Portuguese regions exhibit high scores in energy infrastructure but tend to fall below the EU average in ICT and public services. Likewise, the Andalucía region in Spain demonstrates average performance in energy infrastructure but scores very low in transport and public services which could limit the actual accessibility of these services during critical moments.

To further explore the distribution of CI sufficiency across regions, we applied CI Stock Classification using sectoral medians as reference thresholds. Four categories were defined: High Sufficiency, Moderately High Sufficiency, Moderately Low Sufficiency, and Low Sufficiency.

Figure 2. CI Stock Typologies of NUTS 2 Level Regions in EU

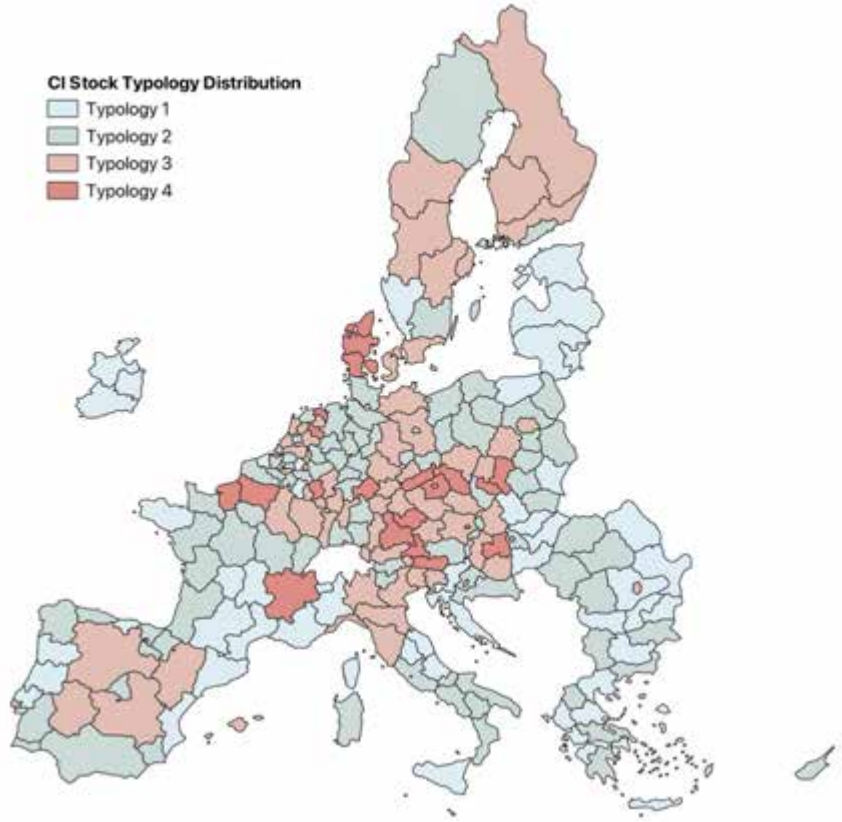

Table 3. Frequencies of CI Stock Typologies

CI Stock Typologies	Frequency	Percent
1. Low Sufficiency (0-2 points)	53	22.65%
1. Moderately Low Sufficiency (3-4 points)	92	39.32%
1. Moderately High Sufficiency (5-6 points)	68	29.06%
1. High Sufficiency (7-8 points)	21	8.97%
Total	234	100.00%

The distribution of CI Stock Typologies indicates that the majority of regions fall into the lower sufficiency categories. Specifically, 22.7% of regions are classified as having low sufficiency (0-2 points), while 39.3% are in the moderately low sufficiency group (3-4 points). Moderately high sufficiency (5-6 points) is observed in 29.1% of regions, and only 9% of regions achieve high sufficiency (7-8 points).

This pattern suggests that a significant proportion of regions have limited or only moderate levels of critical infrastructure provision, with relatively few regions exhibiting comprehensive infrastructure sufficiency across all dimensions. The findings highlight potential disparities in infrastructure availability and point to areas where targeted policy interventions may be necessary to enhance regional resilience.

6. Discussion

The findings highlight significant cross-regional variation. While some regions exhibit balanced and robust infrastructure profiles, many show asymmetries or sector-specific gaps. Importantly, the clustering analysis reveals that most regions fall within moderate sufficiency categories, combining strengths in some sectors with weaknesses in others. This diversity underscores the need for differentiated policy approaches and reinforces the argument that contribution to regional resilience cannot be determined by single-sector performance but by the interplay of multiple critical infrastructure systems.

Within Central Europe, capital regions such as Berlin, Prague, and Vienna emerge as concentrated CI hubs. High scores in these areas may partly reflect their political, economic, and institutional centrality. These regions have historically benefited from sustained investment, higher population densities, and strong institutional frameworks that support infrastructure expansion and maintenance. Similarly, certain peripheral regions in Nordic countries as parts of Sweden and Finland also exhibit high infrastructure scores. This could be attributed to their large geographic size and the extensive spatial coverage of infrastructure, especially transport systems connecting distant settlements to central nodes. A closer look reveals that these regions perform well in the transport and energy sectors, reinforcing the interpretation that both spatial reach and redundancy contribute to their higher resilience potential.

When comparing the composite infrastructure score map with the sufficiency classification, a broad west–south divide remains visible; however, several regional-level differences emerge. At first glance, these may appear to result from the exclusion of electricity line data in the second analysis. Yet, closer inspection reveals deeper structural nuances. For instance, Latvia appears relatively well-positioned in the composite CI stock map, but falls into the Low Sufficiency category upon typology classification. This reflects that while infrastructure quantity may be present, its relative redundant capacity across all critical infrastructure sectors may still be low. Similarly, while regions in Sweden and Finland continue to score high in the composite CI stock indicator, the sufficiency classification reveals certain shifts. These changes suggest that although these regions benefit from high overall CI levels, they may not consistently score high across all four sectors, which indicates insufficiencies in planning. In contrast, Danish regions display more stable patterns across both maps, suggesting a more uniformly distributed and sufficient critical infrastructure stock.

Regions with low CI sufficiency, particularly in Southern and Eastern Europe, may face serious challenges in service continuity and recovery under disruptive conditions. In contrast, capital cities and some larger northern areas benefit from higher levels of sufficiency, though even these may be reliant on centralised nodes or infrastructure corridors that pose vulnerability in cases of failure.

A study by Stanickova & Melecky (2018), built a broad composite index of regional resilience, the most resilient regions were largely in Northern and Western Europe – Scandinavian countries and Western EU regions scored the highest on the resilience index. By contrast, the least resilient were concentrated in the south: the authors note that the "southern circuit" (Portugal, Spain, Italy and Greece) showed the lowest resilience scores among EU regions. The findings in our paper similarly reveal a north/centre–south divide excluding Spain. However, this difference can also be explained by the fact that certain southern European regions have invested in extensive transport and energy networks (partly through Cohesion Policy), so they may not rank at the very bottom in our study based on critical infrastructure. Our findings for Finland and Sweden, on the other hand, invite a reflection on the argument made by Pursiainen (2018), who highlights an emergence of a Nordic model of critical infrastructure resilience. This "nordic model" is characterised by redundancy, preparedness, multi-actor cooperation, and a stronger focus on maintaining functionality over protecting specific assets. According to his study, the Nordic approach combines robust public institutions with cross-sectoral coordination and adaptive governance. These structural and institutional features may help explain the higher infrastructure scores and relative consistency observed in regions of Finland and Sweden in our analysis.

8. Conclusion

This study investigated the distribution of critical infrastructure stock across EU NUTS-2 regions, employing a composite indicator encompassing four essential sectors: transport, energy, ICT, and public services. CI indicators were standardized by both population and land area, ensuring that both demographic accessibility and spatial coverage were taken into account. In a subsequent analytical step, regions were classified into four distinct categories based on sectoral median thresholds, allowing for a nuanced comparison of infrastructure sufficiency across the European context.

The findings reveal significant spatial disparities. While some regions (particularly in Central and Northern Europe) exhibit consistently high critical infrastructure scores, others, especially in Southern and Eastern Europe, show notable gaps or unbalanced profiles. Regions located in central Europe like Berlin, Vienna, Prag and parts of Sweden and Finland benefit from high spatial reach and sufficiency, particularly in transport and energy. In contrast, Southern regions may have strong energy capacity due to natural resources but often underperform in transport and public services. A key insight is that strength in one sector does not guarantee strength in others. Many regions exhibit a mix of high and low performances, highlighting the need for just critical infrastructure provision and regional planning. The classification results confirm this: only 9 percent of regions fall into the high sufficiency category, while nearly one-quarter face serious gaps. Most regions occupy an intermediate space, with strengths in some areas but weaknesses in others.

However, this study has limitations and the principal limitation concerns data availability. Critical infrastructure data is often difficult to access due to security concerns and the fact that much of it is managed by private entities. While the use of OpenStreetMap (OSM) data is common in similar research, its reliability may be affected by its reliance on user-contributed reports, highlighting the need for further data verification. The predominance of private sector operation in many CI sectors also presents a significant barrier to accessing comprehensive open data.

Furthermore, as previously discussed, the definition and prioritization of what constitutes critical infrastructure can differ substantially between nation states' agendas. Looking ahead, an important step would be to identify, through broader studies, those critical infrastructure sectors that provide essential services that are mainly for public good and are as independent as possible from state and market interests. On this basis, developing a more expansive composite indicator including additional sectors based on public perceptions of essential services, such as housing or elderly services, could enhance the assessment of CI sufficiency and societal resilience.

Lastly, while this study primarily addresses the sufficiency of critical infrastructure, future research should also examine other dimensions emphasized in the literature, such as connectivity and redundancy, to provide a more holistic assessment of regional resilience. Additionally, future research could benefit from experimenting with alternative clustering methods such as hierarchical clustering, k-means, or density-based approaches to explore whether different techniques yield distinct or more nuanced typologies of CI provision. Comparing results across multiple clustering methods could provide deeper insights into the robustness and sensitivity of regional classifications and their implications for policy.

In sum, this study demonstrates the value of moving beyond single-sector or investment-based assessments toward a more spatially grounded, cross-sectoral understanding of critical infrastructure. The composite indicator developed here offers a useful practical tool for identifying vulnerabilities and guiding resilience-focused regional planning. As regions face growing environmental and socio-economic risks, ensuring the sufficiency of critical infrastructure will be essential for building more resilient regions.

Abstracts
Firstly, the experience of improving living quality in the UK, Japan and Hong Kong, China is systematically collated, and based on the experience, the minimum living standards of eight countries, namely, the US, Canada, the UK, Italy, Germany, Japan, South Korea and China, are also collated.Secondly, combining the data from the 7th National Population Census, residents' interviews and field research, we quantitatively assessed the current per capita housing situation in Dashilan in terms of spatial size, basic functional spaces, architectural performance and basic equipments, and the living environment, and found out the gaps between them and the minimum standards of domestic and foreign countries.Finally, it puts forward suggestions for improving the living quality from the aspects of standard setting, housing survey and supervision, dynamic database platform construction, and sustainable updating mechanism.

Keywords: historic and cultural block; per capita housing status; living quality; minimum living standards; residentially vulnerable groups

1. Introduce

With the increase in the total amount of housing construction in China and the continuous improvement of the housing system, the per capita area of housing in cities and towns has reached 40.8 m^2(National Bureau of Statistics, 2021), which is one of the highest in the world, and has basically solved the problem of insufficient housing.However, in the face of the reality of rapid urbanisation and urban population growth, the quality of housing for the urban population is poor, with more than 30% of the resident population lacking a safe, healthy and dignified living environment, a phenomenon that is particularly prominent in historical and cultural districts. Beijing Dashilan Historical and Cultural Block is such a typical neighbourhood, which is confined to multiple reasons such as property rights, cultural preservation, location and funding, making it difficult for the population to be relocated and for the foreign population to gather, in addition to the fact that the current renewal planning is still limited to public space and street facade improvement, and that there is a lack of quantitative assessment of the current housing situation per capita, which does not have a clear grasp of the bottom-line housing needs of the residents, thus influencing the renewal timetable.

<<Universal Declaration of Human Rights>> states that "Safe and affordable housing is a fundamental human right." UN-HABITAT calls on countries to: "Prioritise the needs of the vulnerable groups of people living in housing, establish minimum standards of accommodation acceptable to the occupants and build safe, healthy and sustainable human settlements."To sum up the background, this study quantitatively assesses the current housing situation per capita in the Dashilan Historical and Cultural Block by drawing on the experience of 3 countries in upgrading the quality of housing and the minimum living standards of 8 countries, and makes recommendations.

2 .International Experience in Residential Quality Improvement and Minimum Living Standards

2.1 Experience of improving the quality of living in the UK

The UK housing system consists of three types of housing: owner-occupied housing, social housing and private rented housing.Today, the number of people living in overcrowded, unsafe and unhealthy housing in the UK is decreasing, with overcrowding in only 9 of London's 250,000 homes in 2021 (London, 2021), as a result of the UK Government's efforts in the following 4 areas:

(1) Setting minimum living standards to guarantee a minimum level of safe, healthy, and dignified living.In 1935, minimum space and room standards (collectively referred to as overcrowding standards) were set out in the-

Housig Act-(HA) to guide the assessment of privately rented housing (WILSON W, 2020).The application of the HA was expanded in 1985 to guide all types of housing assessment.In 2004, the <<Housing Health and Safety Rating>> (HHSRS) was added to the HA, supplementing the minimum standards for basic functional space, building performance and basic equipment, and the living environment (GOV.UK, 2022).In 2005 the-Minimum Living Home Standard-(Shelter England, 2005). 2012 saw the launch of a review of standards, repealing (with the exception of the standards in HA) all previous minimum standards. The nationally harmonised-Nationally Described Space Standard-(NDSS) was introduced in 2015 (GOV.UK, 2015). 2021-The Human Habitation Act-re-emphasises the overcrowding standards in HA and the HHSRS as minimum standards for human habitation.

(2) Regular housing surveys based on minimum living standards.Since 1967, the UK government has conducted surveys on housing stock and living environment, once every 5 years before 2000, and once every year thereafter. English Housing Survey (EHS) is organised by local governments, and since 2007, it has been commissioned to a professional survey team, CADS (GOV.UK, 2019).The scope of the EHS survey covers the whole country, with a sample of 6,200 dwellings randomly sampled by region, and residents can also apply for the survey voluntarily through the EHS helpline.The EHS consists of a physical survey and a household questionnaire interview, with approximately 130,000 households interviewed each year.Finally, the results of the survey are evaluated according to the minimum standards in the HA, and then housing security policies are formulated to improve the quality of living.

In 2006, the UK government also introduced the "Housing Health and Safety Rating System", in which local environmental health officers assess the likelihood and severity of the existence of 29 types of potential health and safety hazards in housing once every 2 years, and the system is relatively simple, and households can also make their own assessments in Table 1.According to the severity of the hazards, they are classified into 4 types of risks. For housing with Type 1 risks, a demolition order is issued, and the government is responsible for demolishing the housing and rehousing the occupants who have become homeless due to the demolition of the housing; for housing with Type 2 risks, a no-occupation order is issued, and the government is responsible for repairing and stating that the use of the housing in violation of the rules is a criminal offence; for housing with Type 3 and 4 risks, a "Repair Notice" and a "Danger Awareness Notice" are issued to remind the occupant to carry out repairs to the property, and the property is reassessed after 28 working days (GOV.UK, 2022).

Table 1: Housing health and safety rating system indicators

physiological requirements	1.damp and mould growth; 2.excess cold; 3.excess heat; 4.asbestos and MMF; 5.biocides; 6.carbon monoxide and fuel combustion products; 7.lead; 8.radiation; 9.uncombusted fuel gas; 10.volatile organic compounds
psychosocial requirements	11.crowding and space; 12.entry by intruders; 13.lighting; 14.noise
protection against infection	15.domestic hygiene, pests and refuse; 16.food safety; 17.personal hygiene, sanitation and drainage; 18.water supply
protection against accidents	19.falls associated with baths; 20.falling on level surfaces; 21.falling on stairs; 22.falling between levels; 23.electrical hazards; 24.fire; 25.flames, hot surfaces; 26.collision and entrapment; 27.explosions; 28.position and operability of amenities; 29.structural collapse and falling elements

(3)Focusing on vulnerable groups of residents.For low-income families, it has introduced a "savings deposit, rent-and-buy" policy, under which they can acquire home ownership by paying rent for a limited period of time until the total amount of rent paid equals the total amount of the property; and a "shared ownership" policy, under which they can purchase a part of the house and shared ownership", where by a person buys a part of a house and pays a lower rent for the remainder, with the ownership shared between the Government and the individual; and the provision of housing for older people to help them live independently and reduce social care and health costs (London, 2021).

(4) Effective use of vacant housing.A requirement that homes cannot be left empty for more than 6 months or they will be compulsorily acquired for use as social housing; and incentivising the re-use of empty homes through the introduction of a council tax vacancy premium (London, 2021).According to statistics, the number of empty homes in London in 2021 will be less than 1% of the total housing stock.

2.2 Japan's experience in improving living quality
Japan's housing development can be broadly divided into 3 phases: the phase of housing supply before 1975, the phase of improving the quality of living from 1975 to 2006, and the phase of meeting the diversified housing needs of residents after 2006.

(1) Housing supply phase: "The Public Housing Supply Programme" was implemented to make it the responsibility of local governments to solve the housing difficulties of low-income people, and to systematically provide low-rent public housing for the underprivileged.

(2) Stage of improvement of living quality: housing survey, establishment of minimum living standards, and effective use of vacant housing.In 1950, the Japanese government conducted a housing survey once every 5 years on housing stock and housing use (Ministry of Land, Infrastructure, Transport and Tourism, 2018).In 1976, the Ministry of Land, Infrastructure, Transport and Tourism established the-Minimum Living Standards-as the basis for the housing survey, and gradually reduced the proportion of households that were below the minimum standards (Ministry of Land, Infrastructure, Transport and Tourism, 1976).The 1977 housing survey was supplemented with surveys on satisfaction with housing and the surrounding living environment, the existence of plans for residential improvement, and intentions for residential improvement.The scope of the survey was general housing nationwide, and 10,000 households were randomly sampled from the Housing and Land Statistics Survey and interviewed by questionnaire.

The vacant house survey was started in 1980 and is conducted once every 5 years to obtain basic information on vacant houses nationwide (Ministry of Land, Infrastructure, Transport and Tourism, 2019).Based on the results of the vacant house survey, empty houses that affect the surrounding living environment are scrapped; the government and communities provide a counselling mechanism for owners of vacant houses to reduce the proportion of vacant houses; the government is responsible for repairing and repurposing empty houses with unknown owners into special housing for the elderly, shared housing, temporary housing, or space for public activities, etc.; and support is provided to civil society organisations to collect information and conduct research and study activities through empty houses, and education and publicity activities to propose countermeasures for the reuse of empty houses.

(3) Stage of diversified housing needs: 2021 Introduced the <<Basic Plan for Residential Life>>, raised the <<Minimum Living Standard>>, and specified that in the post-epidemic era, in order to secure remote workspaces and regional workspaces, etc., within residences, we will promote the construction of an integrated residence and home learning environment, as well as promoting the construction of a non-contact environment by promoting the installation of express lockers and automatic faucets, etc.(Ministry of Land, Infrastructure, Transport and Tourism, 2021).

2.3 Hong Kong, China's experience in upgrading living quality
Public housing in Hong Kong is equivalent to subsidised housing in inland China. Public housing is divided into 2 major categories, namely public rental housing and public subsidised sale housing. Public rental housing includes low-cost housing (highly subsidised, low rent) and public rental housing (rent is set according to the cost of the project and the income of the tenants), while public subsidised sale housing mainly consists of Home Ownership Scheme flats and Sandwich Class Housing Scheme flats which are sold at cost, with a low downpayment and no interest payment.

To ensure fair allocation of public housing, Hong Kong has established a stringent application, allocation and

transfer system.The "Spacious Household Policy" stipulates that households with living space exceeding the prescribed standards should be relocated to PRH flats of suitable size, with priority given to seriously over-occupied generously sized households in accordance with the criteria set out in Table 2, by removing from the list of generously sized households families with disabled members or elderly persons aged 70 or above, and placing families with elderly persons aged 60-69 at the bottom of the list of generously sized households to be relocated.The Government has been working on the following measures to improve the living conditions of the elderly"The Rent Allowance for Elderly Scheme" provides cash rent allowance to elderly applicants for renting private flats in lieu of public rental housing allocation."The Shared Elderly Persons Priority Scheme" provides for immediate allocation of public housing to 2 or more elderly persons who agree to share a public housing unit."The Harmonious Families Priority Scheme" requires young families and at least 1 elderly parent or dependent elderly relative to choose to share 1 flat or 2 nearby flats, depending on the choice of districts and the number of flats suitable for the family's circumstances.In 2021, the "Living Space Improvement Transfer Scheme" stipulates that public housing tenants with a per capita living space of less than 7 may apply for transfer, while families with a living space of less than 5.5 are called "crowded households" and are subject to mandatory transfer; for families with persons who are pregnant for more than 16 weeks, wheelchair users, quadriplegics, or those who need long-term dialysis, an additional family member can be counted in the calculation of the per capita area (Housingauthority, 2021).

Table 2: Spacious household standard

Priority treatment standard for spacious households (	30	42	53	67	74	85

2.4 International minimum standards of accommodation

Facing the reality of rapid urbanisation and urban population explosion, in order to effectively solve the housing problems of middle and low-income people, the United States, Canada, Italy, Germany, South Korea and other countries have also formulated the minimum living standards, see Table 3.Each country takes the bedrooms, kitchens, toilets, and bathrooms as the mandatory functional spaces, and the availability and working condition of the structural solidity, water supply, drainage, power supply, heating and other equipment as the mandatory indicators.And ventilation, lighting, noise, indoor temperature and air quality have been the focus of housing assessment and investigation in all countries (Zhao, J., 2024).In addition, the UK and South Korea take gender and age differences into account when allocating bedrooms. The overcrowding standard in the UK HA stipulates that married or cohabiting couples, adults aged 21 years and above, a pair of same-sex adolescents aged 10-20 years old, and a pair of children aged under 10 years old (irrespective of gender) should be allocated a separate bedroom; in Korea, the-Minimum Living Standard-stipulates that couples share a bedroom, children over 6 years of age are separated from their parents, children of opposite sexes over 8 years of age are separated from each other, and elderly parents have a separate bedroom.

Note: Note: ① The full name of MPS is Minimum Property Standards; MHHS is Minimum Housing and Health Standards; IM is Istruzioni Ministeriali; HBO is Hessische Bauordnung. ② The unit of area is m^2.③ In (), it means that there are children living in the house, [] there are elderly people, and {} there are wheelchair users.④Total living area in the US and Canada includes bedroom, living room, kitchen-cum-dining room, and bathroom; PM includes bedroom, living room, kitchen, bathroom, and storage space; NDSS includes bedroom, living room, kitchen-cum-dining room, bathroom (toilet and shower), and storage space; Italy includes bedroom, living room, kitchen, bathroom, and storage space; Japan includes bedroom, living room, kitchen, dining room, bathroom, and storage space; South Korea includes bedroom, living room, kitchen, dining room, bathroom, and storage space; and Japan includes bedroom, living room, kitchen, dining room, bathroom, and storage space.space; Korea includes bedroom, living room, kitchen (or kitchen-cum-dining room), bathroom; China includes bedroom, living room, kitchen, dining room, bathroom.⑤"K" refers to kitchen, and "DK" refers to dining room and kitchen; ⑥the 1976 Japan and 2004 Korean minimum standards are intended to be compared with the current standards.

3. Per capita housing situation in the Dashilan Historical and Cultural Block

3.1 Study area and data

Dashilan is the most central block of the Chinese capital and the traditional commercial centre of old Beijing, as well as one of the first batch of Chinese Historical and Cultural Block, adjacent to Tiananmen Square and the National Centre for the Performing Arts, and an integral part of Beijing's Central Axis, in Fig. 1. Dashilan covers an area of about 1.26km^2 , and there are 3886 courtyards and 114 hutongs in the neighbourhood, which have retained the intact spatial texture of the courtyards and the hutongs.By the end of 2020, the resident population in Dashilan will be about 29,000 (including 58% of aborigines and 42% of foreigners), with the household population 1.75 times the resident population, the elderly aged 60 or above accounting for about 26% of the resident population, and the population with bachelor's degree or above accounting for only 20%, so that ageing and low education have turned Dashilan into a depression of human capital.

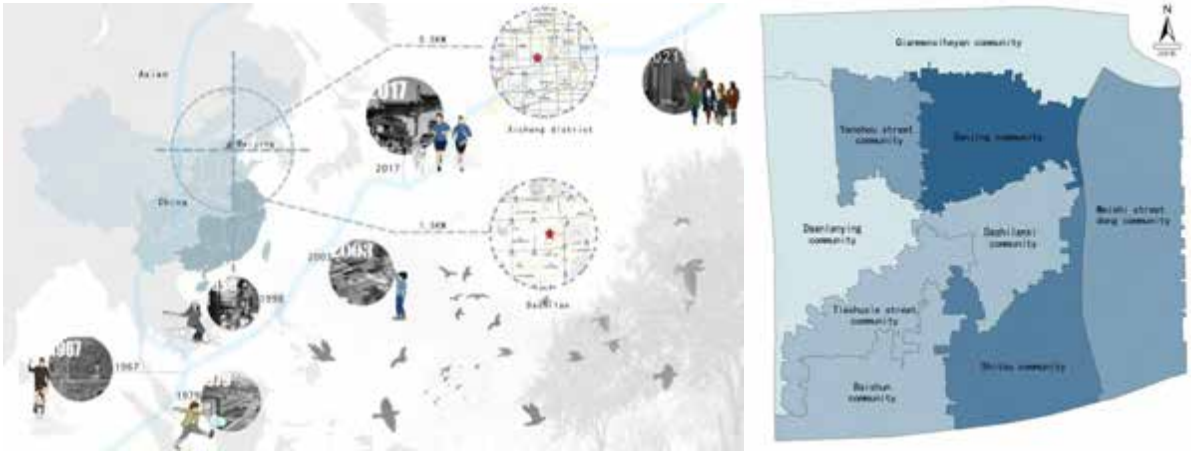

Fig. 1 Location map of Dashilan

This study used 3 types of data: the 7th National Population Census (the 7th Census), resident interviews and field research.The 7th Census took the zero hour of 1 November 2020 as the standard time point to census the population of mainland China, and the data of the 7th Census used in this study were provided by the Bureau of Statistics of Xicheng District, Beijing.Between November 2021 and June 2022, the research team visited households and organised more than 20 resident interviews, to obtain the opinions and needs of the residents.

This study mainly adopts the GIS analysis method, which imports the spatial units of the compounds during the 7th Census survey into GIS and transforms them into the form of shp data, and associates the population and spatial data based on the community code (Adcode) and the building code (BuildingNo), and then accurately assigns the population information to the compounds in which they reside, in order to assess the current status of the per-capita housing in each compounds.

3.2 Space size

3.2.1 Per capita living space

The living space of Dashilan residents is seriously insufficient, overcrowding is common, in Fig. 2., and living in an overcrowded environment for a long period of time will seriously jeopardise the physical and mental health of the residents (Susanto, D., 2022).The per capita living area of the resident population in Dashilan is 6.98m^2, and the median per capita living area is 7.5m^2 and the plural is 7.5m^2.Compared with the per capita minimum standards of various countries, it is lower than the America's 14 m^2, Canada's 13.5 m^2, the UK's 22 m^2, Italy's 21 m^2 ,Germany's 9 m^2, Japan's 18.8 m^2, South Korea's 14 m^2, Hong Kong, China's 7 m^2, of which about 50% of the residents' per capita living space is lower than Hong Kong's "squeezed households" standard of 5.5 m^2 Of these, about 50% of the residents have a living space per capita that is less than the Hong Kong "crowded household" standard of 5.5 m^2 and 86% of the residents have less than the standard parking space area of 12.5 m^2 for a private car.In addition, China's statistical yearbook shows that in 1989, China's urban per capita living area of 10.4 m^2, 2021 Beijing urban

per capita living area of 25 m^2, Dashilan as the location of China's capital city's most central block, the average per capita area even less than China's average level in 1989.

There is a big difference in the per capita living space of different groups, in Fig. 3. The per capita living space of the aborigines is 8.1 m^2, while the per capita living space of the foreign population is only 5.7 m^2, and the living space of the foreign population is even more narrow compared to that of the aborigines.The per capita area of households with infants and young children under the age of 6 is 6.3m^2, that of households with elderly people over the age of 60 is 9m^2, that of households with elderly people over the age of 80 is 11.8m^2, and that of households with disabled people is 7.6m^2.Among the disadvantaged groups, the living space of the senior elderly is relatively spacious, but it is still below the minimum standard of each country.

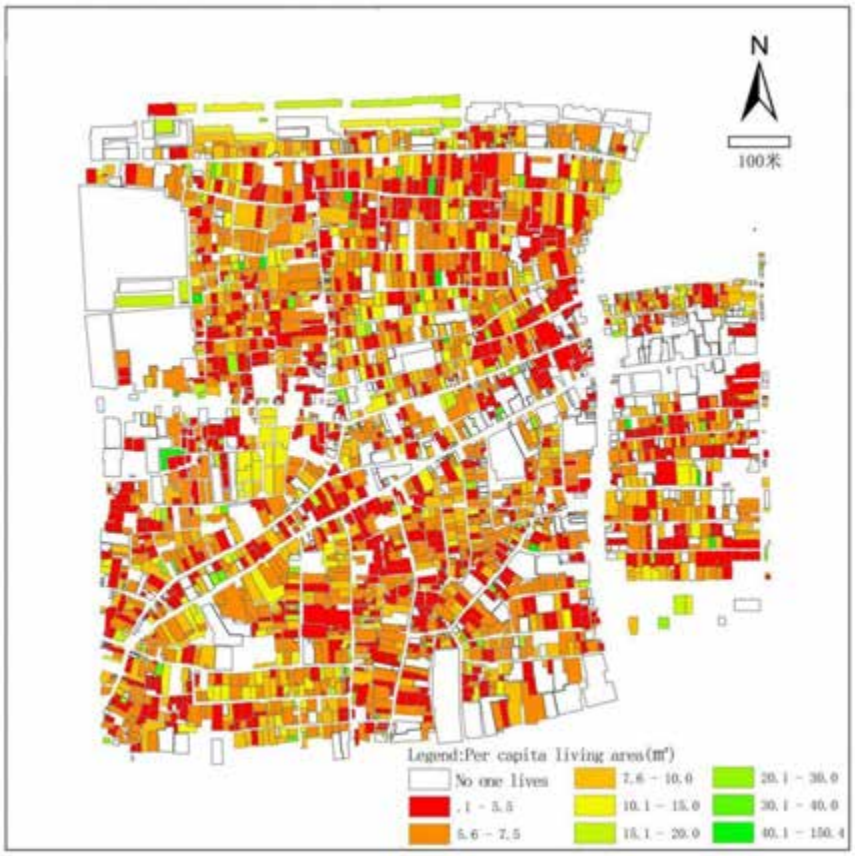

Fig. 2 Distribution map of per capita living area in courtyard

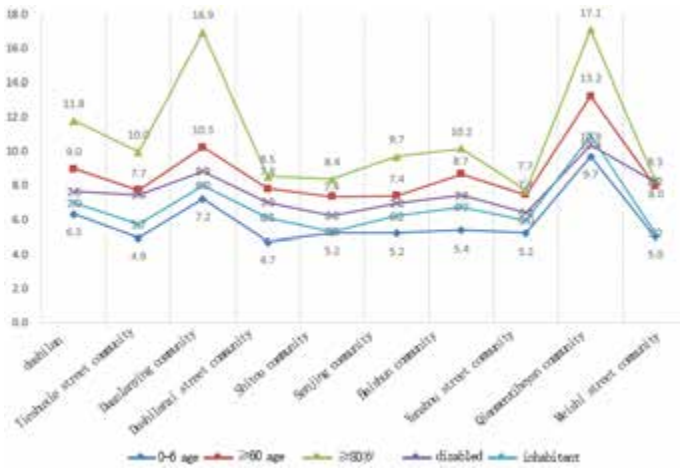

Fig. 3 Per capita living area of different groups

3.2.2 Number of rooms per capita

The overcrowding in Dashilan is again reflected in the number of rooms per capita, which is 0.55, with 79 of the resident population failing to meet the minimum standard of one room per capita, as shown in Fig. 4. In addition, as shown by the number of rooms per capita, which is 0.55, households do not take into account the differences in age and gender in the allocation of rooms; after all, not all people living in Dashilan are couples.

There are also differences in the number of rooms per capita among different groups, as shown in Fig. 5. The number of rooms per capita for the indigenous population is 0.6, while the number of rooms per capita for the foreign population is 0.5, and both the per capita living area and the number of rooms per capita of the foreign population are smaller than those of the indigenous population.The number of rooms per person in households with infants and young children under 6 years of age is 0.5, the number of rooms per person in households with older persons over 60 years of age is 0.7, the number of rooms per person in households with older persons over 80 years of age is 0.8, and the number of rooms per person in households with persons with disabilities is 0.7. Among the vulnerable groups, only infants and young children have rooms per person that meet the minimum standards of each country.

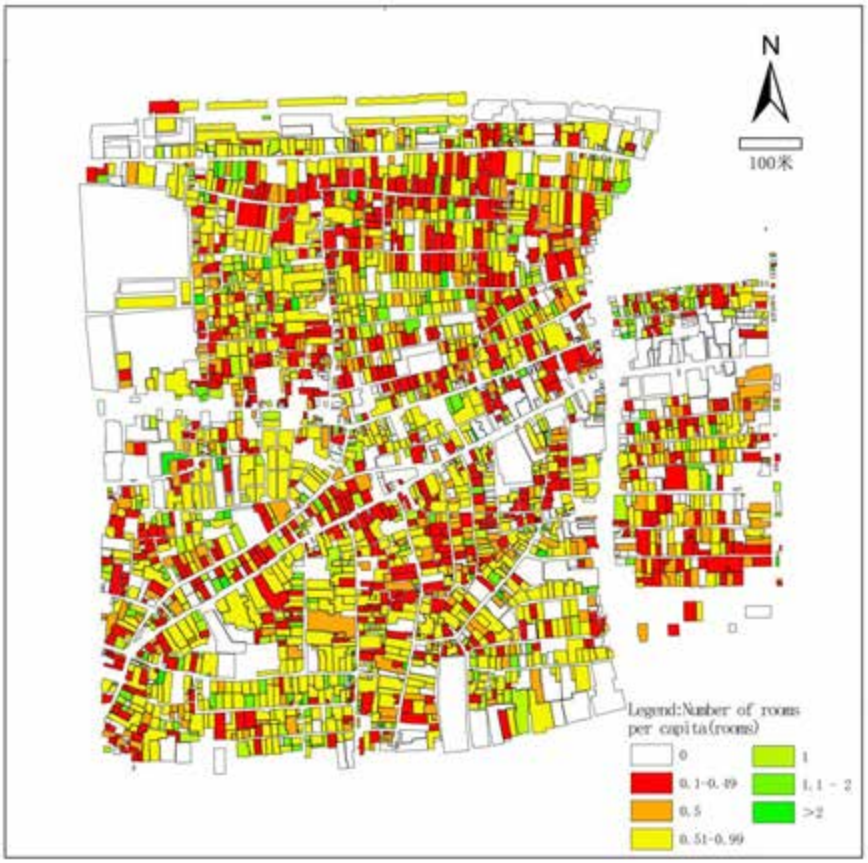

Fig.4 Distribution of the number of rooms per capita by courtyard

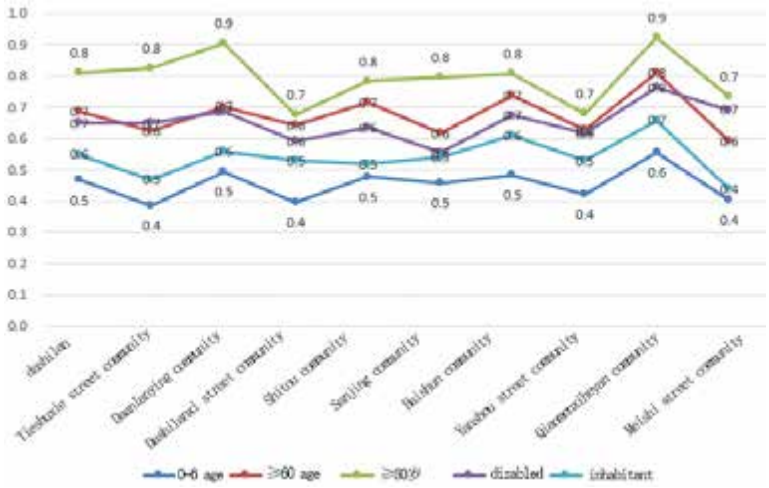

Fig. 5 Number of rooms per capita for different groups

3.3 Basic functional space

3.3.1 Kitchen

In all countries, separate kitchens are a mandatory basic functional space, while only 50 of households in Dashilan have a kitchen.Households in Dashilan are predominantly 2-3 person in size, with 0.55 rooms per person, indicating that a high proportion of households with kitchens have kitchens integrated with bedrooms.In addition, the field study found that some households have kitchens in the hutongs because of limited living space; if such kitchens were not counted, less than half of the households in Dashilan would have independent kitchens.

3.3.2 Toilet and bathing facilities

States have also made toilets and bathrooms mandatory basic functional spaces and stipulated that at least one separate toilet should be guaranteed in every housing unit.Only 18 of households in Dashilan have a separate toilet, and 75 have bathing facilities, but bathing facilities are not the same as separate bathrooms.In the symposium on "whether to support the inclusion of toilets in the courtyard/household", 11 residents expressed their views, of which 10 did not support the inclusion of toilets in the courtyard/household and 1 was neutral.The reasons for this are, on the one hand, that the living space is too small, and on the other hand, that the public toilets in Dashilan can cover all the courtyards within 80 m,in Fig .6. Therefore, whether or not to promote the use of toilets in courtyards/households in the near future should be assessed in the light of the needs of the residents and the availability of funds.

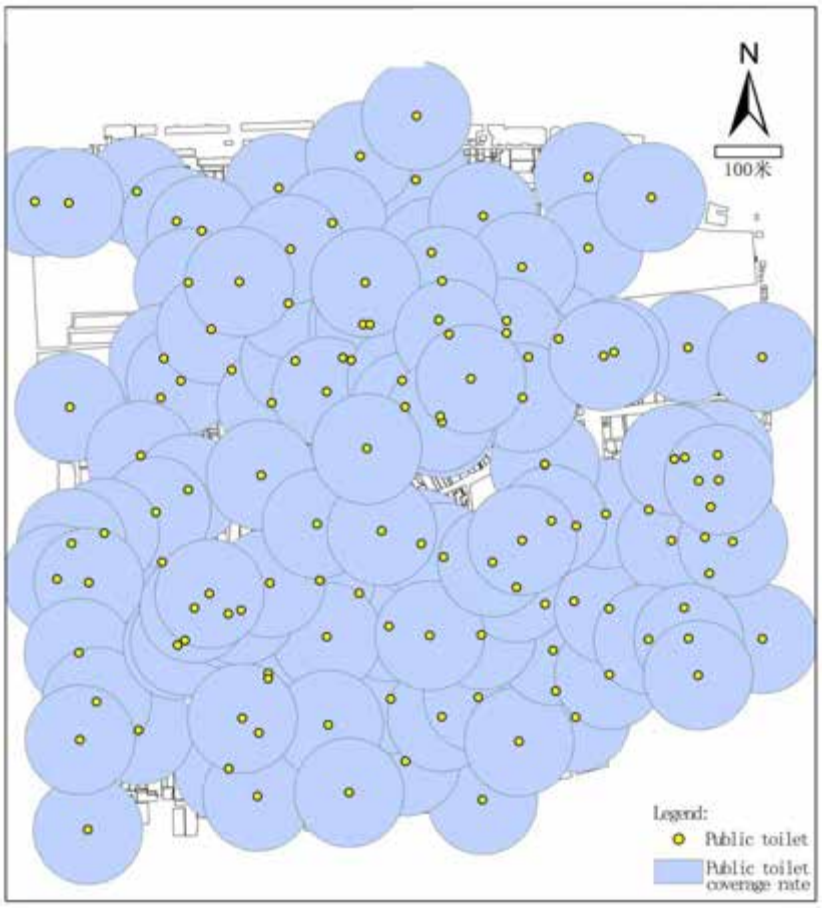

Fig. 6 80m coverage of public toilets

3.4 Building performance and basic equipment

3.4.1 Structural safety

Dangerous housing refers to the structure has been seriously damaged or load-bearing components have been dangerous components, at any time may lose the structural stability and load-bearing capacity, can not guarantee the safety of residence and use of the house, based on the degree of damage to the house will be divided into 5 categories of dangerous houses, 1 category of dangerous houses with the greatest degree of damage.Dashilan has 1,406 dangerous houses, accounting for 37% of the total compound of Dashilan (4, 5 types of dangerous houses mainly), private houses in dangerous houses accounted for a slightly higher proportion of about 51%, public houses accounted for 49%.In 87% of the dangerous houses, there are still residents living there, 27% of the dangerous houses have infants and young children living there, and 23% of the dangerous houses have elderly people over 80 years old living there, in Fig. 7.

Detailed analysis of the 61 randomly selected courtyards in the field study found that due to the long-term lack of maintenance and risk prevention awareness, some buildings in the block have more serious roof leakage phenomena and component collapse hazards, and the tilt rate of some building walls is even greater than 2%, which seriously exceeds the upper limit of the hazardous conditions stipulated by various national norms, and is very likely to damage the persons and properties safety of block residents in the event of torrential rains, high winds, continuous rain and other weather conditions.

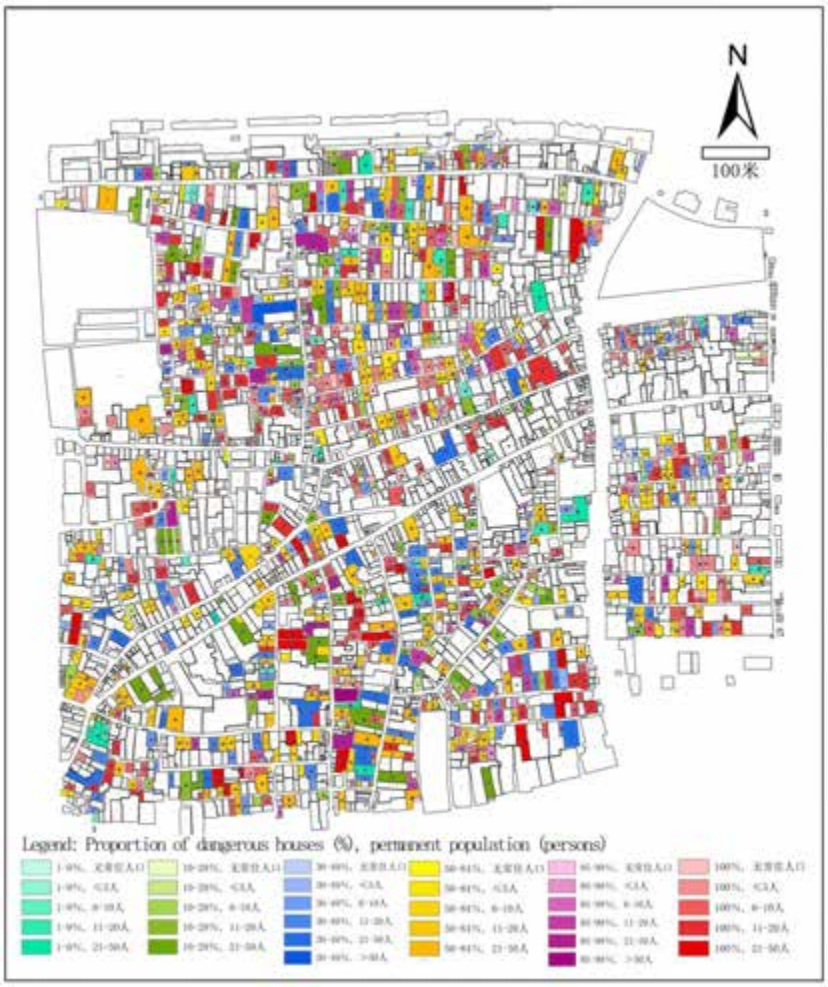

Fig. 7 Proportion of resident population in courtyard with different degrees of dangerousness

3.4.2 Water supply and heating equipment

Minimum standards in each country stipulate that water supply is a basic requirement for normal residential life, and the water supply in Dagestan is good, with 93% of households having piped water and 7% having no piped water.

Studies have shown that living in temperatures below 16°C for long periods of time during the winter months increases the risk of respiratory and cardiovascular diseases significantly in older people (Appolloni, 2021).We compared the indoor temperatures in a random sample of 10 compounds with those in urban buildings and found that the average indoor temperature in Dashilan in winter was only 5°C.The reason for this is that Dashilan was converted from coal to electricity in 2019, but some residents only heat their homes at night when they sleep because they cannot afford the high cost of electricity.

3.5 Living environment

The overall living environment in Dashilan is poor.Through household visits and resident meetings, we collected a total of 2,613 residents' opinions and demands on the living environment, and used GIS to group residents' opinions into the courtyard units they lived in, in Fig. 8. Residents mainly reflected indoor humidity, poor indoor lighting, frequent termite and rat infestation, waste accumulation encroaching on the courtyard, water accumulation and ice in the courtyard, noise nuisance from commercial operations and housing construction, and poor neighbourly-known neighbourhood relations.etc.For example, one resident reported: "The interior is very humid, the walls are mouldy, the air does not circulate, and you can only turn on the lights during the day when you can't see the light."

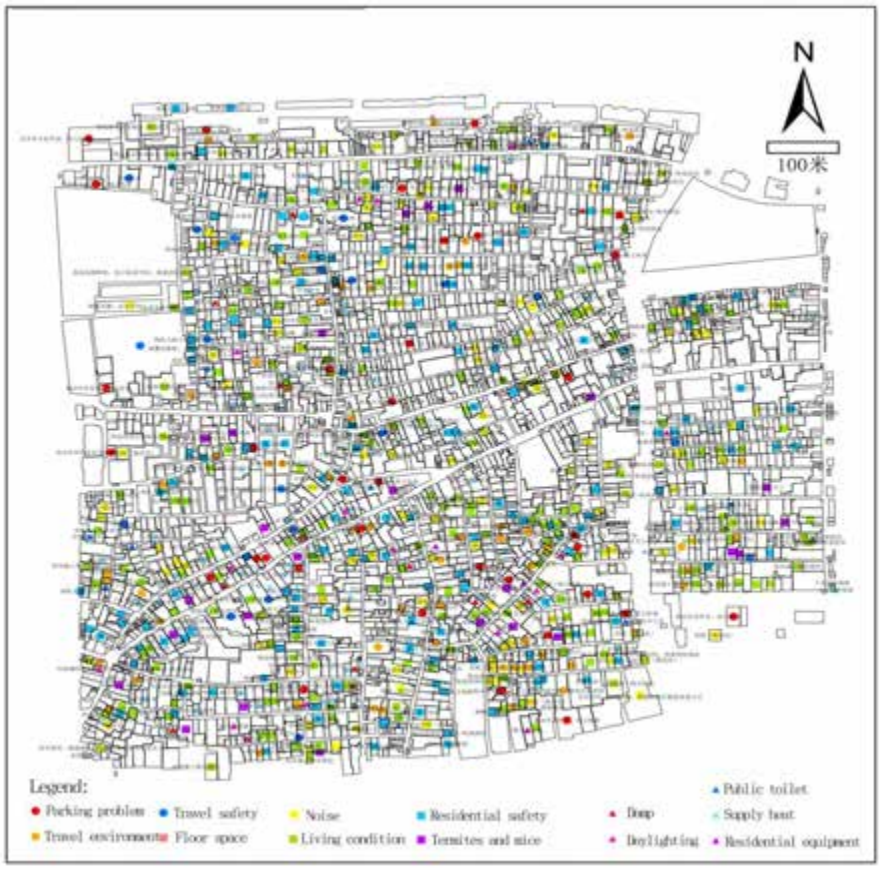

Fig. 8 Distribution of views of the people

4. Suggestions for improving the living quality of Dazhalan Historical and Cultural Quarter

4.1 Establishment of minimum occupancy standards for historic and cultural districts

Due to the lack of minimum living standards for historic and cultural block the minimum standards for ordinary urban housing in various countries were used for the assessment.However, it should be noted that housing in historic and cultural block has a unique historical background, spatial texture and structure, so the minimum living standards for historic and cultural block should be formulated by taking into account the special spatial form of the housing in historic and cultural block, the housing stock, as well as the human body size, activity characteristics and family structure of the inhabitants.Based on the current per capita housing situation, housing stock, spatial form of Dashilan, as well as the family structure and needs of the residents, this study initially proposes the minimum living space standards in Table 4, taking bedrooms, kitchens, bathrooms (including toilets and baths), and storage spaces as the mandatory basic functional spaces.

Table 4: Minimum living space standards for Dashilan

Family size (persons)	Bedroom area (m²)	Kitchen area (m²)	Toilet area (m²)	Storage space area (m²)	Area per capita (m²)
1	4.5	2.5	2	1	10
2	10	2.5	2	1.5	8
3	15.6	3	2.4	1.5	7.5
4	21.9	3.7	2.4	2	7.5
5	28.6	3.7	3.2	2	7.5

4.2 Housing survey and supervision

A survey on the current status of housing per capita is conducted every 2 years based on the minimum living

standards, including spatial size, basic functional space, building performance and basic equipment, living environment, and housing opinions and needs.At the same time, a survey of vacant housing is conducted once a year.Residents and social organisations are allowed to assess the current housing situation on their own, as well as to conduct surveys of vacant houses.

The minimum living standards will be used as the basis for the vacating of housing in historic and cultural districts (including application for rent refund, application for rent exchange, and application for improvement). For example, in the case of application for rent exchange, 3 categories of families will be divided into those who are far below the minimum standards, those who happen to meet the minimum standards, and those who are far above the minimum standards, and a differentiated housing area subsidy policy will be formulated; in the case of application-based improvements, reference is made to Hong Kong's public housing allocation system, with priority given to improving the living conditions of households below the minimum standard and those belonging to disadvantaged groups, and mandatory relocation is made for households that seriously fall below the standard.

Use the minimum standard of accommodation as the basis for tenancy management, prohibit the renting of housing below the minimum standard, and impose administrative penalties or fines on landlords who rent out housing in violation of the regulations.

4.3 Dynamic database platform construction

Using GIS to build a dynamic database platform for different subjects to use together. Overlay the spatial mapping map, census information, housing survey information, etc., and build a street-lane-courtyard-house-people database platform. The street office and the responsible planner are responsible for regularly updating the database platform, dynamically monitoring, scientifically planning and accurately managing, and quantitatively evaluating the per capita housing situation in Dashilan for a long time, so as to realize "one base map" and promote the improvement of living quality.

4.4 Sustainable updating mechanism

The Government is playing a leading role in upgrading residential quality, and is constantly improving the mode of public participation, implementing updates that reflect public opinion and respond to people's livelihoods, and integrating "top-down" and "bottom-up" approaches.The Government will also insist on population depopulation, while at the same time resolving the problem of "separation of people and households", optimising the age structure of the neighbourhoods, and introducing excellent industrial resources such as high-end cultural and creative industries, scientific and technological innovations, residence and tourism, so as to enhance the economic vitality of the block.Promote the revival of Dashilan's history, culture and common people's spirit, and promote the "cultural industry in the community" and "cultural activities in life" mode of block renewal.

5. Conclusion

This study systematically collates the experience of the UK, Japan and Hong Kong, China in improving living quality, and finds that they are all based on bottom-line thinking, and improve living quality by setting minimum living standards, housing surveys, paying attention to the disadvantaged groups of people living in the area, and making effective use of vacant housing.Based on this, we also collated the minimum living standards of various countries and assessed the current per capita housing situation in Dashilan, and found that there is still a big gap between the per capita housing level and the international minimum standards, and then put forward 4 aspects of enhancement suggestions.

This study hopes to reveal the housing problems that exist in Beijing's historical and cultural blocks by assessing the current per capita housing situation in Dashilan, a typical historical and cultural block, and suggests that a minimum housing standard should be guaranteed through housing surveys and regulation based on minimum living standards.The limitation of this study is that it only focuses on the housing problems that exist in the actual physical space, and does not explore the housing problems that exist in the areas where the government has

introduced the "housing vacate" policy and the "symbiotic courtyard" and "translocation courtyard" policies, and we should further explore the fundamental demands behind the residents' apparent discourse in the future.

Note

An Assessment on Provincial Differentiation of Housing Problem in the Turkish Case

Tolga LEVENT
Department of City and Regional Planning, Mersin University
tolgalevent@mersin.edu.tr

Abstract
Housing has emerged as a prominent urban problem in Türkiye during recent decades. Despite its quantitative overproduction, homeownership percentages have significantly decreased from 2002 to 2025, especially among low- and middle-income groups. This decrease turns the housing problem into a near-crisis situation. Most studies focus on this problem at the national level and overlook provincial differentiations. This study addresses one dimension of this gap by analysing the provincial distributions of residential ownership status profiles. By using hierarchical cluster analysis, it identifies spatially differentiated profiles across Türkiye. Contrary to expectations, the analysis reveals that "higher socio-economic development often correlates with lower homeownership". The study argues for reformulating housing policy through flexible, context-dependent, province-level strategies rather than national approaches.

Keywords: housing problem; residential ownership status; socio-economic development; provincial differentiation

1. Introduction

Apart from being a shelter, housing has many different functions. It serves socio-cultural functions to perpetuate social relations and to reproduce the urban environment, while concurrently it has economic functions as a product, a consumer good, an investment tool for appropriating speculative value increases, and a financial security tool, especially in economic crises (Tekeli, 2010). Since these functions, particularly socio-cultural ones, have diverse influences on the physical and psychological well-being of individuals, housing emerges as a critical topic in the realm of human rights.

Following World War II, the right to housing gained legal and international recognition as a part of social and economic rights. As it is declared in the Universal Declaration of Human Rights (Article 25/1), "[e]veryone has the right to a standard of living adequate for the health and well-being of himself and of his family..." (UN, 1948). This standard of living not only includes food, clothing, medical care, and other necessary social services but also housing.

Housing as a fundamental component of cities is crucial for individuals since it influences nearly every aspect of daily life. It not only protects individuals from the undesirable effects of the environment but also provides a private space to achieve a sense of privacy. Safe and stable housing enables the reproduction of different social relations and encourages stronger social networks and community involvement, while frequent relocations or housing insecurity can disrupt relationships, routines, and sense of belonging. Housing expenditures, whether in the form of rent or mortgage, frequently constitute the largest household expenses. These high costs can limit expenditures on other necessities, such as food, healthcare or education, leading to economic strain. Adequate housing provides a safe, clean environment that fosters both physical and psychological health, whereas poor conditions can lead to stress, illness, and long-term health problems. Furthermore, its location affects not only access to essential services such as education, employment, healthcare, and public transportation, thereby influencing life opportunities, but also daily routines, including commuting time, which in turn impacts overall quality of life.

Due to this foundational role, the housing problem, which encompasses any obstacle hindering individuals from accessing safe, affordable, and adequate housing, has always been a significant priority on national agendas. The objectives to deal with this problem are similar: to produce sufficient housing for the increasing populations, to ensure equal opportunities for various socio-economic groups in accessing housing, and to offer a diverse range of housing options that meet different needs (Alkan and Uğurlar, 2015:5). Since varying development levels

and socio-economic structures differentiate the level of housing problems from country to country, countries are expected to formulate their own context-dependent strategies by approaching the housing problem, taking their unique circumstances into account.

These context-dependent strategies should commence with the (re)definition of the housing problem. This study is such an attempt to redefine the housing problem in Türkiye by taking into account the provincial differences in residential ownership statuses. There are, actually, numerous studies examining housing problems in the Turkish context. Some of these studies have regional or provincial concerns, although they are not interested in residential ownership statuses. Conversely, the other studies focusing on residential ownership statuses mostly consider this problem at the national level without questioning regional or provincial differentiations. The first group of studies misses one of the basic dimensions of the housing problem, while the choices of the second group create an illusion as if the housing problem is the same everywhere and the high level of socio-economic heterogeneity at the national level is not reflected in the housing problem. To overcome these problems, this study aims to analyse provincial differentiations of residential ownership statuses and reveal whether their spatial repercussions are similar in developed and underdeveloped parts of Türkiye.

The study has three sections following the introduction. The second section first discusses the historical development of the housing problem in Türkiye. In the second part of this section, there is a general and quantitative description of the recent housing problem. With this description, it becomes possible to present different dimensions of the housing problem. The third section consists of two parts that focus on analysis. In the first part, there is a hierarchical cluster analysis of the residential ownership status profiles in each province. This analysis generates clusters of provinces based on the similarities in their profiles. This part concludes with a visualisation of the clusters using cartographic resources. In the second part, these clusters are simultaneously evaluated with the socio-economic development levels of provinces to ascertain whether there are spatial correlations between residential ownership statuses and those development levels. Assuming that the national housing policies are predominantly inefficient, the fourth and last section discusses the basic aspects of a housing policy that takes into account provincial differentiations.

2. A General and Quantitative Description of the Housing Problem in Türkiye

Housing has always been one of the significant urban problems in Türkiye. This problem has existed since the early Republican period. It possesses, however, distinct characters across different periods.

In the early Republican period, the housing problem was not very severe. During this period, Türkiye was mainly an agrarian society with a markedly low rate of urbanisation. Due to the low levels of demand for urban land, its speculative value was not very high, leading to significantly reduced housing production costs. Under these circumstances, local authorities had the opportunity to provide affordable urban land for urban development where individuals can construct their residences (Tekeli, 1982).

After World War II, urbanisation increased significantly. This rapid urbanisation triggered not only an increase in the housing demand but also a decrease in the amount of suitable land for residential development, hence raising urban land prices. Considering these changes, self-housing could not become a viable option for middle- and low-income groups anymore. Housing cooperatives appeared as an alternative for housing production for middle-income groups. Two laws, Law No: 634 on Condominiums, enacted in 1965, and Law No: 775 on Squatters, enacted in 1966, facilitated the production of housing through cooperatives (Özkan, 2009). Low-income groups, on the other hand, started to produce informal housing (Alkan and Uğurlar, 2015), in the form of either squatter units or shared title deed residential units.

In the 1980s, liberal macroeconomic policies and open market conditions began to exacerbate the housing problem in Türkiye (Alkan and Uğurlar, 2015). The central government established the Mass Housing Development Administration in 1984 to assist housing cooperatives. In the 1990s, however, the Housing Development Administration was compelled to limit the budget for cooperatives because the budget designated for mass housing

was reduced. These financial problems led to a decrease in the number of housing cooperatives (Özkan, 2009).

During the 2000s, the high market interest rates and consequently the increasing cost of establishing housing cooperatives became the main reason why these cooperatives started to lose their importance. Another reason is the emergence of profit-driven and speculative housing production for middle- and low-income groups (Özkan, 2009). Nonetheless, they are limited in numbers. This phenomenon explains why rental housing emerged as the main reply to housing problems for these income groups. However, the central and local governments have not prioritised the provision of rental social housing (Balamir, 1999), and their limited attempts to regulate rents have proven ineffective in addressing excessively high housing rents.

Since the early Republican period, the primary approach to addressing the housing problem encompasses two dimensions: increasing housing supply with different types of housing supply models and enhancing homeownership rates.

In the first dimension, namely the intention to increase the housing supply, Türkiye demonstrated a notable increase. Quantitatively, there has been an overproduction of legal housing. Concerning illegal housing, the overproduction of housing may be anticipated to be considerably greater. Due to an excess in housing production, approximately half of the households live in relatively new residential buildings constructed since 2001 (TUIK, 2021). According to Alkan (2015), the amount of housing production is approximately two times bigger than the actual needs in years 2011 and 2012; yet it became three times bigger in years 2013 and 14. Türel and Koç (2015) have similar statements about the overproduction of housing in Türkiye, and they assert that the reason for this overproduction is the limited control over the housing sector. However, since this overproduction is only for high-income groups, it could not be a comprehensive solution to the housing problem.

The second dimension focuses on the intention to enhance homeownership rates. Despite the overproduction of housing, homeownership rates, especially for low-income groups, have been steadily declining. The cause of this decline is not only the inadequacy of their capital for housing but also their restricted access to financial credit supports (Türel, 1996). This reduction has been very pronounced over the past two decades. From 2002 to 2023, the homeownership rate in Türkiye has decreased from 73.1% to 56.2% (Gökçe, 2024:141). According to the Survey on Building and Dwelling Characteristics, the decrease in the homeownership rates is slightly less, 60.7% in 2021 (TUIK, 2021). Although there is no consensus on the exact numbers, these decreases become noteworthy when the increase in the population and the decline in the average household sizes are considered. Namely, between the years 2002 and 2023, the overall population of Türkiye increased by 27.3% (UNPD, 2024), while the average household size dropped from 4.16 to 3.14 individuals (Yükseler, 2004; TUIK, 2023). This means that the number of households had increased from 16,117,788 to 27,188,655 in the same period. Evaluating all these numbers concurrently, it becomes possible to state the number of homeowners increased by approximately 3,500,000, while non-homeowners increased by approximately 7,500,000.

The quantitative changes have adversely affected individuals, especially low-income groups, as indicated by numerous research studies (Bayraktar and Yılmaz Bakır, 2019; Alkay and Övenç, 2019). The overall homeownership rate has decreased from 61.1% to 56.1% due to the gradual increase in housing prices between 2014 and 2024. This decrease is not uniform across all income groups. The homeownership rate among high-income groups has decreased from 65.4% to 61.4% in the same period. For middle-income groups, the change has been from 58.6% to 56.3%. Although the decreases are 4.0% and 2.3%, respectively, low-income groups have declined by 12.0%, from 57.8% to 45.8% (10Haber, 2025). The data clearly indicates that the housing problem in Türkiye is intensifying. This housing problem progressively moves towards a near-crisis situation due to the persistent rises in the cost of housing construction and prices, drastic decreases in purchasing power, and significant reductions in mortgage accessibility.

3. Provincial Analysis of the Housing Problem: Focus on Homeownership Rates

As previously stated, there have been significant decreases in homeownership rates in Türkiye during the past two decades, prompting numerous studies. These studies, however, are very general and draw deductions mostly at the national level, which fails to elucidate the spatial differentiations of homeownership.

This does not imply the absence of housing studies at regional or provincial levels. There are a limited number of such studies in the Turkish context. One of those limited studies focuses on both the changes in construction costs and housing price index in seven Turkish metropolitan cities and housing affordability in NUTS1 regions (Alkay and Övenç, 2019). Another study analyses the relationship between housing prices and inflation in seven selected NUTS2 regions (Teke İlhan and Gökçe, 2023). The last study concentrates on clustering the provinces with reference to the similarities in housing demand (Akay, Çelik and Kıral, 2019). While these studies assess regional and provincial differences and similarities in housing regarding certain aspects, they neglect to address residential ownership statuses. The studies concerning homeownership, conversely, do not consider their regional or provincial differentiations (Aydın, 2019).

This study aims to bridge this research gap in the Turkish context. It distinguishes itself by offering a spatialised understanding of homeownership in Türkiye, demonstrating that considering housing problem at the national level obscures critical provincial differentiation. This spatial insight is considered a starting point for effective housing policy formulation. In this framework, the study first analyses the provincial differences in residential ownership statuses and then co-evaluates these findings alongside the socio-economic development levels of Turkish provinces.

3.1. Provincial Differentiations of Residential Ownership Statuses

Studying residential ownership statuses spatially in Türkiye is challenging due to data limitations. The 2021 Survey on Building and Dwelling Characteristics conducted by the Turkish Statistical Institute enables, however, studying them at the provincial level. The survey provides a cross-tabulation of four residential ownership statuses, namely homeowners, tenants, others[1], and unknown, for each province. This cross-tabulation delineates distinct profiles of residential ownership statuses for each province. However, cluster analysis can detect the similarities and differences among these profiles.

Cluster analysis is an exploratory statistical method that forms groups according to similarities in the characteristics of multivariate data (Härdle and Simar, 2003; Jobson, 1992; Gore, 2000). Hierarchical cluster analysis is one of the most advantageous methods in cluster analysis, as it does not require presumptions regarding the number of clusters (Sharma, 1996). There are different types of hierarchical cluster analysis, including single linkage (nearest neighbour), centroid clustering, and Ward's method, which differ from each other in the linkage criteria they use. This study employs Ward's Method due to its suitability for spatial analysis (Levent, 2007).

The dendrogram (Figure 1) created using Ward's Method in IBM SPSS Statistics Version 23[2] shows that there are four groups based on how similar the residential ownership statuses are (Table 1).

In the first cluster (C1), the average percentage of homeowners is 64.8%, above the national average by 4.1%. The cumulative percentage of homeowners and others[3], who do have similar ways of approaching housing, is 75.7%.

1 There are two groups of individuals within the "others" category. The first group comprises those occupying lodging houses owned by the state, municipalities, or companies. These individuals mostly do not pay housing rents, or very limited housing rents below market rates. The second group comprises those occupying mother's/father's houses, houses owned by relatives/friends, caretaker's residential units, waqf houses, or disaster houses, all of whom do not incur rental expenditures.

2 Square Euclidean distance is used as the measure by applying Ward's Method.

3 Homeowners and others are evaluated together, as their percentages exhibit significant parallelism across all clusters. In clusters with a high percentage of homeowners, there is also a high percentage of others, or vice versa. The reason for this parallelism is the similarity between homeowners and others who typically do not incur rent or have minimal housing expenditures akin to homeowners. Since these expenditures account for limited shares of their consumption expenditures, they do not generate

Conversely, the average percentage of tenants in this cluster is 22.2 %, the lowest among the other clusters.

The second cluster (C2) has a character similar to the first cluster (C1). The average percentages of homeowners and others in the second cluster exceed national averages, while the average percentage of tenants is below those averages. Nonetheless, the deviations from the national average percentages are not as pronounced as those in the first cluster (C1). Moreover, the cumulative percentage of homeowners and the others in this second cluster (C2) is 72.4%, slightly lower than the cumulative of the first cluster (C1).

The third cluster (C3) comprises solely two provinces, namely, Ankara and İzmir. They are the second and third biggest and most developed provinces in Türkiye. The average percentages of homeowners and others are, respectively, 60.1% and 8.3%. In this third cluster (C3), the average percentage of homeowners is slightly lower than in the clusters (C1 and C2), while the average percentage of tenants is somewhat higher than the national average. The cumulative percentage of homeowners and the others is also lower than the one at the national level. The percentage of the unknown category is the lowest in this category[4].

The fourth cluster (C4) only includes İstanbul, and it has fundamentally a similar profile to the third cluster (C3). Nevertheless, the percentages of homeowners and others are lower, while the percentage of tenants is much higher compared to the third cluster (C3). The size of the province likely explains why only one province forms a cluster in the dendrogram. Approximately 16.3% of all homeowners in Türkiye reside in this province.

Mapping these clusters on a provincial map illustrates the provinces with high and low percentages of homeowners, tenants, and others (Figure 2). As mentioned before, the biggest cluster (C1) has 55 provinces, predominantly medium-size and small provinces. These provinces are located in the Inner Anatolian, Eastern Anatolian, and South-eastern Anatolian regions and in the eastern parts of the Aegean region. The second cluster (C2) includes 23 provinces, most of which are coastal provinces. The eight provinces in the Black Sea regions can be regarded as exceptions. Instead of these eight coastal provinces, this cluster includes eight inland provinces, namely Denizli, Eskişehir, Konya, Kayseri, Kahramanmaraş, Gaziantep, Şanlıurfa, and Diyarbakır, where provinces are governed by the metropolitan municipalities. What is intriguing is that this cluster (C2) includes only the provinces with metropolitan municipalities. There are only four provinces with metropolitan municipalities outside this cluster, namely Erzurum, Malatya, Van, and Mardin, located in the Eastern and South-eastern Anatolian regions. There are two clusters (C4 and C3) where average percentages of homeowners are less than the national average percentage. Actually, there are only three provinces, namely İstanbul, Ankara, and İzmir, in these two clusters; yet, they contain approximately 32.1% of all residences.

budgetary problems for them. Consequently, others are similar to homeowners more than the tenants, although they do not own a house.

4 Within these clusters, the unknown category is different than the other categories. The percentages in the clusters are comparatively low; thus, it can be deemed a somewhat ineffective category in generating the clusters. Additionally, the average percentages of this category fluctuate in clusters. The average percentages are below the national average in the first cluster (C1) and the third cluster (C3). It is exactly the same in the second cluster (C2). In the fourth cluster (C4), however, the average percentage of the unknown category is more than the national average percentage. These explain the exclusion of the unknown category from the evaluations.

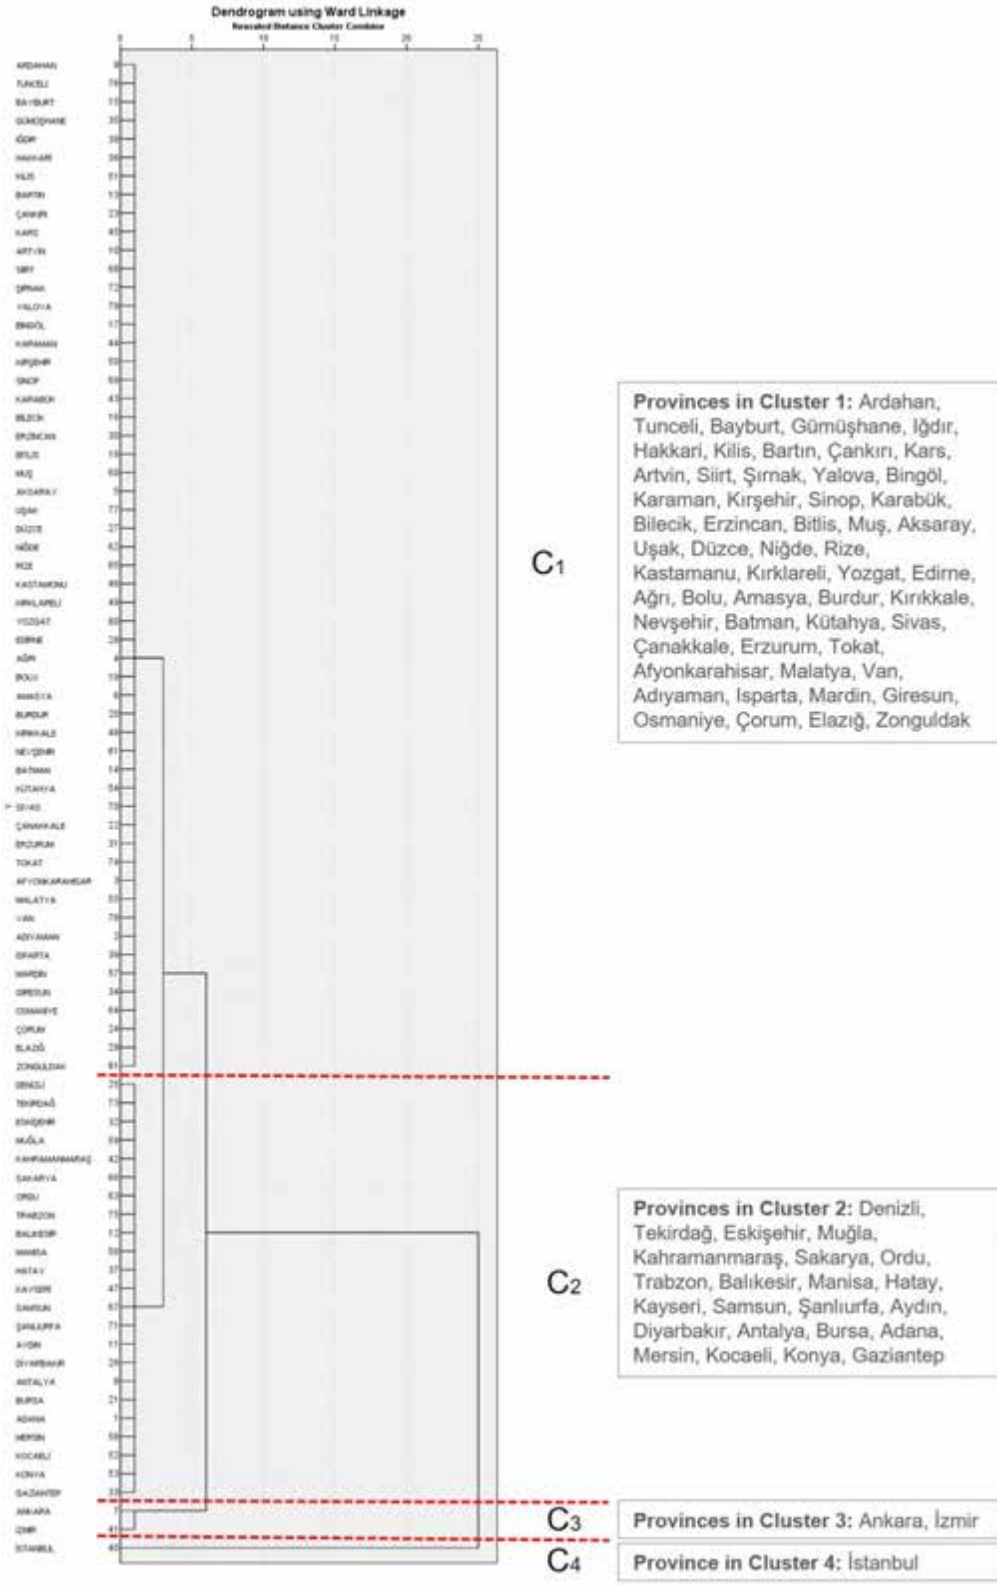

Figure 1. Dendrogram presenting the Clusters of the Residential Ownership Status Profiles

Table 1. Cluster Profiles of Residential Ownership Statuses

Clusters		Homeowners	Tenants	Others	Unknown
C1	Percentage (%)	64.8	22.2	10.9	2.2
	Total (55 provinces)	4,168,838	1,410,546	687,455	136,400
	Average	75,797	25,646	12,499	2,480
C2	Percentage (%)	62.7	25.3	9.7	2.3
	Total (23 provinces)	6,682,231	2,806,643	1,055,612	249,845
	Average	290,532	122,028	45,896	10,863
C3	Percentage (%)	60.1	29.9	8.3	1.8
	Total (2 provinces)	2,032,271	1,010,792	27,5416	58,700
	Average	1,016,136	505,396	137,708	29,350
C4	Percentage (%)	52.6	37.1	7.5	2.8
	Total (1 province)	2,501,473	1,763,740	356,488	133,385
Türkiye	Percentage (%)	60.7	27.6	9.4	2.3
	Total	15,384,812	6,991,720	2,374,972	578,329
	Average (81 provinces)	189,936	86,318	29,321	7,140

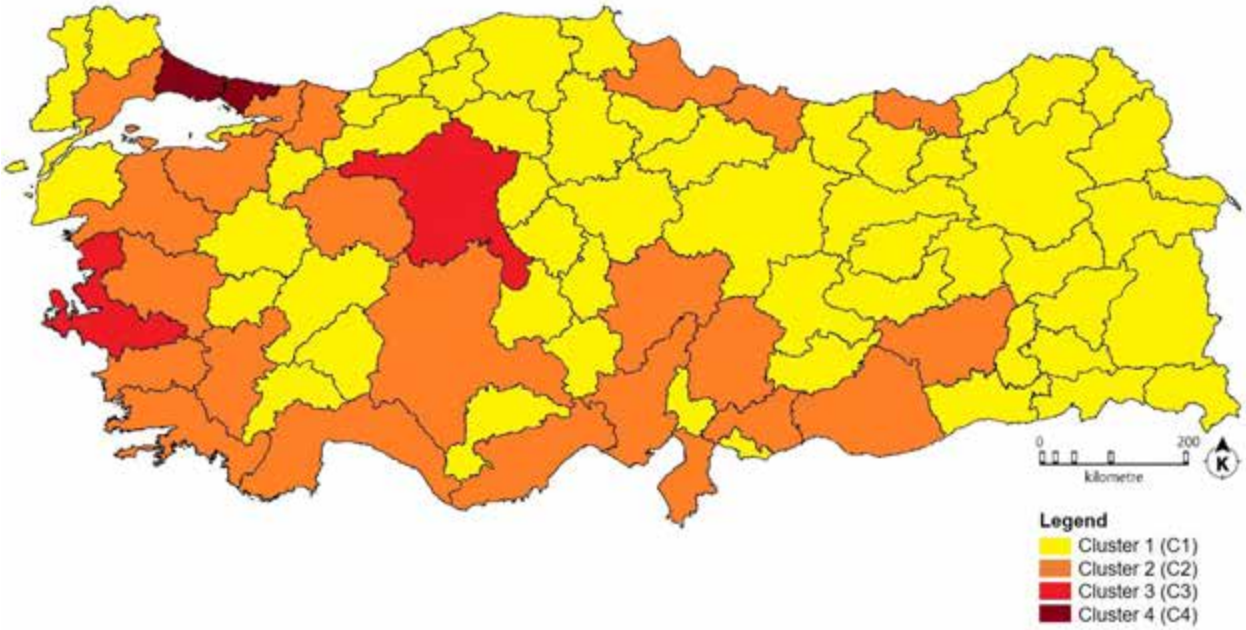

Figure 2. Provincial Differentiation of the Profiles of Residential Ownership Statuses

3.2. The Relationships Between Residential Ownership Statuses and Socio-Economic Development Levels

The provincial distribution of similar profiles of the residential ownership statuses provides a spatial description concerning the housing problem. To better understand this distribution and generate further explanation, it should be co-evaluated with different domains such as population dynamics, environmental risks, and infrastructural capacity. The socio-economic development levels of provinces are one of those domains, and this study proceeds with it.

The official study on socio-economic development levels is the Study on Socio-Economic Development Ranking of Provinces and Regions (SEDI-2017), which was conducted by the Ministry of Industry and Technology in 2019. Based on the official data from 2017, the study measures the relative development levels of all provinces across Türkiye. The data used in the preparation of this study is classified as demography, employment, education, health, competitiveness, innovative capacity, finance, accessibility, and quality of life variables (Sanayi ve Teknoloji Bakanlığı, 2019). The study is not only for identifying regional disparities but also for defining an information base for regional planning studies and public investment allocation. The output of the study is the socio-economic development ranking of provinces, which can also be represented spatially (Figure 3).

According to this map, there is a clear east-west divide in Türkiye. The eastern part of Türkiye is underdeveloped, while the western part is comparatively developed. Nonetheless, this split is not a pure divide. In the eastern part, there are four developed provinces, namely Samsun, Trabzon, Rize, and Gaziantep. The first three provinces are in the Black Sea region, while Gaziantep is located in the South-eastern Anatolia region. Similarly, there is one underdeveloped province, Afyonkarahisar, located in the western part of Türkiye.

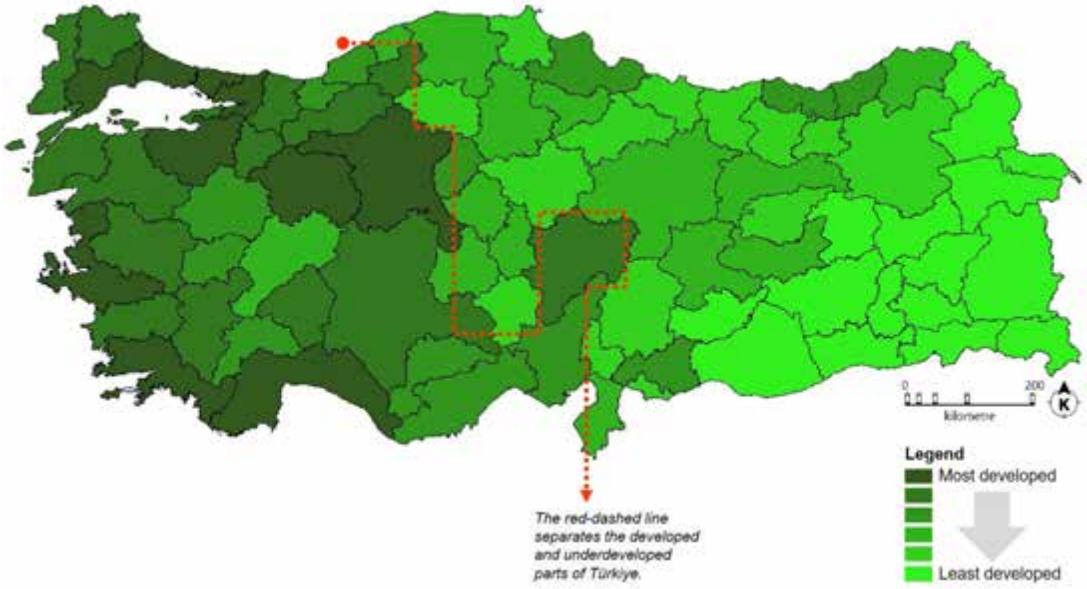

Figure 3. The Socio-Economic Development Levels of Turkish Provinces (SEDI-2017)

When the clusters are co-evaluated with the west-east divide, it can be easily stated that the majority of provinces of the first cluster (C1) are mainly in the underdeveloped part of Türkiye (39 out of 55 provinces). This cluster possesses the lowest average score calculated for the socio-economic development rankings of provinces, namely -0.360. In this cluster, however, the percentages of the homeowners and the others are relatively high. The results show that the percentage of homeowners in the underdeveloped part Türkiye is higher than expected. On the contrary, approximately 65.2 % of the provinces of the second cluster (C2) are in the developed part of Türkiye. For this cluster, the average score calculated for the socio-economic development rankings of provinces is 0.483, which is comparatively high relative to the overall score. What makes this cluster intriguing is that the percentages of homeownership in its provinces are slightly higher, although these provinces are mostly in the developed part of Türkiye. The remaining clusters (C3 and C4) encompass the most developed provinces; yet, the

percentages of homeowners are significantly low, while those of tenants are high (Table 2).

Table 2. Relationships Between Clusters and Socio-Economic Development

Cluster	Provinces in the Developed Part (n)	Provinces in the Underdeveloped Part (n)	Total Number of Provinces (n)	Average Scores for the Socio-Economic Development Rankings
C1	16	39	55	-0.360
C2	15	8	23	0.483
C3	2	-	2	2.322
C4	1	-	1	4.051
Türkiye	**34**	**47**	**81**	**0.002**

There are three basic findings of the co-evaluation of residential ownership statuses and the socio-economic development levels of provinces.

Firstly, there is a negative correlation between socio-economic development levels and the number of homeowners and a positive correlation between socio-economic development levels and the number of tenants. The higher the positions in the socio-economic development ranking, the lower the percentages of homeownerships. This negative correlation makes housing primarily a problem for developed provinces in Türkiye.

The second finding is another negative correlation between the number of residences and the number of homeowners. Despite the substantial quantity of residences in big metropolitan cities, the percentage of homeowners remains comparatively low. This negative correlation demonstrates that an increase in housing supply does not correspond to an increase in homeownership percentages.

The third finding is the exceptional areas in the synthesis map (Figure 4). These exceptional areas can be classified into two categories: the provinces in the developed part of Türkiye that are similar to the provinces in the underdeveloped part of Türkiye and the provinces in the underdeveloped part of Türkiye that are similar to the provinces in the developed part of Türkiye.

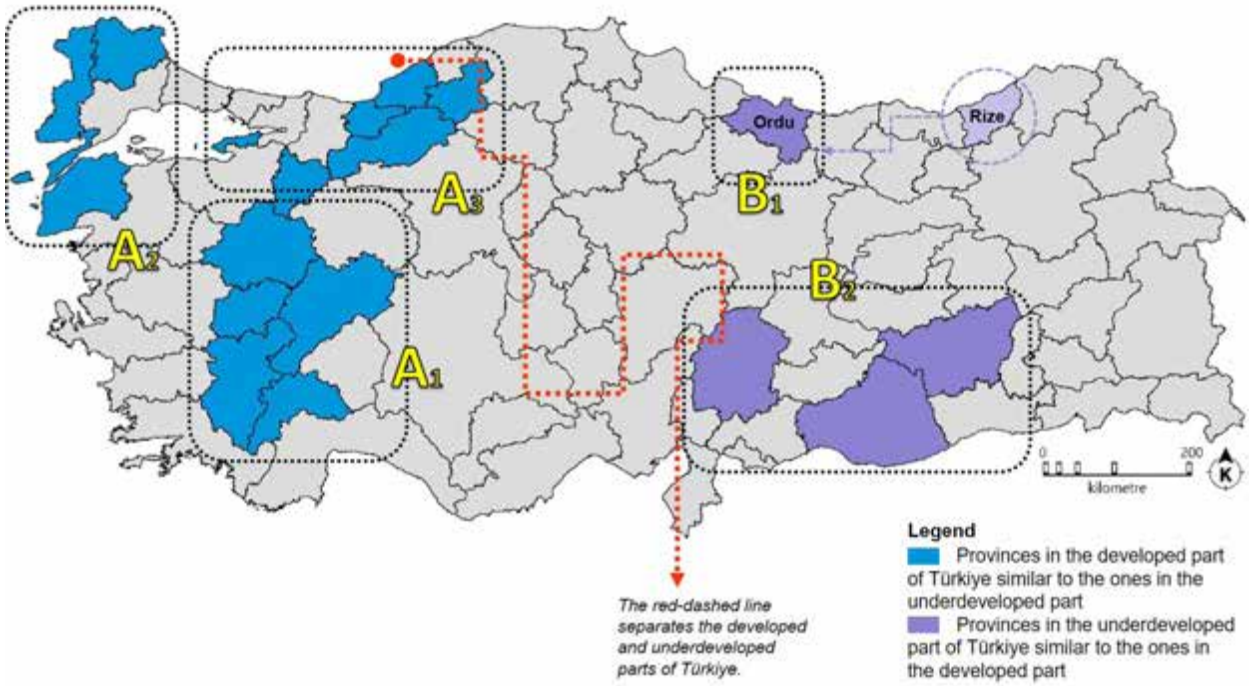

Figure 4. The Synthesis Map

The first category consists of three groups. The first group (A1) contains five provinces from the eastern part of the Aegean region and the northern part of the Mediterranean region, namely, Kütahya, Uşak, Afyonkarahisar, Isparta, and Burdur provinces. Afyonkarahisar province is in the fourth socio-economic development rank and is the least developed province in the western part of Türkiye. Its socio-economic development score is less than the overall average of Türkiye. This group has an average socio-economic development score of 0.240 but an average percentage of homeowners of 65.8%. The second group (A2) contains the Kırklareli, Edirne, and Çanakkale provinces in the north-western part of Türkiye. Although they are in the second socio-economic development rank and have an average socio-economic development score of 0.546 (higher than the average of the second cluster in Table 1), their average percentage of homeowners is 65.7% (higher than the average of the second cluster in Table 1). In short, this group includes well-developed provinces with high homeownership percentages. The third group (A3) is located in the western parts of the Marmara region and contains the Zonguldak, Karabük, Düzce, Bolu, Yalova, and Bilecik provinces. These provinces belong to either the second or the third socio-economic development ranks, with an average socio-economic development score of 0.526 and an average percentage of homeowners of 63.0%.

The second category includes the provinces in the underdeveloped part of Türkiye that resemble those in the developed part of Türkiye. Such a pattern with Samsun, Trabzon, Rize, and Gaziantep provinces exists on the map of socio-economic development levels, as explained before. Within the synthesis map, while the Rize province is excluded, the Ordu (B1), Kahramanmaraş, Şanlıurfa, and Diyarbakır provinces (B2) are included. It seems as if the Ordu province appears instead of Rize province. While the former one has a metropolitan municipality, the latter one does not. The Kahramanmaraş, Şanlıurfa, and Diyarbakır provinces are all located in the South-eastern Anatolian region. Once again, the provinces have metropolitan municipalities.

4. Conclusion

This study has aimed to understand provincial differentiation of the housing problem in Türkiye by co-evaluating the residential ownership statuses and the socio-economic development levels of provinces.

There are several limitations that emerged during the course of this study. First, the data on residential owner-

ship statuses vary across different studies, which creates inconsistencies in comparative analysis. This study utilises the official data provided by the 2021 Survey on Building and Dwelling Characteristics, which, while comprehensive, may not align with other data sources. Second, the socio-economic development data are drawn from the Study on Socio-Economic Development Ranking of Provinces and Regions (SEDI-2017), which, although the most recent available, is outdated and may not properly capture the existing socio-economic context. Third, the classification of provinces as developed and underdeveloped provinces is relatively simplistic and includes a few notable exceptions that are challenging to elucidate. Additionally, the study does not account for rural-urban distinctions within provinces, even though ownership patterns may significantly differ between these areas. The practice of averaging ownership percentages and socio-economic scores within clusters has the potential to blur internal variations and lead to overgeneralised conclusions. Finally, although housing ownership statuses can be meaningfully evaluated through various provincial lenses such as population dynamics, environmental risks, or infrastructural capacity, this study limits its scope to socio-economic development levels, which narrows the range of contextual factors considered in the analysis.

Despite the number of these limitations, the findings of the study reveal a striking and counterintuitive pattern: higher socio-economic development often correlates with lower percentages of homeowners and higher percentages of tenants. This negative correlation challenges the conventional belief in the domain of housing that economic development naturally leads to improved homeownership rates. Furthermore, the findings indicate that an increase in housing supply, especially in metropolitan areas, does not automatically lead to increased homeownership, particularly among low-income groups.

One of the fundamental dimensions of Türkiye's housing problem is the significant inequality in access to housing across different income groups. While the national policy framework has succeeded in achieving a quantitative increase in housing production, this production has disproportionately served high- and middle-income groups. The most disadvantaged individuals, namely low-income groups, encounter growing exclusion from homeownership due to high mortgage rates, limited savings, and the absence of sufficient rental support from the central and local authorities.

Except for the extraordinary post-earthquake situations, Türkiye has structured its housing policy as a centralised framework. It mostly fails to accommodate the regional and provincial differentiations that may arise mainly with socio-economic development levels, population dynamics, environmental risks, and infrastructural capacity. This study focuses on the co-evaluation of the provincial differentiations of the residential ownership statuses and the socio-economic development levels of provinces. Such an evaluation assumes that the solution to the housing problem should be proposed not at the national level but at the provincial level, and housing policy should be reformulated through provincially differentiated lenses. This reformulation means a change of intention from rigid, national, and "one-size-fits-all" types of housing policies to flexible, provincial, and context-dependent strategies that are sensitive to local socio-economic realities.

The reformulation should start with a comprehensive assessment of provincial needs. With this assessment, it is possible to develop tailored housing strategies for special purposes. For instance, a province with high homeownership rates but insufficient housing stock may focus on supply-side interventions, whereas provinces with low homeownership rates may benefit from financing programmes for the availability of affordable housing for both the potential homeowners and tenants.

In sum, this study represents a minor attempt to develop a spatial understanding of the housing problem by focusing on the co-evaluation of residential ownership statuses and the socio-economic development levels of provinces. By acknowledging that its content is insufficient to comprehend the complex and multidimensional housing problem in Türkiye, it may inspire future studies that can integrate different domains such as environmental risk, urban-rural dynamics, and infrastructural capacity into this provincial lens. With the help of those studies, it becomes possible to effectively address the growing housing problem in Türkiye and develop a more holistic and equitable housing policy.

Abstract
This study aims to examine the social impacts of legal regulations introduced in Turkey's housing and planning legislation between 2002 and 2024, with a specific focus on Istanbul. Conducted in two stages based on document analysis and literature review, the research evaluates the legislative changes during this period and their social repercussions. The findings reveal that these regulations have led to consequences such as displacement, social fragmentation, loss of sense of belonging, gentrification, and the weakening of public interest. The study emphasizes the need to reconsider planning policies in light of the principles of spatial justice and social inclusivity.

Keywords: Neoliberal policies; social dimension of the planning legal framework; Istanbul Metropolitan Area.

Introduction

The 2000s marked a period in which neoliberal policies became spatially embedded in Turkey, leading to significant transformations in planning legislation and a restructuring of planning institutions. During this time, extensive legal arrangements were implemented to facilitate real estate investments, construction processes, and land supply in favor of market actors. Central institutions were granted considerable authority and resources, resulting in a centralization of the planning process. In particular, the establishment of the Ministry of Environment and Urbanization in 2011 further expanded the central government's planning powers while narrowing the jurisdiction of local authorities. The legislative changes in planning and the rapid increase in construction driven by growth strategies based on the construction sector have, rather than resolving economic, spatial, and social issues, exacerbated them—especially increasing the social costs for low-income groups and, after 2020, for segments of the middle class. These problems have manifested more severely in major cities such as Istanbul (Alkay, 2020; Balaban, 2012; Balaban, 2021; Çoban, 2012; Keleş, 2014; Şengül, 2009).

The aim of this study is to examine the social implications of legal reforms in planning legislation during the 2000s—a period when neoliberal policies were spatially institutionalized and the new government pursued a construction- and housing-oriented economic agenda—within the Istanbul Metropolitan Area. Structured in two stages based on document analysis, the study covers the 22-year period between 2002 and 2024. In the first stage, legislative reforms from 2002–2010 and 2010–2024 are examined in detail. In the second stage, the study analyzes the literature based on field research conducted in the Istanbul Metropolitan Area.

The modern city constitutes one of the primary arenas of conflict between the often contradictory interests of different social groups (Şengül, 2009). These divergent interests and objectives form the basis of socio-spatial transformation. As an extension of the construction sector—where such conflicting interests are highly concentrated—the housing sector has rapidly transformed urban space and continues to do so. The groups that suffer the most from this transformation compel a critical interrogation of the concept of urban justice. According to Soja (2009), the state plays a pivotal role in the realization of urban justice. Fainstein (2014) defines the just city through the principles of equity, democracy, and diversity. Lefebvre (2013) argues that prioritizing the exchange value of urban space over its use value constitutes the foundation of urban injustice and inequality. For Harvey (1973), the use value of housing lies in its ability to meet fundamental needs such as shelter, belonging, and security. In contrast, the exchange value of housing is determined not only by its basic production costs—such as materials and labor—but also by added elements like credit interest and land rent (Harvey, 1973). Moreover, housing can function as a status symbol, representing wealth and power, and thus carries a prestige value. Which of these values comes to the fore is determined by the political agenda; under contemporary neoliberal policies,

exchange and prestige values have gained prominence (Aslan, 2019). As a result, housing has increasingly been transformed from a basic need into an investment commodity driven by exchange value.

According to Castells, the city is a collective space of consumption, and spatial justice can be achieved when influential actors balance the production of housing and infrastructure. Additionally, social movements and equilibrium within society play critical roles in ensuring urban justice. The failure to establish such balance leads to social (e.g., lifestyle, ethnicity, race, religion), economic (e.g., income-based), and socio-spatial discrimination and exclusion (Şengül, 2009). This dynamic erodes interactions among different social groups, eventually severing already fragile social ties and exacerbating intergroup conflict in contemporary cities (Kurtuluş, 2005).

Harvey (1973) emphasizes that achieving social justice depends on the fair and equitable distribution of the surplus generated through cooperative production (Harvey, 1973; Giritlioğlu & Özden, 2020; Şengül, 2009). Within this framework, policies that prioritize the use value of housing emerge as crucial for fostering urban justice. This study aims to analyze whether the existing legal and institutional framework safeguards the right to housing for broad segments of society, and whether it encourages production models based on use value that can counter the commodification of housing as an investment object.

Changes in the Legal Planning Framework in Turkey during the 2000s

The 2000s represent a period of major transformation in Turkey's planning legislation and institutional structure (Alkay, 2020). During this time, the implementation of neoliberal policies and the new government's construction-driven economic agenda necessitated a strong public apparatus. The Housing Development Administration of Turkey (TOKİ), originally established in 1984 and later restructured as a more autonomous body in 1990, gained substantial power especially after a series of legal reforms introduced from 2003 onward (Oluğ, 2015).

To facilitate real estate and construction investments—particularly the supply of land in favor of market actors—comprehensive legislative changes were made to the planning framework. These reforms granted extensive authority and resources to central institutions, leading to a more centralized structure in the planning system (Balaban, 2012).

Period of 2000–2010

Following the 2001 economic crisis, the stock market collapsed, while interest rates, inflation, and unemployment increased. As a result, early general elections were held, and the 2002 elections resulted in a strong single-party government (Kapusızoğlu, 2011). Instead of pursuing a long-term policy to address the country's structural problems, the new government adopted a growth-oriented, construction-based policy. Due to its strong interlinkages with other sectors, the construction and housing sector was regarded as a driving force for rapid economic growth—a sort of growth engine (Balaban, 2021; Yeşilbağ, 2016). Within this framework, housing and construction investments, urban transformation, and the Housing Development Administration of Turkey (TOKİ) became prominent. In accordance with the Squatter Housing Law No. 775, planned land supply was implemented to eliminate unhealthy settlements and ensure orderly urbanization (Ataöv & Osmay, 2007; Şenyapılı, 2006). An Emergency Action Plan concerning urbanization was formulated, aiming to construct 250,000 housing units within the first five years, with a total of 500,000 units projected to begin construction by 2011. To accelerate housing and construction processes, the legal framework of planning and the structure of TOKİ were revised, granting TOKİ significant authority (Justice and Development Party, cited in Ulusoy, 2020).

Throughout this period, extensive deregulation efforts were undertaken to facilitate real estate and construction investments, including granting certain public institutions unlimited authority in planning (Balaban, 2012; Balaban, 2021; Alkay, 2020). There were 76 legal arrangements containing deregulation measures. The first group of these (26 out of 76) redistributed authority among state institutions for the preparation of land use and urban development plans. Specific institutions were authorized to prepare land use plans for designated areas. For example, Law No. 5398 of 2005 authorized the Privatization Administration to prepare zoning plans for state-owned properties included in the privatization program. Law No. 4957 of 2003 transferred the authority for urban

development plans in tourism regions from local governments to the Ministry of Culture and Tourism. Law No. 5162 of 2004 granted TOKİ the authority to prepare all types of plans on lands transferred to its ownership. These legal changes aimed to shift planning authority from local governments to central authorities to facilitate a faster planning process for investments.

The second group of legislative changes (17 out of 76) that eased the urban planning framework granted certain public institutions unlimited planning powers. For instance, the Ministry of Public Works and Settlement was authorized to prepare development plans without being bound by the rules and conditions of existing urban planning legislation. These measures aimed to bypass or simplify existing planning regulations and development controls for specific projects and investments.

The second form of deregulation involved legal arrangements concerning public lands and properties. A significant portion of these reforms aimed to facilitate the sale of public lands and properties for development projects or private investments. For example, Law No. 4916 of 2003 authorized the Minister of Finance to revoke the designation of public property and put it up for sale at any time (Balaban, 2011; Balaban, 2012; Balaban, 2021).

Law No. 5216 on Metropolitan Municipalities, enacted in 2004, abolished the concept of adjacent areas and expanded zoning plan boundaries. Amendments to the Land Office Law and the Mass Housing Law through Law No. 5273 (2004) allowed for the transfer of treasury lands to TOKİ without charge. The 2005 "General Regulation on the Production, Allocation, Leasing, and Sale of Land, Housing, and Workplaces by Municipalities" granted municipalities the authority to provide land and housing to meet housing needs. Under this regulation, municipalities were permitted to engage in joint projects and establish partnerships with TOKİ and other relevant public institutions (Uyanıker & Alkay, 2019).

In 2005, Law No. 5366 on the Preservation by Renovation and Use by Revitalization of Deteriorated Immovable Historical and Cultural Assets was enacted with the aim of preventing or eliminating urban decay in historically and culturally significant areas, and to meet the increasing demand for housing in parallel with population growth in cities. Urban transformation projects under this law were intended not only to preserve and revitalize historical and cultural assets, but also to create residential, commercial, and social infrastructure areas and to take measures against disasters. Article 3 of the law states that municipalities may carry out urban transformation projects in cooperation with TOKİ (Kaplan, 2017).

In parallel with international markets, demand for real estate and real estate investments increased significantly. In response to these developments, the Capital Markets Board of Turkey (CMB) officially introduced the definitions of "valuation expert" and "real estate valuation company" in 2001 through the communiqué titled "*Communiqué on the Principles Regarding Companies to Provide Real Estate Valuation Services within the Framework of Capital Markets Legislation and Their Listing by the Board.*" The enactment of Law No. 5582 in 2007, titled "*Law on Amendments to Various Laws Regarding the Housing Finance System,*" along with subsequent regulations by the CMB, institutionalized real estate valuation as a specialized profession (Büyükkaracığan, Altınışık & Uzun, 2017).

Real Estate Investment Trusts (REITs), which were initially introduced through legislation in 1995 as a means to bring transparency and address financing challenges in the real estate market, also evolved during this period under the regulatory authority of the CMB. The real estate sector's central role and macroeconomic conditions played a significant role in the development of REITs (Büyükkaracığan, Altınışık & Uzun, 2017). REITs became prominent actors in urban transformation processes due to their tax exemptions and financial advantages. Simultaneously, TOKİ (the Housing Development Administration of Turkey) strengthened its cooperation with the private sector by engaging in housing production through models such as "revenue sharing" and "land-for-flat" agreements with large construction firms (Bektaş, 2021).

However, the 2008–2009 mortgage crisis in the United States and related global financial turmoil also affected Turkey, leading to a decline in demand for real estate and a drop in property prices. To promote homeownership

among middle- and low-income households, Law No. 5582 on Housing Finance (Mortgage Law), enacted in 2007, introduced a system with favorable conditions—such as a 20% down payment and repayment periods extending up to 10 years—supported by low interest rates (Alkan, 2015; Alkay & Övenç, 2019; Büyükkaracığan, Altınışık & Uzun, 2017).

A key characteristic of the post-2001 crisis period was the central positioning of the construction and housing sector as a driver of economic growth. Housing production was supported through urban transformation and large-scale projects, and the planning system underwent significant deregulation to accelerate this process. The transfer of planning authority to central government institutions led to the marginalization of local governments in decision-making processes, contradicting the principles of democratic governance endorsed by the European Charter of Local Self-Government. Housing supply policies were shaped not according to local needs and priorities but through a technocratic approach, emphasizing economic growth and capital accumulation over the right to housing. As a result, the exchange value of housing was institutionally prioritized over its use value.

Post-2010 Period

With the Decree Laws No. 644 and 648 enacted in 2011, the Ministry of Environment and Urbanization was granted extensive authority, including:

- the preparation and implementation of physical plans of all types and scales;
- the ability to conduct, commission, and approve surveys, maps, zoning plans, and parceling plans and amendments for public lands and areas authorized by the Council of Ministers;
- the authority to issue building permits and occupancy permits ex officio in cases where local administrations fail to do so within two months from the application date;
- and the power to conduct, commission, approve, expropriate, and implement all types and scales of plans and projects within special project areas and those carried out by the Housing Development Administration (TOKİ), as well as to issue permits and establish condominium ownership.

These changes marked a significant centralization of planning authority and a reduction in the powers of local governments. The 2012 Law No. 6306 on the Transformation of Areas Under Disaster Risk enabled institutions and private actors to reintroduce plots located in built-up areas back into the market. TOKİ's responsibilities regarding urban transformation were considerably expanded, further aligning urban policy with a centralized governance model. Similarly, Law No. 6292 allowed for the registration of 2B forest lands, effectively increasing the amount of land available for housing production.

The merging of TOKİ with the Land Office and Emlak Konut and its incorporation into the Ministry of Environment and Urbanization through the 2018 Decree Law No. 703 significantly increased its institutional power and centralized structure. Although the stated aim of these legal and regulatory changes was to create a rapid planning system that considered market mechanisms and minimized planning-related financial burdens, the outcome has been a highly centralized, fragmented, hierarchical system marked by uncertainty and low institutional reliability. The planning system has evolved into one in which actors operate according to their economic and political power (Alkay, 2020; Giritlioğlu, 2022; Kuran, 2022; Uyanıker & Alkay, 2019).

This centralization has undermined the coherence of planning decisions. As authority was transferred to investment-oriented institutions, the overall control and coordination of planning processes diminished. The legal and institutional transformations between 2002 and 2024 and their concrete applications in the Istanbul Metropolitan Area are examined in this study through a review of empirical research in the literature, with attention to their social implications. Following the introduction of the Presidential Government System in 2018, the trend toward centralization in planning and housing policies intensified. The Ministry of Environment and Urbanization became directly affiliated with the Presidency, and its oversight and steering capacity over institutions such as TOKİ and Emlak Konut increased. Decision-making processes became less subject to institutional plurality and public oversight, concentrating power in the executive branch. This shift led to an urban policy framework that is increasingly detached from democratic participation and local needs. The post-2018 era can thus be

characterized as one in which technocratic planning approaches were institutionally reinforced and market-oriented mega-projects were prioritized (Alkay, 2020; Giritlioğlu, 2022; Kuran, 2022; Uyanıker & Alkay, 2019).

Taken together, these legal reforms and institutional transformations demonstrate that the planning system has been shaped more by market dynamics and centralized political authority than by social needs. The loss of local authority, the weakening of democratic accountability, and the delegation of planning to technocratic mechanisms have resulted in the exclusion of vulnerable and low-income groups from decision-making processes. Consequently, these developments have deepened inequalities in urban space, institutionalized spatial injustices, and caused severe issues in access to housing, property, and the right to the city—especially in metropolitan contexts such as Istanbul. In this regard, analyzing not only the legal framework introduced between 2002 and 2024 but also its exclusions and tangible manifestations in urban life is essential for understanding its broader societal implications (Alkay, 2020; Giritlioğlu, 2022; Kuran, 2022; Uyanıker & Alkay, 2019).

Societal Impacts of the Legal Reforms Implemented Between 2002 and 2024 in the Istanbul Metropolitan Area
In parallel with the legal regulations enacted after the year 2000, both the policies aimed at the provision of new housing and the interventions in existing residential areas have deepened the socio-spatial segregation among income groups in Istanbul. This process has led to the spatial fragmentation of different social groups within the city, the displacement of lower-income groups, and the acceleration of gentrification dynamics.

In parallel with the legal regulations introduced during this period, closed and secured housing projects, typically targeting middle- and upper-income groups, have further reinforced spatial segregation, while also restricting the use of public spaces and weakening social interaction within the city.

Urban Transformation Practices in Istanbul under Laws No. 775, 5366, and 6306
The Küçükçekmece Ayazma–Tepeüstü Urban Transformation Project, implemented between 2004 and 2007 under Law No. 775 on Slums through the cooperation of TOKİ and local governments, is one of the first examples in Istanbul where an informal settlement community was collectively displaced and resettled. This transformation process, which affected approximately 1,440 households and 7,800 individuals, not only involved a physical spatial intervention but also led to the dissolution of social fabric and transformation of everyday life practices. The community relocated to the housing units constructed by TOKİ in Bezirgânbahçe lost their networks of solidarity due to the spatial constraints and social isolation imposed by gated community life. Targeting a predominantly Kurdish population, this intervention revealed not only the economic but also the cultural and identity-based dimensions of urban transformation.

The process also significantly limited the displaced community's access to urban opportunities, particularly hindering the use of public space and sustainability of social life for women and children. Households relocated to a peripheral area with limited transportation options suffered substantial losses in their daily routines and economic activities. This situation demonstrates that displacement is not merely a change of physical space but also a rupture in social and cultural terms. Moreover, the community's exclusion from decision-making processes during the transformation highlights the technocratic implementation of the intervention, disregarding participatory planning principles (Tok and Oğuz, 2013; Uzunçarşılı Baysal, 2013; Waite, 2023).

Under Law No. 5366 on the Renewal, Protection, and Use of Deteriorated Historical and Cultural Real Properties, the Sulukule Urban Transformation Project, carried out through a TOKİ–local government partnership, drastically transformed the spatial, social, and cultural fabric of Sulukule—one of the oldest known Roma settlements in the world after India. The project triggered a gentrification process in the area inhabited by the Roma community, causing a rise in property values and rental prices, which made it impossible for existing residents to remain. According to the legal regulations, individual homeowners and tenants were offered housing units in TOKİ's Gaziosmanpaşa–Taşoluk site without down payment and with 180-month installments. However, low-income Roma households could neither afford the monthly payments nor cover the maintenance costs of these units, leading to their inability to remain in the new housing.

In addition, due to incompatibility with apartment living and the peripheral location of the new settlement, many Roma residents returned to neighborhoods surrounding Sulukule. A significant portion of the newly built housing units in Sulukule was rented out to migrants who could afford the higher rents. During this process, Fatih Municipality's construction of a sliding iron gate to separate the transformed area from the remaining Roma-inhabited zone symbolically marked both physical and social segregation. Thus, the project is regarded as an institutionalized practice of spatial segregation and social exclusion (Fareghi Bavilolyaei and Ökem, 2018; Uçan Çubukçu, 2011; Uysal, 2012; Yalçıntan and Çavuşoğlu, 2009).

Similarly, under Law No. 5366, the Tarlabaşı Renewal Project was implemented with the support of the Ministry of Environment by the Istanbul Metropolitan Municipality and the Beyoğlu Municipality. The project aimed to transform the area into a new urban structure consisting of luxury housing, offices, shopping centers, cafés, and hotels through phased residential renewal (Kuyucu and Ünsal, 2010). The Tarlabaşı Renewal Project represents an intervention aimed at radically altering the existing socio-economic structure of the area. This transformation process led to the displacement of Roma, Kurdish, immigrant, and low-income groups, and the area was reimagined as a residential and touristic destination catering to higher-income groups. In this context, the project is considered a typical example of gentrification, reflecting the spatial exclusion of disadvantaged urban communities from the city center and the capital-driven revaluation of urban land (Sakızlıoğlu, 2020; Tsavdaroglou, 2020).

Under Law No. 6306 on the Transformation of Areas Under Disaster Risk, in the Tozkoparan Neighborhood—redeveloped in cooperation with the Ministry of Environment, Urbanization and Climate Change, Istanbul Metropolitan Municipality (IMM), and Güngören Municipality—the promise of "on-site transformation" could not be fulfilled. The high costs and payment conditions of the newly offered housing units made it impossible for low-income groups to continue living in the area. Throughout the process, objections raised by the beneficiaries and collective resistance from the local community brought the social legitimacy of urban transformation policies into question. Lawsuits and protests filed against the project revealed not only the physical but also the political and legal dimensions of the transformation. Furthermore, as in many other urban transformation projects, the expropriation processes were widely criticized for being arbitrary and lacking transparency (Çınar Erdüzgün and Çınar Yöreş, 2019; Duman and Coşkun, 2016).

Also under Law No. 6306, Fikirtepe was declared a "risky area" in 2013, and demolition began in 2014 through a partnership between the Ministry of Environment, Urbanization and Climate Change and TOKİ. The transformation process introduced an entirely new urban scenario, radically different from the area's existing physical, social, and economic structure. The planning approach adopted aimed to attract middle- and upper-income groups to the region and transform the area's previously negative image and low socio-spatial status. The Fikirtepe Urban Transformation Project, dominated by luxury and branded housing developments, aspires to offer a self-contained living environment where users can meet all their basic needs without leaving the project area. According to the Fikirtepe Regional Report by REIDIN, the average unit sales price, which was around 2,000 TL per square meter in 2005, exceeded 8,000 TL by 2017, while rental prices rose from 500 TL to 1,500 TL (Bülbül Akın and Türkün, 2019; Köseoğlu and Sönmez, 2022; Tarakçı, 2021; Uyanıker, 2020).

The examples discussed demonstrate that urban transformation policies are not limited to the physical reproduction of space but also lead to the dissolution of social fabrics, the deepening of identity-based divisions, and the erosion of spatial justice. A key commonality across these processes is the displacement of low-income and vulnerable communities to peripheral areas, thereby reproducing urban inequalities and poverty. Particularly in state-led projects, the use of legal instruments prioritizes market-driven rent extraction over the principle of public interest, revealing a contradiction between transformation processes and the principles of justice and participation. In this context, the displacement of squatter settlements, historic neighborhoods, and areas inhabited by disadvantaged groups under the guise of urban renewal can be interpreted as one of the most pronounced manifestations of neoliberal urbanization practices.

Other Regulatory Arrangements, Financial Instruments, Public-Private Partnerships, and Large-Scale Projects

Although the 2007 Housing Finance System Law No. 5582 (the Mortgage Law) was enacted to facilitate housing access for low- and middle-income groups, its implementation in Istanbul failed to deliver the expected social benefits. In theory, the mortgage system aimed to ease homeownership through low-interest, long-term loans. However, due to Istanbul's high housing prices and the required 20% down payment, low-income groups were largely unable to benefit from this system. Mortgage loans were predominantly utilized by high-income or at least upper-middle-income households. Housing increasingly became a form of "financial investment," where appreciation and profit potential outweighed the use value of the home.

Mortgage-based housing finance significantly increased household indebtedness and created economic vulnerability, particularly for the middle class. When analyzing the distribution of mortgage homeowners in Istanbul, it is evident that those taking out large loans were concentrated in districts such as Beşiktaş, Şişli, and Sarıyer, while those with lower amounts were located in areas like Silivri, Sultangazi, and Şile. This demonstrates a strong socioeconomic link between access to credit and spatial preferences, highlighting how inequality is spatially manifested. Studies also show that the average income level of mortgage recipients was 6.3 times higher than the minimum wage. Therefore, it can be concluded that the system did not offer an accessible housing solution for low-income groups; instead, it promoted financialization by increasing household debt (Alkay & Övenç, 2019; Aslan, 2019; Büyükkaracığan et al., 2017).

In the 2000s, alongside newly enacted regulations in Turkey, new financial and structural models that enabled partnerships between the private sector and TOKİ (Housing Development Administration of Turkey) were developed in the field of housing production. In this process, especially the revenue-sharing and construction-rights-in-return-for-land models came to the fore as key methods for utilizing public land and integrating private capital into the process. The legal basis for these projects was laid by the 2004 Law No. 5162, which granted TOKİ the authority to make and implement all types of plans, and the 2004 Law No. 5273, which enabled the transfer of Treasury-owned lands to TOKİ free of charge by amending the Land Office and Housing Development Laws.

The 2005 "General Regulation on the Production, Allocation, Leasing, and Sale of Municipal Land, Housing, and Workplaces" granted municipalities the authority to produce land and housing. Moreover, Law No. 4916 paved the way for the use of public lands in joint ventures with the private sector, thus providing a legal basis for the development of public-private partnership models on public land. In addition, Real Estate Investment Trusts (REITs) were enabled to become influential actors in urban transformation processes (Alkay, 2020; Giritlioğlu, 2022; Kuran, 2022; Uyanıker & Alkay, 2019).

In this context, the Zorlu Center project is a large-scale mixed-use development (residential, shopping mall, hotel, and cultural center) constructed in central Istanbul along the Levent-Zincirlikuyu corridor, on the former site of the General Directorate of Highways. One of the key legal instruments that enabled this project was Law No. 4916, enacted in 2003. This regulation facilitated the sale and transfer of publicly owned properties and created a legal framework for opening state-owned investment lands to the private sector. The Zorlu Center plot was sold to the Zorlu Group through privatization under this law. The project significantly altered the spatial structure and social fabric of the area. Due to its design catering to high-income groups, it led to the socio-economic exclusion of lower- and middle-income residents in the surrounding neighborhoods and deepened socio-spatial segregation. Furthermore, the commercialization of public spaces and their transfer to private control transformed forms of urban belonging and social interaction (Özoral, 2015).

The Varyap Meridian project, developed through the partnership of Varyap and Emlak Konut REIC, was built near the Ataşehir Financial Center and was planned as a mixed-use development, offering residential, office, and commercial spaces. Designed with a sustainable architectural approach and awarded a LEED certificate, the project features high-rise, modern towers aimed at high-income segments. The Ataşehir Financial Center, where the project is located, was declared by the Council of Ministers in 2009. Subsequently, with Decree Laws No. 644 and 648 enacted in 2011, extraordinary planning powers were granted to the Ministry of Environment and

Urbanization, thereby removing the area from the jurisdiction of local governments. In this context, the allocation of publicly owned land by Emlak Konut to private developers through revenue-sharing models reflects the process of transferring public assets into private profit. Key criticisms of the project include the lack of integration with the local community, the creation of a gated and inward-looking settlement, a significant increase in the local population, inadequate infrastructure and public amenities to support this population, and increased pressure on transportation networks (Aslankan, 2019; Kurultay & Peksevgen, 2012).

The Başakşehir and Kayabaşı projects, jointly carried out by the Ministry of Environment and Urbanization, TOKİ, and Emlak Konut REIC, were designed as large-scale housing developments where the private sector participated via revenue-sharing models. Located in the northwestern development corridor of Istanbul, these projects aimed to provide both social housing for low- and middle-income groups and luxury housing for high-income groups within the same development. The administrative infrastructure for these projects was shaped by the post-2010 merger of TOKİ with the Land Office and Emlak Konut, and its subordination to the Ministry via Decree Law No. 703. In particular, the "Yenişehir" urban center was established in the Kayabaşı area. However, in practice, a clear physical and social separation between social and luxury housing areas has been observed. Criticisms include inadequate public spaces, the peripheral location causing transportation issues, and other social problems. The projects have also been critiqued for their gated residential forms and for the marginalization of social housing residents (Baş & Yüzer, 2015; Doğan & Özbayraktar, 2023).

In settlement areas along the northern corridor such as Arnavutköy, Tayakadın, and Göktürk, intensive residential and mixed-use projects have been planned on the grounds of proximity to the airport. These projects, developing around Istanbul Airport, are predominantly implemented by private sector contracting firms under the guidance of the central government and within a supportive legislative framework. Key actors in these projects include the Ministry of Environment, Urbanization, and Climate Change, which holds substantial planning authority; as well as publicly affiliated entities such as TOKİ and Emlak Konut GYO, which play active roles in land allocation and implementation processes. Mega projects like Istanbul Airport have been constructed through decisions made at the central level that contradict the 1/100,000-scale Istanbul Environmental Plan. Subsequently, special plans were prepared for these areas, and development was directed without adherence to established planning principles. Furthermore, the conversion and market opening of 2B forest lands into title deeds under Law No. 6292 expanded the project zones in the northern corridor. In addition, influenced indirectly by İGA (Istanbul Grand Airport) -the company that built and operates Istanbul Airport- contractor construction firms and real estate investment trusts also play significant roles in projects in the surrounding areas. In the planning processes, higher-level documents such as the Istanbul Environmental Plan have been disregarded, and development has been steered through special plans prepared by central actors, considerably limiting the influence of local governments (Erbaş, 2018; Özalp & Sönmez, 2022).

The legal and institutional foundation of this development was primarily established by Law No. 4916. This law facilitated the sale and transfer of Treasury-owned immovables for public investments, paving the way especially for large-scale projects. Additionally, Law No. 6292 enabled the sale of 2B lands that had lost their forest status, marking a significant step that facilitated the opening of ecologically sensitive northern areas to development. The Ministry of Environment and Urbanization, established under Decree Law No. 644 and later granted expanded authorities by Decree Law No. 648, has assumed direct responsibility for preparing and approving plans at all scales, institutionalizing a centralized planning practice. Accordingly, planning processes around Istanbul Airport have largely been conducted outside the scope of local governments and under the supervision of central actors. The exercise of these authorities must be understood not only within the scale of planning but also in the context of the capital-driven spatial restructuring of the urban environment. In housing production, investor demands and market dynamics have been more decisive than local priorities and social needs. The narrowing of local governments' authority has led to a decline in democratic oversight of planning processes, resulting in negative outcomes such as weakened spatial justice for established residents, deficiencies in social infrastructure, and disruptions in essential services like transportation. Moreover, direct interventions by the central government beyond the planning framework have led to the loss of important natural assets and the transfer of public lands

into private ownership, generating high social costs that threaten ecological sustainability and social cohesion in the long term. Opening ecologically sensitive areas such as northern forests, water basins, and agricultural lands to development poses serious challenges to both ecological sustainability and climate resilience. Additionally, the population movements toward these regions have produced a form of spatial expansion disconnected from the city and lacking adequate urban services. Consequently, the settlement development around Istanbul Airport stands out as an example where centralized planning powers are concentrated, public lands are opened to market-based use, and ecological values are subordinated (Erbaş, 2018; Özalp & Sönmez, 2022).

These projects demonstrate that large-scale residential and mixed-use developments, which have accelerated in Istanbul in recent years, not only transform the physical environment but also reshape the social fabric. Developed through public-private partnerships, these projects highlight problems such as spatial density, social segregation, limited public spaces, and insufficient ecological sensitivity, which deepen class-based, spatial, and cultural divides in the city. This situation raises critical debates regarding urban cohesion, social justice, and quality of life.

Discussion and Conclusion

This study aims to examine the social implications in Istanbul of the legislative changes in planning regulations enacted between 2002 and 2024. During this period, characterized by the spatialization of neoliberal policies, the right to housing has shifted from being a fundamental social need to a vehicle for investment, a symbol of social status, and a means of generating profit. As Lefebvre (2013) emphasized, the prioritization of exchange value over use value in urban spaces has become a key driver of urban injustice and inequality. The transformation experienced in Turkey during the 2000s is marked by a restructuring of planning legislation in favor of capital interests and the centralization of planning processes (Alkay, 2020; Balaban, 2012).

The document analysis conducted within the scope of this study evaluates the periods 2002–2010 and 2010–2024 separately, analyzing the content and orientation of legislative amendments introduced during these years. Subsequently, the social effects of these transformations in the Istanbul Metropolitan Area are assessed comprehensively through field-based literature studies. The findings reveal that the legal reforms in question have exacerbated inequalities, social exclusion, displacement, and spatial polarization in urban areas, particularly through urban transformation practices and new housing developments. Especially gated, high-density residential projects targeting middle- and upper-income groups have reproduced social segregation, undermined neighborhood culture, and contributed to the detachment from public spaces (Çınar-Erdüzgün & Çizmeci-Yöreş, 2019; Kılıç & Ayataç, 2019; Sönmez, 2019).

Displacement has become widespread, particularly in the context of urban renewal projects involving low-income neighborhoods, forcing long-time residents to relocate to the urban periphery, thereby losing their social ties and historical sense of belonging. In this context, social fragmentation has become apparent not only in luxury residential developments but also in mixed-use projects that include social housing; spatial proximity has failed to ensure class integration. The concept of public interest has emerged as a central point of contention in many projects due to insufficient public spaces, restricted accessibility, and the dominance of private interests. The loss of social cohesion has manifested itself in the weakening of communal life, neighborhood solidarity, and public interactions in newly developed settlements.

The effects of gentrification have been particularly pronounced in centrally located and prestigious areas, where the exclusion of low-income groups has coincided with an intensification of housing production for wealthier populations. As housing production has increasingly been shaped by principles of economic accessibility, fragmentation based on income levels within the urban space has deepened. Consequently, housing has become a difficult necessity not only for vulnerable groups but also for the middle class. This has created a serious social problem in terms of both the right to the city and the right to housing (Bülbül-Akın & Türkün, 2019; Doğru, 2021; Ayhan, 2019). Reforms at the legislative level have treated urban space primarily as a source of investment and profit, a perspective that has undermined social cohesion, reduced quality of life, and intensified social alienation.

One of the study's limitations is its exclusion of first-hand narratives, lived experiences, and micro-level comparative case analyses from groups directly affected by the legal reforms in Istanbul. However, this limitation also presents an opportunity for future research. In-depth interviews and ethnographic studies with individuals residing in various socio-economic regions of Istanbul can offer more nuanced insights into the everyday effects of legislative changes. Furthermore, comparative analyses of similar legal transformations in different cities could enhance understanding of both the diversity of legal implementations and the varied forms of spatial injustice they produce.

In conclusion, it is evident that the transformation of planning legislation must be addressed in alignment with the principles of social equity, spatial justice, and the right to the city. This study is significant in that it reveals the social implications of the spatial manifestations of neoliberal policies, particularly those stemming from legislative changes in housing and planning. By analyzing the effects of Turkey's rapidly evolving planning regulations between 2002 and 2024 on a major metropolis like Istanbul, the study interrogates contemporary and critical issues such as displacement, social fragmentation, loss of social cohesion, and gentrification. In this respect, it offers both a theoretical and practical foundation for re-evaluating justice, equity, and the public interest in urban planning. Moreover, by providing a comprehensive assessment of the role of local governments, trends in centralization, and the class character of housing production, the study contributes to future legislative reforms and academic research in this field.

Housing Justice in Urban Regeneration from a Hierarchical Perspective: Practice and Reflection on the Case of Nanjing, China

Mengjia Qiu, Li Bao*
Affiliation: Southeast University
Email: chan0408baek@163.com

Abstract
This study explores housing justice in China's Urban Regeneration, specifically through the "Housing Justice-Spatial Hierarchy" framework in Nanjing's Xiaosongtao Lane project. Departing from Western paradigms, it emphasizes justice within China's state-led, collective-interest-oriented context, highlighting distinct challenges and practices. The research reveals how distributive, procedural, and recognition justice dynamically interact across urban, community, and building scales. Key findings include the efficacy of "one-household, one-policy" and "courtyard negotiation" for resident participation and refined governance. Xiaosongtao offers a unique "local solution" for historic urban areas, balancing preservation, residents' diverse needs, and economic viability. However, tensions persist, particularly regarding economic burdens for vulnerable groups and the depth of resident influence in core decisions.

Keywords: Housing Justice, Urban Regeneration, Spatial Layering, Hierarchical Analysis, Nanjing Xiaosongtao

1. Introduction

1.1 Research Background and Problem Formulation: Housing Justice Challenges in Urban Regeneration

Global urban development paradigms have shifted from high-speed outward expansion to the regeneration of existing urban stock, making community transformation a core contemporary issue. Following a period of rapid urbanisation, China has also entered an era focused on its existing building stock, where the effective regeneration of residential settlements and the enhancement of public well-being are crucial. Within this context, non-traditional historic districts, in particular, often face problems such as environmental degradation due to aging infrastructure, outdated facilities, and a lack of essential services. The regeneration of these areas involves navigating multiple demands, policy conflicts, and resource negotiations. More critically, urban regeneration profoundly impacts residents' life chances, social networks, and cultural memories, bringing housing justice to the forefront as a central concern. Inadequate regeneration methods frequently expose disadvantaged groups to risks of involuntary relocation, escalating living costs, and social network disruption, thereby exacerbating urban spatial inequality and revealing underlying structural in justices. These issues urgently demand a systematic and equitable response.

Existing research has addressed various dimensions of housing justice, including distribution, procedure, and recognition; however, these studies predominantly offer single-dimension analyses and lack an integrated perspective. Furthermore, few studies have systematically examined the spatial distribution and interaction mechanisms of these justice dimensions within the urban regeneration process. Urban regeneration is a complex practice characterised by the intertwining of multi-scale spatial dynamics and governance forces. Consequently, housing justice issues are transmitted and often distorted across multiple levels, including urban policy, community governance, and architectural design. For instance, land policies at the urban level influence the initial conditions for justice; negotiation mechanisms at the community level determine the scope for participation; and spatial design at the architectural level shapes daily living experiences. Therefore, a comprehensive understanding of the generative mechanisms of justice issues is difficult to achieve from a single level or through abstract principles alone.

This study posits that the realisation of housing justice is a spatial and hierarchical process. It requires concrete practical analysis to understand how different justice dimensions interact—synergizing or conflicting—at the distinct levels of the urban, community, and building. To this end, this research aims to construct and apply an analytical framework that integrates multidimensional justice perspectives with hierarchical analytical methods. Through an in-depth case study of the Xiaosongtao area in Nanjing, this study seeks to reveal the complex

mechanisms and practical logics of housing justice in the regeneration of China's non-traditional historical settlements. The objective is to provide both theoretical and practical insights for understanding and promoting housing justice in the context of urban regeneration..

2. Theoretical Perspectives and Analytical Framework

2.1 Justice in Urban Regeneration: Dimensions, Interactions, and Considerations in the Chinese Context

As a significant practice that reshapes urban space and social structures, the ethical implications of urban regeneration have garnered increasing academic attention. The regeneration process is not merely concerned with improvements to the physical environment; it also profoundly affects resource distribution, social power dynamics, and the well-being of residents. Research widely indicates that while regeneration can improve living environments, it may also produce inequitable outcomes such as involuntary relocation, the severance of social networks, the destruction of local culture, and even the "gentrification" affecting original inhabitants. In this context, positioning "Justice" at the core of urban regeneration research and practice has become a critical benchmark for evaluating the value and sustainability of regeneration projects. However, the central question, "What constitutes just regeneration?" continues to evolve in both theory and practice.

"Housing Justice," as a core component, presents unique characteristics in its conceptualisation and pathways to realisation within China's specific socio-cultural and institutional contexts. While Western Justice theories often emphasise individual rights, market mechanisms, and legal procedures, discussions of housing justice in China must be more deeply embedded in the state-led urban development model, the policy orientation towards "people's well-being" (民生), traditions of collectivism and community consultation, and the complex logic of property rights and resource allocation under the socialist market economy system. Therefore, building upon common justice dimensions such as distribution, procedure, and recognition, this section pays particular attention to the specific manifestations and challenges of these dimensions in China's urban regeneration practices. This approach aims to construct a more context-sensitive analytical framework for subsequent research.

2.1.1 Single-Dimension Focus: Distributive, Procedural, and Recognition Justice in Housing

Existing research on housing justice and justice often approaches the issue from distinct yet interrelated dimensions, with distributive justice, procedural justice, and recognition justice as three core perspectives. In the context of urban regeneration in China, the specific manifestations and focal points of these dimensions differ.

(1) Distributive Justice: Focusing on the Rational Allocation of Housing Resources and Opportunities

Distributive justice is foundational to housing justice research, centering on how the benefits and burdens of housing resources, related public services, and urban regeneration outcomes are equitably distributed among different social groups. This concerns not only "who gets what quality of housing" and the associated cost-benefit sharing but is also, in the Chinese context, closely linked to the state-led housing security system, the complexity of historical property rights (e.g., the coexistence of public, reformed, and private housing), and distinctive Chinese policy practices such as "resettlement before relocation".

A key focus of current research on distributive housing justice is the "adequacy and comprehensiveness of compensation," which extends beyond singular material criteria, revealing inherent complexities and challenges. Numerous studies demonstrate that focusing solely on explicit indicators like housing sise and monetary compensation is insufficient to cover the full spectrum of losses residents incur due to relocation or community restructuring. Non-material losses—such as the disruption of social ties, dilution of cultural identity, and reduced spatial convenience—have emerged as crucial but often overlooked indicators of distributive justice. Their effective assessment and compensation pose a common challenge for academics and practitioners alike (Du et al., 2022).

Simultaneously, the "spatial dimension" of housing allocation has received increasing emphasis. This highlights the close connection between housing and location choices, access to quality public services (such as education, healthcare, and transportation), and the resultant development opportunities and social interaction spaces. The

aim is to promote the elimination of spatial segregation and opportunity deprivation arising from housing location disparities, fostering a more equitable allocation of urban resources (Feitosa et al., 2024). This requires housing allocation policies to transcend individual housing units and focus on equitable resource distribution and spatial inclusiveness for the entire community. Furthermore, the pathways and challenges of remedial allocation mechanisms (e.g., preferential rehousing rights, targeted subsidies) designed to redress historical injustices caused by discriminatory policies or unfair planning (such as the historical "redlining system") for specific groups have also become an important frontier in distributional justice research(Thurber et et al., 2024).

Despite considerable advances in distributional justice research, a persistent practical challenge is how to scientifically quantify and integrate multiple distributional factors (especially non-material socio-cultural factors). Another is ensuring that distributional outcomes genuinely benefit the most vulnerable groups within a complex market and policy environment, avoiding elite capture and the "egalitarian trap".

(2) Procedural Justice: Ensuring Inclusiveness and Transparency in Housing Decision-Making Processes
Procedural justice focuses on the justice of housing-related policymaking, planning, and project implementation processes. It emphasises that all stakeholders, especially disadvantaged groups, should have equal opportunities for participation, full access to information, and the ability to exert substantial influence on decision-making (Healey, 1997). Its core lies in ensuring openness, transparency, and empowerment in the decision-making process, positing that a fair process is a necessary prerequisite for achieving a just outcome. In China, the practice of procedural justice is often associated with government-led multi-party consultation mechanisms, innovations in grassroots community governance (e.g., "courtyard consultation meetings" and "residents' councils"), and the challenge of balancing efficiency with guaranteed participation.

However, the practice of procedural justice in housing is fraught with tensions and dilemmas. Research commonly reveals a significant gap between 'formal participation' and 'substantive impact'. Information asymmetries (e.g., professional jargon in planning schemes that is difficult for ordinary residents to understand), power imbalances (e.g., the dominant role of developers or government in agenda-setting and decision-making), and technological and cultural barriers often lead to the marginalisation of disadvantaged groups' voices, reducing participation to a "formalism" devoid of substance(Shahrad et al., 2025). Therefore, enhancing procedural justice hinges on marginalised groups to transition from passive recipients to active negotiators. This includes not only improving their access to information and comprehension, and ensuring their bargaining power in multi-party negotiations, but also establishing effective channels for conflict resolution and grievance redress, as well as ensuring the possibility of power-sharing and co-decision-making at the institutional level(Wang & Xu, 2024).

Additionally, some studies have begun to focus on the role of emotions in participation (Cao et al., 2024) and the unique value of informal community networks and 'bottom-up' advocacy planning (Hewidy and Harsia, 2025) in compensating for the shortcomings of formal procedures. These informal approaches aim to promote substantive justice by lowering participation barriers while increasing the depth and trust involved in the process. The fundamental challenge for procedural justice research lies in how to strike a delicate balance between pursuing administrative efficiency and ensuring broad, deep participation; how to design decision-making mechanisms that accommodate a plurality of voices while effectively reaching consensus; and how to genuinely internalise the concept of procedural justice into daily governance practices.

(3) Recognition Justice: Respecting Identities, Cultures, and Experiences Related to Housing
Recognition justice is a relatively new but increasingly important dimension in housing justice theory. It moves beyond material distribution and procedural participation to focus on societal respect for and acknowledgment of the identities, cultural values, lived experiences, and deep connections of different groups—especially marginalised ones—to specific spaces. This serves as a means of resisting stigmatisation, symbolic violence, and exclusion from power (Honneth, 1995; Fraser, 2003). In China's urban regeneration, recognition justice is particularly reflected in the protection of the overall character of historical districts and specific period architectural styles, the continuation of traditional neighborhood lifestyles and public interaction spaces, the incorporation of indig-

enous residents' "local knowledge" and collective memory, and respect for and responsiveness to collective sentiments associated with "unit" (单位) cultures and compound memories formed in specific historical periods.

In the housing field, the core research agenda for recognition justice exhibits rich connotations. First is the deep integration of cultural identity and spatial representation. Research emphasises that housing policy, planning, and design must transcend purely functionalist considerations to actively respond to residents' diverse cultural backgrounds and lifestyle needs. By demonstrating respect for the cultural practices, religious beliefs, and collective memories of specific groups in housing design and community building, their identity, dignity, and sense of belonging to the community can be ensured(Mosseray et al., 2025). Second is the practical exploration of historical memory and restorative recognition. In response to housing trauma caused by historically unjust policies (e.g., apartheid, forced evictions) affecting specific communities, recognition justice advocates for publicly acknowledging historical mistakes, establishing memorial mechanisms, and implementing compensatory or preferential resettlement policies to repair community trust and promote social reconciliation(Thurber et al., 2024). Third is the legitimisation of experiential knowledge and the establishment of epistemic justice. Recognition justice forcefully challenges the monopoly of expert discourse in housing decision-making, advocating that residents' "local knowledge" and real needs, based on long-term life experiences, be considered legitimate and valuable bases for decision-making. This promotes "knowledge justice" in planning and research.

However, in practice, research on recognition justice also faces significant challenges: how to translate the abstract principle of recognition into concrete policy tools and spatial intervention strategies; how to avoid the pitfalls of "symbolic recognition" and ensure that recognition is combined with practical resource redistribution and power restructuring; and how to effectively promote social cohesion while respecting cultural pluralism, thereby avoiding the potential "paradox of recognition".

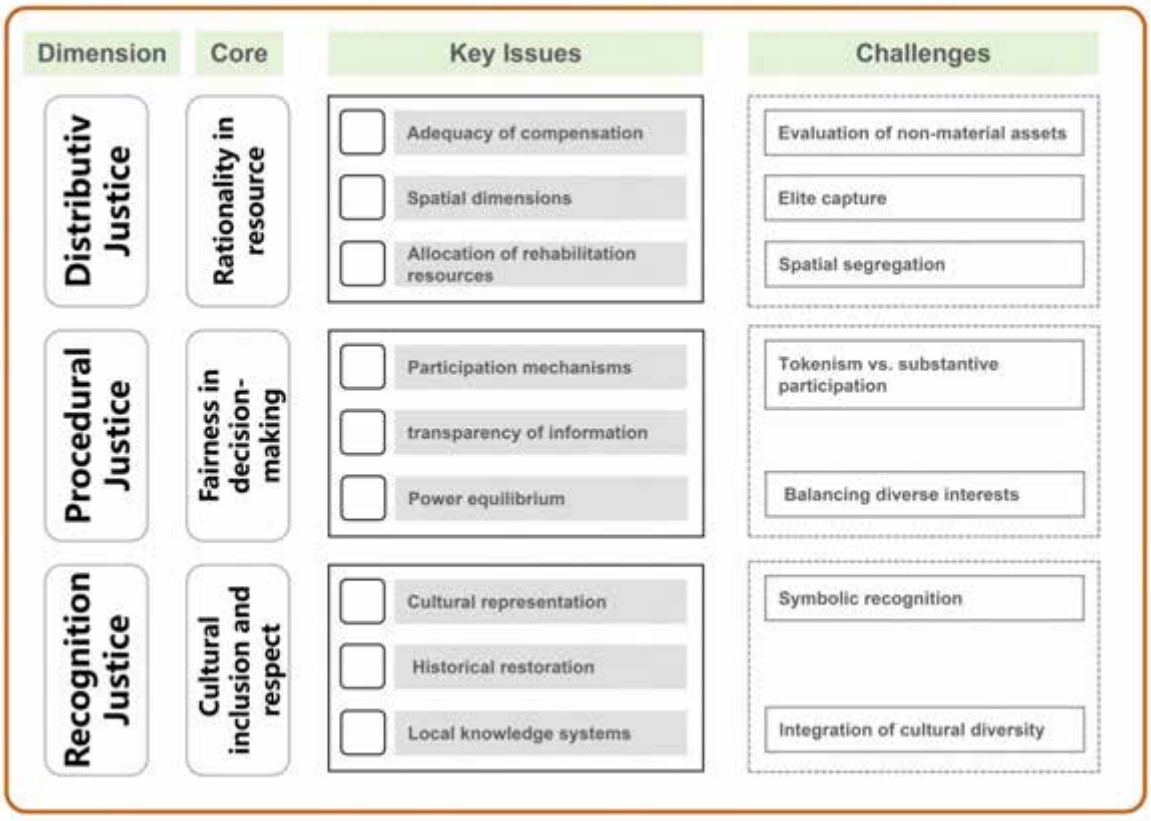

Figure1. Three Dimensions of Housing Justice

2.1.2 Integration of Multidimensional Perspectives: Towards Dynamic and Interactive Housing Justice
Given the inherent complexity and multifaceted nature of housing justice and justice, particularly in China's context of rapid development and profound transformation, the limitations of a one-dimensional analytical framework have become increasingly apparent. Consequently, a growing body of research advocates for adopting a multidimensional and integrated perspective, wherein distributive, procedural, and recognition justice are viewed as an organic, interrelated, and dynamically interacting whole.

Research indicates that justice in housing resource allocation is profoundly affected by the inclusiveness of housing decision-making processes; processes lacking full consultation or transparency tend to result in housing allocation programs that are more likely to deviate from justice goals, especially to the detriment of disadvantaged groups (Schmitt & Weck, 2024). Concurrently, the recognition of specific resident groups' identities and needs directly reshapes the pattern of allocation and spatial design of housing resources. For example, if the special needs of particular groups (recognition justice) can be incorporated into the planning, design, and allocation of housing resources (distributive justice) in subsidised housing or community regeneration projects, the dignity and quality of life for these groups can be significantly enhanced.
However, inherent tensions and conflicts often exist between different dimensions of justice in housing policy and practice. For instance, in urban regeneration involving housing demolition and resettlement, the pursuit of adequate procedural consultation and interest balancing may prolong project cycles, thereby affecting the immediate distributional justice for a segment of the population urgently needing transitional or resettlement housing(Johnson & Wang, 2024). Similarly, specialised housing design catering to the housing practices of specific cultural groups (recognition justice), while enhancing cultural sensitivity, might also affect the overall availability or inclusiveness of affordable housing due to increased costs (distributional justice). This potential conflict among multiple dimensions necessitates an understanding and practice of housing justice that transcends static standards and possesses the capacity for dynamic adjustment. This is especially crucial in the real-world context of urban regeneration in China, which is often characterised by tight schedules, intensive tasks, and extremely complex stakeholder interests.

Drawing on concepts from the Capability Approach and the Dynamic Justice Framework (DJF)(Weghorst et al, 2024), studies suggest that achieving housing justice requires attention to the differing core demands of various groups at different life stages or in specific housing situations, and the corresponding adjustment of policy priorities and resource allocation strategies (Kimhur, 2022). Therefore, understanding and promoting housing justice and justice in urban regeneration requires moving beyond static judgments of a single dimension towards a dynamic, interactive, and integrated view of justice. This obliges researchers and practitioners to focus not only on "what to share" and "how to share" (distributive justice), and "who participates" and "how to participate" (procedural justice), but also on "who is seen" and "whose values are respected" (recognition justice). It also requires an in-depth analysis of how these three dimensions shape each other, interact, and collectively determine the final housing justice outcome within specific social, economic, and institutional contexts.

2.2 Hierarchical Analytical Perspectives: Understanding Systemic Justice Challenges (Space-Specific)
Urban regeneration is not a singular, homogenous intervention but a systematic project involving different spatial scales, multiple actors, and complex socio-economic relationships. The complexity of housing justice, one of its core issues, stems not only from the intertwined influence of multiple justice dimensions but also from its inherent spatial attributes and multi-scale characteristics. Housing inequities often manifest uniquely at different spatial levels (e.g., regions, cities, neighborhoods, and individual building units). The interactions and shaping influences of policies, resources, power, and the built environment across these levels form complex causal chains and influence mechanisms (Harvey, 1973; Lefebvre, 1991). Thus, a systematic understanding of, and effective intervention in, housing justice requires moving beyond single-scale or "de-spatialised" approaches to an analytical perspective that can endogenously accommodate and resolve this spatial complexity.

2.2.1 Theoretical Origins and Practical Necessity of Hierarchical Analysis
Adopting a hierarchical perspective to analyze housing justice issues is rooted in a profound understanding of

the interaction between space and social relations, and it resonates with the complex governance realities of China's urban regeneration practices.

(1). Theoretical Origins: Space as a Container and Shaper of Social Relations
Theoretically, urban space is not a homogenised backdrop but is structured by different levels of power relations, institutional arrangements, and social interactions (Lefebvre, 1991). Housing, as a key social resource and spatial entity, sees its distribution, access, and experience deeply embedded in these multi-level spatial structures. From national-scale laws and regulations, to urban-scale planning controls, to community-scale governance rules, down to building-scale spatial design, each tier embodies specific resource allocation logics, power mechanisms, and spatial production processes. These collectively shape residents' housing opportunities, experiences, and even their socio-economic status. Hierarchical analysis provides an effective framework for decoupling and systematically examining these key processes and elements that operate at different, interrelated spatial scales to influence housing justice (Brenner, 2001). It prompts us to operationalise abstract justice principles in concrete spatial contexts, asking: "Where does injustice occur?", "Who benefits or suffers at what spatial scale?", and "How do interventions at different spatial scales affect the overall pattern of justice?".

(2). Practical Necessity: The Hierarchical Governance Characteristics of Urban Regeneration in China
In practice, China's urban regeneration is characterised by a distinctive hierarchical governance model that combines top-down policy transmission with bottom-up feedback and consultation (Wang et al., 2021). Macro-guidelines at the national level (e.g., the principle of "Retain, Renovation, Demolition and Donstruction" – must be translated into specific local policies and planning indicators by provincial, municipal, and district governments (urban level). The implementation of these policies and indicators necessitates complex negotiations and interactions with community organisations, development agencies, and local residents on specific project sites (community level). The final outcomes of regeneration are then materialised in the form of concrete architectural space and living quality (building level).

The challenges of housing justice therefore manifest differently at various levels:
At the urban level, it may involve the uneven regional distribution of subsidised housing and the concentration or exclusion of high-quality public resources.

At the community level, it may relate to procedural injustices in demolition and resettlement processes, lack of participation in public space creation, or the disruption of social networks due to regeneration.

At the building level, it may concern the universality and inclusiveness of housing design, variations in spatial quality, or the neglect of specific groups' needs.

A single-scale analysis, whether focusing on macro policies or micro practices, can hardly capture the transmission, distortion, and cumulative effects of justice issues across these different spatial levels, risking what Brenner (2001) terms "scale blindness". As Swyngedouw (2004) points out, the "cross-scale reconfiguration" (rescaling) between local actions and broader scale contexts is key to understanding contemporary urban governance. Thus, adopting a hierarchical analytical perspective can more clearly reveal how housing justice issues are constructed, amplified, or mitigated within the particular governance structure of urban regeneration in China.

2.2.2 Hierarchy in This Study: Focusing on Policy-Governance-Space Interactions
Based on the aforementioned emphasis on the spatiality of housing justice, and drawing upon common practices in urban geography, planning, and governance studies, this research focuses its analysis of housing justice in urban regeneration on the following three core, interrelated levels that effectively reflect mechanisms of spatial influence:

• **Urban Level:** Encompasses macro policies, strategic planning, and resource allocation rules led by national and local governments. This level influences the initial allocation of housing resources, regional equalisation of

opportunities, and the establishment of fair starting points for projects. The focus is on how land policy, housing supply structure, infrastructure accessibility planning, and the designation of historical and cultural preservation zones shape the urban's overall housing justice ecology.

• **Community Level:** Involves meso-level governance, consultation, interest coordination, and environmental improvement within the scope of a specific project or land parcel. This includes local government, community organisations, residents, development entities, and other stakeholders. It serves as a key arena for the implementation of macro-policies, multi-interest negotiations, and the realisation of procedural justice. The focus is on how program development, resident participation mechanisms, demolition and resettlement negotiations, community public space and amenities, and social network maintenance affect the experience of justice within the community.

• **Building Level:** Relates to micro-physical space, architectural design, technology application, and their direct impact on residents' daily living experience and the degree to which diversified needs are met. This is the direct carrier for the materialisation of justice concepts and individual perception. The focus is on how justice and empowerment at the micro-level are reflected in unit typology, spatial quality, public area design, material choices, spatial adaptability, and residents' autonomy in design and use.

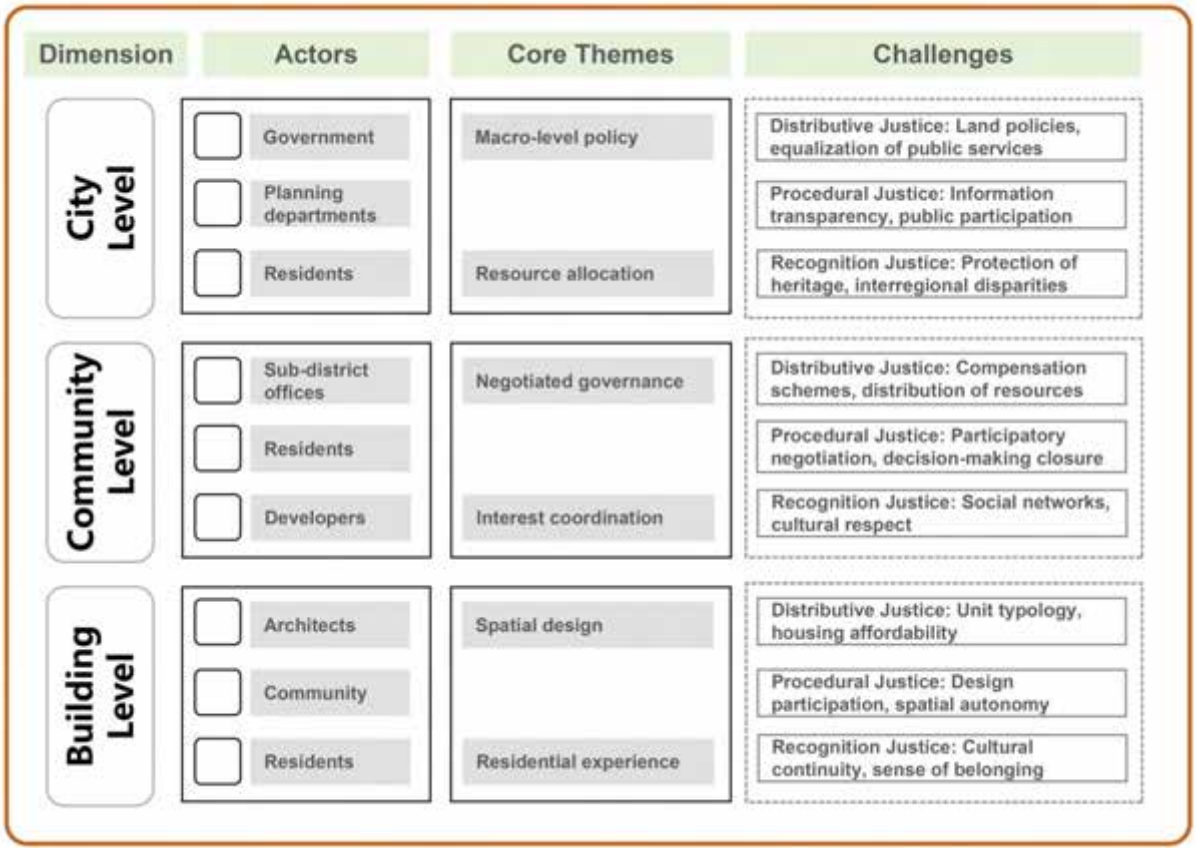

Figure2. Three Dimensions of Urban Spatial Analysis

2.3 Analytical Framework: Integrating Housing Justice Dimensions and a Tiered Perspective

To combine the understanding of core housing justice dimensions (Section 2.1) with the hierarchical approach to analysis (Section 2.2), and to construct a specific analytical tool for subsequent case studies, this study proposes the "Hierarchical Framework for Housing Justice" (see Table 1).

Table 1: Hierarchical Framework for Housing Justice

Level of Analysis	Key Actors	Key Arenas	Focus Areas	Distributive Justicce	Procedural Justice	Recognition Justice
Urban	Government ; Urban Master Plan	Macro Policies & Regulations	Structural resource allocation; justice in policy starting points; Legitimacy of macro-rules	• Justice in resource allocation • Public service equalisation • Fair cost and benefit distribution	• Transparency of decision-making information • Early public participation • Monitoring of policy implementation	• Recognition of historical/ cultural values • Consideration of regional/group differences
Community	Street/Neighborhood administration,Residents,Community planners	Consultation platforms, Project programs	Meso-governance processes; Mechanisms for interest harmonisation; Effectiveness of community participation	• Justice of entitlement programs • Community resource sharing • Balance in interest negotiations	• Inclusivity of consultation platforms • Justice of consultation rules • Constraints on community decision-making	• Maintenance of social networks • Respect for lifestyles/ cultures • Atmosphere of trust and cooperation
Building	Designers,Builders,Residents (users)	Architectural spaces	Micro-spatial quality; Living experience; User empowerment	• Guarantee of living space • Spatial quality and efficiency • Housing affordability	• Participation in design process • Autonomy in space use • Transparency of technical information	• Meeting diverse needs • Spatial expression of identity/culture • Guarantee of residential dignity

This framework is the central methodological tool of this study. Its core purpose is to systematically "locate" and "dissect" housing justice issues in urban regeneration. It systematically couples the core dimensions of housing justice (distributive, procedural, and implicitly, recognition justice) with the three core analytical levels of urban regeneration (urban, community, and building). The aim is to reveal the specific manifestations of housing justice issues at different spatial scales, as well as their intrinsic correlations and transmission mechanisms.

3. Case Study: Hierarchical Housing Justice Practices in the Regeneration of Xiaosongtao, Nanjing

This study selects the urban regeneration project of Xiaosongtao in Nanjing as a representative case to analyze the mechanisms and complexities of housing justice in the regeneration of non-traditional historical settlements in China, applying the hierarchical housing justice framework developed previously. Located in the core of Nanjing's old urban, the Xiaosongtao project is a typical case that combines historical and cultural values with pressing challenges related to residents' livelihoods. Its regeneration process spans multiple levels, from macro-policy guidance to micro-spatial implementation, and involves dynamic interactions among the government, residents, planners, developers, and other actors. This provides a rich empirical basis for examining the impacts of different practice layers on housing justice.

3.1 Research Design and Case Overview

3.1.1 Selection and Application of Research Methods

This study employs a combination of case study methodology and spatial analysis to explore housing justice practices in the regeneration of non-traditional historical settlements through multi-dimensional empirical analysis. Based on field research, the study utilises in-depth interviews (with residents, planners, government officials, and other key actors), participatory observation (e.g., of community councils, consultation mechanisms), and analysis of planning texts and spatial data (e.g., planning indicators, architectural designs) to systematically collect empirical data across social, spatial, and economic dimensions. The case study focuses on policy, governance, and spatial interactions at the "urban-community-building" levels, integrating methods such as spatial morphology comparisons and functional layout optimisation analysis, to dissect the specific practices of hous-

ing justice within the hierarchical framework as demonstrated by Xiaosongtao's "localised response".

Figure3. Aerial View of the Xiaosongtao Lane Site before Urban Regeneration

3.1.2 Case Overview

The Nanjing Xiaosongtao Lane Regeneration Project is situated in the core area of Nanjing's old urban, covering approximately 10,100 square meters. The buildings primarily consist of high-density, ground-floor brick and wood structure lilong-style residences from the Republican Era (1912-1949). Some buildings possess historical and cultural value. However, the overall living environment required significant improvement, facing issues such as aging infrastructure, insufficient public services, diverse and complex property ownership (including historical private houses, early housing reform units, and tenants, with a notably aging population of property owners), and certain safety risks. (See Figure X for the location and pre-regeneration condition of the case study area).

In 2020, guided by Nanjing Municipality's "Guiding Opinions on Urban Regeneration of Residential Lots," which advocates a principle of "retain, renovation, demolition and construction" ("留改拆建") applied differentially, the Xiaosongtao site commenced its regeneration. It was positioned as a pilot project to explore an "organic regeneration" path characterised by "government guidance, market operation, and multi-stakeholder participation". The Xiaosongtao case reflects common characteristics of current urban regeneration in China, especially in historical urban areas:

Figure4.Surrounding Conditions of the Project **Figure5.**Aerial View after Update

• **Market-oriented operation under government guidance:** The project is guided by the government (with urban, district, and street-level linkage) in planning, policy support, and overall supervision. Simultaneously, a state-owned platform company (Nanjing Historic Urban Area Protection and Construction Group Co., Ltd.) was introduced as the primary implementation body, exploring market-oriented mechanisms in old urban regeneration(Chen et al., 2025).

• **Complex property rights structure and diversified social demands:** The historical diversity of housing property rights, coupled with social networks and neighborhood sentiments formed by original residents over time, made interest coordination and social relations maintenance crucial aspects of the regeneration process.

• **Policy orientation of "people-oriented" and "prioritizing livelihood improvement":** In the current stage of urban development, the transformation of non-traditional historical settlements is accorded significant importance for improving public well-being. Upgrading living conditions and safeguarding residents' rights and interests became key objectives of project implementation.

• **In-depth participation of grassroots governance and construction of consultation mechanisms:** Project promotion relied on the deep involvement of the grassroots governance system (street and community administrations), seeking to build consensus and ensure smooth implementation through a multi-party consultation platform.

Therefore, the regeneration practice in Xiaosongtao represents an important local endeavor to balance multiple goals—historical preservation, livelihood improvement, and economic feasibility—and to explore pathways for achieving housing justice within China's specific institutional and cultural context. Its strategic choices and practical effects offer valuable references for understanding similar regeneration projects.

3.2 The Urban Hierarchy: Reconciling Justice in a Macro Framework

Urban-level planning and policies established the macro framework, basic principles for resource allocation, and value orientation for the regeneration of Xiaosongtao Lane. These had a guiding influence on subsequent paths and specific measures to achieve housing justice at the community and building levels.

Figure6. Framework of Urban-Level Justice Dimensions and Spatial Practices

3.2.1 Resource Allocation under the "Retain, Renovation, Demolition, and Construction" Approach: Balancing Historic Preservation Priorities with Distributional Justice

Facing challenges of high protection requirements and limited development space in neighborhoods with historical elements, Nanjing's municipal policies of "organic regeneration" and "retain, renovation, demolition and construction" provided a somewhat flexible guiding framework for resource allocation to Xiaosongtao at the urban level. This aimed to balance the rigid constraints of historical landscape protection with residents' urgent needs for improved living conditions. The Nanjing Xiaosongtao Unit (NJZCA030) Detailed Control Plan explicitly mandated the preservation of existing street texture, scale, and interface of Xiaosongtao Lane, listing several buildings for retain, repair, or reconstruction. This urban-level consideration of recognition justice for the historical lineage controlled the overall development intensity of the site through planning controls (e.g., setting a cap on the floor area ratio for new residential sites).

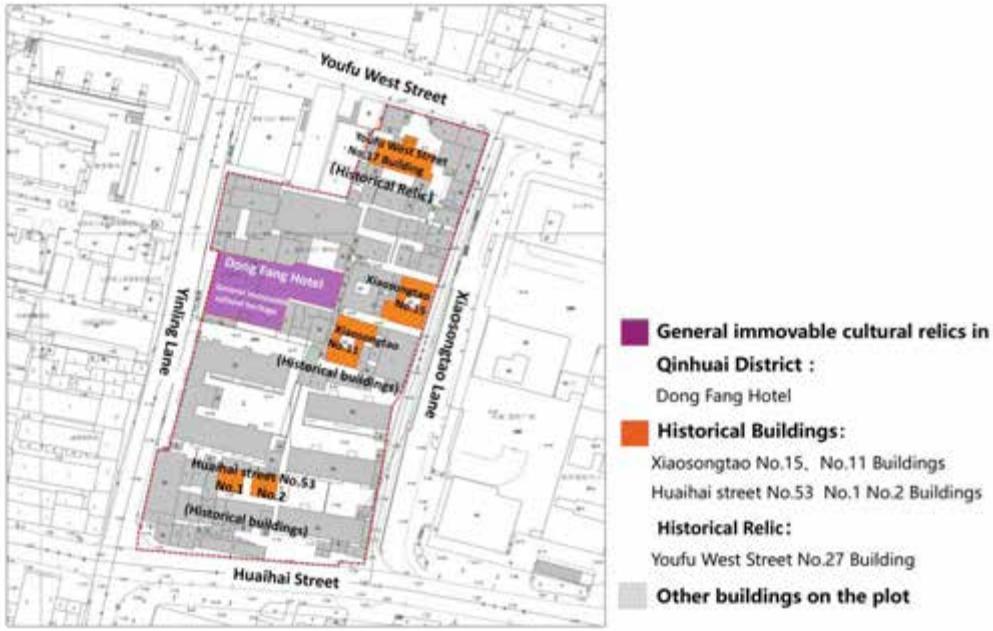

Figure7. Historical Elements of Xiaosongtao Lane Site

This "conservation-first" strategy reflects respect for the urban's historical fabric. Concurrently, the plan permitted a moderate increase in development intensity on suitable sites (e.g., the floor area ratio of some mixed commercial and residential sites was slightly higher than that of purely residential sites). Floor area ratios for different sites were set distinctively, aiming to provide a degree of economic support for the district's overall regeneration and reserve space for improving indigenous inhabitants' living conditions and public service facilities. For example, the floor area ratio for new residential sites (e.g., NJCa03019-11) was controlled at ≤2.0 to ensure harmony with the surrounding historical environment, while for some mixed commercial/residential sites in better locations with relatively less impact on the landscape (e.g., NJCa03019-26), it was set at ≤2.6.

A key aspect of resource allocation justice at the urban level is how to effectively allocate resources under limited planning conditions, balancing investment in historic landscape conservation with satisfying residents' diverse housing needs. This includes avoiding situations where an overemphasis on low-density protection renders regeneration projects economically unviable, potentially transferring excessive renovation costs to original residents. This requires careful, fine-grained consideration. Decisions at this level also cascade down, affecting the design of compensation and resettlement programs (distributive justice) at the community level and the extent of spatial improvements at the building level. (Reference to floor area ratio adjustment in the Nanjing Xiaosongtao Unit (NJZCA030) Detailed Control Plan).

Figure8. Comparison before and after Adjustment of Plot Ratio in the Previous Plan Nanjing Xiaosongtao Unit (NJZCA030) Detailed Control Plan

3.2.2 Refined Governance Procedures under the "Organic Regeneration" Framework: Policy-Led Construction of Procedural Justice

The regeneration of Xiaosongtao Lane adhered to the "organic regeneration" concept promoted by the urban of Nanjing, emphasizing a shift from "large-scale demolition and construction" to "refined management". The urban-level policy framework (e.g., the "Guidelines for Urban Regeneration of Residential Lots") established general principles of "government-led, market-operated, public participation, and professional collaboration." This laid a systematic foundation for the Xiaosongtao project to conduct multi-stakeholder consultations at the community level, fostering procedural justice.

In the planning approval process, designating the project as a "Model Old Neighborhood" and emphasizing "fine-tuned regeneration" encouraged the full consideration and incorporation of views from street and community administrations, residents, property rights units, and professional teams (e.g., architects, planners) in the design and implementation of the specific plan. In the Xiaosongtao project, the architectural team played a "full-process role from pre-planning, planning and design to post-implementation management" and undertook "community building and public participation" work. This reflects urban-level procedural recognition and support for professional engagement in grassroots consultation. This procedural design, combining "top-down" policy guidance with "bottom-up" practical exploration, aimed to enhance the scientific basis, democratic nature, and local adaptability of regeneration decision-making, thereby promoting justice at the procedural level.

3.2.3 Value-Oriented Revitalisation of Historical Lineage: Incorporating Residents' Life Imprints in Recognition Justice

At the urban level, the regeneration of Xiaosongtao not only pursued the retain of physical form but also strove to integrate the urban's historical narrative with the imprints of residents' lives. This reflects a recognition of local identity and residents' emotional connection to place, contributing to recognition justice.

Figure9. Remodeling of 27 Youfu West Street

The plan's "maximum preservation" of Xiaosongtao Lane's existing street texture, scale, and interface, and the "in-situ preservation and restoration" of historical buildings such as No. 27 Youfu West Street (as shown in Figure 9), are direct manifestations of the urban's recognition of its historical and cultural value. Furthermore, the orientation of urban regeneration was not to "museumise" historic districts but to reintegrate them into contemporary urban life through functional implantation and spatial revitalisation. For example, at the urban planning level, some preserved buildings were permitted to introduce cultural, creative, or small-scale commercial functions related to community life, provided their appearance was maintained. This aimed to restore neighborhood vitality and provide residents with new spaces for interaction and experience. This strategy sought to protect historical "symbols" while recognizing residents' rights to be present and use the space as "subjects of life". The urban's advocacy for an "efficient space and open architecture concept," and design guidelines such as "solving the diversified living space needs of special-needs households by raising the floor height," also reflect concern for residents' specific living needs and quality of life improvement.

However, a critical consideration for the urban in pursuing recognition justice is how to acknowledge historical and cultural values while ensuring that regeneration outcomes benefit the original community and avoid the negative effects of "gentrification".

3.3 The Community Level: Shaping Justice in Consultative Governance

The community level is the key arena where urban regeneration policies are translated into concrete practices and where multiple interests engage in direct dialogue and negotiation. In the regeneration process of Xiaosongtao Lane, community-level governance practices actively responded to and attempted to resolve complex housing justice challenges across the three dimensions—distribution, procedure, and recognition—by constructing a multi-party consultation platform, exploring refined interest adjustment programs, and focusing on the maintenance of social and cultural capital.

Figure10. Framework of Community-Level Justice Dimensions and Spatial Practices

3.3.1 "One Household, One Policy" and Multiple Choices: Exploring Distributional Justice in Refined Compensation and Resettlement

Facing the complexity of housing ownership and diverse resident demands in the Xiaosongtao area, community-level regeneration governance did not adopt a "one-sise-fits-all" approach to compensation and resettlement. Instead, it actively explored and practiced a "one household, one policy" (一户一策) fine-tuned program for rights and interests, striving to achieve more targeted distributive justice.

For residents with different property rights (e.g., private housing, early housing reform units, tenants), family structures (e.g., elderly families, multigenerational families, single youths), and affordability levels, the community working group, in collaboration with a professional team, provided over 50 options(Aliprantis et al., 2023). These included monetary compensation, off-site resettlement, and in-situ rehousing (with various unit types and appropriate area improvements). This "menu-style" program design granted residents a degree of autonomy in choice, avoiding the sense of being "averaged out" or "deprived" that a single standard might cause. For instance, elderly residents with a strong desire for in-situ living were given priority for on-site relocation with suitable age-friendly modifications. Families needing improved living space were offered the possibility of increasing their area within policy limits, supplemented by a reasonable cost-sharing mechanism.
In formulating compensation standards, beyond statutory assessment procedures, the community level also attempted to introduce more flexible value recognition methods. For example, considerations included the property's locational value, historical contributions (for some early residents), and potential non-material losses from relocation (e.g., operational losses, disruption of social networks). This aimed to align the compensation scheme more closely with residents' actual experiences and reasonable expectations.

	Usable Area	Floor Height	Household Number
1#	39.2-60㎡	2.8m	49
2# North-South	32-72.3㎡	2.8m	39
2# East-West	19.8-45.4㎡	2.8m 3.6m	27

Figure11. Resettlement Housing Program Table

This refined "one household(Bao et al., 2024), one policy" approach, while increasing governance costs and negotiation difficulty, was centered on recognizing individual differences and striving for more substantive distributional justice through differentiated resource allocation. The project's ultimate achievement of 100% sign-up from property-owning households reflects the efforts of all parties to reach an allocation acceptable to the majority of then-current residents through negotiation.

3.3.2 "Courtyard Consultations" and Professional Empowerment: Building Procedural Mechanisms for Inclusive Participation

At the community level, the Xiaosongtao Project emphasised constructing a multi-level, multi-form consultation platform to ensure procedural justice. This highlighted active interaction and continuous consultation among multiple actors, including residents, community managers (street and neighborhood committees), representatives of the implementing body, and professionals (architects, planners).

In addition to district-level policy briefings and resident representative meetings, more targeted consultation activities were conducted in "courtyard" or building-based consultation meetings. According to statistics, since the project's inception, over 28 formal courtyard consultation meetings were held to discuss program interpretation, express demands, and mediate conflicts.

Figure12. Consultative Meeting

These small-scale consultation units, organised and coordinated by community managers, ensured effective information transmission and orderly progress of consultations. Representatives of the implementing body directly participated in dialogues, explaining program details and policy boundaries to residents and listening to feedback. Faced with complex planning programs and policy provisions, ordinary residents often experience an information disadvantage. Against this backdrop, the architectural team actively assumed multiple roles—as interpreters of policy, translators of technical language, and facilitators of multi-party communication—thereby enhancing inclusive participation. They "established close contact with residents to understand their living habits and transformation needs," explained the program in an accessible manner, assisted residents in articulating their needs, and fed representative needs and reasonable suggestions back into the design and decision-making processes.

As the most direct stakeholders, residents' opinions and demands were the starting point and core content of the consultation. For example, repeated discussions and revisions on issues such as the relocation transition period, details of compensation standards, and types of return housing allowed residents' reasonable demands to be reflected in program optimisation(Zhang & Wang, 2024). The deep engagement and interactive learning of all actors throughout the project led to dynamic adjustments in the planning and design program. This iterative consultation process reflects the program's adjustment and adaptation under pressure, enhancing decision-making flexibility and responsiveness to on-the-ground needs.

By constructing this small-scale, multi-round, professionally empowered consultation mechanism with multiple actors, community governance in Xiaosongtao endeavored to break down information barriers and balance power relations. It enabled more residents to substantively participate in regeneration decisions closely related to their interests, thereby promoting procedural justice and providing practical support for establishing "a more inclusive, transparent, and substantively influential consultative governance platform".

3.3.3 "Neighborhood Living Rooms" and the Continuity of Memory: Practices for Reinventing Community Identity and Recognition Justice

Beyond physical space improvement, Xiaosongtao's regeneration practice also carefully responded to residents' valuation of original social networks, local culture, and emotional identity at the planning and design level. It was committed to laying the groundwork for recognition justice (at the community level) and fostering a sense of community identity in the community's future(Rahimi & Alavi, 2024).

During conceptual iterations, the project team recognised that the core of organic urban regeneration lies in the relative stability of property rights, considered key to maintaining the texture, spatial appearance, and "local vibrancy" (烟火气) of the old urban. Therefore, while respecting existing property rights, the regeneration program focused on enhancing the community's public nature and cultural identity through spatial design.

In response to the lack of public space in non-traditional historical settlements, the regeneration plan consciously incorporated shared spaces such as "neighborhood living rooms," "shared courtyards," and community activity rooms. These are envisioned as future carriers for residents' interaction and cultural inheritance. The plan's concepts of preserving and repairing public facilities that carry collective memories, incorporating local cultural elements into new spaces, and considering the continuation of original neighborhood relationships in resettlement all reflect a forward-looking acknowledgment of the community's history and its residents' emotions. These community-building planning ideas, centered on respecting residents' original lifestyles, community belonging, and the sense of life carried by stable property rights, aimed to further enhance the community's social resilience post-regeneration. Whether these planned shared spaces and community-building concepts can effectively activate neighborhood interactions and gain acceptance from residents in the future will be an important test of the degree of recognition justice achieved and remains to be seen in subsequent practice.

3.4 Architectural Hierarchies: Materializing Spatial Empowerment and Justice

The building level is the material carrier for the final realisation of housing justice concepts, directly related to residents' daily life experience, living quality, and identity. The regeneration practice in Nanjing's Xiaosongtao Lane, through refined spatial utilisation, inclusive design participation, and skillful translation of local cultural veins in micro architectural space design, actively explored effective paths to achieve housing justice and improve quality of life within the historical texture. It also attempted to respond to the specific housing needs of disadvantaged groups in its design.

Figure13. Framework of Building-Level Justice Dimensions and Spatial Practices

3.4.1 Balancing "Livability" and "Economy": Efficient Use of Small Spaces and Quality Assurance

Facing the reality that original housing in the Xiaosongtao area was generally small and partially dysfunctional, the architectural-level regeneration design was committed to maximizing residents' basic living needs through efficient utilisation and quality assurance within limited space, while also considering the economics of regeneration costs.

One of the design highlights was the adoption of the 3.6-meter-height "high-efficiency unit design" in some units of the new Building 2. Designers expanded usable space within standard floor areas (e.g., approximately 40-60 square meters) using techniques like staggered floors, partial mezzanine levels (e.g., raised sleeping or storage

areas), integrated furniture, and vertical storage. For example, a standard one-bedroom unit was optimised into a more functional one-bedroom plus multifunctional area, or designed to accommodate more family members within the same area, responding to situations where some original residents had larger households and limited living space.

Figure14. Partial Floor Plan

On the basis of ensuring structural safety, the regeneration design emphasised improving basic living qualities such as lighting, ventilation, sound insulation, and thermal insulation, seeking to achieve independent, hygienic, and functional kitchen and bathroom facilities. For example, technical measures like rationally designing window-to-wall ratios, adopting energy-saving window and door materials, and installing additional external wall insulation were used to improve the living comfort of the original old housing. These designs aimed to safeguard basic living functions and enhance spatial quality while endeavoring to control construction costs, seeking a better balance between livability and affordability, thereby responding to distributive justice requirements at the micro-level.

3.4.2 Co-creative Design and Individualised Adaptation: Exploring Procedural Justice with Resident Participation

To ensure that renewed housing could effectively support residents' diverse lifestyles and practical needs, Xiaosongtao Lane actively introduced resident participation mechanisms into the architectural design and renovation process. This gave residents a certain degree of influence on design and autonomy in spatial adjustment, especially for rehousing relocated households, and focused on providing diversified unit type programs.

Through various forms of household interviews and discussions, the design team gained an in-depth under-

standing of the specific housing needs of different families (including the elderly, disabled, and other disadvantaged groups). Guided by the "one household, one policy" principle, these needs were transformed into specific spatial solutions(Nourian et al., 2023), which in itself constituted an important practice of procedural justice at the architectural level. Consequently, for the two new multi-story residential buildings on the Xiaosongtao site, the design team planned nearly a dozen unit types, ranging from 19 square meters (sufficient for basic living) to over 70 square meters (relatively generous). This diversified "menu" of unit types was designed to maximise the match with different family structures, population sises, and the actual conditions of original living spaces.

In addition to providing a series of well-designed standard unit options, the project also granted residents a degree of influence and autonomy in their own living space arrangements, offering flexibility between standardised design and individual needs. For instance, residents were allowed to choose from pre-designed options for interior decoration materials and the configuration of some non-load-bearing walls, or to make limited personalised adjustments, provided safety and overall appearance were maintained. This "bottom-up" feedback mechanism enhanced the local adaptability of the design program. The architectural regeneration process in Xiaosongtao Lane thus transformed from a unilateral "provision" by designers to a process where residents became design participants with a certain degree of voice, enhancing the adaptability of the final space and residents' sense of identity.

3.4.3 Translation of "Old and New Symbiosis" and "Memory of Place": Recognizing Local Identity in Architectural Discourse

While pursuing modern residential functions, the architectural regeneration of Xiaosongtao Lane also attached great importance to respecting and translating the local historical lineage and memory of place(Thaler et al., 2025). It strove to embody the recognition of residents' identity and local characteristics in the architectural vocabulary of new or renovated buildings.

Building components with historical value from the area (such as old bricks, tiles, stone slabs, and wooden beams) were, where conditions permitted, collected, restored, and reused, skillfully integrated into the design of new buildings or landscapes. This "new life for old materials" approach perpetuated the historical memory of the place at a material level, enabling residents to feel a familiar "old flavor" in the new environment—a recognition of their emotional memory and cultural roots. Notably, the renovation and reuse design for No. 15 Xiaosongtao retained its courtyard layout and original structure and façade, focusing on public reuse of the space and allowing for various functions, including community service facilities, knowledge-based creative industries, and cultural consumption venues.

Figure15. Patio space before #15 remodel vs #15 Remodeled Patio Space

In terms of forms, materials, and colors of newly built or reconstructed buildings, the project focused on drawing inspiration from traditional Nanjing dwellings, modernizing their translation and expression. This attempted to create a spatial environment that not only met modern living needs but also evoked place memory, carried local

culture, and strengthened residents' identity. For example, design elements like roof forms, courtyard layouts, and door and window styles drew on traditional features but utilised new materials and techniques to achieve both "spirit and form" rather than simple retro imitation. These designs responded to residents' deep-seated emotional needs and sense of cultural belonging, representing a concrete expression of recognition justice at the architectural level. For long-time elderly residents, retaining familiar architectural elements and spatial ambiance was particularly important to help them establish continuity and a sense of belonging in their new living environment. However, whether this translation of culture and memory can be understood and recognised by all residents, especially the younger generation or newly relocated individuals, needs reinforcement through community activities and cultural heritage initiatives.

4. Discussion and Conclusions

Based on the theoretical perspective and hierarchical analytical framework of housing justice and justice, this study conducted an in-depth case study of the Xiaosongtao Lane urban regeneration project in Nanjing. The aim was to reveal the specific manifestations, internal correlations, and realisation mechanisms of housing justice at different spatial levels in the regeneration of non-traditional historical settlements in China. This chapter synthesises the preceding analysis, discusses the main findings, theoretical contributions, and practical implications of the study, and points out its limitations and future research directions.

4.1 Key Findings: Characteristics of Housing Justice Practices under Tiered Interaction

The regeneration practice of Xiaosongtao Lane vividly demonstrates that housing justice in urban regeneration is not a static, single-dimension goal. Instead, it is a complex process where the three core dimensions—distribution, procedure, and recognition—are dynamically interwoven and interact across the three spatial tiers of the urban, community, and building.

1. The Transmission of Power and Resources Between Levels Shapes the Boundaries and Paths for Realizing Justice:

(1) **Top-down Impacts:** urban-level macro-policies and plans (e.g., prioritizing historic preservation, controlling floor area ratios) directly set the "ceiling" for resource allocation at the community level and the scope of negotiable issues. For example, the urban's justice-oriented approach to recognizing historical contexts limited development intensity through planning controls. While this protected the landscape, it also increased pressure on the project's economic balance, which in turn posed challenges for distributional justice in compensation and resettlement standards at the community level, and constrained possibilities for large-scale spatial upgrading at the building level. Similarly, the urban-level procedural framework of "government-led(Liu et al., 2025), professional collaboration" provided a legitimizing basis for community-level consultation and participation, but also limited the substantive boundaries of its deliberations.

(2) **Bottom-up Feedback and Adaptation (Limited):** Although Xiaosongtao was a pilot project, residents' demands and consultation outcomes at the community level (e.g., strong demand for a "one household, one policy" program, modifications to specific unit designs) did have a substantial impact on the dynamic adjustment of the project's program. For instance, residents' demands for high-efficiency unit designs and barrier-free facilities, collected through multiple rounds of "courtyard consultations" at the community level (procedural justice), directly influenced design plans at the building level (distributive and recognition justice), enhancing the local adaptability of the finalised space. However, whether this feedback can be institutionalised and upwardly influence policymaking for subsequent similar projects at the urban level remains to be seen.

(3) **Synergy and Conflict Between Levels:** Refined governance mechanisms at the community level (e.g., the in-depth involvement of community planners and architects) effectively promoted residents' participation depth and voice (procedural justice) in the architectural design process, bridging the gap between professional expertise and residents' needs. Simultaneously, however, the pursuit of a high degree of personalisation and quality enhancement at the architectural level (e.g., diversified unit types and reuse of old materials

under the "one household, one policy" approach) significantly increased coordination difficulty at the community level and the overall economic costs of the project (a challenge to distributive justice).

2. Uniqueness of the "Localised Response"

(1) **Connotation and Practical Characteristics of "Justice" in the Chinese Context:** Unlike Western societies, which typically focus more on individual rights protection and market-driven procedural justice, the practice of "justice" demonstrated by Xiaosongtao is more profoundly marked by China's national conditions. Firstly, government leadership and a focus on public well-being are distinctive features. The government consistently played a central role in goal-setting, resource input, and process regulation, with enhancing people's livelihoods and maintaining social stability as important value orientations. This often prioritised considerations of distributional justice (such as refined rehousing through "one household, one policy," and high-efficiency unit design to meet actual housing needs), striving to achieve "tangible and perceived justice outcomes". Secondly, traditions of collective bargaining and community-based governance continue to play an important role in China's grassroots governance(Li & Wang, 2023). Mechanisms like "courtyard consultations" reflect efforts to balance individual interests within a collective framework, emphasizing community consultation to resolve conflicts and build consensus, which contrasts with Western models that often emphasise more atomised individual participation. Thirdly, the dynamic balance between efficiency and justice is a common challenge for urban regeneration in China. Xiaosongtao's pursuit of a 100% signing rate reflects both respect for and absorption of individual demands, as well as grassroots governance's consideration of efficiency and overall project progress.

(2) **Differences in Justice Issues Compared to Western Urban Regeneration:** In Western urban regeneration, vigilance against gentrification, correction of market failures, and protection of ethnic minority and marginalised groups' rights are often the focus of justice discussions. In the Xiaosongtao case, although it also faced issues of resettling disadvantaged groups and community identity, the core conflicts and resolution paths are more characteristic of the Chinese context. For example, the complexity of historical property rights issues (intertwining public, reformed, and private housing) is rarely seen in Western cities, making the starting point and program design for distributional justice extremely complex. Additionally, China's policy of "preservation, renovation, demolition and construction" in regeneration, as well as the trade-offs between historical and cultural preservation and modern residential function enhancement, are unique. While the West often emphasises interest regulation through strict legal frameworks and market mechanisms, China relies more on government administrative control, policy guidance, and negotiation and mediation approaches reflecting local practices.

(3) **Characteristic Justice Issues in the Historical Dimension:** Situated in a historic district, Xiaosongtao's justice challenges are naturally overlaid with a historical dimension. The first is balancing historical and cultural heritage preservation with residents' modern needs. A core feature is how to meet residents' needs for more comfortable and modern living spaces (distributive justice) through design innovations like "high-efficiency unit designs," while preserving historical features (a manifestation of recognition justice). Secondly, it involves recognizing "local knowledge" and residents' historical sentiments. Xiaosongtao's attempts to "revitalise old materials" and perpetuate place memory reflect respect for the cultural ties and emotional belonging that residents formed with a particular space over time. Thirdly, it pertains to maintaining historically formed neighborhood relationships. Considering "group relocation" in the resettlement process and attempting to continue social networks of acquaintances also reflects Chinese society's emphasis on "relationships" and community harmony in regeneration(Gao & Bai, 2024). These historical considerations enriched the connotation of justice and raised higher requirements for regeneration strategies and methods.

4.2. Theoretical and Practical Insights

(1) **Theoretical Contributions:**Through the empirical analysis of the Xiaosongtao case, this study validates and deepens the analytical framework for housing justice that integrates three levels ("urban-community-build-

ing") and three dimensions ("distribution-procedure-recognition"). It explains the complex interaction and transmission mechanisms among various levels and dimensions of justice, providing a theoretical tool for understanding housing justice beyond a one-sided perspective. Concurrently, applying justice theory to the specific context of urban regeneration in China reveals its theoretical explanatory power and on-the-ground practice characteristics. It highlights the localised features of housing justice's realisation paths, core contradictions, and evaluation criteria within China's specific institutional background—characterised by strong government dominance, complex historical property rights structures, policy logics oriented towards "public well-being" and "harmony and stability," and a grassroots governance culture emphasizing collective bargaining. This contributes empirical evidence for developing a more inclusive and locally adapted justice theory for urban regeneration and echoes the literature's call for attention to specific justice practices in the Chinese context.

(2) **Practical Implications:**The Xiaosongtao project offers multiple insights for the regeneration of historic residential areas:For Policymakers: Recognise the systemic and hierarchical nature of housing justice in regeneration. Grant localities and communities greater practical flexibility under macro policy frameworks, establish smooth upward and downward feedback mechanisms, and seek a dynamic balance among multiple goals. For Planners and Architects: Integrate justice concepts throughout the entire design process. Assume multiple roles as spatial designers, technical supporters, and communication facilitators, respecting professional judgment while fully incorporating residents' "local knowledge". For Community Managers and Implementation Agents: Strive to build more inclusive, transparent, and influential platforms for consultation and governance. Fully harness the enthusiasm of multiple actors, emphasise procedural justice and the universality of outcomes, and pay attention to the integration and sustainable development of the renewed community.

4.3 Dilemmas and Challenge

The urban regeneration experience in Xiaosongtao, while offering valuable insights, also highlighted several persistent dilemmas and challenges inherent in striving for housing equity. Rigid urban-level historic preservation mandates, coupled with the financial pressures of project self-balancing, constrained the potential for enhancing distributional justice; "premium" improvements, necessary for some upgrades, remained a significant financial burden for certain households in need. Furthermore, while the "one household, one policy" approach aimed for tailored solutions, questions persist regarding its capacity to ensure substantive "equivalence" across diverse programs. In terms of procedural justice, although consultative mechanisms were established, residents' substantive influence was often confined to specific aspects of the project, seldom extending to core decision-making processes. Finally, the long-term realization of recognition justice—manifested in the sustained, effective use of community shared spaces and the genuine establishment of cultural identity—hinges on continuous, subsequent investment in community building and governance, the enduring effects of which are yet to be determined.

To address these limitations and to further advance the understanding of housing justice in urban regeneration, future research could be pursued along several key avenues. Firstly, conducting cross-case comparative studies is crucial to test the broader applicability of the analytical framework and to identify context-specific variables influencing equity outcomes. Secondly, undertaking long-term tracking and comprehensive post-renewal assessments will be vital to understand the far-reaching impacts of renewal interventions on housing equity and community well-being. Thirdly, there is a need to explore innovative mechanisms for promoting justice, including the study of effective pathways to enhance housing justice by integrating emerging governance tools and participatory approaches. Such research will be instrumental in developing more robust strategies for creating fairer, more inclusive, and sustainable living environments in the ongoing process of urban transformation..

In summary, the regeneration practice of Nanjing's Xiaosongtao Lane is a valuable attempt to explore housing justice in historical urban areas in China during a specific period. Its experience demonstrates that realizing housing justice is a process of multi-party participation, dynamic adaptation, and continuous improvement.

This requires ongoing exploration and optimisation of strategies based on respecting history, prioritizing public well-being, and balancing interests. Future urban regeneration practice and academic research should continue to deepen the understanding of housing justice's complexity. Particularly in China's unique socio-cultural and institutional context, the focus should be on how to construct more locally adapted paths to justice realisation, with a view to jointly promoting the creation of fairer, more inclusive, and more sustainable living environments.

Abstract
This paper presents the experience of Università Iuav di Venezia as a consultant to UNDP/PAPP in developing design strategies for a transitional community neighborhood in the Gaza Strip. Recognising the complexity of the humanitarian crisis and the challenges posed by protracted and evolving conflict, the paper proposes an adaptive and replicable design framework. The strategy shifts from a rigid conventional top-down model to an adaptive, bottom-up methodology, introducing design processes guided by a cohesive urban vision. The strategy proposed involves an integrated and incremental set of phased interventions, implemented through a community-based and area-based approach. The outcome is a transitional community neighborhood designed to meet immediate recovery needs while facilitating long-term reconstruction efforts. The proposed transitional housing system provides a medium-to long-term solution, with the potential to evolve into permanent housing or public services according to contextual needs. Flexibility remains a core design principle, enabling site-specific urban configurations tailored to the distinctive characteristics of different locations within the Gaza Strip.

keywords: transitional housing; early recovery; community-based approach; sustainable reconstruction;

Introduction

The paper presents a transitional community neighborhood design developed by a joint team from the Università Iuav di Venezia[1] as part of a collaboration with the United Nations Development Programme / Programme of Assistance to the Palestinian People (UNDP/PAPP) – the UN Office established through the UN General Assembly Resolution 33/147 of 20 December 1978, which called upon UNDP to «improve the economic and social conditions of the Palestinian people [...]»[2].

Within this framework, Università Iuav di Venezia conducts research on planning and design strategies aimed at supporting UNDP through in-depth knowledge and on-the-ground experience in urban and territorial transformation processes, with a particular focus on post-conflict reconstruction. The results of this research, carried out by a team of researchers and expert consultants, were recently published in the book *Proactive Reconstruction* (2025), presented at the 2025 Venice Biennale of Architecture.

A recent follow-up phase of the research focuses on the development of a transitional[3] community neighborhood, conceived as a pilot project to test and verify design hypotheses related to technological solutions that enable high levels of flexibility, adaptability, and incremental development. The pilot project will act as a testing ground for fully constructed building elements, with subsequent possible large-scale applications.
The approach is intentionally tentative and empirical. The project remains open to plural design expressions, strongly shaped by the changing and evolving needs of different population groups. Thus, flexibility and adaptability are precisely the qualities that enable the project to integrate insights proposed by local communities, local authorities, and international non-governmental organizations. Implementing a pilot project is crucial, as it permits the testing of key assumptions and the rectification of any potential shortcomings.

The research aims to provide an alternative design to the prevailing standard of transitional sheltering response in emergency contexts. Currently, sheltering solutions are built within a short time frame and then rebuilt or upgraded multiple times on the same site due to the protracted nature of displacement situations and the delay in implementing formal reconstruction (Picker and Pasquetti, 2015; Agier, 2002). In contrast, our research introduces an alternative approach that starts with the construction of a structure capable of evolving over time: initially addressing urgent, short-term emergencies and progressively adapting to meet long-term necessities. The temporal dimension is inherent in the project's process-driven character.

This processual approach starts from the recognition of the impossibility of outlining a fixed design solution and rather embraces the role of the designer as a definer of spatial principles (Gregotti, 1966) and of urban metamorphosis (Albrecht and Benevolo, 1990; Benevolo 1996) within a range of infinite variations.

Given the geopolitical uncertainties in the Middle East and the ongoing devastation affecting not only the Gaza Strip but also parts of the West Bank – particularly within the Palestinian territories – identifying suitable locations for the placement of the designed units remains challenging. However, mathematical models, applied through

1 Namely, the Urbicide Task Force and C.SCARPA research centers (www.urbicide taskforce.iuav.it; www.iuav.it/it/strutture-e-reti-di-ricerca/centro-superiore-c.scarpa).

2 The UNDP Programme of Assistance to the Palestinian People, established under UN General Assembly Resolution 33/147 (1978), aims to improve the socio-economic conditions of Palestinians and support the establishment of a viable state capable of ensuring development and resilience. Key interventions focus on governance, enhancing justice, cohesion, and institutional reform; economic empowerment through sustainable, self-reliant poverty reduction; environmental improvements in water, services, and climate adaptation; and infrastructure development in energy, transport, housing, education, and healthcare for marginalized areas.

3 "Transitional housing or transitional community neighbourhood" generally refers to an intermediate housing or neighbourhood solution for displaced people between emergency shelter and long-term accommodation for displaced people, considering three different types of solutions at different times. In this paper, however, "transitional" is understood as a gradual process of stabilization—on the same structure from temporary shelter to increasingly stable—and as a potential transformation of these spaces into public areas and services following reconstruction.

automated and parametric approaches, can provide valuable support in planning reconstruction processes in advance, while anticipating issues related to urbanization dynamics.

Design choices are inherently influenced by the characteristics of the territory in which a project is located. These factors include topographical conditions, location, climate, economic factors, and larger socio-political dynamics. For example, to design interventions in the Gaza Strip today means responding to a complex web of regulatory, logistical, and material limitations, including above all the policies enforced by the Coordinator of Government Activities in the Territories (COGAT). Among its many roles, COGAT controls the flow of goods into Gaza, including construction materials labeled as "dual-use": items that could have both civilian and military applications, and are therefore subject to strict restrictions. This regulatory context became a key element of the transitional community neighbourhood. Materials have been selected not only for their capacity to be sourced and manufactured locally, as well as strengthening the local labor economy, but also because they comply with the restrictions imposed by COGAT. Therefore, constraints were reframed as an opportunity to introduce innovative, context-sensitive features into the transitional housing model. The design process must therefore remain context-specific, taking into account local conditions striving, as much as possible, for an adaptive design strategy.

Reconstruct in Uncertainty / A revised/An evolving approach to reconstruction
The research on the transitional community neighborhood is based on broader investigations conducted at Iuav since 2016, which has focused on methods and forms of urban and housing reconstruction following natural disasters or conflicts (Galli, 2024).

The comparative analysis of reconstruction processes, in both quantitative and qualitative terms, has provided valuable benchmarks for refining future reconstruction patterns. However, the unprecedented scale of current destructive phenomena calls for innovative solutions capable of putting past lessons into practice.

In fact, we are witnessing a substantial change in the form of conflict, or of perpetual instability (non-peace), which sees a progressive increase in the involvement of civilians, both victims and targets, compared to the past. The consequence is that cities have become the preferred battlefields, and their destruction, via ground or air, has become a primary strategic goal for military and political purposes.

This condition leads to the reemergence of the term "urbicide" in urban discourse, defined as the deliberate violence against cities, their destruction, and the intentional elimination of physical space, collective memory (Caro, 1974; Bogdanovic, 1993; Ribarevic-Nikolic and Juric, 1992; Graham, 2005), as well as the displacement, fragmentation, or erasure of the communities that inhabit them.

When comparing these past events with the current situation, it is important to note that historical urban reconstructions, particularly those following World War II, typically occurred once a period of pacification had been achieved. While the planning for reconstruction often began and even progressed during wartime, with a prime example being the drafting of the London Plan developed while London was experiencing significant bombing from the Blitz, the actual rebuilding largely commenced after hostilities ceased.

Unlike past eras, the persistent and ever-changing nature of contemporary conflicts means that planning for reconstruction solely after peace is secured is no longer a viable approach.

Gaza, sadly exemplifies this reality. If the conflict is viewed not solely through the lens of the most recent war between Israel and Hamas, but rather as an escalation within the broader Israel-Gaza conflict, or even as a phase of the ongoing Israeli-Palestinian conflict, its implications become more evident. As a result of this protracted violence, eight United Nations Relief and Works Agency (UNRWA) refugee camps were established in the Gaza Strip, most of them between 1948 and 1952, following the 1948 Arab-Israeli War.

In the face of this protracted conflict (Azar *et al.*, 1978), the fundamental assumptions for both an emergency-type response and traditional reconstruction efforts no longer hold true. Protracted displacement and extended stays in refugee camps have marked the failure of emergency-oriented responses, leading to various forms of waste from social, environmental, economic, and urban perspectives.

At the same time, traditional top-down reconstruction efforts do not meet the circumstances needed for success, due to both the geopolitical uncertainty required to ensure the viability of such operations and the exceptional scale of destruction of the urban fabric.

We therefore advocate an alternative reconstruction approach - one that does not forgo a long-term perspective - while enabling rapid interventions, based on updated data, guided by parametric calculations, and that is capable of adapting to unforeseen changes.

Data-driven Approaches to Urban Recovery in Conditions of Prolonged Uncertainty

In response to these complex challenges of post-conflict reconstruction under conditions of prolonged uncertainty, a new methodology has been evolving — one that advances the integration of parametric design logic within spatial data infrastructures to support real-time, evidence-based urban recovery. This approach reflects a broader trend in urban planning toward computationally enhanced decision-making, in which geospatial technologies and algorithmic models are employed to simulate, evaluate, and iteratively refine planning strategies in dynamic, data-intensive environments (Batty, 2013). These tools provide a rapid and objective means of supporting complex decision-making processes. While they cannot substitute for on-the-ground surveys, they offer valuable insights during the earliest stages of response. These systems are increasingly able to synthesise heterogeneous datasets, from satellite imagery and cadastral maps to demographic surveys and on-the-ground observations (when available), into coherent and actionable spatial intelligence. Within this context, two computational modules were designed and tested to support recovery planning through a structured, data-driven methodology. Specifically in the Gaza Strip — one of the most severely impacted and densely populated crisis regions — these tools provide a valuable framework for planning amidst extreme infrastructural devastation and persistent geopolitical volatility.

The first — the Land Selection Module — is a powerful analytical tool designed to identify appropriate sites for transitional shelter and the relocation of displaced communities. It is grounded in physical and social recognition processes, implemented through a complex, multi-level evaluation process. At the physical level, the module operates at the urban scale to assess damage severity using high-resolution satellite imagery and orthophotos. This analysis is based on a standardised classification system applied to a 250-meter grid, resulting in a damage-density matrix that ranks areas according to the extent of destruction and the concentration of affected populations. The results are then cross-referenced with land ownership information—specifically prioritising public or semi-public lands, such as government or *waqf*[4] parcels, to identify legally and procedurally viable sites for immediate intervention. From a social perspective, the module incorporates principles of community attachment by prioritising areas that allow displaced populations to return as close as possible to their original homes. The main objective is to preserve existing social relationships and support the stability of cultural and communal life. The result is an interactive heatmap that highlights and ranks potential intervention areas according to socio-spatial relevance toward a recovery-oriented planning strategy.

The first simulation was performed using only two space layers: damage assessment and land ownership. Although these serve as a solid starting point, a more accurate and better-adapted application would require

4 According to Muslim law, *waqf* refers to the act of relinquishing the benefits or income derived from an owned asset, so that it can be used for a good cause or public benefit. The person who makes the *waqf* retains legal ownership of the asset, but its use is permanently dedicated to a charitable purpose. The asset, often land or property, cannot be sold or inherited once it becomes *waqf*, even though it still legally belongs to the person who made the donation. David Santillana, *Istituzioni di diritto musulmano malechita*, Roma, Istituto per l'Oriente, 1938, II, pp. 412–451.

additional spatial variables. To name just a few: proximity to functioning or partially damaged infrastructure, access to public services, or buffer zones from the Israeli-controlled border could drastically improve the accuracy of the outcome. A key feature of the module is its capability to apply different weights to the chosen parameters and sub-criteria, enabling decision-makers and planners to adjust the influence of individual parameters according to shifting operational conditions or specific planning agendas. This flexibility preserves the entire tool's applicability despite political and humanitarian uncertainty while maintaining a data-driven approach and strategic consistency.

Based on these outputs, the second module — the Neighbourhood Simulation Module — enables the investigation of context-driven sheltering solutions. Instead of forcing a single solution on all, it provides an opportunity to test a variety of spatial typologies: modular units, tents, prefabs, caravans, etc, despite the constraints and possibilities of a given site. This module supports quick and easy comparative analysis of planning scenarios based on a multi-criteria assessment, in order to identify the most sustainable and operationally feasible spatial configuration.

The two modules provide a flexible yet methodologically rigorous technological infrastructure that can easily adjust to shifting conditions and still remain consistent with long-term strategic goals. More than technical instruments, the Land Selection and Neighbourhood Simulation modules are "knowledge systems"—translating uncertainty into an organised, transparent, and public urban reconstruction procedure.

In addition to simulating initial emergency responses, it would be beneficial to implement the platform for the reconstruction and development phase, too. By adjusting data and criteria, it can serve as a valuable tool for coordinating all actors involved in reconstruction. It can function as an open online space accessible to a variety of users and be user-friendly, including the local population with whom programmatic decisions can be shared, donors to ensure transparency of funds, as well as technicians and researchers.

A Bottom-up Strategy

The coordination of reconstruction efforts becomes a crucial dimension of the process. While parametric tools can significantly support such coordination, what can truly shift the paradigm is, above all, an approach grounded in small, self-contained units, whose aggregation will ultimately lead to comprehensive reconstruction. For this reason, the luav design strategy—an alternative to standard emergency strategies—advocates for a bottom-up approach composed of small-scale interventions applied at both the architectural and urban scale.

At the architectural scale, transitional community neighborhoods are conceived as pieces of urban fabric designed to host small communities. These neighborhoods are initially composed of housing units, each hosting around 12 people and arranged along a main street. Gradually, an increasing number of housing units expand around the existing structures, extending onto contiguous plots of land.

At the following stage, some rooms of the housing unit can be reconverted into public facilities such as markets, taking advantage from the facing on the street frontage. Gradually, other houses can be converted at the ground floor into public facilities such as schools or small clinics, while inhabitants relocate to upper levels. The ground floor of the building can thus evolve over time, scaling its equipment and facilities to the community's needs.

Different communities may inhabit different transitional community neighborhoods, constructed in parallel. The overall process resembles, in fact, the development of multiple pilot projects; rather than the execution of a single, unified plan, resulting in a potentially heterogeneous outcome.

The strategy adopts a bottom-up approach, conceptualized and implemented directly with and by the local community. It emphasizes the self-organization of a local workforce, positioning community members as active agents in the reconstruction process through participatory design mechanisms (Lozano, 1990). This method

seeks to respond to the needs and aspirations of local populations by fostering inclusive and context-sensitive planning.

The incremental and evolutionary structure is not designed for unlimited growth. There is, in fact, an optimal dimension, an urban and human scale, that limits the growth of the neighborhood. The optimal dimension has been researched over time by architects and planners, and almost all agree that the neighborhood should extend at a maximum of 500 meters in radius, conferring on the neighborhood, or cell, a walkable scale (Piacenti, 2024).

At the urban scale, the strategy envisions a cellular pattern made of neighborhood or urban cells, a constellation of small or micro cities, defined and polycentric multifunctional units, interspersed within green and productive zones, with a certain degree of autonomy and capable of mutual interaction. This configuration can be reached through an area-based approach that focuses on a specific, defined geographic area as the primary unit for planning, implementation, and coordination, rather than focusing solely on specific sectors (such as health, education, or transportation). It is a decentralization strategy of financial resources and infrastructure that enables simultaneous interventions across multiple areas, thereby optimizing the use of time and fostering more rapid recovery and reconstruction.

The bottom-up approach attempts to go beyond the standard and common reconstruction process, which operates by layers and delegates or assigns to specialized offices the planning of a specific area of expertise (e.g., health or education, or roads).

In the complex society of our contemporary era, it is necessary to work on approximation and uncertainty, making it preferable and safer to experiment on a small scale rather than to reason on the understanding of increasingly unpredictable global phenomena. The approach functions as a dynamic design system, intended to manage urban transformation through the deployment of specific components that catalyze positive environmental change. It acknowledges the necessity for ongoing adaptation and refinement in response to external pressures and evolving conditions.

Permanent Temporariness: Transitional Housing

Within this broader framework of dynamic urban transformation, transitional housing emerges as a key field for experimentation and innovation. It marks a significant paradigm shift from the conventional emergency shelters typically used in post-conflict contexts[5]. First, the structure is designed to maximize flexibility to accommodate different unit sizes, housing options, and functional uses (Figure 1).

Units can consist of one or two floors (in accordance with adopted technological solutions) and adjusted to meet the needs of single or multi-generational families. A comparative analysis between transitional housing solutions and traditional shelters reveals that, at an early stage (t), the accommodation capacity of both types can be equivalent. However, considering an evolutionary time frame (t), while conventional structures tend to maintain an unchanged number of inhabitants, the modules proposed by our research demonstrate greater flexibility and adaptability. These allow for a potential increase in the accommodated population, responding dynamically to any new or different needs of the settled population. The housing module is conceived according to a principle of incrementality, so as to allow progressive adaptation to the housing needs of the families welcomed in the emergency phase, foreseeing the possibility of elevation to accommodate new members and support the natural evolution of the family unit.

According to the most recent data (2024) from the Palestinian Central Bureau of Statistics (PCBS) on household composition, the average size in the Gaza Strip was 5.3 people. The predominant type of housing across the five governorates (Gaza, North Gaza, Khan Yunis, Deir al-Balah, and Rafah) revealed that the apartments were the most common, accounting for 77.8% of all households. This was followed by independent houses (21%), villas (0.2%), and other types, such as independent rooms, tents, caravans, or barracks, which together accounted for

5 see: Corsellis, T., & Vitale, A. (2005). Transitional Settlement: Displaced Populations. Oxfam GB.

around 1% (based on 2020 data). In 2022, the PCBS recorded an average of 3.5 rooms per housing unit and an average occupancy of 1.7 people per room; however, a significant proportion—ranging from 36% to 40%—lived in dwellings with more than two people per room. The most severe overcrowding was observed in independent rooms and unconventional housing, where over 60-70% of families lived with more than three people per room.

In the 2024 annual report published by PCBS, most households in Gaza are identified as nuclear families, typically consisting of parents and children, but a significant portion are extended families, often including grandparents, uncles, and aunts, due to social traditions and economic necessity. A growing number of female-headed households has been recorded, particularly following the 2023–2024 escalation and the loss of male breadwinners. Displaced households have become increasingly common, often consisting of merged or recombined family units living in temporary shelters or host families' homes (PCBS, 2025).

As previously mentioned, the project is based on the principle of incremental flexibility. This applies not only to the speed with which it responds to the housing emergency but also to its ability to adapt over time to the community's future needs as well as the entire population. For example, structures designed with a modular system from the outset can be converted into public spaces to serve the community. Thanks to their modularity and reversibility, the housing modules can be repurposed for different functional configurations, even for public use, such as clinics, classrooms, market spaces, and other urban services.

A further key element characterizing the project proposal regards the courtyards (both private and public) that increase the quality of life for the inhabitants and provide outdoor spaces for meeting and conviviality that are usually lacking in standard housing solutions. Courtyard buildings, in fact, ensure high-quality space and climatic performance. Roofs are also a potential advantage: initially configured as mere roofs, they can be imagined as terraces providing each unit with a private outdoor space.

The mentioned adaptability and incremental nature of the project concern not only the capacity to respond to changing housing needs or to allow for future reconfigurations, but also the construction process of the housing modules. The building structure is conceived according to a multiscalar and incremental ratio, and takes the form of a frame structure enclosed with lightweight walls, such as fabric or tarpaulin walls, that, in an emergency phase, can immediately provide displaced persons with safety and protection from the elements.

In later stages, the progressive integration of more stable building components, such as prefabricated panels instead of tarpaulin walls, allows the structure to evolve, challenging the notion of the city as a stable and permanent entity. The phases of emergency and reconstruction follow one another seamlessly.

Future reconfigurations are permitted and guaranteed by the adoption of off-grid technologies such as waterless WCs, solar and photovoltaic panels, and rainwater harvesting.

The adoption of these off-grid systems eliminates the need for extensive underground infrastructure and, more importantly, significantly increases the flexibility and reconfigurability of spaces for various functions beyond just housing. This is because it removes the constraints imposed by traditional plumbing stacks, drainage columns, and other fixed utility connections.

Currently, some of these systems are expensive, especially their more advanced versions. However, it's also true that substantial investments from various actors are typically available during the initial construction phases of refugee camps. Furthermore, the larger the scale of intervention, the more accessible these new technologies become. Therefore, new refugee camps could be transformed into experimental laboratories for innovative and low-energy impact technologies.

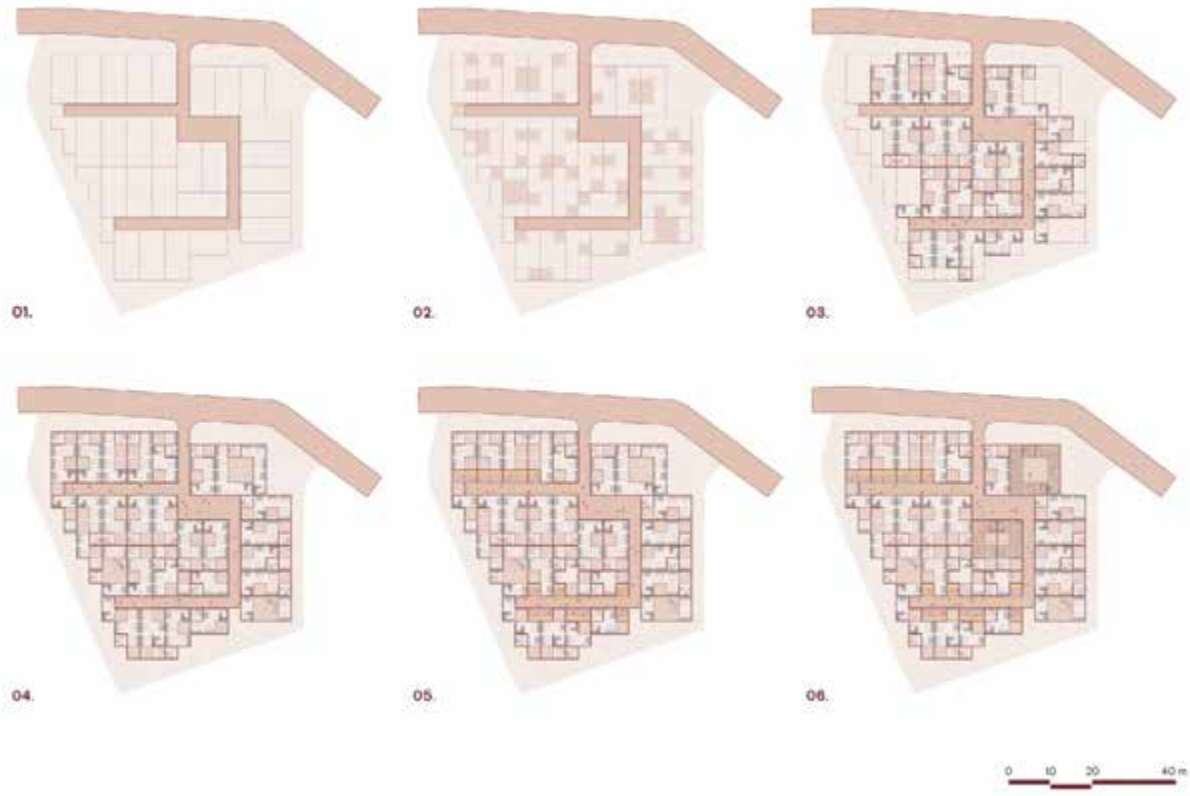

Figure 1: Transitional community neighborhood implementation process: 1) Plot definition; 2) Open space definition; 3) First housing units; 4) Housing unit development; 5) Markets; 6) Facilities.

Transitional Housing as an Alternative to Refugee Camps

The transitional housing approach offers several advantages compared to the current model of standard refugee camps. Originally conceived as temporary solutions for accommodating displaced people during emergencies, refugee camps tend, as a matter of fact, to assume a long-term character and frequently evolve into stable communities that increasingly reflect urban contexts, far exceeding their intended function (Picker and Pasquetti, 2015). Over time, these refugee camps have transitioned from tents or emergency shelters to more permanent structures, often built with concrete and steel. Examples include Dadaab in Kenya, Cox's Bazar in Bangladesh, and several Palestinian Refugee Camps established in Lebanon, Jordan, Syria, the Gaza Strip, and the West Bank in response to the 1948 exodus (*Nakba*). This physical and spatial consolidation reveals the inefficiency of prefabricated shelters—which are designed for short-term use but have been inhabited for decades—and the gradual deterioration of the living conditions of refugees. Moreover, camp growth and development usually occur spontaneously. Camps are therefore disorganised and fragmented in terms of services and infrastructure as demonstrated by the case of the Zaatari refugee camp, which has expanded over a period of thirteen years to become a complex community with its own social, economic, and urban characteristics, but also with important management problems (wastewater, electric grid, etc.). These examples demonstrate the importance of accepting indeterminacy and adopting principles of flexibility in designing resilient communities. Michel Agier's notion of "city-camps" (Agier, 2002) aptly captures this transformation, emphasizing the convergence between camps and cities. Nevertheless, refugee camps continue to be conceived primarily as provisional spaces for humanitarian intervention by international organisations, failing to adequately engage with their long-term urbanising dynamics. According to the 2005 UNHCR *Handbook for Planning and Implementing Development Assistance for Refugees Programmes*, planning is categorized into three distinct phases: "short-term humanitarian

and transitional planning," "multi-year development planning," and "macro-policy and global development." However, these phases are often treated as separate frameworks with discrete objectives, whereas, in practice, the processes of emergency response, recovery, and long-term development tend to overlap and evolve fluidly over time (Duffield, 2013). In this context, time emerges as the critical factor shaping the consolidation and normalization of what were initially intended to be temporary emergency camps.

In contrast, the transitional housing approach avoids land waste, allowing for integration with the existing urban fabric and helping to prevent sprawl and uncontrolled expansion.

It also offers advantages from a social point of view, involving refugees as active participants in the reconstruction process by building their own homes or working for construction companies and material production factories; after an initial phase of assistance, they can become productive members of society. At the same time, it creates jobs and employment opportunities for local people, contributing to the revitalization of the local economy. Additionally, transitional housing is a more economically competitive alternative to refugee camps because the short lifespan of prefabricated shelters contrasts with the prolonged duration of many camps. This discrepancy can lead to significant savings in resources and costs.

Given that refugee camps tend to last for several decades, and given the possibility that their structures may be transformed to meet new needs, one of the fundamental aspects concerns land ownership issues. If the neighborhood cannot be established on public land, it is necessary to adopt a system that ensures the protection of pre-existing property rights both during the transitional phase and in the subsequent phase of consolidation. In addition to official documentation regarding land ownership, local practices and any forms of collective or communal land use must also be taken into account in order to ensure fair treatment of the rights of both refugees and landowners.

Incremental Housing Prototype

In post-conflict reconstruction, the selection of appropriate technologies addresses complex challenges involving social, economic, technological, and logistical aspects. Resource scarcity–especially the limited access to construction materials, energy, and water–hampers rebuilding efforts. In the context of Gaza, these issues are intensified by COGAT's policy regulation of the entrance of all goods into the Gaza Strip, including items designated as "dual-use." The list includes items that are broad categories, further constraining reconstruction. Therefore, the search for alternatives strongly depends on specific constraints, in addition to a relief analysis of the area, a market analysis, and a review of administrative and organizational factors that affect the accurate choice of technology.

Emerging research highlights the potential of lightweight, modular materials that are easy to transport and assemble. These alternatives offer a flexible, cost-effective response suited to unstable environments and limited industrial capacity, providing a promising pathway for sustainable reconstruction in constrained and ever-changing settings (Johnson, 2007; Caron and Kelly, 2008).

The layout of the transitional community neighborhood is based on a regular structural bay of 3 meters (Figure 2). The modular, point-based structure allows for the expansion of units in both directions.

The standard residential unit measures 6 x 12 metres and comprises six 3 x 3 meters rooms and 18 square meters of open space, distributed in one or two courtyards. The structural frame is designed to accommodate up to two levels, hosting up to 12 people.

Given the regular structural frame, it is possible to divide or combine multiple housing units to meet diverse needs. This flexibility addresses situations like overcoming an emergency, which requires an increase in per capita living space, or accommodating growth in family size.
The structure is able to expand and transform in response to territorial specificities and social dynamics, acting

as a generative matrix of a new urban model. Designed according to an incremental and multi-scalar logic, the structure is configured in the early stages of recovery as a light device and then evolves into a more stable and permanent structure in the subsequent phases.

This standard layout enables high residential density, required by the densely populated environment, recognizing an increased value for open space. Moreover, it shapes an introverted urban form, which is not new in the context of the Arab city. Historically, organic growth and gradual transformation have characterized cities in this region. As happened 1.000 years ago, we imagine that this process of growth can gradually reshape the geometric urban fabric of the new city to the point of totally camouflaging the new structure on the historical built environment. The simple structure can morph into a city, temporally articulating the space.

There is quite a bit more to these processes than simply a change in physical form and urban morphology. Unimagined uses and patterns can arise in dense urban conditions.

Urban design can be adapted to the specific characteristics of each site and replicated across various areas in the Gaza Strip or other territories, generating site-specific urban configurations, a city that builds and regenerates itself.

At both scales of intervention, the strategy is incremental. This means that the risks of incorrect development forecasts are minimized, ensuring the functioning of the urban cell or a small residential neighborhood at every stage of its evolution.

Figure 2: Plan of incremental housing aggregation example.

Fiberglass Technology

To support this incremental approach, the choice of construction technology plays a pivotal role. The structure proposed is based on the use of lightweight fiberglass, which fulfills two key functions: it enables rapid construction within a timeframe comparable to early recovery interventions, while providing housing units with the lifecycle of a permanent building and dignified living conditions (Figure 3).

We can compare the current proposal with two different alternatives: prefabs (including C-boxes, readapted containers, modular housing units, etc.) and recovery using traditional technologies (concrete structures with brickwork). Prefabs can be bought on the market and installed easily and quickly on-site following approval. They have an estimated cost of around 2450-400 dollars per square meter, but come with a limited lifecycle (from 5 to 15 years of expected life). At this stage, plans for their disposal and replacement with more permanent solutions cannot be made. Prefabs also do not provide high-quality space, either in terms of private living space or public space. These solutions are not particularly suitable for the climate (corrosion, heat, etc.), and sometimes require shared facilities such as kitchen and bathroom services. Traditional technologies have limited feasibility of implementation in the short term due to materials shortages (concrete, iron, etc.), restricted site access, and unclear property definitions. In the longer term, the use of traditional technologies will face further limits due to the necessity of heavy machinery (cranes, mixers, etc.) and the high water consumption.

The advantages of fibreglass can be grouped into seven principal categories: flexibility, effortless construction, efficiency, durability, feasibility, collective engagement, and convenience.

The fiberglass structural design is inherently modular and scalable, enabling it to accommodate a wide range of unit sizes, residential typologies, functional programs, and user modifications. Both public and private spaces are conceived as multifunctional and temporally adaptable, allowing customization based on evolving needs and available financial resources, including materials, finishes, and technological solutions.

The construction methodology prioritizes simplicity and speed. Fiberglass structures can be assembled rapidly without the use of cranes or heavy machinery and, in many cases, without the need for preliminary site leveling. Selected components can be preassembled to further accelerate on-site construction, making the process more accessible and feasible even under resource-constrained conditions. The system is designed for deployment using unskilled or semi-skilled labor, fostering inclusivity and enabling community-based implementation. Moreover, the use of lightweight materials facilitates easy disassembly, relocation, and reassembly, thereby extending the functional utility of each structural unit.

In terms of efficiency, the project could offer housing with superior acoustic and thermal insulation, anti-seismic structures, and sustainable features like rainwater collection and renewable energy supply. Its layout ensures security, privacy, and comfort, while courtyard buildings enhance spatial quality and climate performance.

The use of fiberglass components — characterized by a lifecycle of 25 to 30 years — elevates the typology from temporary shelter to semi-permanent housing. This shift redefines the concept of transitional housing by embedding longevity and sustainability into its core. Involving local people in designing and building temporary housing not only aligns with local needs and preferences but also fosters a sense of ownership and place. Furthermore, components are reusable, recyclable, and integrated into new life cycles, reducing material waste and environmental impact over successive housing cycles.

The project complies with the regulatory framework of COGAT and leverages construction materials that are readily available on local and international markets. This ensures ease of implementation within existing legal and logistical constraints. The structural materials are readily available on the market and could be produced locally in a second phase. The potential for local production in later phases further enhances economic sustainability. While fiberglass is the preferred material for the pilot phase, alternative materials such as steel, concrete, and recycled rubble may be employed to suit contextual and economic variations, thus increasing the adaptability

and scalability of the project.

The construction of temporary housing generates new skills through training and employment opportunities for local people. Community participation is central to both the design and implementation processes, ensuring that the final built environment reflects the lived experiences, cultural practices, and aspirations of its users.

From an economic perspective, the long lifespan of fiberglass structures makes them a cost-effective solution within a long-term planning framework. Although the pilot phase exhibits a higher cost per square meter due to limited-scale production, this figure is expected to decrease significantly in full-scale deployment scenarios, where economies of scale can be leveraged. Indeed, considering the entire life cycle, the proposed solution offers clear advantages in terms of cost. The prefab modules most commonly used for the construction of refugee camps have a service life of approximately fifteen years, according to technical documentation provided by the manufacturers. However, as early as the third to fifth year after installation, these prefab units require significant maintenance interventions, primarily due to water damage. The most frequent repair works concern roofs, which are damaged by rain, as well as the flooring and walls, which deteriorate due to heavy use and rising damp. The proposed solution involves the use of materials with significantly greater durability. Although this requires a higher initial investment, it ensures a lower overall cost when the full life cycle of the shelter is considered.

Moreover, the holistic inclusion of both private and public covered spaces in cost assessments underscores the project's value as a complete urban system rather than a collection of discrete housing units.

Designing for Transition in an Age of Instability

While awaiting reconstruction for the Palestinian population, the reasoning developed for the specific case of the Gaza Strip can be projected to many other contexts and situations. The possibility of replication appears evident in all other contexts of post-conflict reconstruction, as low-level, low-intensity, persistent conflicts are increasingly envisioned to be the pattern of the future (Kaldor, 1999).

Currently, 56 armed conflicts are underway in the world: the Myanmar conflict, the insurgency in the Sahel, the Sudanese conflict, the Russo-Ukrainian War, and the Ethiopian civil conflict, to mention the major ones. Overall, the ongoing conflicts involve 92 countries – almost half of all countries worldwide – and have displaced over 100 million people.

Increasingly, violence is directed against civilians, and the scale of forced population displacement per conflict is increasing.

Beyond refugees, there are many other categories of people involved in displacement dynamics and unstable contexts. This includes migrants, as well as residents of areas facing pressures such as climate change, social issues, extreme urban and demographic growth, inequalities, criminality, and inadequate urban planning (Albrecht and Galli 2023).

All these pressures challenge permanence as a default condition for cities. This open-ended time of modes of living needs a design. It is thus imperative to think about inhabiting as a fact of transition and subject to change, and to plan the process and forms of its implementation.

The combined impacts of conflict, disaster, climate change, and social and economic pressures paint a difficult scenario for "our common future"[6] and call for a transition to new models capable of transforming this overwhelming sum of pressures into design factors. Urban areas are at the center stage of such a transition, being at the same time the areas most responsible for the current risks (70 percent of global emissions, 50 million urban inhabitants involved in war, a projected 216 million climate migrants), those benefiting from the current paradigm (50 percent of the global GDP comes from 380 cities, 83 percent of scientific products and patents), those more involved by future modifications (sea level rise alone will threaten 800 million people by 2050), and are, quite possibly, a significant part of the solution.

In conclusion, these arguments move beyond business-as-usual intervention protocols and offer an updated approach to early recovery and reconstruction. This approach emphasizes temporariness as a core design factor, without abandoning design practice and the pursuit for an urban form, even amid the uncertainties of habitation duration.

Acknowledgments

The reasoning presented in this article is the result of research applied to the specific case of Gaza, developed through the collaboration with UNDP/PAPP. This partnership provided access to various working and study materials, including existing plans, ongoing plans, as well as data on refugee camps developed by UNHCR, and also facilitated connections with NGOs, local technicians, and local authorities.

The ongoing collaboration between PAPP and Iuav facilitates an iterative refinement of the strategy through continuous engagement with a broad range of stakeholders. This process ensures contextual relevance by incorporating feedback from institutional partners and external experts. Developed jointly with UNDP/PAPP, key national institutions, and specialized consultants, the project embodies a dynamic and participatory approach, characterized by ongoing consultation and stakeholder involvement.

Planning for Compact Cities: The Interplay of Housing Provision and Urbanisation[1]

Abstract
Due to its role as a major driver of urbanisation, housing provision should be given significant attention in contemporary debates on compact urbanisation policies. However, housing systems' relationship with planning is often opaque, characterised by informal institutions and planning practices. We discuss the opportunities provided by housing system theory concepts – particularly the housing provision chain – as a powerful aid in analysing public action in planning and the resulting modes of urbanisation. We provide the case of Croatia to demonstrate the ways in which the trajectory of the housing system influenced and was influenced by spatial planning practice, and how it can account for apparently paradoxical and unsustainable urbanisation outcomes, hinting at the potential of housing policies to achieve compact urbanisation objectives.

Keywords Housing Systems; Housing Provision; Spatial Planning; Croatia; Planning practices

1. Introduction

Recent policy discussions at the level of the EU and some of its member states on the introduction of quantitative targets to contain land take (ESPON, 2024) appear to loom over another great European challenge – that of housing affordability. Questions are being raised over the way housing provision will be impacted by and respond to restrictions in the supply of developable land (Evers, Katurić and Van Der Wouden, 2024). These discussions present an opportunity to rethink the ways in which housing provision, spatial planning, and the resultant modes of urbanisation are interlinked and to sharpen our conceptualisations of their mutual relationships in different characterised by diverse planning and housing systems.

The concern with land take and soil sealing and the policy initiatives such as "no net land take" originate in environmental policy, but strongly impact spatial planning (Tennekes and Evers, 2024; Evers, 2025)the European Union has affected spatial planning in the member states through its environmental policies. To investigate the mechanism by which EU policy becomes joined up to spatial planning, we invoke the concept of 'coupling' from systems and organizational\nscience. We show that coupling is established not only at the EU policymaking level (e.g. within a directive's text. Spatial governance and planning authorities - whose practices are in often oriented toward growth - will increasingly need to adapt their practices to promote more compact urbanisation. A great deal of spatial planning researchers and professionals may share this ambition, as the concerns with social, economic, and environmental costs of "urban sprawl" and the benefits of compact urban planning are widespread in planning literature. However, achieving these ambitions in practice is all but simple.

Firstly, taking stock of all relevant drivers influencing the demand for and supply of developable land is made difficult by their multiplicity and heterogeneity. Some drivers can be directly controlled by public policy; a part of those are accounted by spatial planning policy (zoning, urban regeneration), but decisions impacting these drivers are also made in other policy sectors, which may not be well-coordinated with spatial planning – for instance, transport infrastructure, public transport, agriculture, property taxation, territorial governance and inter-municipal competition. Some drivers cannot be directly controlled by legislation and regulations, and those

1 The abstract was originally submitted with the title "Homeownership and Urban Sprawl: Spatial Planning in Croatia's Post-Socialist Housing System"

include demographic changes, dynamics of the economy, and preferences of consumers and enterprises (Colsaet, Laurans and Levrel, 2018).

Secondly, spatial planning inevitably involves trade-offs between competing claims on the use of limited space. Different economic and policy sectors require land to operate, and spatial governance and planning has the final, formal say on what land is allocated to which use. As part of its broad overview of the sustainability of urbanisation in Europe, the ESPON project SUPER (2020) conceptualised these concerns as trade-offs between the three dimensions of sustainability – social, environmental and economic. In the report, three ideal-typical modes of urbanisation[2] – compact, polycentric and diffuse – were weighed against each other along the dimensions of sustainability. To take the example of housing, as one of the sectors which compete for land, SUPER's assessment found that urban containment policies, theoretically, cause housing prices to rise as land supply is decreased, which could negatively affect social sustainability due to reduced affordability. However, compact urbanisation contributes positively to other aspects of social sustainability, such as more equitable spatial distribution of public services, as well as environmental and social sustainability through several mechanisms (e.g. by preserving ecosystems in unbuilt areas or contributing to agglomeration economies). Conversely, diffuse urbanisation could positively contribute to housing affordability, while negatively impacting many aspects of the social, economic, and environmental dimensions.

To understand why planning systems produce certain modes of urbanisation, one should ask how these trade-offs are managed in practice in a particular context. European spatial governance and planning systems exhibit significant variation in their capacities to control spatial development, in formal tools which they use to regulate urbanisation, in levels of flexibility and certainty, and in the less formal practices and institutions through which they operate. (ESPON, 2018; Berisha et al., 2021, 2024), as well as in the relationship between spatial planning and property rights (Hartmann et al., 2025). Trade-offs are made most explicitly in planning systems traditionally seen to belong to the comprehensive integrated family, but they are also, naturally, made in other systems, where the influences of different policy areas and the rationales of trade-offs may be less explicit.

Especially the latter group of cases, turning the researcher's attention to these practices and informal institutions would lead to enhanced understanding of the planning system's operation – knowledge which may pay off by helping to design more effective policies. Aspirations of planners and policymakers often run afoul of the institutions in which they operate (Dembski, 2025). New regulations designed to boldly alleviate systemic issues are put forward with normative optimism, only to find that "changes in planning law are unsuccessful if they are not congruent with informal and formal institutions at the 'street-level' and if there is a lack of sufficient incentives to change the behaviour of local actors." (Buitelaar, Galle and Sorel, 2011, p. 928). If newly introduced compact city policies are to avoid that fate, their design should be more grounded in the qualitative understanding of institutions. The SUPER report conceptualised varied planning systems as a "black box of local practices," which, in a particular territory, "converts" land supply and demand into specific urbanisation outcomes through its decision-making process. Understanding, conceptualising, and empirically studying planning systems entails prying the lid off the "black box" to reveal the formal and – crucially - informal institutions which determine how trade-offs are made in a particular context and which may make or break attempts at policy reform.

In this paper, we argue that this should be done to qualitatively understand the relationship between planning and housing provision. Housing is a major driver of urbanisation, which is why it is important to understand how it factors in planning trade-offs in different territories. The answers are invariably very far from the simplistic relationship between housing land supply and demand. To begin the analysis, we start with the postulates of housing system theory, a well-developed body of work that explores the ways through which housing is embedded in wider welfare regimes. Specific relations between the state, market and family - which form deep-seated, structural factors in a society – condition particular systems of housing provision. They are composed of varied

2 Instead of *urban sprawl* or *land take*, the authors of SUPER use *urbanisation* to refer to the expansion of built areas. As a more analytically precise term unburdened by negative connotations, it facilitated the multi-dimensional evaluation undertaken by the project. Our paper adopts this terminology.

arrangements between land supply, the scale at which housing is produced, the profit regime of developers and builders, modes of public value capture and opportunities by actors in housing provision to extract developer gain. Conceptualised in this way, the components of housing provision clearly hold great relevance for planning and modes of urbanisation. Spatial governance and planning tools in a given system enable or inhibit the forms which various dimensions of housing provision will take, and, conversely, planning systems and their tools are shaped by the broader housing system. Modes of housing provision are central to housing system literature and its classifications of housing systems, but explicit links between housing system theory and the form of urbanisation to which it housing provision is inextricably tied remain underexplored.

We argue that there is potential in applying housing regime theory to spatial planning as a way to explicitly conceptualise those planning practices and institutions that often work in a hidden way, sometimes producing counter-intuitive outcomes and frustrating attempts at reform – such as the turn to more compact and resource-efficient urbanisation. The next section seeks out the links between housing and planning systems, after which those links are examined empirically in the case of Croatia, where the transformation of the housing system since the 90s produced changes in the prevailing modes of urbanisation, leading to pervasive diffuse development, contrary to stated objectives of national policy.

2. Housing system theory: exploring the links between housing provision, spatial planning and urbanisation

Housing system theory has been developed since the 1990s as a response to the limitations of earlier comparative housing research. At the time, much of the literature either lacked a coherent theoretical framework or was dominated by convergence theories, which assumed that globalisation would lead all developed countries toward a uniform, market-oriented housing model. This perspective tended to dismiss national differences as mere bumps on the road toward a homogenised housing system in all developed countries (Kemeny and Lowe, 1998). Some housing scholars discovered welfare regime theory as a powerful foundation to explore housing systems. Applying to housing the concepts from Esping-Andersen's The Three Worlds of Welfare Capitalism (1990), the approach explored the enduring influence of deep-seated institutional and societal structures on housing systems. This approach has since been developed by a range of scholars (e.g. Matznetter, 2002; Allen et al., 2004; Arbaci, 2007, 2019; Mandič, 2012; Stephens and and Sunega, 2015; Hoekstra, 2020; Stephens, 2020)2007, 2019; Mandi\\uc0\\u269{}, 2012; Stephens and and Sunega, 2015; Hoekstra, 2020; Stephens, 2020 who have explored the ways in which housing systems are embedded within broader welfare regimes.

Within this framework, three broad regime types are typically identified: liberal, corporatist, and social-democratic. The strand of literature focusing on housing provision developed the idea that each regime type is associated with distinct configurations of housing provision, which can be analysed through four key dimensions: promotion, production, land supply, and consumption (Barlow and Duncan, 1994). These dimensions form what is often referred to as the housing provision chain. The structure of this chain determines the extent to which promoters and producers are able to capture development gains, and it reflects the broader political and institutional context in which housing is provided.

In liberal regimes (most frequently associated with English-speaking countries), housing provision is typically dominated by large private developers who both promote and build housing speculatively for the market. These actors are able to capture substantial development gains. In contrast, social-democratic regimes (most prominent of which are the Nordic countries) tend to tightly control development gains through a combination of public land ownership, binding zoning regulations, and non-profit housing promotion. These systems aim to decommodify housing by limiting its exposure to market forces and ensuring access based on need rather than ability to pay. In corporatist regimes (usually encompassing Central European countries), decommodification and control of development gain are partial, less overt and less ideologically symbolic. Self-promoted housing is a frequently encountered method of partial decommodification.

Understanding the dominant modes of housing provision in a given context is essential for assessing the degree of commodification or decommodification within the housing system, which is a central concern of welfare re-

gime studies. However, the housing provision framework also offers valuable insights into other areas of urban development, including spatial planning and urban form.

For example, Arbaci (2007, 2019)including for the first time Southern Europe. It investigates the ways in which the diverse housing systems, embodied in wider welfare regimes, shape and reflect different principles of stratification, and consequently, it reveals the different ways in which the resulting mechanisms of differentiation crucially influence the scale and nature of patterns of ethnic and socio-spatial segregation, particularly among low-income and vulnerable groups. Spatial and social dimensions of segregation are disentangled in each welfare/housing regime (four ideal-typical clusters has used housing system theory to explain patterns of socio-spatial segregation in Southern European countries. She argues that the prevalence of familialistic housing systems, which are characterised by limited direct public intervention in housing, the prevalence of self-promoted and self-built dwellings, high rates of homeownership and intergenerational transfers of housing wealth, has produced distinctive forms of urban segregation that differ markedly from those observed in other parts of Europe. These patterns cannot be understood without accounting for the role of housing provision in shaping the spatial distribution of social groups.

This line of inquiry builds on earlier work on Southern European housing systems (Allen et al., 2004; Allen, 2006) who examined how Southern European countries were able to meet massive post-war housing demand without direct state involvement. Their answer lies in the widespread practice of self-promotion, which was facilitated through indirect state support. Authorities often chose to ignore informal housing promotion and to zone sufficient land for development, thereby enabling rural-urban migrant households to mobilise family resources and construct their own homes. This led the authors to employ the concept of public action, which focuses on the horizontal coordination of policy areas and includes not only direct interventions but also indirect actions and strategic inaction. In this view, what is left unregulated or unenforced can be as significant as formal policy measures.

In exploring and theorising planning systems it is difficult to account for such indirect action or even inaction - not least because of the often-opaque nature of planning practices, which demand a researcher's substantial qualitative familiarisation with the workings of the planning system in a particular context, leading to case studies providing the most insights. In planning literature, the influences on planning beyond the formal regulations and plans have been theorised through the concepts of planning cultures (Knieling and Othengrafen, 2009; Sanyal, 2025) and institutions (Buitelaar, 2007; Buitelaar, Galle and Sorel, 2011; Salet, 2018). The former refers to "the beliefs, discourses and behaviours of practitioners and depositories of technical knowledge in shaping the concrete practices through which spatial governance and planning systems make their purposes operational" (Berisha et al., 2021, p. 3), and the latter attempts to understand planning through rules and norms that condition the relationships between subjects, such as governments, businesses and citizens, which refers to both formal rules, such as regulations and zoning plans, as well as informal norms.

Housing system theory can provide a powerful lens through which to interpret these dynamics. By linking housing provision to broader institutional arrangements, it allows researchers to explain specific planning practices and outcomes that might otherwise appear idiosyncratic or contradictory. Rather than treating such cases as anomalies, the theory enables a more systematic understanding of how housing and planning systems co-evolve. In the remainder of this paper, offer the case of Croatia to illustrate the application of housing system theory to explain planning institutions and concepts. We begin by examining the formal regulations that shape urbanisation and the ways in which planning authority is exercised in practice. We then turn to the housing provision system, tracing its transformation over time and analysing how it has influenced and been influenced by spatial planning practices.

3. Housing systems, spatial planning and urbanisation: The case of Croatia

3.1 Croatian spatial governance and planning system and practices

According to the Physical planning act (Official Gazette 153/13 - 67/23), the 556 municipalities of Croatia are responsible for zoning land within their territories and granting building permits based on zoning plans. These municipal spatial development plans are binding and there is little room for negotiation or discretion in the permitting process. The plans define the boundaries of the building area of a settlement (građevinsko područje naselja, GPN), which functions as an urban growth boundary. Residential development is strictly prohibited outside of this delineated area. Within the GPN, land is further categorised into developed and undeveloped parts, with the latter representing the reserve of greenfield land for future urbanisation. In theory, this system provides municipalities with considerable autonomy in shaping urban development. However, in practice, it has led to the widespread zoning of large reserves of undeveloped land, often far exceeding the volume of development that could be realistically expected based on declining or at best stagnant demographic projections (Vlada RH, 2021).

A second policy area highly influential in determining the mode of urban development is the provision of communal infrastructure. Municipalities are responsible for developing and maintaining local infrastructure, including roads, sewage systems, electricity grids, and public lighting (Utilities act, Official Gazette 68/18 - 145/24). To finance these services, they levy communal contributions (a one-time fee paid by developers) and communal fees (a recurring charge for property users). The former represents the only land value capture mechanism available in the planning system. However, the communal contribution is typically lower in peripheral areas of a settlement, effectively subsidising infrastructure provision for greenfield development. Moreover, the scope of infrastructure required to develop the undeveloped part of the GPN is minimal - usually limited to road access, sewage facilities, and electricity - without obligation to provide public green spaces, schools, healthcare facilities, or public transport. The financial burden of even this limited infrastructure is likely considerable. Although comprehensive data is lacking, it can be inferred that the costs are often not fully covered by the collected fees. Some municipalities have recently raised their communal contributions in response to inflation, despite the political unpopularity of such measures, indicating that communal infrastructure costs can indeed pose a significant strain on municipal budgets.

Despite the considerable freedom theoretically afforded by the planning system for municipalities to shape the urbanisation of their territories, municipalities across Croatia appear to converge on similar, unsustainable urbanisation practices - i.e. zoning of excessive amounts of developable land which invites diffuse urbanisation and subsidising infrastructure for peripheral development. The outcome of this convergence is the proliferation of diffuse urbanisation, with many newly-constructed settlements lacking services and requiring residents to depend on personal vehicles in meeting their basic needs (Šišak and Lukić, 2025). This process of metropolitanisation should not be equated with the development of idyllic middle-class suburbia of the Western European imagination. Aside from the lack of urban amenities, the urban form, while still dominated by single-family houses, is increasingly influenced by the construction of medium-sized and large apartment buildings of urban character, frequently criticised for their impact on the character and identity of the periurban landscape (Svirčić Gotovac, 2015).

This prevailing mode of urbanisation has been criticised as unsustainable, both by the broader community of spatial experts, as well as national spatial planning authorities (Croatian Spatial development Institute, 2017; MPGI, 2021; Vlada RH, 2021). This critique is particularly striking given the country's demographic trends: since 1990, Croatia has experienced continuous population decline, even in its major cities. The only areas showing modest population growth are the peri-urban zones of large cities, yet even there, the increases are marginal. Nevertheless, diffuse urbanisation continues unabated, suggesting a disconnect between formal policy goals and actual planning outcomes. This disconnect between formal policy documents and practice clearly points to hidden structural factors, informal institutions shaping practices. We argue that the housing system has much to do with it. next is an overview of housing provision forms, using the framework of Barlow and Duncan (1994)

3.2 Housing provision and urbanisation: During and after socialism

In Croatia, which was then a federal republic of Yugoslavia, the second half of the 20th century was marked by massive rural-urban migrations corresponding to rapid industrialisation. The state and the social sector (a specific feature of Yugoslav socialism, run by nominally worker-managed enterprises, many of which were large and economically and politically influential) attempted to alleviate chronic urban housing shortages by acting as promoters of housing (Tandarić, Watkins and Ives, 2019). Housing production under this system was entrusted to large construction companies, and the separation meant that builders collected little development gain. Instead, their profitability depended on productivity improvements, which they pursued through innovations such as modular construction, standardised layouts, and economies of scale (Marčetić, 2020). Land for development was provided by local authorities, who possessed the legal authority to expropriate - with compensation - land which they designated for urban expansion (Krtalić, 2004). This took place on agricultural land at the edges of cities, where most plots were small and privately owned. The combination of large-scale construction and land readjustment enabled by expropriation powers led to state/social sector promoted housing to take on a compact form. Regarding consumption, the produced housing units were allocated to tenants under a system of occupancy rights - a tenure that, while not equivalent to ownership, was highly secure, inheritable, and associated with minimal rents that often failed to cover long-term maintenance costs (Marčetić, 2020).

Despite these efforts, the state-social housing system was unable to meet the full extent of housing demand. Allocation rules tended to favour skilled workers, leaving large masses of formerly rural, generally unskilled workers to fulfil their housing needs in a most un-socialist way – through private investment into self-promotion, the practice of privately financing and constructing their own homes (Marčetić, 2020). More than a half of dwellings constructed in Croatia during the socialist period were self-promoted (Čaldarović, 1987). To construct their dwellings, households commissioned small-scale private builders or constructed the dwellings themselves. For that reason, the buildings took the form of single-family houses. Land supply was concentrated on the edges of urban areas where land was not immediately nationalised and could hence be bought from private owners. However, no land readjustment mechanisms were applied, and the resulting settlements followed the fragmented, inherited patterns of agricultural land parcels. This made the provision of public infrastructure and services highly challenging. By simultaneously acting as promoters, builders and customers, households captured development gain in a manner that can be interpreted as a form of partial decommodification (Katurić, 2016; Katurić, Simov and Gregar, 2018).

A significant portion of this self-promoted development was informal - constructed on legally owned land but without the necessary permits and often in violation of zoning regulations. Authorities, aware of the limitations of the state-social sector, largely turned a blind eye to these practices. Over time, many of these informal developments were legalised on a piecemeal basis. This dynamic bears a strong resemblance to housing systems in Southern Europe, where informal self-promotion was similarly tolerated and even indirectly supported by the state. During this period, land markets remained underdeveloped, constrained by legal restrictions and a chronic undersupply of housing. Both occupancy rights in the state-social sector and private ownership in the self-promoted sector offered secure tenure, and both systems were primarily oriented toward fulfilling immediate housing needs rather than generating profit.

The break-off from Yugoslavia and its move away from socialism saw significant changes to housing policies enacted during the 1990s, and initiated a transformation of the overall housing system. One of the most consequential reforms was the "give-away" privatisation of the state and social sector housing stock. Tenants were allowed to purchase their homes at deeply discounted prices, and most did so, motivated by the uncertainty of the transition period. This policy, rooted in neoliberal ideology, also served a pragmatic function: it acted as a "shock absorber" for the anticipated social and economic upheavals of the post-socialist transition, including rising unemployment, growing inequality, and the retrenchment of the welfare state. This massive transfer of housing represented a step toward establishing an asset-based welfare system (Zrinščak, 2003; Mandič, 2010, 2017). Homeownership became the dominant and most secure tenure, while public rental housing was residualised and private rental markets remained poorly regulated, often informal, and lacking in tenant protections.

This shift affected the housing provision system, which gradually transformed and took on more speculative features. State-social promotion ceased. Large construction companies were fragmented and downsized due to the collapse in demand for large-scale housing projects. The shift toward homeownership had profound implications for housing production. With the cessation of state-social promotion, large construction companies were fragmented and downsized due to the collapse in demand for large-scale housing projects (Marčetić, 2020). Simultaneously, legal reforms strengthened individual property rights and curtailed the ability of public authorities to expropriate land. Even land readjustment tools, which could have enabled municipalities to coordinate infrastructure provision while preserving private ownership, remained absent from the legal framework (Krtalić, 2004). The informality of self-promoted housing from the socialist period was systematically resolved by the government's concerted effort to legalise the housing stock built without the required permits. While informal self-promoted homeownership was sustained in the socialist period through ignoring or even tacit approval, the systematic legalisation undertaken between 2011 and 2018 sanctioned all prior construction, while sending a strong signal that future illegal construction would not be accepted. A large portion of the self-provided housing stock was thus legitimised, facilitating its inclusion into the by then already developed housing market (Habrun, 2018).

The housing provision system which emerged in this period can be seen as a continuation of the poorly regulated self-promoted sector of the socialist period. Land supply was entirely left to the multitude of small-scale landowners, and in absence of land readjustment mechanisms, the availability of solely small, individual parcels for development stimulated small-scale housing production. The growing sector of private builders – a continuation of the small private enterprises building for the neds households in the socialist period - increasingly also operated as promoters, developing housing with the sole intention of rapid sale on the market. The new, speculative housing provision mechanisms permitted developers to extract development gain. Self-promotion also remained present, albeit less frequently through self-building (Rodik, Matković and Pandžić, 2019), as households continued to seek more affordable means of gaining ownership over a dwelling by extracting some of the development gain themselves.

Overall, the transformation of the housing system in Croatia was characterised by increased commodification, driven by speculative behaviour among firms and a growing societal reliance on homeownership as a form of asset-based welfare. This shift was not entirely new but rather an evolution of the socialist-era system, which had already established secure tenures and a strong cultural preference for homeownership. In the post-socialist context, housing increasingly became a vehicle for investment and savings. Households began to leverage their real estate assets through tourism rentals, a practice that initially emerged in small coastal municipalities but has since expanded to larger coastal cities and the capital, Zagreb (Vizek, Barbić and Časni, 2024). Since the early 2000s, mortgage credit has played an increasingly important role in facilitating access to homeownership, further embedding housing within financial markets and reinforcing its role as a cornerstone of household welfare.

4. Discussion

Having described the Croatian spatial governance and planning system and its outcomes on the mode of urbanisation, as well as the systems of housing provision and their embeddedness in an evolving housing system, we turn to the questions posed in the first two chapters: we discuss how the apparently paradoxical spatial planning practices observed across Croatian municipalities can be conceptualised and explained by institutions which are significantly conditioned by the housing system, which shapes both the housing needs and the forms of housing provision through which these needs are fulfilled.

The introduction of real estate markets and the development of speculative mechanisms in housing provision led to increases in housing unaffordability, while the housing system simultaneously incentivises households to purchase housing, despite the great expenses of doing so. The specific system of housing provision through which the need for homeownership can be fulfilled is highly influenced by the path-dependent development from the largely informal self-promoted modes of the socialist period. The small scale of production and lack of land

readjustment tools led to the predominance of development on individual plots, whose spatial structure reflects the patterns "inherited" from previous, agricultural uses.

Seen in this light, municipal zoning practices can be understood as a crude form of decommodification adapted to the capacities of local governments and the housing system's structures. Seeking to increase land supply by permitting development over large, mostly agricultural areas and, thus, reducing land prices can be seen as an overriding objective. This objective also accounts for communal infrastructure policies which enable greenfield development and reduce infrastructure cost for the developer – but not the municipality. However, the lack of public value capture mechanisms frustrates this objective. Speculative pressures in land provision are allowed to run unhindered. By selling plots at prices reflecting the "highest and best use", landowners pocket development gain without hindrance and pass the costs on to producers and consumers. When housing is produced by speculative builders, they also extract development gain by selling constructed units at the highest price the market will bear, placing great strain on households of lower and increasingly those of medium incomes.

Besides making land cheaper as a tradeable commodity, the zoning practices of municipalities also seek to enable self-promotion on inherited, previously agricultural land. This permits local residents to avoid the costs extracted by speculative land transactions and market developers. Such practices can be considered as a form of decommodification, allowing households - including those to whom market purchase would impose an unbearable strain - to attain the indispensable status of homeowners. However, as the "site selection" for self-promotion of inherited land is essentially random, housing provided in this way is often located in rural areas, lacking proximity to urban amenities, which can only be accessed by car, which leads to the well-known social and environmental costs of car-centric development in periurban regions.

The widespread availability of developable land can be conceived of as an institution of contemporary Croatian planning. Throughout the country, citizens expect their municipalities' planning departments and elected local governments to make land available for development and keep infrastructure cheap (and just sufficient to enable access by car to urban amenities in more central locations). Local authorities are happy to provide these, using spatial governance and planning as a part of their limited toolkit to improve the living conditions of their citizens as best as they can and – hopefully - even to attract new residents. These institutions of the more broadly understood planning system explain the central government's reluctance to enact stricter urban containment policies and the ineffectiveness of those initiatives which are put in force. It also paints a pessimistic picture for the prospects of potential European land take containment legislation in Croatia. Taking the established institutions and their political significance into account, there can be no doubt that their disruption would induce political resistance potentially fatal to the policy's objectives.

However, understanding spatial policies through their drivers in the wider sphere of housing systems points to a way out of this lock-in. Directing policy efforts at housing rather than land use may prove a more effective, though laborious and (at least in the case of Croatia) poorly explored path. Public action in housing should overcome its uncritical assumptions and seek to transform the housing system in such a direction to enable decommodified, secure and affordable provision of housing beyond market-based homeownership; if reliance on unsustainable urbanisation practices is to be avoided, stimulating more varied arrangements between housing promotion, production, land supply, and consumption should be the aim – for instance, through introducing land readjustment, robust cost rental and other non-profit forms of promotion, and sustainable regeneration of brownfield sites and deteriorated urban housing in compact urban cores.

5. Conclusion

This paper offered housing system theory and the housing provision concept as a valuable analytical tool for understanding spatial planning practices and the often-opaque institutional arrangements that shape them. By examining the case of Croatia, we have demonstrated how the housing system, through its structural features and historical trajectory, induces municipalities to adopt similar spatial governance and planning policies, even when these policies are socially, economically, and environmentally unsustainable.

Our analysis has shown that the Croatian planning system's tendency toward diffuse urbanisation is not merely a result of weak regulation or poor implementation, but is deeply embedded in the institutional logic of the housing system. The legacy of self-promotion, the dominance of homeownership as the only viable tenure, and the absence of mechanisms for land readjustment and public value capture all contribute to a planning environment in which municipalities are incentivised to zone generously and subsidise greenfield development. These practices are further reinforced by citizens' expectations and the limited fiscal and institutional capacities of local governments.

We have also highlighted why central government policies aimed at curbing these practices often encounter difficulties in design and experience lacklustre implementation. Planning regulation must take careful account of the institutional context in which it operates. Housing system theory offers a promising framework for doing so, which is why further work on introducing housing systems theory in planning literature and spatial planning institutions and practices in housing literature would be welcomed.

The conclusions drawn from the Croatian case may be especially relevant to other contexts characterised by widespread self-promotion, binding zoning regulations, and an oversupply of developable greenfield land. These features are common in Southern and Southeast European countries, whose housing systems have been variously described as Mediterranean/ familistic and post-socialist, and whose planning systems are often classified as conformative or belonging to the urbanism family. However, the issues of land oversupply, diffuse urbanisation, and rising housing unaffordability are by no means confined to these regions.

We suggest that more explicit and systematic study of the often opaque ways in which housing systems interact with planning institutions and practices - and how these interactions shape the resulting modes of urbanisation - could yield valuable insights for a broader range of European contexts. By prying open the "black box" of local planning practices and examining the institutional logics that underpin them, researchers and policymakers alike may be better equipped to design interventions that are more effective and also more attuned to the complex realities of urban development.

Predicting Housing Prices: The Case of Ankara Housing Market

Duygu Çayan, Özgül Burcu Özdemir Sarı
Affiliation: Gazi University, METU
Email: duygucayan@gazi.edu.tr, bozdemir@metu.edu.tr

Abstract
The housing market is crucial for economies, especially in Türkiye, where economic instability has caused rising housing prices. This study aims to predict trends in the city's rental market using a dataset of 20,000 listings. By using advanced data analysis and machine learning, the research seeks to identify patterns and forecast rental price movements, benefiting households and policymakers. Valuing housing is complex due to its varied characteristics, prompting the use of hedonic pricing theory. This involves a regression model that links housing prices to their features. While traditional linear regression has been used, non-linear machine learning models often provide more accurate predictions. The research offers a framework for predicting housing market trends and fostering equitable urban development, addressing housing needs in Ankara and beyond.

Keywords: Housing Price Prediction, Housing Affordability, Machine Learning, Türkiye, Ankara

1. Introduction

Accurate estimation of house prices is crucial for a broad spectrum of stakeholders across multiple sectors. In this context, not only households but also a diverse range of actors—including landlords, investors, real estate agents, financial institutions and government bodies—require reliable housing price information for their respective purposes. As a critical sector and a major driver of economic activity, the housing market holds significant importance in nearly all economies, and Türkiye is no exception. The country's ongoing economic instability has further heightened the housing sector's relevance.

Given its pivotal role in the Turkish economy, the performance of the housing market is essential not only for ensuring macroeconomic stability but also for addressing issues of housing affordability. However, house prices in Türkiye tend to be volatile, fluctuating in cycles of rise and decline. Despite this, in major cities such as İstanbul, Ankara and İzmir, prices have shown a consistent upward trend. According to a report from the Central Bank of the Republic of Türkiye in April 2025, the Housing Price Index increased by 32.9% in nominal terms. Analysing the housing price indexes for Istanbul, Ankara, and Izmir reveals that in March 2025, prices increased by 2.7%, 2.8%, and 0.2%, respectively, compared to the previous month. Year-over-year comparisons show that index values increased by 34.4%, 41.9%, and 30.9% in Istanbul, Ankara, and Izmir, respectively. In April 2025, the Consumer Price Index recorded an annual change of 37.86%, according to the Turkish Statistical Institute (TURKSTAT, 2025). When comparing nominal housing price growth to consumer inflation, Ankara stands out because its housing prices have increased slightly more than the inflation rate. The widespread price increase across Türkiye, especially in Ankara, has intensified the focus on monitoring changes in housing prices and addressing affordability issues.

This study focuses on Ankara, the nation's capital, as a case study to forecast housing market trends across nine districts. It utilizes a comprehensive dataset comprising 20,000 rental listings collected from a prominent real estate platform. The dataset includes key property features such as price, type, number of rooms, floor area, age, floor level, and geographic location. By applying advanced data analysis and machine learning techniques, this research aims to uncover patterns in rental price behaviour and generate predictive insights. These findings are expected to contribute meaningfully to urban planning strategies and the formulation of effective housing policies.

The remainder of this paper is organized as follows: Section 2 provides a brief review of previous research on housing price estimation, outlining the theoretical and empirical framework for the analysis developed in Rosen (1974). In Section 3, the data and methodology used in this study are described. Section 4 presents and discusses

the empirical results. Building on these findings, Section 5 offers a discussion of the results, while Section 6 outlines the policy implications and concludes the paper.

2. Estimation of Housing Prices

Understanding house price trends and producing accurate estimates are also critically important from the perspective of urban planning and development (Kang et al., 2021). However, predicting housing prices is a complex and multifaceted task, as it involves a combination of structural, economic, social, locational, and market-related attributes that must all be considered during valuation processes (Mankad, 2022). This complexity has led many studies on housing prices to rely heavily on hedonic pricing theory (Crespo & Gret-Regamey, 2013).

The initial formal contribution to hedonic price theory was made by Court in 1941, who developed a hedonic price index for automobiles (Bartik, 1987). Two primary approaches have significantly influenced the theoretical development of hedonic prices. The first approach is based on Lancaster's consumer theory (1966), while the second stems from Rosen's model (1974) (Chin & Chau, 2003). Malpezzi (2003) points out that Lancaster advanced microeconomic theory by focusing on the demand side of the market, emphasizing that utility is derived not from the goods themselves but from their characteristics. The Hedonic Price Model, first formalized by Rosen in 1974, conceptualizes a product as a bundle of characteristics, each contributing to its overall price. As Rosen (1974) explains, "Hedonic prices are defined as the implicit prices of attributes, derived from the observed prices of differentiated products and the specific quantities of characteristics associated with them." In simpler terms, a house's price reflects the cumulative implicit value of its individual features, which cannot be priced independently. A hedonic equation is essentially a regression model that relates a house's price to its various characteristics. A differentiated product is defined by a vector of attributes Z = (z1, z2, ... zn), where each zi represents a specific attribute. The market price of a product can thus be expressed as a function of its attributes, p(z) = p (z1, z2, ... zn). This means that the price of the house, p(z), is a function of its characteristics. To estimate the implicit prices of individual attributes, Rosen proposes a regression-based approach where product prices are regressed on their characteristics. This estimation process represents the first step in Rosen's two-stage hedonic pricing model.

The application of the hedonic price model to the housing market is based on several fundamental assumptions. One is the heterogeneity of housing products. Malpezzi (2003) discusses that hedonic models arise due to heterogeneity in the market, including both heterogeneous housing stock and heterogeneous consumers. Housing products are considered heterogeneous due to their differences in locational, structural, or neighbourhood attributes. Each house possesses a unique set of characteristics that influence its value. Also, a house is a long-lasting good that has a significant lifespan, allowing houses of varying ages to coexist within the same market. Furthermore, certain features of a house may be valued differently depending on the geographical location. Homebuyers have distinct utility functions that lead them to value different characteristics across houses differently, in addition to the problem of the presence of different characteristics across houses (Sirmans, Macpherson, and Zietz, 2005).

Another theoretical construction underlying this approach is the "implicit market." The concept of implicit markets refers to the processes of producing, exchanging, and consuming commodities that are primarily (and perhaps exclusively) traded in "bundles" (Sheppard, 1999). This means that implicit markets refer to situations where individual components of a product are not sold separately, but rather as part of a bundle. Some goods, such as automobiles, workers, and houses, can be grouped into a single "market," despite their heterogeneous nature. These markets can't be analysed with traditional economic models because they don't have a single price; instead, they feature a range of prices based on quality and characteristics. The hedonic approach addresses this by suggesting that these goods comprise aggregates of homogeneous parts. While the overall bundle may lack a uniform price, the individual attributes share a more consistent price structure (Sheppard, 1999).

In earlier research, the hedonic pricing model—typically based on linear regression and estimated using Ordinary Least Squares (OLS)—has been widely used to predict housing prices. However, the relationship between property

values and their determining factors is often nonlinear and more intricate than linear models can adequately capture (Sheppard, 1999). Key issues such as model specification methods, multicollinearity among independent variables, interactions between predictors, heteroscedasticity, non-linearity of relationships, and the presence of outliers can substantially undermine the model's reliability and effectiveness in accurately assessing housing values (Limsombunchai, 2004). To address rising prediction errors and heteroscedasticity at higher price levels, the hedonic pricing model is often utilized in a semi-logarithmic form (Goodman & Thibodeau, 1995; Sirmans, Macpherson, and Zietz, 2005; Fletcher, Gallimore, and Mangan, 2000). While the semi-logarithmic form helps mitigate heteroscedasticity and capture some non-linearity, several studies have pointed out its limitations. They have limited flexibility in modelling complex, non-linear interactions between housing attributes and prices. In response, various alternative modelling approaches have been developed, many of which offer significant advantages over traditional methods. Recent studies have shown that non-linear models utilizing machine learning techniques provide more accurate and reliable predictions. These models improve upon standard approaches by learning directly from data and continuously refining their predictive capabilities. Among the most commonly used and effective machine learning algorithms for housing price prediction are artificial neural networks, gradient boosting, and random forests.

This study focuses on using random forest machine learning techniques for predicting house prices. Random Forest is a powerful classification algorithm that enhances predictive accuracy by averaging outcomes from multiple decision trees, each trained on different subsets of the dataset (Adetunjia et al., 2022). It uses a process called bagging, or bootstrap aggregating, to train individual trees on random samples. This approach reduces overfitting and improves the robustness of the model. As an ensemble model, Random Forest combines predictions from various trees using majority voting or averaging, resulting in higher accuracy than a single decision tree. This method is particularly effective for large datasets with complex relationships, revealing intricate patterns among the features (Truong, Nguyen, Dang, and Mei, 2020).

3. Data and Methodology

The dataset for this study is sourced from hepsiemlak.com, a prominent real estate platform in Türkiye. It consists of 19,333 house-for-sale advertisements collected in June 2024. This dataset includes key information such as property prices, the number of rooms, the gross area of the house, the floor, the age, housing types (including flat, residence, detached house, etc.), and the neighbourhood in which it is located (Table 1).

Table 1. List of Attributes

Attribute Name	Data Type	Description
price	int64	House price
totalRooms	int64	Number of total rooms (3, 4, etc.)
area	int64	Area of the house (gross)
floor	int64	The floor it is located on
age	int64	Age of the house
housingTypes	int64	House's type (flat, residence, detached house, etc.)
neighborhood	object	The neighborhood in which it is located
district	object	The district in which it is located

The dataset was thoroughly examined for outliers using the Interquartile Range (IQR) method. An outlier, denoted as x, is identified if it falls outside the established boundaries. Specifically, this occurs when the value of x is lower than the lower quartile minus 1.5 times the IQR or higher than the upper quartile plus 1.5 times the IQR. This systematic approach enhances the understanding of the data's distribution and helps maintain the integrity of the analysis. After applying this method to the price column of the dataset, a total of 790 outliers were identified

and subsequently removed. This process significantly enhanced the quality of the dataset, which now comprises 18,543 entries.

The data on Ankara's housing stock, collected during the first stage of the study, encompasses a total of 22 districts, as shown in Table 2. However, it is evident that sufficient data could not be obtained, particularly from districts outside the central areas. Consequently, the focus of the study was narrowed to the central districts, which have a more substantial representation of the housing stock. As a result of this process, the dataset was reduced to 16,903.

Table 2. Number of data by districts

YENIMAHALLE	4033203.88	3650000.00	824

This study employs a comprehensive methodological framework that incorporates both linear regression and random forest models to predict local housing prices. The linear regression model assumes a straightforward linear relationship between the dependent variable and the explanatory variables. In contrast, the random forest model leverages an ensemble learning approach, using multiple decision trees to capture complex interactions and non-linear relationships within the data. The effectiveness of both models is assessed by comparing their prediction accuracy through metrics such as mean absolute error and R-squared values. This comparative analysis aims to enhance our understanding of which model provides superior forecasting capability for local housing markets.

4. Empirical Results

Exploratory data analysis is a crucial preliminary step prior to developing a regression model. Figure 1 illustrates the average housing prices across various districts in Ankara using a grayscale colour scheme to represent price levels. Darker shades correspond to higher average prices, while lighter shades indicate lower ones. According to the map, Çankaya, Gölbaşı, and Yenimahalle stand out with significantly higher average housing prices compared to other districts. In contrast, Etimesgut, Pursaklar, and Keçiören fall into the mid-priced category, represented by medium gray areas. The lightest shades mark the most affordable districts, which include Altındağ, Mamak, and Sincan.

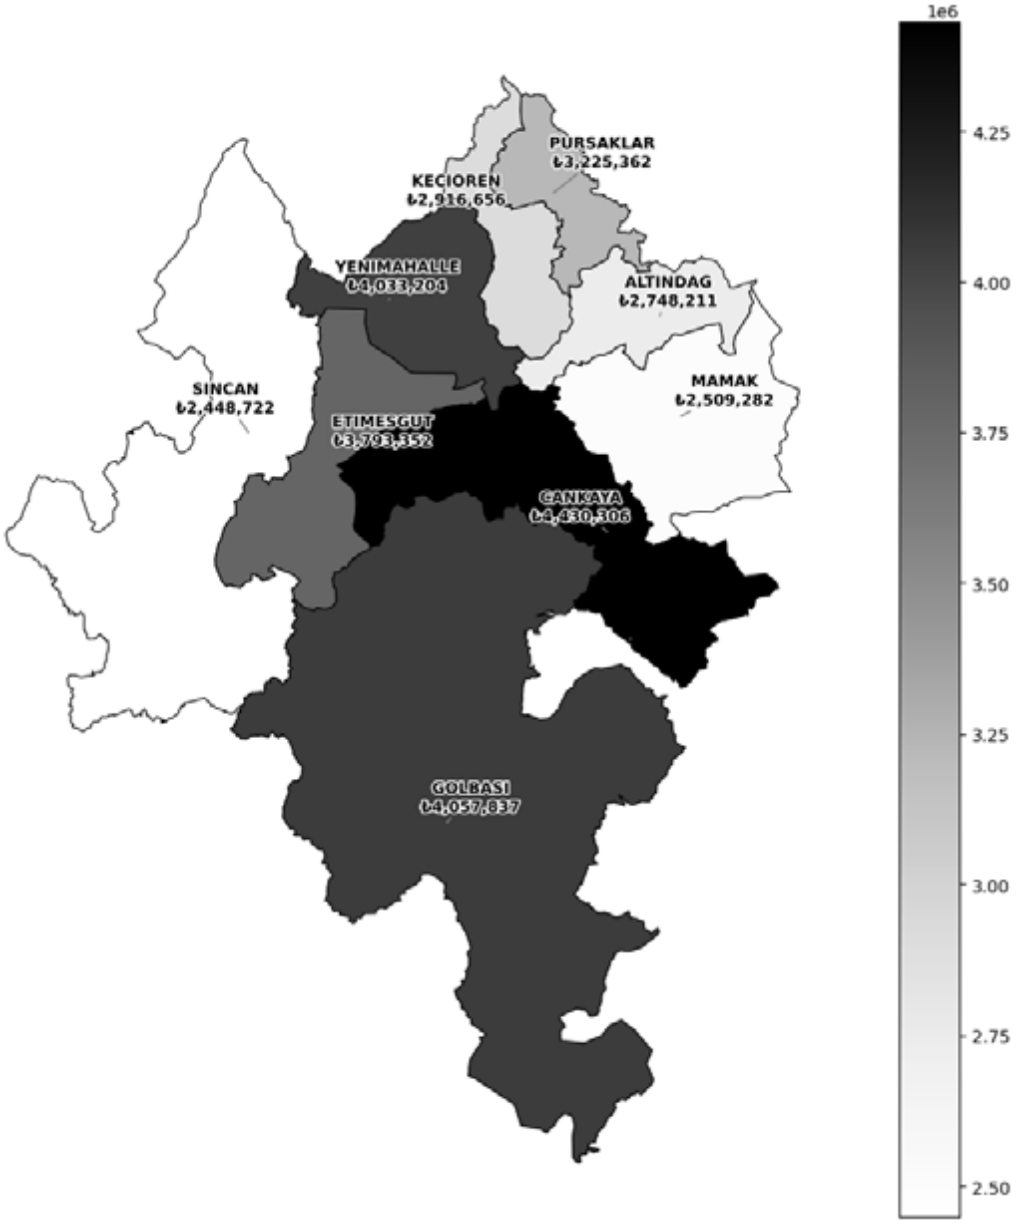

Fig. 1. Average Price by Districts

Figures 2, 3, 4, and 5 compare the distribution of price with its log-transformed counterpart, log Price. The histograms in Figures 3 and 4 reveal a pronounced right skew, while the Q-Q plot shows significant deviations from a normal distribution, especially in the tails. This indicates that the price distribution is not normal. In contrast, the histograms in Figures 5 and 6 appear more symmetrical and bell-shaped. The Q-Q plot for the log-transformed

prices aligns much more closely with the theoretical normal line, exhibiting only minor deviations in the tails. This suggests that log-transformed housing prices (log Price) is approximately normally distributed.

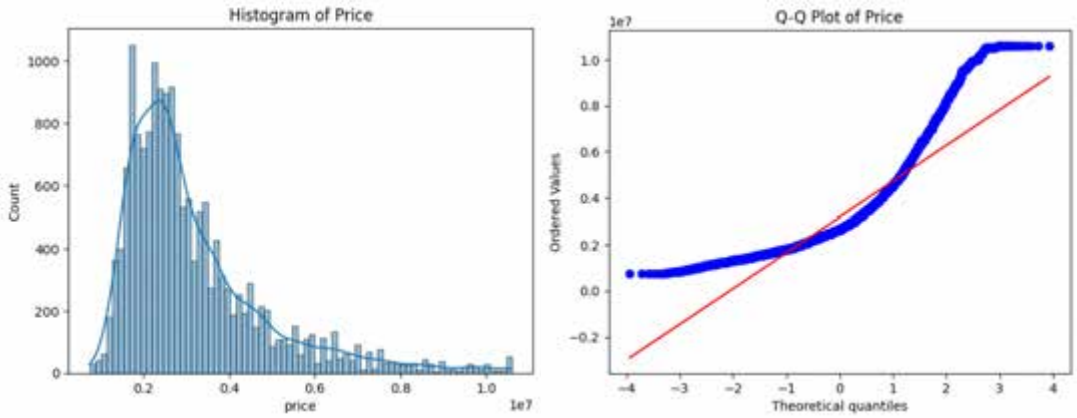

Fig. 2 and 3. Histogram and Q-Q Plot of Price

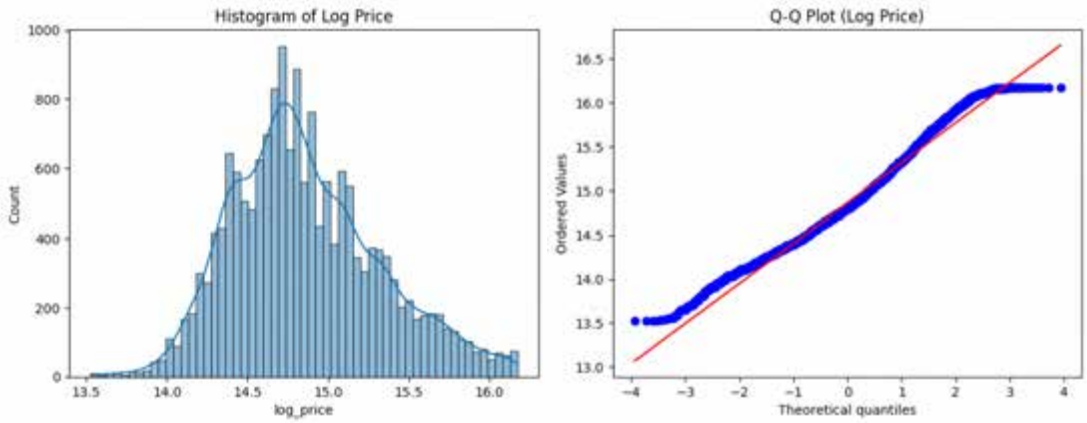

Fig. 4 and Fig. 5. Histogram and Q-Q Plot of Log Price

Figure 6 presents a box plot illustrating the distribution of log-transformed housing prices (log Price) across various districts in Ankara. The x-axis represents the log Price, while the y-axis lists the districts. Each box depicts the interquartile range (IQR), which captures the middle 50% of the data. The horizontal line within each box indicates the median log Price for the corresponding district. The whiskers extend to show the range of values excluding outliers, which are represented by individual circles.

According to the plot, there are significant variations in housing prices across 9 districts. Çankaya emerges as the most expensive district on average, characterized by a wide price range and a substantial number of high-end outliers. Sincan, Mamak, and Altındağ appear as the most affordable districts, with lower median log Prices. Etimesgut and Yenimahalle fall into the mid-range category, exhibiting moderate price levels along with some variability. Districts such as Pursaklar and Altındağ display tighter distributions, suggesting relatively more homogeneous housing markets in those areas.

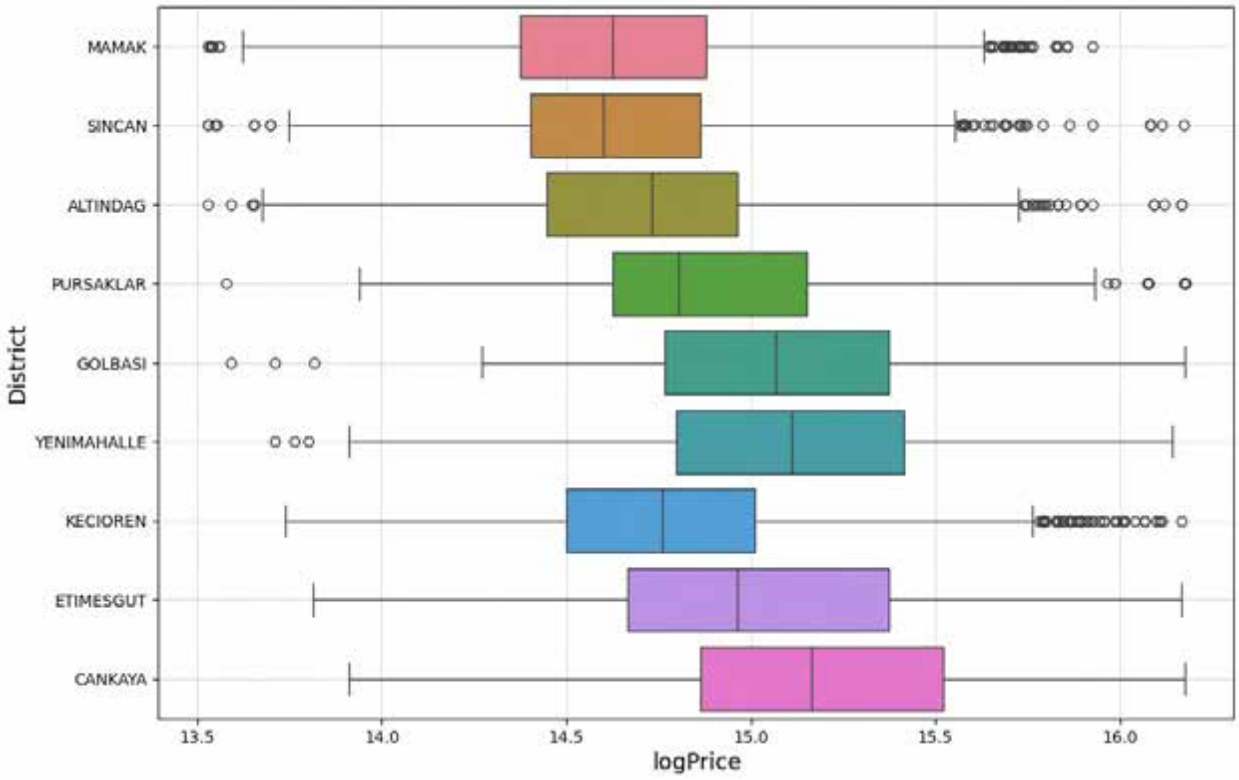

Fig. 6. District Log Transformation of price

Figures 7 and 8 illustrate the overall distribution of unit prices, which follows a right-skewed pattern. The average unit price is approximately ₺23,300, while the median is ₺20,562. This difference suggests that some high-priced properties are elevating the average price. Among the districts, Gölbaşı and Çankaya have the highest average unit prices, indicating they feature more upscale or premium housing markets. In contrast, Sincan, Mamak, and Altındağ are among the most affordable districts. Additionally, Gölbaşı exhibits the greatest price variability, indicating a wide range of property types, while Sincan shows more consistent pricing. These trends underscore significant spatial disparities in housing costs across the region.

Fig. 8. Descriptive Statistics for Unit Price by Districts

Before constructing the models, it's crucial to preprocess the data to improve the models' ability to learn patterns effectively. Specifically, numerical values were standardized to bring them into a comparable range, which aids in achieving better convergence during training. Meanwhile, categorical values, such as those in the district column, were transformed using one-hot encoding, which generates binary variables for each category.

The correlation matrix (Fig. 9) offers valuable insights into the relationships between various housing characteristics and their impact on pricing. It shows that price correlates moderately to strongly with area (m²) at 0.58 and with total rooms at 0.45. This correlation indicates that larger homes tend to command higher prices in the housing market. Additionally, there is a significant negative correlation of -0.24 between price and building age, suggesting that newer properties generally have higher prices. This trend can be attributed to the modern amenities and superior construction standards often found in newer homes, making them more attractive to buyers. Moreover, the high correlation of 0.82 between area (m²) and total rooms raises concerns about multicollinearity, which should be carefully considered in predictive modelling. Multicollinearity can obscure the true relationships between independent variables and the dependent variable, leading to less reliable predictions. Upon further examination of the data, it becomes clear that specific property types display distinct pricing trends. For example, villas show a positive association with price, likely due to their luxury appeal and larger lot sizes. In contrast, flats exhibit a negative correlation with pricing, which may reflect their smaller size or less desirable features compared to other property types. Locational differences also play a significant role in pricing dynamics. Certain districts, such as Çankaya, are positively correlated with higher prices, presumably because of their central location, better amenities, and perceived prestige. Conversely, areas like Sincan and Altındağ show negative relationships with price, which may be linked to socioeconomic factors, market demand, or varying levels of property development in those districts. This pricing disparity highlights the importance of location in housing prices.

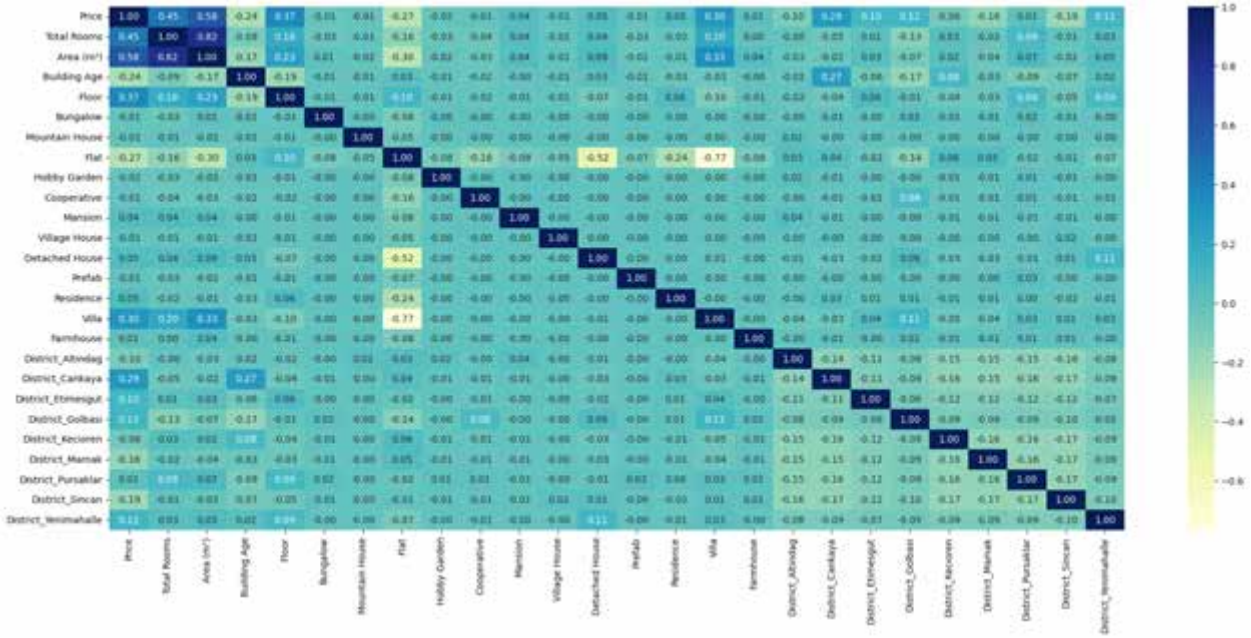

Fig. 9. Correlation Matrix

4.1. Baseline Model Results

In the study, a baseline model was developed to compare linear and random forest models. This baseline model predicts housing prices based solely on the average price per neighbourhood. The results of the model are presented in Table 3. It has a Mean Squared Error (MSE) of approximately 1.7 trillion, indicating a substantial average error in squared units. The Root Mean Squared Error (RMSE) is around 1,310,163, which represents the average prediction error in actual price units—this is quite high and suggests that the model lacks precision. The R-squared (R^2) value is 0.367, meaning the model explains only about 39.9% of the variance in housing prices.

This implies that while neighbourhood averages provide some predictive power, the baseline model is relatively weak, and more sophisticated modelling, such as using multiple features, is necessary for improved accuracy.

Table 3. Baseline Model Results

Mean Squared Error	1,716,527,408,237.00
Root Mean Squared Error	1,310,163.00
R-squared	0.3998

Figure 10 shows predicted housing prices versus actual prices. The red dashed line indicates where predictions would perfectly align with actual values. Many points are close to this line, suggesting reasonably accurate predictions, but there's more variability at higher price ranges. This indicates the model is less precise with expensive properties, reflecting some significant under- and overestimations. While it captures the general trend, it shows room for improvement through additional features or more complex modelling techniques.

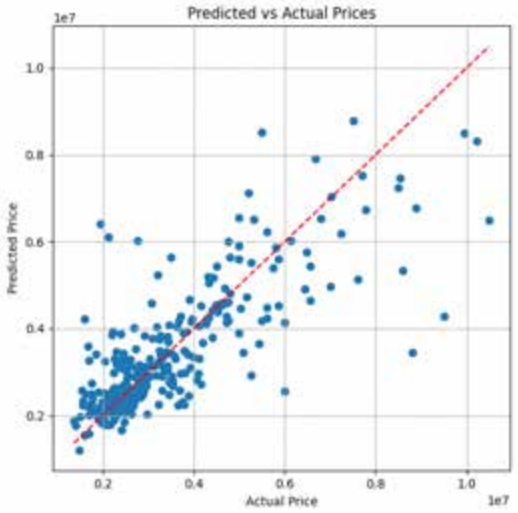

Fig. 10. Baseline Model Predicted and Actual Price

4.2. Linear Regression Results

In the second phase of the study, housing prices were assessed using a linear regression model. The outcomes of the model are outlined in Table 4. The Linear Regression model exhibits a moderate level of predictive performance, with an R-squared value of 0.6108. This indicates that approximately 61% of the variability in housing prices can be explained by the model's features. However, the high Mean Squared Error (over 1.1 trillion) and a Root Mean Squared Error of about 1,045,316 suggest that the model's predictions significantly deviate from the actual prices in absolute terms. This level of error may be considerable, depending on the typical price range in the dataset. Overall, while the model identifies some meaningful trends, its precision is limited, indicating significant room for improvement. This could potentially be achieved through the use of more advanced modeling techniques or enhanced feature engineering.

Table 4. Linear Regression Results

Mean Squared Error	1,092,686,523,151.36
Root Mean Squared Error	1,045,316.47
R-squared	0.6108

Figure 11 illustrates the predicted housing prices compared to the actual prices generated by the Linear Regression model. There is a general upward trend, indicating that the model captures some relationship between the features and the target variable. However, the predictions tend to cluster within a narrower price range. Notably, the model underestimates the prices of high-end properties while overestimating some lower-priced ones. This is evident as many data points significantly deviate from the red dashed line, which signifies perfect prediction. The scatter of points, particularly at both the high and low ends of the price spectrum, visually reinforces the earlier numerical evaluation, highlighting the model's difficulty in accurately capturing the full variability of housing prices.

Fig. 11. Linear Regression Predicted and Actual Price

Applying a logarithmic transformation to the target variable (price) in the linear regression model resulted in a slight improvement in explanatory power, with the R^2 value increasing from 0.6108 to 0.6168. More significantly, the Root Mean Squared Error (RMSE) experienced a dramatic decrease from over 1 million in raw prices to just 0.28 on a log scale. This indicates a substantial reduction in relative error. The findings suggest that the model is more effective at predicting proportional (percentage) differences in price rather than absolute price values. Additionally, log transformation stabilizes variance and diminishes the impact of extreme outliers, leading to more consistent predictions across various price ranges. Although the log price transformation slightly improved the model's predictive accuracy (as reflected by a higher R^2 value), converting the predictions back to actual price values resulted in significantly inflated estimates. This suggests that while the log transformation helps with model fitting, it may distort the predicted values when inverse-transformed, especially in the presence of skewed data or outliers. For this reason, the actual price value was used as the dependent variable in the study instead of the log transformation of the price.

4.3. Random Forest Results

In the third phase of the study, housing prices were evaluated using a random forest model (see Table 5). The Random Forest Regressor model, after undergoing hyperparameter tuning, achieves an R^2 of 0.7233. This indicates that the model explains approximately 72% of the variance in housing prices, which is a significant improvement over linear regression. The model's Root Mean Squared Error (RMSE) is around 881,343 reflecting a lower average prediction error and demonstrating its ability to effectively manage the complexity and nonlinearity of the housing data. When compared to the untuned version, which had an R^2 of 0.7227 and an RMSE of approximately 882,200 the tuning process has resulted in a modest improvement. Overall, this tuned Random Forest model provides robust and reliable results for predicting property prices.

Table 5. Random Forest Results

Mean Squared Error	776,765,523,406.89
Root Mean Squared Error	881,343.02
R-squared	0.7233

Compared to the linear regression model, the scatter plot for the Random Forest Regression (Figure 12) shows a more accurate alignment of predicted prices with actual prices, particularly for mid- to high-range properties. While both models display some spread, the Random Forest's predictions are generally closer to the diagonal reference line, indicating improved accuracy. It captures nonlinear relationships better, reducing systematic underestimation of expensive properties seen in the linear model. Although slight over- and under-predictions remain, especially at the extremes, this plot visually confirms that Random Forest provides a more reliable fit than linear regression in modelling complex housing price patterns.

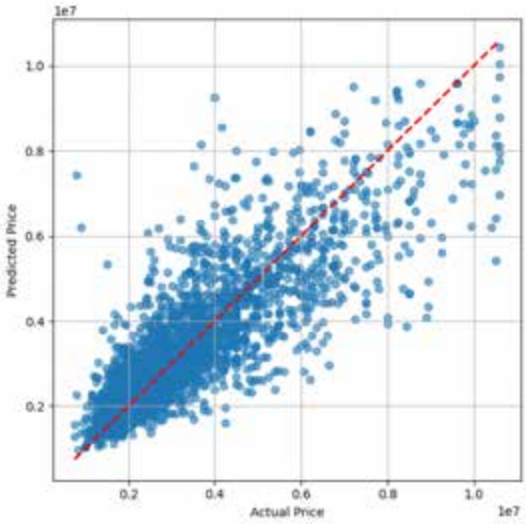

Fig. 12. Random Forest Predicted and Actual Price

5. Discussion

This study aims to achieve a more precise estimation of housing prices by utilizing advanced analytical methods. To accomplish this, it compares both linear and non-linear specifications of the hedonic price model, a widely recognized framework in housing market research. Table 6 compares actual housing prices with predictions made by Linear Regression and Random Forest models across the 15 most expensive neighbourhoods. The Linear Regression model tends to underestimate housing prices, particularly in high-value areas such as Fatih Sultan, Mutlukent, and Çukurambar. This indicates the model's limitations in capturing non-linear patterns and extreme values. In contrast, the Random Forest model provides more accurate and stable predictions, often aligning closely with actual prices and even slightly overestimating in some cases, such as in Koru. This suggests that the Random Forest model is better suited for capturing the complex relationships present in housing data and performs more robustly in high-price segments. However, both models exhibit certain deviations from actual prices, which highlights opportunities for further improvement.

Table 6. The comparison Linear Regression and Random Forest Prediction with Actual Price

Neighborhood	Actual Price	Linear Regression Prediction	Random Forest Prediction
Fatih Sultan	9,850,000	6,378,664	7,845,811
Mutlukent	8,600,000	5,563,571	6,469,399
Çukurambar	8,525,000	5,180,941	5,590,277
Üniversiteler	8,500,000	4,030,711	4,646,521
Emniyet	8,475,000	6,275,043	6,284,633
Koru	8,450,000	4,414,746	3,867,666
Kızılırmak	7,833,333	5,140,973	6,797,407
Alacaatlı	7,815,000	5,886,321	6,887,986
Koparan	7,700,000	10,320,204	9,194,666
Bademlidere	7,606,250	7,221,187	7,895,229
Yaşamkent	7,180,000	7,017,621	7,152,333
Bağlıca	6,740,580	4,632,440	5,920,819
Malıköy	6,649,166	6,962,850	6,251,322
Bahçelievler	6,587,500	4,444,840	5,760,515
Beştepe	6,500,000	4,066,717	5,365,666

Based on the results of the predictive modelling, housing affordability in Ankara varies significantly across neighbourhoods. Certain neighbourhoods, such as Fatih Sultan, Mutlukent, Üniversiteler, and Çukurambar, consistently show high actual prices, indicating low affordability, particularly since the model tends to underestimate these values. This underestimation may be due to unobserved amenities or factors that contribute to desirability, which are not fully captured by the model's features. Additionally, the substantial prediction errors in high-priced neighbourhoods suggest that affordability challenges in these areas may be more severe than initially indicated by the data. In contrast, the model performs better in moderately priced neighbourhoods, which may imply more predictable and accessible housing conditions in those locations. To enhance the analysis and provide a more comprehensive understanding of affordability across the city, incorporating socioeconomic indicators such as household income, employment rates, and demographic characteristics would be beneficial.

The analysis indicates that the neighbourhoods with the highest housing prices—Kızılırmak, Çukurambar, Üniversiteler, Mutlukent, Yaşamkent, Koru, Alacaatlı, Fatih Sultan, and Bağlıca—are clustered along the Eskişehir Road, to the west of the city centre. It can also be inferred that the properties in the adjacent neighbourhoods of Çayyolu and Beytepe are unaffordable. Furthermore, high housing prices are observed in the neighbourhoods located west of the Konya Road, which serves as one of Ankara's main transportation axes. These neighbourhoods include Beştepe, Emniyet, İşçi Blokları, and Çiğdem. In Gölbaşı, the neighbourhoods of Ballıkpınar, Hacılar, Tulumtaş, and Koparan also experience elevated prices. This trend can be attributed to the fact that the housing typologies in these areas are primarily detached homes.

The analysis highlights a concerning trend of increasing housing unaffordability in Ankara, especially in neighbourhoods along the Eskişehir and Konya Road corridors. These areas, known for their high-income residents and mainly planned developments with detached single-family homes, have seen substantial increases in property prices in recent years. As a result, housing in these districts has become prohibitively expensive for middle- and lower-income residents. This ongoing rise in housing costs worsens spatial inequality throughout the city. Not only is housing affordability compromised, but the diverse socio-economic backgrounds that once characterized

these neighbourhoods are also increasingly at risk. The current scenario in Ankara highlights a significant trend of urban segregation, where many individuals find the aspiration of owning a home increasingly out of reach. This reality not only deepens existing social divides but also inhibits community cohesion, ultimately impacting the overall cohesion within the city.

6. Conclusion

Given the increasing economic pressures and rising housing prices in Turkey, especially in Ankara, it has become crucial to develop accurate and effective methods for predicting housing market trends. To monitor housing market dynamics, the hedonic price model has long been used to monitor housing market dynamics. However, this model has some structural limitations. Predicting housing prices is challenging. The Central Bank of Türkiye has published a Residential Property Price Index monthly since 2010 to monitor price movements, but it only includes dwelling units valued for housing loans, representing just 35–40% of the market (Özdemir Sarı, 2019). This limits its effectiveness in capturing the overall housing market dynamics. Traditional hedonic price models often use linear regression methods, which fail to account for the complex, non-linear relationships between housing prices and their attributes. This study proposes an innovative approach aimed at refining housing price estimates by effectively addressing the inherent limitations of traditional hedonic models and significantly enhancing the representativeness of the data utilized. Through a comprehensive analysis that compares linear regression and random forest methodologies, the findings indicate that the random forest model consistently yields superior predictive accuracy and reliability.

The findings highlight growing concerns about housing affordability in Ankara, revealing significant disparities between neighbourhoods. Wealthier districts along the Eskişehir and Konya Road corridors—such as Fatih Sultan, Çukurambar, Mutlukent, and Alacaatlı—consistently show high property prices, which predictive models often underestimate. This discrepancy indicates that these areas likely possess unmeasured qualities, such as better amenities or prestige, that structural features alone do not capture. Consequently, affordability in these neighbourhoods is probably even lower than suggested, creating barriers for middle- and low-income households. Additionally, the concentration of high-priced, low-affordability neighbourhoods in the western and southwestern parts of the city reveals a trend of spatial and socioeconomic segregation. The increasing exclusivity of these areas, combined with rising prediction errors in high value zones, suggests a widening gap in access to housing. To fully understand and address this issue, future modelling efforts should incorporate socioeconomic indicators and neighbourhood-level attributes. Doing so would help capture the complex nature of urban housing markets and support more informed urban planning and policy decisions aimed at improving housing accessibility and equity.

The current analysis relies solely on structural characteristics of housing and neighbourhood as a binary variable. Incorporating additional location-specific and neighbourhood attributes, such as proximity to amenities, schools, public transportation, crime rates, and green spaces, has the potential to significantly enhance the accuracy of the predictive model. Urban housing markets exhibit considerable complexity, rendering them ineffective as a singular, homogeneous market. This complexity arises from a variety of factors, including socioeconomic diversity, varying demand and supply dynamics, and distinct local regulations. As a result, making predictions tailored to specific sub-markets within the urban landscape can lead to improved prediction rates and more reliable insights into housing trends and pricing fluctuations.

Nigerian Housing Development Policies Impact on Lagos Housing Deficit (1960 – 2020) A Critical Literature Review)

Oluwapelumi Obayanju
Technische Universität Berlin
Faculty VI Planning Building Environment
Institute of Urban and Regional planning
Department of Urban renewal and Settlement planning.
oluwapelumi.obayanju@campus.tu-berlin.de

Abstract
This paper critically examines the evolution of housing development policies in Lagos, Nigeria, from 1960 to 2020, and their subsequent impact on the housing deficit in the region. The literature review integrates various scholarly sources that explore the historical context, the emergence of different housing policies, and the effectiveness of these strategies in addressing the housing gap in Lagos. This research finds out and evaluates the predominant housing development strategy within the housing development phases, and its implementation in Lagos Nigeria,
The findings highlight that despite numerous policies implemented by the Nigerian government, the housing deficit remains a persistent challenge due to issues at the level of execution, funding, and gaps between the policies and the populace. This research aims to contribute to the understanding of how policy evolution shapes housing development and proposes recommendations for more effective approaches in the future.

Keywords: Housing: policies, development, deficits, challenges, implementation

1.0 INTRODUCTION

The evolution of housing development policies in Lagos has been driven by the city's rapid population growth and urbanization since Nigeria's independence in 1960. The migration of people seeking better opportunities has intensified the housing deficit, leading to a series of policy interventions aimed at providing affordable housing solutions (Owolabi et.al 2023; Heinrich Böll Stiftung 2023). Despite the efforts, Nigeria faces a housing deficit of around 22 million, with Lagos accounting for approximately 4.7 million of these figures (World Bank, 2023; Oluwatayo & Amole, 2021; Heinrich Böll Stiftung 2017, 2023). The cost of housing continues to rise, making it unaffordable for low and medium-income earners. Over the years, five National Housing Development Phases from 1960 to 2020 have attempted to address the housing gap, but many planned housing units were never constructed.

State-initiated housing in Nigeria began during the colonial era, particularly after the 1920s bubonic epidemic in Lagos. Housing projects were initially targeted at expatriates, leading to the creation of Government Reserved Areas. Direct Housing Construction emerged as a predominant strategy for low-cost housing schemes. This approach, along with Site and Services strategies, has remained prevalent (Bello, 2019; Ayoade & Onifade 2020; Chinwe 2015). Other strategies include Slum Clearance and Resettlement and Core Housing/Incremental Housing (Olotuah, Taiwo 2015; Ibimilua & Ibitoye 2015; NBRRI 2013). However, these initiatives have not effectively reduced the housing deficit.

Currently, approximately 60% of Nigeria's population lives in urban centres, with most state-led housing interventions focused on these areas (World Bank Data, 2024). Lagos, as the case study for this research, exemplifies the urban housing crisis. The paper evaluates the various housing development phases to identify the predominant strategy implemented during each period and assess its effectiveness. Despite the numerous policy phases, the critical question of how to reduce the housing gap and provide affordable housing for urban middle-income and low-income demographics remains unanswered. This research aims to trace the missing links in the effectiveness of Nigerian housing development policies from 1960 to 2020, using Lagos as a case study. The study benchmarks each housing development phase against the realization of estimated housing stocks to understand the practical outcomes of stated policies.

2.0 METHOD AND DEFINITIONS

2.1 Method

This publication is conducted using critical literature analysis (Rachel R.N 2024, Jack Caulfield 2025) by reviewing literatures and analysing the key thread of thought regarding housing development policies and deficits in Nigeria and Lagos City to identify the way forward in the Nigerian context.

The data collection process in the literature review is structured around this main theme of evaluating the successive housing development policies in Nigeria and finding the predominant housing policies, this enabled to trace the missing link in the effectiveness of the Nigerian Housing development polices 1960-2020, with Lagos as case study. Within the context of the literature reviews, the following questions served as guiding compass; What lead to the initiation of each housing development phases and the proposed number of housing units that were planned for each phase? How the realizations and the non-realization of stated housing stocks for each housing development phase has led to the current housing deficits? How the patterns of the relationship between the challenges of each predominant housing strategy have evolved over time to the current housing backlogs? How the predominant housing strategies has been operationalized in Lagos Nigeria within the time frame 1960 – 2020. The literature comes from peer-reviewed outlet such as journals, conference proceedings, book chapters, also included were other documents from organizations, government parastatals, and research institutions within housing research framework. These questions were the key words that were used for data collection, from the bulk of search results, the total of the cited references was eventually reviewed, and this led to the conclusion and findings.

2.2 Case Study

The case studies within the context of this research refers to the studied literatures and the geographical urban context of Lagos city with respect to its housing polices and deficits.

Research identifies Lagos as a significant case study due to its rapid urbanization and housing deficit. As Africa's largest city and projected to be the world's largest by 2100, Lagos' housing policies have evolved since the colonial era and the establishment of the Lagos Executive Development Board in 1948 (World Bank, 2023; Victor, 2022; Ayoade & Onifade, 2020).

The city was central to the First National Housing Development Scheme from 1962 to 1968 and has seen various state-initiated housing policies since 2000 (Olotuah & Taiwo, 2015; UNHabitat, 2015; Aduwo et.al, 2016).

2.3 Definition of Terms

2.3.1 Housing

According to the Nigerian National Housing Policy Handbook (2010), housing involves providing safe, comfortable, functional, affordable shelter within a neighbourhood, supported by continuous maintenance. Housing includes sustainability attributes like energy efficiency and resource conservation for improved quality of life (Nigerian Government, 2007). UN-Habitat (2022) defines housing as a physical structure providing shelter and necessary services for health, security, and well-being. The World Health Organization (WHO, 2021) emphasizes housing's role in public health, considering the residential environment and its impact on well-being. The Universal Declaration of Human Rights states that adequate housing is a fundamental right for health and well-being (United Nations, 1948). Overall, housing encompasses social, economic, and environmental aspects contributing to the quality of life.

2.3.2 Housing Development Policy

Researchers such as Moore 2019, Schmidt 2023 asserts that housing development policy consists of laws, regulations, and administrative practices aimed at producing and delivering housing. It provides guidelines and goals but does not specify detailed strategies, establishing limits for discretionary actions. The primary goal of Nigeria's national housing policy is to make decent shelter available and affordable for all. It addresses land ownership, housing finance, and construction and delivery (Nigerian Government 2007). A policy requires a strategy

for enforcement to achieve the intended programmes of action.

2.3.3 Housing Deficit

Housing deficit refers to the gap in the number of houses needed to accommodate a population (Moore 2019). It includes inadequate shelters and overcrowded conditions. The deficit can be measured annually or as a backlog. It is also defined as the difference between households and permanent dwellings and can be estimated for a specific period or date.

In Lagos, 75.0 per cent of the housing deficit affects families earning less than three times the minimum wage (World Bank 2020)

3.0 RESULTS

Housing is a critical issue in Nigeria, driven by rapid urbanization and population growth. The country's housing deficit is estimated to be around 22 million units, placing immense pressure on housing markets (Akeju, 2007). This demand has led to informal settlements, inadequate housing conditions, and overcrowding. Challenges include inadequate funding, high building material costs, lack of infrastructure, and inefficient policies (Ibem & Amole, 2010). The underdeveloped mortgage market and complex land tenure systems, governed by the Land Use Act of 1978, further complicate housing development (Omirin, 2002). Bureaucratic delays and inconsistent government policies also hinder progress.

Successive Nigerian governments have introduced initiatives to improve housing. The National Housing Policy (NHP), revised in 2012, aims to provide affordable, sustainable housing by encouraging private-sector involvement and public-private partnerships. The Federal Mortgage Bank of Nigeria (FMBN) was established to provide long-term credit facilities to mortgage institutions. The National Housing Fund (NHF), managed by the FMBN, encourages Nigerians to contribute towards homeownership (Akinmoladun & Oluwoye, 2007). However, the effectiveness of these policies is limited by corruption, fund mismanagement, and the NHF's inability to meet housing finance demand (Olotuah & Bobadoye, 2009).

Mass housing schemes like the Federal Housing Authority (FHA) estates aim to provide affordable homes to low- and middle-income earners. Despite efforts, the number of houses built remains insufficient to meet the housing deficit (Ibem, 2011). Private-sector involvement through public-private partnerships (PPPs) has increased, with projects like Lekki Gardens and Eko Atlantic City addressing urban housing needs (Olayiwola, Adeleye, & Ogunshakin, 2005). However, private developments often cater to higher-income groups, excluding many low-income earners (Makinde, 2014).

To address the housing crisis, experts advocate sustainable policies targeting urban low- to middle-income earners, such as slum upgrading and urban renewal, to improve informal settlements (Ibem & Aduwo, 2013).

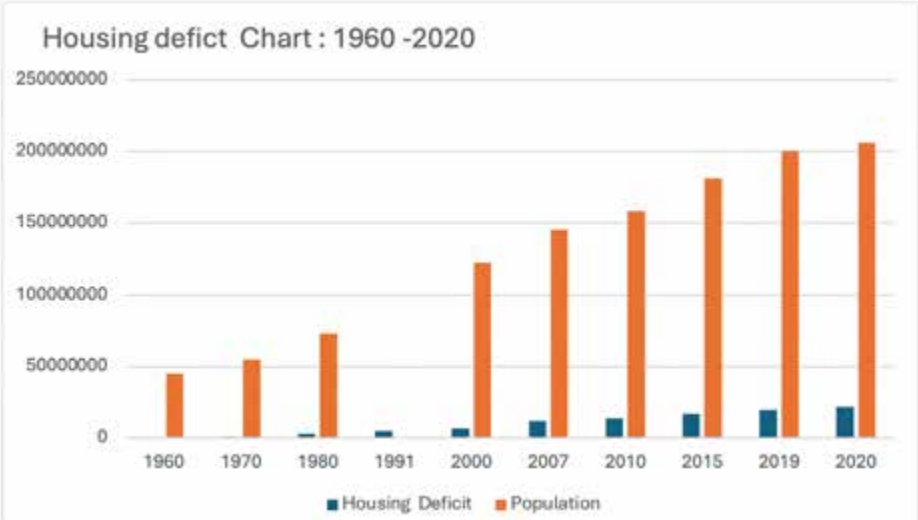

Figure 1. Housing deficit trend chart in Nigeria between 1960-2020
Sources: FMWHN (2007), Aribigbola (2008), Ibem (2011), UNHabitat (2006,2015), World Bank (2016), Pison (2019), Federal Mortgage Bank of Nigeria (2020); Adeoye et al. (2020), Statista (2024)

Private-sector developments often cater to higher-income groups, excluding most Nigerians (Makinde, 2014). Experts recommend sustainable policies targeting urban low- to middle-income earners, such as slum upgrading and urban renewal, to improve informal settlements (Ibem & Aduwo, 2013). By providing essential infrastructure like roads, water, and electricity, the government can significantly enhance living conditions for millions residing in informal housing, addressing the widespread housing crisis in Nigeria (Ibem & Aduwo, 2013).

3.1 History of National Housing Development Policy Phases in Nigeria (1960-2020)

Ayoade, A. & Onifade, V. (2020) stated that the Nigerian Public Housing involvement began in the colonial time following the 1920s eruption of the bubonic epidemic in Lagos. During the period 1900 – 1960, government involvement was targeted particularly on the delivery of accommodation for foreign personnel and selected native personnel-the government did not attempt to provide housing for the public. Since the independence of Nigeria in 1960 the government had adopted various strategies in its intervention in housing. The Federal Government has over the years made substantial allocations to the housing sector in the various National Development Plans (Olotuah O, Taiwo A.A ;2015).

PHASE	YEAR	HOUSING DEFICIT	NATIONAL POPULATION	HOUSING POLICY
First National Development Plan (1962-1968)	1960	500,00	45,000,000 million	Direct Housing Construction
	1970	1 million	55,000,000 million	
Second – Fourth National Development Plan (1970-1985)	1980	3 million	73,000,000 million	

Fifth National Development Plan (1962-1968)	1991	5 million		Site and Services Housing Policy + Direct Housing Construction
	2000	7 million	122,000,000million	
	2007	12 million	145,000,000 million	
	2010	14 million	158,000,000 million	
	2015	17 million	181,000,000 million	
	2019	20 million	200,000,000 million	
	2020	22 million	206,000,000 million	

3.1.1 The First National Development Plan (1962-1968): Adoption of Direct Housing Construction

The First National Development Plan was Nigeria's inaugural attempt at systematic economic planning after gaining independence in 1960. The plan aimed at transforming the economy from a colonial-dependent structure into a more diversified and self-reliant one. It focused on industrialization, agriculture, transportation, education, and urban development, with significant allocations to infrastructure and social services (FRN,1981). Housing was a component of the broader urban development agenda, reflecting the growing demand for residential accommodation due to rapid urbanization, particularly in Lagos. The effort of government at housing provision was focused principally on Lagos, the then capital city of Nigeria, as it became the centre of economic activities under the development plan, the city attracted a significant influx of migrants from rural areas seeking better economic opportunities. This migration led to a population surge in Lagos, causing an unprecedented demand for housing. By the mid-1960s, Lagos' population had nearly doubled, putting immense pressure on the city's infrastructure and available housing (Mabogunje,1990). The government recognized the need to address this housing crisis, but the rapid rate of urbanization outpaced development efforts.

The Federal Government proposed the construction of 61,000 housing units but only 500 units (less than 1%) were built. The political chaos and the resulting civil war (1966-1970) contributed to the marginal progress recorded during this period.

Under the First National Development Plan, the Nigerian government-initiated housing projects to address the urban housing shortage. The Lagos Executive Development Board (LEDB) played a central role in implementing these projects. One of the notable projects was the construction of low-cost housing estates, such as the Surulere Housing Estate, which was developed to provide affordable housing for middle- and low-income earners. Despite these efforts, the number of units produced was insufficient to meet the growing demand.

The housing estates built during this period provided some relief but were largely inadequate for Lagos' rapidly growing population.

This resulted in total of 60,500 housing deficit backlog in Lagos Nigeria, according to Macrotrend, (2024), the total population growing from 926,000 – 1,353,000 during this time frame.

The First National Development Plan laid the groundwork for future housing policies in Lagos, even though its immediate impact on housing supply was limited. The period highlighted the need for more comprehensive urban planning and a targeted housing policy. It also set the stage for subsequent development plans, such as the Second National Development Plan (1970-1974), which gave greater emphasis to housing and urban development, attempting to address the deficits left by the first plan.

3.1.2 Second National Development Plan (1970-1974): Development of Estates

The Second National Development Plan (1970-1974) followed the first national development plan with the aim of addressing the country's post-civil war reconstruction and economic development needs. This plan aimed to improve various sectors, including housing, infrastructure, and industry, with Lagos being a focal point due to its status as the economic hub and the capital at the time.

In Lagos, the federal government initiated several housing programs under the Plan. For instance, the Federal Housing Authority (FHA) was established in 1973 to oversee housing development across the country, with Lagos being a major beneficiary due to its status as the capital. The FHA's early interventions included the construction of large public housing estates aimed at providing affordable homes for low- and middle-income earners.

One of the notable housing projects initiated during this period was the construction of FESTAC Town, designed as a residential area for participants of the 1977 Second World Black and African Festival of Arts and Culture (Omirin, 2002). Although FESTAC Town was planned during the 1970-1974 development period, its completion occurred later. Still, the town represents the impact of federal planning and urban development policies initiated under the Second Plan.

The Federal Government initiated the National Housing Programme and Direct house construction for the public during the Second Development Plan Period. It planned to build 59,000 housing units throughout the federation. In that plan period government also established the National Council on Housing which consisted of all State Commissioners of Works and Housing. Monies allocated by the federal government and some state governments were negligible while some states did not allocate money for such programs.

The impact of the Second National Development Plan on Lagos' housing sector was mixed. While the government made significant strides in constructing public housing estates, the population growth in Lagos, driven by rural-urban migration, far outpaced the available housing stock. Between 1963 and 1974, Lagos experienced a population explosion from about 665,000 to over 1.4 million people (Mabogunje, 1990). This rapid growth led to severe housing shortages, despite the government's efforts.

The Plan's focus on state-driven housing schemes reflected a broader national strategy of public sector involvement in housing delivery. However, bureaucratic inefficiencies, poor implementation, and corruption marred the realization of many of the ambitious housing projects (Agboola, 1997). As a result, housing deficits in Lagos continued to grow, leading to the proliferation of informal settlements and slums across the city.

Nevertheless, the development plan did have lasting impacts on Lagos' urban landscape. Large-scale public housing estates such as Surulere and Dolphin Estate are products of the government's post-civil war efforts to provide mass housing for Lagosian (Onibokun, 1985). These estates helped shape the city's urban development pattern, though they ultimately fell short of solving the housing crisis.

3.1.3 Third National Development Plan (1975-1980): Mortgage Loan and Public official quarters

In the Third Development Plan government pledged to provide housing for all income groups, especially low-income groups, and to ensure that average urban workers did not pay more than 20% of their monthly income as rent.

The thrust of the government's effort was the direct construction of housing units at the Federal and State levels, increased construction of quarters for public officials, and expanded credit facilities to enhance private housing construction.

A target of 202,000 housing units was set by the Federal Government of Nigeria (FGN), however, the actual number of units constructed was 28,000 which was only 14% of the target set (FGN, 2004) or about 3% of the actual housing shortage of 867,000 by 1975 (Benjamin, 2000).

3.1.4 Fourth National Development Plan (1981-1985): Affordability and citizen participation

The Fourth National Development Plan witnessed a housing provision drive based on the concept of affordability and citizenship participation, this was necessary because of economic difficulties, particularly after the oil bust of the early 1980s, affected housing policies, and the government introduced Structural Adjustment and Economic Liberalization Program (SAP), this reduces the government's ability to fund large-scale housing projects

diminished, leading to a shift in focus towards private sector participation.

The government planned the construction of 160,000 housing units nationwide between 1979 and 1983. It proposed the construction of 2,000 houses for each of the then 19 states and Abuja annually, out of which 80% was earmarked for low-income earners. By 1983 only about 20% of the set target was achieved (FGN, 2004, Olotuah 2020).

The second phase of the housing program (with a target of 20,000 dwellings to be built all over Nigeria) was initiated mid-way through the first phase. It did not take off in several states mainly because of undue politicization and the uncooperative attitude of the state executives.

Precisely 47,500 housing units were built across Nigeria, and 2,634 housing units were built in Lagos Nigeria, and Lagos population grew from 2,736,00 to 3,500,000 during this time frame.
The planned housing unit to be built in Lagos during this phase was 10,000 units, however 2,634 housing units were realised, this created a backlog of 7,366 housing units

3.1.5 Fifth National Housing Policy Phase (1984 -2020 – till present): Combination of Strategy
The strategies of the government in the realization of its housing programs changed in 1984 from direct housing construction to the provision of sites and services. The sites-and-services program was handled by the Federal Ministry of Works and Housing. Between 1984 and 1988, the ministry developed 20 estates with 11,393 serviced residential plots.

In 1991 the Federal Government formulated the National Housing Policy, the goal of which was to ensure access to adequate and affordable housing for all Nigerians by the year 2000. Towards achieving the goal of the National Housing Policy, it was estimated that a total of eight (8) million housing units would be required to cater to the existing and future needs of the population. These were further broken down into five million for the urban areas and three million for the rural areas. Eight hundred thousand (800,000) housing units were estimated to be constructed yearly to meet this need.

In 1994 the Federal Government initiated a new housing scheme and proposed to build 121,000 housing units in state capitals where housing needs were acute. Only 1,114 housing units were completed (in Kado Estate Abuja) and commissioned on 15 December 1994 (Benjamin, 2000).

In 2004 the Federal Government proposed the construction of 18,500 housing units throughout the federation, with at least 500 units in each of the states of the federation and the Federal Capital Territory. The program took off in April 2005 in Ekiti State.

The major thrust of the Fifth National Housing Policy was the development of a housing finance system geared towards ensuring an enabling environment for the generation of housing finance, with the private sector as the main source. For the realization of this objective, the National Housing Fund (NHF) was established by the enactment of Decree No. 3 of 1992. Decree No. 82 of 1993 reorganized the mortgage industry with the deconsolidation of the Federal Mortgage Bank of Nigeria (FMBN). The NHF was established primarily to address the constraint of the mobilization of long-term funds for housing development and to nurture and maintain a stable base for affordable housing finance. Thus, it was to facilitate the mobilization of low-cost funds as long-term loans for building, purchasing, and improving houses.

The poor performance of the National Housing Policy in meeting its set goals and objectives led to a comprehensive review, which culminated in the Housing and Urban Development Policy of 2002. The new National Housing Policy was proposed in 2002, and its first draft came into publication in January 2004. The 2002 National Housing Policy was aimed to increase housing supply, provide affordable housing, increase Public-Private Sector Participation and land reforms, but these were not achieved because many of the housing projects catered more to the middle and high – income groups

3.2 EVOLUTION OF HOUSING DEVELOPMENT IN LAGOS CITY

3.2.1 Lagos City: Urbanization, Housing Development and Government Actors

Lagos, Nigeria's commercial center, faces significant housing challenges, including a shortage of quality housing, infrastructure, overpopulation, poverty, and inequality. These issues have led to high rents, overcrowding, slums, and substandard housing (Housing and SDG IN Urban Africa, 2021). Urbanization is characterized by high population densities, urban sprawl, and informal settlements, with about 66% of residents living in slums lacking basic services (UN-Habitat, 2020). Estimates indicate a housing deficit of over 3 million units (Olotuah, 2016), exacerbated by rapid growth, high land prices, and ineffective housing policies.

Before 1928, planned residential areas in Lagos were limited to Ikoyi, Apapa, Ebute Metta, and Yaba. Ikoyi housed expatriates, while the other areas had some planned road networks. Lagos Island's indigenous housing was unplanned and overcrowded, leading to influenza epidemics and bubonic plague between 1924 and 1930. The Lagos Executive Development Board (LEDB) was established in 1928 to clear slums and relocate families to Surulere. Planning authorities have since become important in metropolitan Lagos.

The Ikeja Area Planning Authority (IAPA) was created in 1956 to control development outside the Federal Capital Territory. In 1958, the Western Nigeria Housing Corporation was established to provide housing finance. In 1972, the LEDB, IAPA, and Epe Town Planning Authority merged to form the Lagos State Development and Property Corporation (LSDPC) to improve efficiency in the housing sector (Lagos State Government, 2022).

The Jakande administration (1979-1983) implemented a massive housing development program, but rapid population growth and economic challenges, including the introduction of the SAP in 1986 and increased petroleum fuel prices in 1994, have exacerbated housing issues. The federal government's 1994 National Housing Scheme for Lagos has stalled due to rising building material costs. Despite five phases of the National Housing Development Plan (1962-2020), affordable housing for middle and low-income residents remains an unresolved issue, with a housing deficit of around 4.7 million units in Lagos (Heinrich Boell Foundation, 2017, 2023).

3.2.3 Lagos Housing Development Distribution

Lagos is divided into two main areas: the Island, with affluent neighbourhoods like Ikoyi, Victoria Island, and Lekki, and the mainland, which has middle-class areas like Surulere, Yaba, and Ikeja, alongside informal settlements. The Island is known for luxury developments driven by high land values (Aluko, 2011). Rising housing costs on the mainland push middle-income earners to less-serviced areas (Ajibola et al., 2012). Housing development in Lagos is unequal, reflecting socio-economic disparities. Government efforts often exclude the urban poor, while private sector focus on luxury housing exacerbates inequality. Addressing these housing challenges requires more inclusive policies and equitable development distribution.

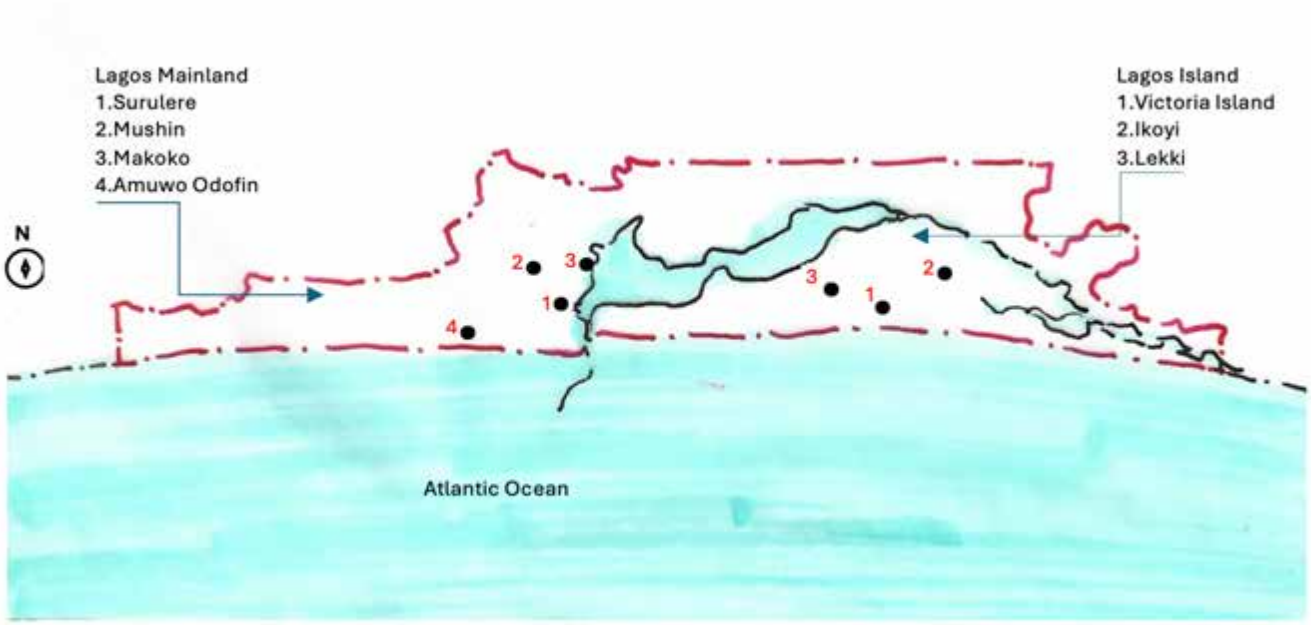

Figure 2. Map of Lagos showing Island (High Income earners areas - Victoria Island, Ikoyi, Lekki) Mainland (Middle income areas-Surulere, Yaba, Ikeja, Low-income areas – Mushin, Ajegunle, Makoko) and the distribution of the post-independence housing projects within the city

3.3 THE PREDOMINANT HOUSING POLICIES AND PROGRAMMES IN LAGOS (1960 – 2020)

From the forgoing evaluation of the five successive housing development policies phases, and how the unrealised housing unit target led to the accumulated deficit, one can see that the two predominant housing development policies are Direct Housing Construction and Site-Services System of housing development has been used so far in Nigerian and as well in Lagos City, this is further established what researchers such as Egidario B. Aduwo, Patrick A. Edewor, Eziyi O. Ibem (2016) stated , that successive governments in Nigeria have since the mid-1920s engaged in different strategies in attempts to resolve urban housing challenges confronting low-income earners, and these strategies are the two predominant housing development strategies are Direct Housing Construction and Site -Services Policy.

3.3.1 DIRECT HOUSING CONSTRUCTION

3.3.1.1 Slum Clearance and Resettlement Strategy

Slum clearance or slum evacuation is an urban renewal strategy aimed at redeveloping low-income settlements into new developments or housing. This method has long been used to rebuild urban areas (Young 2016). Slum upgrading, another approach, aims to address legal, physical, social, and economic issues in an area. This includes legalizing land tenure and improving infrastructure and services, which fosters a sense of ownership and investment among residents (City Alliance 2024).

Slum upgrading involves repairing and renewing areas to prevent further deterioration. It is a cooperative effort between the state and residents, where the state provides serviced sites for residents to design and build their own housing (Amany Ragheb; Rsha El-Ashmawy, 2021). The approach became popular in Africa in the 1970s and 1980s, heavily influenced by the World Bank's views on minimal state involvement and community participation. However, Werlin (1999) argues that relying on a minimal and often weak state to address slum issues is an illusion, and there are reservations about the effectiveness of community participation (Adama 2020).

In Lagos, Nigeria, from 1960 to 2020, slum clearance and resettlement projects reflected the city's rapid urbanization and the challenges of managing informal settlements. These efforts have often been characterized by a tension between urban modernization goals and the needs of the city's poor. While there have been attempts to improve living conditions through upgrading and resettlement, these efforts have frequently fallen short, leading to ongoing housing and urban development challenges.

Implementation of Slum Clearance and Resettlement Strategy in Lagos
Obalende and Mushin Slum Clearance Attempts(1960s-1970s): In the late 1960s, the Lagos Executive Development Board (LEDB) initiated early attempts at slum clearance, focusing on areas like Obalende and Mushin. However, these efforts were relatively small in scale and often displaced residents without providing adequate resettlement options.

Maroko Evictions (1970s-1980s): One of the most significant slum clearance projects occurred in 1990, under the military regime of General Raji Rasaki. The government forcibly evicted over 300,000 residents from the Maroko slum, located in a prime area close to Victoria Island. The stated aim was to reclaim the land for development and address environmental concerns. The Maroko evictions were highly controversial, criticized for their brutality, lack of proper resettlement, and the failure to provide adequate compensation. The cleared land was later developed into high-end real estate, highlighting the socio-economic divide in Lagos.

Olusosun and Other Clearances (1990s – 2000s): As Lagos continued to grow, more slums were targeted for clearance. The Olusosun slum, located near the city's main landfill, was one such area. Evictions were often justified on the grounds of environmental health and urban renewal, though they frequently led to displacement without adequate alternatives for the residents.

Makoko and Otodo-Gbame Evictions (2012,2017): High-profile evictions in areas like Makoko (a waterfront slum) and Otodo-Gbame highlighted ongoing tensions between slum residents and the state. In 2012 and 2017, these communities faced forced evictions, often justified by the government as necessary for environmental reasons or urban development. These evictions were widely criticized by human rights organizations for their lack of due process and failure to provide resettlement options.

Badagry and Ikorodu Resettlement Program (2010s – 2020s): In recent years, there have been some efforts to provide resettlement for displaced communities, but these have often been inadequate. New resettlement areas, such as those in Badagry and Ikorodu, are usually far from the city centre, lacking basic infrastructure, and often fail to meet the needs of displaced residents.

Overall, slum clearance and resettlement projects in Lagos have been characterized by a tension between the goals of urban modernization and the needs of the city's poor. While there have been attempts to improve living conditions through upgrading and resettlement, these efforts have often fallen short, leading to ongoing challenges in housing and urban development.

3.3.1.2 Core Housing Strategy
Core housing policy refers to the set of principles, strategies, and measures implemented by governments and institutions to ensure that citizens have access to adequate, affordable, and safe housing. It is a key component of social policy aimed at addressing housing needs, reducing homelessness, and ensuring that housing is accessible to all socio-economic groups, particularly vulnerable populations. (OECD 2021, UN -Habitat 2020, World Bank 2020)

The core housing strategy evolved significantly in Lagos between 1960 - 2020 due to various factors, including population growth, urbanization, economic changes, and government policies Despite government efforts, informal and incremental housing development which is a parallel self-made system emerged as a solution to the housing deficit. Individuals and communities began building homes in phases, often starting with basic struc-

tures and gradually improving them as resources allowed.

Implementation of Core Housing in Lagos
Surulere, Ikeja and Shomolu Housing Estates (1960-1979): The Nigerian Building Society (NBS) and Lagos Executive Development Board (LEDB) played significant roles in housing provision, this LEDB was tasked with initiation of the construction of low-cost housing estates like Surulere, Ikeja, and Shomolu under the National Housing Program (NHP) to address housing shortages.

Low-Cost Housing Schemes (1980 – 1999): The 1980s and 1990s were marked by economic instability, structural adjustment programs (SAPs), and military rule. These factors hindered large-scale housing development. The Federal Government launched the Low-Cost Housing Scheme, targeting middle- and low- income earners. However, the program was hampered by corruption and mismanagement, therefore due to the inadequacies of government housing schemes, many Lagos residents turned to self-help housing strategies. This period saw a significant rise in informal settlements, with residents building incrementally as resources became available.

Increase of incremental Housing and beginning of high-end developments (1999-2015)
The return to civilian rule in 1999 brought renewed attention to housing, with the government recognizing the need for more sustainable urban development strategies. The Government initiated the 2002 National Housing Policy which emphasized private sector involvement and encouraged public-private partnerships (PPPs) in housing delivery. However the private sector involvement focused on high-end housing development such as Lekki Peninsula Development, this led to the persistence of informal settlements, such as Makoko, reflected the ongoing reliance on incremental housing. Residents continued to build and expand their homes in stages, often without formal approval or infrastructure.

Home Schemes and Incremental Housing (2015 – 2020) The Lagos State Government introduced policies aimed at improving housing supply, such as the Lagos State Home Ownership Mortgage Scheme (Lagos HOMS). However, these initiatives primarily benefited the middle and upper classes. Despite modernization efforts, the gap between housing demand and supply remained vast. Incremental housing remained a common strategy for the urban poor, with many of these building on the city's outskirts in areas with limited infrastructure.

The core housing strategy in Lagos has largely been shaped by the challenges of rapid urbanization, economic fluctuations, and inadequate government interventions. Incremental housing has played a crucial role in accommodating the city's growing population, particularly for low-income earners. While government policies have attempted to address housing shortages, the informal and incremental approach remains a dominant method for many Lagos residents, reflecting both the resilience and challenges of urban living in Nigeria's largest city

3.3.2 SITES-AND-SERVICES STRATEGY
Site and Service housing policy, used in developing countries, provides low-income families with plots of land equipped with basic infrastructure like roads, water, sanitation, and electricity, allowing them to build homes incrementally (UN-Habitat 2011, World Bank 2002). In Lagos, Nigeria, this strategy addresses urbanization challenges, housing shortages, and informal settlement growth. First introduced in the late 1960s and early 1970s, influenced by global urban planning trends and organizations such as the World Bank, the approach involved providing serviced plots with essential infrastructure, leaving housing construction to beneficiaries. Despite varying success from the 1960s through 2020, the goal was to offer cost-effective housing solutions by enabling families to construct their homes over time, adapting to their financial capabilities (UN-Habitat 2011, World Bank 2002).

Implementation of Site and Services Policy in Lagos Nigeria
FESTAC Town and Satellite Town Project (1970s - 1980s): In the 1970s, Lagos saw its first major Sites-and-Services projects. The Lagos State government, in partnership with the Federal government and international donors, developed several such projects. Notable examples include the FESTAC Town project and the Satellite Town scheme.

Despite good intentions, the projects faced significant challenges. The allocation of serviced plots was often marred by corruption and political interference, leading to the exclusion of low-income earners, the primary target group. Additionally, many allocated plots remained undeveloped for years due to a lack of financial capacity among allottees to construct houses.

Lagos Metropolitan Development (1990s - 2000s): By the 1990s, the effectiveness of the Sites-and-Services strategy was increasingly questioned. The focus shifted towards more comprehensive urban renewal programs that involved not just the provision of serviced plots but also the direct construction of housing units by the government or private developers. The World Bank continued to support Sites-and-Services projects in Lagos, but with a renewed emphasis on integrating these with broader urban development programs, including slum upgrading and the provision of social services. Projects like the Lagos Metropolitan Development and Governance Project (LMDGP) in the early 2000s included elements of the Sites-and-Services approach.

Resurgence and Modern Applications (2010s - 2020): From the 2010s to 2020, Lagos saw renewed interest in the Sites-and-Services strategy due to rapid population growth. The government recognized the limitations of market-driven housing solutions and incorporated the strategy into broader urban development policies. Modern applications focus on creating sustainable communities with pre-established infrastructure, as seen in projects like Eko Atlantic City. However, challenges such as land acquisition, financing, and effective public-private partnerships persist. Critics argue the strategy may not adequately support low-income groups without more support. The Sites-and-Services strategy in Lagos highlights the broader urbanization challenges in Nigeria. For success, it needs a holistic approach that integrates housing with social, economic, and environmental planning (UN-Habitat 2011, World Bank 2002).

4.0 CONCLUSION

This study emphasizes that housing development policies in Lagos have been crafted in response to disease outbreaks, rapid urbanization, population growth, and socio-economic challenges such as inequality and poverty. These policies are shaped by a combination of international frameworks, national government initiatives, and local interventions aimed at addressing housing deficits and improving living conditions.

Analysing the National Housing Development Policy in Nigeria from 1960 to 2020 reveals ambitious plans often hindered by inadequate implementation and socio-economic challenges. Lagos, as the epicentre of Nigeria's urban growth, illustrates the complexities of addressing housing in a rapidly expanding metropolis. While there were periods of progress, persistent housing deficits and increased rural-urban migration highlight the challenges. The direct housing construction policy, particularly in terms of slum upgrading and resettlement, has faced resistance due to social inequality and the disintegration of social networks. The Site and Service housing policy, which faces challenges like land acquisition and ineffective public-private partnerships, offers liberty in construction choices and has seen less resistance, leading to the development of satellite towns that help decongest Lagos City.

The rapid urbanization of Lagos led to increased housing demand, but the supply was insufficient, resulting in the growth of informal settlements. Despite government efforts, the housing deficit continued to grow significantly. During 1962–1980, Lagos' population grew from 926,000 to 2,572,000, with 28,500 housing units realized, leaving a backlog of 234,500 units.

The Structural Adjustment Program (SAP) of the mid-1980s exacerbated economic hardships, reducing the government's capacity to invest in housing. Increased private sector involvement often catered to higher-income earners, leading to high-cost private housing estates, while the housing needs of the lower-income population remained unmet. The urban population of Lagos grew from 2,736,000 to 14,368,000 within this period, with only 2,634 housing units built out of the planned 299,500.

Slum clearance often led to the disintegration of community networks and social support systems, exacerbating

poverty and homelessness. The new developments replacing slums were usually unaffordable for original residents, increasing economic inequality. However, some slum clearance efforts allowed for better urban planning and reduced environmental degradation, although often resulting in new slums due to inadequate resettlement plans.

The core housing strategy in Lagos has been shaped by rapid urbanization, economic fluctuations, and inadequate government interventions. Incremental housing has played a crucial role in accommodating the city's growing population, particularly for low-income earners. While government policies have attempted to address housing shortages, the informal and incremental approach remains dominant, reflecting both resilience and challenges in urban living.

The Sites-and-Services strategy in Lagos, providing plots with infrastructure for incremental housing construction, has had mixed results. While contributing to urban development and infrastructure provision, it has not fully addressed the housing needs of the growing population, especially the urban poor. For effectiveness, this strategy needs to be part of a broader, inclusive urban planning framework, ensuring affordable finance access, transparent allocation processes, and strong institutional support.

In conclusion, the key impacts of housing policies in Lagos from 1960 to 2020 illustrate the need for more inclusive, sustainable, and well-implemented policies to address the housing needs of all residents, particularly the urban poor. Future research could focus on how these predominant housing policies can be further operationalized on a global and local scale within the context of urban housing provision.

Ownership Dynamics of Low-Income Households Under Iran's Mehr Housing Policy (IMHP) (The Case Study of 13 IMHP Residential Complexes in Babol and Babolsar, Iran)

Abstract
Iran's Mehr Housing Policy (IMHP), implemented since 2007, represents the Iranian government's most extensive intervention aimed at providing affordable housing for over two million low-income households. This study examines the effectiveness of IMHP as a home-ownership-centric model through a case study of 13 IMHP residential complexes in Babol and Babolsar (3,031 units). Using quantitative methods, including field surveys and statistical analysis, the research reveals significant gaps between policy objectives and outcomes, with only 27% of units remaining occupied by target beneficiaries. The findings show that some low-income owners rented out their units (23%) or resold them in the informal market (26%) despite resale restrictions. The study advocates for context-based, mixed-tenure solutions that integrate ownership and rental options while accounting for informal housing dynamics.

Keywords: Iran's Mehr Housing Policy (IMHP); Affordable Housing; Ownership Dynamics; Low-Income Households; Informal Market.

Introduction

Housing policies play a critical role in addressing the shelter needs of low-income households, with varying models adopted across different socio-political contexts. The relationship between public housing policies and ownership presents several challenges, often stemming from the tension between the goals of providing affordable housing for low-income households and the realities of market dynamics, socio-economic factors, and policy implementation (Phang & Pacey, 2018; Aalbers, 2016; Rolnik, 2013; Rohe, Van Zandt, & McCarthy, 2002).

Homeownership-centric policies, prevalent in liberal welfare states such as the U.S. and UK, emphasize private ownership as a means of wealth accumulation and social stability (Rohe & Lindblad, 2013; Ronald, et al., 2015; Rohe & Stewart, 1996; Wainer & Zabel, 2020). In contrast, rental-centric models, dominant in corporatist welfare states in Northern Europe like Germany and the Netherlands, prioritize long-term affordability and tenant protections (Scanlon, et al., 2014; Whitehead, et al., 2016; Kemeny, 2006; Ronald, 2008; Kemeny, 1995). The effectiveness of these models remains contested, with scholars debating whether homeownership truly benefits low-income households or exacerbates financial vulnerability (Arundel & Ronald, 2021; Aalbers, 2016; Rohe & Lindblad, 2013).

Iran's Mehr Housing Policy (IMHP), one of the largest social housing initiatives in the Middle East, represents a large-scale effort to promote homeownership among low-income groups through subsidized housing units, akin to homeownership-centric policies. Homeownership rates in Iran declined from 89% in 1976 to 69% in 2006. Under the IMHP, over two million units have been built since 2007 on both state-owned and private land to increase homeownership rates, particularly for low-income households.

Affordable housing, as defined by Freeman and Schuetz (2017), must be sold or rented at below-market prices and occupied by households below a defined income threshold. To achieve this, IMHP employed several implementation tools, including state loans, allocation of state-owned land, building permits on inexpensive suburban plots, and legal and bureaucratic facilitation for applicant registration. More than a decade after the delivery of IMHP units to target households, this study examines the policy's effectiveness in achieving its goals. Specifically, it addresses the question: *Has IMHP, as a homeownership-centric model, led to the ownership and occupancy of housing units by low-income households?*

This study analyzes IMHP through the lens of comparative housing policy frameworks, engaging with two central tensions in contemporary housing scholarship: first, the position of IMHP between homeownership-centric and rental-centric welfare models (Ronald, et al., 2015; Scanlon, et al., 2014; Whitehead, et al., 2012; Kemeny, 2006): and second, the challenges of maintaining affordability in public housing systems for target households amid market-driven resale dynamics (Freeman & Schuetz, 2017; Aalbers, 2016; Hackworth, 2014; Rohe & Lindblad, 2013).

Empirical studies highlight that public housing units are increasingly treated as financial assets, leading to speculation and price inflation that exclude low-income groups (Aalbers, 2016). Market mechanisms often transform public housing into a commodity, benefiting investors rather than low-income residents (Rolnik, 2013). Public housing policies may also displace low-income residents, creating housing more attractive to middle- and high-income buyers (Hackworth & Smith, 2001), or result in mixed-income neighborhoods (lees, 2008). Market incentives encourage low-income owners to resell or rent their units at market prices for profit. Consequently, many public housing programs impose resale restrictions to ensure units remain affordable for future low-income households (Phang & Helble, 2016). These restrictions, commonly used to maintain affordability, have varying impacts on neighborhood stability and socio-economic integration (Rohe, et al., 2002). In some cases, they lead to vacant units (Han, 2014), while in others, they enable low-income households to benefit from housing market gains (Phang & Pacey, 2018) However, they do not account for the effectiveness of informal market practices.

It is expected that IMHP, as a homeownership-centric model, has increased ownership rates among low-income households, given its implementation tools for providing affordable housing and resale restrictions—though the impact of the informal market remains to be analyzed.

This exploratory study employs quantitative methods (field surveys and statistical tests) to investigate ownership dynamics in 13 IMHP housing complexes in Babol and Babolsar, Iran. Using proportional stratified sampling and systematic sampling, 335 questionnaires were distributed across 3,031 IMHP units. The study analyzes vacancy rates, rental trends, and informal resale markets to determine whether IMHP effectively serves its target households or inadvertently facilitates speculative practices.

Finally, this study makes three key contributions to planning theory and practice:

1. It provides empirical evidence on the implementation gaps of large-scale housing programs in Middle Eastern countries.
2. It analyzes how informal market practices subvert formal policy instruments.
3. It offers a critical assessment of homeownership promotion as a poverty alleviation strategy.

Housing Policies and Tenure Typologies

Different housing policies are pursued in various countries, generally to meet the housing needs of low-income groups. Housing-welfare models vary across countries: the asset-based welfare model in the USA and UK (Ronald, 2008); the rental-as-welfare model in Germany (Ronald & Doling, 2010); the family-as-welfare model in Japan and South Korea (Doling & Ronald, 2014; Ronald & Jin, 2010); and state-led ownership in China (Zhou & Ronald, 2017). Most countries have focused on "homeownership" policies to address the housing needs of low-income households, while the "private rental sector" operates as well(Schwartz, 2021; Whitehead, et al., 2016) some countries have turned to "social housing" and "social rental systems" to ensure low-income households meet their housing needs, particularly in Europe and East Asia (Scanlon, et al., 2014; Phang, 2007). Earlier, Kemeny (2006; 1995) distinguished between dualist and unitary rental markets:

- "Dualist rental markets" are found in liberal welfare states (e.g., the U.S., UK), where a small, residual social rental sector exists alongside a dominant profit-driven private rental market. Social housing is stigmatized, and homeownership is promoted as the norm.
- "Unitary rental markets" are found in corporatist welfare states (e.g., Sweden, Germany), where social and private rental sectors compete on equal terms, leading to higher-quality, cost-rental housing.

Kemeny (1992) argues that housing systems are socially constructed, shaped by political ideologies rather than purely economic forces. For instance, the promotion of homeownership in Anglo-Saxon countries reflects neoliberal individualism, whereas rental parity in Nordic countries aligns with collectivist welfare principles. Kemeny defines "path dependency," meaning historical policy choices constrain future reforms. For example, once homeownership becomes entrenched, shifting to rental-based systems becomes politically difficult (Bengtsson, 2009). For this reason, in dualist rental markets, governments try to increase homeownership, while in unitary rental markets, governments focus on social renting. Therefore, various models can be classified into two main categories: homeownership-centric models and rental-centric models.

Homeownership-Centric Models

Homeownership-centric models have benefits and consequences, varying significantly across countries due to differences in housing policies and market conditions. Increasing homeownership rates is the main goal of many housing policies worldwide. In the USA and UK, Southern and Eastern Europe, West Asia, and the Middle East, various housing policies have been designed and implemented based on homeownership.

There are some infamous examples of public housing failures, such as the Pruitt-Igoe and Cabrini-Green projects in the USA and the Aylesbury Estate in the UK. These large-scale public housing projects, despite being owned by poor households, have suffered from concentrated poverty, crime, stigma, poor maintenance, and economic isolation (Jacobs, 1961; Newman, 1972; Venkatesh, 2000; Lees, 2008; Schwartz, 2021). After the failure of large-scale public housing projects, approaches shifted to other forms of intervention in the USA, such as the HOPE VI program, which replaced distressed public housing with mixed-income developments but still emphasized homeownership (Schwartz, 2021).

Homeownership has had different impacts on low-income households. On the one hand, it has improved self-esteem and life satisfaction (Rohe & Stegman, 1994b), civic engagement and social capital (Rohe & Stegman, 1994a), long-term community ties (Rohe & Basolo, 1997), neighborhood stability (Rohe & Stewart, 1996), and wealth-building (Rohe & Lindblad, 2013; Phang, 2004). Wainer and Zabel (2020) illustrate how low-income households that transitioned from renting to homeownership experienced significant gains in wealth compared to households that remained renters.

On the other hand, homeownership has caused low-income households to face unexpected repair costs, predatory lending, foreclosure risks (Rohe & Lindblad, 2013; Rohe & Watson, 2007), and purchases in disadvantaged areas (Rohe & Lindblad, 2013). Aalbers (2016) explains how public housing units in Europe and North America are increasingly treated as financial assets, leading to speculation and price inflation that exclude low-income groups. Rolnik (2013) argues that the privatization of public housing and the introduction of market mechanisms have turned public housing into a commodity, often benefiting investors rather than low-income residents. Lees (2008; 2003) highlights how public housing redevelopment in cities like London and New York often results in mixed-income housing, but low-income residents are frequently excluded due to rising costs and eligibility criteria. Hackworth (2007; 2002) explains how public housing policies in the U.S. lead to neighborhood redevelopment, which can displace low-income residents and create housing more attractive to middle- and high-income buyers. Moreover, some studies highlight declining access to homeownership, particularly among younger generations, due to financialization and market liberalization (Arundel & Ronald, 2021) and increasingly favor older, wealthier cohorts, deepening generational inequality (Lennartz, et al., 2016).

Comparing different European models shows that high homeownership rates (as seen in Southern Europe) can create market inflexibility; countries such as Spain (with a homeownership rate of 85%) suffered more during the financial crisis, whereas balanced tenure systems like Germany (with a homeownership rate of 43%) are presented as models with lower ownership but stable renting and greater resilience (Scanlon & Kochan, 2011; Whitehead, et al., 2012). Ronald (2008) challenges the dominant ideology that promotes homeownership as a universal ideal, arguing that it is deeply embedded in welfare and social policies, often exacerbating inequality. Lees (2021) criticizes policies favoring homeownership, which she argues exacerbate housing unaffordability. She discusses how

new-build luxury developments, often marketed to investors, reduce the availability of affordable rental housing. She contends that the financialization of housing, where homes are treated as assets rather than places to live.

Table 1: Benefits and consequences of homeownership.

Homeownership	
Benefits	**Consequences**
self-esteem and life satisfaction (Rohe & Stegman, 1994b)	Financialization (Aalbers, 2016)
civic engagement and social capital (Rohe & Stegman, 1994a)	Displacement (Hackworth, 2007)
long-term community ties (Rohe & Basolo, 1997)	Generational inequality (Arundel & Ronald, 2021).
neighborhood stability (Rohe & Stewart, 1996)	unexpected repair costs, predatory lending, foreclosure risks (Rohe & Lindblad, 2013; Rohe & Watson, 2007)
wealth-building (Wainer & Zabel, 2020; Phang, 2004; Rohe & Lindblad, 2013)	purchases in disadvantaged areas (Rohe & Lindblad, 2013)

Most critiques of homeownership, such as financialization, displacement, and gentrification, stem from the resale of units by initial owners. Therefore, many public housing programs impose resale restrictions to ensure that units remain affordable for future low-income households. Affordable housing, as defined by Freeman and Schuetz (2017), must be sold or rented at below-market prices and occupied by households below a defined income threshold. However, market incentives encourage owners to resell or rent their units at market prices to earn profits.

Successful public housing policies often include strict eligibility criteria, robust oversight, and measures to prevent resale or exploitation. For example, Singapore's Housing and Development Board (HDB), despite critiques of homeownership in Europe and North America, has been successful in ensuring homeownership for a large portion of its population (over 90%) through policies like mandatory savings via the Central Provident Fund (CPF), subsidized housing loans, and resale restrictions. The government ensures affordability through income-based subsidies, price controls, and long-term leases. Comparing Singapore's public housing resale policies, which allow for limited profit-making, with U.S. policies that often impose stricter resale restrictions, shows how Singapore's approach has enabled low-income households to benefit from housing market gains (Phang & Helble, 2016; Phang & Pacey, 2018).

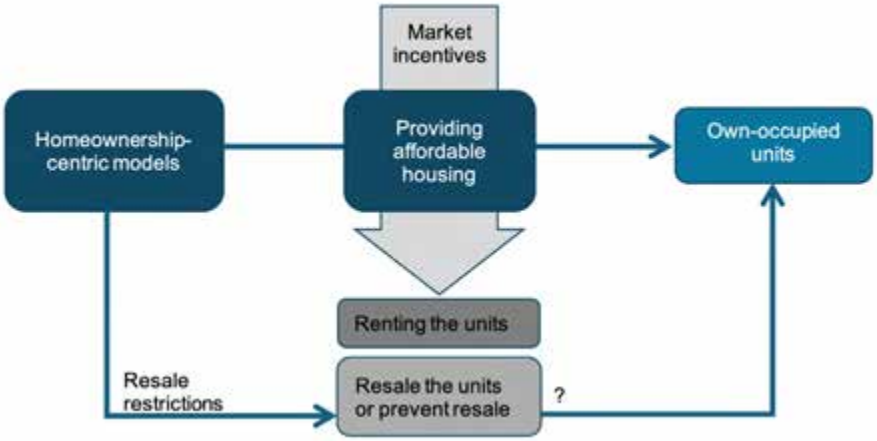

Figure 1: How market incentives encourage the rental or resale of units in homeownership-based models, undermining public housing goals.

Public housing units may be resold or rented at market rates, benefiting investors rather than low-income households (Aalbers, 2016; Rolnik, 2013), so resale restrictions enable low-income households to benefit from housing market gains (Phang & Pacey, 2018). resale restrictions are often imposed to maintain affordability, but their effectiveness varies widely. In some cases, resale restrictions lead to vacant units or disincentivize maintenance (Han, 2014). Rohe et al. (2002) highlight the trade-offs between preserving affordability and allowing homeowners to benefit from market appreciation. Low-income households often rely on home equity as a primary source of wealth, but resale policies affect their ability to accumulate wealth through homeownership. While resale restrictions can help maintain affordable housing stock, they may limit neighborhood turnover, restrict wealth-building potential for low-income households, and propel them into informal markets.

Rental-Centric Models

In various countries, a combination of tenure types—homeownership, private renting, and social housing—is in operation. Homeownership is not the only aspect of housing policy. It is necessary to consider a combination of various tenure types across different contexts. Some countries have a large private renting sector, while others have social renting systems. In the US and UK, homeownership and private renting are the most common tenure types, and high homeownership rates depend on mortgage reliance and family gifts. In contrast, Germany and the Netherlands have a strong rental sector and a legacy of social housing. Each has benefits and consequences that should be considered. Rental-centric models prevent the resale and rental of affordable units in the market by promoting social renting instead of homeownership and private renting.

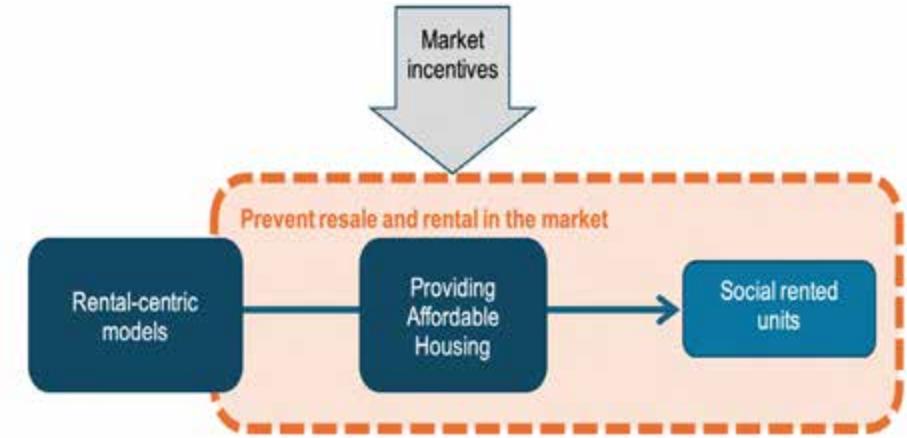

Figure 2: Rental-based models aim to prevent units from being resold or rented on the market.

Kemeny (1995) argues for a shift from market-oriented housing policies to a more social rental model, emphasizing the importance of long-term affordability and tenant rights. Ronald & Kadi (2018) defend social housing and discuss how declining homeownership has led to a resurgence of private renting, often under precarious conditions, and critique deregulation and the erosion of social housing. Schwartz & Meltzer (2015) illustrate the growing affordability crisis in rental markets, particularly in high-cost cities like New York. They argue that high rent burdens correlate with poor health outcomes, emphasizing the need for expanded rental assistance (e.g., Housing Choice Vouchers) and stronger tenant protections. Oxley (2004) argues that social housing is a vital tenure for providing affordable and secure housing. He critiques the overemphasis on homeownership in UK housing policy, arguing that it has often been promoted at the expense of other tenures and can lead to market instability and affordability crises, particularly for lower-income households. Oxley & Smith (1996) acknowledge the growing importance of private renting but highlight its shortcomings, including insecurity and high costs. They believe that social renting should be expanded rather than diminished through right-to-buy policies, which have reduced social housing stock.

Whitehead et al. (2016) and Scanlon (2014) in their comparative study of public housing in Europe, found that countries with strong social welfare systems, such as Austria and Denmark, were more successful in providing affordable housing to low-income groups compared to countries with market-driven approaches. They highlight the growing importance of the private rented sector (PRS) in housing markets, particularly in high-demand cities like London, and note that private renting is no longer just a transitional tenure but a long-term solution for many households, including families. However, they critique the private rental sector for its insecurity, high costs, and variable quality.

Table 2: Comparing tenure typologies: homeownership-centric vs. rental-centric models

	Country	Owner-Occupied	Private Rented	Social Rented	References
Most homeownership -centric	USA	~65% (→)	~30% (↑)	~5% (↓)	HOME VI program, Housing Choice Vouchers (Scanlon, et al., 2014)
	UK	~63% (↓)	~20% (↑)	~17% (↓)	Affordability crises, Buy-to-Let market, Right-to-Buy policies (Ronald & Kadi, 2018; DKM, 2014; Scanlon, et al., 2014)
	Germany	~45% (↓)	~40% (↑)	~15% (↓)	Strong rental sector, tenant protections (Scanlon, et al., 2014; Ronald & Doling, 2010; Whitehead, et al., 2016)
Most rental-centric	Netherlands	~55% (→)	~15% (↑)	~30% (↓)	Social housing legacy, privatization (DKM, 2014; Scanlon, et al., 2014; Whitehead, et al., 2016)

Social housing also has its consequences. For example, units may fall into disrepair due to inadequate funding for maintenance or lack of ownership incentives (Rohe, et al., 2002), or some units built in remote or undesirable locations remain unoccupied due to poor location, lack of demand, or restrictive policies (Han, 2014). Unlike European social housing, Singapore's system was able to address these consequences by making public housing aspirational—even middle-income households live in HDB flats (Phang & Helble, 2016). In Singapore, a small rental sector exists for the lowest-income households, but the focus is on ownership to prevent welfare dependency (Phang, 2007). Phang & Pacey (2018) critique Singapore's minimalist rental sector, which serves only the poorest while reinforcing ownership as the norm. Low-income households without family support may fall through the cracks, as rental supply is tightly rationed.

Iran's Mehr Housing Policy (IMHP)

Iran's housing policies have historically emphasized homeownership over rental solutions, such as housing construction, housing loans, and public-private projects to meet housing needs. According to the last official housing census, 60% of housing units in Iran are owner-occupied versus 31% private rented units. The remaining units often belong to state-owned organizations such as state factories and state universities for the residence of their employees or students. In this sense, Iran's housing market aligns with Kemeny's theory (2006; 1995) of "dualist rental markets," where a small, residual social rental sector exists alongside a dominant profit-driven private rental market and homeownership is promoted as the norm. Similarly, we can see both the asset-based welfare model (like the USA and UK) with high homeownership rates and a large private rental sector (Ronald, 2008), and the family-as-welfare model (like Japan and South Korea) with family assistance to young couples (Ronald & Doling, 2010; Ronald & Jin, 2010).

Iran's Mehr Housing Policy (IMHP) is the largest large-scale social housing initiative launched by the government in 2007 under President Mahmoud Ahmadinejad. IMHP was designed to provide affordable housing for low-income

households by leveraging government resources and private sector participation. Under the IMHP, the government provided free or low-cost land to developers to build housing units. The program aimed to build over two million housing units across Iran, particularly in suburban and less-developed areas. IMHP units were sold at below-market prices, with long-term, low-interest installment plans (up to 15 years) and were given to first-time homebuyers.

The official housing census of Iran showed that homeownership rates had declined from 89% in 1976 to 69% in 2006 (Figure 3). The decline in homeownership over the last decades resembles trends in countries such as the UK (with a liberal market) and the Netherlands (with strong social renting). But despite privatization and market-driven policies in these countries, Iran's government decided to build over two million units to increase homeownership rates, especially for low-income households since 2007, under the IMHP. Nevertheless, the decline in homeownership continued in the next decade, falling to 60%, while private rented units increased to 31%. Thus, the change in the combination of owner-occupied and rental-occupied units under IMHP differs from other countries where market-driven policies were implemented.

IMHP units were constructed in all provinces of Iran, particularly in Mazandaran Province, where 65,000 units were built to accommodate around 200,000 residents. Of these, almost 21,000 units were organized in residential complexes, and the rest were standalone buildings. Under the IMHP, 14 residential complexes with around 3,300 units were built in Babolsar and Babol, where this study was conducted.

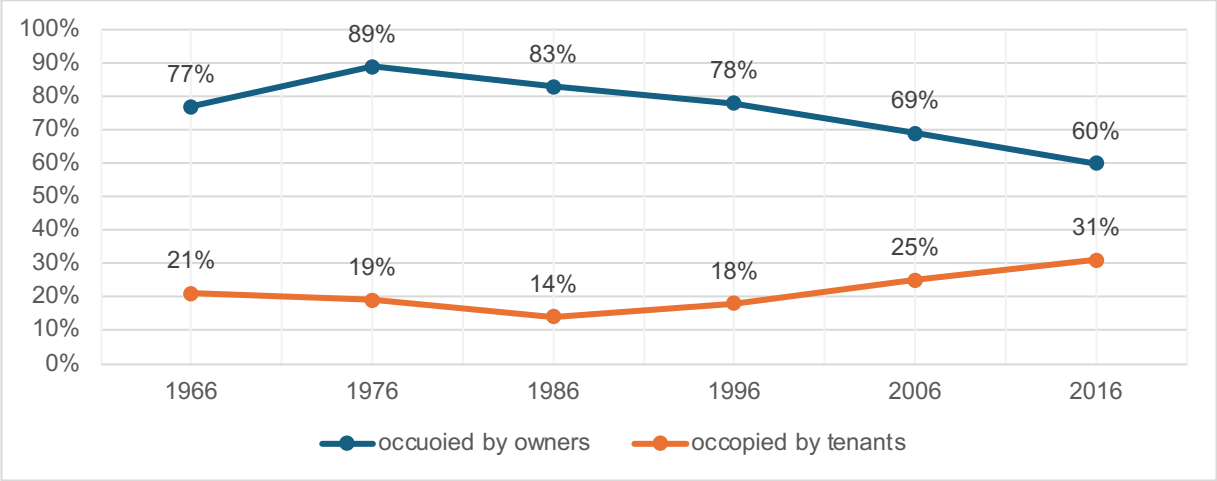

Figure 3: Percentage of units occupied by owners and tenants in Iran, 1966-2016.
Source: Iran's statistical center; https://amar.org.ir/statistical-information/catid/3108

Homeownership by low-income households was the main goal of the IMHP. The government wanted to provide affordable housing and ensure occupancy by low-income households. To achieve this, they employed several implementation tools, including: provision of state loans, allocation of state-owned land, building permits on inexpensive suburban plots, legal and bureaucratic facilitation, applicant registration, and resale restrictions. It was expected that most IMHP units would be occupied by low-income households and none would be resold, although some would likely be rented out.

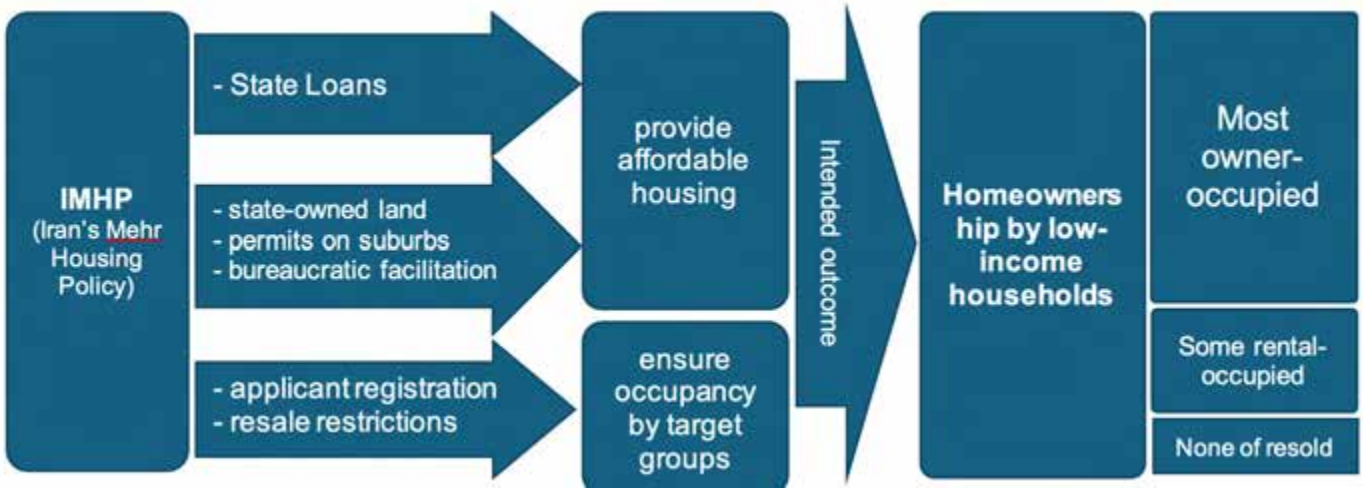

Figure 4: IMHP and its implementation tools to provide affordable housing.

Therefore, the intended outcomes of IMHP were:
- Provide affordable housing;
- Homeownership by low-income households;
- Most owner-occupied, some rental-occupied;
- State loans, state-owned land, permits on suburbs, bureaucratic facilitation;
- Applicant registration and resale restrictions to ensure occupancy by target groups;
- No resale of units.

Methodology

Given the goals of IMHP and the research questions of this study, we needed to determine which units were occupied. If a unit was vacant, follow-up visits were conducted to confirm its vacancy status. We decided to investigate housing complexes that were more accessible for subsequent field surveys. We selected 13 IMHP housing complexes[1] in two cities of Mazandaran Province, Babol and Babolsar, comprising 3,031 units: Mehshahr (No.1), Kiamehr (No.2), Omid Oshib (No.3), Arezoo (No.4), Velayat (No.5), Golsar (No.6), and Farzanegan (No.7) in Babol; Moalleman (No.8), Talash (No.9), Narenjestan (No.10), Danesh (No.11), Andisheh (No.12), and Persia (No.13) in Babolsar (Figure 3). Some of these complexes are located inside the administrative municipal boundary, and some are outside. These complexes varied significantly in ownership—state-owned versus self-owned.

In the initial phase, we conducted a pilot survey using systematic sampling methodology. From each residential complex, we selected 20 samples to estimate the rate of vacant units. The distribution of questionnaires followed a carefully designed protocol to ensure sampling homogeneity across all complexes. When initial visits identified vacant units, follow-up visits were conducted to determine whether these vacancies were temporary or permanent. This phase revealed an average vacancy rate of 24% across all complexes, with notable variations between different developments. For instance, the Golsar (No.6) and Omid Oushib (No.3) complexes in Babol demonstrated near-complete occupancy (100% and 95%, respectively), while the Persia (No.13) and Narenjestan (No.10) complexes in Babolsar showed significantly higher vacancy rates (58% and 45%, respectively).

The second phase involved a more detailed survey to collect additional variables of interest, including ownership patterns and tenancy characteristics. Due to the differences between complexes, we employed stratified ran-

1 . There are totally 14 IMHP housing complexes in Babol and Babolsar, but only we were permitted to do survey in 13 complexes.

dom sampling with proportional allocation to enable meaningful cross-complex comparisons.

Table 3: Total sample size using proportional stratified sampling

Target Population	Occupied Units (%)	Sampling Population	Margin of Error (d)	Probability (pq)	Confidence Level (Z)	Sampling Method	Sample Size
3,031 households	75.8%	2,296 households	0.05	0.25	95%	Stratified random (proportional)	330 samples

Our sampling framework accounted for a target population of 3,031 households, with a 75.8% occupancy rate (2,296 occupied households). Initial calculations suggested 330 samples were required (see Table 3). However, after refining the proportional allocation, the final sample size was adjusted to 346 to ensure optimal distribution (see Table 4).

Table 4: Refined sample allocation by residential complex

No.	Complex Name	City	Total Units	Occupied (%)	Stimate of Occupied Households	Final Samples
1	Mehrdasht	Babol	346	80%	277	40
2	Kiamehr	Babol	320	81%	260	39
3	Omid Oshib	Babol	300	95%	285	38
4	Arezoo	Babol	240	85%	205	27
5	Velayat	Babol	168	79%	133	20
6	Golsar	Babol	144	100%	144	21
7	Farzanegan	Babol	120	82%	99	17
8	Moalleman	Babolser	298	67%	199	21
9	Talash	Babolser	186	81%	151	28
10	Narenjestan	Babolser	320	55%	175	24
11	Danesh	Babolser	294	69%	202	32
12	Andisheh	Babolser	120	80%	96	20
13	Persia	Babolser	175	42%	74	19
Total			3,031	75.8%	2,296	346

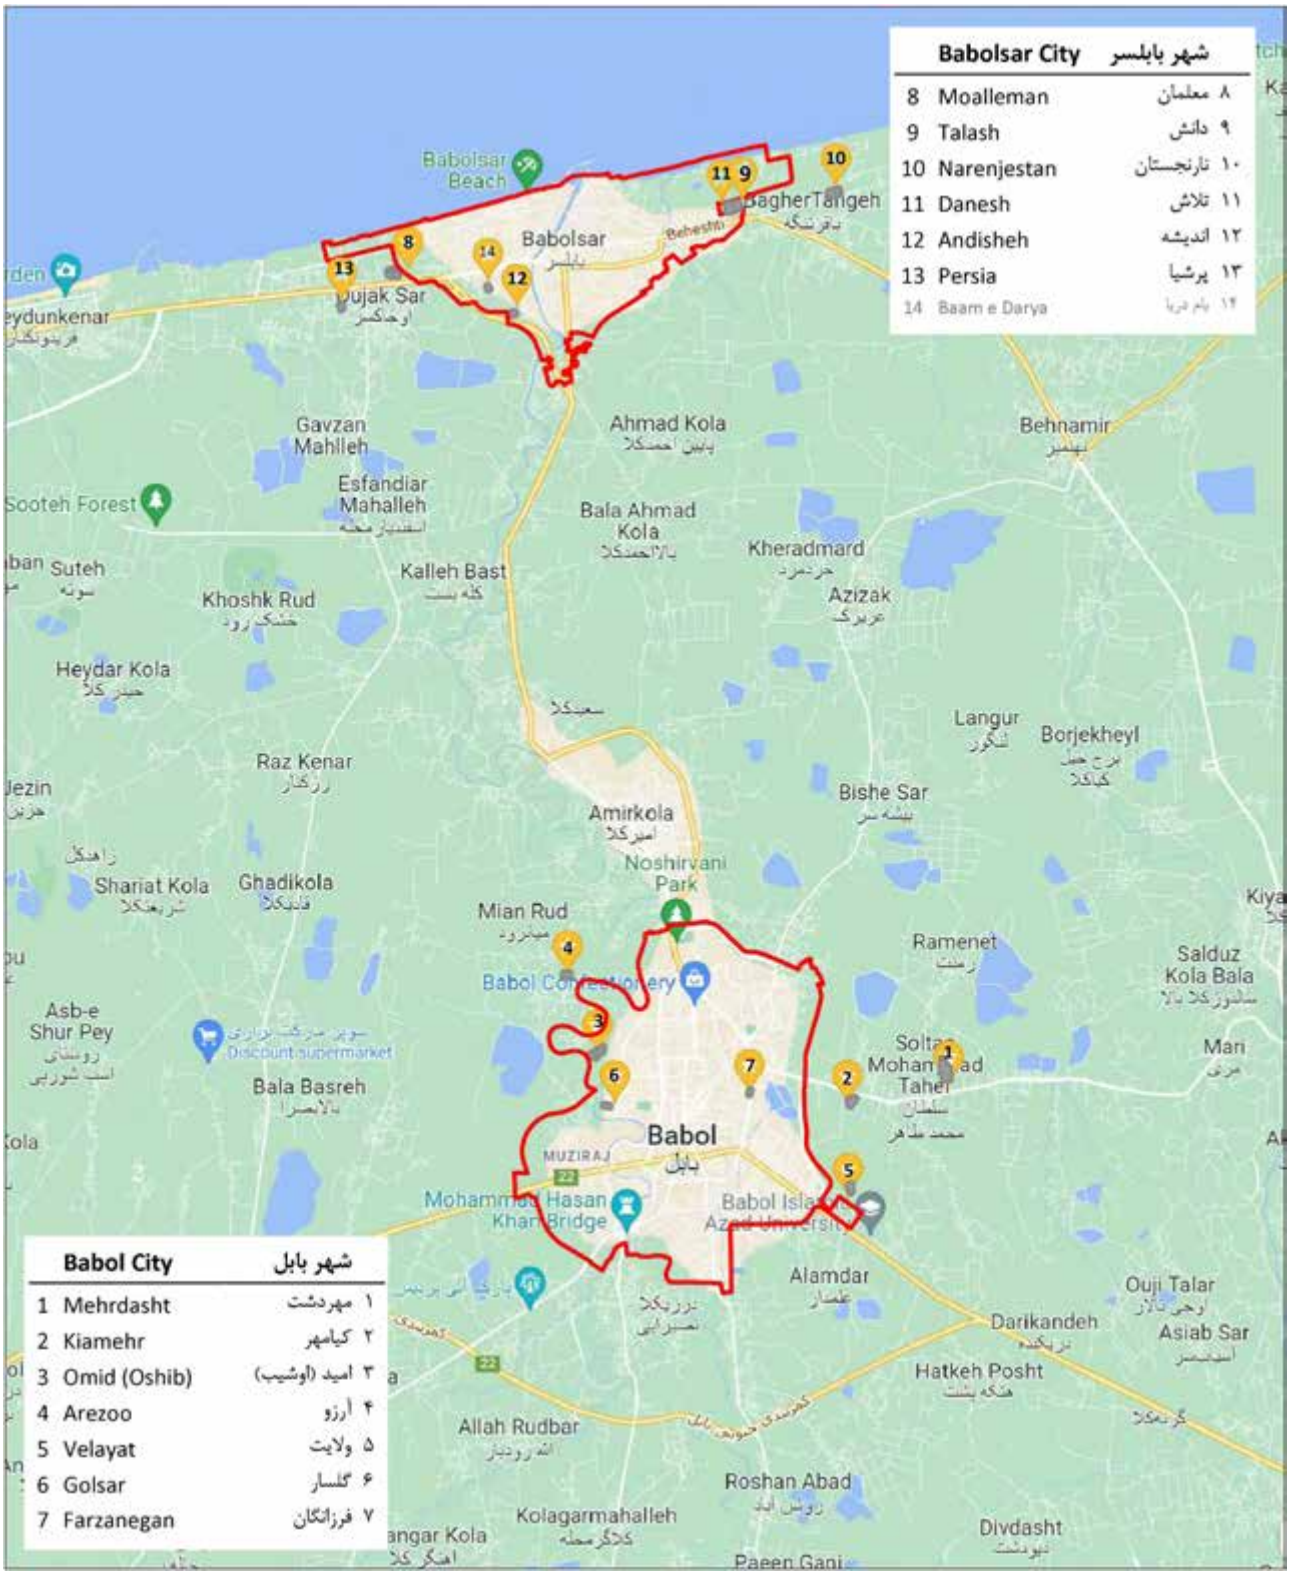

Figure 5: The location of 13 IMHP housing complexes in Babol and Babolsar.

Thus, this exploratory study employs quantitative methods (field surveys and statistical tests) to investigate ownership dynamics in IMHP housing complexes in Mazandaran Province. Using proportional stratified sampling and systematic sampling, 346 questionnaires were distributed across 13 IMHP housing complexes in Babol and

Babolsar, encompassing 3,031 housing units.

IMHP's Non-Occupied Units

To answer the research questions, we analyzed the field survey data in four steps. First, we need to know what rate of IMHP units haven't been occupied in different complexes?

The main goal of IMHP was to provide housing for low-income groups solely for residential purposes. Vacant units represent wasted resources and fail to address housing needs. Therefore, if IMHP units were vacant, the goal of this policy was not achieved. The results of the pilot survey show that in some complexes, the rate of non-occupied units was very high, for example, 58% in Persia (No.13) and 45% in Narenjestan (No.10). (Both of these complexes are located outside the border of Babolsar City.) Regardless of the causes, these units were out of reach of target groups, so the goal of IMHP was not achieved in these complexes. In contrast, the lowest rate of vacant units was in Golsar (No.6) and Omid Oshib (No.3)—both located inside the border of Babol City. It seems that complexes located at the top of Figure 6 were more successful in achieving the goals of IMHP. In total, 24% of IMHP units were vacant, indicating that a quarter of IMHP goals were not met.

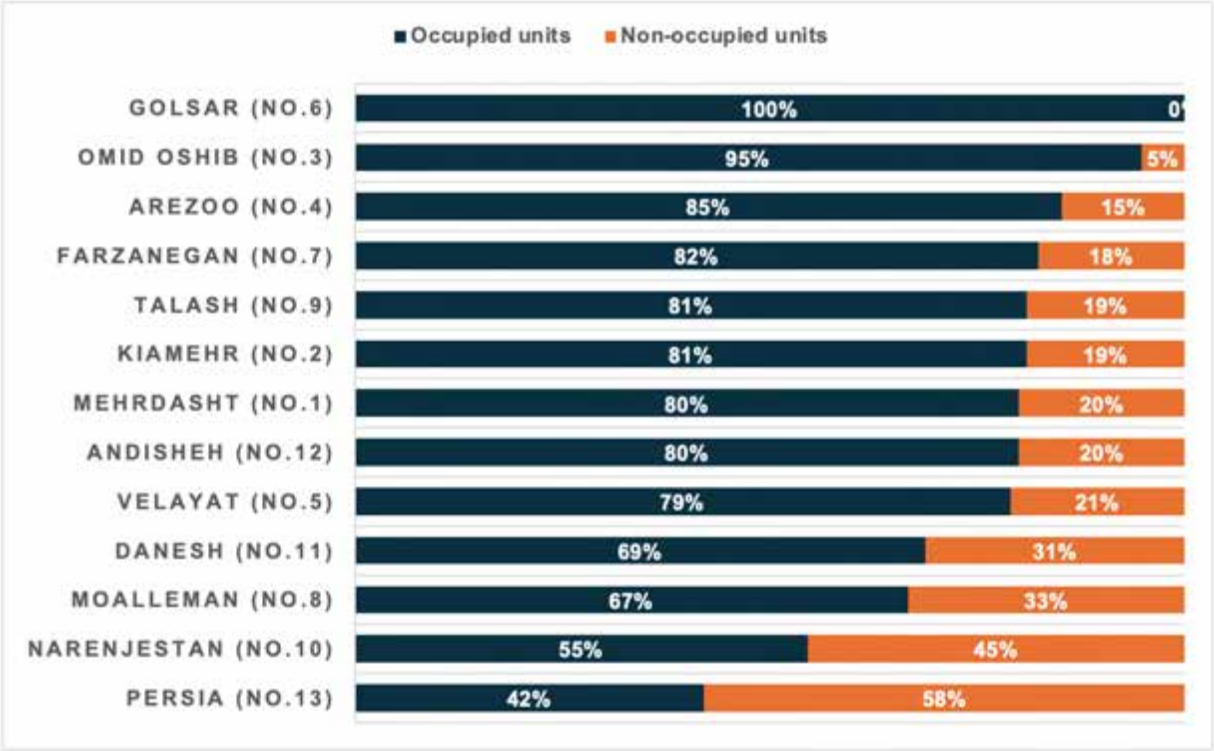

Figure 6: Percentage of non-occupied units in each IMHP complex.

IMHP's Rented Units

Iran's housing policy focused on ownership by low-income groups, not tenancy. Therefore, if owners rent their units, it indicates they need money for monthly household expenses, not a home—which contradicts IMHP goals. In the second step, we need to know what rate of IMHP units were rented in different complexes. As shown in Figure 7, the highest rate of rented units was in Moalleman (No.8)—located outside Babolsar's border—where 54% of units were rented. In this complex, only 13% of units were occupied by owners, placing it at the bottom of the chart. Next, in Andisheh (No.12)—located inside Babolsar's border—40% of units were rented. In contrast, the lowest rates of rented units were in Mehrdasht (No.1) at 12% and Persia (No.13) at 13%. In the rest of the complexes, the rate of rented units ranged between 19% and 27%. In total, 23% of IMHP units were rented to earn profit.

Overall, 52% of IMHP units are owner-occupied, which is lower than the national homeownership rate (60% in 2006).

The rate in 5 complexes is close to 60%, while the rate in 5 others is below 47% due to the large number of vacant and rental units. Only 3 complexes have over 68% owner-occupied units. Therefore, it seems IMHP, as a homeownership-centric model, has not succeeded in increasing the homeownership rate.

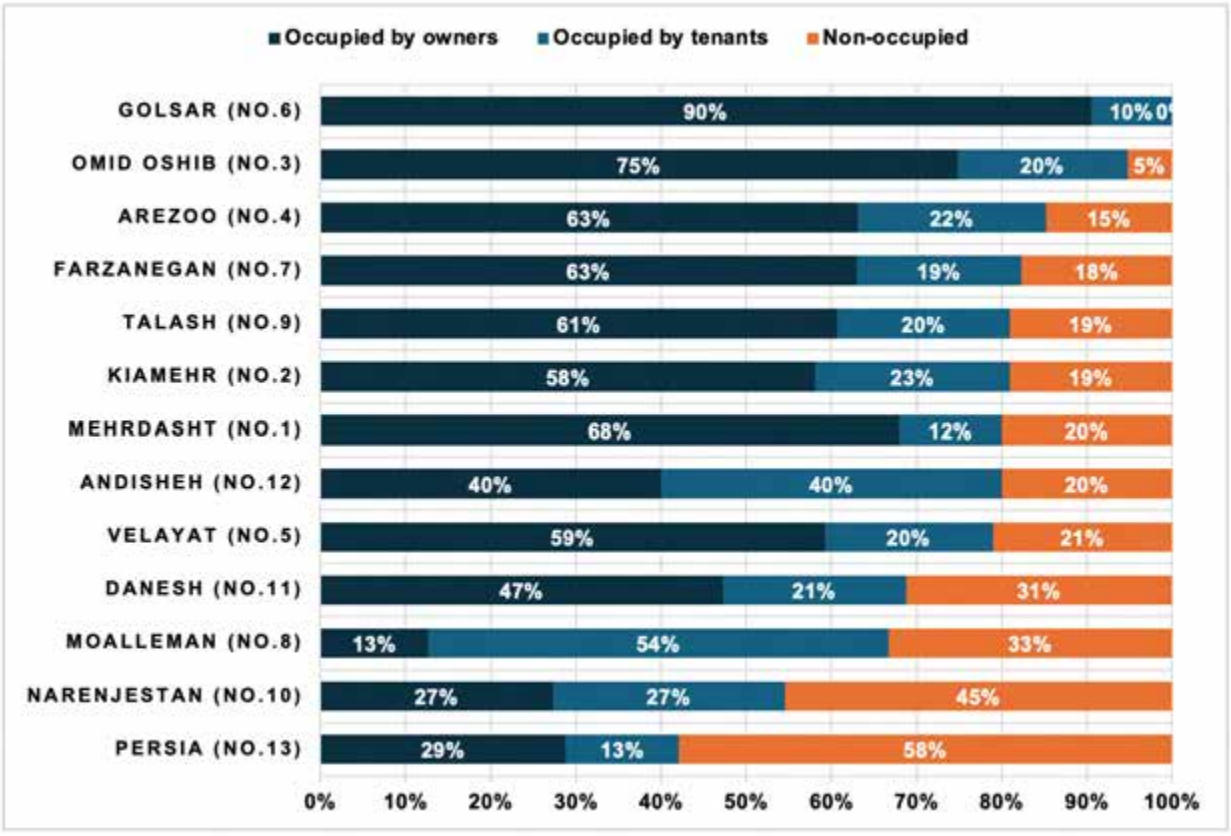

Figure 7: Percentage of units occupied by owners and tenants in each IMHP complex.

IMHP's Resold Units

To ensure units were occupied by low-income households and not resold, IMHP used applicant registration and resale restrictions. If units were resold to new owners, IMHP goals were not achieved. Therefore, in the third step, we have to know what rate of units were occupied by new owners who have bought their units later outside the IMHP mechanism? Observations showed that IMHP units were resold in informal markets despite resale restrictions. As a specific example, Golsar (No.6) appeared to be the most successful complex due to its low rented units (10%) and no vacant units, but it was determined that 80% of units were resold and occupied by new residents. In this case, IMHP units became a trade commodity for low-income households who profited from the difference between affordable housing prices and market rates. Similarly, in Arezoo (No.12), half of the units were resold to new owners in the informal market.

In total, the survey results show that 26% of IMHP units were resold by low-income households to others in the informal market. After subtracting resold units, the homeownership rate declines to 27%.

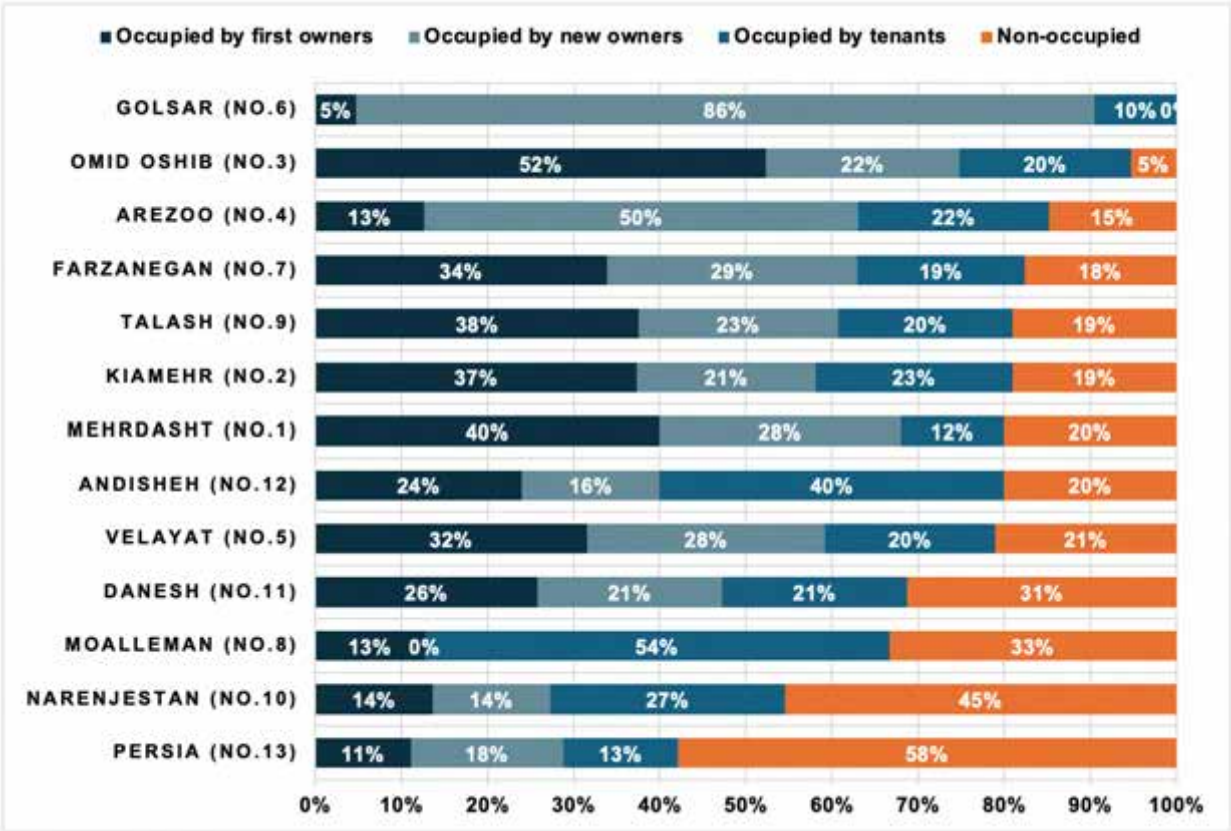

Figure 8: Percentage of units occupied by new owners in each IMHP complex.

IMHP's Occupied Units by Target Groups

In total, 24% of IMHP units were vacant, 23% were rented to earn money, 26% were resold by low-income households to new owners, and only 27% were occupied by target groups (see Figure 9). In Omid Oshib (No.3), over half of the units were occupied by first owners who were target groups, making it the only IMHP complex with a home-ownership rate above 50%. In the rest of the complexes, this rate was below 40%. At the bottom of the chart (see Figure 8) there are six complexes below the average, indicating they were unsuccessful in achieving IMHP goals.

Table 5: Comparison of IMHP units with highest rates.

Highest Rates of			
Vacant Units	**Rented Units**	**Resold Units**	**Own-Occupied Units by Target Groups**
Persia (No.13): 58%	Moalleman (No.8): 54%	Golsar (No.6): 86%	Omid Oshib (No.3): 52%
Narenjestan (No.10): 45%	Andisheh (No.12): 40%	Arezoo (No.4): 50%	Mehshahr (No.1): 40%

The context of various cities can impact the outcomes of public housing. In this case, IMHP's outcomes in Babolsar and Babol were very different, despite their proximity (less than 30 km apart). Babolsar is a touristic coastal city near the Caspian Sea, while Babol is a central plains city. The percentage of homeownership/rental units likely differs between these cities. Comparing the data from Babolsar and Babol (see Figure 9) shows that the rate of vacant units in Babolsar was higher than in Babol (36% versus 15%). Additionally, the rate of rented units in Babolsar was higher than in Babol (28% versus 18%). In other words, the goal of IMHP was not achieved for two-thirds of the units in Babolsar. In Babol, it appeared that 67% of units were occupied by IMHP target groups, but the results showed that half of these were resold in the market, with new owners replacing the target groups. In Babol, 34% of units were resold to new owners, compared to 16% in Babolsar. Finally, it can be stated that only 33% of units in Babol and 21% of units in Babolsar reached the target groups in line with IMHP goals.

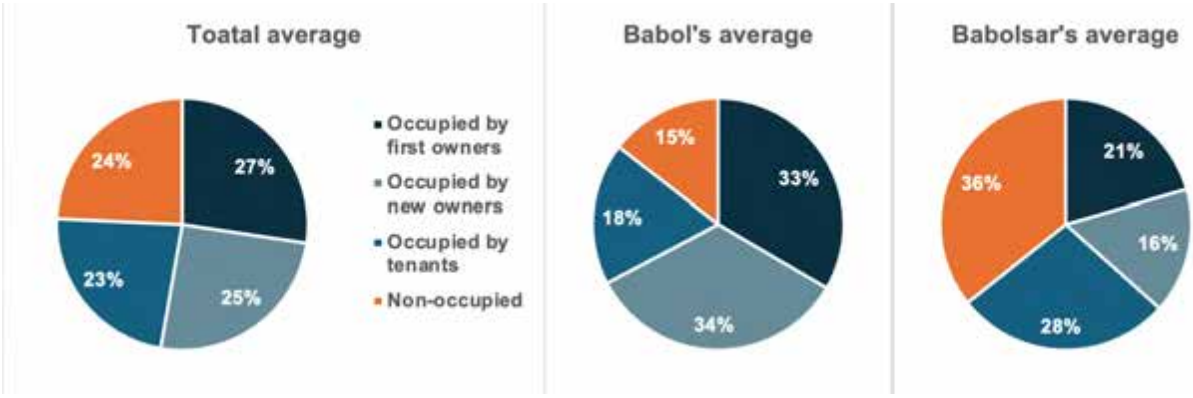

Figure 9: Comparison of the rate of units occupied by new owners between Babol, Babolsar, and total average.

Discussion

The findings reveal significant discrepancies between IMHP's objectives and actual outcomes, reinforcing critiques of homeownership-centric models (Ronald, et al., 2015; Scanlon, et al., 2014; Whitehead, et al., 2012; Kemeny, 2006). While the policy aimed to provide affordable homeownership for low-income households, only 27% of units were occupied by the intended beneficiaries. A substantial portion (24%) remained vacant, suggesting inefficiencies in allocation or locational disadvantages (Han, 2014). In particular, in two cases—Persia (No. 13) and Narenjestan (No. 10)—vacancy rates were 58% and 45%, respectively. These complexes are located outside Babolsar City's urban boundary, where poor accessibility and undesirable locations exacerbate vacancies.

Additionally, 23% of units were rented out, indicating that financial incentives led low-income owners to treat IMHP housing as income-generating assets rather than permanent residences—a phenomenon observed in other homeownership-centric models (Arundel & Ronald, 2021; Aalbers, 2016; Scanlon & Kochan, 2011). Specifically, Moalleman (No. 8) and Andisheh (No. 12) had the highest rental rates (54% and 40%, respectively). Both are located in Babolsar, a tourist coastal city, highlighting how the region's socio-economic context influences rental trends.

Most strikingly, 26% of units were resold, bypassing IMHP's resale restrictions. This aligns with critiques of homeownership policies in which subsidized housing becomes commodified, benefiting initial buyers rather than sustaining long-term affordability (Wainer & Zabel, 2020; Rolnik, 2013). However, a key difference in Iran is the existence of an active informal market, where bureaucratic resale restrictions alone cannot counter market incentives. The case of Golsar (No. 6), where 80% of units were resold, exemplifies how market incentives distort policy goals. These findings echo Singapore's experience, where resale restrictions balance affordability with wealth accumulation (Phang & Pacey, 2018), but unlike Singapore, IMHP lacked robust enforcement mechanisms.

Geographical disparities further highlight policy shortcomings. Babolsar, a tourist coastal city, had higher vacancy (36%) and rental rates (28%) than Babol, suggesting that demand-side factors (e.g., seasonal migration, investment speculation) influenced occupancy. Conversely, Babol's lower vacancy rate (15%) masked high resale

activity (34%), revealing that even occupied units often deviated from policy intent.

Comparative analysis suggests IMHP's dualist rental market structure (Kemeny, 2006; Bengtsson, 2009) exacerbated these issues. Unlike unitary rental systems (e.g., Germany's social renting), IMHP's reliance on homeownership without complementary rental safeguards left low-income households vulnerable to market pressures. The policy's failure to curb informal resales mirrors challenges in liberal markets, where financialization displaces target beneficiaries. Finally, three key discussion points emerge from our analysis:

• **The Paradox of Homeownership Promotion:** The data show that only 27% of units remained with original low-income beneficiaries, challenging the homeownership-centric model. This aligns with Ronald's (2008)critique of the "homeownership ideology," where policy instruments become disconnected from household realities. The high resale rates (26%), particularly in Babol, demonstrate what Bengtsson (2009) terms the "asset-based welfare trap"—where subsidized housing becomes a liquid asset rather than stable shelter.

• **Informality and Governance Challenges:** The prevalence of informal resales despite formal restrictions reflects broader debates about state capacity in Iran. Bureaucratic controls alone cannot counter market incentives, and community-level enforcement is often lacking. Policy instruments assume formal market behaviors that do not align with local realities.

• **Spatial Mismatches and Policy Design Flaws:** The stark differences between Babol (15% vacancy) and Babolsar (36% vacancy) highlight the importance of locational factors in housing policy success. The higher rental conversions in Babolsar (28% vs. 18% in Babol) further illustrate how tourist economies distort housing markets in ways that homeownership-centric policies cannot address.

While this study provides critical insights into IMHP's implementation gaps, several limitations must be acknowledged:

• **Sample Scope:** The analysis focuses on two cities (Babol and Babolsar), which, while illustrative, may not capture regional variations in Iran's housing markets. Future studies could expand to other IMHP projects in Mazandaran Province and other provinces of Iran to test generalizability.

• **Temporal Dynamics:** The study examines a snapshot of IMHP outcomes. Longitudinal tracking of units (e.g., resale price trends, generational transfers) would reveal whether deviations from policy goals intensify over time.

• **Policy Context:** The findings reflect IMHP's performance under specific economic sanctions and inflation rates in Iran. Comparative studies in stable economies could disentangle policy flaws from macroeconomic shocks.

Conclusion

This study demonstrates that Iran's Mehr Housing Policy (IMHP), as a homeownership-centric model, has achieved only 27% of its objectives across 13 case studies in Babol and Babolsar, while 73% of IMHP units were either vacant, rented, or resold. High vacancy rates, rental conversions, and informal resales indicate systemic flaws in targeting, enforcement, and market regulation.

The IMHP case studies reflect several critical lessons for housing policy and planning practice:

• Challenges the universality of homeownership as a welfare tool;

• Highlights the need to conceptualize informality as integral to policy frameworks;

• Demonstrates the centrality of spatial equity in policy design.

We argue that while homeownership has benefits, it is not a sufficient solution to the housing affordability crisis. We advocate for a context-based, balanced approach and propose the following policy recommendations for housing policymaking and implementation in Iran:

• **Understanding informal market mechanisms**: Formal bureaucratic regulations alone cannot achieve housing policy goals.

• **Hybrid tenure models**: Introduce affordable rental options alongside ownership to diversify housing solutions.

• **Consideration of socio-economic realities**: Economic conditions and social priorities of Iranian households significantly influence housing policy outcomes.

• **Context-based policymaking and urban planning**: Differences in cities, locations, and communities must be considered in policy design.

Ultimately, IMHP's mixed results highlight the need for adaptive housing policies that balance ownership incentives with protections against market exploitation. Further research should explore participatory approaches, where beneficiary feedback informs policy adjustments to enhance effectiveness and equity. Housing policies should choose between rigid idealism and adaptive pragmatism. IMHP's legacy should inform Iran's next steps—not as a failure, but as a catalyst for systemic reform.

ETHICS, VALUES AND PLANNING

Planning for gender health justice: A scoping review and research agenda

Kimberley Kinder, Sophia Spence
Affiliation: University of Michigan Taubman College of Architecture and Urban Planning
Email: kkinder@umich.edu, hffckr@umich.edu

Abstract:
Urban planning plays a crucial role in advancing social justice, public health, and gender equity in parallel. Increasingly, scholars are investigating the field's potential to simultaneously enhance outcomes across all three areas through planning for gender health justice. This scoping review assesses the extent to which planners are incorporating gender in healthy cities scholarship, including current work already being done in this area and gaps where further research is needed. Our analysis suggests that planners are making progress on violence against women in public spaces and planning deficits related to women's unpaid care labor. However, our review also indicates that further research is needed to address more diverse forms of gender violence, expand the scope of gendered health issues being investigated, and incorporate a more holistic understanding of gender identity. Based on these findings, we outline an integrated research agenda designed to support planning scholars in advancing gender health justice.

Keywords: gender, health equity, healthy cities, social justice

Introduction:

The purpose of this scoping review is to develop a holistic research agenda to bolster urban planners' capacity to advance gender health justice. Although gender health equity is a strong focus in other fields like public health and social work, we argue that, on the whole, the field of urban planning could do more to take responsibility for its capacity to influence gendered health outcomes. We believe that planners have a unique and vital role to play in addressing gender health disparities because the urban built environment plays a role in creating and perpetuating these disparities. At the same time, urban planning and policymaking can facilitate better health outcomes and advance gender health justice. To that end, we argue that urban planning researchers can and should play a critical role in addressing gender health inequities in our communities.

Through a scoping review of planning literature, which was recently published with the Journal of Planning Literature, we explore the extent to which planning scholarship incorporates a gender-sensitive approach towards planning for healthy cities (Kinder & Spence, 2025). We uncover key gaps in this area and use them to build out a preliminary gender health justice research agenda for planning scholars focused on addressing diverse forms of gender violence, expanding understandings of gender health disparities beyond health disparities associated with mothering, and integrating the health needs of transgender and nonbinary populations.

Methods:

Our findings are based on a scoping review of planning literature published in the last decade. Our scoping review followed the recommended multi-stage reflexive approach, which consists of (1) research question formation, (2) search strategy, (3) evidence screening and selection, (4) data extraction, and (5) data analysis (Arksey and O'Malley 2005; Peters et al. 2020; Tricco et al., 2018). As a first step, we formulated our research question as: to what extent does urban planning incorporate gender in efforts to plan for healthy cities?

In the second phase, search strategy, we reviewed peer-reviewed articles published in English between 2014 and mid-2024 with a triple focus on planning, health, and gender in the Global North. We used the Web of Science database to search for articles, following the precedent of other recent planning literature reviews (Kim 2023; Lee et al. 2024; Xiao and Watson, 2019). In order to find articles that focused on planning, health, and gender, we searched for articles that included the term "health" as well as one or more of the following gender-related terms: "gender", "women", "woman", "girl", and "transgender". In order to retain our focus on planning literature,

and in keeping with other recent planning literature reviews (Hartt et al., 2024; Pothukuchi, 2021), we searched a hand-selected list of the top 35 planning journals as identified by Goldstein and Maier (2010). Next, following another recent precedent (Kim, 2023), we conducted a second search of the same terms in journals included within Web of Science's predefined regional and urban planning category. This search strategy resulted in a total of 1,567 articles that merited possible inclusion in this review.

As part of the third phase, evidence screening and selection, we uploaded RIS data for these 1,567 articles into Rayyan, an application that facilitates literature review screening. After reviewing the titles and abstracts of each article and removing duplicates, we reached agreement on 109 articles that merited possible inclusion in this review. In order to assess whether each article contained a significant triple focus in all three of our focus areas (planning, health, and gender), we carefully reviewed the full text of each article. This process resulted in a mutually agreed upon list of forty-one articles to be included in this scoping review.

The fourth phase, data extraction, revealed a number of interesting themes. The forty-one articles included in this review represent a diverse range of planning and health topics. With a total of 121 co-authors and very little overlap between authors and articles, it is clear that there is a growing scholarly community interested in planning for gender health justice. Moreover, more than two-thirds of our sample were published within the last five years, suggesting a recent increase in research interest on this topic. However, there was less diversity in publication sources: just twelve journals published the entirety of planning for gender health justice scholarship in the last ten years.

Table 1: Journals included in this scoping review.

Journal	Number of articles
Landscape and Urban Planning	7
Urban Studies	6
Cities	5
Housing Policy Debate	4
Transportation Research Part A - Policy and Practice	4
Environment and Planning C - Politics and Space	3
Environment and Planning A - Economy and Space	3
Journal of the American Planning Association	2
Journal of Urban Affairs	2
Environment and Planning E - Nature and Space	1
Urban Planning	1
Urban Affairs Review	1

The geographic focus of the articles was more or less evenly distributed between Europe and North America, with a small number focused on Australia.

Table 2: Geographic focus of articles included in this scoping review.

Geographic Focus	Number of articles
Europe	19
North America	18
Australia	3
Europe & North America (dual focus)	2

The articles were also roughly evenly split between qualitative and quantitative methods..

Table 3: Methods used by articles included in this scoping review.

Methods	Percentage of articles
Qualitative methods	56%
Quantitative methods	44%

The most common planning topics in this review were transportation and public safety. The remaining articles considered housing, urban green space, right to the city, economic development, care planning, energy planning, climate adaptation planning, indigenous planning, neighborhood planning, healthy city planning, land use, and gentrification.

Table 4: Planning topics included in this scoping review.

Planning topic	Number of articles
Transportation	10
Public safety	8
Housing	5
Urban green space	4
Right to the city	2
Economic development	2
Care planning	1
Energy planning	1
Climate adaptation planning	1
Neighborhood planning	1
Healthy city planning	1
Land use	1
Gentrification	1
Indigenous planning	1

The most common health topic by far was violence, following by wellbeing, reproductive health, and the health benefits of nature. Other health issues explored included environmental justice, physical activity, healthcare, urban health, aging, mortality, disability, and healthy cities.

Table 5: Health topics included in this scoping review.

Health topic	Number of articles
Violence	17
Reproductive health	4
Wellbeing	4
Health benefits of nature	3
Environmental justice	3
Physical activity	2
Aging	1
Disability	1
Healthcare	1
Mortality	1
Urban health	1
Healthy cities	1
Mental health	1

Most articles had a primary gender focus on women, with some articles exploring issues pertinent to girls and transgender individuals.

Table 6: Gender focus of the articles included in this scoping review.

Gender focus	Percentage of articles
Women	90%
Older women	2.5%
Girls	2.5%
Transgender	2.5%
Women and transgender (dual focus)	2.5%

After conducting the initial data extraction, we used NVivo – a qualitative data analysis software program – to code the articles during the fifth phase, data analysis. We coded the articles based on key themes identified during the third and fourth phases, including violence, social reproductive, health issues unrelated to violence or social reproduction, gender identities other than cisgender women, and mentions of planning as a determinant of health. We then analyzed the coded material to develop the research agenda presented in this paper.

Conceptualizing gendered violence beyond the gender fear gap:
The first component of our gender health justice research agenda is the opportunity for planning research to conceptualize planning's role in gendered violence beyond women's fear of unknown assailants in public space. As the focus of seventeen articles – over 40% of our sample – violence was by far the most commonly researched gendered health issue in this scoping review. This research reveals the value of investigating violence as an expression of gendered health disparities from a health perspective. At the same time, it reveals opportunities for the field to expand its understanding of gender violence.

The articles in this review often discuss violence in the context of the "gender fear gap" (Jiang et al., 2014), which is framed as women's disproportionate experiences of fear in public spaces compared to men (Agusti et al., 2022; AitBihiOuali & Klingen, 2022; Navarrete-Hernandez et al., 2021). Specifically, this gap focuses on women's fear of harassment and assault by strangers in public spaces, leading many to "restrict their mobility, to varying degrees, because they feel afraid" (Sandberg & Ronnblom, 2015, 2665; see also Lee et al., 2018). The gender fear gap compromises women's right to the city by creating "fear-based exclusion" from urban locations and resources (Loukaitou-Sideris et al., 2024, 212; see also Biswas & Sweet, 2024). This exclusion in turn limits women's access to education and employment opportunities, directly and indirectly compromising their health and wellbeing (Agusti et al., 2022; AitBihiOuali & Klingen, 2022; Navarette-Hernandez et al., 2021).

The gender-fear gap is an important issue for planners to reckon with. That said, the overwhelming emphasis on the gender-fear gap in planning scholarship on gendered health issues reveals a missed opportunity to engage with other types of gendered violence. We found evidence that this hyper-focus on women's fear of unknown male assailants in public spaces is matched by a near total-silence on other forms of gender violence that are also heavily influenced by urban infrastructure and policymaking.

Some planners are reluctant to address intimate partner violence, arguing that "it is inappropriate and naive to expect violence indoors should be tackled by urban planners" (quoted in Sweet and Escalante, 2015, 1831). However, other research included in this review reveals that urban planning and policymaking shapes gendered vulnerability to IPV. One area that is notably influenced by planning is housing. Access to high quality, affordable, and stable housing is critical to avoiding, escaping, and recovering from IPV (Ballen et al., 2024; Martino et al., 2020; Thomas et al., 2020). However, emergency and affordable housing is often located in areas with limited access to economic opportunities or public transit due to zoning laws and housing market conditions, despite the fact that women are more likely to be low-income and less likely to access a private vehicle (Ballen et al., 2024; Fan et al., 2016; Martino et al., 2020). These inadequacies "could mean the difference between gaining employment, education, or social support and hence not returning to an abusive partner" (Martino et al., 2020, 4; see also Thomas et al., 2020).

This is where planners have an opportunity to play a role in preventing and responding to IPV. Rethinking housing, land use, and transportation policies could be an act of violence prevention championed by planners, changing the current reality in which "violence and housing instability combine to become a major cause of poor health in women" (Martino et al., 2020, 2).

In addition to IPV, this scoping review revealed opportunities for planners to address the gendered components of structural violence. Due to the feminization of poverty, women "more often reside in socioeconomically deprived areas" (Johansson & Haandrikman, 2023, 1242) and "bear the brunt of poor environments" (Navarrete-Hernandez et al., 2021, 2). Women, therefore, are disproportionately impacted by the "slow violence" of extreme urban disinvestment (Vasudevan & Smith, 2020; see also Moffett-Bateau, 2024), which exposes residents to air pollution, water contamination, and unsafe housing, in combination with limiting access to health promoting resources like accessible and affordable grocery stores, green spaces, and housing. Women are also disproportionately exposed to neighborhood violence in these areas, resulting in chronic stress which, when "sustained over a long period of time, can make residents more vulnerable to disease and more susceptible to negative coping behaviors" (Zuberi et al., 2016, 548).

Other examples of structural violence often neglected by planners include transphobic harassment in public spaces (Smith et al., 2023), the "hypercriminalization" of Black women living in gentrifying areas (Versey, 2023), the gendered dimensions of Islamophobic hate crimes (Hancock et al., 2018), and poor public housing conditions (Moffett-Bateau, 2024).

Taken together, this evidence suggests that planners recognize violence as an important planning-related gendered health issue. While most of this research focuses on the gender fear gap, emerging research demonstrates opportunities for planners to play an increased role in addressing the gendered dimensions of interpersonal and structural violence.

Conceptualizing gendered health disparities beyond caregiving:
Our next finding concerns reproductive labor, which was a dominant framework within the planning literature on gendered health disparities. Twenty-nine articles – nearly 70% of our sample – invoke women's gendered role as caregivers as a primary frame of reference. What this invocation does, either implicitly or explicitly, is equate "gender" as a frame of analysis with "cis women engaging in mothering tasks", which then implies that gendered health disparities are health disparities related to the act of mothering. While we recognize the importance of care work as a factor in gendered health outcomes, we also argue that planning researchers should expand their conceptualization of gender health disparities beyond disparities associated with parenthood and caregiving. For instance, planners should attend to health disparities that affect younger and older women outside of childbearing years, health disparities that affect women regardless of whether or not they are parents, and health disparities specific to transgender and/or nonbinary gender identities.

The overwhelming focus of the articles that invoke caregiving is on mothers caring for minor children. In this context, care refers to the labor that is "necessary to maintain existing life and reproduce the next generation" (Binet et al., 2023, 284), which is disproportionately performed by women (Morris, 2018). Caregiving is an important gendered health issue for planners to reckon with. Although this work—and the infrastructure necessary to support it—has historically been undervalued within national governments (Horton 2022) and spatial policymaking (Martino et al. 2020), emerging research demonstrates that "the crisis of care is an urban planning problem" in that care became harder, more complex, or compromised "when environmental components for care were absent, inadequate, inaccessible, or spatially disconnected," and that planning can address these barriers by making care visible and valued "in the design and evaluation of policies and interventions in the built environment" (Binet et al. 2023, 284). This infrastructure could improve women's health—not just the health of their dependents—directly through improved access to safe mobility, healthy food, and medical care, as well as indirectly through increased access to health promoting resources related to economic advancement and leisure pursuits (Binet et al. 2023; Colley et al. 2022).

Transportation planning researchers are making notable progress on this issue. Multiple articles in this scoping review concern the ways in which car-oriented land use and transportation planning "reinforces traditional gender relations" and their associated gender health disparities by connecting men to better paid, commuter-based employment, while leaving more care-burdened women with few options beyond underpaid, local, part-time work work (Giacomantonio et al. 2024; Lee et al. 2018; Navarrete-Hernandez et al. 2021; Sandberg and Ronnblom 2015; Sandow et al. 2014). Moreover, transportation systems center the needs of male commuters more than female caregivers, who tend to take more frequent and shorter trips, often in the context of chauffeuring children and/or trip chaining (AitBihiOuali and Graham 2021; AitBihiOuali and Klingen 2022; Giacomantonio et al. 2024; Johansson and Haandrikman 2023; Lee et al. 2018; Navarrete-Hernandez 2023). Researchers call on planners to redesign transportation systems to better accommodate the needs of caregivers, which would support their health and the health of their dependents (AitBihiOuali and Graham 2021; AitBihiOuali and Klingen 2022; Giacomantonio et al. 2024; Johansson and Haandrikman 2023; Lee et al. 2018; Navarrete-Hernandez 2023). We strongly support research at the intersection of planning, health, and caregiving, even as our second finding in this area calls on planners to address gender health disparities that affect women and gender minorities regardless of whether or not they are caregivers.

Although many studies in this review both explicitly and implicitly connect gendered health disparities to women's roles as mothers, others demonstrate that inequitable health outcomes impact women regardless of whether or not they are parents. These studies reveal that, even without caring for minor children, women still experience increased health risks associated with climate change (Amorim-Maia et al. 2023), substandard housing (Morris 2018), aging in place (Byles et al. 2018), food systems (Amorim-Maia 2023; Versey 2022), disabling environments (Fabula and Timár 2018; Martino et al. 2020), and neighborhood disinvestment (Lee et al. 2018; Moffett-Bateau 2024). Regardless of their status as caregivers, women have less access to the health promoting benefits of public space (Navarrete-Hernandez et al. 2021), green space (Colley et al. 2022), urban cycling (Giacomantonio 2024), paid work (Agustí et al. 2022; Ballan et al. 2024), and homeownership (Morris 2018). Additionally, women with or without children in the home appeared to receive the fewest benefits from and were exposed to

the greatest risks associated with gentrification (Versey 2022) and super-commuting (Morris 2018; Sandow et al. 2014; Kroesen 2022). In addition to planning for care infrastructure, this research presents important opportunities for planners to develop more diverse responses to gendered health injustices.

One way to respond to this call is for planning researchers to expand their research to include health disparities impacting older women and girls, who are less likely to care for minor children. While a majority in our sample address the health needs of mothers, very few investigate gendered health outcomes experienced by older women and girls. These articles include research on the positive health impacts of schoolyard greening which "stimulates physical activity, but only in girls" (van Dijk-Wesselius et al. 2018, 23), and the need to develop cycling infrastructure and programming tailored to the needs of adolescent girls (Giacomantonio et al. 2024). On the other end of the age spectrum, "gendered disadvantage across the lifecourse means that women may not have been as well set-up in later life, and hence have fewer resources" to manage the health challenges associated with aging (Byles et al. 2018, 921). Our findings suggest that older women's and girl's specific health needs are underconsidered in planning literature, offering a ripe opportunity for planning researchers to make an impact towards gender health justice.

Conceptualizing gender beyond the cisgender binary:
Another response could be to expand research on planning for the health needs of transgender and non-binary populations. This research is urgently needed given concerns that "systemic cissexism, transmisogyny, and transphobia" in urban planning and related fields "produces marginalisation across public institutions and spaces" including "housing, transportation, and facilities" (Smith et al. 2023, 2). Although numerous articles included in this scoping review mention these groups in passing, these mentions are usually found in the "limitations" section. Just two articles in our sample retain a significant focus on transgender identity (Chlala, 2020; Smith et al., 2023).

While few in number, these studies highlight several areas in which planning research could help the field to more effectively address the health of transgender communities. One area is transportation, which is important given that "transgender and gender-nonconforming individuals" have been found to "experience frequent sexual harassment in transit environments" (Loukaitou-Sideris et al. 2024, 216). Another area involves affordable housing, which matters because, in the U.S., "transgender people ... are four times more likely than cisgendered people to live in poverty, with nearly one-third of Black and Latinx transgender people living on less than $10,000 a year" (Chlala 2020, 1185). A third area is accessible public space, which planning could improve through ordinances requiring or incentivizing "public, accessible, gender neutral toilets in shops and restaurants near the entrance to the building from the open space" (Smith et al. 2023, 5). In all these areas, in addition to producing co-benefits that improve health outcomes for mothers, older women, low-income women, immigrant women, disabled women, and women of color, these planning priorities could disproportionately benefit transgender and nonbinary people, and they could be tailored with those groups in mind (Smith et al. 2023).

Conclusion:
Planning is a determinant of health, and planners have a critical role to play in advancing gender health justice. In this scoping review, we find that planners are making important progress in this area, especially around resolving gendered health disparities related to the gender fear gap and health needs related to caregiving. While these contributions are important and beneficial, we cannot stop here. We have identified critical opportunities for planners to expand their research and advance gender health justice in the process. Specifically, we urge planning researchers to investigate a wide range of gender violence topics including interpersonal violence and structural violence, to expand their focus on gendered health issues beyond disparities associated with caregiving to include girls and older women, and to holistically incorporate the health needs of transgender and nonbinary individuals.

Expanding planning research on gender health disparities to include these health topics and identity groups can enable the field to develop actionable infrastructure and policy recommendations advancing gender health equity in communities across the world. In sum, we applaud the valuable contributions urban planning is already making towards addressing gender health disparities, and we urge the field to scale up these efforts by embra-

cing an expanded research agenda for gender health equity.

PROPERTY MARKET ACTORS

The financialisation of actors, practices and instruments. Insights from Milano's urban market

Alberto Bortolotti
Department of Architecture and Urban Studies, Politecnico di Milano
alberto.bortolotti@polimi.it

Abstract
Financialisation has become increasingly relevant in urban studies, highlighting the growing role of financial actors, practices and instruments which are shaping cities. Milano has a unique position as a middle-size and gateway city located between Continental and Mediterranean Europe and these circumstances made it a magnet for institutional investment. This research investigates such financial mechanisms in Milano, considering the global and European influence pressuring Milano's urban development, planning, and governance. Drawing on empirical studies and existing research, it analyses investment patterns, actor strategies, and regulatory frameworks. This study adopts an interdisciplinary approach to reveal the complex ties between finance and urban transformations, aiming to support equitable, sustainable development and contribute to both academic and policy debates.

Key Words: Financialisation, Milano, Real estate markets

Full Text

Over the past decades, the concept of 'financialisation' has gained prominence in urban studies, reflecting the growing influence of financial actors, practices, and instruments in shaping major urban markets. This phenomenon, as explored by scholars such as Epstein (2005), Leyshon and Thrift (2007), Krippner (2011), Christophers (2011), Gotham (2012), Raco et al. (2019), and Aalbers (2019), reflects the pivotal role of real estate investments and financial strategies for the management of built environment and urban development.

Relevant academic studies have shown that real estate markets are globally interconnected yet locally grounded and geographically heterogeneous (Holm et al., 2023; Van Loon et al., 2017). In the current economic phase, the financialisation of real estate has turned the sector into a central pillar of the entire financial market, accounting for more than 70% of global investment (Barnes et al., 2016). Accordingly, real estate represents one of the most significant investment asset classes, contributing roughly 10% of global GDP and underpinning unprecedented growth in terms of value and investment volumes, especially in emergent financial hubs (Singapore, Dubai, Doha etc.) (Bracken et al., 2021).

Focusing on the principal cities for the attractiveness of such investments, comparative analyses illustrated that property value trends before and after the pandemic (2018-2022) (Parker, 2021; Bracken et al., 2021; Holzhey et al., 2022) exhibit a moderate risk of a 'housing bubble,' with overvaluation ranging between +0.5% and +1.5%. This risk, however, is mitigated by transnational investment flows entering and exiting the continental financial systems of the EU and the US. These flows, facilitated by the financialisation of real estate assets, effectively neutralise the cyclical nature of the major property markets (Holzhey et al., 2022; Barnes et al., 2016).

Despite the COVID-19 pandemic, particularly housing prices in the Eurozone and financialisation have stabilized or even boosted investment volumes, displaying resilience amid economic turbulence which is supposed to increase over the upcoming years due to the announced interest rate cut (ECB, 2025).

As Volpi (2024) pointed out, the geopolitical influence exerted by the major asset management firms, the so-called "Big Three" (BlackRock, Vanguard, and State Street), is also significantly impacting real estate, particularly through the financial instruments that underpin major urban development initiatives. Specifically, the hegemonic control these financial funds wield over leading credit rating agencies enables them to shape perceived investment risk (Agnew, 2012) associated with securitizations, mortgages, licenses, and other instruments tied to real estate assets. Moreover, the trading of equity stakes in key institutional investors, banks, and corporations

involved in territorial transformation (e.g., BlackRock's holdings in UniCredit, Intesa Sanpaolo, and Atlantia in Italy) entails substantial implications for agglomerated economies, real estate actors and planning tools dealing with real estate markets.

Within this context, the mobilisation of investments is not exclusively driven by returns or risk diversification, but also by the power relations embedded in the geopolitical positioning of cities within the real estate arena. According to Budenbender et al. (2017), real estate represents a case of 'geopolitics of the multiple' in which real estate markets are both shaped by and shaping the circulation of capital, intertwined with soft power and low-geopolitics strategies of cities (Agnew, 2012).

Moreover, the implicit subordination of local and national governments to the capital mobilised by the real estate sector led to a geopolitically reconfiguring its sphere of influence, generating high returns and new specialities, horizontally, across socioeconomic activities, and vertically, across diverse territorial contexts. Clear examples of such dynamics are the participation of municipal delegates in real estate fairs and events.

Following these premises, this ongoing research aims to explore the interrelationships among planning and economics studies to promote new pathways for equitable urban development in an increasingly financialised landscape. Within this context, it frames the nature and characteristics of real estate financialisation in Milano by examining on the one hand, urban planning and policy instruments, and, on the other, data from real estate investment funds.

In other words, building on solid research (Anselmi & Vicari, 2020; Conte & Anselmi, 2022; Bortolotti, 2023) and empirical analysis conducted with State datasets on property transactions, this study is unveiling the multifaceted financialisation processes influencing Milano's urban market by addressing the patterns and impacts of property investments in urban development and real estate management; the regulatory, programming, and planning instruments that enable real estate finance; and the roles, perceptions and strategies of the key actors operating in this arena.

This research focuses on Milano, an emblematic city for contemporary urban transformation in Southern Europe and aims to uncover the intricate connections between global predatory financial mechanisms and local urban development related to capital accumulation liberated by Milanese households and enterprises. In this regard, this working paper tackles the specificity of Milano in being a gateway city as middle size metropolis geographically and geopolitical bridging Continental and Mediterranean Europe, two fundamental elements which made Milano a magnet for institutional financial investment and enormously renovated the city in comparison to the rest of the country.
