How Spatial Factors Affect Respiratory Health in Coal Resource-based Cities: a Case-control Study in Eastern Yunnan Province, China

Yuxing Zhao & Lan Wang

Abstract:
Urban planning can affect respiratory health. Due to industrial and mining pollution, unique urban and rural spatial structure, etc., the built environment factors of coal resource-based towns have special impact paths on respiratory health. Lung cancer is one of the cancers with the highest incidence and mortality rates worldwide. Qujing City, located in the eastern part of Yunnan Province, China, is dominated by the coal mining industry. Since the survey in the 1970s, it has been the area with the highest incidence of lung cancer in China. Compared with the national average, the standardized mortality rate is 3 times that of men and 5 times that of women. Existing studies are mostly centered on the field of epidemiology, among which there are few studies on spatial influencing factors and the research indicators are single. This study aims to explore the association between environmental factors and the risk of lung cancer in residents in coal resource-based urban and rural areas at different stages of the life course, and propose corresponding intervention measures.

The study adopted a case-control study based on life course theory. Lung cancer patients and healthy controls were interviewed in two local hospitals, and individual-level influencing factors that could not be obtained through external data were obtained through questionnaires. Among them, non-spatial factors such as smoking history were confounding factors and were controlled; spatial influencing factors such as migration history and living environment history were the core content of the study. On this basis, Landsat remote sensing images were identified through supervised classification methods in ENVI5.6, and pollution sources such as mining land and industrial land were extracted. Frequency matching was established according to gender and age (±2 years old), and 51 cases in each case group and control group were obtained. The exposure ratio in the case group and the control group was compared through spatial statistics and the use of non-conditional Logistic regression model.

The study found that the case group and the control group showed obvious urban-rural differences in space. Compared with the control group, the hotspots were mainly concentrated in rural areas, and the case clustering was strongest when the analysis radius was 2km. After controlling for factors such as fuel use and housing type, long-term residence within 2km of a coal mine was still a significant risk factor after adjustment (OR: 2.433; 95%CI: 0.951-6.222). The living environment has a heterogeneous effect on the incidence of lung cancer at different stages of the life course. After adjustment, living in earthen houses in early adulthood (25-44 years old) (OR: 2.891; 95%CI: 1.144-7.311), living in brick and wood houses in middle-aged and elderly (45 years old and above) is a risk factor in univariate analysis (OR: 2.759; 95%CI: 1.159-6.567), while living in concrete houses during the development period (0-24 years old) (OR: 0.108; 95%CI: 0.013-0.894) and early adulthood (OR: 0.292; 95%CI: 0.103-0.823) may have a protective effect. Although cooking in the kitchen and the main room, and the type of stove, were not included in the final model, the univariate analysis still indicated the health risks of poor ventilation and indoor pollution. The above research provides a basis for promoting the implementation of health equity planning at the micro and medium levels.

Keywords: Resource-based cities; Lung cancer; Case-control study; Residence history; Life Course; Health equity

1. Introduction

Urban and rural space is the main carrier of human activities, directly or indirectly affecting people's physical and mental health through complex paths. "Healthy city planning" is based on reducing health risks, optimizing health resources, and promoting healthy behaviors. It regulates and shapes space. It is an important policy tool for achieving health promotion and disease prevention and control, and plays an important role in "preventing disease" at the population level (Wang L, 2023). Respiratory health is an important research area in the field of healthy cities. A large number of scholars have explored the ways and mechanisms to promote respiratory health around four types of urban space elements: land use and facilities, development intensity and form, road traffic system, green space and open space. However, compared with other types of towns, the impact path of built environment factors on respiratory health in coal resource-based towns is special: for example, industrial and mining pollution has a stronger explanatory power for respiratory health results (Wei H, et al., 2022), and lower aggregation levels and more small and medium-sized settlements may also have some impact on the action path (Lu S, et al., 2020).

Qujing City, Yunnan Province, located in the eastern Yunnan region of China, is extremely rich in coal resources

and has formed a coal industry chain dominated by coal-fired power, coking, and chemical industry. Various pollutants generated by widely distributed coal mines, coal washing plants, coking plants, etc., bring long-term health risks to local residents. Eastern Yunnan is a high-incidence area of lung cancer in China. A retrospective survey of causes of death in the 1970s showed that the lung cancer mortality rate in Xuanwei was 4.1 times and 7.9 times that of the national male and female lung cancer mortality rates during the same period. At present, compared with the national average, the standardized mortality rate is 3 times that of men and 5 times that of women. Since the 1970s, a large number of studies from an epidemiological perspective have shown that factors such as coal type, frequency and amount of use (Barone-Adesi, et al., 2012), stove type (Hu W, et al., 2014), and years of work in coal mines (Hosgood III HD, et al., 2012) are related to the incidence of lung cancer. However, in existing studies, the number of studies on spatial influencing factors is small and the research indicators are single. This study aims to explore the spatial influencing factors of lung cancer in resource-based towns in eastern Yunnan and propose corresponding spatial intervention measures.

2. Materials and methods

2.1.Study Area

This study takes Fuyuan County and Xuanwei City under the jurisdiction of Qujing City, Yunnan Province as the research objects. Fuyuan County has a total area of 3,348 square kilometers and a total population of 840,000; Xuanwei City has a total area of 6,070 square kilometers and a total population of 1.19 million. The two places are located in the eastern part of Yunnan Province, which is a slope area where the Yunnan Plateau transitions to the Guizhou Plateau and belongs to the Wumeng Mountain System. Most areas have relatively straight peak lines and relatively gentle mountain tops, which are shallowly cut mountains with small terrain slopes and small relative height differences. The local plains between the mountains are called “Bazi”, which are usually economic centers with prosperous agriculture and dense population.

Fuyuan and Xuanwei both belong to the coal-bearing belt of the eastern Yunnan coalfield, which is distributed to the east of the Niu Shoushan uplift. The coal-bearing strata are consistent with the tectonic axis of the earth, and the coal types are distributed in strips from southwest to northeast. The coal in the two places is shallowly buried and easy to mine. Since the late Ming Dynasty and early Qing Dynasty, people have mined coal for cooking and heating in the two places.

Through field research, it was found that there are a large number of pollution sources such as coal mines and thermal power plants adjacent to towns, coal is easily available, local residents burn coal indoors, and pollution diffusion conditions are poor, which poses health risks.

2.2. Research Framework

This study adopts the research framework of epidemiology. First, the current situation study in descriptive epidemiology is used to describe the distribution of diseases or health and other factors affecting the incidence of lung cancer, which can reveal the phenomenon and provide clues for etiology research. In this study, the average nearest neighbor, nearest neighbor hierarchical cluster analysis, and multi-distance spatial cluster analysis were used. Subsequently, the case-control study in analytical epidemiology was used to test the above hypothesis and explore the impact of built environment exposure at different stages on the incidence of lung cancer from the perspective of life course. In this study, the logistic regression analysis method was used.

2.3. Data Collection

2.3.1.Health Outcomes

The cases were new lung cancer cases from two local hospitals in Qujing in the past five years, and the controls were patients from departments of the two hospitals that were not related to respiratory diseases (such as orthopedics, etc.). Through face-to-face interviews and filling out questionnaires, individual-level confounding

factors and spatial influencing factors that could not be obtained through external data were obtained. 162 questionnaires were obtained from April 7 to August 2024. After excluding samples that had lived outside the research scope for a long time, whose addresses were not accurately located, and whose some indicators were missing, a total of 138 samples were obtained, including 72 cases and 66 controls. A database was established in EpiData3.1, and frequency matching was performed according to gender and age (plus or minus 2 years old), and 51 cases and 51 controls were obtained. Oral informed consent was obtained from all study subjects.

2.3.2.Spatial Factors

Spatial influencing factors focus on the meso-micro scale. The meso-level includes spatial relationships (the distance between the residence and the pollution source), wind environment (wind direction), and topography (relatively flat areas, surface undulation). The micro-level includes residential history (house structure, ventilation conditions), stove type, and cooking location.

The address data of the samples came from the questionnaire. The urban samples were accurate to the road intersection, and the rural samples were accurate to the natural village. The spatial location was performed in ArcGIS Pro. The pollution sources include mining land and industrial land. Using the remote sensing images of the Landsat-8 satellite in December 2019, the results of the third land survey in Fuyuan County were used as samples, and the maximum likelihood method was used for supervised classification. Mining land and industrial land were identified in ENVI5.6. The wind direction is plus or minus 30 degrees from the local dominant wind direction.

Relatively flat areas (RFA) are areas with a relative height of no more than 30 meters within a range of 300m*300m around the grid according to GDEMV3 30M resolution digital elevation data. The relief degree of land surface (RDLS) represents the average altitude, the proportion of flat areas, and the elevation range of a specific area. The calculation formula is as follows:

$$RDLS=ALT/1000+Range(H)*[1-P(A)/A]/BM$$

Where ALT is the average altitude within 2 km of the sample, Range(H) is the difference between the highest and lowest altitudes within 2 km, P(A) is the area of relatively flat area (RFA) within 2 km, A is the total area of 2 km, and BM is the benchmark altitude of mainland China (500 m).

Micro-level data were obtained through questionnaires.

2.3.3. Non-spatial Factors

Non-spatial influencing factors include the respondent's smoking history (cumulative smoking duration, smoking amount, passive smoking), occupational exposure history (occupation type, employment duration, whether engaged in coal-related industries), life fuel use history (fuel use type, use duration, use amount), personal medical history and family genetic history. The above data were obtained through questionnaires.

2.4.Analytical Methods

2.4.1.Spatial Analysis

1-Average Nearest Neighbor

The average nearest neighbor is the ratio of the "average observed distance" to the "expected average distance". If the index is less than 1, it is a clustered mode, and if the index is greater than 1, it is a discrete mode.

2-Nearest Neighbor Hierarchical Cluster Analysis

The nearest neighbor hierarchical cluster analysis method is used to explore the hot spots of spatial distribution of point data (Zhan D, Meng B, 2013). This method defines a threshold distance (random nearest neighbor

distance) for clustering, and only points closer than the threshold distance will be selected for clustering. The first clustering forms the first-order clustering, followed by subsequent clustering to form second-order and third-order clustering until all clusters converge into a single cluster or clustering fails. This study used Crimestat 4.02 software to compare the hot spots of the current residence distribution of the case group and the control group to explore the differences in distribution and agglomeration between the two.

The study found significant differences in their distribution: the clusters of the case group were located in rural areas; the clusters of the control group were located in Fuyuan County, Housuo Town and Yingshang Town.

3-Multi-distance Spatial Cluster Analysis (Ripley's K function)
Ripley's K function is used to analyze the spatial distribution pattern of points at different distance scales (Zhan D, Meng B, 2013). Its principle is to calculate the number of other points within a certain distance r around the point (K observed value) and compare it with the theoretical value of completely random distribution (K expected value). If the K observed value at a specific distance is greater than the K expected value, the distribution is more clustered than the random distribution at that distance; if the K observed value is less than the K expected value, the dispersion is higher.

2.4.2. Case-control Study Based on Life Course Theory
Case-control study is the most commonly used analytical epidemiological research method, mainly used to explore the causes or risk factors of diseases and test etiological hypotheses. Its basic principle is to use a group of patients who have been diagnosed with a specific disease as the case group, and a group of individuals who do not have the disease but are comparable as the control group. Through inquiries and other methods, the subjects' previous exposure history to various possible risk factors is collected, and the differences in the exposure ratios of each factor between the case group and the control group are compared to see whether they are statistically significant.

Chronic diseases are affected by a variety of factors over a long period of time, and the occurrence of chronic diseases cannot be explained entirely by exposure in adulthood (Zheng Y, He D, 2015). Exposure at different ages may directly or indirectly affect health in adulthood (Bever A M, Song M, 2023). The life course theory holds that in the course of life, various factors independently, cumulatively, and interactively affect health and disease in adulthood (Kuh D, et al., 2003). Exposure to air pollution at a younger age may have more harmful effects because organ systems are still developing (Portengen L, et al., 2023). Lung development begins in early pregnancy and continues to grow until the age of 25, when lung function reaches a physiological stable period (Mahmoud O, et al., 2023). Since the age of 45, the incidence of lung cancer has increased rapidly. According to the life course, it is divided into three time periods, namely the development period (0-24 years old), early adulthood (25-44 years old), and middle-aged and elderly (45 years old and above). The association between risk exposure and lung cancer incidence in the three time periods was calculated separately.

SPSS29.0 was used for data analysis in this study. Cross-tabulation was used for univariate studies, and conditional logistic regression was used for multivariate studies to calculate the odds ratio (OR) and 95% confidence interval (95% CI) between risk factors and lung cancer incidence. Each continuous variable (each risk factor for cumulative exposure duration) was converted into a categorical variable using a dichotomy method, and the critical point was the average value of the control group.

3. Results
3.1.Spatial Statistics
The average nearest neighbor calculation was performed on the case group and the control group in Fuyuan and Xuanwei, and it was found that the degree of clustering of the case group in both places was higher than that of

the control group (table). Through the nearest neighbor hierarchical cluster analysis method, it was found that the clustering areas of the case group were mostly located in rural areas, while the clustering areas of the control group were located in urban areas, and there was a significant difference in the distribution of the two. Through multi-distance spatial cluster analysis, it was found that the case group was clustered within 21.5km, and the degree of clustering was the highest at 2km, while the control group was clustered within 21km, and the degree of clustering was the highest at 5km (Figure 1).

Table 1 Average nearest neighbor of the case group and the control group

Group		Nearest neighbor ratio	Z score	P value
Fuyuan	Case group	0.47	-7.38	0.00**
	Control group	0.82	-2.57	0.01**
Xuanwei	Case group	0.46	-4.53	0.00**
	Control group	1.01	0.09	0.93

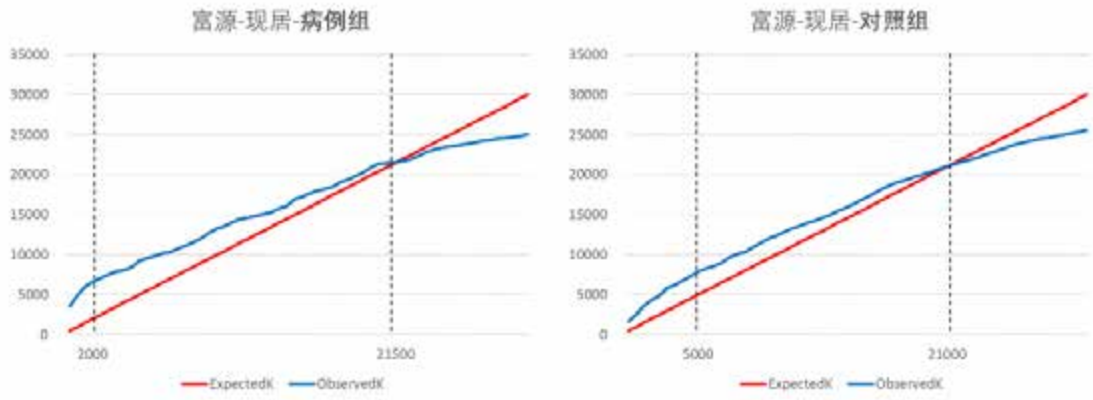

Fig.1 Multi-distance spatial clustering of case group and control group

In summary, the study found that the degree of clustering in the case group was higher than that in the control group, and the spatial distribution and scale of the clusters were significantly different, indicating that the local incidence of lung cancer was affected by spatial factors.

3.2.Case-control Study Results

3.2.1. Univariate Analysis

The odds ratios of spatial influencing factors are shown in Table 2.

In terms of the spatial relationship between residence and pollution sources, living within 2km of a coal mine for a cumulative period of 50 years is associated with a 4-fold risk of lung cancer (95%CI: 1.691-9.256). Living within 1km of a coal mine for a cumulative period of 30 years is also associated with an increased risk of lung cancer (OR: 2.220; 95%CI: 1.004-4.908). From the perspective of different life stages, long-term residence within 1km of a coal mine in middle-aged and elderly people is associated with a 2.4-fold risk of lung cancer (95%CI: 1.088-5.368); living within 1km of a coal mine during development and early adulthood is also a risk factor, but it is not significant in the study. Living within 1km of an industry for 26 years is less associated with lung cancer. However, in terms of stages, long-term residence within 1km of the surrounding industry during the developmental period was negatively correlated with the incidence of lung cancer (OR: 0.475; 95%CI: 0.212-1.066), while long-term residence within 1km of the surrounding industry during the middle-aged and elderly period was positively correlated with the incidence of lung cancer (OR: 2.218; 95%CI: 0.958-5.131), although the two were not statistically significant. The

area of mining land within 2km of the residence was weakly associated with the incidence of lung cancer, and it was not significant. Being born in the downwind area closest to the coal mine was positively correlated with the risk of lung cancer (OR: 1.680; 95%CI: 0.739-3.818), but it was not statistically significant. In terms of housing structure, from the perspective of the whole life course, living in a civil house for a total of 28 years was associated with a 2-fold risk of lung cancer, but it was not significant (95%CI: 0.928-4.499); living in civil houses and concrete houses for a long time was weakly associated with the incidence of lung cancer. In terms of life course, during the developmental period, living in concrete houses was negatively correlated with the risk of lung cancer (OR: 0.108; 95%CI: 0.013-0.894); living in earthen houses and brick-wood houses was not significantly associated with the risk of lung cancer. In early adulthood, living in earthen houses was positively correlated with the risk of lung cancer (OR: 3.391; 95%CI: 1.499-7.668), living in concrete houses was negatively correlated with the risk of lung cancer (OR: 0.292; 95%CI: 0.103-0.823), and living in brick-wood houses was weakly associated with the risk of lung cancer. In middle-aged and elderly age, living in brick-wood houses for 3 years was positively correlated with the risk of lung cancer (OR: 2.759; 95%CI: 1.159-6.567), living in concrete houses for 6 years was positively correlated with the risk of lung cancer (OR: 3.853; 95%CI: 1.665-8.915), and living in earthen houses was weakly associated with the risk of lung cancer.

In terms of cooking location, cooking in the main room for 9 years in early adulthood was positively correlated with the risk of lung cancer (OR: 2.220; 95%CI: 1.004-4.908), and cooking in the kitchen in middle-aged and elderly age was positively correlated with the risk of lung cancer (OR: 6.500; 95%CI: 2.722-15.521).

Table 2 Spatial influencing factors and lung cancer risk

Characteristic	Case (n=51)		Control (n=51)		OR(95%CI)
	No	Yes	No	Yes

25-44 years old ever smoked	28	23	26	25	0.854(0.392-1.860)
45 years and over ever smoked	31	20	29	22	0.850(0.386-1.873)
Worked in coal-related jobs	33	18	32	19	0.919(0.410-2.060)
Have a family medical history	32	19	37	14	1.569(0.680-3.624)
Have a personal medical history	46	5	47	4	1.277(0.323-5.057)

3.2.2. Conditional Logistic Regression

Due to the limited sample size of this study, the significant variables in the univariate study were included in the binary logistic regression model using the stepwise method. The input variables were living within 2km of the coal mine for a total of 50 years, living within 1km of the coal mine for a total of 30 years, living within 1km of the coal mine for a total of 9 years for people aged 45 and above, living in earthen houses for 6 years for people aged 25-44, living in brick and wood houses for 6 years for people aged 25-44, living in concrete houses for 1 year for people aged 0-24, living in concrete houses for 6 years for people aged 25-44, living in concrete houses for 6 years for people aged 45 and above, cooking in the main room for 9 years for people aged 25-44, cooking in the kitchen for 8 years for people aged 45 and above, using bituminous coal for 11 years for people aged 25-44, using bituminous coal for 3 years for people aged 45 and above, and using floor stoves for 4 years for people aged 45 and above.

The odds ratio of the independent effect of each influencing factor is shown in Table 4. The study found that long-term residence in earthen houses in early adulthood was positively correlated with the risk of lung cancer (OR: 2.891; 95%CI: 1.144-7.311); the use of bituminous coal for 3 years in middle-aged and elderly people was positively correlated with the risk of lung cancer (OR: 3.612; 95%CI: 1.431-9.731); and living within 2km of a coal mine for a cumulative period of 50 years was positively correlated with the risk of lung cancer (OR: 2.433; 95%CI: 0.951-6.222).

Table 4 Independent effects of various influencing factors on lung cancer risk

Characteristic	Case(n=51)		Control(n=51)		OR(95%CI)	P Value
	No	Yes	No	Yes		
25-44岁居住土木房达6年	20	31	35	16	2.891(1.144-7.311)	0.025
45岁后使用烟煤达3年	29	22	42	9	3.612(1.431-9.731)	0.011
居住在煤矿2km内达50年	12	39	28	23	2.433(0.951-6.222)	0.064

4. Discussion

4.1. Spatial statistical analysis

In spatial statistics, it was found that the degree of agglomeration of the case group was higher than that of the control group, indicating that in addition to the agglomeration of towns and villages, there are other spatially related factors that cause the cases to agglomerate. The study found that when the research range was 2km, the degree of agglomeration of the case group was the highest, and when the research range was 5km, the degree of agglomeration of the control group was the highest, indicating that with a range of 2km, the environmental factors around the study sample were a suitable distance for the impact of lung cancer. The analysis of the agglomeration hotspots of the case group and the control group found that the hotspots of the control group were in Fuyuan County, Housuo Town, and Yingshang Town, which were urbanized areas with concentrated populations; while the hotspots of the case group were mainly distributed in rural areas. There were significant urban-rural differences between the two, and the urban-rural differences are the content that needs to be paid

attention to in subsequent studies. In addition to geographical location, urban-rural differences also include different living environment quality, fuel use types, occupations, living habits, etc. The combined effect of multiple factors has created lung cancer hotspots in rural areas.

4.2. Univariate analysis

In the univariate analysis, long-term residence within 2km of a coal mine was positively correlated with the risk of lung cancer; living within 1km of a coal mine in middle-aged and elderly age was positively correlated with the risk of lung cancer, while similar trends were shown in the developmental period and early adulthood, but not significant. The middle-aged and elderly stage of the sample corresponds to the period from 2000 to the present. Some studies have shown that the local incidence of lung cancer has dropped significantly after the 1970s thanks to the improvement of stoves (Lan Q, et al., 2002). Although some studies have shown that early life exposure has a greater impact on lung cancer (Portengen L, et al., 2023), the exposure risk in middle-aged and elderly age should not be ignored.

Studies have shown that long-term residence within 1km of industry is not significantly associated with the risk of lung cancer, but in terms of life course, living around industry in the developmental period tends to be a protective factor, while living around industry in middle-aged and elderly age tends to be a risk factor. This may be because industrial areas have changed from “development centers” in the early years to “environmentally degraded areas” in recent years: in the developmental period of the research sample (corresponding to the 1960s-1990s), industrial areas are often the places where various resources are most concentrated, such as schools for children of workers and miners, employee hospitals, and unit housing, providing better education and health resources, thereby promoting early health; while in the middle-aged and elderly period of the research sample (corresponding to the 2000s to the present), non-industrial areas have generally achieved rapid development, while the aging of infrastructure around industrial areas, the accumulation of industrial pollution, and the deterioration of the ecological environment have increased the risk of exposure to coal dust, heavy metals, etc., which has become a health burden. In addition, people with higher socioeconomic abilities may choose to move out of the most polluted industrial areas and move into new urban areas far away from industry. In subsequent studies, analysis of urban-rural differences and socioeconomic levels should be included. (Subsequent analysis of socioeconomic level, whether living in urban/mining areas, and facilities poi)

In terms of the structure and materials of the house, living in earthen houses in early adulthood and brick-wood houses in middle-aged and elderly age are risk factors for lung cancer; long-term residence in concrete houses is not significantly associated with the risk of lung cancer, but in terms of life course, it is a protective factor in the developmental period and early adulthood, while it is a risk factor in the middle-aged and elderly age. The house structure may affect indoor ventilation, and thus affect the diffusion of pollutants. Tile houses with earthen structures and brick-wood structures are typical local residential forms, usually two-story, with the first floor for the main room (living, cooking) and bedrooms, and the second floor for bedrooms or for storing sundries; there are doors and windows on the front facade, no windows on the back wall, and poor ventilation conditions. Tile houses with earthen structures are usually older, while brick-wood structures are more recent. The form of concrete houses is no different from that of other regions, with complete rooms and through-the-hall wind conditions. Living in concrete houses during development and early adulthood is a protective factor, probably because concrete houses have better ventilation capacity and are easier to be equipped with smoke exhaust systems, and are also a sign of a higher socioeconomic level. Living in earthen houses in early adulthood and brick-wood houses in middle-aged and elderly age are risk factors, which may be due to the poor ventilation of earthen and brick-wood houses, and are also related to poor socioeconomic levels. The study found that living in concrete houses in middle-aged and elderly age is a risk factor, which is contrary to common perception. This may be because concrete houses are more common in urban areas and industrial and mining areas, thus exposing people to environmental pollution for a long time. In addition, due to the good airtightness of the house, if

the windows are not opened for ventilation, pollutants may accumulate. (Subsequently supplemented with floor plans, socioeconomic levels, and whether living in urban areas/mining areas)

In terms of cooking location, cooking in the living room in early adulthood is a risk factor; cooking in the kitchen in middle-aged and elderly age is a risk factor; cooking in the kitchen during development and early adulthood tends to be a protective factor, although not significant. This may be because there is a clear partition between the kitchen in development and early adulthood, which can effectively reduce indoor air pollution in the living area; in middle-aged and elderly age, due to the change of family roles, they need to mainly undertake cooking tasks, and pollution is easy to accumulate in the kitchen, resulting in higher pollution exposure. (Further analysis will be conducted based on whether or not the person is responsible for cooking at home)

In terms of stove use, the use of fire pits in each life course showed a tendency to be a risk factor, although it was not significant, which is consistent with the conclusion of existing studies that pollution generated by burning organic matter indoors cannot be discharged. Using a floor stove in middle-aged and elderly age is a risk factor, probably because it is still more polluting than gas stoves. (Gas stoves will be added later)

Among non-spatial influencing factors, the duration of coal use in early adulthood and middle-aged and elderly age is a risk factor, which is consistent with existing studies.

4.3. Multivariate Analysis

In the multivariate analysis, it was found that long-term living within 2km of a coal mine, living in earthen houses in early adulthood, and using bituminous coal in middle-aged and elderly age were risk factors for lung cancer.

Although some variables (such as cooking in the kitchen, using floor stoves, and living in concrete houses for many years) were shown as risk factors or protective factors in the univariate analysis, they were not included in the final model. This may be due to the following reasons: 1) There was collinearity between the variables, or the variables themselves were mediators or proxy indicators of other key exposure factors. For example, “cooking in the living room at the age of 25-44” and “living in earthen houses” both reflected fuel exposure and ventilation conditions under low living conditions. “Brick and wood houses” are the intermediate type of housing structure, and their ventilation and pollution isolation capabilities are between earthen houses and concrete houses. Their protective or risk effects may be masked; 2) The exposure time of some variables is relatively short, such as using floor stoves for 4 years for people over 45 years old, and the exposure period is relatively short; 3) The direction of action of some variables is inconsistent at different stages of life. For example, concrete houses are usually regarded as variables with protective effects, but there are also proxy variables such as other environmental factors such as proximity to industrial and mining areas that are eliminated.

Through multivariate logistic regression model, the study revealed the core influencing factors of meso-scale, micro-scale and confounding factors among many influencing factors.

5. Conclusions

5.1. Researching Conclusions

This study used a case-control study based on life course theory. Through spatial statistics, univariate and multivariate logistic regression analysis, it systematically explored the association between environmental factors and lung cancer risk in residents in coal resource-based urban and rural areas at different life course stages, and the following conclusions were drawn:

1) There are significant urban-rural differences in spatial distribution, and 2km is the sensitive radius of environmental exposure to lung cancer. The case group showed higher spatial agglomeration, and hotspots were

mainly distributed in rural areas; the hotspots of the control group were concentrated in densely populated urban areas. Spatial scale analysis found that when the analysis radius was 2km, the agglomeration of lung cancer cases was the strongest, indicating that environmental exposure within a 2km range had a strong impact on the incidence of lung cancer and should be used as a key spatial unit for future environmental health intervention.

2) Even if the use of fuel factors such as bituminous coal is taken into account, long-term residence around coal mines is still a significant risk factor for lung cancer. Both univariate and multivariate analyses showed that living within 2km of a coal mine for more than 50 years significantly increased the risk of lung cancer. The risk of living within 1km of a coal mine in the middle-aged and elderly (after 45 years old) is higher, indicating that the long-term accumulation of industrial pollution and the exposure effect at an advanced age cannot be ignored.

3) The characteristics of the living environment at different stages of the life course have heterogeneous effects. Living in earthen houses in early adulthood (25–44 years old) is a risk factor for lung cancer, which may be related to poor ventilation conditions and the use of highly polluting fuels; living in brick and wood houses in middle-aged and elderly (≥45 years old) is also a risk factor, suggesting that environmental aging may increase the health burden on the basis of unimproved quality of life. In contrast, living in concrete houses during development and early adulthood showed a certain protective effect, which may be related to better ventilation conditions and higher socioeconomic status; but living in concrete houses in middle-aged and elderly people showed a risk tendency, suggesting that concrete houses may be a proxy indicator of exposure to industrial areas or highly enclosed polluted environments.

4) Although the location of cooking in the kitchen and the main room and the type of stove were not included in the final model, they are still important risk factors. Cooking in the main room (early adulthood) and cooking in the kitchen (middle-aged and elderly) are both potential risk factors for lung cancer, reflecting the problem of no isolation between the living area and the cooking area and the diffusion of indoor pollutants. The use of floor stoves in middle-aged and elderly people is also a risk factor. Although these variables were not retained in the multivariate model, they still have certain public health significance as behavioral indicators of ventilation and combustion pollution.

5.2. Planning inspiration: meso- and micro-level interventions

In terms of spatial intervention, at the meso level, we should identify high-risk areas for lung cancer and make the 2km area around coal mines the key intervention area for public health; distinguish urban and rural differences and strengthen pollution detection around industrial and mining areas. At the micro level, we should promote the renovation of rural houses and the renewal of ventilation facilities, incorporate the concept of "through-hallway wind" into local architectural design, and improve the effect of natural ventilation; promote the supply of clean energy (such as electricity, gas, etc.) in rural areas.

In terms of policy recommendations, industrial and mining planning should conduct health impact assessment (HIA) and no longer be dominated by economic benefits alone; for residents who have lived in coal mines and highly polluted areas for a long time, lung screening should be vigorously promoted; and clean energy and healthy buildings should be promoted.

5.3. Research deficiencies and follow-up work

Socioeconomic attribute variables have not been included. The current model lacks variables such as the respondents' education level and occupation type, which may misestimate the actual effects of residential location and house structure. The changes in residential history at the urban and rural levels have not been sorted out. Urban and rural differences include multiple influencing factors such as environmental pollution, fuel type, ventilation conditions, and medical accessibility. For example, living in a concrete house for people over 45 years old is a risk

factor. It may not be a problem with the house itself, but "the house is located in an urban area or an industrial and mining area." Subsequent research needs to further analyze whether people have moved from rural areas to cities during their life course. The interactive effects of multiple variables have not been taken into account, ignoring the synergistic effects between variables.

Who gets less urban greenness: A case study of Sydney

Yunzheng Zhang[1], Fubin Luo[2,*]
[1] University of New South Wales, [2,*] City University of Hong Kong
[1] yunzheng.zhang@unsw.edu.au, [2,*] fubin.luo@my.cityu.edu.hk

Abstract
Inequalities in urban greenness have been investigated based on multi-source data. However, studies in Australia often overlook eye-level greenness - an important measure that captures human-perceived greenery. This study examines Sydney's eye-level greenness using Google Street View images and employs Geographically Weighted Regression (GWR) to analyse its association with neighbourhood socio-economic status. The findings reveal that older adults in central Sydney may experience inadequate greenness. Female, unmarried, non-English, indigenous, less-skilled, and unemployed individuals are more likely to face insufficient greenness outside the city centre. Additionally, foreign-born, low-income, carless, and less-educated individuals may experience greenery shortages in both central and suburban Sydney. This study explores Google-Street-View-derived urban greenness – a less employed data source in Australia, offering valuable insights for policymakers in mitigating green space inequalities.

Key words: Green inequality; Google Street View; Eye-level greenness; Australia

1. Introduction

Urban greenery provides substantial benefits to both urban environments and individuals, such as mitigating urban heat island effects and improving air quality (Luo, Zhang and Zhang, 2025), encouraging physical activity (Lu et al., 2019), and fostering social interactions (Enssle and Kabisch, 2020), thereby contributing to enhanced human well-being. However, urban greenery is often unevenly distributed in cities, particularly in the context of urban consolidation. In settings characterized by socio-spatial differentiation driven by market forces, socio-economically advantaged populations tend to enjoy greener urban environments, while disadvantaged groups are more likely to reside in areas with limited greenery. This disparity has led to concerns about green gentrification (Sharifi et al., 2021). Against this backdrop, green space inequality emerges as a critical issue within the discourse of environmental justice, highlighting the need to promote equity in the planning of urban greenness.

Like many other cities influenced by neoliberal urbanism, Australian cities are experiencing increasing socio-spatial differentiation under market forces, which channels populations of varying socio-economic status into distinct urban areas. This process has the potential to exacerbate inequalities in green space access, which requires further exploration. While several studies in the Australian context have examined green space inequalities using land use data (Mushangwe et al., 2021) or satellite imagery (Lin, Meyers and Barnett, 2015), these data sources predominantly capture urban greenness through aerial perspectives, failing to adequately represent the experiential quality of eye-level greenery that characterizes urban dwellers' daily visual environments. Recently, street-view imagery has gained traction in green space research for its ability to capture human-scale greenness. Nevertheless, studies employing this data source in Australia remain limited.

Drawing on data at Statistical Area Level 1 (SA1) from Sydney, this study addresses the following research questions:

(1)What is the spatial distribution of eye-level greenness in neighbourhoods across Sydney?

(2)How are neighbourhood socio-economic statuses associated with eye-level greenness?

To answer these questions, the study first employs machine learning techniques to extract eye-level greenness from Google Street View imagery and visualizes its spatial distribution. It then applies a Geographically Weighted Regression (GWR) model to examine the spatially varying relationship between neighbourhood socio-economic status and eye-level greenness.

The remainder of the paper is structured as follows: Section 2 reviews relevant literature on green space inequality and socio-economic status. Section 3 outlines the research methods. Section 4 presents the findings, followed by a discussion of implications and policy recommendations in Section 5. Section 6 concludes the paper.

2. Literature review: Green space inequality in relation to socio-economic status

Urban greenness provides significant environmental and health benefits, prompting growing scholarly interest in equitable green space planning. Existing green space studies have utilized green space data from various sources, with the most commonly used being parkland use data derived from online maps (Feltynowski et al., 2018)and urban green space management in particular, require proper data on urban green spaces. The potential of urban green spaces to provide benefits to urban inhabitants (ecosystem services or local statistical authorities (Zhang and Luo, 2024), as well as vegetation coverage extracted from satellite imagery such as Landsat (Zhang and Luo, 2025) and Sentinel (Aryal, Sitaula and Aryal, 2022). However, these data sources primarily offer a bird's-eye view of greenery and fail to adequately capture the green environments as perceived by individuals at the human scale, thereby motivating the exploration of alternative data sources.

In response, street view imagery has recently gained traction in green space research. This emerging data source captures eye-level greenness, offering a more human-centred perspective for assessing green space exposure (Zhang and Luo, 2025). Consequently, it has been increasingly adopted in the literature (Li, 2021; Liu et al., 2023; Zhang and Luo, 2025).

Existing literature has extensively examined inequalities in the exposure, availability, accessibility, and use of green spaces across different socio-economic groups. For example, scholars have argued that women have historically been overlooked in urban planning processes, leading them to bear a disproportionate burden of social injustice (Walker, Frediani and Trani, 2013). However, a study in Iran suggests that gender justice in the use of green spaces is achievable, with both male and female residents having their needs adequately met (Rahimi et al., 2023). In the Chinese context, a study conducted in Guangzhou reveals that neighbourhoods with higher proportions of older adults are at greater risk of green space inequality (Yang, Yang and Zhou, 2022). Furthermore, family structure and marital status have also been identified as potential indicators of social vulnerability, which may lead to unequal access to green spaces (Rahman and Zhang, 2018). Ethnicity is another important dimension of green space inequality. For instance, a study across Sydney, Newcastle, and Wollongong found that individuals who do not speak English at home are more likely to face inadequate access to parkland and open grass areas. Similarly, those born in Italy, Lebanon, Vietnam, or China were found to be disproportionately affected by insufficient parkland provision (Mushangwe et al., 2021). In the Australasian context, indigenous people represent a structurally disadvantaged group. A study in New Zealand showed that indigenous communities are more likely to experience lower levels of green space availability and accessibility (Zhang et al., 2024). Moreover, neighbourhoods with more affluent residents such as those with higher incomes or car ownership may enjoy greater access to green space (Dai, 2011; Astell-Burt et al., 2014), while less affluent communities may experience limited green space availability. Educational attainment also plays an important role: a study in Germany demonstrated that urban greenery is unevenly distributed based on education levels (Wüstemann, Kalisch and Kolbe, 2017). Additionally, unskilled workers may be spatially segregated into disadvantaged neighbourhoods, which often lack basic amenities and infrastructure such as urban green spaces (Csomós et al., 2021). In relation to labour force status, a study in Shanghai found that subdistricts with higher unemployment rates exhibit lower levels of green space access (Shen, Sun and Che, 2017). Overall, green space inequality is intricately linked to socio-economic status, warranting continued and in-depth scholarly inquiry into these associations.

3. Research method

3.1 Study area and research framework

This study focuses on Sydney (Figure 1), a neoliberal city in Australia marked by pronounced socio-spatial differentiation driven by market forces, where urban greenery is unevenly distributed across different urban neigh-

bourhoods. The analysis is conducted at the Statistical Area Level 1 (SA1), a geographic unit commonly used in neighbourhood-level research (Zhang and Luo, 2024, 2025). Each SA1 typically contains a population ranging from 200 to 800 individuals, with an average of approximately 400. To minimize potential bias in the calculation of proportional variables, we excluded SA1s with populations fewer than 20 and those without any street view sampling points. After this filtering process, 11,328 SA1s were retained for analysis.

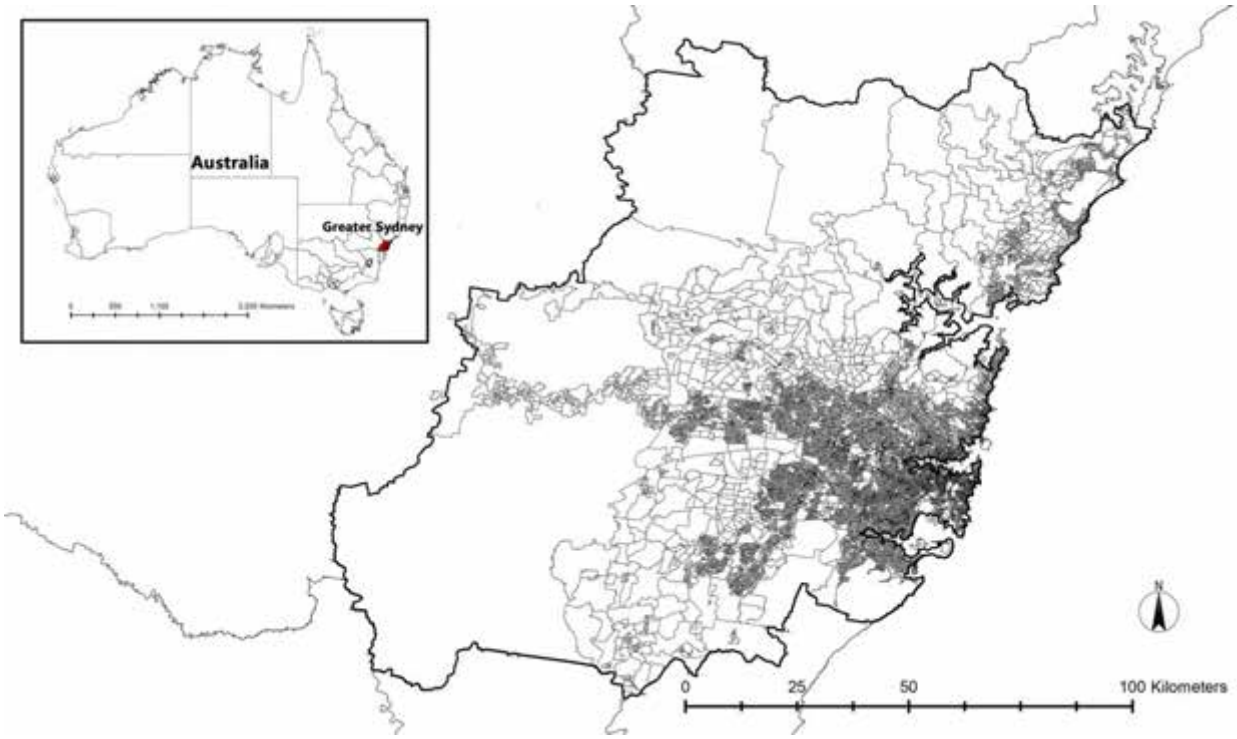

Figure 1. The location of Sydney.

As outlined in the research framework (Figure 2), this study first maps the eye-level greenness of neighbourhoods in Sydney and subsequently employs a Geographically Weighted Regression (GWR) model to examine its spatially varying association with neighbourhood socio-economic status.

Figure 2. Research framework.

3.2 Data

This study draws on two primary data sources. Eye-level greenness was calculated using Google Street View imagery, while socio-economic variables at the SA1 level were obtained from the 2021 Australian Census released by the Australian Bureau of Statistics (ABS). The variables used in the analysis were derived from these sources, with further explanations and descriptive statistics provided in Sections 3.2.1 and 3.2.2, as well as in Table 1.

3.2.1 Dependent variable: eye-level greenness

As shown in Fig. 2, the calculation of eye-level greenness includes the following steps: First, the road network data in Sydney was acquired from OpenStreetMap. Second, 199,090 image-generating points with 100 m intervals were created using ArcGIS. Third, the coordinates of these points were fed into a Python-based crawler to download four Google Street View (GSV) images per point, with headings of 0°, 90°, 180°, and 270°, each with a 90-degree field of view. After removing points with invalid or missing imagery, we retained 144,850 valid points, which includes a total of 579,400 street-view images. Fourth, we used the Deeplab_v3 image segmentation algorithm, trained on the Cityscapes dataset (https://www.cityscapes-dataset.com/), to extract the street view greenness from each image using Python. Fifth, the ratio of vegetation pixels to the total number of pixels across the four images for each point was calculated, yielding the Street View Greenness (SVG) indicator for that location.

$$SVG_singlepoint = \frac{Vegetation\ pixels\ of\ four\ images}{Total\ pixels\ of\ four\ images} \quad (1)$$

After that, the average SVG of sampling points within each SA1 was calculated as the eye-level greenness of that SA1.

3.2.2 Independent variables: socio-economic status

Eleven variables that capture neighbourhood socio-economic disadvantages at the SA1 scale were selected as dependent variables for their potential relevance to green space inequality (as shown in the literature review): the proportion of females, the proportion of individuals aged 65 and older, the proportion of individuals without partners, the proportion of individuals who speak English not well or not at all, the proportion of populations born abroad, the proportion of indigenous populations, the proportion of low-income (weekly income < AUD 800) households, the proportion of dwellings without cars, the proportion of populations whose educational levels are below bachelor, the proportion of populations whose occupations are not in the manager, administrator, and professional categories, and the proportion of unemployed individuals. The VIF values of all the selected independent variables are smaller than 5, indicating no multi-collinearity.

Table 1. Descriptive statistics of dependent and independent variables.

	Mean	S.D	Min.	Max.
Dependent				
Eye-level greenness	0.282	0.129	0.000	0.840
Independent				
female	0.506	0.035	0.000	0.986
age65+	0.156	0.097	0.000	1.000
noPartner	0.126	0.060	0.000	0.708

3.3 Geographically Weighted Regression (GWR)

To explore the equity issue in urban greenness, we employed the Geographically Weighted Regression (GWR) model to examine the associations between neighbourhood socio-economic status and eye-level greenness. Compared to frequently used linear regression models such as the ordinary least squares (OLS) regression which yields constant coefficients across the whole sample, the GWR model allows the coefficients of explanatory variables to vary across geographic locations, thereby capturing the spatial heterogeneity of these relationships (Kang et al., 2021). The GWR model is specified as follows:

$$y_i = \beta_0(u_i, v_i) + \sum_k \beta_k(u_i, v_i) X_{ik} + \varepsilon_i \qquad (2)$$

Where y_i is the eye-level greenness at SA1 *i*; $\beta_0(u_i, v_i)$ represents the intercept at SA1 *i*; $\beta_k(u_i, v_i)$ is the coefficient (weight) of the *k*th independent variable estimated for each SA1 *i*; ε_i is a random error.

4. Results

4.1 The spatial pattern of neighbourhood eye-level greenness in Sydney

Figure 3 illustrates the spatial pattern of neighbourhood eye-level greenness in Sydney. A general trend is observed whereby eye-level greenness increases from the central urban area toward the suburban regions. Specifically, neighbourhoods in the southern and western parts of the city exhibit relatively lower levels of eye-level greenness compared to those in the north. Notably, the southwestern region of Sydney is recognized for its concentration of socio-economic disadvantage. Accordingly, it is essential to further investigate the relationship between neighbourhood socio-economic status and eye-level greenness. Such analysis can deepen the understanding of green space inequality and offer valuable insights for advancing environmental justice through urban planning and design policies.

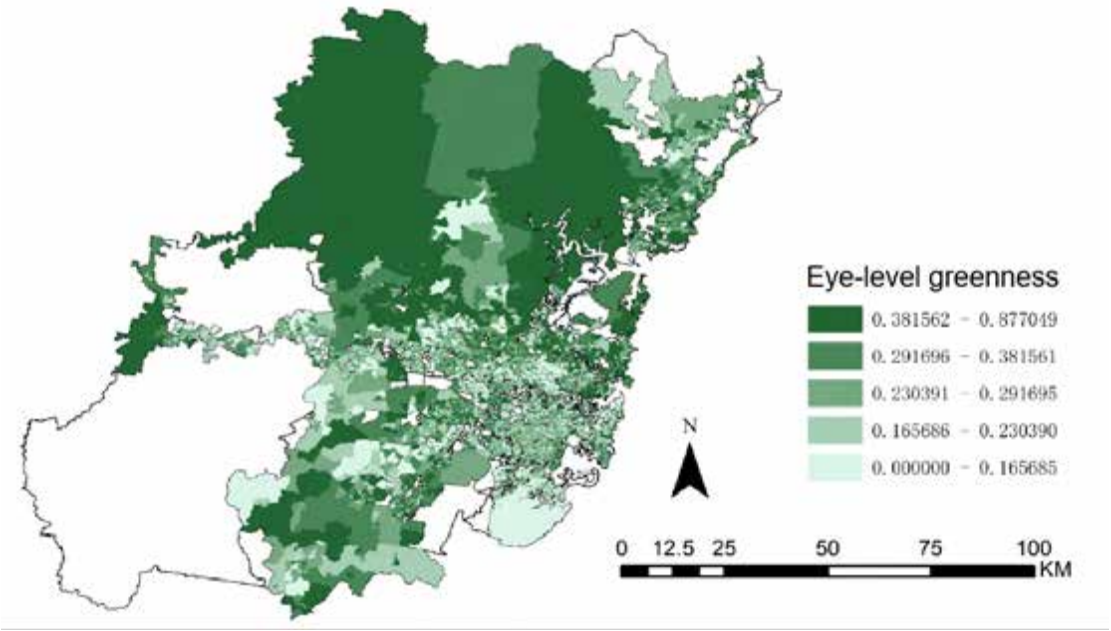

Figure 3. The spatial pattern of neighbourhood eye-level greenness in Sydney.

4.2 Association between neighbourhood socio-economic status and eye-level greenness

Table 2 shows the regression result summary of both the OLS model and the GWR model. The OLS model suggests that the higher proportions of females, individuals without partners, foreign-born, carless, less-educated, and less-skilled people are significantly associated with insufficient eye-level greenness. The adjusted R^2 values of the OLS and the GWR models are 0.206 and 0.465 respectively, indicating that the GWR has better performance than the OLS and spatial heterogeneity exists in the association between neighbourhood socio-economic status and eye-level greenness.

Table 2. Regression result summary of the OLS and the GWR models. (All coefficients are standardized.)

	OLS		GWR	
	Coef.	**Sig.**	**Coef.(median)**	**Coef.(mean)**
female	-0.068	0.000	-0.028	-0.038
age65+	0.304	0.000	0.148	0.150

R^2	0.207		0.473	
Adjusted R^2	0.206		0.465	

Since GWR has better performance compared to OLS, we further explain the associations between the selected socio-economic variables and eye-level greenness based on the results of the GWR model. Figure 4 presents the results of the GWR model, reflecting the spatially varying relationships between neighbourhood socio-economic status and eye-level greenness in Sydney. Neighbourhoods highlighted in red indicate a negative association between the examined socio-economic disadvantages and eye-level greenness, whereas those highlighted in blue indicate a positive association.

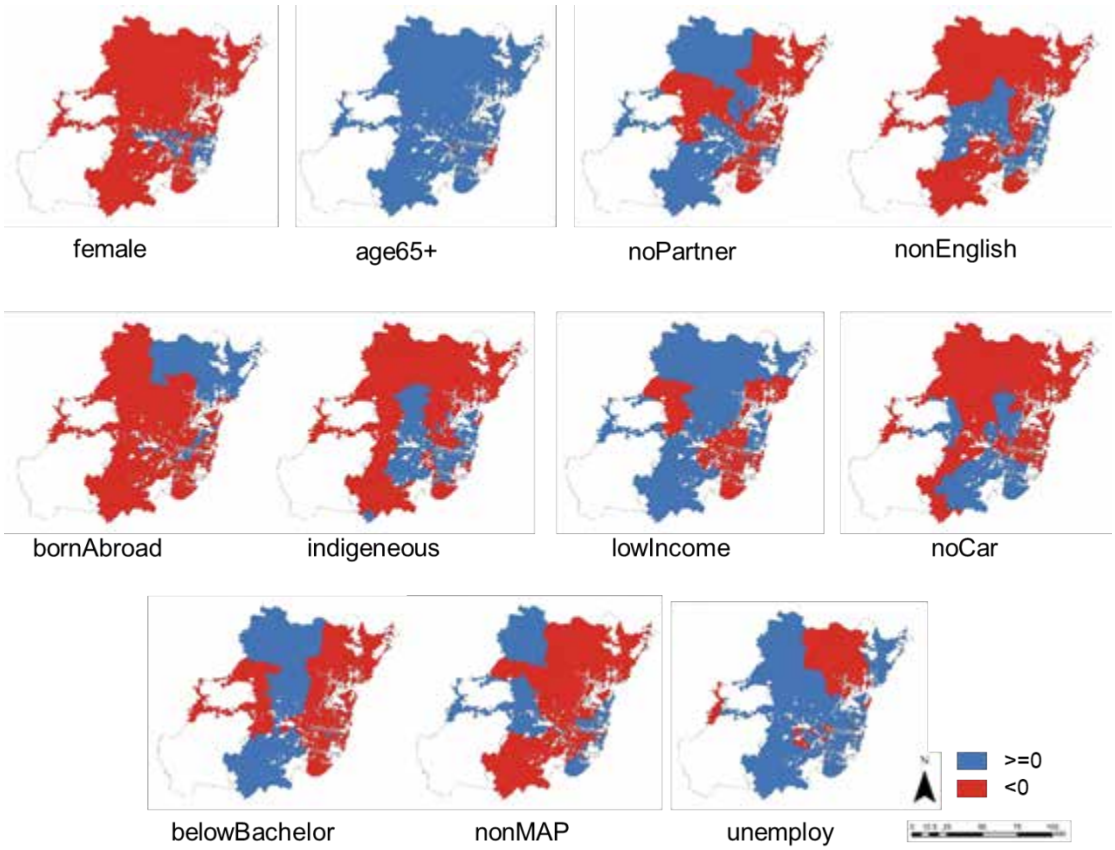

Figure 4. Associations between neighbourhood socio-economic status and eye-level greenness. (All coefficients are standardized.)

Female
In areas near the city centre and the western transport corridor, neighbourhoods with a higher proportion of female residents are associated with greater street-view greenness, whereas those outside these regions exhibit lower eye-level greenness.

Age65+
Neighbourhoods with higher proportions of older adults (65+) in the eastern city centre exhibit lower eye-level greenness, whereas this association is positive in most other regions of Sydney.

NoPartner
In many eastern and some western regions, neighbourhoods with higher proportions of individuals without partners tend to have lower eye-level greenness. Conversely, in the eastern city centre as well as some northwestern and southwestern areas, the association is positive.

NonEnglish
Most northern and southern neighbourhoods show a negative association between higher proportions of non-English speakers and eye-level greenness. In contrast, neighbourhoods in the eastern centre and some western suburban areas exhibit a positive association.

BornAbroad
Neighbourhoods with higher proportions of foreign-born residents generally have lower eye-level greenness, except for some suburban neighbourhoods in the north.

Indigenous
In suburban Sydney, neighbourhoods with higher proportions of indigenous residents tend to have lower eye-level greenness, whereas those in the eastern city centre or some western suburbs exhibit higher levels of human-perceived greenness.

LowIncome
Neighbourhoods with higher proportions of low-income households in eastern regions and some western fringes are associated with lower eye-level greenness. In contrast, such neighbourhoods in western suburbs and some northeastern areas show higher levels of greenness.

NoCar
In many suburban and eastern central areas, neighbourhoods with higher proportions of carless households have lower eye-level greenness. However, in some northwestern and southern areas, the association is positive.

BelowBachelor
Neighbourhoods with higher proportions of less-educated individuals in eastern and some western regions display lower eye-level greenness, while those in northwestern and southwestern suburbs show higher greenness.

NonMAP
Across suburban regions, neighbourhoods with higher proportions of low-skill workers tend to have lower eye-level greenness. However, in some areas near the city centre or peripheral zones, these neighbourhoods exhibit higher greenness.

Unemploy
In most regions of Sydney, neighbourhoods with higher unemployment rates are associated with higher eye-level greenness. However, some southwestern and northern neighbourhoods with higher employment rates are characterized by lower levels of greenness.

5. Discussion and policy implications

5.1 Discussion

The case of Sydney demonstrates a decline in eye-level greenness alongside urbanization, with central areas exhibiting higher eye-level greenness while suburban neighbourhoods are significantly greener. This spatial pattern aligns with observations in other global cities, such as Shanghai (Wu et al., 2019), New York (Li, 2021), and London (Pan, Bardhan and Jin, 2021), as urban centres are dominated by built-up areas, with limited space left for urban greenery.

Green space inequality is evident in less socio-economically advantaged neighbourhoods. In Sydney, older adults in the eastern central areas are more likely to experience lower eye-level greenness. This negative association can also be observed in other urban contexts, such as in Guangzhou, China (Yang, Yang and Zhou, 2022). A possible explanation is that those residing in the city centre are long-term residents, and they age alongside

the densification of urban cores over time. Females, unmarried individuals, non-English speakers, indigenous people, low-skilled workers, and unemployed individuals face greater insufficiency of greenness outside the city centre. These populations may concentrate within certain socio-economically disadvantaged suburban neighbourhoods, wherein green resources are limited. Furthermore, other less-advantaged populations, such as overseas-born individuals, those with lower incomes, those without car ownership, and those with lower educational attainment tend to experience lower human-perceived greenness in both central and suburban areas. These associations are supported by evidence in existing literature (Dai, 2011; Astell-Burt et al., 2014; Wüstemann, Kalisch and Kolbe, 2017; Mushangwe et al., 2021).

5.2 Policy implications

To mitigate green space inequalities across socio-economically stratified neighbourhoods, tailored urban greening interventions should be differentially implemented according to distinct spatial and demographic characteristics. In the city centre where urban consolidation limits available space for traditional greening, vertical greenery, such as green façades on buildings, could enhance eye-level greenness and should be implemented in dense urban environments. In suburban areas where socio-economically disadvantaged groups (including higher proportions of females, unmarried individuals, non-English speakers, indigenous people, low-skilled workers, and unemployed individuals) reside, maintaining sufficient tree coverage is crucial. This requires the local government to scientifically and systematically consider green space planning during suburban development. Furthermore, the institutional coupling of subsidized housing initiatives with green infrastructure development emerges as a demonstrably effective policy mechanism for advancing environmental justice, ensuring socioeconomically disadvantaged groups gain equitable access to green urban environments.

6. Conclusion

Guided by the environmental justice discourse, this study examines equity in urban greenery by investigating the associations between neighbourhood socio-economic status and eye-level greenness in Sydney, Australia. The findings reveal that older adults residing in the eastern central areas of Sydney are more likely to experience lower levels of eye-level greenness, while females, unmarried individuals, non-English speakers, indigenous people, less-skilled workers, and unemployed individuals tend to encounter insufficient greenness outside the city centre. Furthermore, foreign-born, low-income, carless, and less-educated individuals are generally exposed to less eye-level greenness greenery in both central and suburban areas.

Drawing upon these findings, the study proposes a differentiated urban greening framework that accounts for distinct spatial contexts. Specifically, implementing green façades in the city centre may help enhance eye-level greenness. In socio-economically disadvantaged suburban neighbourhoods characterized by higher proportions of the aforementioned vulnerable groups, it is crucial to maintain adequate tree canopy coverage and to integrate green space planning with the development of affordable housing projects.

A key limitation of this study is its reliance on cross-sectional data, which precludes the identification of causal relationships between socio-economic status and eye-level greenness. Future research should incorporate longitudinal data by regularly collecting street-view imagery to facilitate deeper insights into the causal dynamics of green space inequality.

Despite this limitation, by leveraging street-view imagery, a data source underutilized in Australian green space research, this study contributes novel insights into spatial inequality in urban greenery. It elucidates how socio-economic disadvantage correlates with eye-level greenness and extends the environmental justice discourse with an Australian case study, thereby supporting future international comparative research.

Abstract
Aging in Place is increasingly central to debates on urban aging, especially in the context of demographic transitions and endless urbanization. While often framed as a desirable goal both for individuals and welfare systems, it can also expose older adults to hidden vulnerabilities. Remaining in the same setting over time may exacerbate forms of exclusion, isolation, or distress. Aging must therefore be seen as a situated and dynamic process, shaped by the evolving interaction between individuals and their environments. Reframing Aging in Place through this lens reveals the need to move beyond static, universal models. This is the premise of the CASA project, which explores how urban and housing contexts influence aging trajectories, offering tools to support more inclusive, context-sensitive policies for healthy longevity.

Keywords: Aging in place, age-friendly city, healthy longevity, empowerment, inclusion

Introduction

In the near future, cities will become the stage for a dual, epochal transformation. On one hand, the global population aged 60 and over is rapidly increasing, with projections suggesting it will double in the coming decades (WHO, 2023). On the other hand, for the first time in history, the majority of people are choosing to live in urban areas—a trend that, since 2008, has been profoundly reshaping human geography (UNFPA, 2007; UN, 2024) and, along with it, people's lifestyles.

Italy offers a clear illustration of this dual shift. The country is experiencing a dramatic decline in birth rates—reaching new historical lows—alongside a steady rise in life expectancy (ISTAT, 2024a). These trends are significantly altering the population structure, leading to an increasingly aging society, with a notable rise in the proportion of people aged 65 and over. In this context, medium-sized cities play a crucial role, acting as true pillars of Italian life and hosting a significant portion of the national population (OECD, 2014).

The Italian city of Bergamo is a perfect example of this reality: a complex and layered territory, where the historic urban fabric coexists with new expansions, and where residents over the age of 65 represent a significant proportion, higher than the national average (ISTAT, 2024b). Here, stories of urban growth, strategic connectivity, and the challenges of demographic change converge, prompting new reflections on the cities of the future.

In this scenario, it becomes essential to understand how health and the urban environment can mutually influence each other, and how population aging might transform the way we design and experience our cities. The World Health Organization (2017) calls for an integrated approach that places the well-being of older adults at the center, promoting a model of "active aging" in which health and quality of life are closely interwoven with the

urban environment.

Within this framework, the concept of Aging in Place (AIP)—growing older in one's own home and community—has emerged as a key focus in contemporary debates on aging, particularly in urban contexts. As populations age and cities evolve, scholars and policymakers increasingly promote AIP as a pathway to healthier, more independent, and economically sustainable aging (Pynoos, 2008). This model aligns closely with older adults' preferences to remain in familiar surroundings, maintaining their routines, identity, and social networks (Wiles et al., 2012). However, although the AIP paradigm holds great potential, it is not without complexities or criticisms. As noted by Golant (2015) and reaffirmed by other scholars, remaining in one's own home may, in some cases, exacerbate rather than alleviate vulnerability— effectively keeping individuals stuck in place (Cadmus et al., 2023), rather than supporting healthy longevity.

This article aims to present the reflections emerging from the analysis of these tensions within the Italian PNRR CASA Project. It begins by exploring the evolution and appeal of Aging in Place (AIP), then delves into the critiques that challenge its long-term sustainability. The discussion is framed through the multidimensional concept of vulnerability, which—rather than being viewed as a sign of failure—should be recognized as a crucial dimension to be actively addressed in AIP-related policies and practices

Toward a multidimensional understanding of aging

In today's demographic landscape, aging is no longer a marginal issue: it is one of the structural features of our time. The steady global increase in the older population marks a turning point that challenges traditional conceptions of age, productivity, and social roles. Older adults do not represent a homogeneous group, but rather a population that is increasingly diverse in social, economic, cultural, and functional terms. This complexity calls for a critical reconsideration of aging—not as a problem to be solved (Phillipson, 2013), but as a structural condition of modern societies to be addressed with foresight.

For many years, medical sciences have described aging as an "innate and immutable" process (Powell & Hendricks, 2009), contributing to the construction of a medicalized paradigm of old age. This paradigm still persists today as a deeply rooted cultural legacy, evident in everyday life through the ongoing prevalence of ageist stereotypes (Butler, 1975).

Morganti's theoretical perspective aligns with a much-needed shift in the study of aging. In her model of "Longevity as Responsibility", Morganti (2024) describes aging within a situated life course perspective—not merely as a biological process, but as a multidimensional experience influenced by personal, social, and environmental factors. As Morganti (2022) asserts, "To study aging is to accept the challenge of understanding the ultimate complexity of human beings". This vision resonates with the New Map of Life, launched by the Stanford Centre on Longevity (2022), which encourages a rethinking of life stages through a map in which the final phase remains to be drawn—not as a time of fragility and loss of self-determination, but as a space of potential.

These models help to overcome deficit-based views of aging, proposing theoretical frameworks rooted in agency, responsibility, and potential. They represent a true paradigm shift, inviting us to recognize older adults as active agents and valuable contributors, rather than passive recipients of care. At the same time, we must acknowledge the profound inequalities that shape the experience of aging. These intersect with factors such as class, gender, ethnicity, geography, and disability, producing vastly different conditions of later life. While some may experience aging as a time of freedom and fulfilment, others encounter isolation, poverty, and frailty. As Morganti (2022) reminds us, aging healthily is both a right and a responsibility. It requires personal commitment in taking responsibility for one's own aging trajectory, and at the same time, political engagement aimed at

addressing structural injustices, ensuring equitable access to resources, and safeguarding the right to age with dignity and autonomy.

The demographic transformation associated with aging is not a challenge to be feared, but an extraordinary opportunity to reconceptualize later life as a stage rich in potential (Morganti, 2022). Embracing this challenge means investing not only in healthcare and pensions, but also in social planning, policymaking, and urban design, through empowerment strategies and the promotion of active aging as a path toward healthy longevity.

Aging in Place: navigating longevity through autonomy, responsibility, and environment

The concept of Aging in Place (AIP) represents one of the most significant and concrete responses to the challenges posed by demographic aging. It is grounded in the idea that older adults should have the opportunity to continue living in their own environment—autonomously, safely, and with social integration—even in the presence of functional limitations or care needs. This perspective reflects not only a pragmatic orientation linked to the efficiency of welfare systems (Pynoos, 2008)—which tend to prioritize home-based solutions over institutionalization—but also embodies a dignified and relational vision of aging, one that values the connection to place and territory as crucial dimensions of well-being in old age.

Viewed through the theoretical lens of "Longevity as responsibility" (Morganti, 2024), AIP gains further conceptual depth. Longevity, in this framework, is not a neutral or purely biological condition, but a dynamic process that involves individuals, communities, and institutions—all of whom share responsibility for creating the conditions that support active and sustainable aging. In this sense, inhabiting one's old age means far more than simply remaining at home: it implies being embedded in a context that affirms one's right to continuity, identity, participation, and self-determination. AIP, in fact, encompasses a plurality of dimensions: physical (accessible housing, safe neighbourhoods), social (proximity networks, meaningful relationships), cultural (recognition of the role and skills of older people), and political (local services, inclusive urban planning).

Recent studies have highlighted how the desire of older adults to remain in their own homes reflects not only a practical need, but also a deep emotional and identity-based connection with the places they inhabit (Wiles et al., 2012; McGrath & Hand, 2021). The home, the neighbourhood, the community thus become spaces dense with meaning—capable of holding memories, routines, and relationships. The relational dimension of AIP is emphasized in the definition offered by the World Health Organization, which affirms that older adults should be able to "remain at home in their familiar environment and maintain relationships that are important to them" (WHO, 2020). The ability to sustain meaningful social ties—with family, friends, and neighbours—has been identified as a key protective factor against frailty, depression, and cognitive decline (Holt-Lunstad et al., 2015; Bourassa et al., 2017). At the same time, scholars have urged a more nuanced discussion of AIP—one that foregrounds place and its intersectional dimensions. Not all places are created equal: differences in accessibility, safety, and social cohesion produce uneven opportunities for quality aging in place (Greenfield, 2018; Yarker et al., 2024). This calls for a rethinking of domestic and urban space through the lens of spatial justice, with attention to disparities shaped by gender, class, ethnicity, and disability. In this light, dwelling is not a neutral act, but a negotiated and situated process that demands both political awareness and design innovation. Conceiving AIP as a "journey"—as suggested by Rogers et al. (2020)—also helps overcome a static view of both place and and the aging individual, and instead embrace a dynamic, process-oriented, and transformative view. Aging, then, becomes a trajectory marked by change, along which individuals can implement adaptive strategies to preserve their flow and well-being (Morganti, 2024).

Defining Aging in Place univocally remains a rather complex task, as many scholars observe and describe it from

different perspectives (Rogers et al., 2020). A more comprehensive understanding must reflect the heterogeneity and complexity of the concept. The theme of Aging in Place prompts significant reflection across multiple disciplines, raising important questions about the ambiguity of its definition and its implications in terms of spatial justice and inequality (Finlay et al., 2021).

Aging in place between ideals and limitations: critical perspectives and vulnerability

While the dominant discourse often tends to romanticize Aging in Place, a growing body of literature calls for a more critical perspective, raising doubts about its actual effectiveness for all individuals—particularly in the absence of adequate support systems. Golant (2008), for instance, highlights how the idealization of AIP may overlook the complexity of older adults' experiences, potentially concealing situations of isolation, neglect, and decline. Similarly, Wiles et al. (2012) question the assumption of the home as an inherently positive place, emphasizing that the experience of AIP is not universally empowering but is instead deeply contingent on context, resources, and relationships.

In this context, Aging in Place reveals its inherently ambivalent nature. On the one hand, it remains the preferred option for many older adults (Cutchin, 2003), who associate it with several benefits: environmental familiarity, a sense of control and autonomy, continuity with personal history (Golant, 1984), and the perception of home as a strategic economic asset—both as a safeguard for future health-related expenditures and as an inheritance to pass on to future generations (Di, 2003). Over the past two decades, public policies have largely reinforced these preferences, aligning with broader trends toward deinstitutionalization and home-based care. On the other hand, however, AIP can exacerbate everyday challenges such as mobility issues, limited access to healthcare services, and social isolation (Plouffe & Kalache, 2010; Thomas & Blanchard, 2009). From this perspective, AIP reveals its "dark side": while it can certainly represent an opportunity, it may also expose older individuals to forms of vulnerability that hinder the fit between person and environment (Lawton & Nahemow, 1973), negatively affecting their ability to cope with the challenges of aging.

Within this framework, vulnerability emerges as a key concept in evaluating the extent to which AIP can be considered a sustainable or problematic aging strategy. Vulnerability is a complex and multidimensional concept, often associated with terms such as "fragile," "exposed," "susceptible," or "powerless" (Schroeder & Gefenas, 2009). However, the New Oxford Dictionary defines it as "the state of being exposed to the possibility of being harmed or attacked, physically or emotionally" (Tong, 2014), suggesting a condition that can be situational and relational rather than intrinsic to the individual. Schröder-Butterfill and Marianti (2006) offer a particularly useful definition, describing vulnerability as "a high risk of negative outcomes resulting from a combination of exposure to risk, lack of resources, and an inability to cope." From this perspective, vulnerability is not an inherent characteristic of old age, but rather the result of interactions among personal, environmental, structural, and relational factors. The authors emphasize the importance of protection, attributing a central role to the concept of coping, understood as the set of personal resources used to deal with difficult or stressful situations—a crucial protective mechanism against vulnerability. Alongside individual capacities, social and support networks, as well as formal protections offered by health and social services, play a key role. Nevertheless, vulnerability is frequently conflated with frailty in much of the aging literature, where older adults are often depicted as physically, psychologically, or socially diminished (Sarvimaki & Stenbock-Hult, 2016). Schröder-Butterfill and Marianti (2006) challenge this reductive view, arguing that frailty is only one dimension among many. Exposure to external risks, the nature and severity of those risks, and an individual's adaptive capacity all contribute significantly to vulnerability in later life—regardless of physical condition.

As previously discussed, acknowledging the broad heterogeneity of aging is essential. This involves taking into

account the psychological dimensions that characterize this stage of life (Morganti, 2022) and resisting ageist assumptions that homogenize older adults into a single, vulnerable group. The World Health Organization has echoed this imperative through its 2016 global campaign to combat ageism (WHO, 2021), and more recently via the endorsement of an international "Charter on Ageism in Healthcare" signed by leading scholars worldwide (Ungar et al., 2024).

The study of vulnerability in older adults can be approached from multiple perspectives, as highlighted by Channer (2020), given the wide array of contributing factors. To fully capture its complexity, it is helpful to distinguish between various categories of vulnerability, even though they often overlap and interact. For example, psychological aspects can influence physical vulnerability: it has been demonstrated that negative self-perceptions of aging predict adverse outcomes in performing daily living activities (Moser et al., 2011). Similarly, economic vulnerability, particularly low income, has been consistently identified in cross-sectional studies as a key factor in older adults' exposure to disadvantage (Smeeding et al., 2008; Stewart et al., 2011; Allan et al., 2011; Clarke & Gallagher, 2013). According to Allan and colleagues (2011), economic conditions are central to any comprehensive assessment of vulnerability in old age. Some studies highlight the interplay between economic and social or relational vulnerabilities. For example, older adults experiencing financial hardship are more likely to face mobility restrictions (Ryser & Halseth, 2012), which can lead to increased social isolation. Scholars agree that this subgroup is particularly susceptible to negative outcomes (Clarke & Gallagher, 2013; Dong et al., 2012).

Since social vulnerability is contextually shaped rather than innate, it can also be exacerbated by medical conditions: physical impairments may restrict mobility, impede social interaction, and intensify feelings of isolation (Rapaport et al., 2015). Given its dynamic nature, social vulnerability is not limited to economic poverty, but includes events and conditions that undermine social, cultural, political, and economic relationships (Cruz et al., 2019).

Environmental vulnerability, by contrast, concerns the relationship between the older adults and the physical environment in which they live. It emerges from the interaction between population characteristics, access to services, and infrastructure. Due to its complexity, the study of vulnerability in urban life allows for a deeper understanding of the "causes of the causes"—that is, the social determinants that shape a vulnerable urban population (Marmot & Wilkinson, 2006). Understanding this form of vulnerability requires multi-level interventions that address not only the physical, social, and economic environment, but also the institutional and regulatory frameworks that shape everyday life.

Among individual vulnerabilities, we must consider not only potential declines in health, but also in mobility or cognitive functioning, as well as mood disorders—often exacerbated by social isolation. Individual vulnerabilities become critical when they interact with the environment—when people perceive physical or psychological barriers in their surroundings, leading them to feel restricted in their everyday lives. These factors can, in turn, undermine safety and independence, increasing exposure to the risk of aging trajectories marked by frailty (such as falls, illness, or isolation).

As previously discussed, economic vulnerability intersects with environmental factors in significant ways: when older adults lack the financial means to maintain or modify their homes, access home-based care, or meet basic living expenses, they are at heightened risk of housing insecurity, which can generate chronic instability and anxiety, thereby reducing quality of life and reinforcing pathways toward frailty. Social and relational vulnerability, resulting from the loss of meaningful relationships, withdrawal from community life, or absence of informal support networks, may require an Aging in Place approach supported by strong social infrastructures—such as

community centres, accessible transportation, and intergenerational initiatives—capable of promoting active aging and, above all, fostering a cultural shift toward the assumption of personal responsibility in the aging process. As outlined previously, the risks of isolation and loneliness can have significant negative consequences for mental health (Nicholson, 2009).

From a Bronfenbrennerian ecological perspective (Bronfenbrenner, 1979), environmental vulnerability can be located at the mesosystem level, where the individual interacts with settings immediately outside of their proximal networks. From there, it extends across further levels, up to the macrosystem, which includes cultural, institutional, and regulatory contexts. Institutional vulnerability, for instance, can stem from inadequate public policies: fragmented, expensive, or inaccessible services can expose older adults to trajectories of frailty. A lack of coordination among health care, housing, and local welfare systems represents a significant risk. This ecological framework enables a multidimensional interpretation of vulnerability—one shaped by dynamic interactions between the individual, the environment, and wider societal systems.

Recent research conceptualizes advantages and disadvantages in later life—including in health, social connectedness, and financial stability—as cumulative outcomes of life course processes. Over time, these processes lead to growing heterogeneity among older adults, with vulnerability unevenly distributed and associated with highly diverse outcomes (Cihlar et al., 2023). In line with this view, Shin et al. (2021) analysed vulnerability as a multidimensional concept, identifying six distinct profiles based on four dimensions: material, physical, mental, and social. Among these, the combination of health and social vulnerability had the most significant negative impact on subjective well-being, followed by profiles that also included material vulnerability. The results support the notion that vulnerability, in relation to perceived well-being, must be approached from a multidimensional perspective. Cihlar et al. (2023) further reinforce this perspective, showing that social support can significantly buffer the negative impact of vulnerability on quality of life. From this multidimensional and ecological standpoint, aging appears not as a fixed condition but as a process shaped by the accumulation of heterogeneous changes over time, across multiple life domains and environmental contexts (Cihlar et al., 2023). Given this complexity, Aging in Place cannot be regarded as a one-size-fits-all solution or as universally desirable. Rather, it is an option that requires a context-sensitive understanding of both individual and environmental characteristics in order to be sustainable. The balance between personal capabilities and environmental demands must be dynamically monitored, with a view to preventing vulnerability and promoting autonomy, in support of active and responsible aging, and ultimately of healthy longevity.

The thin space between people and places in "Aging in Place" studies:
In light of the reflections proposed thus far, we argue that Aging in Place can no longer be considered solely as a linear process or merely as the outcome of individual choices driven by the desire to remain in one's own home. Instead, it is necessary to place this phenomenon within a broader theoretical framework, capable of capturing the interplay between individual characteristics, environmental dimensions, and cultural factors that influence both its experience and feasibility. Aging, in this sense, emerges as a relational and situated process, unfolding within a system of affordances—opportunities for action—that both reflect and influence individuals' ability to act, dwell, and participate in social life. The home and the neighbourhood thus become much more than physical containers; they are transformed into lived and symbolic spaces, contributing to identity construction, biographical continuity, and a sense of belonging.

This approach calls for a paradigm shift. The question is no longer merely whether an environment is accessible or meets specific standards, but rather whether and how that environment supports, sustains, or inhibits the possibility of aging well. From this perspective, affordances—as defined in Gibson's (1977) ecological theory—are

neither objective properties of environments nor purely subjective perceptions but instead emerge in the thin space between individual and context (Butti & Morganti, under review), particularly within their dynamic interaction. Each space, therefore, is not neutral: it becomes meaningful to the extent that it can be used and interpreted by those who inhabit it. Urban spaces offer potential and limitations to older adults not through their architectural features alone, but through the embodied and situated interactions between those features and the individuals engaging with them. Consequently, the design of aging-related policies cannot ignore an integrated analysis of the characteristics of places and the people who live in them, of social networks, cultural norms, and everyday practices.

Moreover, acknowledging that affordances also include relational dimensions—such as the availability of support, social interactions, and mutual recognition—implies recognizing that well-being in old age is intimately tied to the quality of community life. Designing age-friendly spaces cannot be reduced to the removal of architectural barriers or the expansion of service provision. Rather, it requires the adoption of a systemic vision, one that considers the multiple layers of context—as proposed by Bronfenbrenner's ecological model of human development (1979)—as well as the diverse roles that older individuals occupy in daily life, beyond the passivizing lens often perpetuated by ageist stereotypes (Butler, 1975).

The adoption of a complexity epistemology proves, within this framework, not only desirable but indispensable. A reductionist approach, which isolates variables and produces generic models, cannot account for the heterogeneity of the aging experience nor adequately respond to its challenges. Instead, it is necessary to recognize that aging is always a singular experience, rooted in specific places and times, mediated by cultural representations, individual resources, and social constraints. Consequently, any intervention aimed at promoting Aging in Place must be calibrated on the basis of contextual and participatory analyses, capable of listening to the narratives of older people and reflecting their complexity.

In this scenario, it becomes essential to develop research and design practices that place the voices of older adults at the centre, actively involving them in the definition of the spaces in which they live. Autonomy, a sense of control, identity continuity, and the possibility of participating in community life cannot be guaranteed by top-down measures but must emerge from co-constructive processes that recognize older adults as active agents in the production of their living environment. This perspective also helps counter homogenizing logics that treat older adults as an undifferentiated category, instead fostering a personalized approach attentive to differences in gender, class, culture, health, and individual history.

Conclusions

Drawing from the considerations discussed, the need to overcome simplistic and universalizing views of aging and Aging in Place becomes evident. Studies on AIP should embrace a complex epistemological approach, capable of capturing the dynamic interaction between people and places, between evolving subjectivities and specific urban and cultural contexts. Aging is not a uniform process but a unique and situated journey, constructed through continuous interaction with the affordances offered by the environment and the meanings individuals attribute to the places of their daily life. For this reason, it is urgent to recognize older adults as active actors capable of influencing their own life trajectory. Promoting empowerment, awareness, and self-determination among older people also means combating ageist stereotypes and valuing the plurality of experiences. The integration of Bronfenbrenner's ecological model of development offers a useful tool to analyse AIP through multiple levels of interaction, from micro to macro, thereby restoring complexity and depth to the phenomenon of aging.

In Italy, the debate on AIP remains limited and often dominated by sectorial perspectives, with little attention

to the experiential and relational dimensions of aging. For this reason, we consider it fundamental to initiate multidisciplinary and contextually situated research paths, capable of enhancing local experiences, dialoguing with the culture of living and dwelling, and recognizing the subjectivity of older adults as a central element in the construction of inclusive urban environments.

It is within this theoretical horizon that the PNRR CASA project is situated, aiming to deepen the relationship between housing conditions, urban space, and aging trajectories in medium-sized Italian cities. The project adopts a multidimensional and multilevel approach to analyse how specific urban configurations can support or hinder healthy aging pathways, taking the city of Bergamo as a case study—a territorial reality paradigmatic for its spatial, social, and institutional characteristics. Through the integration of data from institutional and territorial sources at the neighbourhood level, it seeks to capture different forms of urban and housing vulnerability, as well as the potentials of contexts to promote autonomy, participation, and well-being among older adults. The ultimate goal is to develop a model, applicable to other medium-sized Italian cities, able to provide a vulnerability index of the over-65 population.

In line with the assumptions of Aging in Place and inspired by complexity epistemology, CASA aims to overcome reductive views of aging by promoting a situated and relational reading of interactions between individuals and environments. In this sense, the project aspires to provide knowledge tools useful for defining more inclusive and aware urban policies, capable of addressing the challenges posed by population aging in an equitable and sustainable manner.

We believe that only through this paradigm shift will it be possible to design cities and policies that support aging with full responsibility and promote healthy and active longevity.

Abstract
This study examines how migration is addressed in the field of urbanism and, in particular, urban design. Migration, which significantly affects space and social life in today's cities, is often discussed in the literature through policy and regional/urban scale studies, while its relationship with urban design remains limited. Urban design decisions can influence migrants' lives, either reinforcing or overcoming social divisions. Using bibliometric analysis, this study explores how the migration-urban design relationship is shaped and identifies literature gaps. Data were collected from Scopus, ULAKBIM TR Dizin, and DergiPark databases. Findings show that migration is mainly associated with topics like housing, urbanization, gentrification, and segregation, while concepts like integration and cultural adaptation remain underexplored. The results aim to guide future research in this field.

Keywords: migration, urban design, city planning

1. Introduction

Migration, as a fundamental phenomenon that transforms social, economic and spatial dynamics throughout history, has been on the research agenda of different disciplines. However, academic studies on this multi-layered phenomenon have mostly been shaped from the perspectives of sociology, economics and political science, while spatial planning and design disciplines have been relatively limited. However, migration is not only the physical relocation of individuals, but also a complex process that has direct effects on the production, use and remodelling of urban space.

This study aims to analyse how the issue of migration is handled in the context of urbanism and especially urban design, both in the world in general and in Turkey in particular, on the basis of conceptual relations. In this context, it is aimed to reveal the prominent themes, trends and gaps in the production of knowledge on migration. Within the scope of the research, migration is analysed in relation to the concepts of urbanism and urban design, and how these relations are established in the existing literature is questioned.

Methodologically, bibliometric analysis method is used in the study in order to evaluate the relationship between migration and research topics in the field of urban design. Thus, both how migration is represented in literature and the conceptual links established with the discipline of urban design will be analysed systematically. This analysis aims to contribute to identifying the limits of spatially based academic production on migration and to shed light on the gaps in knowledge in this field.

2. Conceptual Framework

2.1.Migration

Migration refers to the movement of people across a state border or within a country. These movements are defined as population movements based on the displacement of people, regardless of their duration, nature or cause (Perruchoud & Cross). The migration process often causes social, environmental, economic and political transformations and has an impact on both the sending and receiving societies. In today's globalised world, it is seen that migration phenomenon emerges as a result of social and economic development. In this context, migration can contribute to the improvement of economic and social conditions, but it can also pave the way for the formation of various inequalities (Castles, De Haas, & Miller, 2014).

According to Tekeli (2006), migration is a social process that enables settlement systems to adapt to changing conditions. Factors such as transformations in the political and economic external relations of the society or economic inequalities at regional level require the settlement structure to adapt to new conditions. When this adaptation is not achieved, disadvantaged social groups emerge within the city and significant segregation is

experienced in the urban fabric. This incompatibility can be shaped depending on factors such as income level, class structure, ethnic and religious characteristics of the society (Tekeli, 2006). One of the main causes of socio-spatial segregation is large-scale migration movements and race-based discrimination. These large-scale urban migrations experienced in certain periods lead to polarisation in the labour market and increase in injustice in income distribution. With migration and the factors that trigger this process, the boundaries of spatial segregation become more apparent (Erder, 1997). With large-scale migration processes, the socio-spatial segregation of migrants is accompanied by social exclusion and racial discrimination. With the globalisation process, there has been a concentration at the upper and lower ends of occupational fields; the weakening of the middle class has increased occupational polarisation and deepened discrimination against migrants (Fahey & Fanning, 2010).

Migration management is considered as a process that is mostly under the jurisdiction of central governments around the world. The global increase in migration movements in recent years has been defined as a 'migration crisis' by many governments. Looking at this process from a perspective based on 'crisis management' and centralised decision-making structures, migration management poses various challenges for different social groups. According to the 2020 World Migration Report of the International Organisation for Migration (IOM), there are currently around 272 million international migrants, accounting for approximately 3.5% of the world population (IOM, 2020). Accordingly, migration management has become an increasingly critical issue in the context of a significant mass of people (Çevik, 2021). Migration, in its most general definition as human mobility, has the power to change and shape the destiny of cities as well as nations.

In line with this general framework, we will now proceed to examine how migration intersects with urban design and with which conceptual approaches this relationship is addressed in the literature.

2.2. Migration and Urban Design Relationship

While the structural characteristics of urban space shape society, society also produces new spatial organisations. In this process, inequalities emerging in social relations are reflected in space; similarly, inequalities produced at the spatial level have an impact on social relations (Lefebvre, 1974).

In this framework, the reflections of the phenomenon of migration on urban space in Turkey constitute an important area of investigation. Turkey has faced intense migration movements since the mid-20th century. Considering the urbanisation process in Turkey, Kıray states that the urban structure is shaped in line with both the socio-economic development process and the class structure. In particular, gecekondu areas, which were formed as a result of the inability of the population migrating from rural areas to the city to settle in the city, constituted a clear example of spatial segregation (Kıray, 1998).

The relationship between urban design and migration has a complex and multidimensional structure. Migration movements are effective in many areas from the physical structure of cities to social dynamics. In this process, the effects of migration on the urban structure bring about the formation of cultural diversity and new identities in the urban space, while bringing integration and social cohesion processes to the agenda. Housing and zoning policies need to respond to the changing needs arising from migration; at the same time, it necessitates the development of new approaches in line with environmental and sustainable urban development principles. An effective urban design approach can contribute to the formation of sustainable and livable cities by producing a balanced solution between the challenges and opportunities brought by migration (LeGates and Stout, 2020).

In line with this conceptual framework, examples that concretise the relationship between migration and urban design through the impact of spatial transformations on social structure are noteworthy. In this context, the 'Comuna 13' project in Medellín, Colombia offers a meaningful example of implementation. Within the scope of the project, the effective use of urban art in public spaces, increasing the level of accessibility and supporting social integration were aimed. These interventions aimed to improve the living conditions of socio-economically disadvantaged communities, strengthen social cohesion and reduce security problems. The Comuna 13 example

is important in terms of demonstrating the potential of urban design to transform social segregation shaped by migration and to promote social interaction and integration through space. (Comunaproject.org, n.d.) (Dorene, 2022)

Figure 1: Images of the Columbia 13 project (taken from Dorene, 2022)

As can be seen from the example cited, urban design has an important role in the spatial and social transformations that emerge with migration. Spatial arrangements shape not only the physical environment but also the forms of social interaction and the inclusiveness of urban life. In this context, it is clear that urban design decisions can directly affect the living conditions of migrants, reinforce spatial segregation and social divisions, or transform these processes to create a more inclusive urban environment. Therefore, the need to take into account the phenomenon of migration and the needs of migrants in urban design processes stands out as an important conceptual and practical requirement (Tuohy and Talen, 2017).

In this respect, it is clear that the phenomenon of migration should be addressed in a more holistic and inclusive manner in urban design processes. In the remainder of the study, the methodology and analysis process applied in order to analyse these relationships in more depth on the basis of the literature will be explained in detail.

3.Method

In this research, bibliometric analysis method was used to understand the reflections of migration on urbanism and especially urban design. This method enables the quantitative analysis of academic publications produced by individuals or institutions within a specific discipline, in a specific time period and in a specific geography, and the relationships between these publications (Arslan, 2022) (India, 2024). In this context, the analysis aims to reveal the dimensions of the concept of migration in the literature and the place it occupies in the context of urbanism and urban design.

Within the scope of the analysis, not only the concept of migration, but also the prominent themes, trends and conceptual frameworks in the literature related to this concept have been evaluated. In particular, the extent to which social and spatial issues directly related to migration, such as integration, have found a place in the urbanism and urban design literature has been examined; thus, priorities and gaps in the literature have been tried to be revealed.

3.1. Bibliometric Analysis Process

While creating the bibliometric data set within the scope of the research, leading academic databases such as Scopus, ULAKBIM TR Index and DergiPark were used. These databases were preferred in order to search the national and international literature published in the fields of migration, urbanism and urban design in a comprehensive manner. During the data collection process, academic publications published using the relevant keywords were selected and exported in a format suitable for analysis.

VOSviewer software was used to visualise the data obtained during the bibliometric analysis process and to reveal the relationships between the subject clusters. Through the programme, keyword matches, conceptual concentrations and thematic distributions were presented as word networks and maps. In addition, word clouds were created in line with the results obtained, and visual traceability of the prominent themes related to the subject of migration in the literature was provided.

Thanks to this method, it has been systematically revealed with which concepts the issue of migration has been handled in the context of urbanism and urban design both in Turkey and internationally, and which themes have come to the fore.

3.2. Bibliometric Analysis Findings

Scopus Database Findings

In the bibliometric search conducted using the Scopus database, a total of 377,216 publications were found as a result of a general search with the keyword 'migration'. These publications point to a very large body of literature dealing with migration in various aspects. However, when the search scope is narrowed down with the concept of 'urban studies', the number of relevant publications decreases to 24,898. This decrease shows that the treatment of migration in the context of urban studies is relatively limited. When the term 'urban design' is added to the search, the number of publications is only 1,627. This result reveals that the subject of migration has been the subject of very few studies in urbanism, especially within the framework of urban design.

When a geographical limitation centred on Turkey was added to the filtering process, only 25 publications were found in this conceptual intersection. This situation clearly shows that the number of academic publications addressing the relationship between migration, urbanism and urban design together in the Turkish context is extremely limited.

Table 1: scopus database data

Used filters	Number of publications
"migration"	377.216
+"urban studies"	24.898
+"urban design"	1.627

The network map shown in Figure 2 was created based on the publications obtained as a result of the search in the Scopus database with the keywords 'migration' and 'urban design' and visualised using VOSviewer software with bibliometric analysis method. The visualisation reveals which concepts are associated with migration and urban design in the literature, the density of the relations between them and the conceptual clusters. Each node in the visual represents a specific keyword, and the links between nodes represent the frequency of these concepts being used together in the same publication. The size of the nodes reflects the frequency of repetition of the keyword in the analysed publications, while clusters with the same colour indicate thematic groups that are located within close meaning areas.

The fact that concepts such as 'urban planning', 'urbanisation', 'housing', 'urban development' and 'urban design' are at the centre and with dense connections shows that the subject of migration is generally studied in the context of urban design by associating it with these titles. Concepts such as 'integration', 'segregation', 'gentrification', 'accessibility' and 'neighbourhood', on the other hand, highlight the effects of migration on social space with their social context. On the other hand, it is observed that concepts such as 'migrant', 'gated communities', 'exclusion' and 'place attachment' are positioned in relatively lower groups. This situation suggests that there are special areas where studies on the spatial experiences and belonging relations of migrant individuals are

concentrated thematically, although they are few in number. In the literature, it is seen that the issue of integration under the titles of 'migration' and 'urban design' is addressed in a limited number of studies through the concept of 'integration'. This situation reveals that the number of academic productions in which the relationship between migration and urban design is addressed from the perspective of social integration is insufficient.

As a result, this analysis provides an important basis for understanding which concept clusters the phenomenon of migration is associated with, in which areas it is concentrated and which thematic gaps exist when it is addressed within the framework of urban design.

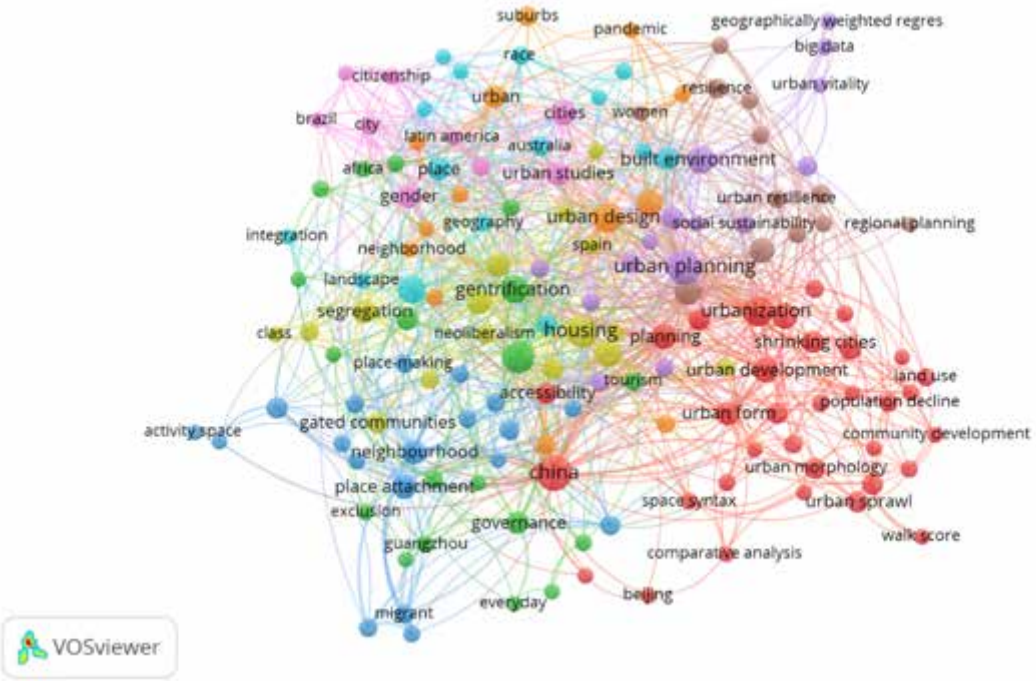

Figure 2: Keyword analysis using the Scopus database

The author network map in Figure 3 was created based on Scopus data searched with the keywords 'migration' and 'urban design' and visualised by bibliometric analysis method through VOSviewer program. The map reflects the collaboration structure created based on the citation relationships of researchers working in this field and academic clusters in the literature. Each node represents an author and the lines between nodes represent the citation or co-publication relationships between authors. Node size represents the author's visibility in the analysed literature, i.e. citation density, while clusters with the same colour represent a specific collaboration group or academic communities working on similar topics.

In the map, Li, Zhigang stands out as the largest and centrally located node. This shows that this author is one of the important reference points in the literature on the themes of 'migration' and 'urban design'. Names such as Wu, Fulong; Liu, Yuqi; Lin, Sainan; He, Shenjing have also gained an active place in the literature by being both cited and involved in various collaborations. The existence of distinct clusters among authors shows that researchers working on migration and urban design issues mostly collaborate within their own groups and that academic networks with regional or thematic axes are formed. The dense connections especially among China-based authors also reveal that the production in this field is significantly concentrated in certain geographies.

This analysis is important not only in terms of identifying the most cited authors under the titles of migration and urban design, who play a leading role in the literature, but also in terms of showing around which regional or thematic networks the existing literature is shaped.

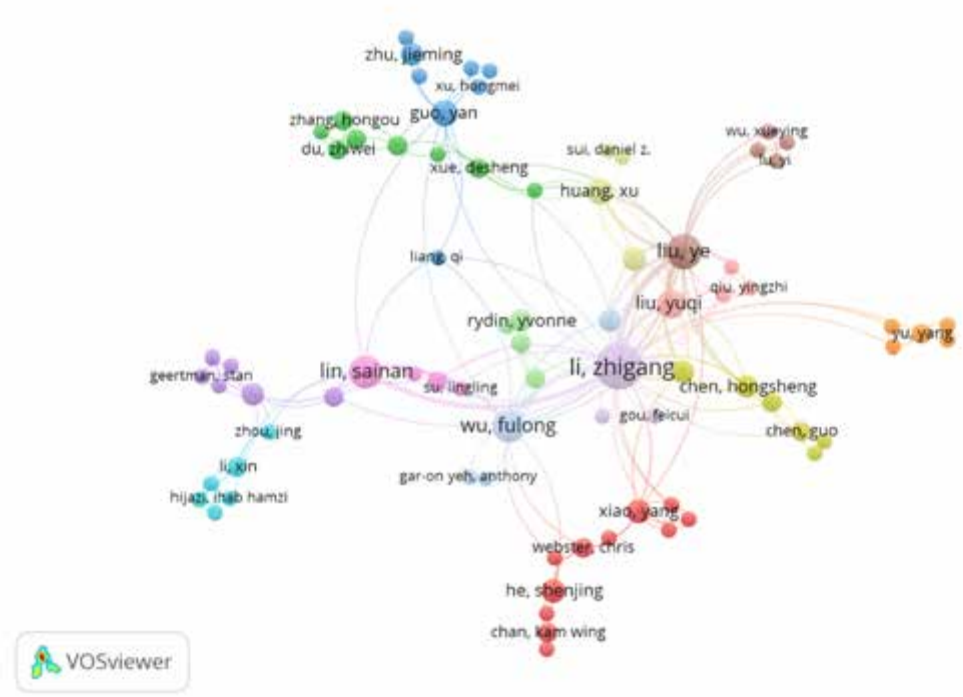

Figure 3: Author-citation analysis using the Scopus database

Figure 4 visualises the keyword network of publications produced in Turkey. This analysis is based on the results obtained by filtering the keywords 'migration' and 'urban design' in the Scopus database. The clusters that stand out in the visualisation provide important clues about the conceptual frameworks and themes around which the relationship between migration and urban design is shaped in the literature.

As a result of the analysis, it is seen that on the one hand, concepts such as 'urban regeneration', 'urban politics', 'Ankara', 'squatters' and 'Islamic neoliberalism' cluster together; on the other hand, concepts such as 'urban renewal projects', 'squatter rehousing projects', 'social space/abstract space', 'neoliberalism' and 'Islam' form a second cluster. This structure shows that migration is strongly associated with urban regeneration policies, slum areas, neoliberal urban policies and social spatial production processes in Turkey. The analysis also reveals that academic production on the relationship between migration and urban design is largely discussed through urban regeneration practices and the socio-spatial effects created by these practices.

These findings support that the interactions between migration, spatial change and social structure, emphasised in the previous sections, are intensified in the Turkish context, especially in urban regeneration and spatial policy debates.

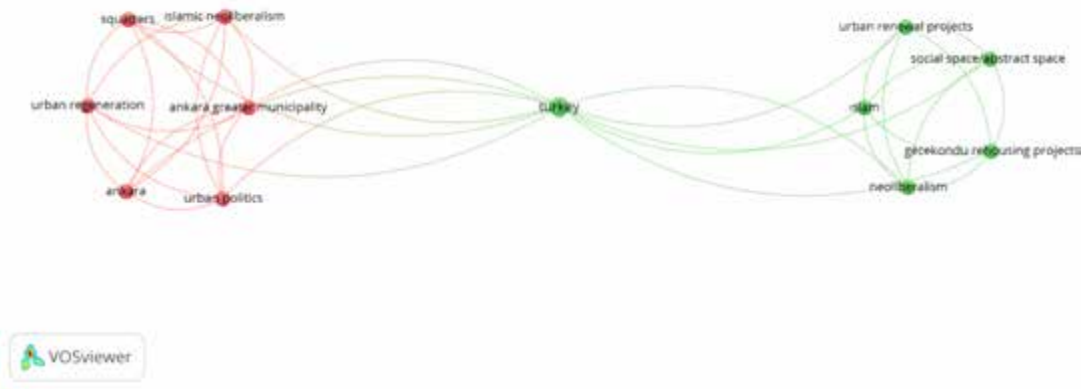

Figure 4: Keyword analysis of publications produced in Turkey using Scopus database

Figure 5 visualises the author-citation analysis of publications produced in Turkey. This analysis is based on the results obtained by using the keywords 'migration' and 'urban design' in the Scopus database. The visual represents the citation relationships and interaction networks of the authors producing in this field within the literature.

As a result of the analysis, it is seen that certain authors are cited more intensively and stand out in the field. Names such as 'Taşan-Kok, Tuna', 'Eraydın, Ayda', 'Batuman, Bülent', 'Paköz, Muhammed Ziya' and 'Baycan-Levent, Tüzin' are among the notable authors in the literature in this field. The relatively scattered distribution of the authors shows that academic studies on the intersection of migration and urban design have not yet formed a distinct and strong research network. This situation also reveals that this topic is an emerging research area in the literature and needs more interdisciplinary cooperation and deepening. This finding also supports the assessments highlighted in the previous sections that point to gaps in the literature and lack of conceptual coherence.

Figure 5: Author-citation analysis of publications produced in Turkey using Scopus database

The results of the analysis from the Scopus database show that the concept of migration is predominantly addressed within the framework of themes such as 'gated communities' and 'spatial segregation in settlements' in the international literature. However, it is also associated with the concept of 'integration', albeit at a more limited level. In the Turkish context, it is noteworthy that studies on the relationship between migration and urban design are limited to a narrower range of topics and that this relationship has not yet been sufficiently deepened in the literature.

ULAKBIM TR Index Database Findings

ULAKBIM TR Index is an important national database that compiles and makes available academic and scientific studies carried out in Turkey. In this study, the TR Index database was used to filter the abstracts of the publications through certain keywords. As a result of the analysis, it has been determined that studies on migration and urban context show an increasing trend over the years. While an increase in the number of publications has been observed especially since the 2000s, it is seen that this increase has accelerated significantly in the last five years. It was determined that the highest number of publications was reached in 2021 and a total of 411 publications were recorded in this year.

According to the filtering results, 3,624 publications were identified with the keyword 'migration'. If this number is used with the concept of 'city', the number of publications decreases to 236. When concepts that narrow the filtering are added, 5 publications were identified with 'urbanism', 1 with 'urban planning', 2 with 'urban planning' and only 1 with 'urban design' (see Table 2). This finding shows that academic studies produced at the intersection of migration and urban design are quite limited in the Turkish context.

Table 2: Ulakbim TR dizin database data

Used filters	Number of publications
"migration"	3.624
+"urban"	236
/ + "urbanism"	5
/ + "city planning"	1
/ + "urban planning"	2
/ + "urban design"	1

In the data set obtained, the scans were evaluated in a more qualified and detailed manner due to the lack of sufficient number of publications on the intersection of migration and urban design. In this framework, the results are visualised and presented through word clouds in order to reveal conceptual trends and thematic relationships more clearly. In Figure 6, the word cloud reflecting the main study topics obtained as a result of the analyses made in the ULAKBIM TR Index database is visualised. When the prominent key concepts in the image are examined, it is seen that the concept of 'migration' has a central position. In addition, concepts such as 'belonging', urban sociology', 'urbanisation process', 'cultural adaptation' and 'transformation processes', which emphasise social and spatial dimensions, also draw attention. In addition, elements that point to more specific contexts such as 'urban architecture', administrative structure' and 'Hatay' as a place name also come to the fore.

This structure shows that the migration phenomenon is mainly addressed in the literature in Turkey in relation to social belonging, cultural adaptation and urbanisation processes, and that it is still a limited but potentially developing research area in the spatial context.

Figure 6: Ulakbim TR index database word cloud

DergiPark Database Findings

DergiPark is a comprehensive database that brings together scientific studies published in Turkish academic journals and provides open access to them in a digital environment. In this study, a search was conducted using keywords identified in the abstract sections of publications in the DergiPark database.

The data obtained from the analysis are presented in Figure 7. According to this analysis, 6,507 publications were identified using the keyword 'migration'. When the keyword 'urbanism' was used alongside 'migration', this number dropped to 10 publications, while three publications were identified with 'urban planning' and five with 'urban design' (see Table 3).

Table 3: Dergipark database data

Used filters	Number of publications
"migration"	6.507
+"urbanism"	10
/ + "urban planning"	3
/ + "urban design"	5

These results suggest that migration is a significant topic in general literature, but research addressing it in the context of urban planning and design is limited. Consistent with previous database analyses, the findings once again highlight that the relationship between migration and urban design in Turkey is a topic that has not yet been sufficiently explored in academia.

Figure 7 shows a word cloud visualisation of the key concepts obtained from the DergiPark database analysis. Due to the limited amount of data available, the word cloud method was used to highlight conceptual trends and demonstrate which themes stand out in the literature more clearly. Key concepts that stand out in the visualisation include 'urban design', 'heritage area', 'urban open space', 'urban area adequacy', 'urban landscape', and 'Diyarbakır', which refer to spatial and local contexts. Themes such as 'socio-spatial approach', interdisciplinary approach', ecological design' and 'user preferences' also hold a significant place in the literature.

Figure 7: DergiPark database word cloud

This structure reveals that the DergiPark database addresses the topics of migration and urban design, particularly in terms of spatial quality, the protection of heritage areas and urban open spaces. However, studies focusing directly on the context of migration are limited in number.

The DergiPark database analysis shows that the topic of 'migration' generally reflects the current state and social dynamics of contemporary cities. It is also noteworthy that publications produced in Turkey within the scope of urban design largely address the themes of 'housing', 'urban transformation', and 'informal settlements'. Consistent with previous database analyses, these findings indicate that academic studies on the relationship between migration and urban design remain limited in scope, highlighting the need for further in-depth research in this area.

In this context, trends in the literature and research gaps have been identified based on the findings of the analysis. The conclusions drawn from these findings will be evaluated in detail in the final section.

4. Conclusion

The analyses conducted aimed to reveal how the relationship between migration and urban design is addressed in the literature at a conceptual level. Within the framework of the stated objectives, themes related to migration in urban planning and urban design were evaluated and gaps in the existing literature were identified.

The analysis results showed that academic publications related to migration increased in the 2000s, with this trend accelerating significantly in the last five years. This trend indicates the growing importance of the issue in the context of current urban dynamics and social changes. Findings show that migration is predominantly addressed in international literature in terms of spatial segregation themes such as "closed communities" and "segregation in settlements". However, it has also been observed that it is associated with the concept of "integration", albeit to a lesser extent. A similar pattern emerges in the context of publications produced in Turkey: migration is primarily addressed in relation to "urban transformation", "slum formation" and "housing", while studies addressing concepts such as "adaptation" and "cultural integration" are quite limited.

Overall, it can be concluded that the relationship between migration and urban design remains limited in the literature, highlighting the need for more comprehensive, interdisciplinary, and inclusive research in this field. In particular, considering urban design as a tool that supports 'integration' and 'adaptation' processes, and discussing these issues through public spaces, could be an important direction for future research.

These findings provide concrete evidence of the gap in the literature that motivated this study. Notably, the dearth of studies examining migration from an urban design perspective underscores the necessity for more comprehensive research on this subject.

The limitation of the study is that only the Scopus, TR Dizin and DergiPark databases were used in the bibliometric analysis. This has limited the scope of the analysed publication set. Nevertheless, the analyses provide valuable insights into trends and research gaps in the existing literature.

In conclusion, this study emphasises the need for more comprehensive and diverse research at the intersection of migration and urban design, particularly the importance of incorporating social cohesion, integration and public space perspectives into urban design processes.

Acknowledgment
This article was developed based on the outcomes of the course KET 596: Scientific Research, Ethics, and Seminar, offered in the Spring Semester of the 2023–2024 academic year. The authors would like to express their sincere gratitude to Assoc. Prof. Dr. Eren Kürkçüoğlu for his valuable contributions to the preparation of this study.

The Urban Factors in Highly Skilled Migration Motivation: The Case of Turkish Professionals in the Netherlands

Hülya Saçın, Ahmet Burak Büyükcivelek
Affiliation: Middle East Technical University, Middle East Technical University
Email: hulya.sacin@metu.edu.tr, aburakb@metu.edu.tr

Abstract
This study investigates the role of the "urban factor" in the location choice motivations of highly skilled individuals migrating from Türkiye to the Netherlands. Using a mixed-method approach, the research compares spatial (transportation, infrastructure, public facilities, spatial quality, cost of living) and non-spatial (economic, political, social, personal) factors affecting migration decisions, based on data collected from participants via online survey. The findings indicate that for highly skilled participants, spatial elements hold equal importance to economic and social reasons in their migration decisions. While contributing to discussions on talent migration and urban competitiveness, the study highlights the necessity of inclusive, liveable, and holistic planning policies for cities to attract human capital and facilitate integration processes.

Key words: Highly Skilled Migration, Urban Competitiveness, Locational Preferences

1. Introduction

In recent decades, international migration has undergone a profound transformation, increasingly characterized by the mobility of highly skilled individuals. Unlike traditional migration patterns, this new wave is not primarily driven by survival or displacement but rather by aspirations for professional development, creative autonomy, and integration into global knowledge economies. Highly skilled migrants—often associated with the creative class—are not only economic actors but also contributors to the cultural, social, and technological dynamism of cities. As such, their locational choices hold significant implications for urban planning, regional development, and national competitiveness.

Cities and regions are no longer passive recipients of global talent; they actively compete to attract and retain it. This competition has intensified in recent years due to demographic shifts, labour shortages in specialized sectors, and the increasing relevance of innovation-based growth. In this context, urban environments have become key arenas for global talent flows. Notably, the Netherlands has emerged as a prominent destination for highly skilled migrants, including an increasing number of professionals from Türkiye. This trend raises critical questions regarding the spatial and non-spatial factors that influence mobility decisions and shape urban experiences for this group.

This study aims to investigate the locational preferences and decision-making processes of highly skilled Turkish migrants in the Netherlands. It seeks to understand how spatial factors—such as infrastructure, transportation, environmental quality—interact with non-spatial determinants like social cohesion, administrative efficiency, safety, and cultural inclusivity to inform migration trajectories. Grounded in a mixed-methods research design and informed by theoretical frameworks, the research provides both conceptual clarity and empirical insight into the drivers and lived experiences of this increasingly mobile population.

By focusing on the Turkish case within the Dutch context, the study not only contributes to the broader literature on highly skilled migration and urban attractiveness but also addresses a critical gap in understanding the interplay between individual agency and structural urban conditions in migration decisions. Ultimately, it offers guidance for policymakers, planners, and scholars seeking to navigate the complex dynamics of global talent mobility in an era where cities must simultaneously be engines of economic growth and spaces of social inclusion.

2. Highly Skilled Migration: City, Economy, and Global Competition

In the contemporary era, highly skilled migration has emerged as a distinct form of mobility, differing notably from other types of migration. As a result, its definition, underlying motivations, and impacts also take on unique characteristics.

The new economic order that emerged from modern life and urbanization driven by capitalism was initially shaped by Fordist production models, which emphasized mass production and regular working conditions (Murphy & Redmond, 2009). Over time, however, knowledge-based economic systems began to replace traditional modes of production. Scott (2006) defines this transformation as an innovative economy composed of high technology, financial services, and cultural-artistic sectors.

In this context, Markusen (2006) and Florida (2012) emphasize that the creative class—characterized by highly educated, innovative, and mobile individuals—contributes significantly to the economic growth of cities. According to Florida (2012), the creative class is a fundamental driver of both economic and cultural development due to its problem-solving and creative thinking capacities. Similarly, Cedefop (2010) defines highly skilled individuals as well-educated and competent people specialized in particular sectors.

From this perspective, human capital, referring to the stock of knowledge, skills, and experience possessed by individuals, is of critical importance for innovation and productivity (Becker, 1964). Glaeser et al. (1995) argue that cities with higher levels of human capital experience faster growth, while Florida (2012) suggests that the creative class fuels urban economic dynamism and attracts investment and labor, thus supporting urban development. Florida's (2012) framework reinterprets the traditional human capital model, expanding it to include technology, art, culture, education, and managerial professions (Darchen & Tremblay, 2010). Moreover, highly skilled individuals not only contribute economically but also enhance social and cultural dynamism through active participation in urban life (Florida, 2012). Glaeser and Saiz (2003) note that cities with an educated population tend to have a higher quality of life and become more attractive, while Rodrik et al. (2004) highlight that these regions foster strong institutions that promote economic growth.

Cities function not only as economic hubs but also as cultural, political, and social centers where knowledge production, innovation, and creativity converge (Brown & Męczyński, 2010). Therefore, urban development is closely linked to dynamic production systems and work-life relations (Scott, 2006). The geographic clustering of knowledge-based economies enhances global economic networks and increases the competitiveness of cities on an international scale (Murphy & Redmond, 2009).

Global competition to attract highly skilled migrants is expected to become even more intense soon. The need for skilled talent is increasing not only in developed nations but also in rising economies. Consequently, the Netherlands is competing for talent not just with countries like the United States and Germany, but also with emerging players such as Brazil and Türkiye. This increased competition is often described in popular discourse as the 'battle for the brightest,' the 'brain race,' or the 'war for talent' (Berkhout, Heyma, Volkerink, & Werff, 2016).

Creative class members—highly skilled individuals—drive both cultural development and economic growth by producing knowledge-based content (Scott, 2006; Glaeser, 2005). They shape urban identity, boost investment appeal, and stimulate economic dynamism. Cities attracting such talent benefit from enhanced innovation, collaboration, and productivity. Florida (2012) terms these professionals "creative human capital," emphasizing their central role in the "new economy" and in fostering both economic and cultural progress (Murphy & Redmond, 2009). A city's ability to retain this group is essential for local development and is intertwined with global skilled migration dynamics. For developing countries, this often manifests as brain drain, leading to economic losses from unrecouped educational investments and sectoral labor shortages (Beine, Docquier & Rapoport, 2008; Lowell & Findlay, 2001). The departure of skilled labor undermines innovation, service quality, and competitiveness. Retaining creative talent is thus vital for economic vitality and socio-cultural sustainability (Glaeser & Saiz, 2003; Rodrik et al., 2004).

3. Defining Highly Skilled People

The definition of highly skilled individuals varies significantly depending on the context and purpose of classification. In political and administrative settings, lawmakers and institutions may define highly skilled persons based on salary thresholds or national policy needs. For instance, certain migration policies, such as the EU Blue Card system, identify a highly skilled migrant as someone earning at least 1.5 times the average national salary. However, this approach can exclude professionals engaged in high-level scientific research if their earnings fall below this threshold. Danış (2023) highlights it and then illustrates this limitation by highlighting the case of a doctoral researcher at a European university who, despite working on an advanced research project, does not qualify as "highly skilled" due to income criteria.

In addition to income-based definitions, educational attainment serves as another fundamental criterion. According to the International Organization for Migration (IOM), a highly skilled person is generally defined as someone with at least two years of post-secondary education. Similarly, scholars such as Borjas (2005) and Cerna (2013) emphasize education and occupational status in their definitions. A common approach in the literature is to utilize occupational classifications. For example, Czaika and Parsons (2017) refer to the first three major groups of the International Standard Classification of Occupations (ISCO) to identify skilled professions. Likewise, visa regimes such as the U.S. H-1B and the EU Blue Card consider a combination of education, income, and occupation.

While education and income remain the most prevalent measures, some scholars have approached the concept from a broader socio-economic and cultural perspective. Mellander and Florida (2007), as cited in Dai, Zhou, Keane, and Huang (2012), categorize the concept of the "creative class" according to three criteria: educational level, income, and occupational sector. Florida (2012) defines this group as workers engaged in occupations rooted in creativity, innovation, and knowledge production. Their primary economic function is to generate new ideas, develop technology, and create content. This definition encompasses a wide spectrum of professions within both the creative and knowledge-based industries. The creative industries include fields such as advertising, architecture, fashion design, the arts, publishing, and media production, while the knowledge industries span ICT, finance, law, R&D, etc.

In parallel with Florida's (2012) approach, other scholars have adopted a similarly inclusive framework. Clark, Lloyd, Wong, and Jain (2003) offer a comparable perspective, identifying the creative class as individuals contributing to the knowledge economy and cultural production. Their classification includes medical professionals, academic staff, financial analysts, consultants, legal professionals, and other experts in intellectually and creatively demanding sectors. These professions are further grouped into science, technology, education, business, cultural industries, and service/recreation. While the former are valued for their problem-solving and knowledge advancement, the latter—such as artists, designers, and writers—contribute to cultural vibrancy and enhance cities' attractiveness through tourism and investment.

Howkins (2002) situates the creative class within the global creative economy, valuing original ideas, innovation, and design over physical goods. His definition spans advertising, architecture, media, R&D, education, and even law, where intellectual autonomy is central. Despite such frameworks, defining the highly skilled remains complex. Salt (1997) underscores conceptual and data-related challenges, proposing a typology that reflects group heterogeneity—covering professionals, managers, and technical experts. This model accounts for education levels, mobility patterns, and includes transferees, consultants, technicians, healthcare workers, etc.

4. Drivers of Highly Skilled Mobility

The creative class consists of individuals with innovative thinking, problem-solving abilities, and cultural production skills, characterized by high levels of education, a tendency toward independent work, and the capacity to integrate easily into diverse cultural environments and global labour markets (Florida, 2012). These individuals actively contribute to the economic and cultural development of cities by working in sectors that form the core dynamics of the knowledge economy, as mentioned. Therefore, the international mobility of highly skilled people holds strategic importance in today's global economy. They tend to prefer locations where they can expand their

opportunities, express their freedoms, and further develop their skills.

In this context, studies on the factors influencing the settlement decisions of highly skilled migrants have been addressed at various levels and scopes. This study will examine these influencing factors under two main categories: spatial and non-spatial. Non-spatial factors include Florida's (2012) 3T model as well as personal trajectories as discussed by Liu and Shen (2014) and Chen and Rosenthal (2008), and Florida's (2012) soft factors. Spatial factors, on the other hand, will be evaluated under the categories of Florida's (2012) Hard Factors and Quality of Place, and urban amenities.

4.1. Non-Spatial Drivers of the Highly Skilled Mobility

Highly skilled individuals, often referred to as the creative class, are central to the economic and cultural development of cities through their capacity for innovative thinking and cultural production. These individuals form the backbone of the knowledge economy and are positioned at the core of global competition. Florida (2012) offers a comprehensive framework for understanding the factors that attract and retain this talent through his well-known "3Ts" model.

However, it is essential to recognize that individuals' migration decisions are not shaped solely by structural or economic factors. Different life stages and personal circumstances also play a critical role in shaping their mobility preferences. While young professionals often prioritize career prospects and urban dynamism, families and retirees tend to prefer locations that offer high living standards and quality public services (Liu & Shen, 2014; Chen & Rosenthal, 2008).

Soft factors—like cultural amenities, environmental quality—shape a city's identity and liveability. Though intangible, they significantly influence highly skilled migrants' location choices by enhancing lifestyle quality and fostering inclusive, vibrant urban environments that appeal to creative and talented individuals.

4.1.1. 3T Model of Florida

Among the conceptual frameworks proposed to understand the location choices of talented individuals, Florida's (2012) 3T model stands out as a pioneering approach. According to this model, the three fundamental pillars that attract highly skilled individuals are: Technology, Talent, and Tolerance.

The first component, Technology, refers to the infrastructure and institutional environment fostering innovation and technological advancement, including universities, research centres, and high-tech firms central to knowledge-based economies. Talent encompasses not only formally educated individuals but also those with creativity, problem-solving skills, and entrepreneurial potential (Florida, 2005). The third component, Tolerance, reflects a region's openness and receptivity to diverse lifestyles, cultures, and ideas. As Asheim and Hansen (2009) emphasize, regions that embrace diversity and encourage open dialogue offer a supportive environment for creativity and collaboration, attracting a more dynamic and skilled workforce.

Together, these three dimensions form a synergistic environment that enhances a city's or region's ability to compete in the global knowledge economy by appealing to highly mobile, skilled individuals.

4.1.2. Personal Trajectories

In addition, personal life trajectories significantly influence individual migration decisions. Life course theory emphasizes that age, life stage, family status, and career progression intersect with mobility preferences and constraints. For instance, Liu and Shen (2014) demonstrate that the preferences of older adults and retirees are often shaped by their search for high-quality services, healthcare, and environmental amenities. These groups tend to relocate to areas offering comfort, safety, and access to recreational opportunities.

Conversely, younger individuals in the early stages of their professional lives tend to be more mobile and responsive to economic opportunities and urban vibrancy. Chen and Rosenthal (2008) emphasize that young, single, and

highly educated individuals are more likely to migrate toward dynamic urban centres that offer career advancement, cultural richness, and social networks. In contrast, married individuals or those with children prioritize stability, access to quality education, and secure neighbourhoods.

Moreover, Whisler et al. (2008) classify university graduates into six different life stages and find that the relative importance of quality-of-life indicators, such as cultural amenities, urban infrastructure, and work-life balance, varies significantly across these groups. These findings highlight the necessity of understanding migration decisions as evolving processes shaped by both personal and contextual factors over time.

4.1.3. Soft Factors

A third group of non-spatial drivers, often termed soft factors, refers to the intangible and experiential elements that shape individuals' perceptions of places. These include lifestyle quality, cultural and artistic opportunities, environmental aesthetics, social diversity, and community tolerance (Florida, Mellander & Stolarick, 2008). Unlike hard infrastructure, these elements are less quantifiable yet profoundly influence locational attractiveness, particularly for the creative and highly skilled population (Asheim & Hansen, 2009).

Soft infrastructure refers to the cultural, social, and physical qualities shaping a city's identity and perceived liveability (Helbrecht, 2004). According to Murphy and Redmond (2009), Brown and Męczyński (2010), and Trip (2007), soft factors fall into three categories: cultural and recreational amenities (e.g., festivals, museums, cinemas, shopping centers, sports facilities); urban environmental conditions (e.g., cleanliness, noise and air pollution, waste management); and tolerance and openness toward minorities, immigrants, and diverse socioeconomic or sexual backgrounds. These factors significantly affect a city's liveability and its ability to attract and retain highly skilled migrants.

4.2. Spatial Drivers of the Highly Skilled Mobility

In the literature, it is emphasized that the migration decisions of highly skilled individuals are shaped not only by economic opportunities but also by the spatial characteristics of the places they reside in. In this context, the spatial factors influencing high-skilled migration are examined in this section under three main headings: "hard factors," "quality of place," and "urban amenities."

4.2.1. Hard Factors

Hard factors refer to tangible and measurable elements such as economic structure, transportation infrastructure, and access to healthcare and education. According to Florida (2012), leading components among these include employment opportunities, competitive wages, and robust infrastructure. Musterd and Gritsai (2013) note that while employment is the primary determinant for location choices among creative individuals in Europe, hard and soft factors are evaluated together. In this regard, quality of life elements are described as "the icing on the cake." Similarly, Sezgin (2021) emphasizes that although employment forms the basis of migration motivation, cultural diversity, urban aesthetics, and quality of life also influence decision-making processes.

Studies by Murphy and Redmond (2009), Brown and Męczyński (2010), and Trip (2007) classify hard factors under the following categories: public services, transportation infrastructure, and cost of living. Public services include street safety, police and healthcare services, and social security systems. Transportation infrastructure refers to public transit, intra- and inter-city connectivity, and bicycle lanes. Cost of living encompasses housing prices, basic consumer goods, leisure activities, and transportation expenses. These elements directly impact individuals' everyday experiences and strongly influence location choices.

According to Mash (2022), hard factors also cover broader economic and physical conditions. These include land and housing availability, taxes and subsidies, proximity to suppliers and clients, transportation access, the presence of a skilled workforce, and proximity to research institutions. Administrative flexibility and efficiency in bureaucratic procedures also play critical roles in decision-making processes. Collectively, these factors are particularly important for investors and creative professionals.

4.2.2. Quality of Place

In several studies, quality of place is identified as a significant factor in attracting and retaining highly skilled individuals. Florida (2012) and Trip (2007) argue that certain urban characteristics—such as diverse social and cultural amenities, environmental quality, recreational opportunities, and community ties—play a decisive role in location decisions. Based on Trip's (2007) framework, Brown and Męczyński (2010) define quality of place through ten sub-categories.

The first is diversity, which relates to functional diversity, distinctive neighborhoods, and sufficient population density. Unique amenities include individual sports facilities, recreational spaces, retail and dining venues per capita, and public gathering areas. Vibrancy and culture refer to the variety of cultural and musical events, while aesthetics are assessed through architectural quality and urban heritage. Environment encompasses natural assets, environmental quality, brownfield redevelopment, and sustainability principles.

On the other hand, technology, talent, creativity, openness, and safety in quality of place headings are key to urban attractiveness and part of a holistic quality of place framework (Trip, 2007; Florida, 2012). Florida links these to the "creative class," echoing earlier theories. Darchen and Tremblay (2010) see this as an extension of Jacobs' ideas, while Glaeser (2005) highlights urban idea generation, reinforcing the relevance of creative environments.

4.2.3. Urban Amenities

Urban amenities constitute another important dimension that can influence location choices of highly skilled individuals. Landry (2000) argues that originality, spatial diversity, cultural and entertainment facilities, public spaces, and openness and tolerance are effective in attracting such individuals. However, there is no consensus in the literature regarding the impact of urban amenities. Some studies (Greenwood & Hunt, 1989; Arntz, 2010; Niedomysl & Hansen, 2010, as cited by Darchen and Tremblay, 2010) suggest that their influence on migration decisions is limited, while Storper and Scott (2009) challenge the rationale behind this assumption. Conversely, Liu and Shen (2014) report growing evidence in Western literature indicating that urban amenities have become increasingly influential in shaping migration trends and urban growth.

Glaeser et al. (2001), through the concept of the "consumer city," propose that modern urban growth is linked to the services and consumption opportunities cities offer, particularly in attracting highly skilled human capital. Arntz et al. (2023) also note that certain urban amenities—such as restaurants, nightlife, and cultural venues—can serve as attractions for highly skilled workers and influence their migration decisions. Drawing on Glaeser's (2005) perspective, Storper and Scott (2009) argue that attracting highly skilled individuals requires offering high-quality public schools, safe streets, and affordable housing.

5. Methodology, Case, Data

The Netherlands was selected as the case study for this research due to its increasing attractiveness to highly skilled migrants in recent years. An OECD report (2023) highlights that the country received approximately 171,000 new immigrants in 2021. According to Statistics Netherlands (CBS), the Turkish-Dutch community surpassed 170,000 between 1996 and 2022. In addition, the Global Competitiveness Report (Schwab, 2019) ranks the Netherlands fourth globally, with an overall competitiveness score of 82.4, and a notably high score of 84.6 in the highly skilled labour.

Projections by the Netherlands Interdisciplinary Demographic Institute (NIDI) and CBS estimate that by 2050, around 40% of the Dutch labour force will consist of immigrants (Moca-Grama, 2020; Pieters, 2020, as cited in Haşar, 2020). Furthermore, Türkiye is identified as one of the most significant countries of origin for graduate immigrants in the Netherlands, accounting for nearly 7% of all foreign knowledge workers (OECD, 2023). In the same year, migration from Türkiye to EU countries rose by 34%, reaching 71,000 individuals, with the Netherlands among the primary destinations.

5.1. Research Design and Approach

In that case, this study employs a mixed-methods design, combining quantitative and qualitative approaches for a deeper understanding of migration drivers (Creswell & Plano Clark, 2007). A semi-structured online survey—distributed via Google Forms using voluntary and snowball sampling—targeted highly skilled Turkish professionals in the Netherlands. It included Likert-scale, multiple-choice, and open-ended questions to capture both standardized data and personal insights. A pilot study improved clarity and alignment with the spatial and non-spatial migration factors. Ethical approval was granted by METU's (Middle East Technical University) Human Research Ethics Committee, and all responses were anonymous with informed consent obtained.

5.2. Analytical Framework: Spatial and Non-Spatial Factors

The conceptual framework of this study is grounded in the well-established distinction between spatial and non-spatial factors. Spatial factors are primarily linked to physical and infrastructural elements of urban planning and design, while non-spatial factors pertain to social, cultural, administrative, and economic drivers that are not directly tied to the built environment but nonetheless influence locational preferences.

Based on this classification, the study constructs its analytical model to evaluate how these categories of factors shape the international mobility decisions of highly skilled migrants. In this context, the research is guided by the following central question: **"**To what extent do spatial and non-spatial factors respectively influence the migration preferences of highly skilled people relocating from Türkiye to the Netherlands?"

These question serves as the analytical foundation for both the design of the survey instrument and the interpretation of empirical findings. It also aims to contribute to the broader scholarly discourse on international highly skilled migration by offering a structured comparison between tangible and intangible drivers of mobility.

Spatial-based variables are directly related to urban planning and physical infrastructure. Five primary categories were identified:

- Public Facilities: Encompassing healthcare, education, commercial and cultural services, recreational and shopping amenities, and urban scale.

- Transportation: Addressing urban transit systems, intercity connectivity, bicycle infrastructure, and parking accessibility.

- Infrastructure: Covering access and quality of essential services such as electricity, water, internet, as well as environmental factors like waste management and cleanliness.

- Urban Aesthetics: Evaluating the visual and spatial quality of the city, including preservation of natural and historical heritage.

- Cost of Living: Focusing on the affordability and accessibility of housing, land, and commercial spaces.

- Non-spatial factors, though indirectly shaped by spatial policies, are not directly tied to the built environment. These were categorized into six groups based on previous research (Murphy & Redmond, 2009; Brown & Męczyński, 2010; Musterd & Gritsai, 2013; Trip, 2007; Masch, 2022; Florida, 2012):

- Cultural and Recreational Activities: Availability and diversity of concerts, festivals, and theatres.

- Social Structure: Perceived community cohesion and social integration.

- Safety: Low crime rates, resilience to natural hazards, and general urban security.
- **Climate Conditions**: Comfort and sustainability of local weather patterns.

- **Public Administrative Services**: Efficiency and accessibility of administrative processes, residence and work permits.

- **Consumer Diversity**: Breadth of goods and services, particularly relevant to creative and financially independent individuals.

5.3. Data Analysis Methods

Quantitative data were analysed through descriptive frequency and numerical (percentage) analysis, enabling the identification of dominant patterns and trends. Open-ended qualitative responses were evaluated using thematic analysis by open, axial and selective coding methods (Moghaddam, 2006) to uncover deeper insights into participants' subjective experiences and motivations.

5.4. Participant Profile

A total of 198 highly skilled migrants participated in the survey, with 196 responses deemed valid and included in the final analysis. The majority of participants (90%) were between the ages of 25 and 44, with 46% in the 25–34 age group and 44% in the 35–44 age group. In terms of gender distribution, 73% identified as women, 25% as men, and 2% as LGBTI+. Regarding marital status, 71% of the participants were married, 18% were single, 7% were married with children, and 4% fell into other categories. The educational background of the sample was notably high, with 99% holding at least a bachelor's degree; specifically, 43% had completed a master's degree and 12% held a doctoral degree. Professionally, the sample was dominated by engineers, who constituted 38% of respondents. IT professionals followed this at 11% and researchers and academics at 8%. Other professional fields, including finance, marketing, healthcare, architecture, and design, were each represented by 4% to 7% of participants. The creative service sector had the lowest representation, with only 1.5% of respondents employed in that area.

Figure 1: Geographical Distribution of Highly Skilled Turkish Participants in the Netherlands

Geographically, participants were concentrated in major urban centers such as Amsterdam, Rotterdam, and Eindhoven. Smaller numbers were located in cities like Groningen, Enschede, and Nijmegen. Key factors in location choice included employment opportunities and perceived quality of life.

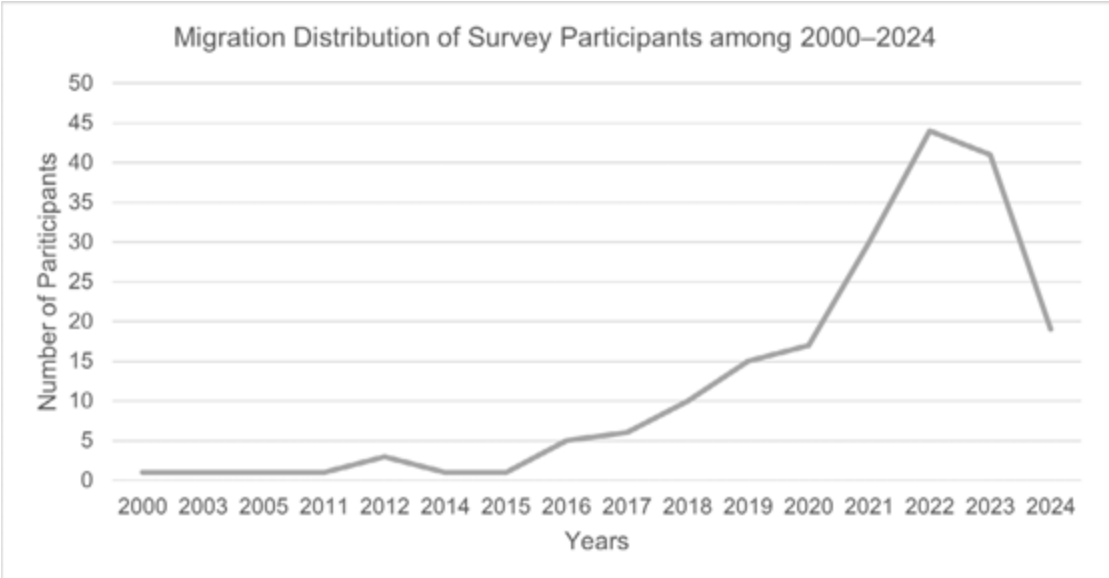

Figure 2: Annual Migration Distribution of Survey Participants among 2000–2024

Migration timing analysis showed an average length of stay of 40.3 months. A notable increase in migration occurred post-2016, attributed to domestic political instability, economic crises, and rising unemployment in Türkiye. Migration peaked between 2020 and 2022, spurred by the digitalization of work, remote employment opportunities, and increased living costs during the COVID-19 pandemic. A decline was noted in 2023–2024, likely due to stricter immigration and visa policies in European countries.

6. Findings

The survey results show that family ties are generally not a determining factor in decisions to migrate to the Netherlands; 93.4% of the participants find this factor unimportant, while the presence of friends and relatives is not a motivation for migration for the majority (67.3%, "not suitable"). However, family or personal reasons are important for some; 34.7% of the participants stated that they chose the Netherlands because of their spouse, partner or family's employment situation. While educational background is ineffective for most (89.3%,"not suitable"), education plays a role in the decision to stay in the Netherlands for a small number (9.7%). On the other hand, employment conditions are a very important factor in migration decisions, with 45.9% of the participants seeing this as a "priority factor". Living conditions are similarly influential, with 63.8% seeing this as a "priority factor". Participants indicated that urban and social factors make the Netherlands attractive. These results reveal that migration decisions are mostly based on individual, economic, occupational and urban conditions.

It is clear that participants consider working and living conditions a priority in their migration decisions. How they define these conditions is illustrated in Tables 3 and 4, supported by excerpts from their responses to open-ended questions.

Table 1: Categorization of Participant Responses Regarding Living Conditions

PART OF RESPONSES	CODING	F	P (%)
"Green cities, beautiful architecture, urban planning" *"Environmentally friendly, calm, harmony with nature"* *"Less dense cities"* *"Ability to use public transport and bicycles"* *"Having the 15-minute city concept"* *"Short distances"* *"Easy access to other European countries"* *"Environmental cleanliness"* *"Availability and cleanliness of parks/gardens, availability of day-care centers in residential areas, financial and regional availability of activities/courses for children"* *"Accessible urban services"* *"Access to free education for children"* *"The salary and opportunities offered by doctoral programs were attractive"* *"Quality of education"*	Urban and Environmental Factors	146	30,1
"Welfare level of society" *"High purchasing power"* *"Work life balance"* *"Low inflation"* *"Financial accessibility (house, car, vacation)"* *"International environment"* *"Liberal lifestyle, high rate of English speaking, relatively low racism"*	Economic and Finance	96	19,8
"Stress-free life" *"Protection of human rights"* *"Individuality of religious values"* *"Feeling safe on the street at all hours as a woman"* *"Security, safety, peace"* *"People speak English and are used to immigrants"*	Social and Cultural Environment	193	39,8
"Social state concept" *"Democracy"* *"Reliable legal system"* *"Fair progress of bureaucracy"* *"Living away from politics"* *"Secularism"*	Governance and Public Administration	35	7,2
"Quality of life"	QoL	15	3,1

Participants' responses, analysed through open, axial, and selective coding (Moghaddam, 2006), highlight the strong influence of distinct features on migration decisions. Key factors included access to green spaces, environmental cleanliness, efficient and reliable public transport, and high urban accessibility. Low population density and compact city layouts were also valued, especially in reference to the "15-minute city" concept, which supports time efficiency and quality of life. Proximity to other European countries further enhanced settlement preferences.

Education was another vital factor. Free, high-quality schooling and academic opportunities, especially at the doctoral level, shaped long-term professional goals. Economic motivations cantered not only on income but also on financial stability, purchasing power, job security, and access to basic needs.

The social and cultural environment including safety, low discrimination, personal freedoms, and multicultural integration played a key role. Widespread English use and respect for diversity were seen as essential. Lastly, strong governance—marked by democracy, legal reliability, and transparent institutions— legal-political stability reinforced security and supported long-term planning.

Table 2: Categorization of Participant Responses Regarding Living Conditions

PART OF RESPONSES	CODING	F	P (%)
"The weekly working hours are generally 36-40 hours, and flexible work opportunities are common" "Low hierarchy, open communication culture, and employee appreciation" "Humane working conditions, work-life balance" "Flexible work models" "Employees are entitled to 20-25 days of paid vacation per year" "Dismissal procedures are regulated, and job security is high" "Work-life balance, vacations"	Work-Life Balance and Working Conditions	124	43,1
"High salary" "Fair wage policies" "Purchasing power"	Salary and Economic Factors	87	30,2
"Job descriptions are clear" "PhD programs and job opportunities" "Education and career development opportunities" "Professional development opportunities"	Job Description and Career Development	29	10,1
"Variety of alternatives" "International job opportunities"	Sectoral and Professional Opportunities	40	13,9
"Taxes are high (37-49%), but social services are good" "Tax advantages may be available for foreigners"	Taxation and Being a Social State	8	2,8

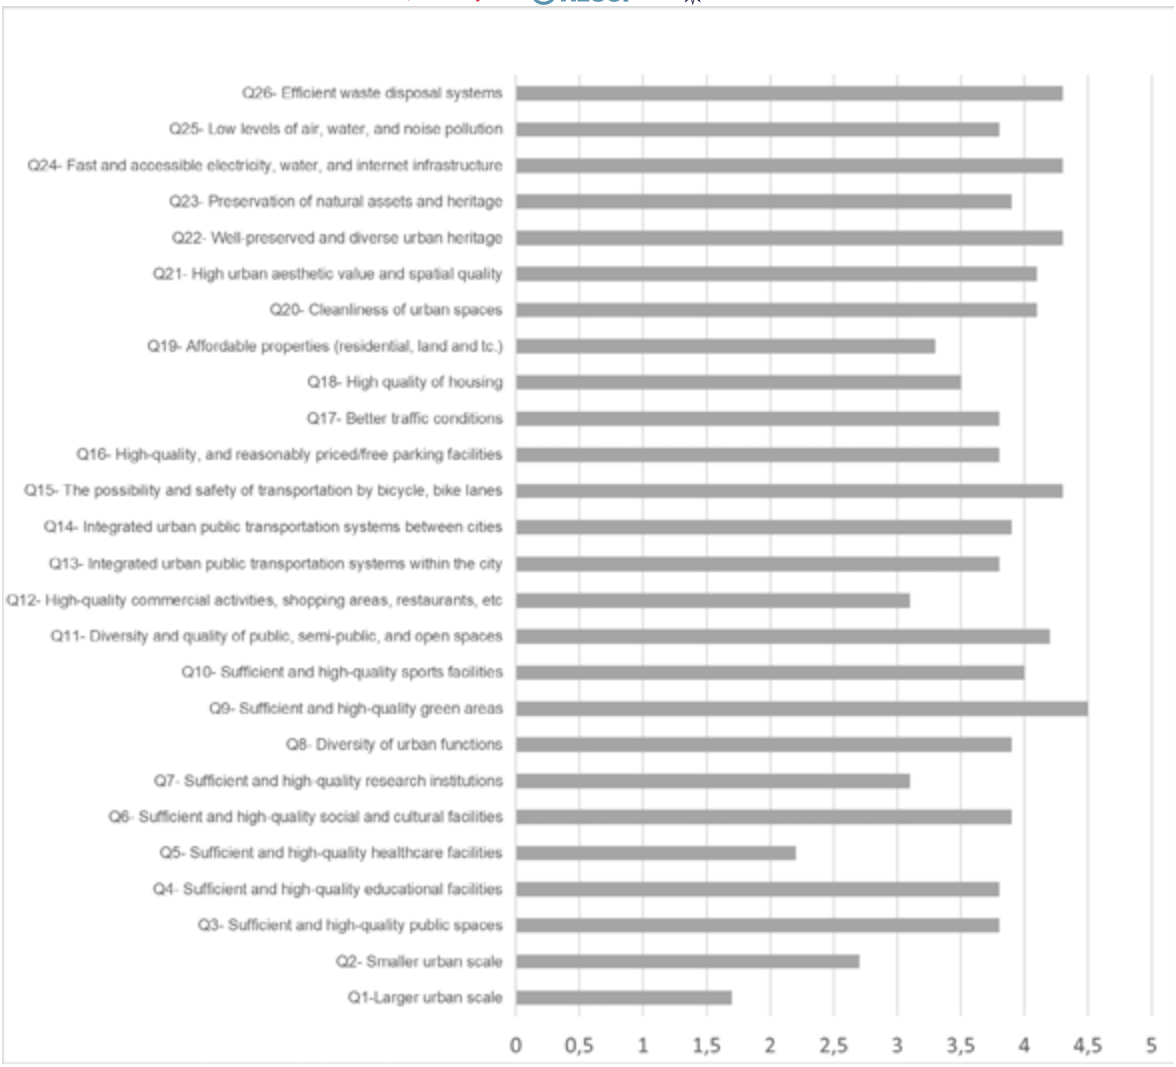
Participants' responses regarding work-life balance and working conditions come right after living conditions. It frequently emphasized flexible working arrangements, 36–40 hours of weekly work, horizontal organizational

structure and open communication environment. High job security, 20–25 days of paid leave per year and regular dismissal procedures were evaluated as important elements indicating the stability of the work environment. Responses regarding salaries and economic conditions reveal that strong purchasing power and fair wage policies are effective in attracting employees. In terms of job description and career development, respondents emphasized the clarity of job descriptions and the importance of various career opportunities regarding sectoral and professional diversity in the labor market and international job opportunities. In the views on the taxation system and the concept of the social state, it was stated that high tax rates are balanced with strong social services and that tax advantages and incentives offered to foreigners are an effective strategy in attracting international labor particularly highly skilled ones.

6.1. Assessing Spatial Factors

The analysis of spatial factors reveals that urban infrastructure, environmental quality, and mobility systems play a crucial role in the settlement choices of highly skilled Turkish migrants. Notably, a significant proportion of participants assigned high priority to access to high-quality green areas (Q9, 69.9%), the quality of public infrastructure such as electricity, water, and internet (Q24, 60.7%), safe and efficient bicycle infrastructure (Q15, 60.2%), and well-preserved urban heritage (Q22, 57.7%). Additionally, waste management systems (Q26, 55.6%) and urban aesthetics (Q21, 54.1%) were prioritized by more than half of the respondents. These findings collectively suggest that highly skilled migrants are particularly sensitive to the functionality, sustainability, and aesthetic value of their urban environments.

However, while spatial factors generally play a significant role in shaping mobility decisions, the level of importance attributed to individual features varies. For instance, elements such as city size (Q1, Q2; 68.2%, 32.7%), the availability of sufficient and high-quality healthcare services (Q5, 42.3%), and the provision of adequate, affordable parking facilities (Q16, 39.8%) were evaluated as less critical by a considerable segment of participants. This indicates that certain spatial dimensions hold a more limited role in the decision-making processes of highly skilled Turkish migrants, despite the broader relevance of spatial context.



Supporting this interpretation, the average score assigned to spatial factors on a five-point Likert scale was calculated as 3.7, underscoring the general importance attributed to urban infrastructure and environmental quality. Particularly prominent among the highly rated factors were access to sufficient and high-quality green spaces (4.5), cycling infrastructure and safety (4.3), well-preserved urban heritage (4.3), reliable and accessible infrastructure services (4.3), and efficient waste management systems (4.3). These findings highlight that participants place considerable value on the quality of infrastructure, landscape design, and historical fabric of the urban environments in which they reside (Florida, 2012).

In addition, other urban attributes such as access to sports facilities, diversity of public spaces, urban aesthetics, and cleanliness also received relatively high scores, further indicating that urban quality of life emerges as a central criterion in this case. Well-integrated public transportation systems, dedicated bike lanes, accessible highways, and international airports facilitate ease of movement and access to urban amenities (Glaeser et al., 2001). Similarly, cities become more attractive when traffic congestion is low and effective recycling services are available and consistently implemented (Lloyd & Clark, 2001). The cleanliness of streets, air quality, and overall visual character of the urban setting—as well as access to natural environments—have a demonstrably positive effect on individuals' physical and emotional well-being (Lloyd & Clark, 2001). Furthermore, the significance of monuments, architecture, and environmental quality in shaping urban appeal is also highlighted in the work of Brown and Męczyński (2010).

Conversely, certain factors such as city scale (1.7) and the perceived quality of healthcare services (2.2) were evaluated with relatively low scores, indicating their limited influence in pre-migration assessments. Interestingly, some of these less prioritized elements, such as healthcare and parking, emerged as sources of dissatisfaction

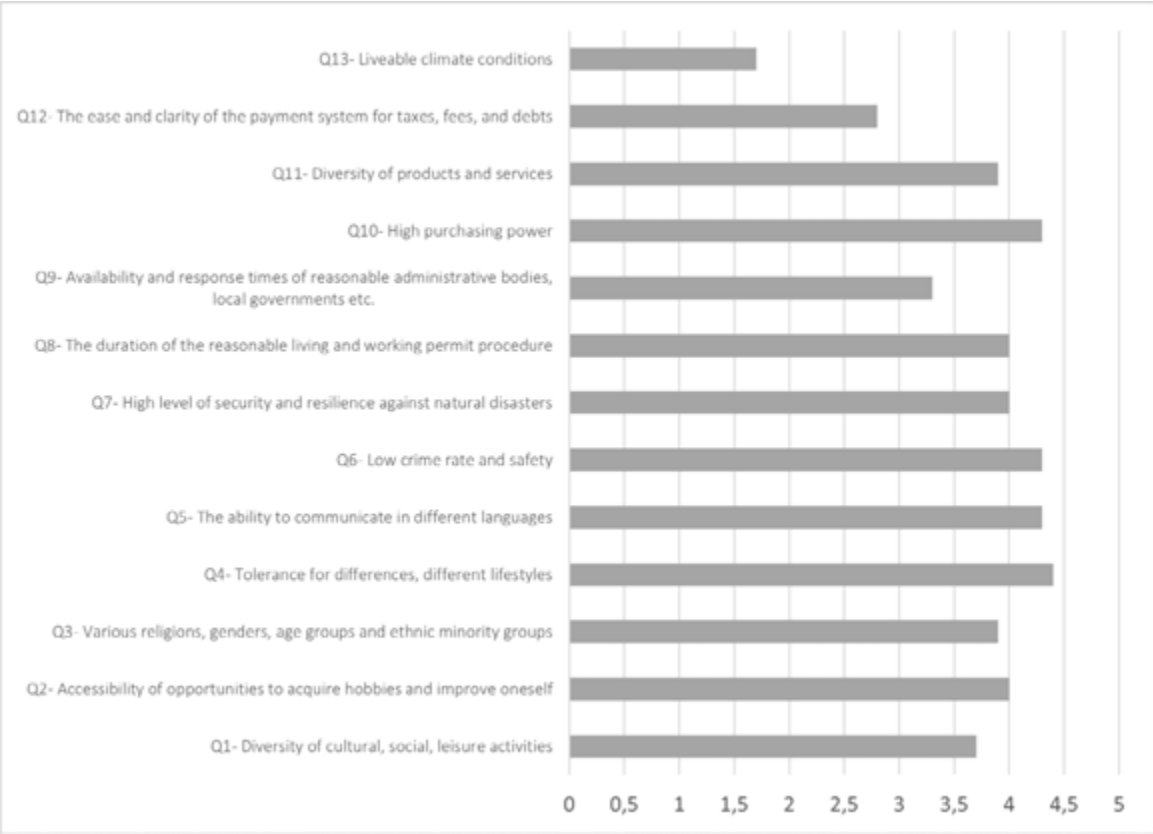
after migration. This suggests that pre-migration decision-making may benefit from a more comprehensive and forward-looking planning process that takes potential long-term needs into account.

In line with this, Landry (2000) emphasizes that a set of specific urban attributes such as authenticity, spatial diversity, cultural and entertainment amenities, the vibrancy of metropolitan life, access to public spaces, openness to diversity, and tolerance are particularly attractive to highly skilled individuals.

6.2. Assessing Non-Spatial Factors

On the other hand, non-spatial factors proved to be equally influential in shaping migration preferences. Public safety (Q6, 59.7%) emerged as particularly salient. Multilingual communication opportunities (Q5, 57.7%) and the level of cultural tolerance (Q4, 57.7%) were also marked as highly significant. Administrative efficiency in obtaining residence and work permits (Q8, 51.5%) and cultural inclusivity (Q3, 44.9%) followed. Protection from discrimination (Q7, 49.5%) and access to diverse consumer goods and services (Q11, 40.3%) were relatively less emphasized. These findings underscore that psychological comfort, social integration, and legal-economic stability are central to the formation of place attachment and the well-being of highly skilled migrants in this context.

One notable exception among non-spatial factors was climate. More than half of the participants (55.6%) indicated that "liveable climate conditions" (Q13) did not apply to their decision-making processes. This suggests that climate is a secondary concern of highly skilled participants compared to spatial, institutional, economic, and social variables.



Similarly, non-spatial factors were also attributed to high levels of importance, with an overall average score of 3.7 on the five-point Likert scale. The highest-rated dimensions included tolerance for different lifestyles (4.4), opportunities for multilingual communication (4.3), low crime rates and general safety (4.3), and high purchasing

power (4.3). These findings indicate that social cohesion, cultural diversity, and safe living environments play a decisive role in the urban preferences of highly skilled individuals. Moreover, factors such as administrative efficiency in obtaining residence and work permits (4.0), resilience to natural disasters (4.0), and access to a wide range of goods and services (3.9) were also evaluated positively, demonstrating their relevance in decision-making processes.

As Florida, Mellander, and Stolarick (2008) suggest, talented individuals from diverse backgrounds are more likely to feel at home in cities that foster an inclusive and tolerant culture. Complementing this view, Clark et al. (2003) emphasize that decisions regarding city selection extend beyond employment opportunities to encompass a broad array of life-quality factors. High earnings potential, professional growth opportunities, and a stable economic infrastructure further attract migrants (Storper & Scott, 2009). Additionally, crime rates are underscored by also Brown and Męczyński (2010) as a critical element shaping a city's appeal.

Conversely, certain variables such as the transparency of tax and fee systems (2.8) and liveable climate conditions (Q13, 1.7) received comparatively low scores. In particular, the low evaluation of climate-related factors suggests that this group of migrants tends to prioritize economic, social, and administrative criteria over environmental variables in their decision-making processes. Masch (2022) identifies such elements—including administrative flexibility, taxation, subsidies, and the availability of a skilled workforce—as "soft factors," which, along with climatic considerations, are shown to be less influential in this context (Murphy & Redmond, 2009; Brown & Męczyński, 2010; Musterd & Gritsai, 2013).

Taken together, the findings illustrate that both tangible urban infrastructure and intangible socio-cultural conditions jointly shape the decisions of highly skilled migrants. A particularly notable outcome is the fact that spatial and non-spatial factors received equal average scores (3.7), suggesting that both categories are perceived as equally significant in shaping migration preferences. This equilibrium indicates that physical urban elements are evaluated in conjunction with social attributes like inclusivity, safety, cultural diversity, and administrative functionality in that case.

In other words, for Turkish highly skilled individuals in the Netherlands, urban liveability is not solely determined by the social atmosphere and institutional arrangements offered within it, but also by the quality of the physical environment. This balance underscores the multidimensional nature of mobility decision-making in today's global labour market. Rather than being driven solely by economic or environmental considerations, location choices are increasingly grounded in holistic assessments. Consequently, for cities aiming to attract and retain highly skilled migrants, the development of integrated and sustainable urban policies—addressing both physical infrastructure and social cohesion—plays a critical role in ensuring long-term attractiveness.

7. Conclusion

This study set out to explore the locational preferences and migration drivers of highly skilled Turkish individuals who have relocated to the Netherlands, with a particular focus on the influence of spatial and non-spatial factors. Drawing on a comprehensive literature review, theoretical frameworks such as the 3T model and life-course perspectives, and empirical findings from a mixed-methods survey, the research reveals that highly skilled mobility is shaped by a complex interplay of tangible urban attributes and intangible socio-cultural, economic, and political conditions.

The results show that spatial factors—particularly urban infrastructure, environmental quality, green spaces, and cycling infrastructure—play a crucial role in shaping settlement preferences. Participants placed significant value on well-preserved urban heritage, waste management systems, and urban aesthetics. However, some physical attributes such as city scale and healthcare services were rated as less critical in pre-migration evaluations, though they later emerged as sources of dissatisfaction post-migration. This highlights a potential gap between expectations and lived experiences that cities must address through more comprehensive planning.

Equally important, non-spatial factors demonstrated a high degree of influence on migration decisions. Safety, cultural tolerance, multilingual communication, and administrative efficiency were among the most decisive variables. The prominence of these factors indicates that psychological comfort, legal clarity, and inclusive urban atmospheres are key components of urban attractiveness for highly skilled migrants. Notably, climate conditions—which are often assumed to influence migration—were rated among the least important factors in this context.

A particularly significant finding of the study is the nearly identical average scores assigned to spatial and non-spatial dimensions (3.7 out of 5), underscoring their equal importance in the migration decision-making process. However, when disaggregated, social and cultural factors appear to slightly outweigh physical attributes in overall impact. This suggests that cities aiming to attract and retain global talent must not only invest in infrastructure and services but also foster a tolerant, inclusive, and culturally rich environment.

In sum, the migration decisions of Turkish highly skilled individuals are not determined by a single dimension but shaped by the combined effects of quality of life, institutional efficiency, urban functionality, and socio-cultural climate. This underscores the need for integrated, holistic urban strategies that address both material and experiential dimensions of city life. As global competition for talent intensifies, cities that balance these attributes will be better positioned to sustain long-term economic vitality and social cohesion.

8. Limitations

The findings of this study should be evaluated within the framework of some methodological and practical limitations. Due to the dynamic and context-specific nature of the migration phenomenon, temporal and spatial variables are important. This situation limits the generalizability of the findings to different periods or geographical contexts.

Although the participants showed a certain diversity in terms of age, gender, marital status, education level and occupational fields, the sample was concentrated in knowledge-based fields such as engineering, informatics and academia.

In terms of time, most of the participants migrated after 2016. This migration movement accelerated even more after 2020 and reached its peak in 2022. The number of participants migrating in 2023 and 2024 was lower. The data only reflects a certain period. Therefore, the study has limited capacity to make inferences about long-term trends. Although there was diversity in terms of time, demographics and occupation, equal representation could not be achieved among the subgroups.

Data collection was conducted only through a survey, and qualitative methods were used only within the survey. This situation made it difficult to obtain in-depth information.

Urban Form and Social Exclusion: A Spatial Perspective on Residential Segregation in Czech Cities

Pavlína Suchá
Affiliation: Faculty of Architecture, Czech Technical University in Prague Czech Technical University in Prague
Email: pavlina.sucha@cvut.cz

Abstract
Urban residential segregation, shaped by historical, economic, political, and cultural factors, varies in its spatial form, which varies across regions (Dadashpoor, 2024). Recent approaches by architects and planners explore links between the built environment and the inhabitant's socioeconomic traits, highlighting specific spatial features that can reinforce segregation (Vaughan et al., 2005; Knaap & Rey, 2024; Legeby, 2013). This study builds on these approaches and proposes a framework focused on spatial connectivity and accessibility in relation to socioeconomic deprivation in the Czech Republic. The focus is on access to amenities, public transportation, and urban connectivity. The research methodology is grounded in identifying localities with high concentrations of socially excluded residents, using available data on recipients of the subsistence allowance (Sýkora, 2015).

Keywords: Residential Segregation; Urban Form; Spatial Inequality; Urban Design

Introduction

Despite significant advances in research on urban segregation, the phenomenon continues to shape the social and spatial fabric of cities worldwide. Defined as the physical separation of socioeconomic or ethnic groups within urban areas (Musterd, 2020; Musterd et al., 2016; Massey & Denton, 1988), segregation not only reinforces inequalities but also limits opportunities for social mobility and integration (Musterd, 2023).

Socioeconomic inequalities in urban settings have garnered growing scholarly attention; however, the complexity of residential segregation, rooted in a combination of historical, economic, and spatial factors, necessitates a multidisciplinary approach (Vaughan & Arbaci, 2011). The concentration of disadvantaged groups in specific neighbourhoods has been linked to stigmatisation, discrimination, and reduced access to essential services, with profound consequences for both individual well-being and community cohesion (Musterd, 2023; Van Kempen & Bolt, 2012). Moreover, the spatial configuration of urban environments plays a significant role in shaping patterns of social inclusion and exclusion, underscoring the importance of spatial justice as a critical dimension in addressing urban inequalities (Lehman-Frisch, 2011; Massey, 1993; Van Kempen and Bolt, 2012).

While the adverse impacts of segregation, including unequal access to education, employment, and healthcare, are well documented (Yue et al., 2024), less attention has been paid to how spatial structures and urban morphology contribute to these patterns, particularly in post-socialist contexts. Current policy efforts, such as those by the European Union or SDG policy goals by the United Nations (Eurocities, 2023; United Nations, 2024), aim to address social exclusion and inequality, yet effectively integrating these goals into urban policies remains a significant challenge.

This study seeks to contribute to addressing this challenge by examining the spatial features of residential segregation in the Czech context, where socioeconomic exclusion can be traced through the concentration of people reliant on state welfare systems (Agentura pro sociální začleňování, 2024; Sýkora, 2023). By developing a theoretical framework that links spatial connectivity, accessibility, and residential segregation, this study aims to contribute to practical policy interventions.

Literature review

Conceptual Approaches to Studying Segregation

The exploration of urban segregation varies depending on the analytical perspective adopted. Musterd (2023)

identifies four dimensions of segregation based on sociodemographic characteristics. The first concerns class or social status (Sassen, 2001; Atkinson, 2006; Musterd, 2020). The second encompasses race and ethnicity, sometimes considered alongside religion and migration (Phillips, 2010). The third pertains to demographic attributes, such as age and life-cycle stage, while the fourth involves cultural distinctions, which may be reflected in differing lifestyles and educational levels. Although approaches to studying segregation may differ, this paper focuses specifically on the spatial aspects of socioeconomic segregation, following the assumption that spatial distance corresponds to social distance and that poverty often concentrates in particular areas and disadvantaged neighbourhoods (Musterd, 2020; Duncan and Duncan, 1955; Park, Burgess and McKenzie, 1925).

Within the discourse on residential segregation, scholars frequently distinguish between voluntary and involuntary forms of segregation (Dadashpoor, 2024; Musterd, 2020). Voluntary separation typically involves the self-selected separation of affluent groups into exclusive residential enclaves, such as gated communities. In contrast, involuntary segregation refers to the marginalisation of low-income populations, often manifesting in concentrated areas of poverty, such as ghettos or slums. However, the boundary between voluntary and involuntary segregation is not always clear-cut. What may appear as voluntary separation can, in some instances, be shaped by shared cultural or social characteristics or driven by a collective desire for security and cohesion (Dadashpoor, 2024; Toušek, 2007).

The distinction between what is sometimes termed "chosen" enclaves and "enforced" ghettos (Peach, 2005) highlights the complex interplay between individual agency and structural constraints. While ethnic concentration in specific neighbourhoods may initially offer certain advantages, such as social support networks and access to culturally familiar services, it can also create barriers to long-term integration and broader societal inclusion (Musterd, 2023). This phenomenon is particularly evident within the broader context of macroeconomic and political processes (Vaughan and Arbaci, 2011; Peach, 2005).

Musterd (2020) warns against the simplistic categorisation of segregation into 'good' and 'bad' forms. Such binary distinctions risk overlooking the nuanced and context-dependent nature of segregation. Although the emergence of gated communities represents a significant dimension of socio-spatial stratification, this study focuses specifically on exclusionary forms of segregation that affect marginalised populations.

The Multidimensional Nature of Exclusion

Spatial exclusion is the most visible manifestation of the broader phenomenon of social exclusion. Residential segregation forms part of the process that confines certain groups of people to specific regions, settlements, localities or buildings (Toušek et al., 2018). When these groups are defined by ascribed characteristics such as ethnicity, religion, nationality or similar attributes, the process can be understood as discrimination (Sýkora and Temelová, 2005).

However, social exclusion in its entirety does not necessarily equate to poverty, although it is often a contributing cause (Madanipour, 2011; Musterd, 2020). Exclusion can be understood at multiple levels and may take different forms depending on cultural, political and economic contexts. Madanipour (2011) argues that various forms of exclusion underpin all social relations. The division of life and activities into private and public spheres creates boundaries that are both temporal and spatial in nature. The author also conceptualises exclusion as an issue of access to places, activities, resources, information and other vital components of everyday life.

The Physicality of Urban Space: Influence on Social Life

Since the concept of the "right to the city" was introduced in the 1960s by the French philosopher and sociologist Henri Lefebvre, urban studies have increasingly grappled with space not only as a physical structure but also as the product of social ties, relations and dynamics. Lefebvre, followed later also by David Harvey, called for the democratisation of urban planning, arguing that all inhabitants have a stake in shaping their urban environments (Lefebvre, 1968; Harvey, 1973). Edward W. Soja builds on Lefebvre's work by arguing that our geographies, or lived spaces, are socially produced and not merely physical forms. According to Soja, justice and injustice are

embedded in the multi-scalar geographies we inhabit, from households to the global economy (Soja, 2010). At the same time, Soja rejects spatial determinism, warning that it would narrow the scope of the discussion. Instead, he advocates for a comprehensive approach that recognises the mutual influence of space and society for the reason that it is evident that some form of inequality will always exist.

There is ongoing debate in the literature regarding the extent to which the physical characteristics of a settlement influence the social ties among its residents (Vaughan and Arabaci, 2011). While some scholars argue that neighbourhood environments play a significant role in shaping individual behaviour and health outcomes (Galster et al., 2010), this relationship is complex and not always straightforward.

Space can be perceived as an expression of social relationships and, simultaneously, as a factor that influences them. When individuals face restrictions in their social opportunities, their spatial mobility is similarly constrained, and therefore, their personal experience of exclusion deepens (Madanipour, 2011). In turn, spatial inequalities tend to reinforce existing social inequalities (Vaughan, 2007; Madanipour, 2011).

The Role of Housing Policies and Spatial Planning

Regarding the approach to housing policy, Madanipour (2011) identifies two processes. First, the real estate market treats space as a commodity, creating socio-spatial segregation through residents' differential access to this commodity. This represents a purely market perspective. On the other hand, spatial and urban planning seeks to regulate and rationalise urban development and impose a form of order in the public interest. These two processes often contradict each other and produce what Madanipour calls the collectivisation of difference, meaning sharper social differences within smaller spatial units.

Following this idea in the context of post-socialist countries, Kovács (2020) refers to this urban transformation as mosaic-type urban development, where through the lens of administrative units, the population may be diverse, i.e. that people of different socioeconomic status live in the same neighbourhood, but in reality, they are small sharply segregated structures.

Dadashpoor (2024) identifies a potential driver of segregation in what is described as a form of invisible segregation, indirectly conditioned by the decisions of governing bodies and influenced by housing and social policies. As Luděk Sýkora et al. (2010) note, residential segregation also encompasses a spatial planning dimension. At various scales, spatial planning documents contain tools that can potentially contribute to desegregation. Furthermore, social segregation is acknowledged as a concern within national policy frameworks.

However, Musterd and Ostendorf (2009) caution that focusing solely on residential segregation may be insufficient to understand the social dynamics at playfully.

Research relying heavily on census data often emphasises segregation at the city-wide or neighbourhood scale, which can vary in conceptualisation. Moreover, everyday experiences of ethnic segregation may be more accurately reflected in other spatial settings such as streets, community centres, workplaces, parks, and other public spaces, and these sites may hold particular significance for vulnerable communities. For these groups, the spatial boundaries of social interaction differ from those captured by residential data (Phillips, 2007).

Moreover, architectural or urban form alone cannot be directly blamed for social problems. Bill Hillier (1996) emphasises the importance of analysing the spatial configuration of environments and how these influence patterns of movement and interaction. This approach provides a more nuanced understanding of the relationship between architecture and social behaviour (Hillier, 1996).

Detour to Post-Socialist Transition and Urban Transformation

In the twenty-first century, metropolitan Europe has become increasingly unequal, with a persistent and widening gap between high- and low-income populations observed across the continent (Musterd, 2017). To under-

stand the roots of segregation in Central Europe, particularly in the Czech Republic, it is essential to take a brief detour and examine the economic and urban transformations that have taken place over the past few decades.

The political changes following the collapse of the Soviet Union and the subsequent economic transformation brought dramatic shifts for all countries of the former Soviet bloc. The roots of the current patterns of segregation lie in this historical context.

Under state socialism, housing was considered a universal right, which in practice led to the mass construction of prefabricated housing estates and the expansion of the housing stock through the subdivision of expropriated apartments into multiple housing units (Kovács, 2020). However, this right was not distributed evenly. Socialist cities were characterised by a particular form of segregation based on allocated privileges, reflecting a marked stratification of society (Häussermann, 2008). Housing thus became, to some extent, a tool for distributing these privileges (Lux and Sunega, 2014).

The trajectories followed by individual republics in Central Europe after the fall of socialism differed considerably. For example, Tsenkova (2006) describes how the transition to a market economy, technological change, and industrialisation also transformed the urban environment.

Massive housing construction, housing allowances, expropriation, and rent regulation created a substantial publicly owned housing stock, which partially substituted for social housing. At the same time, there was no significant support for people in social need from other entities such as charities or churches. This absence contributed to a deepening of socio-spatial inequalities following the fall of the regime and large-scale privatisation (Lux and Sunega, 2014).

The privatisation of housing stock and the restructuring of the economy led to greater income diversification and the emergence of new socio-spatial inequalities (Kovács, 2020).

Another common feature across the former Soviet bloc countries is the high level of private ownership within the housing stock. Due to large-scale privatisation in the 1990s and 2000s, almost 90 per cent of the housing stock in the Czech Republic is now privately owned (Lux, 2014). Lux (2014) further notes that in the 1990s, nearly all housing stock was transferred to cities and municipalities, which became the largest owners of real estate. However, government limitations on their rights, combined with often outdated housing lacking repair funding, created difficulties. At a time of stagnant economic growth and some disillusionment with the economic transformation, privatisation emerged as a convenient tool to relieve municipalities of unwanted burdens and secure voter support. This process was also accompanied by widespread distrust of social housing, which, despite being built under favourable conditions in the 1990s, frequently ended up in private hands (Lux, 2014).

The lack of a sufficient public sector housing stock, combined the absence of governmental legislation on social housing, has led to the current situation of socioeconomically segregated neighbourhoods so-called excluded localities (Toušek, 2018). As the author notes, this term is rather challenging to grasp and lacks a clear definition. The Analysis of Socially Excluded Localities in the Czech Republic[1] (Čada et al., 2015) defines a socially excluded locality as "a space (house, street, neighbourhood) where there is a concentration of people who can be identified as having characteristics associated with social exclusion," further noting that such areas are negatively and symbolically labelled by the surrounding population. The spatial forms of socially excluded localities can vary in both size and structure; however, there are no clear implications for urban form that would allow for their consistent spatial identification.

Knowledge Gap: Urban Structure and Residential Segregation

Despite over a century of research on urban segregation, the settlement patterns of segregated populations remain insufficiently understood (Vaughan and Arbaci, 2011). Much of the comparative study to date has primar-

1 Translated by the author of this text from: Analýza sociálně vyloučených lokalit v ČR.

ily focused on capital cities, limiting broader generalisations about segregation across different urban contexts (Musterd et al., 2017).

Comparing levels of segregation and the approaches used to analyse them presents a range of methodological challenges. As Musterd (2023) notes, units of analysis can vary considerably depending on the research objective. Additionally, the spatial dimension of segregation can be studied using a variety of analytical methods, each influenced by the availability, type, and granularity of data employed.

While the causes and consequences of social exclusion have been widely studied, the traditional segregation measures often rely on predefined administrative boundaries, which can obscure the fluid and continuous nature of social and demographic distributions (O'Sullivan and Wong, 2007). O'Sullivan and Wong (2007) highlight that traditional segregation measures often rely on administrative boundaries. Because these units are arbitrary, the results can vary significantly depending on the size and shape of the areas chosen. This issue, where the scale or zoning of spatial units affects the analysis outcome, is known as the Modifiable Area Unit Problem (MAUP). This problem arises when discrete units show mixed populations, making it challenging to detect actual segregation patterns.

A notable challenge is addressed in the literature regarding the relationship between urban structure and residential segregation, a topic that has garnered growing scholarly attention in recent years (Vaughan et al., 2005; Legeby, 2013; Maffini and Maraschin, 2018; Knaap and Rey, 2024). A more comprehensive understanding of residential segregation necessitates analysing the spatial configuration of cities. This involves understanding the complex interrelationships between discrete urban elements and the city as a whole (Vaughan and Arbaci, 2011).

The presented analytical framework aims to contribute to this evolving field by addressing the issue at a broader spatial scale, with a specific focus on the built environment, particularly in terms of connectivity and accessibility. The objective is to develop a conceptual framework capable of examining multiple levels of spatial segregation, thus enabling a more nuanced understanding of how physical urban form shapes patterns of social division.

The contribution of this study to spatial planning practice lies in identifying the specific characteristics of segregated areas and the spatial factors that contribute to social exclusion. A data-driven approach offers the potential to apply these insights to other urban areas, providing an objective and quantitative perspective. This approach can support the formulation of more effective planning policies by identifying potential spatial factors that drive residential segregation.

Developing a Framework to Address the Spatial Dimensions of Residential Segregation

This study proposes a framework that emphasises connectivity and accessibility as spatial factors associated with residential segregation. By focusing on measurable spatial parameters commonly used in urban planning, it investigates how these elements correlate with the concentration of socioeconomically excluded populations. To bridge spatial analysis with practical planning, the research is scaled down to individual buildings and plots, which are the fundamental units used in neighbourhood and city-level masterplans.

The central research question is whether objective spatial patterns can be consistently identified in areas where segregated populations reside. A data-driven, quantitative approach ensures both replicability and applicability across different urban contexts. It aims to offer a methodological toolkit for assessing segregation at finer structural scales, supporting integration into urban design and planning practices.

The framework builds on extensive research into residential segregation in the Czech Republic, providing a robust foundation for broader comparative studies (Agentura pro sociální začleňování, 2024; Sýkora, 2010; Sýkora, 2023; Čada et al., 2015).

The study examines spatial features of segregation through the lens of accessibility to opportunities and the

permeability of the built environment. Segregation is analysed across three dimensions:

- Urban morphology, understood as the structural fabric that enables or constrains movement and access.
- Transportation and mobility.
- Access to public amenities.

Figure 1 illustrates each step of the proposed framework. In the next stage of the research, this framework will be applied to three Czech cities, selected as case studies based on their status as regional centres located in structurally deprived regions.

While recognising the importance of other factors, such as the quality of public space and patterns of social interaction, this research limits its focus to quantifiable spatial features at the building and plot levels in alignment with the tools and scales available to urban planners.

The following section will discuss each component of the framework, along with its theoretical and methodological foundations.

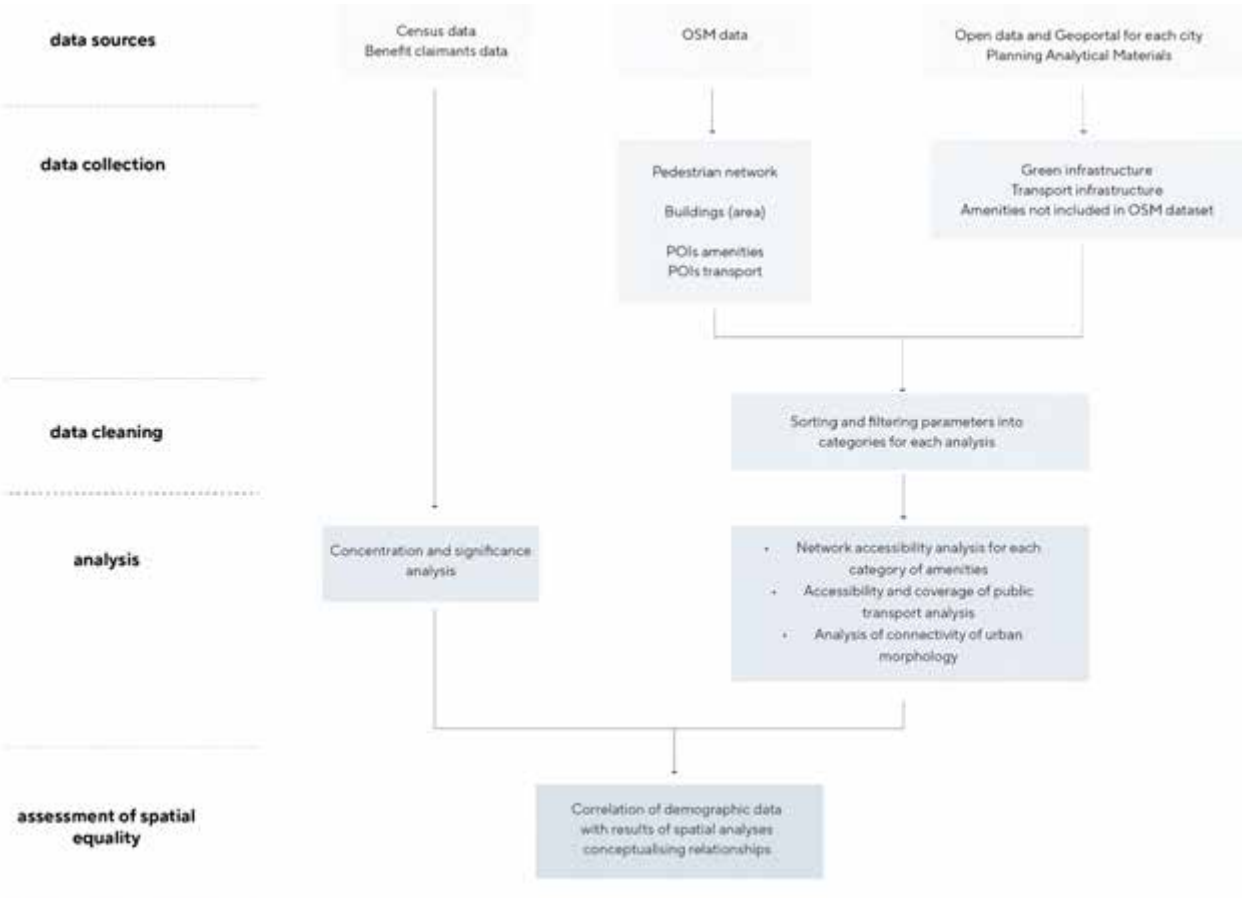

Figure 1: Proposed framework for assessing the spatial dimension of residential segregation.

Data

This study builds on existing analyses of residential segregation conducted within the Czech Republic. It draws on annually reported data based on the Methodology for the Identification of Localities of Residential Segrega-

tion[1](Sýkora, 2023). This data will be further refined to reflect specific residential structures by incorporating additional sources, including academic research and municipal reports on residential segregation in the surveyed cities.

The Methodology for the Identification and Evaluation of Segregation Sites identifies areas of segregation and assesses the suitability of social housing in preventing deeper exclusion. It assesses segregation at the level of primary settlement units (ZSJ) through three main steps: defining the target social group, identifying areas of concentration using statistical data, interviews, and discourse analysis, and evaluating findings with field verification to ensure that concentration reflects actual social exclusion (Sýkora, 2023).

The methodology utilises the abbreviation SPO PNZ, i.e. "co-assessed persons for the provision of a subsistence allowance". These are the populations at risk of poverty. The provision of the allowance is linked to the household and encompasses a wide range of individuals in varying social positions. Information on the location of public infrastructure will be sourced from open data platforms and mapping services provided by individual municipalities. Data on the street network and built environment will be obtained from OpenStreetMap (OSM), and these datasets will be further tailored and processed to meet the requirements of spatial analysis.

Urban Morphology and Spatial Configuration

Studies of urban morphology provide a framework for analysing the physical structure of cities. Configurational approaches focus on the spatial arrangement and interconnectivity of fundamental urban elements such as plots, buildings, and streets. These structural relationships shape how cities function, influencing movement patterns, social interactions, and access to resources (Hillier and Hanson, 1984; Hillier, 1996).

Research using configurational theory has explored the links between urban form and social deprivation, highlighting how spatial configurations may contribute to the concentration of disadvantaged populations (Vaughan et al., 2005; Legeby, 2013; Maffini and Maraschin, 2018; Knaap and Rey, 2024). Recent studies suggest that analysing and classifying distinct urban forms can help identify which spatial patterns are more susceptible to socioeconomic exclusion (Venerandi et al., 2024).

Evaluating Urban Morphology: Urban Morphometrics

Advancements in geographic data analysis and the growing availability of geospatial data have given rise to a data-driven branch of urban morphology known as 'urban morphometrics' (Araldi and Fusco, 2019; Fleischmann et al., 2021; Porta et al., 2022). This approach typically involves quantifying urban form across numerous metrics at the building level, using clustering techniques to define morphological regions or urban types, and profiling them for comparative analysis (Venerandi et al., 2024).

Drawing on digital mapping sources such as street networks, building footprints, and morphological tessellations, these methods enable the classification of homogeneous urban tissue types. This systematic approach supports comparative studies of urban form, facilitating a deeper exploration of how spatial patterns relate to broader issues, such as environmental quality, public health, and social inclusion. This study builds on established methods in urban morphology (Fleischmann et al., 2021), selecting a set of spatial characteristics to guide the analysis of urban form, as shown in Table 2. The chosen variables are aligned with the research objective of examining connectivity, accessibility, and permeability within the built environment.

This approach will generate a dataset that can be correlated with the distribution of socioeconomically excluded individuals to gain an understanding of the variables associated with segregation.

Table 2 Primary morphometric characters from the Methodological foundation of a numerical taxonomy of urban form, sorted by "element" (Fleischmann et al., 2021).

Element	Set of parameters	Data Source
building	Area of building Height of a building Volume of the building Perimeter of a building Courtyard area of a building Circular compactness of a building Corners of a building Squareness of a building Equivalent rectangular index of a building Elongation of a building Centroid - corner distance deviation of a building Centroid - corner mean distance of a building Solar orientation of a building Street alignment of a building Cell alignment of a building	OSM data
tessellation cell	Longest axis length of a tessellation cell Area of a tessellation cell Circular compactness of a tessellation cell Equivalent rectangular index of a tessellation cell Solar orientation of a tessellation cell Street alignment of a building Coverage area ratio of a tessellation cell Floor area ratio of a tessellation cell	OSM data
street segment	Length of a street segment Width of a street profile Height of a street profile Height to width ratio of a street profile Openness of a street profile Width deviation of a street profile Height deviation of a street profile Linearity of a street segment Area covered by a street segment Buildings per meter of a street segment	OSM data
street node	Area covered by a street node	OSM data

adjacent buildings	Shared walls ratio of adjacent buildings Number of courtyards of adjacent buildings Perimeter wall length of adjacent buildings	OSM data
neighbouring buildings	Alignment of neighbouring buildings Mean distance to neighbouring buildings Mean inter-building distance between neighbouring buildings Building adjacency of neighbouring buildings	OSM data
neighbouring cell	Weighted neighbours of a tessellation cell Area covered by neighbouring cells Mean distance to neighbouring buildings	OSM data
neighbouring segments	Reached cells by neighbouring segments Reached area by neighbouring segments	OSM data
neighbouring nodes	Degree of a street node Mean distance to neighbouring nodes from a street node Reached cells by neighbouring nodes Reached area by neighbouring nodes	OSM data
neighbouring tessellation cell	Gross floor area ratio of neighbouring tessellation cells	OSM data
block	Weighted reached blocks of neighbouring tessellation cells Area of a block Perimeter of a block Circular compactness of a block Equivalent rectangular index of a block Compactness-weighted axis of a block Solar orientation of a block Weighted neighbours of a block Weighted cells of a block	OSM data
street network	Local meshedness of a street network Mean segment length of a street network Cul-de-sac length of a street network Reached cells by street network segments Node density of a street network Reached cells by street network nodes Reached area by street network nodes Proportion of cul-de-sacs within a street network Proportion of 3-way intersections within a street network Proportion of 4-way intersections within a street network Weighted node density of a street network Local closeness centrality of a street network Square clustering of a street network	OSM data

Mobility and Connectivity

Residential segregation can also be understood as a consequence of limited interactions and co-presence in public space (Legeby, 2013). As argued by Rokem and Vaughan (2018), segregation is shaped and potentially reshaped by patterns of mobility. Connectivity, defined as the opportunity for encounters between different population groups, is, therefore, a key consideration in addressing issues of social and spatial justice. A potential tool for assessing the intensity of flows and potential interactions in public space, as highlighted in the research mentioned above is the Space Syntax method. Developed in the 1970s by Bill Hillier, Julienne Hanson, and colleagues at The Bartlett, University College London, the Space Syntax method established a foundational link between spatial configuration and social phenomena in urban environments (Hillier and Hanson, 1984; Hillier, 1996). Their research demonstrated that the layout of spaces influences pedestrian movement, the distribution of safety, and the vibrancy of public life. Today, Space Syntax represents a broad interdisciplinary field encompassing diverse analytical tools and methodologies for quantitative spatial analysis across multiple scales.

Mobility patterns expressed not only through walkability but also via the coverage of public transportation systems, play a crucial role in urban planning, as transport infrastructure has the potential to either bridge or deepen social divides (Rokem and Vaughan, 2018). By shifting focus from where people live to where they travel in their daily lives, a more nuanced understanding of urban social dynamics can be achieved (Kolkowski et al., 2023). Focused interventions, such as the introduction of new public transport lines, have been shown to significantly improve access to essential services (Lee and Miller, 2018).

Evaluating mobility

This framework addresses both structural and service-related aspects of urban accessibility. The street network is analysed using the Space Syntax method, and public transport coverage is assessed using data from local municipalities, including connection frequencies; both analyses are linked to individual buildings. This approach aims to capture the actual daily mobility opportunities available to residents in different parts of the city.

Table 2 Accessibility standards for public Infrastructure, selected categories translated by the author of this text (Maier et al., 2020).

Type of Public Infrastructure	Description / Reference Point for Accessibility: Starting / Destination	Accessibility Standard	Data Source
Public Transport Stop	Building entrance / Platform centre	500 m (300 m) 600–700 m	OSM data / Open City Data

Accessibility in the Urban Environment

Accessibility in urban environments is commonly defined as the degree to which residents can efficiently reach essential services and destinations (Hansen, 1959; Nicoletti, Sirenko and Verma, 2023). Despite its importance, travel remains constrained by existing infrastructure and various physical or invisible barriers. Ensuring equitable access to urban services, institutions, and economic opportunities is widely recognised as a key component of sustainable development and improved quality of life (Weiss et al., 2018).

However, access to public infrastructure often reflects underlying socioeconomic disparities. Research shows that socioeconomically disadvantaged populations are frequently underserved by public amenities, experiencing limited access to services such as healthcare, education, and community infrastructure (Nicoletti, 2022; Ashik, Mim and Neema, 2020; Lee, Jeong and Go, 2024; Weiss et al., 2018; Hosseini et al., 2022). While some communities benefit from a diverse range of accessible facilities, marginalised and spatially segregated populations face

persistent obstacles in reaching these services (Van Wee and Geurs, 2011). In response, urban planners have increasingly advocated for a more equitable distribution of resources (Hosseini, 2021).

Evaluating Spatial Accessibility

There is an ongoing debate about the best approaches for evaluating spatial accessibility. Many scholars argue that analyses should extend beyond simple walking distance to incorporate travel time, demand, and service capacity (Ashik, Mim and Neema, 2020). Building on these insights, this study focuses on assessing the accessibility of key urban amenities, as defined by methodology issued by the Czech government: Accessibility standards for public amenities[2] (Maier et al., 2020). Walking distance is calculated from individual buildings to the nearest type of public amenity based on the categories shown in Table 1. These measures will later be correlated with the spatial concentration of socially excluded residents to better understand inequalities in urban service provision.

Table 1 Accessibility standards for public amenities, selected categories translated by the author of this text (Maier et al., 2020).

Type of public amenities	Description / Reference Point for Accessibility: Starting / Destination	Accessibility Standard	Data Source
Education			
Kindergarten	Residential building / Kindergarten	600 m (400 m)	OSM data / Local Geoportal of Planning Analytical Materials
Primary School	Residential building / Primary School	600 m	OSM data / Local Geoportal of Planning Analytical Materials
Social services:			
Day Service Center and Day Care Center	Residential building / Social Care Facility	600 m	OSM data / Local Geoportal of Planning Analytical Materials
Facility for children and youth, weekly care centre, intervention centre	Residential building / Social Care Facility	Location in the municipality	OSM data / Local Geoportal of Planning Analytical Materials
Healthcare			
General practitioner, paediatrician, dentist, gynaecology and obstetrics, pharmacy	Residential building / Doctor's office, Pharmacy	600 m	OSM data / Local Geoportal of Planning Analytical Materials
Culture:			
Library	Residential building / Library	15 min walk or travel	OSM data / Local Geoportal of Planning Analytical Materials
Community Centre	Residential building / Community Centre	600 m (depending on the position in the municipality)	OSM data / Local Geoportal of Planning Analytical Materials
Multipurpose Hall	Residential building / Multipurpose Hall	Location in the municipality	OSM data / Local Geoportal of Planning Analytical Materials
Public Administration			

3 The title translated by the author of this text from: Standardy dostupnosti veřejné infrastruktury

Post Office / Postal Counter	Residential building / Post Office	Location in the municipality	OSM data / Local Geoportal of Planning Analytical Materials
Civil Protection			
Volunteer Fire Station	Residential building / Fire Station	1 000 m	OSM data / Local Geoportal of Planning Analytical Materials
Fire Station	Fire Station / Any location	According to the legal definition	OSM data / Local Geoportal of Planning Analytical Materials
Permanent Shelter for Residents	Residential concentration areas / Permanent Shelter	500 m	OSM data / Local Geoportal of Planning Analytical Materials
Playgrounds:			
Playground for Preschool Children	Residential building / Playground	200 m	OSM data / Local Geoportal of Planning Analytical Materials
Playground for Younger School Children	Residential building / Playground	500 m	OSM data / Local Geoportal of Planning Analytical Materials
Playground for Youth and Adults	Residential building / Playground	500 m (1 000 m)	OSM data / Local Geoportal of Planning Analytical Materials

Discussion and conclusion

This study presents a framework for identifying potential spatial factors contributing to residential segregation by linking them with data on the location of segregated residents, as identified in previous comprehensive studies on segregation in the Czech Republic (e.g. Sýkora, 2023; Čada et al., 2015). The analysis is conducted at a scale relevant to urban planning practice.

By refining the spatial scale to the level of individual buildings and plots, the study aims to bridge academic research with practical urban planning, providing concrete insights that can inform planning decisions.

The analytical framework integrates multiple methodologies to investigate three dimensions of spatial segregation. First, it examines urban form as a structural barrier and a defining feature of settlement patterns. Second, it considers mobility, focusing on the walkable street network and the extent of public transport coverage. Third, it assesses accessibility to public amenities and services as a measure of spatial equity. Each dimension will be analysed for every building in the selected cities, and the results will be correlated with data on the concentration of socially segregated populations. Findings within the proposed research framework could provide deeper insights into the underlying patterns of spatial segregation and enhance existing research on segregation, particularly in the context of spatial planning and urban design.

This research project does not address a broader temporal scope or investigate the dynamic processes underlying social exclusion. Incorporating a longitudinal perspective and analysing patterns at the scale of individual buildings could yield a more comprehensive understanding of the migration trajectories of socially excluded populations, particularly when situated within broader regional trends. Such an approach would benefit from a qualitative analysis of spatial planning documents and policies, tracing the arguments and. A historical examination of planning paradigms would provide essential context for understanding how approaches to segregation have evolved in response to shifting political, economic, and social conditions.

Abstract
The inclusion paradigm raises a paradoxical question: how inclusive is inclusion in contexts marked by deep socio-economic vulnerability? Digitalization — especially through the "smart city" model — claims to promote inclusion but often reinforces inequality by placing responsibility on individuals and ignoring structural barriers. Drawing on the '(E)Welfare in the City' project in Rozzano, south of Milan — part of Italy's PNRR-funded M.U.S.A. program — this paper rethinks digital inclusion through ecological thinking. By combining insights from urban planning, sociology, and design, the project co-designs inclusive digital solutions with both youth and older residents, at the same time leveraging Rozzano's strong local networks that everyday address pressing challenges such as poverty, school dropout, and demographic complexity. The goal is to create place-based, equitable digital futures that respond to the lived realities of marginalized communities.

Keywords: digital divide; welfare; co-design

1. Introduction

In an increasingly digitized society, inclusion must be recognized not as a secondary objective, but as the very foundation of democratic digital transformation. The modernization of public services — particularly welfare — has often focused on efficiency and cost-effectiveness, overlooking how such transformations may deepen exclusion for those already on the margins. The term inclusion, frequently used in policy discourse, is too often limited to notions of access — providing broadband or devices — without questioning whether individuals and communities are genuinely empowered to participate in the digital public sphere.

This paper argues for a radical rethinking of digital inclusion: not as a technical issue to be solved through infrastructure investment alone, but as a social, spatial, and relational process grounded in local realities. Inclusion is about people — about dignity, agency, participation, and the right to shape the systems that shape their lives.

This text reflects on physical and digital spaces for social inclusion in the metropolitan area of Milan through the on-going E-Welfare in the City project. It is led by Politecnico di Milano, funded under the M.U.S.A. program within the framework of the National Recovery and Resilience Plan (PNRR), and offers a concrete application of this inclusive, ecological design approach in Rozzano, Italy.

A municipality on the outskirts of Milan, Rozzano is often labelled as a "marginal" territory: it has a large concentration of public housing, high unemployment, and low educational levels among the population. Yet it also possesses dense social networks and active civil society organizations. These characteristics — significant socio-economic fragility but also a rich network of local actors combating social exclusion — make it both a challenging and fertile ground for inclusion-based innovation. In this setting, digitalization is approached not as a purely technical endeavor but as a catalyst for rethinking and reconfiguring social, territorial and spatial relations.

Presently, the project is in the process of co-designing a hybrid welfare access point that would be responsive to the local community's needs through co-design and community participation. As the work is still on-going, this paper will reflect on the progress thus far, specifically how those of us involved in the E-Welfare in the City project have begun to understand the relationship between 'inclusion' and 'digitalization' and focusing on the supply of some welfare services and youth capacity building. The discussion draws on the project's process of research & action, unpacked through interviews and joint work with local actors, and on reflections on the project's participatory design workshops.

The paper is organized into two main sections. The first section focuses on how the concept of inclusion has been taken up in the digital turn. While much existing discourse centers around simply providing access or developing digital skills, this section shifts the focus towards the conditions by which 'smart citizenship' can emerge. Grounding this discussion in the case of Rozzano — specifically pulling from the PNRR-supported investment aimed at expanding Italy's digital facilitation network — it offers concrete examples of how the 'digital divide' is neither a monolithic category nor a challenge that can be overcome through a universal, 'one-size-fits-all' program. As the PNRR investment is exposing persisting social and digital vulnerabilities in Rozzano, there is the need to build from the outcomes of this 'digital inclusion' program, crafting a space and digital services that are actually responsive to the diverse needs of the communities it intends to serve.

Building from this, the second half of this paper aims to expand the concept of 'digital inclusion', framing it as a systematic, relational, and contextual practice. Drawing from the Rozzano case, this section introduces the E-welfare in the City's ongoing pilot program Spazio Verso and details how it is proposing a 'new kind of space' within this frame — one that is co-created with local actors to address the communities' varied social and digital vulnerabilities in Rozzano.

Ultimately, this paper argues that 'digital inclusion' is not an individual achievement but a collective one, and as such, it considers the ways 'exclusive inclusiveness' — a means to account for the diversity of experiences within these systems — may actually be a promising way forward.

2. Inclusion as a Cornerstone of Digital Transformation

2.1. Digitization and Urban Transformation

The digitization of urban spaces, propelled by technologies like artificial intelligence (AI), automation, and informatization, is profoundly transforming society and public spaces. This transformation began in the mid-2000s, in parallel to the advent of the "smart city", which was initially a North American industrial proposal reflecting the urban and the third industrial revolutions driven by digital technology.

Framed as a new economic space for the deployment of connected sensors and devices — aimed at optimizing urban management, governance, and, ultimately, commercial exploitation by a select few actors — the smart city has increasingly promoted a discourse of individual responsibility regarding the level of "smartness" (Kitchin, 2021; Vanolo, 2014) that each person is expected to demonstrate. This trend echoes the broader shift associated with the rise and consolidation of neoliberal political ideologies since the 1980s, characterized by a growing emphasis on personal accountability and a parallel disregard for structural and systemic determinants of social conditions. Within this logic, precarious employment is seen as the result of individual shortcomings — such as inadequate education, a poor CV, or insufficient effort in pursuing better opportunities — rather than as the out-

come of labor market deregulation and the broader deterioration of working conditions, ultimately leading to escalate social and economic exclusion. By obscuring the processes of legitimation and implementation — how deep and pervasive they are, how they are integrated into local contexts (Angelidou, 2017; Kitchin, 2014), and what choices are made regarding the promotion or neglect of social objectives such as justice (Datta & Odendaal, 2019; Papa & Ferreira, 2018; Papa & Lauwers, 2015) — the smart city reveals weak and underdeveloped visions of long-term sustainability and social inclusion.

Rather than being truly "smart," smart cities risk becoming dystopian: polarized, unlivable — in the literal sense of uncivil — not built for those who inhabit them, inhumane.

Unexpectedly, the COVID-19 pandemic was a stress test for these models (Languillon-Aussel, 2021), exposing the weaknesses of the smart city model. As the pandemic forced the widespread adoption of simplistic, analogue solutions (e.g., social distancing markers), it exposed the rigid, non-adaptive nature of many digital systems, which were confined to their original programming and couldn't evolve quickly in response to new challenges (ibidem). Contactless services, QR codes, and remote access systems were designed for users who had the right device, the necessary skills, and stable connectivity. Those without these prerequisites found themselves further excluded — not just from services, but from participation in public life. What happened, on the other hand, was that digital technology became essential for maintaining continuity during the pandemic — particularly for teleworking and social events — absorbing much of the functionality that had previously depended on physical spaces. It also facilitated a neoliberal stance that rejected public and collective spaces in favor of private ones, prompting a reconsideration of space itself. In this way, the decade that began with global social movements like Occupy Wall Street, the Arab Spring, and Spain's Indignados — movements that transformed public spaces into sites of protest — ended with a shrinking of (public) spaces (ibidem) and the evident deficiencies of the smart city model, highlighting the urgent need to rethink and reconfigure the relationship between physical urban spaces, city services, and the digital realm.

As we are increasingly called to reconceptualize space not merely as a physical, Euclidean construct, but as a dynamic sphere of transversal, intergenerational exchange — where services and access to citizenship rights unfold across both material and digital infrastructures — it becomes essential to critically examine the ways in which digital technologies are reshaping the access to and uses of physical space and transforming both individual and collective behaviors. For urban environments to maintain their relevance in the digital age, they must continue to serve as sites of civic engagement, anchored in territorially and socially shared forms of belonging.

In this context, the question is not simply how to build smart cities, but under what conditions smart citizenship can emerge — understood as the cultivation of a digitally literate, civically engaged, and socially responsible publics. This shift in focus necessitates a more nuanced exploration of the socio-spatial consequences of digital transformation, particularly within vulnerable communities, where such technologies often risk deepening, rather than bridging, existing digital and social divides.

Inclusion, therefore, cannot be reduced to technological provision alone; it must be understood as a design principle grounded in participation and attentiveness to those most at risk of marginalization. This, in turn, demands a profound cultural and political reorientation — from a top-down, efficiency-driven logic toward one rooted in care, equity, and responsiveness to diverse lived realities.

Reliable internet access is increasingly recognized as a critical component of digital inclusion, not only in terms of affordability but also availability. In many public housing contexts, for example, residents often contend with substandard or inconsistent connectivity. However, digital inequality extends well beyond mere access to the internet. It also encompasses the quality of that access, including the reliability of service and the accountability of providers, particularly in low-income neighborhoods and among individuals who rely primarily on smartphones as their point of connection.

Digital inclusion is shaped by a constellation of interrelated factors such as income level, educational attainment, and residential geography. These disparities in turn contribute to unequal access to essential opportunities, including education, employment, and civic participation. Indeed, the notion of the "digital divide" is not monolithic.

At least four distinct levels of digital inequality and exclusion (van Dijk, 2005) can be identified:

- First-level digital divide – Access Divide, which concerns the availability of digital infrastructure, including devices, software, connectivity, and power supply.

- Second-level digital divide – Usage Divide, which focuses on the differences in the ways and frequencies with which people use technologies, as well as the activities carried out online (such as information gathering, communication, education, etc.). People with more limited or superficial use of technologies are less able to fully take advantage of the benefits of the digital society.

- Third-level digital divide – Skills Divide, which refers to the ability to effectively use digital tools and platforms, encompassing not only technical competencies but also critical awareness, such as understanding personal data privacy.

- Fourth-level digital divide – Structural inequalities, that arise from broader socio-demographic factors such as gender, age, socio-economic status, and citizenship, reflecting how digital exclusion intersects with and amplifies pre-existing social inequalities.

Digital literacy, in fact, can either be a key factor in enabling upward mobility or an element deepening the digital divide, particularly among vulnerable groups.

Importantly, as digitalization advances, inequalities do not simply worsen linearly. Instead, they intersect with other factors such as generational gaps, the economic affordability of hardware, software, and information, as well as social and cultural capital. Moreover, digital divides manifest not only at the individual level but also across multiple layers: between individuals occupying different societal roles (e.g., citizens, welfare recipients, caregivers, workers, active volunteers, and more); across institutions, reflecting disparities in resources available at specific service locations (e.g., schools in education, hospitals and clinics in healthcare, social service centers); within networks of institutions, such as the coordinated social service offices within a municipality; and across geographic contexts, acknowledging that not all municipalities or regions are equally equipped.

This means that, within the ongoing process of digitalization, digital divides play a crucial role in enabling individuals to exercise their rights and responsibilities as citizens. Framing this within Amartya Sen's capabilities approach, it becomes clear that neither access nor skills alone are sufficient for digital inclusion. What truly matters is whether individuals are genuinely empowered to convert digital resources into meaningful outcomes — outcomes that enhance their well-being, development, and access to urban rights, while also expanding their agency within their families, communities, and the territories they inhabit.

2.2. Harnessing the National Recovery and Resilience Plan (PNRR) as a Catalyst for Digital Inclusion in Vulnerable Communities

The COVID-19 pandemic not only accelerated the adoption of digital technologies and services, but also starkly exposed the barriers that many face in accessing and benefiting from digital services. Given that these barriers were not new but rather intensified by the pandemic, the EU Commission designed the Recovery and Resilience Facility (RRF) to not simply act as a temporary recovery instrument but also as a systematic response, supporting investments and reforms to make EU Member State economies more sustainable and enabling them to address local challenges. The RRF stands out from other EU programs given its sheer size — i.e., €750 billion through the NextGenerationEU funds, the largest budgetary instrument in EU history — but also its funding model. The RRF is financed through international capital markets (instead of the EU budget), implemented via a multi-level man-

agement model, and distributed through results-based payments (tied to achieving certain targets rather than expenditure costs). While thematic requirements are minimal, the RRF outlines six key policy areas of relevance to the EU, two of which have been highlighted together as complementary priorities to address digital divides: digital transformation and social and territorial cohesion.

Given a recognition of the significant delay in the Italian context regarding digitalization, Italy's National Recovery and Resilience Plan (PNRR) — the plan drafted by Italy to access the funds of the RRF — allotted, in 2021, 27% of its fund[1] to digital initiatives, surpassing the required 20%, and demonstrated a particular interest in the development of digital skills (i.e., Investment 1.7. Basic Digital Skills), to help mitigate the social impacts of the pandemic. This investment aims to reduce the digital exclusion in Italy by improving digital skills among at-risk populations through creating a network of young volunteers to provide digital education and support and by expanding the network of digital facilitation centers to develop the digital skills of at-risk populations through both in-person and online training.

In the program to expand Italy's digital facilitation network, digital inclusion is not only the driving force but the main aim, as is evident in the programs' three main targets: (T1) increasing the digital skills and digital inclusion of 2 million citizens, (T2) offering 3 million digital training services, and (T3) increasing the number of facilitation centers from 600 to 3.000 throughout the country. While this is a temporary instrument, the digital facilitation network is intended to be a structural action, and as such, the implementing entities (i.e., the Region or a third party) were pushed to consider how the facilitation centers can continue operating after the end of the investment.

Given the multi-level management of the digital facilitation network, this effort towards digital and social inclusion has been able to play out differently across regional and local levels. As this program has been entrusted to the regions, its implementation regionally varies in aspects, such as, but not limited to, the method in which services are distributed and the requirements for digital facilitation centers and their facilitators. In Lombardy, the Region claims to have promoted a 'learning by doing' strategy in an effort for more practical and reflective skill acquisition and to create a stronger connection between citizen preferences/needs and the digital facilitation offerings. The service model adopted is based on a one-shot, voucher-based provision system[2]to deliver pre-packaged facilitation services (referred to as 'service baskets'). Lombardy Region has implemented this strategy through its territorial branches, such as the Metropolitan Agency for Training, Guidance and Employment (AFOL) — particularly active in the Milan metropolitan area — and the vocational training centers (CFPs), building from its pre-existing networks and programs.

As one of ten professional training centers in the network of Metropolitan AFOL, Rozzano's vocational training center (CFP) became an active facilitation center in the region in fall 2024. Primarily, it is a vocational training center in Rozzano that provides three-year courses in sectors such as beauty, electronics, and IT. Rozzano's CFP plays a critical role in combating school dropout rates and social exclusion by offering professionalized and personalized education and enrichment activities. While not all 10 CPFs in AFOL's network have joined the initiative, Rozzano's CFP's manager responded positively to the call.

Consulting the Region's guide for facilitators and interviewing two on-site facilitators in Rozzano's CFP, our research team has attempted to understand how this PNRR sub-investment is being managed across levels, the types of services that are offered, and if these services are responsive to the local needs in the context of Rozzano.

1 Italy is the largest beneficiary under the RRF, approved for a €194.4 billion recovery plan (€71,780 billion in grants; €122,602 billion in loans).

2 The so-called "dote" (endowment) system has become the main way to deliver social and employment services in the Lombardy Region in the last quarter of century, based on a political approach strongly inclined towards quasi-markets (Sabatinelli and Villa, 2015).

As depicted in Figure 1, Rozzano's CFP, like all other digital facilitation centers, is responsible for a four-step process to provide and register training services: (1) intake, (2) provision of services, (3) registration of services, and (4) validation of services. As many in the community still perceive the CFP only as a school, to raise awareness of the CFP's additional digital training services, they have focused on the 'old-but-gold' method of a flyer — in particular, because they did not perceive digital campaigns to be as effective to reach citizens in need of digital skills training — and meeting at-risk populations where they are — e.g., organizing with the president of the senior citizens' center.

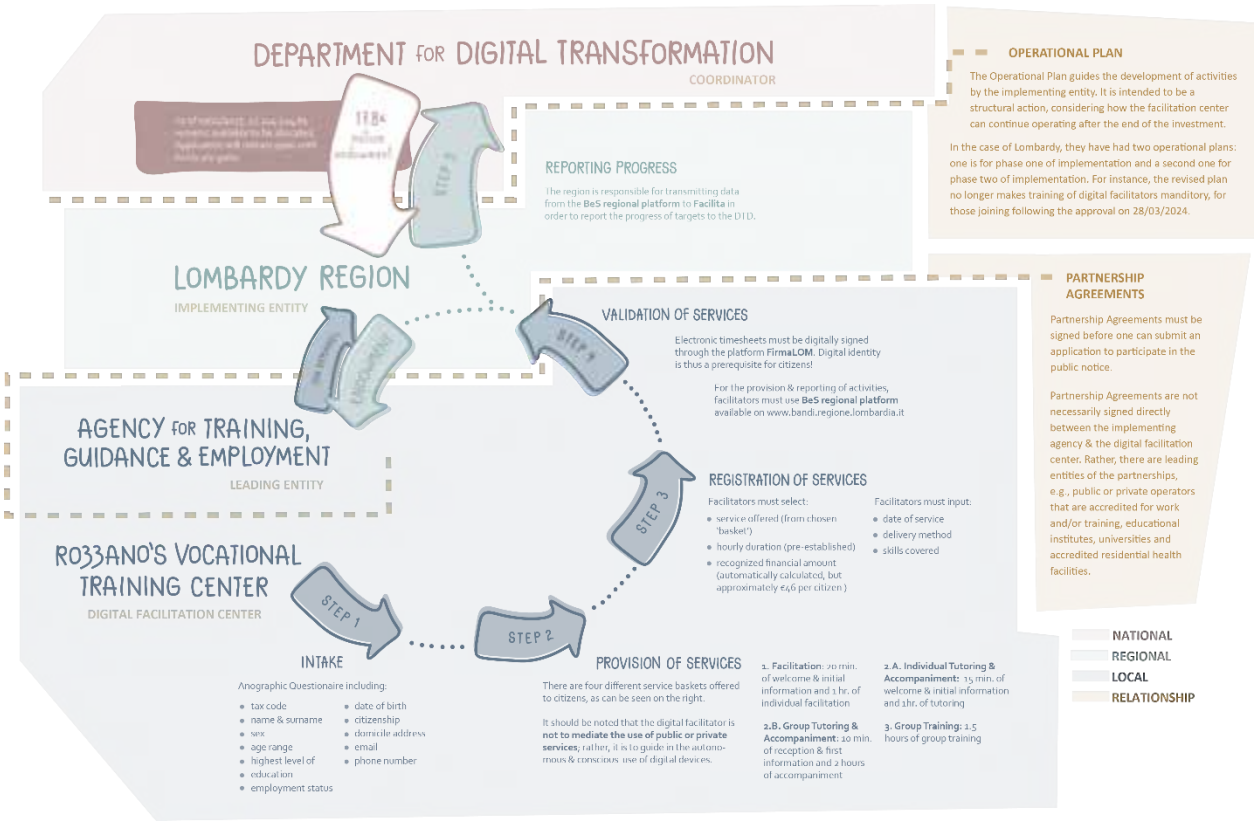

Figure 1. The registered digital facilitation process in Rozzano's CFP

Elaboration by Aubrey Toldi

According to the on-site facilitators, all citizens who have received a training service to date have reserved their voucher online, not via a 'walk-in'. This creates a paradox in which, to access the digital facilitation pathway, one must already possess basic digital competence. As elaborated on by one of the two on-site facilitators, P.T.: "Basically, to be recognized as someone in need of digital support, you already need to have some digital skills — which is kind of ironic. Meanwhile, we're thinking of people who are truly struggling with technology, who still use their smartphones mostly just for phone calls, if anything at all"[3]. Without minimal digital skills, the service is challenging (if not seemingly impossible) to access.

If citizens are able to register, they can choose one of the four offered service baskets. Within all four options, it should be noted that the facilitation services are not intended to mediate citizen's use of public or private welfare services, rather, the focus of this initiative is to guide the autonomous and conscious use of digital devices. Yet, mediation is the very assistance that many in Rozzano need. The principle on-site facilitator A.E. states: "Here's

3 Original quotation in Italian: "Cioè, in pratica, per essere riconosciuto da facilitare devi già avere delle competenze, in buona sostanza! Mentre noi ci immaginiamo le persone che hanno proprio difficoltà, che usano il telefono ancora come telefono o poco più."

a fairly significant issue right from the start, in my opinion: the people who receive—or are still receiving—digital support in the Lombardy region are required to already have a SPID[4] or an electronic ID card. And that's a first barrier that definitely acts as a filter, because while we can support them with a range of digital issues, we can't issue a SPID or an electronic ID card ourselves"[5]. The need for mediatory services in the community is echoed by the facilitator P.T.: "Unexpected needs emerged from the people who attended, such as small, practical issues related to using smartphones. Therefore, we dedicated the last session to an online grocery shopping app. But even that was somewhat limited by the fact that the topic had already been set: it was going to be about smartphone use. Sometimes we get our students' parents who come in because they need to send an email and don't know how. For example, they might need to request a document from their child's middle school, and they just hand us the phone saying, 'Can you write it for me?'"[6].

Without registration, the facilitators can still deliver training services, but these services cannot be registered within the monitoring system. A.E. notes that in practice this is a common occurrence, providing an example of one such instance: "We just completed a digital facilitation course with about twenty elderly participants, but we were only able to officially include four or five of them in the digital support program. The others couldn't be enrolled because they didn't have a SPID, or they couldn't remember the password for their electronic ID card, or they had the PIN and PUK but hadn't completed the full activation process for the card. So, unfortunately, we couldn't include them in the official project"[7]. Since the endowment is distributed by individual service registered, the leading entity (in this case, AFOL) will not receive compensation for these services provided. It should be noted, though, that even when compensation is received, the facilitators are not remunerated for their services, but rather, it has been given as an additional workload.

The service must be validated by the citizens who receive the training (i.e., digitally signing the electronic timesheet) through yet another platform — FirmaLom. A.E. details the challenges of this application: "We helped them download the app, which didn't work very well at first... It was the app for digital signatures. But again, there was the prerequisite of having either a SPID or an electronic ID card"[8]. While the operational plan details that exceptions can be made for certain populations lacking a digital ID, e.g., persons with disabilities or non-Italian citizens who cannot have a SPID, CIE or eIDAS identity, it appears that this alternative validation system may not have been well-communicated to those on-the-ground or perhaps is not applicable in the cases they mentioned.

While this program certainly opens up a space of (some) possibilities, the regional approach, in many ways, failed

4 The SPID (Public Digital Identity System) is Italy's official system for digital identity. It serves as a verified online identity, enabling both citizens and businesses to securely access a wide range of online services offered by public authorities and authorized private entities. These services include tax filings, health records, educational platforms, and more, all accessible through a single username and password. Without SPID, accessing these services would not be possible.

5 Original quotation in Italian: "Con una problematica secondo me abbastanza significativa alla partenza: che le persone che venivano, che vengono tuttora facilitate, per quanto riguarda la regione Lombardia, devono essere già in possesso di SPID o carta d'identità elettronica. E questa è una prima soglia che sicuramente fa da filtro, perché noi possiamo facilitarli su tutta una serie di problematiche digitali, ma non possiamo rilasciare lo SPID, così come non possiamo rilasciare la carta d'identità elettronica".

6 Original quotation in Italian: "Poi sì, ne sono venute fuori altre dalle persone che c'erano, altre piccole necessità legate all'utilizzo dello smartphone dalle persone che c'erano, quindi abbiamo fatto l'ultimo incontro su un'applicazione di spesa online… però anche qui un po' vincolato dal fatto che il tema si sapeva che fosse quello, che fosse l'utilizzo dello smartphone. A volte ci capita che ci arrivino dei genitori che devono mandare un'email e non sono in grado perché devono fare richiesta alla scuola media di qualche documento che hanno le medie e ti danno il telefono in mano dicendo 'me la scriva lei'".

7 Original quotation in Italian: "Tant'è che abbiamo appena fatto un percorso di facilitazione con una ventina di anziani di cui siamo riusciti a far rientrare nel progetto della facilitazione digitale solo 4-5 persone, perché non avevano lo SPID, perché non si ricordavano le password della carta d'identità elettronica, perché avevano il PIN e il PUK ma non avevano fatto tutto il processo di attivazione della carta d'identità, per cui non è stato possibile inserirli nel bando".

8 Original quotation in Italian: "Noi li abbiamo aiutati a scaricare l'app, che all'inizio non funzionava benissimo… Li abbiamo aiutati a scaricare l'app per poter firmare digitalmente, però c'era il prerequisito dello SPID o della carta di identità elettronica".

to provide the necessary conditions to meet the specific needs of the citizens of Rozzano. Additionally, despite being envisioned as a systematic response, this program does not structurally (or even economically) support the local actors in contact with the potential beneficiaries of the service; instead, facilitators often simply face an additional workload. And even more, in the PNRR frame it is not possible to account for all the training activities that were actually offered! As this program's funds come to an end later this year, this is a crucial time to reflect on more than simply "what" the technological outcomes of this project are and, instead, open the discussion towards "how" we can build from these outcomes to concretely counteract the social and digital vulnerabilities that came to the surface during its implementation. There is an opportunity to build from the invested resources, current momentum, and lessons learned to more intentionally ground the aim of 'digital inclusion' in the Rozzano context and allow for the construction of more coherent, continuous training paths for its residents.

3. Beyond Access: Redefining Inclusion as a Systemic, Relational, and Contextual Practice

The concept of inclusion must be redefined in relational and situated terms. Relational inclusion emphasizes that access is not only about infrastructure, but about the presence of supportive human relationships: mentors, teachers, educators, facilitators, neighbours, social and community workers. Situated inclusion recognizes that people's ability to engage with digital services is shaped by place: the neighbourhoods they live in, the institutions they encounter, the histories they carry. This approach challenges the prevailing assumption that digital transformation is a neutral, universally applicable process. Instead, it advocates for place-based inclusion, where local context becomes a resource rather than a barrier; participatory design, wherein services are co-created with communities rather than imposed upon them; and hybrid infrastructures, where both physical and digital spaces mutually support one another to foster belonging and agency.

True inclusion begins when users become co-authors of the systems they interact with.

To understand and implement this expansive vision of inclusion, especially applied to digitalization, an ecological framework (Caciagli et al., forthcoming) offers a particularly valuable perspective. This framework situates individuals within broader interconnected systems — social, environmental, institutional, and technological — emphasizing that inclusion must be understood not as an individual achievement but as a collective one (Capone, 2018). People are not isolated actors; their engagement with technology and their capacity to build interdependencies are shaped by diverse starting points, resources, and forms of engagement (Escobar, 2018). An ecological approach, therefore, recognizes the diversity of experiences within these systems.

In this context, digital inclusion is not a final goal but rather a means to a deeper form of participation — what we might refer to as inclusive, smart citizenship. This form of citizenship ensures that everyone, regardless of background or ability, can participate meaningfully in the social, political, and economic spheres of life.

3.1. The Rozzano Case Study: Building an Inclusive Ecosystem of Local Associations and Groups through Digital Services

The E-Welfare in the City project aims to explore how welfare access spaces could be designed in the context of digitalization to promote inclusion and active citizenship. In deciding where to ground the study and the pilot project, Rozzano was selected for several reasons.

Situated 9 km south of Milano and connected to the city center by tram line 15, Rozzano represents a space of profound contradictions. As an area in Milan's periphery, it shares proximity to the city's urban center, but its distinctive social, economic, and infrastructural characteristics set it apart. Rozzano's infrastructure reflects its history as an agricultural area first and later an industrial hub. Over time, the town's economy has transitioned from manufacturing to services, though this shift has been uneven. Socially, Rozzano reflects broader regional trends. The population is aging, with 22% of residents being over the age of 65, which aligns with metropolitan averages.

However, other indicators set the town apart in a more significant way. Rozzano is notably distinguished by its high concentration of public housing and socio-economic vulnerabilities. In the 1960s, Rozzano was chosen to

host a large public housing estate to serve a residential function that supported the attractiveness of industrialized Milan in comparison to less industrialized regions. As a result, approximately 30% of families now live in public housing, far surpassing Milan's 9% and making Rozzano unique within the Italian context (see Figure 2).

Figure 2. Map of the percentage of families residing in public housing (ERP)
Our Analysis and Visual Representation Based on the 2023 Istat Population Census Data. March 14, 2024
Elaboration by Carlotta Caciagli, Andrea Parma, and Paola Piscitelli

Additionally, the town ranks among the lowest in the Lombardy region in income, with an average annual income of €22,000, whereas the average annual income per household in Italy is approximately €30,000 - €32,000, according to the latest available data (2022-2023) from the Italian National Institute of Statistics (ISTAT) (see Figure 3). The town also has a disproportionately low percentage of university graduates, further reflecting its socio-economic challenges.

Unemployment is another pressing issue, with Rozzano having the highest unemployment rate in the southwest metropolitan area at 9.2%, compared to the regional average for Lombardy, including Milan and its metropolitan area, which typically ranges from 6-7% in recent years (ISTAT, 2022). Finally, Rozzano stands out for its younger demographic, with 19% of its population under the age of 19, a figure that exceeds the provincial average of around 15-16% (ISTAT, 2024).

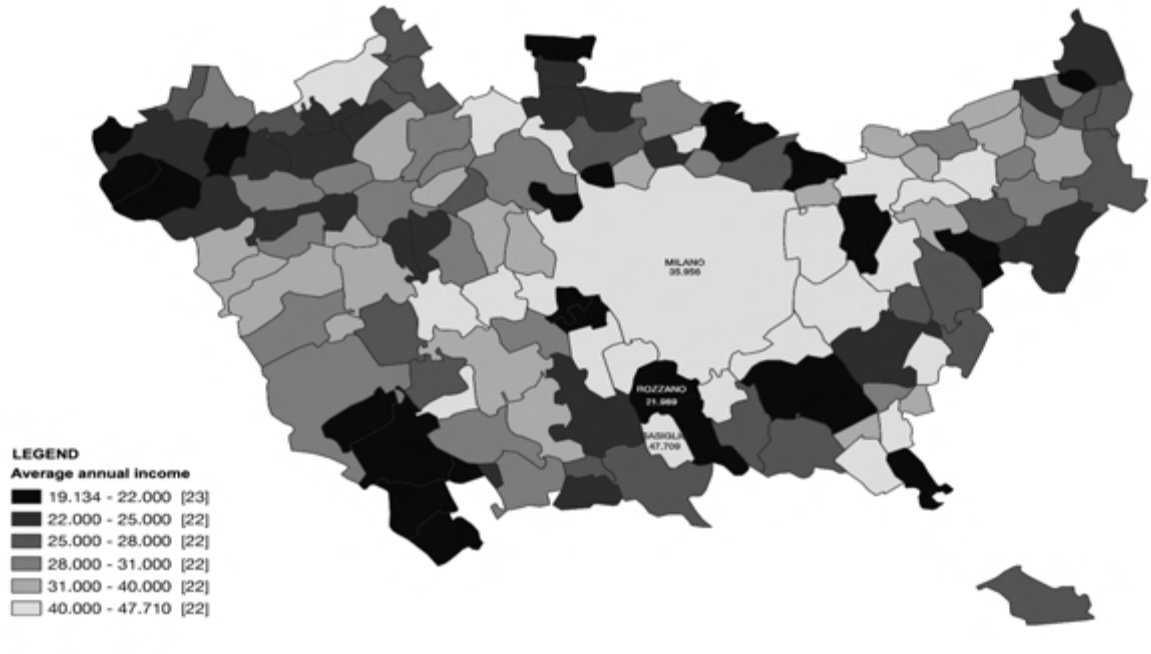

Figure 3. Map of the average income
Our Analysis and Visual Representation Based on the 2021 Istat Population Census Data. March 14, 2024
Elaboration by Carlotta Caciagli, Andrea Parma, and Paola Piscitelli

Indeed, Rozzano is often associated with issues of crime and social exclusion, common features in discussions of marginalized suburban areas. Recently, Rozzano has been included in a significant top-down national funding initiative called Decreto Caivano; it is the only municipality in the North of Italy included in the initiative which targets a few peripheral municipalities or neighborhoods that are considered — somewhat opaquely — to be highly problematic.

Yet, it holds potential as a site for innovation — particularly in the field of digital inclusion and welfare access — given the concentration of third sector organizations (see Figure 4). Rozzano's same socio-economic challenges, including a high proportion of youth who are neither in education nor employment (NEETs), make the town a critical area for social inclusion initiatives, particularly those focused on digital access to services. These initiatives aim to address vulnerabilities by fostering a more inclusive, digitally connected community.

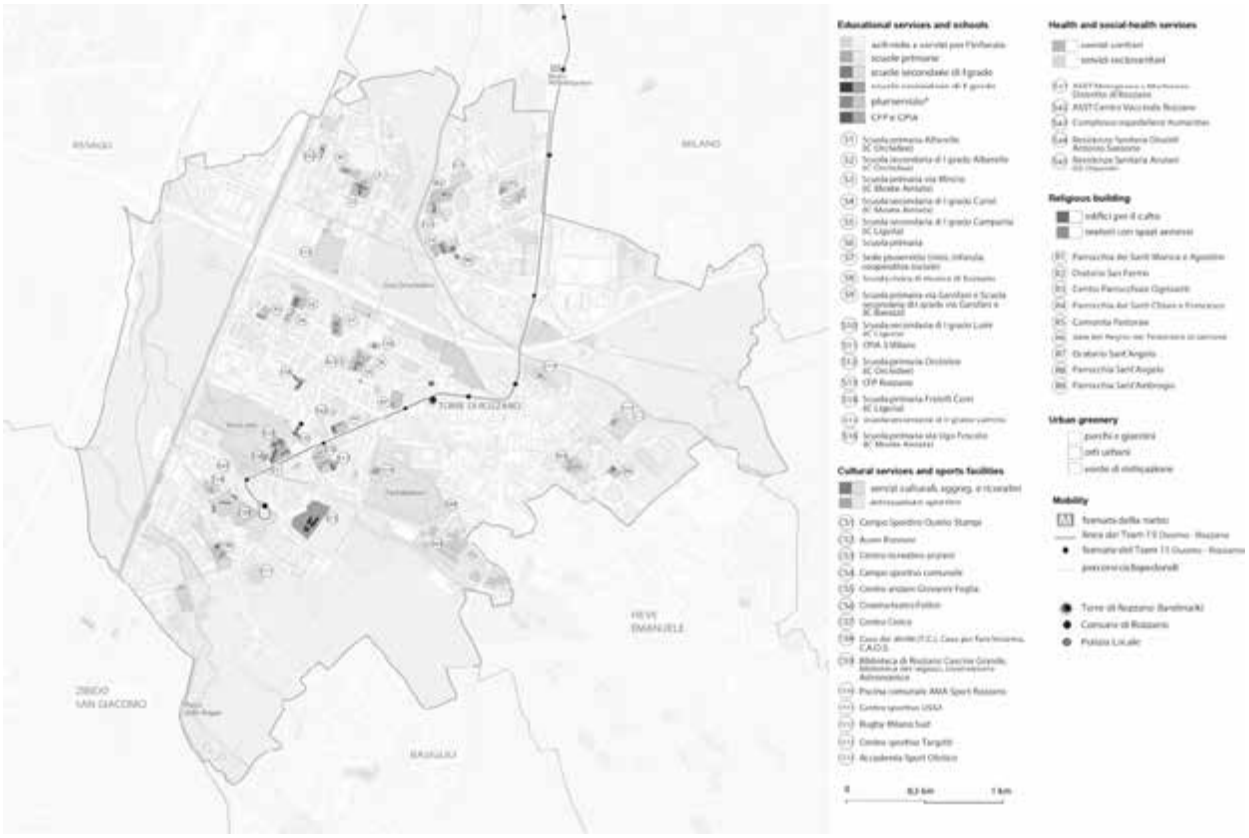

Figure 5. Maps of the context. System of service
Elaboration by Carla Baldissera, Federica Rotondo, and Paola Piscitelli

One of the most notable efforts in this regard is the Tavolo Connessioni, a network of local actors that focuses on preventing youth distress through collaboration and joint case management since 2016[9]. The Tavolo Connessioni network seeks to address the challenges faced by young people in Rozzano by developing continuous management models that integrate local authorities, schools, and social services. Regular meetings are held at the CFP, which plays a critical role in combating school dropout rates and social exclusion by offering personalized education and enrichment activities. Its integration into the Tavolo Connessioni network makes it a pivotal space for local youth.

For these reasons, the E-welfare in the City project began working closely with Rozzano's CFP, where a co-design process was initiated. The co-design approach aims at ensuring that the space and the service that will be created reflect the needs and aspirations of the local community, particularly in terms of their role in supporting vulnerable groups and promoting active digital citizenship. Selected as the approach by our diverse E-Welfare project team — which the project itself is a component of the PNRR — the co-design process brings together

9 The network was established through the Texère – Weaving Connections Together project, funded by Fondazione Cariplo and operating within the Visconteo District, a socio-economic and territorial area that encompasses eleven municipalities, including Rozzano. This district is an organizational and functional division of the broader territorial area (ASST), tasked with ensuring essential services such as foster care, child reception and inclusion, along with initiatives to address poverty. Since March 2019, the Visconteo Sud Milano District has been empowered to define and manage services and interventions specifically designed to combat poverty.

urban planners, sociologists, and designers from the Departments of Architecture and Urban Studies, as well as Design, at the Politecnico di Milano. For, this process is both multidisciplinary, reflecting the diverse composition of the team as well as the local institutions and community members reached out, and embedded, underscoring the importance of grounding design processes in the local context while leveraging existing resources and networks (Figure 5).

The goal of the co-design process is to ultimately realize a pilot project, Spazio Verso, envisioned as a hybrid environment dedicated to supporting access to digitized welfare services. Through the hybridization of physical and digital spaces — places where physical and digital services coexist to reduce the disintermediation brought about by the digitization process and to foster inclusion and participation — the project aims to enhance the community's resilience and foster a sense of belonging and empowerment.

3.2. The co-design of the *Spazio Verso* pilot project. A New Kind of Space Co-Created with Local Actors to Address Social and Digital Vulnerabilities

To effectively prepare for the co-design phase, a comprehensive preliminary analysis was conducted to map the territorial system, specifically visiting 6 key locations identified as important reference points for both young people and the elderly in the neighborhood. These locations included:

- the 'APS Pertini', a senior recreation center;
- the 'Cascina Grande' Library, the local library and a key cultural reference point in both the town and the surrounding area;
- the 'Casa dei Diritti', the headquarters of several local associations working on social cohesion;
- the 'Don Gnocchi-Vismara centre', a semi-residential facility hosting minors at risk of school dropout;
- the 'Laboratorio Giovani', a youth center in Rozzano, supported by Comunità Nuova[10] and operating in the area for 15 years; and
- the above-mentioned Rozzano's CFP (Centro di Formazione Professionale).

Linked to these spaces, we conducted 3 interviews with institutional actors from child and social services and facilitation programs, 3 interviews with local key actors, and 9 interviews with educators and coordinators of third sector bodies, mostly connected with the Tavolo Connessioni.

This preliminary phase highlighted the need to design a relational space that promotes digital citizenship — not just by providing access to digital tools and training, but through a broader, more inclusive approach that actively addresses the exclusionary dynamics amplified by digitalization. This requires a careful integration of service content, the role of digital tools, and the physical environment where these services are delivered.

The core idea solidified: to create a space where the approach to digital facilitation is both intergenerational and transgenerational, with young people involved as active agents, not just passive users, and where they can teach other residents, and in doing so, learn themselves. This was informed by the feedback of educators and social workers, who have stressed in different interviews the necessity of a more personalized and inclusive environment that addresses the specific needs of young people in the community.

Local stakeholders working with youth, in fact, have reported a significant shift in recent years. While an "open access" model once attracted large numbers of young people, post-COVID, it has become clear that more targeted and focused activities are now more effective. A peer-driven model has been identified as crucial in facilitating this change. As one educator from Laboratorio Giovani has noted, the goal should be more and more to create spaces where young people feel their individuality is acknowledged, and where they can choose to engage in workshops and activities aligned with their personal interests. This strategy helps establish spaces that pursue inclusion via being "exclusive", meaning that they aim at fostering a sense of belonging and ownership—critical factors for sustaining youth participation. Thus, the new service and space can be designed to respond to the

10 It was founded by a chaplain of the 'Cesare Beccaria' Juvenile Penal Institute and a group of volunteers.

latent needs of the (youth) community.

Many young people in Rozzano possess limited digital skills. While the majority own smartphones, they typically use them for entertainment or social media, with few using them for more productive purposes, such as searching for information or utilizing digital resources effectively. This highlights a clear need for educational programs that go beyond simple access to technology, and instead focus on enhancing digital literacy, fostering autonomy, and developing transversal skills. In this context, co-design can serve an essential tool for engaging young people in the creation of their own learning environments, transforming them from passive users into active co-creators of the new hybrid space imagined at the CFP, and digital facilitators for their families and the local residents, thus making the CFP a pilot hub for smart citizenship.

In efforts to achieve this, the following co-design program was structured around three primary stakeholder groups identified: Group 1, comprising professionals, educators, municipal representatives, and members of the Tavolo Connessioni network; Group 2, including students from the CFP and youth service participants; and Group 3, consisting of older residents and other potential users from the broader community. The aim was to engage these groups more deeply in understanding both the identified needs and the latent, often unrecognized ones, while exploring possible integrated solutions.

Each group participated in two thematic workshops (see Figure 6) — one focused on services and the other on the spatial environment — resulting in a total of six sessions.

Figure 6. Pictures from the 3 workshops with the TC, the youth and the elderly at the CFP.
Ph. by Matthew Spialtini and Claudia Mastrantoni

The workshops had three main objectives: 1) to define the goals of the co-design process in relation to both service provision and spatial design; 2) to develop and tailor co-design tools suited to the needs of the diverse participant groups; and 3) to structure the engagement strategy, ensuring effective dialogue between all stakeholders.

These objectives gave rise to two core thematic axes: the first, focusing on the service dimension, which encompasses the system of activities, functions, and interactions designed to address local needs and connect users with essential resources and tools; and the second, the spatial dimension, which concerns the physical environment where users engage with each other and with the digital and material components of the services.

However, from the outset, the co-design process emphasized the reciprocal relationship between these two dimensions, with the ultimate goal of creating a physical space that supports an integrated, community-driven e-welfare service. This led to a refined focus on integrating service and space, which helped define the key objectives more clearly:

- To pilot a hybrid space-service model that integrates physical infrastructure, digital tools, and support services to reduce digital exclusion, facilitate welfare access, and prevent early school leaving.
- To improve access to welfare services for the elderly through empowerment and tailored support, while also providing young people with opportunities to apply and develop their skills through hands-on involvement.
- To co-design a multigenerational hybrid hub where physical spaces, digital infrastructures, and capacity-building initiatives converge.
- To envision a model that could be replicated across Rozzano and potentially scaled regionally, anchored by the CFP (Centro di Formazione Professionale) and interconnected with other key communities.

Several critical insights emerged across all workshops, revealing both technological and social needs. Some participants expressed reluctance to assist others with digital tools due to a lack of self-confidence, while others highlighted the absence of a personal computer at home.

A common interest in digital repair, particularly among younger participants, emphasized the potential value of incorporating a hardware repair station into the proposed space.

In our efforts to understand what worked well in the recent municipal initiatives to provide digital facilitation desks for seniors — though unfortunately not on a continuous basis — we found that these desks were generally well-received in Rozzano. They were not only viewed as service points but also as spaces for digital empowerment. At the same time, some social concerns were raised, particularly the need for respectful treatment when seeking assistance, emphasizing the importance of relational dynamics in service design and of spaces enabling users to connect with others and learn to use digital tools in a supportive environment, thus highlighting the value of relational spaces in promoting digital inclusion.

These insights confirmed the validity of our previously discussed ecological approach to the digitalization of welfare, which prioritizes local knowledge, relationships, and resources and aims to design a responsive and adaptable space that addresses the specific needs of the Rozzano's community and evolves alongside their changes.

After the six workshops, a seventh session brought all three groups together for a plenary restitution event at the Cascina Grande Cultural Center, a prominent civic space in Rozzano, where the preliminary findings and the pilot project were presented to the wider local community (see Figure 7).

The Spazio Verso pilot project aims to be a flexible, inclusive, and relational space that responds to the challenges of digital transition in Rozzano. It is conceived as a model for integrating online and offline services, with the goal of promoting autonomy rather than simply addressing immediate needs. Therefore, it must be a flexible and accessible space. Various configurations produced through the workshops include dedicated areas for facilitation and training, spaces for both scheduled and drop-in support, secure storage (e.g., cabinets or lockers) for shared digital equipment, and accessible waiting areas and furniture to accommodate diverse user needs. These recommendations serve as the foundation for the development and co-creation of a physical and service infrastructure promoting inclusive access to e-welfare services in the coming phase of our research project.

Figure 7. Plenary session presenting the outcomes of the co-design process at Cascina Grande
Ph. by Paola Piscitelli

The ideal location for Spazio Verso naturally coincided with the CFP itself, as it played a central role in the process by hosting all the workshops. Additionally, it is a well-known and frequented space for young people and families, well integrated into the local network, and strategically located within the territory.

The CFP had already planned to relocate its main entrance, thus freeing up the current lateral entrance, which serves as a reception area near the administrative offices, just before the actual classrooms. This space, situated at the boundary between the interior and exterior, is particularly suited for alternative forms of access, beyond those of just teachers and students.

However, this shift raises important questions concerning the management of access, opening and closing procedures, and related logistical issues, emerged during the plenary final session, highlighting the need to collaboratively define key aspects of the project. Among the priorities identified were the establishment of a shared governance model for the newly envisioned space, guidelines for its access and use, a manifesto that reflects the project's core values and collective vision, and a shared activation calendar to coordinate the initial implementation of Spazio Verso. These objectives are essential for ensuring alignment among all involved stakeholders and facilitating a cohesive launch strategy.

The next phase of the project will focus on refining and addressing these elements, ensuring inclusive and participatory management. This will involve continuing to engage those who emerged as key stakeholders (such as educators from the CFP), the Municipality of Rozzano, local associations (e.g., Tavolo Connessioni), and residents, ensuring that all voices are considered in the development and operation of the space.

4. Conclusions

By involving individuals with limited digital skills in the design of their own learning content and environments, digital tools can play a multifaceted role: they become more than mere access points, acting as catalyst for fostering a sense of ownership and responsibility. Through this approach, youth are empowered to acquire skills and competencies they may not have previously envisioned, and such spaces can evolve into community hubs, that not only offer digital services but also provide opportunities for socialization, skill-building, and empowerment. In other words, they enable true inclusion.

This approach recognizes that the needs within a community are not uniform. Therefore, while the project proposal must consider how to structure services in complementary ways, it should also apply a model of "exclusive inclusiveness": targeting marginalized territories, populations, and groups by providing them with something exclusive and previously unimagined.

This paper challenges the idea that digital citizenship can be built only through programs that are (apparently) universal – or "one size fits all". Instead, by applying an ecological framework to inclusion, inclusion can be realized as a more multivalent notion, e.g., expanding to entail both relational and situated aspects. This situates inclusion in a network, rather than viewing it as something that can be accomplished through simply providing 'open access'. Co-designing a variety of spaces (or a network of spaces) geared towards addressing a specific community's interests and needs is collectively more inclusive than working towards broad notions of accessibility. In this sense, it can be argued that 'exclusivity' may actually be an unlikely ally to overcome the paradox of inclusion.

What we envision for Spazio Verso is a platform that complements and fills the gaps left by national and regional programs, such as the PNRR and the digital facilitation initiatives implemented locally. While these programs tend to be one-off interventions, Spazio Verso would allow people to come and go as needed, offering courses in multiple sessions that not only address specific issues but also promote empowerment. It may even tackle critical topics such as privacy awareness and other essential issues. While those programs may paradoxically require a digital identity for access, Spazio Verso offers a more accessible model, where individuals can simply walk in, ask questions, schedule appointments when necessary, explore ongoing activities, or even volunteer to contribute, not just seek help.

This is precisely because people and situations are diverse; the solution cannot be "one-size-fits-all". A one-time appointment is not enough for everyone. It can serve as a starting point, around which we can build in a complementary way, avoiding overlaps and gaps by beginning with a deep, specific understanding of the local context.

As progress continues to be made towards Spazio Verso, collaboration between researchers, local institutions, and the community remains on-going. The co-design process continues to focus on crafting ways to not only provide services co-designed by those who will use it, but also to create opportunities for social interaction and community building through developing digital competences.

EDUCATION AND SKILLS

Pedagogy for the future: Equipping students for complex and climate-relevant practice

Tara Lynne Clapp and Mark Groulx
Affiliation: University of Northern British Columbia
Email: tara.clapp@unbc.ca and mark.groulx@unbc.ca

Abstract:
What do students need to know and be able to do to work effectively in the unfolding world of polarization, climate breakdown, and challenges to governance? This central question of core curricula has been at the heart of our work at the University of Northern British Columbia in our recent curriculum transformation. In this paper, we present the theories that guide the work, the learning context, barriers and opportunities in curriculum planning, and our reinvented planning studio curriculum. We will also present the outline of a specific climate action studio within the new structure that combines expected learning outcomes with community partnership and opportunities for relevant climate innovations.

Keywords: climate pedagogy; student learning outcomes; competency frameworks; planning studios

Introduction

What do students need to know and be able to do to work effectively in the unfolding world of polarization, climate breakdown, and challenges to governance? This central question of core curricula has been at the heart of our work at the University of Northern British Columbia in our recent curriculum transformation. In this paper, we present the theories that guide the work, the learning context, barriers and opportunities in curriculum planning, and our reinvented planning studio curriculum progression. We will also describe how we plan to combine 'required competencies' and learning innovation in the first iteration of a new course, the Local Climate Action Studio.

Our first curricular principle is that the future is not like the past. Climate breakdown is affecting communities worldwide, in a litany of fires, floods, droughts and plagues. We are also dealing with a new intensity of divisiveness fueled by profitability – where the information industry accumulates through fear, hatred and distrust. Students will need to be equipped to develop new approaches to a new future.

Our second curricular principle is that the knowledges of the past are vital. The identity of the profession, while contested, also roots us in a set of practices and knowledges that equip us to engage the future, and to avoid reproducing the wrongs of colonialization, scientism and dehumanization.

We introduce this future/past contrast to highlight the contrast between the predictable and programmatic part of planning knowledge, from the unpredictable and developmental. In this contrast, 'the past' is roughly defined as the areas of knowledge defined in standards. In planning education in Canada, we are responsible to our accrediting body, the Planning Standards Board, for the demonstration of specific 'competencies' across subject areas.[1] This is not a 'perfect' contrast, as methods of foresight, future and uncertainty are part of these knowledges. We have found it useful to balance the 'programmatic' with the opportunity for students to learn in ways we did not predict.

In the studio progression along with course work, we have attempted to 'program' such that students learn and are mentored in the planning knowledges 'of the past,' while co-creating the abilities that we expect will allow them to thrive in an uncertain future. We are guided by pedagogical theories that speak to both these cases. For those competencies that are rooted in known practices, we have tried to make better use of 'student learning outcomes' theory. We can articulate these skills, set standards, and attend to student work to measure learning. As we are certain that our students will need to have the capacity to critically and resourcefully develop new practices, we are guided by the theories that emphasise 'development capacity' – transformative learning, and experiential learning.

1 Planning Standards Board, University Accreditation, Competencies, are at this website:

As we report our experience with an ongoing process of curriculum change, we will also present our context, including our opportunities and challenges. Our ongoing effort to manage an institutional change process in a theory-relevant way is a story worth telling.

We have implemented a core progression in studio learning, emphasising experiential and community engaged learning. Our studios have responsibility for 'accreditation competencies,' but it is also important that these studios feature the elements of uncertainty, mentorship, and 'learning-to-learn' that are key to their development as future professionals.

Finally, we will offer some examples of student work and learning that offer examples of both programmatic and/or competency-based learning, as well as what we are seeing as examples of student development in uncertainty.

The learning context: Climate, hegemony through clickbait, and 'best practices'

It is important to work in relationship to the world in which we find ourselves. While the curriculum review and change process is relatively slow, the world changes quickly.

Situated where we are in northern Canada, the future is clearly not like the past. Climate breakdown is affecting communities worldwide. Around us, climate breakdown is taking place in fires, floods, droughts, heat events and diseases both human and ecological. Ecological change renders itself visible in the changes in the availability of country food, in the increases in some wildlife conflicts, and in the extent of recent burns. Many First Nations along the Fraser River have their annual salmon 'catch' brought in from another watershed. This year the forest mosses crunch underfoot in the spring, the sound of impending danger.

Seeking a policy solution to fit the wildfire moment, communities adopt "FireSafe" rules that seek to protect buildings from fire, but at the same time rule out having trees for shade or delight in urban centres. Air conditioners for cooling are now required in buildings that were not designed with a 'hot season' in mind.

Our community context also includes a new intensity of divisiveness, as we harness ourselves to divided digital universes. Divisiveness is not unusual in the world, but it is of recent origin in our small, rural communities. We were not, admittedly, skipping through fields of flowers, but we were fighting over things like land, water and minerals that we all agreed we wanted. Now, community members see each other through the stereotypical and minimizing kaleidoscopes of memes – most of which are not even produced with northerners in mind.

We can see that the new media of cultural hegemony are also profitable, and that the product of this twin motive of profit and control through division is creating a culture that is unready and opposed to the promise of 'public deliberation' and 'give and take' that practical governance needs.

This is the scene that new planners will enter and within which we expect them to pursue justified and deliberated public actions and encourage comprehension and compliance with policies and plans.

Students will need to be equipped to develop new approaches to a new future.

It all seems new, but the knowledges of the past are vital. The identity of the profession, while contested, also roots us in a set of practices and knowledges that equip us to engage the future, and to avoid reproducing the wrongs of colonialization, scientism and dehumanization.

There is a contrast between the predictable and programmatic part of planning knowledge and the new, less predictable and developmental. For the purpose of this contrast, 'the past' is roughly defined as the areas of knowledge defined in standards. In planning education in Canada, we are responsible to our accrediting body

(Planning Standards Board) for the demonstration of specific 'competencies' across subject areas. This is not a 'perfect' contrast, as methods of foresight, future and uncertainty are part of these knowledges. We have found it useful to balance the 'programmatic' with the opportunity for students to learn in ways we did not predict.

Theories and frameworks of curriculum assessment and design in Planning:
There are various representations of the consensus on the set of skills and abilities that professional planners require. These change slowly over time (Anacker 2024). At the present time, the Planning Standards Board accredits Canadian Schools of Planning in part (how) they relate to a set of Planning competencies. These competencies include both 'functional' and 'enabling' competencies. Functional competencies are planning-specific knowledges and practices, while enabling competencies are communicative and relational. The Association of European Schools of Planning stewards a Core Curriculum (AESOP 2024). It is organised to specifically distinguish between knowledge and 'competency,' as the ability to bring knowledge and skill to bear on a situation. In Canada, these distinctions are not currently part of the accreditation vocabulary.

Different schools, different faculty members, and different accreditation teams may view these competencies differently; the 'standards of achievement' are set in this process.

Roughly, the identification of competencies that students are required to learn over the course of an accreditation program is broadly compatible with student learning outcomes theory.

In 'student learning outcomes theory,' a student-orientation in curriculum design and implementation uses 'what students learn' as the measure that should inform the design of assignments, curricular progression, and the assessment of program success. In this theory, the evidence of learning is demonstrated in student work, in what students know and are able to do.

Table 1: Teacher-Centred and Learner Centred Paradigms

Teaching Centred Paradigm	Learner Centred Paradigm
Knowledge is transmitted from professor to students	Students construct knowledge through gathering and synthesising information and integrating it with general skills of inquiry, communication, critical thinking, problem solving and so on.
Students passively receive information	Students are actively involved.
Knowledge can be demonstrated by performance on tests	Knowledge cannot be demonstrated outside its context of application – students must know how to use information in real life contexts
Assessment is used to monitor learning	Assessment is used to promote and diagnose learning
Desired learning is assessed indirectly through performance on objectively scored tests.	Desired learning is assessed directly through papers, projects, presentations and other products like those that they will be expected to produce in the future.
Culture is competitive and individualistic	Culture is cooperative, collaborative and supportive.
Not everyone can pass the test; faculty role is to distinguish between those that can and those that cannot pass.	Everyone ought to be able to learn to use knowledge effectively in a context; some may take more time to do so.

(Huba and Freed 2000)

In the context of a single course, student learning outcomes assessment is the measurement and evaluation of student learning against clearly articulated goals. To assess student learning, faculty must engage in a process of making desired learning outcomes explicit, assessing coursework and student experiences for learning opportunities, feedback and performance, and establishing measurements and assessments of learning outcomes within the course.

The emphasis on the articulation and measurement of learning outcomes is intended to support both faculty and students in identifying and building the knowledge and skills in an explicit and measurable way. In its emphasis on identifying 'differences that make a difference,' the emphasis is on ensuring that students have internalised new concepts into a new constructed framework sufficient to apply them in action.

Ideally, student learning outcomes assessment is linked to the social construction of knowledge through the participation of the students in internalising, conceptualising, and synthesising their new knowledge in work. Bloom's taxonomy of knowledge provides a framework for the sequencing of cognitive knowledge within a class, and across a curriculum. It is a practical and sequential interpretation of how learners construct and adopt and gain competency in new knowledges and practices across cognitive, affective and 'motor' domains (Wellington 2006).

The risk of fully implementing the measurement of student learning outcome theory is the tendency to reduce student learning to the more easily observed elements. It is easier to assess the structure of a paragraph than to assess how well the learner was able to listen and charitably interpret different stakeholder interests.

An increasing demand for measurability and predictability in the classroom leads to a reduced agency for the learner, shifts the content towards the mechanistic or programmatic, and changes the content – reduces – the concept of learning to reproduction of a prescribed action.

On its own, a focus on student learning outcomes assessment can lead to mechanism in teaching and learning – an industrial model of skills learning without reflection. That is, the more clearly an 'action' or 'work product' is defined by the instructor, the less room there is for an individual learner to create new solutions, and the less personal and individualized the 'learning' can be.

More than that - While student learning outcomes theory is a practical pedagogy for novice practice learning, the world demands creativity, resourcefulness, and learners that are capable of things that have not yet been demonstrated. So, while the 'right method' or 'right answer' culture is widespread and many learners require this for a feeling of safety, planners of the future will require the ability to develop, test, critique, and implement new solutions.

If we lived in a world where the solutions and right actions were known, then clearly defining and expressing the right action that each learner should 'do' might be sufficient if mechanistic. While 'demonstrates creativity' could be a student learning outcome, the demand for 'clarity in expectation' is in tension with the need for discovery, novelty and new solutions.

At the program level, conceptually the learning outcomes to be measured are the learnings from a whole set of experiences, demonstrated in capstone or senior level assignments. In fact, student work itself at this level is complex – typically comprising sets of values, skills, knowledges and limitations into products – presentations, reports, recommendations. From a 'whole curriculum' perspective, there is the risk that learning outcomes theory could be implemented in such a way as to amplify the 'reductionism and depersonalisation' problem. On the other hand, the ambition of this project renders it a low risk for us.

In our work, we conceptualize our learners as unique. To the extent that we are trying to assess competencies and qualities that will be expressed uniquely. We are building a smaller set of 'program learning outcomes' that can be mapped against a smaller set of senior-level work products. This measurement will continue to be rough.

For our external audiences of accreditation and program quality, we are developing evidence of learning including examples of student work, employer reports of students' readiness and competence, and student reports of their improved competence and/or confidence in specific skills.

In planning in Canada, we have never gone very far down the path of fully implementing the shift from faculty-oriented curriculum design and assessment (what topics do faculty cover) to student learning oriented curriculum design and assessment (what skills, abilities, knowledges and values do students incorporate in their work?). In the United States, planning schools and the Planning Accreditation Board have been active in this area since 2011 (Clapp and Johnson 2011). Planning schools have shared their work on program learning outcomes and their assessment on the Planning Accreditation Board website (PlanningAccreditationBoardWebsite).

Accordingly, for the most part, the practices of programs, individual faculty and accreditation teams continue to practically emphasise 'what faculty do' over 'what students learn.' The identification and assessment of competencies in the process of program assessment is not necessarily or even typically undertaken in conformance with student learning outcomes theory. For the most part, there has not practically been a shift from 'content' to 'coverage' when it comes to program design and assessment. On the whole, the theoretical push to move from a teacher-centred perspective to a learner-centred perspective has been met by the inertia of institutional practice and measurement capacity. In both of the planning programs where I have been involved in this effort, we adopted a dialogic solution

Curriculum assessment and change: opportunities and challenges
At the University of Northern British Columbia, we undertook – are still in the process of undertaking – an assessment, restructuring and implementation of the core curriculum in the planning program. We had inherited a curriculum and culture where community engaged and experiential learning were valued by faculty but were not well resourced. While efforts to gain appropriate investments in capacity had not borne fruit, we were able to bring about an investment in a 'studio classroom.'

We are situated in the north of British Columbia and of Canada, and our program(s) respond to the context of the economic resource periphery, small cities, vast rural areas, and a complex geography of unceded First Nations, diverse indigenous cultural and language relationships and traditional territories. Our programs are uniquely suited to that context: community planning with a northern emphasis, First Nations Planning, and environmental planning with an emphasis on the policy, resource and ecological relationships of places.

Our curriculum must respond to a framework of competencies that comprise the requirements for an accredited program in planning. As well, our program is undergraduate, so the basic components of a university education must also be present for student development – including critical thinking, communication and literacy, numeracy and the breadth of experience that allows for the development of personal and social perspectives. At the same time, given our location, we have a relatively high proportion of non-traditional students, first generation students, and we find that our new generations of students require the relevance of application.

In a strategic planning exercise at the School level, we decided to invest in an experiential and community engaged studio curriculum, where students would have at least one full studio experience in their last two years(Botchwey and Umemoto 2020; Long 2012). This choice is consistent with the regional context of the School, consistent with the aspirations of the students to be doing real work with real people, and is allowing us to more fully develop the community engagement that faculty and students were doing with more appropriate resources of space and time.

Through our competency mapping undertaken in 2021, we had identified some accreditation competencies that were important in our context and focus where student learning needed to be improved. At that time, we used student focus groups, discussions with employers, and competency mapping by faculty to identify some areas for improvement. In particular, we wanted to augment students learning of the financial and economic context of spatial planning, improve their basic design skills such as iteration and critique, and the incorporation of system factors at diverse scales. Incorporating feedback from earlier accreditation teams as well as our own thinking as relatively new faculty, we wanted to strengthen the program in the areas of decolonization and indigenous rights and title. As relatively new faculty, we also wanted to build our own understanding of the progress

and pacing of student skill-building and assessments through the program.

Involvement in this higher-level curriculum development is reliant on the willingness to collaborate. We are fortunate that so many of our faculty are committed to building their own courses and assessments in relation to those of other faculty members.

Desk-ready planners and the temptations of critical dialogical practice

In the studio progression along with course work, we have attempted to 'program' such that students learn and are mentored in the planning knowledges 'of the past,' while co-creating the abilities that we expect will allow them to thrive in an uncertain future. We are guided by pedagogical theories that speak to both these cases. For those competencies that are rooted in known practices, we have tried to make better use of 'student learning outcomes' theory. We can articulate these skills, set standards, and attend to student work to measure learning. As we are certain that our students will need to have the capacity to critically and resourcefully develop new practices, we are guided by the theories that emphasise 'development capacity' – transformative learning, and experiential learning.

We have implemented a core progression in studio learning, emphasising experiential and community engaged learning. Our studios have responsibility for 'accreditation competencies,' but it is also important that these studios feature the elements of uncertainty, mentorship, and 'learning-to-learn' that are key to their development as future professionals.

In the initial development of the 'studio core progression,' and choices about how we would create titles and conceptual programs for the new progression, we were influenced by:

- The programmatic and conceptual needs of the different majors in our program;
- Input from regional governments about their capacity to engage with studios; and
- Faculty capacity.

Studios that are ideally taken in the third year include:

- Community engagement and inclusion studio – from listening, to facilitation, to process design and engagement messaging;
- Land use and development studio – at the site-to-neighourhood scale, analyzing need, supply, and policy, and developing feasible proposals (volume, density, floor area) within a neighbourhood context

Students may choose from three studios in their last year – depending on their interests, program area, and pace of study. One is a site scale studio in sustainable and inclusive design, one is a relational landscape studio in indigenous planning, and the other is a studio in local climate action.

Local Climate Action Studio 2026: An Example

The Local Climate Action Studio is intended to engage students in the application and synthesis of climate action planning competencies from across the curriculum as well as learning in the class. While others have developed 'climate competencies' intended to inform 'climate education,'[2] through the development of this studio, we will also explore and develop competencies for resilient communities taking climate action.

From an accreditation competencies perspective, we envision this studio as consistently including functional competencies in 'information gathering and analysis,' and 'planning regulatory tools such as the Official Community Plan,' with adaptation and resilience to climate change as a social and environmental issue. As in all of the studios, there are a range of 'enabling competencies' required; the focus in this studio is the development of

2 See Climate Action Competency Framework, for 'business and social purposes,' available at Royal Roads University. https://macal.royalroads.ca/introducing-the-climate-adaptation-competency-framework/

policy fluency, from analysis to recommendation.

Part of the vision and structure for this studio was developed out of an experimental version of the course delivered in Winter 2024. A very strong partnership with a local government including staff and a local elected official created an enriching policy learning opportunity. Students hosted virtual and in-person community engagements in the rural area, completed a policy analysis, and prepared draft policy statements. Students presented their policy work to the local government, and elements of their engagement results and recommendations influenced the Official Community Plan adopted for that area.

The present project is uniquely focused on identifying and mobilizing competencies for climate action(Infield, Seasons, and Lyles 2025), but we also expect the work to produce policy actions, specifically in the Official Community Plan.

Resilience thinking has evolved dramatically - permeating the field of planning. As the unfolding response to devastating wildfires demonstrates, it is no longer tenable for communities to 'bounce back' to a previous state following a climate shock. Planners and other professionals must be able to collaborate from local to national scales to help communities 'bounce forward'. This need to promote system transformability –is widely accepted in theory and increasingly in practice. Less clear is what professional competencies are required to succeed in this work.

Across local governments in northern BC, financial and human capacity is typically scarce. As a result, planners and local government professionals in the north must find creative ways to harness existing local government and/or community functions (e.g., policy tools) to promote resilience building (refs). Promising pathways for this work include the mainstreaming of climate policy and the construction of policy that promotes climate co-benefits (ref).

Most recently, in the Robson Valley the Village of Valemount lobbied senior governments for financial assistance to offset tourism revenues lost to the Jasper wildfire (Labbe, 2025). Set within this context, the UNBC School of Planning and Sustainability and the Regional District of Fraser Fort George (RDFFG) are partnering to advance local climate action through a project that will achieve two objectives:

The project team members listed above will meet for two half day working sessions to co-design the local climate action course.

Dr. Groulx will host virtual conversations with northern professionals leading climate action work in the fields of planning, public health, and natural resource management. These conversations will identify the competencies that future climate action professionals need to promote effective system transformation.

This project focuses on land use policy and community engagement as interrelated leverage areas for identifying and mobilizing competencies that will be required by effective future climate professionals. As the NRESi mission states, it is "together with the community and partners [that we] have the ability through expertise and experience to address and look for solutions" (NRESi 2020, p. 3). Consistent with this mission, as part of this project students will partner with Regional District staff and take part as active participants in the Official Community Plan update for the rural area. Students will prepare a regional climate trend and impacts report, design and implement community climate engagements, run a vulnerability assessment workshop, and take part in a two-day intensive climate resilience policy writing workshop.

Activities in 2026 include climate trend and impacts research, community engagements, a climate vulnerability workshop, and a climate resilience policy writing workshop (hosted in McBride and Valemount). Activities in 2025 prepare for this work.

In developing analytical competency, students will work with PCIC's Plan2Adapt tool and academic and grey literature to produce a report on regional climate trends and impacts.

Building on engagement competencies from an earlier studio, students will design and deliver a series of engagements and workshops that support climate resilience policy development. Students will also host and report on a series of virtual climate engagements designed to document how communities are experience climate impacts across the region.

Students will run a full day vulnerability assessment workshop with local experts. The workshop will be designed based on protocols from ICLEI Canada's Building Adaptive and Resilient Communities (BARC) framework. The BARC framework is designed for use with local government and its tools and processes can be scaled for use in communities of different sizes.

Students will take part in a two-day intensive policy writing workshop designed and ran with input and guidance from local government staff and climate policy experts. Policy development will draw on findings from the vulnerability assessment, as well as knowledge gathered through other course milestones.

Conclusions:
We do our best to equip our students with the adaptability, resilience and system-thinking skills that they will need to be planners in an uncertain world of climate breakdown and political tensions. One of these skills is innovation, another is the creativity of drawing new connections in a new circumstance.

As we work at the program level and at the course level with both the Planning Standards Board competency framework and our overall program learning outcomes, we continue to see the tension between the standardised imagination where all students acquire the same skill set, and the surprise and delight of intense individual and peer development that we see the students experience in studio learning.

Research-Driven Pedagogy: Advancing Transformative Skills in Spatial Justice and Urban Sustainability through Educational Innovation. Insights from the REPLACE Project

Sarah Isabella Chiodi, Lorenzo Liguoro
Politecnico di Milano, Department of Architecture and Urban Studies
Email: sarahisabella.chiodi@polimi.it, lorenzo.liguoro@polimi.it

Abstract
This paper presents a transformative educational initiative developed within the REPLACE project, which integrates university research with civic engagement. Focusing on a pilot workshop conducted in a primary school, the study analyses the design and implementation of The REPLACE Game, a board game that introduces children to spatial justice, sustainability, and cohesion policy through experiential learning. Co-created with university students, the game fosters critical thinking, ethical awareness, and teamwork in young learners while promoting public engagement and pedagogical innovation. The paper outlines the design process, pedagogical goals, and learning outcomes, and discusses further developments in higher education as well. The experiece illustrates how schools can become laboratories of democracy, translating abstract policy concepts into accessible, action-based learning experiences.

Keywords: Spatial Justice, Transformative Learning, Research-Driven Pedagogy, Civic Engagement, Research extension

Introduction

In recent years, universities have increasingly embraced the so-called Third Mission or Research Extension expanding their role beyond teaching and research to include civic engagement, knowledge dissemination, and collaborative innovation. The REPLACE project[1] exemplifies this paradigm by integrating educational innovation with public-oriented research on spatial justice and sustainable development. Within its broader Dissemination and Communication strategy, REPLACE translates complex policy frameworks, such as territorial cohesion and spatial equity, into accessible and engaging formats. This paper focuses on one of its most compelling pilot initiatives: a pedagogical workshop co-developed with the International European School "Altiero Spinelli" in Turin at primary level, centered around a custom-designed board game titled The REPLACE Game.

The article is organized into six chapters. Chapter 1 situates the REPLACE project within the framework of the Third Mission and transformative pedagogy. Chapter 2 introduces the conceptual foundations and rule system of the game. Chapter 3 outlines the implementation strategy of the workshop. Chapter 4 analyzes the educational objectives and observed learning outcomes, while Chapter 5 reflects on the experiential and transformative dimensions of the initiative. Finally, Chapter 6 presents the future developments of the project, particularly its forthcoming expansion into secondary education through the VIBES initiative. By exploring this case study, the article proposes a replicable model of research-driven pedagogy that empowers young learners through experiential, civic-oriented education. It argues that such initiatives are not peripheral but central to the university's evolving public mission and to the cultivation of active, critical, and socially engaged citizenship.

1. From Research to Civic Impact: Educational Innovation in the REPLACE Project

In recent years, universities have increasingly embraced an expanded vision of their societal role, one that transcends the traditional binary of teaching and research. This broader mandate, often described as the Third Mission of the University, encompasses a set of activities that connect academic institutions to wider society through civic engagement, public dissemination of knowledge, and collaborative innovation (Zomer & Benneworth, 2011; Perkmann et al., 2013). Within this framework, new spaces of interaction between academia and civil society have emerged, particularly in domains where research has direct implications for pressing societal challenges such as inequality, urban development, and sustainability. One area where this convergence is espe-

1 The project has been developed within the Department of Architecture and Urban Studies (DAStU) of the Politecnico di Milano and funded by NextGenerationEU and the Italian Ministry of University and Research. It has been coordinated by Sarah Isabella Chiodi, assistant professor at DAStU, Polimi. The activities of extension of the research have been managed by a research group made up of the coordinator, Dr. Lorenzo Liguoro and three Polimi's students: Antonio Perrone, Jana Ondrejkovicova and Teresa Kucich.

cially evident is in the field of spatial and territorial justice, where universities are uniquely positioned to act as mediators between scientific knowledge and public understanding.

The REPLACE project embodies this approach, overcoming the traditional missions of research. While its core research objective is to promote integrated territorial development by bridging regional planning and EU structural funds, the project has consistently operated under the principle that knowledge production must be matched by knowledge dissemination. In other words, the research not only aims to influence policy and planning practices but also to foster awareness and dialogue among diverse segments of the population, including youth and local communities. To this end, the project has developed a Dissemination and Communication strategy, which has been embodied into a dedicated Work Package of the REPLACE project (WP.B): it places significant emphasis on educational outreach, targeting both academic and non-academic audiences. The WP.B has become a cornerstone of the project, encompassing a wide array of initiatives which range from academic publications and international seminars to innovative outreach tools aimed at younger audiences, such as interactive workshops, visual storytelling, seminars in Brazil, and participatory games. Through these activities, the project promotes critical thinking about the socio-spatial dynamics of urban environments, helping to instill foundational knowledge of planning principles and European policy frameworks among new generations.

Among the most innovative dimensions of WP.B is its collaboration with the school, which has served as a platform for translating abstract research themes, such as cohesion policy, spatial inequality, and participatory planning, into accessible and engaging formats for students at various educational levels. This collaboration is aligned with a growing body of literature emphasizing the importance of partnerships between universities and schools as a fundamental expression of the Third Mission (Benneworth et al., 2016; Facer & Enright, 2016). Such alliances are not only vehicles for civic engagement but also catalyze transformative learning experiences that benefit both students and researchers. Schools gain access to contemporary knowledge and new pedagogical tools, while universities are challenged to render their work intelligible and meaningful to broader publics.

The partnership between REPLACE and the Scuola Internazionale Europea Statale Altiero Spinelli in Turin, the only public institution in Italy offering a complete European curriculum from elementary to high school, represents a flagship initiative in this regard. The unique nature of this public European school, which is characterized by a multicultural and international environment[2], provided fertile ground for engaging students with themes of socio-spatial justice and sustainable urban development. This collaboration aims to represent a pilot porject in educational innovation and civic engagement, with specific emphasis on introducing concepts of spatial justice to younger generations.

The activities undertaken with the Spinelli School form the focal point of this article. It will concentrate specifically on the laboratory held in the primary school and the interactive board game created for that occasion. The forthcoming activities with the high school division, which are currently in the design phase and scheduled for implementation in 2025, will also be briefly discussed as part of the project's forward-looking trajectory.

The elementary school initiative was conceptualized as an immersive educational experience built around a workshop and an interactive game titled "the REPLACE Game", co-designed by the research team and a group of bachelor students from the Politecnico di Milano through a structured internal internship. The rationale for engaging such a young audience stemmed from the conviction that spatial justice, despite its complexity, could

2 Families are often multicultural and made by parents both from different countries and multilingual. The School "A. Spinelli" was born as an educational project aimed at Italian and foreign students, formulated in the main European languages: French, English, Spanish, German, in addition to Italian of course. The Istituzione Torinese per una Educazione Responsabile (ITER) has promoted and signed with the School "A. Spinelli", the European Nursery School and the Madr&lingua Association, the Educational Pact for the implementation of the "Language Project", to develop the multilingual competence of all students in a multilingual environment. The Project therefore aims to promote cultural integration through the daily exchange of experiences between students and teachers of different nationalities, in a relationship of dialogue and reciprocity, enhancing multicultural cognitive skills.

be meaningfully introduced through experiential learning. The workshop aimed to familiarize children aged 8 to 10 with ideas such as equity, spatial distribution, and urban form, using language, tools, and activities tailored to their developmental stage. The Game employed role-playing, strategic thinking, and creative problem-solving to simulate urban scenarios in which participants had to balance environmental constraints, social needs, and budgetary limitations: a miniature, age-appropriate metaphor for real-world planning challenges.

A key component of the initiative was the involvement of undergraduate students through an internship program activated within the Department of Architecture and Urban Studies. The **internship**, advertised through a departmental call, offered students the opportunity to contribute directly to the "Impact of Research" component of the project. Participants were tasked with co-designing and conducting educational laboratories in schools located in Italy. The activities spanned a variety of functions: from simplifying complex research findings into school-appropriate narratives, to coordinating hands-on learning experiences, and even participating in the drafting of dissemination materials and articles. Importantly, the internship was formally recognized with academic credits, contributing to the students' graduation requirements and underscoring the pedagogical value of their involvement.

Within the context of the Spinelli elementary school, the interns played a pivotal role. Not only did they assist in classroom activities and support the facilitation of the workshop, but they were also actively involved in the co-creation of the REPLACE Game. Working side by side with the research team, the students contributed to the conceptual design, created the visual content for the game cards (e.g., user profiles, urban functions, infrastructure types), and helped define the operational rules that govern the dynamics of gameplay. This collaborative design process not only enhanced the quality and accessibility of the game but also provided the interns with a real-world application of their academic knowledge, while fostering their skills in communication, team coordination, and design thinking.

As outlined in the internship description, the objectives of the program included educating and engaging younger audiences on EU cohesion policy and spatial inequalities, promoting socio-spatial justice, and developing the interns' own competencies in scientific communication and public engagement. The initiative served a dual purpose: it enriched the pedagogical content delivered to schoolchildren and, at the same time, empowered university students to act as agents of knowledge transfer. In doing so, it created a virtuous cycle in which research, teaching, and civic responsibility reinforce one another.

By focusing on the Spinelli collaboration, and particularly on the elementary school workshop and game, this article sheds light on a replicable model of **research-driven pedagogy**. It proposes that such models are not peripheral but essential to the university's evolving public role. Moreover, they offer an opportunity to reimagine education as a collaborative, multi-level process in which learning flows not only from academia to society but also, in reverse, where researchers, educators, and students co-create knowledge that is responsive to the needs and realities of local communities.

In the chapters that follow, we will provide a detailed account of the Game and its pedagogical framework, including its design process, learning objectives, and classroom outcomes. We will also contextualize these activities within broader educational theories and discuss the potential for scaling such initiatives across different age groups and institutional contexts. Through this exploration, the paper aims to contribute to the discourse on the Third Mission by offering a grounded, practice-based reflection on how universities can meaningfully engage with society to advance spatial justice and sustainable urban futures.

2. Designing the REPLACE Game: Concepts, Mechanics, and Educational Aims

The REPLACE Pedagogical Game was conceived as an educational bridge between the abstract policy framework of territorial cohesion and an engaging, child-centred learning experience. The design team began by distilling three abstract pillars—spatial inequality, sustainability, and social cohesion—into a set of tangible mechanics that players could manipulate, argue over, and re-configure. Central to this translation was the decision to create

a **full-fledged board game**, complete with high-resolution A1 boards, laminated card decks and professionally printed iconography, signalling to pupils that they were engaging with an authentic game world rather than a didactic exercise. At the same time, deliberately "unfinished" elements—pasta shapes for coins and environmental tokens, blank cards awaiting pupils' own structures—left visible the scaffolding of a work-in-progress construction site, inviting collective authorship. Its purpose was to translate complex concepts such as spatial inequality, sustainability, and social cohesion into tangible, interactive mechanics that primary school pupils could manipulate, explore, and reflect upon. The resulting board game combines rigorous design with elements of play, immersing children in urban planning scenarios that require them to navigate trade-offs, prioritise needs, and co-create inclusive, sustainable spaces.

The game was introduced through a multi-session workshop in which pupils, organised in teams, were tasked with reimagining the public space surrounding their school. Activities followed a coherent sequence—from problem identification and scenario building to spatial negotiation and collective reflection—culminating in a simulated redistributive intervention modelled on the logic of EU Cohesion Policy. The use of the school's actual site plan as the game board embedded the activity within a familiar spatial context, reinforcing Gruenewald's (2003) call to treat place as pedagogy and anchoring abstract ethical debates in real environments.

A key design feature was the co-creation process involving intern-researchers, who collaborated with the academic team to prototype and refine the game. Their contribution ensured both conceptual rigor and accessibility, modelling a learning pyramid in which university students, trainee educators, and primary pupils occupied successive rungs. This structure reflects the principles of **service learning**, an educational approach that integrates meaningful community service with academic instruction and reflection. Within this framework, students are not passive recipients of knowledge but active contributors to projects that address real social needs. They designed solutions, implemented activities collaboratively, and participated actively to the workshops. They provided a tailored design for the game and a logo[3] as well. In the context of REPLACE, the university interns engaged not only in the technical design of the educational game but also in its delivery, co-facilitating workshops that directly served younger learners and their schools. This experience embodied the core elements of service learning: community-oriented service, application of academic knowledge in real-world settings, active student involvement in all project phases, and the cultivation of civic awareness. Through this integration of research, design, and action, the REPLACE project nurtured transversal competences such as problem solving, teamwork, and ethical reflection, while fostering a stronger connection between higher education institutions and local communities.

Figure 1. The REPLACE project logo. Two stylised human figures—composed of circles and inverted triangles—symbolise inclusion and the complementarity of differences. The minimalist, symmetrical design visually conveys the project's core values: spatial justice, territorial cohesion, and participatory citizenship, reflecting its commitment to equity through education and dialogue.

This iterative process led to a well-calibrated rule set with clear thresholds and an integrated framework of **pedagogical constraints and ethical goals**. Each group of five to six pupils was assigned the task of **designing an inclusive, functional, and sustainable urban or green space** directly on the actual site plan of their school. To complete this mission, teams had to comply with five compulsory constraints and one ethical objective. First, each group was required to integrate at least three **functions**, in order to diversify the intended uses of the space.

3 The logo has been an original creation designed by the intern student Antonio Perrone.

Second, they had to satisfy the needs of at least three different kind of **users**, thus embedding inclusion into the core of the design process. Third, teams could place no more than fifteen **structures**, including both pre-printed and custom-designed cards, with each structure's physical form reproduced using 5 m² tiles and spatially arranged within the boundary of the map, requiring teams to manage land occupation like a spatial puzzle. Fourth, teams were assigned an asymmetric economic **budget** and were encouraged to spend their entire allocation strategically, as the funds represented earmarked resources intended for the school's improvement. Lastly, **land consumption** was constrained by the number of available tiles: when space ran out, students had to remove or reconfigure structures to make them fit, enhancing spatial reasoning under constraint. Beyond these formal rules, the game introduced an ethical challenge linked to **environmental impact**. Each structure carried an ecological cost, which symbolised emissions or biodiversity loss. While teams began with a generous allocation of tokens, they were encouraged to preserve as many as possible.

Therefore, at the core of the game are six component families. **Structure Cards** (red) include twenty pre-printed elements such as the Hopscotch Grid, Stargazing Telescope, Hammock, Pottery Shed, Pocket Theatre, and Vegetable Garden. Each card specifies its functions, compatible user categories, economic cost (1–5 coins), ecological impact (1–5 tokens), and spatial footprint (in 5 m² tiles). Blank Structure Cards allow pupils to invent their own facilities, encouraging creativity and numeracy.

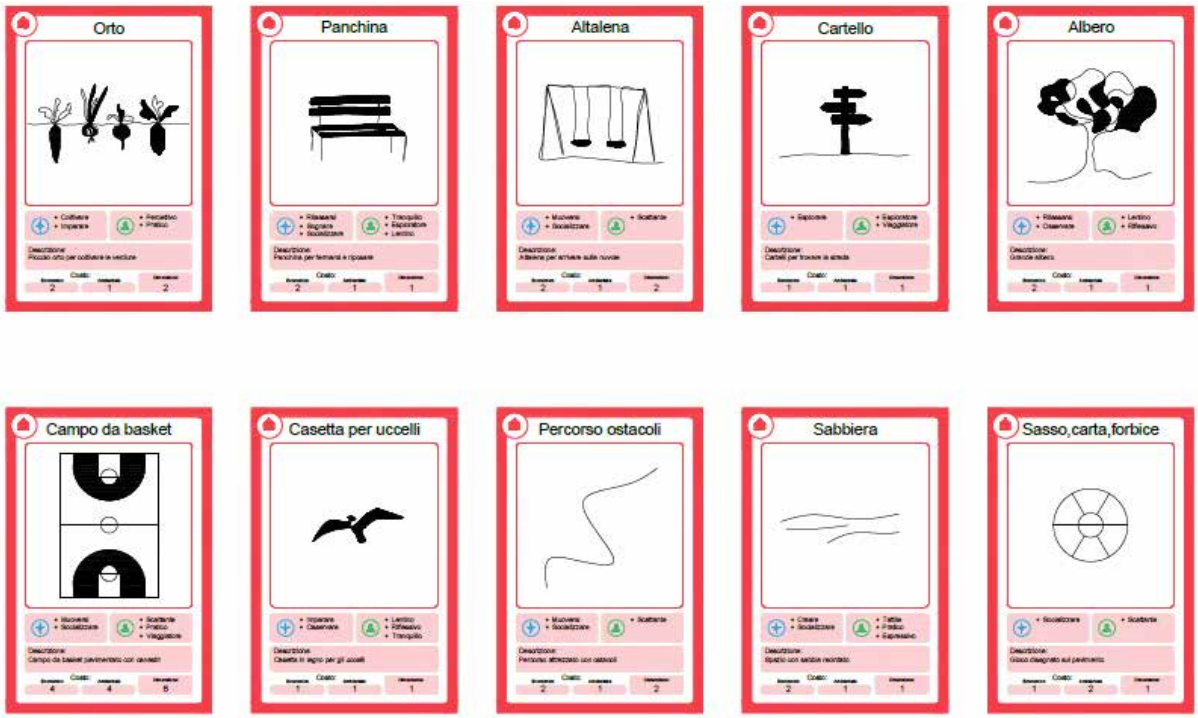

Figure 2. Examples of Structure Cards designed for use in the REPLACE board game. Each card represents a potential spatial intervention, with associated costs in surface area, budget, and environmental impact.

User Cards (green) represent ten accessibility profiles inspired by Italy's Special Educational Needs (SEN) framework: Slow Mover (requires obstacle-free routes and longer transition times), Calm Seeker (benefits from quiet, low-stimulus areas), Quick Mover (needs space for active movement and physical play), Hands-On Learner (prefers interactive and manipulable environments), Tactile Explorer (responds to textured and sensory-rich surfaces), Expressive Communicator (communicates through non-verbal or alternative languages and needs multimodal stimuli), Reflective Thinker (requires calm observation points and time for processing), Sensory Sensitive (sensitive to noise, light, and unpredictable layouts, needs controlled sensory environments), Cultural Traveller (requires inclusive symbols and multilingual access), and Explorer (thrives in open-ended paths and spaces that

reward curiosity and movement). These personas place inclusivity at the centre of spatial design, compelling teams to accommodate different learning styles and physical needs.

Figure 3. Examples of User Profile Cards. These cards draw inspiration from inclusive education frameworks and help players consider the diverse needs of school users when planning interventions.

Function Cards (blue) define the curricular and behavioural goals of each intervention, including Explore, Create, Socialise, Learn, Relax, Move, Observe, Cultivate, Experiment, and Dream. The selection of functions is designed to prompt students to reflect on the multiple functional properties of space and to recognise that certain functions may exclude others. This focus on the functionalisation of public and shared space enabled reflection on how to mediate between individual preferences and collective choices. Together, user and function cards define the brief for each team, determining which combinations of structures best fulfil their stated goals.

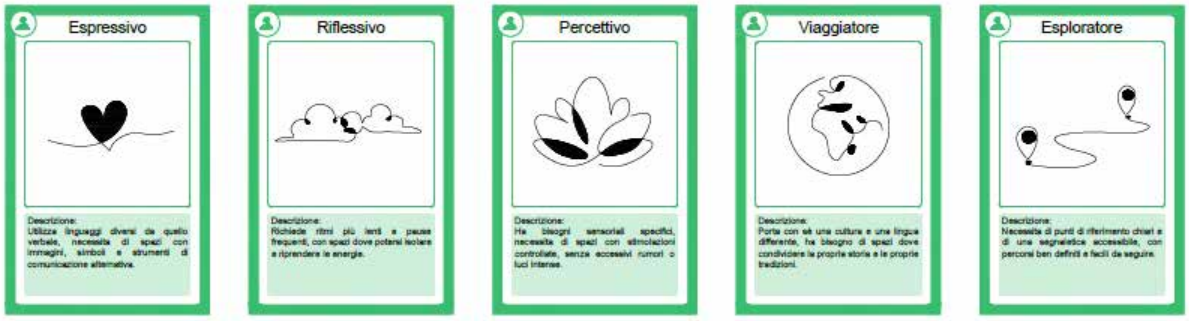

Figure 4. Examples of Function Cards. These cards represent key functions of inclusive public space—such as learning, moving, and socialising—and guide teams in ensuring functional diversity within their designs.

Each team is also assigned six **Role Cards** (teal), which mirror the division of labour in real planning processes: the Master of Ceremonies (MC) selects the functions to be pursued in the space and the users to whom the project should be addressed, chairs group discussions, sets priorities, and delivers presentations; the Supreme Shape Creator (SSC) sketches new structures and quantifies costs and impacts suitable for the selected users and functions; the Dream Architect (DA) curates the structure catalogue by identifying the most suitable structures—both new and standard—to meet user needs and to support the implementation of the selected functions; the Grand Treasury Accountant (GTA) manages finances, negotiates trade-offs, and purchases the structures to be included in the project; the Space Genius (SG) positions the structures within the available space, places tiles, and ensures accessibility and circulation; and the Harmony Guardian (HG) safeguards fairness and ecology, holding veto power and maintaining a public ledger of coins, butterfly tokens, and space used, administers environmental resources, and verifies that teammates' decisions have respected the initial commitments to provide specific functions for selected user profiles. This mutual interdependence enforces constant negotiation and fosters teamwork, as no action can proceed without coordination across roles.

Figure 5. Examples of Role Cards. Each card assigns specific responsibilities—such as managing resources, designing layouts, or facilitating group harmony—encouraging cooperation, accountability, and active participation within the team,

The material components of the game further support its educational goals. The game board—a high-resolution A1 printout of the school grounds—is accompanied by coins (penne-shaped pasta), environmental tokens (butterfly-shaped pasta), and space tiles (white 5 m2 cardboard squares). Pupils must tape together tiles to physically construct the shapes of proposed structures, confronting issues of adjacency, circulation, and land consumption in a kinaesthetic mode.

In sum, the REPLACE Game transforms policy discourse into a dynamic, material, and collaborative exercise. It engages children as designers, planners, and citizens, cultivating the cognitive, ethical, and practical competences needed to imagine more just and sustainable futures.

3. Implementing the REPLACE Workshop: Pedagogical Strategies and Facilitation

The implementation of the REPLACE game workshop followed a carefully designed pedagogical trajectory, combining elements of direct instruction with inquiry-based learning, and progressively guiding pupils through a structured yet flexible educational arc. The process began with a collectively framed discussion on the notions of socio-spatial justice, land scarcity, and sustainability. Rather than delivering a one-way lecture, facilitators employed a dialogic and visual approach, encouraging children to identify inequalities within their own neighbourhood and to reflect on the spatial and material deficiencies of their school environment. This opening activity reframed the map of the school grounds from a neutral diagram into a socially contested and emotionally resonant terrain, setting the stage for more complex spatial reasoning and ethical deliberation.

As pupils moved into the design phase, they began customising their own components of the game. Working in pairs, they created new Structure Cards using blank templates and were asked to estimate three key values—land footprint in tiles, economic cost in coins, and ecological impact in environmental tokens. These estimations were not arbitrary: each proposed structure had to be explicitly linked to a User Card and a Function Card, thereby rooting design imagination in the needs of specific user profiles and tangible programme goals. This creative act, guided by the role of the Supreme Shape Creator, enabled pupils to develop a sense of authorship over the game material while enhancing their numeracy and evaluative skills through peer dialogue and negotiation.

Resource allocation introduced asymmetry as a deliberate pedagogical tool. Facilitators distributed uneven starting budgets—45, 35, or 25 coins per team, along with an equal number of environmental tokens—thereby

making inequality immediately visible. The Grand Treasury Accountant recorded each team's balance on a public scoreboard, prompting early discussions on fairness, responsibility, and the relationship between resources and obligations. This staged disparity would later become the basis for a simulated redistributive intervention, allowing pupils to critically engage with concepts underpinning cohesion policy.

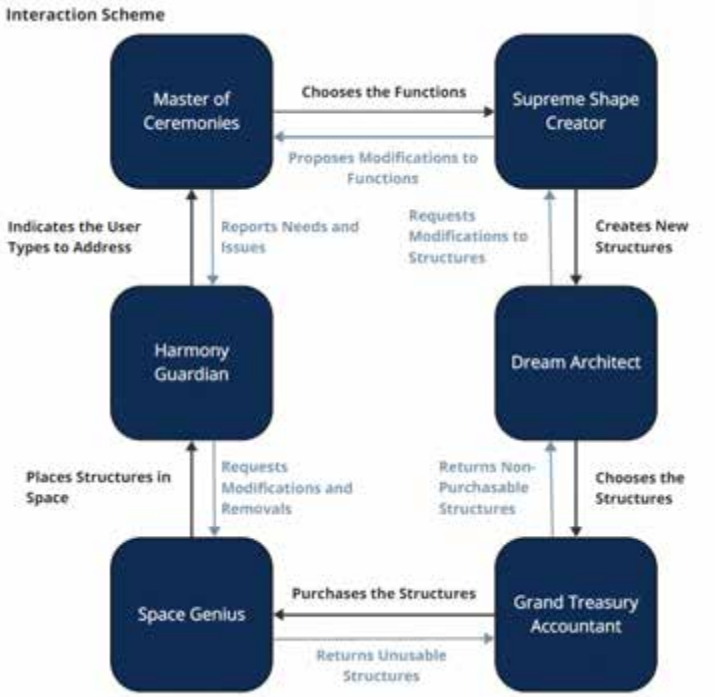

Figure 6. Group roles and interaction dynamics within the REPLACE workshop. The diagram illustrates how task-specific responsibilities (e.g., Space Genius, Dream Architect) structure collaboration and collective decision-making.

The **design phase**, occupying a substantial portion of the workshop, tasked teams with composing spatial layouts using a maximum of fifteen structures, while integrating at least three different user categories. The Space Genius orchestrated the physical placement of tiles on the map, and the Dream Architect curated the final configuration of selected structures. Throughout this process, facilitators maintained a reflective and non-directive presence, asking open-ended questions such as "Who might be excluded from this design?" rather than prescribing answers. This fostered an atmosphere of self-correction and ethical inquiry, as students revised their plans to increase inclusivity and accessibility.

Midway through the session, the workshop simulated **a redistributive shock** modelled on EU cohesion mechanisms. Additional funding was introduced: the team with the lowest initial endowment received the largest injection, followed by moderate support to the middle group and minimal increase for the most advantaged. This moment forced teams to reassess priorities under new conditions of equity, with the Master of Ceremonies in each group renegotiating goals in dialogue with teammates. In this way, abstract principles of distributive justice became embedded in the gameplay itself.

The final segment of the workshop was devoted to presentation and reflection. Teams publicly shared their spatial layouts, remaining coins and environmental tokens, and described the logic behind their decisions. The Harmony Guardian articulated how trade-offs were resolved and whether sustainability and inclusion had been achieved. A concluding plenary discussion, guided by facilitators, invited pupils to reflect on the most challenging dilemmas, the emotional impact of resource redistribution, and what they might do differently in a future

iteration. These conversations surfaced not only the design outcomes but also the values and social reasoning cultivated throughout the activity.

Throughout the workshop, facilitators adopted a deliberately Socratic posture—questioning, mirroring, and guiding rather than evaluating—to create a space of co-inquiry. The classroom thus became a rehearsal ground for collaborative planning and democratic participation, where children could practise critical citizenship through playful yet meaningful engagement with real-world challenges.

4. Learning in Action: Educational Goals and Outcomes

The game was purposefully designed to foster a comprehensive set of competencies that reflect the multidimensional profile of a future-oriented citizen-planner. Among the core learning goals were mathematical reasoning, spatial literacy, communication skills, civic awareness, empathy, and creative problem-solving. These were not addressed in isolation but emerged organically through the mechanics and social dynamics of the game-based experience.

Budget management, for instance, required pupils to engage in continuous arithmetic, calculating expenses, converting spatial units into square metres, and recalibrating available resources following a redistributive top-up. This process embedded mathematical operations such as addition, subtraction, and proportional reasoning within an authentic, time-sensitive scenario, thereby sharpening estimation skills and unit conversion abilities. Simultaneously, the manipulation of 5 m^2 tiles on a scaled map of the school site engaged pupils in spatial reasoning tasks. By repositioning playground equipment or designing new layouts, they developed an understanding of adjacency, circulation, and orientation, acquiring a practical grasp of spatial planning principles.

Communication and teamwork were equally central. The structured distribution of roles, each with distinct responsibilities, required participants to practise active listening, negotiate effectively, and coordinate actions with their peers. The division of powers (for instance, only the Treasury Accountant could release coins, and only the Space Genius could place tiles) reinforced interdependence and the need for clear, respectful dialogue. These dynamics offered a lived experience of relational and communicative competence under conditions of mild pressure and complexity.

The game also served as a rehearsal for democratic practice. Decisions regarding the allocation of resources, the selection of functions, or the response to new constraints were made collectively, with facilitators modelling procedural fairness and encouraging inclusive debate. The figure of the Harmony Guardian, with the authority to veto inequitable or ecologically harmful choices, ensured that deliberation was grounded in shared values of justice and sustainability. In this way, pupils were introduced to the principles of deliberative governance, simulating microcosms of participatory decision-making.

Empathy and social awareness were developed through the use of ten “User Cards”, each inspired by profiles drawn from the Italian framework for Special Educational Needs (BES). These profiles prompted participants to imagine the needs of different users—such as slow movers, sensory explorers, or multilingual learners—and to incorporate accessibility and inclusiveness into their spatial solutions. Children often expressed a sense of responsibility toward “their” users, and many reported adjusting their decisions to better accommodate these imagined perspectives. This affective engagement reflects the emergence of perspective-taking and ethical reasoning, key foundations of civic maturity.

In terms of creative capacity, the presence of blank Structure Cards empowered pupils to assume the role of novice designers. Estimating land take, costs, and ecological impacts became a process of iterative sketching, peer critique, and problem-solving that mirrored real-world design studios. The most inventive teams proposed hybrid installations—such as a combined “Reading-Garden Pergola” or a “Bike-Repair Kiosk”—capable of satisfying multiple user needs and functional goals at once. These examples demonstrated a capacity for divergent thinking and adaptive creativity under constraint.

At a deeper level, the workshop asked pupils to manage three parallel ledgers—**spatial, economic, and ecological**—each governed by different norms and logics. The spatial ledger, linked to physical tiles representing 5 m² units, introduced constraints of shape and fit: an L-shaped pergola or winding footpath might occupy the same area as a rectangle but proved more difficult to position effectively, prompting children to experiment with layout efficiency and spatial optimisation. The economic ledger, represented by penne-shaped pasta coins, captured financial trade-offs: while the objective was to spend the entire budget, groups had to evaluate utility over prestige, understanding that unspent funds held no advantage in the final assessment. The ecological ledger, expressed through farfalle-shaped environmental tokens, reflected the cost of carbon emissions, resource depletion, and habitat loss. Unlike coins, these tokens were best conserved. Though overspending was technically permitted, it carried social consequences, as seen when peers chided others with remarks like "You're wasting butterflies!", thus transforming planetary limits into a shared moral concern.

Balancing these ledgers required pupils to confront complex trade-offs and to understand that land, money, and ecological resources are interconnected but governed by conflicting imperatives. Through this balancing act, they encountered a form of moral arithmetic—"Can we afford it? Can we fit it? Should we do it?"—that encouraged systems thinking and early eco-ethical awareness. The result was a rich, multidimensional learning experience that went far beyond the accumulation of isolated skills, instead nurturing the kind of integrated reasoning necessary for navigating the socio-spatial dilemmas of contemporary urban life.

5. Transformative Learning in Practice: Reflections on Experience, Impact, and Educational Value

The REPLACE workshop demonstrated how play-based learning can integrate complex urban planning concepts with the cognitive, emotional, and social development of primary school pupils. Far from a mere educational diversion, the initiative yielded robust outcomes: students developed spatial awareness, demonstrated empathy toward diverse user profiles derived from inclusive education frameworks, and produced creative, context-sensitive design solutions under a range of constraints. Teachers reported enhanced attention, sustained enthusiasm, and strengthened cooperative behaviour among participants: evidence of the game's ability to merge analytical rigour with affective engagement.

A distinctive feature of the workshop was the pedagogical role of emotion, which acted not as a peripheral effect but as a primary vector of reflection and transformation. The asymmetrical distribution of initial budgets sparked humour, frustration, and pride; the subsequent redistributive intervention triggered surprise in some groups and resentment in others. Rather than downplaying these emotions, facilitators framed them as learning opportunities, inviting pupils to examine their reactions and articulate connections between personal feelings and principles such as fairness, responsibility, and solidarity. These affective dynamics reinforced the ethical foundations of the experience and mirrored the kind of value-based negotiation found in real-world planning processes.

As pupils advanced through the design and evaluation phases, this reflective capacity deepened. When comparing remaining budgets and environmental tokens, students collectively evaluated the outcomes of their decisions not in terms of competition, but mutual improvement. Each team succeeded in meeting the pedagogical requirements addressing at least three SEN profiles, staying within budget, and reducing ecological impact. The final presentations reinforced a culture of shared learning and peer recognition. The result was a shift in classroom dynamics: from individual achievement to collaborative responsibility.

Three pedagogical strengths emerged clearly. First, high levels of sustained engagement: even typically less vocal students remained deeply involved throughout the workshop, forming strong attachments to the needs of "their" users and the success of "their" proposals. Second, the emergence of justice-oriented thinking: pupils began to spontaneously reference equity-based principles such as "fair shares of shade" or "step-free access," revealing the internalisation of inclusive spatial reasoning. Third, inventive capacity under constraint: when challenged by tight budgets and spatial limitations, students produced innovative hybrids—like a pergola that doubled as a sensory retreat—regarded by teachers as exceeding the expected outcomes of standard de-

sign-and-technology curricula.

Alongside these achievements, the pilot also revealed areas for future refinement. A central limitation concerned the documentation of reasoning. Although the negotiation processes were often rich in dialogue and deliberation, much of this was only partially recorded through facilitator notes. Future versions could benefit from integrating tools such as video recordings or structured logbooks to capture the full depth of students' decision-making. Another challenge relates to the game's localisation: while the use of the actual school site enhanced engagement and realism, it also constrained replicability. Addressing this tension will require context-sensitive adaptations—such as replacing the site map with locally relevant public spaces, adjusting economic parameters to reflect regional conditions, and aligning user profiles with national SEN frameworks—to ensure that the pedagogical intent is preserved across diverse socio-cultural settings.

At a broader level, the Game offers a compelling model for translating academic research on cohesion policy, sustainability, and spatial justice into accessible, impactful educational experiences. By employing intergenerational co-design, role-based collaboration, and material proxies for territory, money, and ecology, the game renders abstract planning dilemmas concrete and emotionally resonant. In doing so, it fosters deliberative, imaginative, and ethical competences—skills that are foundational for civic agency and long-term democratic participation.

The decision to use a serious game format is not incidental, but central to the project's pedagogical strategy. Games situate learning in embodied, interactive, and emotionally charged environments, turning abstract concepts into negotiated realities. Within the REPLACE workshop, pupils did not passively absorb content but actively co-constructed meaning, experimenting with choices, negotiating trade-offs, and collaboratively building scenarios. The game thus functioned as a microcosm of territorial governance, where scarcity is felt, roles are distributed, and every spatial decision becomes simultaneously technical and ethical.

This design is grounded in multiple pedagogical traditions. Mezirow's theory of transformative learning is evident in how pupils confronted disorienting dilemmas that challenged their assumptions about justice and responsibility. Wals and Corcoran's vision of sustainability education as experiential, participatory, and action-oriented is embedded in the game's structure, which obliges players to balance environmental, social, and financial factors. Finally, Gruenewald's critical pedagogy of place is realised in the spatial immediacy of the game board—a real map of the school grounds—which reframes space not as a neutral backdrop but as a site of social negotiation.

Within the broader framework of the REPLACE project—which investigates governance and territorial cohesion at the European scale—the workshop stands as a concrete micro-level enactment of these themes. It enables children to "live" the concepts of spatial justice, rather than merely hear about them, and to explore how collective agency can shape public space. The result is not only a model for future replication, but a pedagogical prototype for engaging schools as active laboratories of democracy, where planning literacy becomes a tool for inclusive citizenship.

6. From Simulation to Action: Future Developments and Scaling Potential

The REPLACE project was conceived as a multi-level initiative that interweaves territorial governance, educational innovation, and civic engagement. At its core, the project aims to translate abstract policy constructs—such as spatial justice, sustainability, and territorial cohesion—into concrete, participatory experiences across diverse educational levels and socio-territorial contexts. Among its most impactful outputs, the game-based workshop for primary schools has proven particularly effective in disseminating these concepts through co-design, experiential learning, and inclusive urban literacy. This immersive approach not only fosters foundational planning competences among young learners, but also positions universities as agents of civic imagination and transformation.

In 2025, the project enters a new developmental phase through the launch **of VIBES – Visioni Innovative per un BEne comune nella Scuola**, a participatory initiative targeted at upper secondary students of the Spinelli School.

Building on the pedagogical groundwork laid in the primary-level pilot, VIBES shifts from simulated planning exercises to real-world spatial interventions. It adopts a project-based learning methodology that invites students to critically reinterpret and redesign their school courtyard, engaging directly with the social, environmental, and spatial dynamics of their everyday surroundings.

Structured in three progressive phases—Contextual Exploration and Data Collection, Collaborative Design and Scenario Building, and Project Presentation and Community Engagement—the initiative guides students from situated inquiry to actionable spatial strategies. Supported by researchers from the Politecnico di Milano, participants translate empirical data[4] into design proposals aligned with the principles of equity, sustainability, and cohesion. These proposals are then shared with the broader school community and local stakeholders, fostering intergenerational dialogue and civic visibility.

The VIBES initiative reinforces the longitudinal ambition of REPLACE by extending its core learning objectives (systems thinking, spatial literacy, and democratic participation) across developmental stages. It exemplifies how school environments can evolve from passive spaces of instruction into active sites of civic agency and collaborative design. In this way, education becomes not only a process of knowledge transmission but a platform for public action.

Taken together, the REPLACE project and its expansion through VIBES articulate a robust model for integrating research-driven pedagogy with societal relevance. By embedding abstract concepts within participatory, place-based frameworks, these initiatives demonstrate how schools can serve as laboratories of democracy and how academic research can animate civic life. As parallel efforts across Europe[5] are beginning to show, cultivating the capacity of younger generations to design more inclusive and sustainable spaces is not merely aspirational, it is essential for addressing the socio-environmental urgencies of our time.

Conclusions

This paper has presented the REPLACE project as an innovative model of research-driven pedagogy that bridges academic research, civic engagement, and educational transformation. Through its focus on spatial justice, territorial cohesion and sustainability, the project exemplifies how universities can extend their mission into the public sphere by developing participatory, place-based learning experiences.

The discussion began by situating the REPLACE research extension's activities within the broader framework of the University's Third Mission, underscoring its orientation toward knowledge dissemination and societal impact beyond traditional academic boundaries. It then examined the conceptual development of The REPLACE Game, a pedagogical board game designed to translate complex policy ideas into accessible, experiential learning for primary school pupils. The workshop's implementation and facilitation strategy was analysed in detail, highlighting how co-design, role-play, and structured simulation fostered civic imagination, ethical reasoning, and spatial literacy.

4 Empirical data refers to a digital questionnaire which has been submitted to school mates, school workers and inhabitants in order to investigate the issue of the school courtyard's renewal

5 See, for example: La Città dei Bambini by Francesco Tonucci, an international initiative active in over 200 cities worldwide, which establishes Children's Councils to involve young citizens in urban planning and governance, promoting child-friendly city designs; the Youth Engagement Programme in London, which collaborates with schools to engage students in real urban development projects through workshops with architects and planners, fostering early civic involvement; Helsinki's Nuortenbudjetti, an annual participatory budgeting process where youths aged 12–17 propose and vote on the allocation of approximately €150,000 for youth services, empowering them in municipal decision-making; and the Our Cities project, an Erasmus+ initiative led by the Hill School in Athens, engaging primary school students in exploring their urban environment, identifying infrastructural challenges, and collaboratively designing models of ideal cities, thereby cultivating active citizenship and spatial awareness from an early age.

Subsequent sections explored the workshop's **transformative learning** outcomes. Pupils demonstrated not only increased spatial awareness and mathematical reasoning, but also developed empathy, teamwork, and environmental consciousness. Emotional responses and ethical dilemmas were not incidental but central to the learning process, catalysing reflection and value-based decision-making.
The final part presented future developments, particularly the VIBES initiative, which expands the REPLACE methodology to the secondary school context. Through real-world design challenges and community engagement, this new phase furthers the project's commitment to building civic capacity across educational levels.

Taken together, the REPLACE game and VIBES initiatives align with the principles of critical pedagogy, as articulated by Paulo Freire (1970) and Ivan Illich (1971). Freire's emphasis on education as a practice of freedom, where learners critically engage with the world to transform it, is incorporated in the research extension's activities provided by REPLACE and its dialogic and participatory structure. Similarly, Illich's vision of deschooling society and reclaiming education as a cooperative, learner-driven act echoes in REPLACE's challenge to traditional instructional hierarchies and its relocation of learning into real, contested, spatial environments, as suggested by its transformative educational initiative.

In sum, the REPLACE project offers a replicable, scalable model for integrating research, teaching, and civic responsibility. By aligning academic knowledge with critical pedagogy, it demonstrates how schools can become laboratories of democracy and how educational institutions can cultivate the competences and critical awareness required to address today's most pressing socio-spatial and environmental challenges.

Abstract
«SMART Cities» and its applications represent a high level of complexity, including the skills required for urban solutions based on new models of education, research and policy framework design. This paper elaborates a specific model named UBT "SMART City" (Small Scale Smart Sustain System) which represents an Entrepreneurial Innovation Ecosystem, which could also be used as a Test-Bed for Future and Innovative Urban Planning with a particular focus in education, future-planning concepts and emerging technologies. Located in an Area of 30.000 m^2, the model is the state-of-art Development Program, designed and developed by at University for Business and Technology (UBT), with the aim to modernize and integrate the sustainable and SMART planning, community living standards, advanced technologies, education, innovation and economic and social impact.

Keywords: Smart Cities; Emerging Technologies; Transformative Urban Planning; Sustainable Development; Innovation Ecosystem

1. Introduction and Theoretical Background

• The evolving needs in urban planning education

Higher education institutions play a critical role in advancing urban sustainability. Universities and colleges not only educate the next generation of leaders, planners, and professionals but also serve as hubs for research, innovation, and policy development. They are in a unique position to lead by example, demonstrating sustainable practices through their operations and campus management. Many universities have begun integrating sustainability into their curriculum, offering specialized courses, degrees, and certifications focused on environmental science, sustainable development, and urban planning. These programs equip students with the knowledge and skills needed to address complex sustainability challenges. Additionally, interdisciplinary approaches that combine aspects of engineering, economics, sociology, and environmental studies provide a holistic understanding of sustainability issues.

Research conducted within these institutions is invaluable for the advancement of urban sustainability. By exploring new technologies, materials, and methods, academic research can drive significant progress in areas such as renewable energy, sustainable architecture, and waste management. Universities can also influence policy by providing evidence-based recommendations to government bodies and urban planners.

Moreover, colleges and universities often act as microcosms of larger urban systems, where sustainable initiatives can be tested and refined. From energy-efficient buildings and sustainable transportation options to waste reduction programs, the sustainable practices implemented on campuses can serve as models for broader urban applications.

• The role of education and innovation ecosystems in future cities

Education and innovation ecosystems are crucial in shaping the sustainable, inclusive, and resilient cities of the future. As urban areas increasingly face multifaceted challenges—ranging from climate change and resource scarcity to demographic shifts and governance complexity—the need for well-informed, interdisciplinary, and technologically adaptive urban professionals is greater than ever (OECD, 2020).

Urban Planning Education (UPE) has undergone significant reform since the 1990s, moving beyond technocratic models of environmental management to embrace a sustainability-driven and participatory paradigm. Inspired by global frameworks such as the **Brundtland Report** (WCED, 1987), the **New Urban Agenda** (UN-Habitat, 2016), and the **2030 Agenda for Sustainable Development** (UN, 2015), modern UPE integrates principles of ecological integrity, equity, collaborative governance, and innovation. Contemporary curricula emphasize competences such as strategic foresight, anticipatory thinking, stakeholder negotiation, ethical reasoning, and systems-based problem solving—skills essential for planning in rapidly changing and culturally diverse environments (Friedmann, 1996; Gunder, 2010; D'Alessandro & Zuluaga, 2022).

At the heart of these efforts lies the integration of education with innovation ecosystems. Universities function as living laboratories and microcosms of cities, offering real-world contexts for testing sustainable solutions—from energy-efficient buildings and zero-waste systems to smart mobility networks (Cavada et al., 2016). Innovation ecosystems surrounding HEIs—including research institutes, start-up incubators, policy labs, and civic tech platforms—facilitate cross-sector collaboration, enabling the development and scaling of technologies that advance urban sustainability (Etzkowitz & Leydesdorff, 2000; Carayannis & Campbell, 2009).

The rise of advanced technologies—such as **Artificial Intelligence (AI)**, **Extended Reality (XR)**, the **Internet of Things (IoT)**, and **digital twins**—is redefining the possibilities of urban design, governance, and engagement. AI is increasingly used in predictive modeling, urban analytics, and optimizing resource management (Batty, 2018), while XR technologies (augmented and virtual reality) are transforming the way urban plans are visualized, communicated, and co-created with communities (Portman, Natapov & Fisher-Gewirtzman, 2015). These tools enhance spatial awareness, participatory planning, and scenario simulation, making urban development more inclusive and data-informed (Alizadehsalehi et al., 2020).

Education plays a critical role in equipping future professionals with the technical literacy and ethical frameworks needed to responsibly harness these technologies. Pedagogical approaches are evolving toward **learner-centered, experiential, and transformative models**. **Education for Sustainable Development (ESD)** promotes critical thinking, self-awareness, and systemic understanding, empowering learners to become agents of change (Sterling, 2001; UNESCO, 2017). Incorporating digital tools and immersive technologies into teaching methodologies not only enhances engagement but also fosters interdisciplinary collaboration and creativity (Mulder, 2017).

The paper frames current human development within the convergence era and the Fourth Industrial Revolution (4IR), characterized by the blending of physical, digital, and biological technologies. This era demands interdisciplinary approaches and transformations across political, social, economic, and technological systems, emphasizing sustainability, innovation, and resilience. Cities are viewed as complex adaptive systems requiring integrated governance and policy frameworks. Smart Cities are presented as ecosystems that integrate advanced technologies like IoT, AI, and 5G with urban infrastructure to improve efficiency, quality of life, and sustainability. UBT's Smart City model exemplifies this trend by combining technology, education, and community engagement in an innovation ecosystem that serves as a living lab for sustainable urban solutions.

Despite these promising frameworks, several challenges persist. Small-scale ecosystems such as UBT's Smart City testbed encounter limitations related to resource constraints, scalability, and complexity management. The intricacies of urban systems—spanning infrastructure, governance, and socio-economic factors—require adaptive and multi-level governance approaches to effectively manage complexity and scale innovations beyond localized pilot projects (Batty et al., 2012; Kitchin, 2014).

However, these limitations also offer unique opportunities. Testbeds like UBT's Smart City can serve as models for policy transfer, regional replication, and cross-border learning, especially in contexts of emerging economies where scalable smart city solutions are urgently needed (Albino, Berardi & Dangelico, 2015).

In the context of planning education, UBT's integrated Smart City initiative underscores the critical role of higher education institutions as catalysts for sustainable urban development and social innovation. The initiative's experiential learning environment equips future planners with competencies essential for navigating the complexity of smart urbanism, including systems thinking, anticipatory governance, and multi-stakeholder negotiation skills (Wiek et al., 2011).

Looking ahead, the future outlook for smart city development at UBT involves expanding the testbed's technological infrastructure, scaling pilot innovations to regional urban environments, and deepening partnerships among academia, government, and industry. This evolution will support the broader diffusion of data-driven governance practices that enhance urban resilience and inclusivity, thereby positioning UBT as a regional leader in smart city research and policy influence (Neirotti et al., 2014; Nam & Pardo, 2011).

2. SMART Cities: Concept, Definitions, key dimensions

By 2050, it is estimated that roughly 70% of the world's population will live in cities. With more citizens to serve, and a climate that is rapidly degrading, public service efficiency and effective resource-usage are becoming pressing issues for cities. In this context, ensuring sustainable development and quality of life in complex social ecosystems of cities and urban areas are important concerns. Cities are increasingly aware of the concept of "smart city" and are actively developing strategies towards the goal of becoming "smart" and manage city resources more efficiently while addressing development and inclusion challenges. To understand the concept of smart city, we begin with understanding the conceptual relatives of the model. Although limited in scope, they set the theoretical framework for the holistic notion of the smart city currently understood by the urban planning sphere. The notion of smart city is established from the combination of the knowledge society and digital city. It is defined as a "multi-layer territorial system of innovation" made up of digital networks, individual intellectual capital, and the social capital of the city, which together constitute collective intelligence (Komninos, 2008). Economic competitiveness and innovation achieved through the knowledge-based economy marks a city as intelligent, allowing it to generate a "spatial competitive advantage" through industrial districts, regions, and learning clusters that produce sophisticated R&D and are supported by digital networks and artificial intelligence (Komninos 2008). Based on the exploration of a wide and extensive array of literature from various disciplinary areas, the identified factors– Social, Management, Economy, Environment, Technology, Sustainability, (SMEETS) forms the basis of an integrative framework. This comprehensiveness is the distinguishing factor of the smart city, which integrates a number of physical, institutional, and digital components to create a holistic definition of what smart planning would look like.

• Pillars of Smart City

The structure of smart city is widely comprised by six pillars, namely 1) Social; 2) Management, 3) Economy; 4) Environment; 5) Technology; and 6) Sustainability.

At its core, a smart city framework leverages from the existing legal, economic and technical environment and impacts the social and management aspects in a sustainable manner. Setting a smart city vision and effectively moving towards it with a systems-based approach is imperative to ensure optimum resource efficiency and security, along with preserving socially inclusive growth. Drawing on the literature and the factors considered above, we have conceptualized an integrative framework that explains the relationships between these factors in a more coherent fashion. We have named it as SMEETS framework (Social, Management, Economy, Environment, technology and Sustainability. Each of these factors enables both the public and private sectors to plan and implement Smart City initiatives more commendably. These elements provide a basis for matching how different cities are envisaging their smart initiatives, employing shared services, and the related challenges. This framework also analyses the actual impact of different factors on the success of smart city initiatives. The framework

indicates that each factor is both affecting and getting affected by each other factor. It also indicates that some factors may be more influential than the others depending on the context. The framework can be bifurcated in two levels. The inner level consists of the factors, which have greater impact on the smart city initiatives. This also consists of technology, which is the foundation of smart cities. The outer level factors are the ones, which might get influenced by the inner level before impacting the smart city initiatives. This includes governance and the socio balance of the community apart from sustainability, which should be the basis of any development.

Fig.1. Smart City Framework

A contextually adapted and citizen-centric approach [2], using both human and technological resources, can bring multiple benefits for municipalities, particularly those that are struggling with specific problems - such as inefficient waste management systems, lack of civic participation, or traffic and congestion.

• Definitions and Terminology

A **smart city** is an urban area that uses different types of electronic Internet of things (IoT) sensors to collect data and then use these data to manage assets and resources efficiently. This includes data collected from citizens, devices, and assets that is processed and analyzed to monitor and manage traffic and transportation systems, power plants, water supply networks, waste management, crime detection,[1]information systems, schools, libraries, hospitals, and other community services.[2][3][page needed]

The smart city concept integrates information and communication technology (ICT), and various physical devices connected to the IoT network to optimize the efficiency of city operations and services and connect to citizens.[4] [5] Smart city technology allows city officials to interact directly with both community and city infrastructure and to monitor what is happening in the city and how the city is evolving. ICT is used to enhance quality, performance and interactivity of urban services, to reduce costs and resource consumption and to increase contact between citizens and government.[6] Yet, the term itself remains unclear to its specifics and therefore, open to many interpretations.[10]

Terminology

Due to the breadth of technologies that have been implemented under the smart city label, it is difficult to distill a precise definition of a smart city.

Deakin defines the smart city as one that utilizes ICT to meet the demands of the market (the citizens of the city),

and that community involvement in the process is necessary for a smart city.[27] A smart city would thus be a city that not only possesses ICT technology in particular areas, but has also implemented this technology in a manner that positively impacts the local community.

• Characteristics
It has been suggested that a smart city (also community, business cluster, urban agglomeration or region) uses information technologies to:

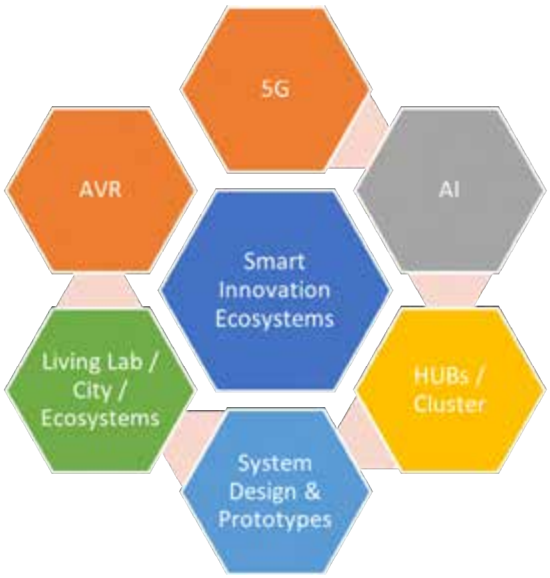
1. Make more efficient use of physical infrastructure (roads, built environment and other physical assets) through artificial intelligence and data analytics to support a strong and healthy economic, social, cultural development.[36]
2. Engage effectively with local people in local governance and decision by use of open innovation processes and e-participation, improving the collective intelligence of the city's institutions through e-governance,[7] with emphasis placed on citizen participation and co-design.[37][38][39]
3. Learn, adapt and innovate and thereby respond more effectively and promptly to changing circumstances by improving the intelligence of the city.[7][40]

According to David K. Owens, the former executive vice president of the Edison Electric Institute, two key elements that a smart city must have are an integrated communications platform and a "dynamic resilient grid." Both are large investments.[46]

3. The UBT "SMART City" Concept
In the context of smart city development, focusing on the functions of everyday urban life is essential to understanding how new technologies and integrated approaches transform living spaces. A unique example in this regard is the **"UBT Smart Self-Sustain System"**, developed by the University for Business and Technology (UBT) in Kosovo. This model represents an innovative and holistic approach aimed at creating a **"city of knowledge"**—an environment where education, technology, healthcare, employment, housing, and community life are intertwined in an integrated ecosystem.

Since its beginnings UBT has always followed the current technological and socio-economic trends and developments, while in certain situations it has taken the leading roal towards future oriented solutions and forward-looking initiatives. In these terms, UBT now bases its scientific, research, teaching and innovation activities on the UNIVERSITY 4.0 Concept, by integrating Fully Digitalized Research and Education Process, CLASSROOM 3.0, Augmented and Virtual Reality (AVR) and 5G Telecommunication Network in its main Innovative and Scientific Campus in Lipjan/Kosovo and its other campuses and premises around Kosovo. The campus has been designed and developed around the small-scale smart city concept by covering all fields of life occurring in an open campus.

UBT Model for Fylly Smart based University is fellow:



This model integrates Smart Systems, Resilience and Sustainability, also the concept of Society 5.0.

At the core of this concept lies the idea of transforming traditional urban functions through advanced technologies and practical learning. This **smart ecosystem** includes more than **150 fields of study**, **300 laboratories**, and a network of **80 functional companies** where students actively engage throughout their studies. **Practical experience and real-world learning** are embedded in every aspect of life, creating a new model for education and professional training.

Urban life functions—such as education, employment, technology, healthcare, public services, culture, and social infrastructure—are integrated into this system. For instance, in the field of healthcare, UBT has built a functional hospital and polyclinic, while in technology, it operates software companies and 5G networks. In the media field, the university has its own radio, television, and news portal, enabling students to directly participate in media content production and digital platform development. Another important aspect of this model is the use of advanced technologies such as **5G, artificial intelligence, virtual reality, robotics, cloud computing, and laser technologies**. These technologies are not only present in laboratories or classrooms but are part of the campus's daily life, offering an integrated learning and working experience. Students learn by solving real-world problems, participating in concrete projects, and collaborating with industry experts, transforming the campus into a **living urban ecosystem**. This system not only meets the demands of modern education but also generates **thousands of new jobs every year**, ensuring a seamless transition from education to employment. The integration of technology, professional practice, and core urban life functions makes this model valuable for study in the context of smart cities, where **innovation, social inclusion, and economic development** converge to create a **sustainable and livable environment**. This approach challenges traditional models of education and urban development, proposing a new paradigm that can inspire the cities of the future.

4. Physical and Technological Components

Campuses and Premises

UBT operates across multiple locations, with main campuses in Prishtina and Lipjan, and branches in Prizren, Gjilan, Ferizaj, and Peja. Its total campus area spans approximately 65,000 m², covering open spaces, green areas,

and parking, with major facilities including the Innovation Campus, City Center Campus, and University Hospital Campus. UBT is home to a community of 15,000 members, comprised by students, staff, and third part community.

To better address emerging needs of physical and operation transformation, UBT has developed its Institutional Strategy and Action Plan for a Green, Carbon-Neutral and Smart Campus. The project focuses on nine key Initiatives, namely: Clean Energy, Building green, Getting around, Sustainable water management, Good food, Zero plastics, Smart technologies, Sustainable landscape, and Print responsibly. The given Initiatives-directly linked with certain SDGs- and related actions & project are briefly summarized below:

Clean Energy / Switch to Renewables: From 252 kWp of electricity need for its campus and premises, UBT premises are generating 50 % of it (126 kWp) from already installed solar panels – and thus from renewable resources. Currently, the institution is looking forward install the rest of panels needed to generate 100 of its electricity by solar panels. This will make the campus and its premises a 100 % renewable energy-based campus.

Building Green/Green Building: The Initiative of "Building green" emphasizes the need for sustainable construction practices and ongoing maintenance to ensure that buildings remain environmentally friendly over time. By incorporating sustainable design, choosing eco-friendly materials, implementing energy-efficient systems, incorporating renewable energy sources, and establishing an ongoing maintenance plan, our campus can create buildings that have a positive impact on the environment and contribute to a green future.

Getting Around / Biking and Walking: Promoting non-motorized transportation options will reduce carbon emissions and foster a healthier lifestyle by developing a campus Master Plan, installing bike racks, implementing a bike share program, promoting biking and walking events, and integrating with public transport.

Never Waste a Drop / Sustainable Water Management: By conducting a water audit, implementing water-efficient fixtures and appliances, implementing rainwater harvesting and greywater recycling systems, improving landscape irrigation practices, and educating and engaging the campus community, UBT campuses are reducing water consumption, conserve resources, and minimize environmental impact.

Good Food, Healthy Planet / Zero Food Waste Campus: By implementing a sustainable sourcing policy, implementing portion control and food recovery programs, implementing a composting program, educating and engaging the campus community, and measuring and monitoring food waste, UBT campuses can contribute to a healthier environment and support a carbon-neutral future.

Zero Plastics, Zero Waste/Single-Use Plastic Free Campus and Minimization of Disposable Items: By implementing a ban on single-use plastics, promoting reusable items, establishing recycling and composting stations, organizing waste reduction and recycling programs, and educating and engaging the campus community, UBT campuses are going to significantly reduce their reliance on disposable plastic products and move towards a Zero Waste future.

When it comes to Principle 6.1- **Minimization of Disposable Items,** it particularly emphasizes reducing the reliance on single-use items in campus' everyday activities, with a particular focus on various faculties, including Medicine and its branches, Nursing, Agriculture and Environmental Engineering, and Food Processing and Biotechnology. This involves identifying alternatives, implementing recycling programs, and promoting responsible usage to minimize waste and promote sustainability. In conclusion, Minimization of Disposable Items underscores the importance of reducing reliance on single-use items in various faculties, including Medicine and its branches, Nursing, Agriculture and Environmental Engineering, and Food Processing and Biotechnology.

Adopting Smart Technologies/AVR: Integration of smart technologies will enhance efficiency, sustainability, and learning experiences by integrating smart building systems, incorporating AVR technologies, implementing IoT

solutions, promoting remote learning, and developing smart campus initiatives.
Sustainable Landscape / Open and Green Areas: The Initiative of "Sustainable Landscape / Open and Green Areas" focuses on creating and maintaining outdoor spaces that are ecologically sustainable and enhance the quality of life on campus. This approach emphasizes using native plants, conserving water, promoting biodiversity, and providing areas for relaxation and recreation.

Print Responsibly/Save the Planet: The Initiative of "Print Responsibly / Save the Planet" emphasizes the need to reduce paper consumption and minimize the environmental impact of printing activities on campus. By promoting responsible printing practices, campuses can conserve resources, reduce waste, and contribute to a more sustainable and Eco-Friendly environment.

The Institution is already implementing all mentioned initiatives, with most of them being fully implemented, and with the rest of initiatives being particularly addressed. Thus, this project proposal contains four important dimensions, namely as following:

a) Description of Green and Carbon Neutral Campus Initiative in context of Institution's long term and strategic orientation
b) Elaborating nine initiatives for making our campus Green, Carbon-Neutral and Smart, including concrete projects to be implemented and actions to be performed
c) Identifying concrete steps, actions and projects that are put in place already
d) Identifying ongoing actions and projects in order to fully implement Institution's initiatives and objective for making its campus Green, Carbon-Neutral and Smart.

Applying Crisis Management Principles in real life and university's everyday operations
The University for Business and Technology (UBT) has developed a robust framework for Institutional Crisis Management, encompassing resilience, economic and financial stability, and technological safeguards. This multi-dimensional strategy ensures UBT's preparedness for diverse challenges, aligning with its commitment to sustainability, operational continuity, and global excellence. Central to this approach are the following pillars: **a) the Sustainable Campus Resilience Program (SCRP); b) an Integrated Program for the Resource Diversification** and **c) Cyber Security Measures Package**- with the triplet integrating environmental sustainability, economic diversification, and technological innovation into a cohesive crisis management model.

UBT strengthens institutional adaptability through resilience-focused initiatives such as the Climate Crisis Response Team, renewable energy implementation, and comprehensive sustainable practices. These efforts align with the Sustainable Development Goals (SDGs), fostering environmental stewardship and institutional readiness for crises, including natural disasters and infrastructure disruptions. UBT continuously evolves its resilience strategies to address emerging risks, ensuring adaptability in a dynamic global landscape. To safeguard economic stability, UBT diversifies its income sources through over 100 Spin-Offs, international research projects, and sustainable procurement practices. These initiatives generate sustainable revenue while providing practical learning opportunities for students and bridging academia with industry. In the technological domain, UBT prioritizes cybersecurity by establishing a Computer Emergency Response Team (CERT), investing in secure IT infrastructure, and incorporating advanced technologies like artificial intelligence for threat detection. The institution's three-pronged strategy—readiness, response, and recovery—ensures robust defenses against evolving digital threats.

Resilience: Strengthening Institutional Adaptability through the Sustainable Campus Resilience Program (SCRP):
Resilience is the cornerstone of UBT's crisis management strategy, enabling the institution to adapt and thrive amidst adversities. UBT's SCRP drives this adaptability by addressing critical dimensions of environmental sustainability and climate crisis management through initiatives such as:

• **Climate Crisis Response Team:** A dedicated team of experts prepared to address environmental risks and enhance institutional readiness. Their task include producing strategic documents and follow-ups of the fulfillment of the strategic objectives of these documents by aligning those with university's everyday operations and practices.

• **Institutional Strategy on Implementing and Promoting SDG-s**: The University has developed an extensive university strategy for dealing with the 17 Sustainable Development Goals (SDGs)- a comprehensive and integrated approach that aims to ensure that the university plays an active role in promoting sustainability across its operations, research, curriculum, community engagement, and institutional culture.

• **Renewable Energy Solutions:** Implementation of solar panels and other renewable technologies to transition UBT's campuses towards carbon neutrality.

• **Sustainable Practices:** Comprehensive recycling programs, water conservation initiatives, and promotion of non-motorized transportation options to minimize environmental impact.

• **Smart Building Practices:** Adoption of advanced technologies for energy efficiency, resource management, and user comfort across all UBT campuses. This includes integrating smart lighting systems, energy monitoring tools, and automated climate control to optimize resource utilization and create sustainable learning environments.

• **Education and Awareness:** Integration of resilience-focused modules into academic curricula, fostering a culture of preparedness and environmental stewardship among students and staff.

Economic and Financial Stability: Diversification as a Shield
UBT recognizes the critical importance of financial resilience in navigating economic disruptions. To this end, the university has adopted a multi-faceted approach to diversify its income sources and mitigate financial risks. Key initiatives include:

• **Spin-Off Ecosystem:** UBT has established over 100 Spin-Offs that generate sustainable revenue while providing valuable services such as business incubation, strategic consulting, ICT solutions, and engineering projects. These Spin-Offs also offer students practical learning opportunities, bridging the gap between academia and industry.

• **International Projects Office:** By participating in and managing international research and development projects, UBT secures funding to support its strategic objectives and operational needs.

• **Sustainable Procurement Practices:** Integrating sustainability criteria into procurement and supply chain management ensures responsible business practices and enhances economic stability.

• **Financial Contingency Planning:** UBT has developed comprehensive financial strategies to address potential enrollment fluctuations due to demographic challenges like migration and low population growth.

UBT's financial resilience strategy is bolstered by its focus on long-term planning and resource optimization. The institution continuously identifies new opportunities for revenue generation, such as partnerships with industry leaders, regional economic collaborations, and consultancy services tailored to public and private sector needs.

Technological Stability and Cyber Security: Safeguarding the Digital Future
In an increasingly digital world, technological stability and cybersecurity are essential components of UBT's crisis management framework. The university's approach includes:

• **Computer Emergency Response Team (CERT):** A specialized team dedicated to monitoring, preventing, and responding to cyber threats.

• **Secure IT Infrastructure:** Investment in secure and resilient systems to support online education, administrative operations, and research activities.

• **Continuous Monitoring and Training:** Regular simulation exercises and training programs to prepare staff and students for potential cyber crises.

• **Promoting Cyber Hygiene:** Educating the UBT community on best practices for safeguarding digital assets and maintaining vigilance against cyber risks.

UBT's cyber strategy is structured around three pillars: readiness, response, and recovery. This ensures the institution remains secure, vigilant, and resilient against evolving technological threats.

UBT has also integrated advanced technologies such as artificial intelligence and machine learning into its cybersecurity measures, enhancing its ability to predict, detect, and neutralize threats in real time. Additionally, the university collaborates with global cybersecurity experts to stay ahead of emerging threats and adopt best practices.

Entrepreneurship

Entrepreneurship and Innovation are priorities within UBT and due to this fact, UBT has managed to create Innovations that have created a long-standing impact on society and that include large ecosystems of knowledge that bring the best and most popular practices of the world to Kosovo. A majority of these practices are the first in the Western Balkans and beyond. UBT's approach to entrepreneurship and innovation is completely different from traditional approaches. By providing many opportunities for students, staff, industry, third parts, and the wider community to develop their ideas and entrepreneurial skills and by enabling them to incubate, grow and get into the market. UBT has constantly invested in developing new education and business venturing concepts, focusing also on creating an environment conducive to entrepreneurial activity that also fosters and inspires the entrepreneurial spirit. Advising and mentoring students, staff, industry, third parts and wider community throughout projects that can be funded donors and industry is an effective method and we expect to further strengthen

So far, more than 30 impactful innovations have been generated, and more innovative projects are being developed and expected to make significant impact for our students, partners, relevant stakeholders and the wider community. These initiatives include developing a **Full-Scale Entrepreneurial Ecosystem** which cultivates a culture of innovation and entrepreneurship within emerging technologies like augmented reality (AR), AI etc. The given ecosystem encourages cross-disciplinary collaboration to turn ideas and research into real-world applications, and supporting startups that arise from the university's incubation programs. In this regard, beside establishing **more than 100 Spin-Offs**, UBT has also established the first innovative center in the region, named **"UBT Accelerator"**. Opened in the Innovative Science Park of UBT, this Accelerator has been in the service of students, staff, industry, and wider community for the development of creative, innovative ideas and the creation of technological advantages.

Furtherly; based on its strategic commitment to foster and support entrepreneurship, UBT has undertaken the following initiatives and has performed the following projects **UBT Start-Up School; 5G Technology Test-Bed; Center of Virtual and Augmented Reality; Artificial Intelligence Lab**, Internet of Things (IoT) Lab, Robotics and Industrial Automation; UBT Smart City Small-Scale Ecosystem; **National Cyber Security and Resilience Lab**; **UBT Research Hubs**; **UBT Junior Hub**; UBT Sport, E-Sport & Art Hub; **UBT Innovation and Technology Hubs**; UBT Knowledge Hub; Tailored Manufacturing and Services; Remote/Contactless Delivery Services; **Creativity Industry Hub;** Central Testing Hub; Smart, Green and Carbon-Neutral Campus; UBT EdTech; UBT Digital Innovation Hub; **National**

Public Policy Simulation Lab; UBT Integrated Media Center; **UBT GIS and Spatial Data Infrastructure Center; UBT High Schools**; **UBT Professional Schools**; Virtualization based Delivery Services; UBT Community Services; **UBT Integrated Health Care Services**; UBT University 4.0; **UBT Go International**; **UBT Science and Technology Park** etc.

When it comes to Spin-Off-s; the followings are only a few among over 100 Spin-Off-s of UBT: **IEME (**Institute for Enterprise Management and Engineering); **Quality Kosova (**Kosovo Association for Management – member of International Project Management Association and European Organisation for Quality) **CA–CASE (**Kosovo Association for Control, Automation and Systems Engineering – member of International Federation of Automation and Control); **KA-SIM (**Kosovo Association for Modelling and Simulation-Member of EUROSIM European Federation of Simulation Associations); **IES (**Intellectual Excellence Service); **IFC (**International Professional Certification and Evaluation); **UBC (**Budapest Joint Transformative Research Centre- jointly with University of Budapest for Technology and Economics and Szent Istvan University); **EON-UBT (**Joint Excellence Centre of Augmented and Virtual Reality – Immersive Technology); **UBT Institute for Urban Studies and Spatial Planning** etc.

"Hub Revolution Your Start Up" Center: In October 2024, UBT inaugurated this center in collaboration with Italian partners at its Smart City campus in Lipjan. The hub serves as an innovation and professional development center, fostering dialogue between academia and business to facilitate knowledge transfer and entrepreneurship.

Gold Venture Investments Western Balkan: Established in partnership with Israel's GVI Global, this company aims to support startups, public and private enterprises, and the civil society sector across the Western Balkans, contributing to sustainable economic development and international market expansion.

Thus; UBT has been playing a crucial role, both in developing the ethos and systems of a smarter society and giving people hope through supporting their journey to attain qualifications, engage in research, development work or entrepreneurial endeavor. UBT has contributed to enhancing employability prospects and personal fulfilment for various segments of the population availing of our services. The Institution has specifically made a mark in helping Kosovo become a member in international bodies, as such as IPMA, EOQ, IFAC, EUROSIM etc.

When it comes to written statements and public engagement toward entrepreneurship, it is important to refer the UBT Integrated Strategy 2027, which is constituted by the following objectives, among others:

- UBT will foster four challenges to regional and global needs: Caring for our environment: environmental science, design, engineering, architecture and social structure; Promoting wellness in our communities: access and equity in education and health outcomes, community-based participatory research, biomedical sciences and entrepreneurship; Food and fuel security: sustainable food systems, precision agriculture, energy production, transmission and storage; Securing the future: cybersecurity, governance and public policy.
- "UBT College will enhance education of undergraduates and graduate students through increased participation in **research, creative and entrepreneurial activities** by 10% by 2022";
- UBT Students will be encouraged to consider **entrepreneurship as a career option** through extracurricular awareness and taster programs, as well as embedded modules, assignments or dedicated degree programs within the UBT suite of curricula.

The university's establishment of over 100 spin-offs and its proactive role in creating more than 80 business functions reflect the broader economic revitalization efforts in Kosovo. UBT's initiatives, such as the UBT Science and Technology Park and the EON Virtual and Augmented Reality Center, illustrate its commitment to advancing technology and fostering a vibrant entrepreneurial ecosystem.

UBT's growth and impact have been profound. It has become a central player in Kosovo's economy, significantly contributing to the job market and individual sectors. For example, 65% of ICT sector employees hold UBT degrees and over 1,000 jobs are created annually through the UBT Ecosystem – including its Spin-Offs, UBT Alumni and newly-established independent businesses supported by the UBT Accelerator – highlighting UBT's direct and

fundamental contribution to Kosovo's growth. The university's international acclaim, including awards like the "European Young Entrepreneurial University of the Year" and high rankings in global university assessments, underscores its pivotal role in positioning Kosovo as a hub for innovation and skilled labor. This is also a reflection on Prof Hajrizi, who understood the needs of his region and created the right opportunities for its development in key sectors.

8. Impacts and Lessons Learned

The implementation and ongoing development of the UBT "SMART City" model—designed as a Small-Scale Smart Sustainable System—has generated multiple layered impacts, particularly within the fields of education, urban planning, and socio-economic-environmental transformation. These impacts can be summarized as follows:

Educational Impact

The UBT "SMART City" has demonstrated significant educational value by fostering future-ready competencies through the integration of theoretical knowledge and practical skills. The model serves as a vibrant community center for experiential learning and interdisciplinary education, enabling students, academicians, and others researchers to use and benefit from emerging technologies such as AI, IoT, AVR, and digital twins. This environment facilitates **skill development in systems thinking, urban innovation, and digital transformation**, while also promoting **knowledge integration across engineering, policy development, urban planning and design, ICT, and sustainability practices**. By incorporating methodologies such as life-cycle-based design and user-centered approaches, the model cultivates problem-solving capabilities aligned with the demands of the 4th Industrial Revolution.

Urban Planning Impact

From a spatial planning perspective, the UBT "SMART City" provides a **scalable and transferable framework** that models how smart infrastructure and urban services can co-exist in a compact, integrated ecosystem. This approach introduces **new planning tools**, including dynamic land-use systems, place-based innovation ecosystems, and real-time feedback. As such, it contributes to a **cultural shift in planning**, moving from static, top-down approaches to **adaptive urbanism**. The model aligns with global trends toward compact, walkable urban forms—similar to the "15-minute city" which could be replicated in bigger scale of urban environments.

Socio-Economic and Environmental Contributions

The UBT "SMART City" Model lies in its ability to support **entrepreneurship, innovation, and job creation** within a community-centric environment. The embedded innovation hubs, spin-offs, and research centers contribute to local development by supporting knowledge-based economies. Moreover, the integration of **sustainable energy systems, green spaces, water and waste management and recycling** reinforces the model's alignment with climate transition.

Finally, the UBT "SMART City" illustrates the necessity of **multidisciplinary collaboration**, **user involvement**, and **iterative design testing** in smart urban development. As such, the model stands as an innovative model of convergence between **pedagogy, urbanism, and technology**, by offering a replicable paradigm for next-generation urban transformation.

9. Challenges and Opportunities

Small-scale entrepreneurial ecosystems, such as those developed by UBT in Kosovo, face inherent limitations that constrain their growth and broader economic impact. These limitations often arise from constrained financial resources, limited local markets, and underdeveloped institutional infrastructure necessary for innovation scaling (Stam, 2015). Although UBT has generated over 30 impactful innovations and more than 100 spin-offs, the size and economic capacity of the local environment limit startups' potential for sustainable market expansion and scaling (Isenberg, 2011). Moreover, emerging ecosystems typically encounter challenges related to immature regulatory frameworks and insufficient access to venture capital, which restrict the transition of ideas from incubation to commercialization (Spigel, 2017).

Managing complexity within such ecosystems requires effective governance and multi-stakeholder collaboration involving academia, industry, government, and civil society (Cohen, 2006). UBT's model integrates education, research, incubation, and acceleration functions to foster cross-disciplinary cooperation, which is critical in innovation ecosystems (Autio, 2014). However, scaling these systems demands overcoming structural bottlenecks, such as fragmented markets and limited human capital specialized in emerging technologies like artificial intelligence and augmented reality (Mason & Brown, 2014). Furthermore, the presence of multiple innovation hubs necessitates coordinated resource allocation to avoid duplication and ensure ecosystem cohesion (Martin & Sunley, 2011). Investments in infrastructure and capacity building are pivotal to support the adoption and diffusion of new technologies (Feldman & Zoller, 2012).

The experience of UBT's entrepreneurial ecosystem reveals significant opportunities for policy transfer, regional replication, and cross-border learning. Given the socio-economic similarities within the Western Balkans, best practices developed in Kosovo can inform regional policy frameworks to promote entrepreneurship and innovation (Rogers, 2003). UBT's partnerships, such as the Gold Venture Investments Western Balkan collaboration and memberships in international bodies like IPMA and EUROSIM, facilitate knowledge exchange and the harmonization of innovation policies (Bercovitz & Feldman, 2008). Innovation hubs like "Hub Revolution Your Start Up" serve as platforms to foster dialogue between academia and business, enabling replication of ecosystem components in neighboring countries with contextual adjustments (Bathelt, Malmberg & Maskell, 2004). Cross-border learning accelerates ecosystem development by integrating diverse experiences and catalyzing regional innovation clusters (Asheim & Isaksen, 2002).

In conclusion, small-scale entrepreneurial ecosystems face limitations related to market size, funding, and institutional maturity, making complexity management and strategic scaling critical for sustainable growth. UBT's integrated ecosystem approach provides a valuable framework for addressing these challenges. Leveraging opportunities for policy transfer and cross-border collaboration can expand the ecosystem's impact, contributing to economic development and innovation capacity building across the Western Balkans region.

10.Conclusion and Future Outlook

UBT's "SMART City" initiative serves as a crucial testbed for future urban planning, enabling applied experimentation with emerging technologies such as the Internet of Things (IoT), artificial intelligence (AI), and augmented reality (AR) within an integrated urban environment. As Prof. Skender Kosumi emphasizes, this living laboratory approach allows researchers and practitioners to analyze complex urban systems in real time, facilitating the development of scalable, adaptive solutions to pressing challenges like energy efficiency, mobility, and environmental sustainability (Batty et al., 2012; Cocchia, 2014). The UBT SMART City campus in Lipjan exemplifies how testbeds can accelerate innovation diffusion and provide empirical data essential for evidence-based planning (Townsend, 2013).

From an educational perspective, the initiative significantly enriches planning curricula by fostering experiential learning and interdisciplinary collaboration. Engaging students directly with cutting-edge technologies cultivates competencies in systems thinking, data analytics, and participatory governance, skills identified as essential for contemporary urban planners (Wiek et al., 2011; Angelidou, 2015). Moreover, embedding the SMART City concept within an entrepreneurial ecosystem aligns with calls for integrating innovation and sustainability into planning education to prepare graduates for dynamic urban futures (Haughton & Hunter, 2004; Sisson & Stough, 2017).

Key lessons for educators, planners, and policymakers emerging from the UBT experience include the necessity of embedding adaptive, technology-driven frameworks within urban planning and education to respond flexibly to rapid technological advances and complex social dynamics (Caragliu et al., 2011; Dameri, 2013).

Looking forward, the vision for UBT's SMART City involves expanding technological infrastructure, deepening multi-stakeholder collaborations, and scaling pilot projects to influence broader urban areas, thereby enhancing

regional resilience and sustainability (Kitchin, 2014; Nam & Pardo, 2011). UBT's initiative positions the university as a regional leader in smart city research and innovation, fostering cross-border knowledge exchange and contributing to policy formulation beyond Kosovo's borders.

Thus, it is to conclude that UBT's SMART City initiative advances planning education and practice by integrating technology, sustainability, and entrepreneurship in a real-world setting, offering a replicable model for other emerging economies. Its ongoing development promises significant impacts on regional urban transformation, equipping future planners with the tools and mindset to design adaptive, inclusive, and resilient cities (Georges et al., 2020; Angelidou, 2014).

Conclusion: Building a Sustainable Future through Education

The role of education in promoting urban sustainability is multifaceted and far-reaching. From early childhood education to higher learning, from community engagement to leveraging technology and policies, education is the cornerstone of a sustainable urban future.

Investing in sustainability education is an investment in our collective future. It empowers individuals to make informed choices, inspires innovation in sustainable practices, and strengthens communities to work together towards common goals. As we strive to create sustainable cities, the knowledge and values imparted through education will be our guiding light, ensuring that urban development progresses in harmony with environmental stewardship and social well-being.

Contemporary UPE is essentially rooted in the sustainable development paradigm, and its principles are part of the curricula of planning schools throughout the developed world. In the 1990s, the growing significance of the environment exerted a major influence on changes to UPE. Following the Brundtland Report, rising global environmental concerns caused the purpose of planning to shift from the seemingly benign management of environmental change to the explicitly normative goal of achieving sustainable development (Davoudi and Pendlebury, 2010). At this time, it became commonplace to see planning as having to be basically oriented toward solving the needs of society within the framework of sustainable development (AESOP, 1995).

However, there are no common core curricula or even universally agreed guidelines for UPE, and even within Europe, planning schools do not agree on the competences professional planners should have (Frank et al., 2014; Mironowicz, 2015). Although some authors have suggested the development of a uniform Western planning doctrine (Kunzman, 2004), there is a considerable need to adapt planning to local circumstances and to recognise the specific features of the environment in which the planning education curriculum and educational approach are applied (Frank et al., 2014; Mironowicz, 2015). Political and socio-cultural realities and specific environmental and ecological challenges make the contextual grounding of UPE essential.

Sismopoli, playing cities in risk

Giuffrè, M.[1], Benigni M.S.[1], Fontana, C.[1] Tomassoni, V.[1]
[1]Consiglio Nazionale delle Ricerche (CNR), IGAG – Istituto di Geologia Ambientale e Geoingegneria.

Abstract
The limited attention given to risk management in public policy, combined with a lack of awareness among civil society, has led major international organizations to recommend innovative and effective communication strategies. These strategies aim to engage communities in the critical issues shaping our cities, foster interest in the spaces we inhabit daily, and promote a culture of prevention.

This contribution introduces Sismopoli, a serious game focused on seismic risk reduction from an urban planning perspective. The game serves as a tool to make complex issues more manageable and understandable. Its goal is to stimulate knowledge-building processes by encouraging players to view the territory as a common good, where risk reduction is a vital component and planning is the key tool for addressing priority issues in urban contexts.

Keywords: Urban planning, seismic risk awareness, serious games, board games

1. Introduction

Over the past fifty years, Italy has experienced seven major earthquakes—averaging one destructive event every seven years—compared to the national average of one seismic disaster every 4–5 years over the last 150 years (D'Agostino, 2024). This significant seismic hazard is compounded by the high vulnerability of buildings and the considerable exposure associated with Italy's dense population and long settlement history (Dolce et al., 2021; Guidoboni, 2018).

Nevertheless, few resources have been invested in proactive urban prevention policies or in awareness-raising and knowledge dissemination initiatives. As a result, risk management remains largely reactive, focusing on emergency response and reconstruction (Benigni et al., 2024; Balducci et al., 2021; Coviello et al., 2021; Fera, 2020).

The inherent uncertainty surrounding seismic phenomena and their management (Doyle et al., 2019), combined with low public risk perception and widespread gaps in relevant knowledge and skills, are key factors that hinder or delay the implementation of effective risk reduction and mitigation strategies (Crescimbene et al., 2014). Behavioral sciences highlight cognitive limitations among both public decision-makers and the general population, which obstruct political and administrative choices and divert attention from these pressing issues (Di Bucci et al., 2017; Speranza et al., 2019; UNDRR, 2022).

International organizations have strongly emphasized the importance of "understanding disasters," promoting the involvement of civil society and the adoption of both formal and non-formal educational approaches—accessible even to non-experts—to build a culture of safety and resilience at all levels, including professional training (ISDR, 2005). Seven years after the launch of the Sendai Framework (UNDRR, 2015), the 2022 Global Assessment Report on Disaster Risk Reduction further underscores the need to move away from top-down, solely scientific approaches in favor of more participatory, community-based Disaster Risk Reduction (DRR) strategies (UNDRR, 2022). Despite these global efforts, awareness of seismic risk remains limited, particularly at the community level.

In Italy, even with the two-decade experience of the Edurisk project and its significant efforts in seismic risk communication, this topic continues to struggle for attention within scientific education (Musacchio et al., 2023; Faravelli et al., 2024). Developing scientific expertise in risk management—especially in relation to urban areas and planning—is inherently complex, interdisciplinary, and multidimensional. Disasters are not merely the result of natural hazards but are also deeply rooted in human systems; studying their impacts requires examining exposure and vulnerability in urban and territorial contexts. Therefore, planning and urban policy must play a central role in defining how territories are used and transformed to reduce disaster risk.

Italy's higher education offerings in seismic risk reduction remain limited, especially outside of specialized technical fields. This gap in higher education mirrors shortcomings at the secondary school level, which in turn affects public awareness.

Engaging citizens in the core issues that shape our cities—both in everyday governance and in extraordinary contexts—can foster interest in the places we live and stimulate awareness around caring for and protecting seismically vulnerable urban areas. This process encourages a "return to the territory" in the territorialist sense, where the land is viewed as a common good (Magnaghi, 2012, 2020). Ensuring equitable access and safety becomes a fundamental right. In this light, seismic risk reduction should be seen as a collective responsibility tied to the public good, requiring integrated approaches and shared action (Di Bucci et al., 2017).

To shift societal approaches to risk, traditional training must be complemented by innovative educational and communication methodologies that allow people to imagine and reflect on potential urban futures (Hawthorn et al., 2023). Serious games—defined as games designed for purposes beyond entertainment (Abt, 1970)—can serve as effective tools to support learning about critical topics such as risk reduction (Schouten et al., 2017).

This article explores how game-based learning can support interdisciplinary education while enhancing community awareness of risk from an active citizenship perspective. We present Sismopoli, a serious game we have designed and begun testing, which focuses on seismic risk reduction in relation to urban planning. The complexity of this subject area—its scenario-based nature and the dynamics involved—makes it particularly suitable for interactive learning methods. Game mechanics allow participants to explore different scenarios, make decisions, and analyze their consequences.

To this end, the study was set up on three educational interpretative paths, both as a conceptual framework for the analysis of existing serious games, and as a guide for the development and objectives of Sismopoli: educating on i) the care of the territory, ii) the understanding of risk and iii) the promotion of community participation.

The contribution proposes a first review of the state of the educational offer related to risks in Italy and the use of serious games in the field of risk education in urban areas (Chapter 2); an analysis of existing games based on a taxonomy focused on the three key educational paths (Chapter 3); the illustration of the current version of Sismopoli declined in the proposed educational objectives (Chapter 4); the results of the initial experiments (Chapter 5); the conclusions and considerations for further developments (Chapter 6).

2. Serious game for urban seismic risk reduction

In Italy, the topic of risk reduction remains marginal in higher education courses related to urban and territorial planning. Similarly, an urban or territorial perspective is largely absent in the disciplinary fields—such as geology and engineering—where risk-related issues are typically addressed.

A lexical analysis of Italian university curricula, based on the Ministerial Decree of 16 March 2007, reveals that the terms territory and environment, when referring to spatial organization and transformation, appear in the educational objectives of degree programs in Earth Sciences, Environmental Studies, Human Geography, Engineering, Technology, and Planning. However, a closer look at the degree classes that include competencies in urban and regional planning reveals a notable absence of terms such as risk, prevention, soil defense, safety, and emergency. The term hazard is limited to programs in geological sciences, while vulnerability and exposure are not mentioned at all.

This suggests that risk reduction is still largely confined to scientific and technical domains such as geology, geotechnics, and engineering. Urban planning education, although occasionally intersecting with geological concerns, addresses them only superficially. The result is a foundational training that lacks a comprehensive understanding of the multiple dimensions of risk.

This gap extends to lower levels of education as well. A study of over 160 textbooks across 36 European countries found a general lack of content and activities aimed at raising awareness, building knowledge, or fostering sensitivity around disaster risk reduction (Komac, 2013).

To bridge this gap, it is essential to develop new tools for risk education—tools that connect disciplines, unify fragmented terminologies, and encourage interdisciplinary collaboration. In recent years, simulations, games, and interactive activities have gained traction in urban planning and governance as means of engaging communities on collective issues, stimulating reflection on the future of cities and territories, and imagining alternative scenarios.

The integration of playful elements into serious contexts—recognized by Abt (1970) as a powerful way to achieve educational goals—has significantly evolved in the past two decades, especially with the advent of new technologies (Ciziceno, 2023). The interactive nature, active engagement, and social dimension of serious games make them particularly well-suited to learning in complex domains such as socio-spatial planning (Kolb et al., 1984; McGonigal, 2011; Chow et al., 2011). Within urban and environmental disciplines, serious games have been employed to explore issues such as land use, transportation, ecological sustainability, and natural resource management (Coppard & Goodman, 1979; Ampatzidou, 2018).

Applying this approach to seismic risk reduction from an urban planning perspective reveals the potential of serious games to foster community awareness and make complex concepts more accessible.

In fact, it is possible to identify several shared characteristics between disaster risk reduction and serious games (see Fig. 1).

Fig. 1. Links between disaster risk reduction and serious game features.

1.The unpredictability of seismic events, inherent in the phenomenon's nature, and the resulting uncertainty of public decision makers in making decisions in complex urban contexts, is appropriately reflected in the typical randomness of games (e.g., random dice rolls or card draws).

2.The scenario-based approach of risk management, centered on managing and planning different options under uncertainty, can be effectively simplified through the simulation aspects of games. This experience encourages hypothetical reasoning, the evaluation of options and strategies, both in terms of potential moves and broader spatial configurations.

3.The roles of stakeholders involved in urban planning closely mirror those of the game. Public and private actors, operating at multiple levels of governance and representing civil society in discussions on complex and interdisciplinary issues, can be assimilated to players interacting in role-playing games, board games, live simulations, engaging in direct dialogue on different issues and testing their ability to collaborate.

4.The complexity of governance in urban risk reduction processes, defined by specific objectives, can be compared to game dynamics. These include abstract elements such as constraints, emotions, storylines and a sense of progression, as well as game mechanics, which include interactions between players, time and resource management and strategy development (Werbach and Hunter, 2020).

3. Three educational paths to raise community awareness

Based on research conducted by the CNR working group (Giuffrè et al. 2025), 39 serious games were analyzed that address issues related to natural risks and their management in complex environments, such as urban areas. The aim was to identify potential overlaps, shared approaches and open questions to develop new proposals that could frame urban risk reduction as a common good.

The analysis was structured around several general and specific parameters related to the three educational paths that the research aimed to explore: a) care of the territory, b) understanding of risk, c) community participation (see Fig. 2).

Fig. 2. Parameters considered to analyze the selected serious games

1) Care of the territory

The analysis investigated how games make us reflect on the concept of territory as a common good, that is, an urban space in which the community relates and recognizes itself. Educating to care for the territory means working with communities, in a material sense - protecting the resources of a specific place - and in an immaterial sense, promoting care for others and relationships that connect or facilitate communication between communities and social groups. The parameters used for the analysis of the games referred to (i) the spatial dimension, understood as the representation of buildings, functions, infrastructures and public spaces to interact with, through game boards, digital screens or abstract forms such as narratives and images, (ii) the community dimension, in which care actions of common spaces were proposed, promoting the sense of belonging to places through cooperation and decisions sharing for the protection of structures and public spaces, (iii) environmental sustainability as a collective objective, highlighting its impact on spatial quality and stimulating reflection on the challenges of management and exploitation of resources.

2) Understanding risk

The aim of this training path is to introduce the community to the concept of natural risk as an interaction between a physical phenomenon and society. This perspective frames earthquakes not only as natural events, but also as events that affect people and property, incorporating both the spatial and socio-cultural dimensions. The parameters used for the analysis took into account (i) the specific type of risk, with particular attention to seismic risk, (ii) the identification of the DRM cycle phase(s) referred to in the game, (iii) the role of the different risk factors and their interactions.

3) Community participation
The third training path is based on the idea that planning for prevention and risk reduction has a strong social and collective dimension, which cannot be separated from a process of sharing with communities (Wisner, 2006). The involvement between experts and citizens implements a process of mutual learning that not only improves knowledge, but also promotes a change in perspective and point of view (Musacchio et al., 2019). The parameters used for the analysis referred to (i) the methods of victory, whether they are linked to the achievement of common or individual objectives, (ii) the presence or absence of moments of discussion and cooperation on the choices to be made during the game, (iii) attention to social cohesion as an educational objective, promoting a culture of relationships, belonging and diversity.

The different games analysis focused on seismic risk or multi-risk, read in the light of the three training paths, shows the almost total absence of games that simultaneously satisfy all the parameters considered. In general, it can be noted that there are few cases in which explicit reference is made to the connection with urban planning and almost never all the phases of the disaster cycle are treated, giving priority only to the phases related to preparation and response; individual game modes are preferred to interactive ones, in which shared solutions are sought, and, from the point of view of the victory of the game, the individual victory prevails or, in the best of cases, mixed, to the detriment of collaborative approaches.

4. Sismopoli, the city that dares to play: scientific context, game description and goals
The topic of seismic risk reduction at the urban scale was introduced in Italy starting from the 80s, when some regional public administrations particularly attentive to these issues, started an intense technical-scientific experimentation on some smaller urban centers. On this occasion, the concept of "urban vulnerability" was introduced, overcoming the approach of mitigating the seismic risk of the single building, towards a systemic prevention perspective extended to the entire settlement; a multidimensional concept influenced by the characteristics of the building, the functional systems (Fiore et al., 2018; Anastassiadis et al., 2007; Kyprianou, et al., 2022) and socio-economic factors (Cutter et al., 2003; Pricope et al., 2019; Blackwood and Cutter, 2023) was thus proposed. This approach began to take shape more concretely in this direction after the seismic event that hit the Abruzzo Region on 6 April 2009. Following the extensive urban damage caused by that earthquake, the Italian government introduced a significant funding program of approximately 1.2 billion euros (Castenetto, 2024) to finance risk management interventions in seismically prone territories. Through the National Plan for the Prevention of Seismic Risk (PNPRS), the State launched an ambitious program of Seismic Microzonation (SM) investigations, Emergency Limit Conditions (ELC) analysis and structural interventions on buildings. Although the allocated funding represents only a small fraction of the average annual expected cost of earthquake damage (Dolce 2012), the PNPRS is the first seismic prevention plan in Italy that considers prevention also from an urban planning perspective on a national scale (Bramerini et al., 2013). These efforts have also favored the systematization of various types of knowledge and a more integrated vision of seismic prevention in urban contexts (Tomassoni et al., 2023).

The technical-scientific evolution of this approach subsequently led to the conceptualization of the limit conditions of settlements (Cavinato, 2013) which define a scale of performance levels for the urban center to be preserved in the event of an earthquake (Bramerini et al., 2013), as a reference for the planning of mitigation interventions. Considering emergency management as the minimum objective, in recent years several experiments have been launched that refer to more advanced levels of settlement performance for the recovery start-up phase (Fontana et al., 2024) and for post-earthquake recovery (Cattari et al., 2024). The logic that accompanies these approaches, and that we can find in the proposed research, refers to a gradual involvement of urban functions and systems in seismic risk reduction policies to ensure ever-increasing settlement performance: starting from the urban system responsible for emergency management, the subsequent recovery start-up objective also involves the school function and with the third, recovery, other urban functions are added, creating an increasingly complex system.

4.1 Sismopoli and the three educational paths

Sismopoli is a multiplayer board game, designed for 2-6 players and tested with students aged 16 and up, but also with a wider audience and with different scientific backgrounds. The aim of the game is to improve urban safety in a simulated settlement, divided into neighbourhoods with housing and urban functions, located in a region with variable local seismic effects due to the specific characteristics of the terrain.

In line with the risk management cycle, players must work together to retrofit buildings hosting public and private functions and ensure the safety of roads and public spaces in preparation for a potential earthquake. This will allow them to effectively manage the emergency phase, facilitate recovery and gradually rebuild more safely.

The performance requirements for the settlement are based on a scale of three safety levels to be achieved (see Fig. 3), gradually more complex: from the minimum safety level (the emergency management) to an intermediate level (the beginning of the recovery phase of the settlement), up to the complete level (the total reconstruction of the affected settlement).

Fig. 3. Different levels of settlement safety: a. emergency management; b. early recovery; c. long-term recovery.

The choice of the security level to be pursued, defined in agreement between the players, implies a different complexity of the gaming experience: each level corresponds to a different number of elements to protect, resources to invest and time to allocate. The main objective is to reduce the vulnerability (transform the buildings from red to green) of all the public use functions considered in the system, as well as of the "interfering" residential functions on strategic routes, whose collapse can interrupt the main communication routes and cause significant delays to emergency operations (Basaglia, 2018). The selected system is highlighted by a red line that connects the various elements and changes configuration depending on the objective, making the game board a dynamic tool (see Fig. 3).

The perimeter path of the board includes: "Interventions", to reduce the vulnerability of private and public buildings; "Knowledge", to deepen the understanding of seismic risk; "Bonus" and "Unexpected", where players encounter positive or unexpected critical situations; and finally, "Earthquake", which triggers the seismic event, affecting all players and elements on the board.

The game is designed to achieve two victories: a collective one, in which the entire urban system reaches the expected safety level, marking the end of the game, and an individual one. If the collective goal is not achieved at the time of the earthquake, the individual success is determined by the number of residential and public use functions still existing in each neighborhood, as well as their vulnerability class.

The general objective of Sismopoli is to contribute to a greater awareness of seismic risk and, as previously mentioned, to stimulate knowledge processes in terms of care of the territory as a common good, considering

risk reduction as a crucial component. The proposed educational paths, translated into various forms in the dynamics and rules of the game, – education on the territory, risk and participation – represent in our opinion the key aspects to address the issue of risk prevention.

The theme of "care of the territory" has been structured around the three parameters identified in Fig.2. The spatial dimension is represented in a game board explicitly inspired by a medium-sized urban system, divided into neighborhoods and streets, where urban and residential functions are positioned. There are ordinary urban functions that satisfy the essential needs of daily life and the residential function, with several homes located along the connecting roads and a central public square, which serves as an emergency area in the event of an earthquake. The key functions related to emergency management are also present. The collective dimension is in line with the specific goal of the game: to make the city safer by prioritizing public functions, streets and the main square, taking into account the available resources, time constraints and priorities of each group of players. Interventions on the urban system and its components lead to a reduction in the potential environmental sustainability caused by debris production and land consumption, which would otherwise occur to meet post-earthquake housing demand.

The theme of "risk understanding", structured around the management of the seismic event, is organized according to the phases of the disaster cycle: the prevention phase, in which the actors strengthen the elements of the chosen safety system and prepare to manage the emergency effectively; the response phase, in which the operational functionality of the three strategic buildings must be guaranteed and the capacity of the emergency area in the main square must be sufficient to accommodate all displaced residents; the recovery phase, in which the reconstruction of collapsed buildings begins, damaged structures are reinforced to reduce vulnerability, and new earthquake-resistant homes are built to better withstand future seismic events. In order to implement targeted interventions aimed at achieving specific levels of safety, actors must understand the role of individual risk factors and their interactions. The components of risk – geological hazard, building vulnerability, and exposure of people and property – form the basis of the game dynamics.

The theme of "community participation" is structured around the assignment of roles: each player is responsible for the safety of a strategic or ordinary function and of one of the six city districts, thus representing both individual interests and those of the entire community. The game includes both collaborative and individual victory conditions, but they are not equivalent. During the game, several moments of discussion and decision-making take place, from the definition of collective objectives to the determination of priority interventions.

Figura 4. Laboratorio Sismopoli

5. Sismopoli Laboratory: playability and first evaluations of the increase in awareness

After developing the prototype and conducting initial team tests, a preliminary assessment of the game's usability and playability was carried out in 2024 during three events: a dedicated workshop at the Institute of Environmental Geology and Geoengineering of the National Research Council (CNR-IGAG); the "I4SCIENCE – European Researchers' Night" event, part of the Horizon Europe - Marie Skłodowska-Curie Actions (MSCA) program for 2024–2025; and the "Malnisio Science Festival 2024." Participants, aged 10 to 49, came from diverse educational and professional backgrounds. Two game masters led the sessions, guiding gameplay and encouraging discussion and group reasoning with active engagement.

After playing, participants completed a 24-item questionnaire adapted from the "Game Experience Questionnaire" (Ijsselsteijn et al., 2013), tailored specifically to serious games and Sismopoli. Preliminary results provided valuable insights into the game's usability and engagement. The mechanics were found to be well-balanced and easy to follow; all participants successfully engaged with the instructions and gameplay on a board they found visually and structurally engaging. This is particularly notable given that a third of the participants were between 10 and 15 years old. Fewer than 10% struggled to understand the game's objectives initially, and 90% agreed that the number of tokens was appropriate for gameplay.

Emotionally, players appeared entertained and engaged. Nearly all expressed a desire to play again and maintained focus throughout, even while others took their turns—actively following decisions made by their peers. Only two participants reported moments of distraction. Most players aimed to make as many moves as possible, hoping their token would land in either the "intervention" or "bonus" spaces. The game's challenge, heightened by time constraints, was seen as satisfying. Around 70% feared landing in the "earthquake" space, which ends the game—indicating successful creation of tension and emotional involvement. Overall, results suggest strong performance in terms of rule clarity, enjoyment, and challenge, with minor adjustments needed to improve the engagement of the educational content.

However, the survey also revealed a notable inclination toward individual competition over collaboration. Despite the game allowing both individual and collective victory modes, approximately 60% of participants admitted to focusing their actions within their own areas of expertise to increase their chances of winning. Only 25%

engaged in discussion with other players, and just one-third reported appreciating or offering advice, indicating limited cooperation.

A second, more structured evaluation phase was carried out as part of the institutional project "Roma Scuola Aperta – Mappa della Città Educante 2024–2025," promoted by the Municipality of Rome to offer educational and training initiatives in schools. The Sismopoli Laboratory was introduced at the "Galileo Galilei" High School of Applied Sciences to assess the game's effectiveness in raising awareness about seismic risk, particularly regarding fostering a sense of responsibility toward the territory as a common good.

The lab was structured in two phases: an initial training session introducing the key concepts of urban seismic risk reduction, followed by a gameplay session to apply the knowledge in an experiential context. Topics addressed spanned multiple disciplines—earth sciences, engineering, urban and territorial planning, environmental and civic education.

To evaluate the laboratory's effectiveness, students completed a paper-based group test consisting of 30 multiple-choice questions, categorized into the three educational themes central to the research: the territory as a common good, risk, and community. The questionnaire included both cognitive and non-cognitive items and was administered twice: at the beginning (pre-test) and end (post-test) of the laboratory. In the first round, responses were based on prior knowledge and opinions; in the second, students answered after having experienced the game and associated discussions.

Evaluation was based on a scale from 1 to 4, reflecting the degree of alignment with the concept of risk awareness—understood here in line with Gambino (2005), as the recognition of territory as the outcome of complex and historically determined relationships between natural and human factors.

An initial set of non-evaluative questions gathered sociographic data (e.g., school distance from home and mode of transport) to provide context regarding students' community relationships and their use of public services.

Questions relating to territory prompted reflection on the idea of the city as the "home of society" (Salzano, 2008)—a place of interaction, functionality, and shared space, where care for the urban environment becomes a collective responsibility. These questions, which were directly addressed in gameplay, encouraged reflection on environmental stewardship and social responsibility.

The risk section assessed technical understanding of hazard factors, their interactions, seismic exposure in Italy, emotional responses, and capacity for reaction. It also addressed necessary skills, involved disciplines, and key stakeholders in risk management.

Finally, the participation section evaluated the extent to which individuals were willing to contribute, collaborate in group settings, and share life experiences in a civic context.

The lab was tested with a fifth-year class of 17 students. Results from the pre-test showed a relatively high baseline of knowledge: on a scale of 1 to 4, scores ranged from 2.8 to 3.6, with a class average of 3.2. The post-test showed a slight improvement, with a minimum score of 3.1, a maximum of 3.6, and an average of 3.3—indicating that, although the class was already well-prepared, the game contributed to a modest enhancement in awareness and understanding.

6. Conclusions

Disaster risk reduction at the urban scale represents a highly complex field of application. It involves multiple disciplinary areas, a variety of public and private stakeholders, and social issues that directly affect citizens and civil society at large. Despite the growing urgency of this issue—highlighted by the increasing frequency of extreme events in Italy and beyond—there remains a noticeable reluctance among public decision-makers and a general

lack of awareness within civil society. This disconnect is also evident in the education sector: disaster risk management is inadequately addressed in both higher education and in primary and secondary school curricula. As a result, the topic is often relegated exclusively to scientific disciplines, where it is approached in a highly sectoral and fragmented manner.

Leading international organizations are urging greater efforts to raise risk awareness in a comprehensive manner—one that encompasses all phases of the disaster cycle. They advocate for innovative and diverse modes of knowledge transmission, including peer-to-peer, formal, and non-formal learning methods.

In this context, the CNR research group has developed Sismopoli, a serious game designed to raise awareness about seismic risk in urban environments. Serious games are increasingly recognized as effective tools for conveying important messages in engaging and interactive formats. Sismopoli aims to foster awareness not only among school and university students, but also within broader civil society, by stimulating reflection on environmental and territorial issues that impact us all.

Sismopoli's primary objective is to promote greater risk awareness and to encourage a renewed sense of connection to the territory—framed as a catalyst for political and cultural change that recognizes the territory as a common good.

Inspired by existing practices in both technical planning and participatory engagement, Sismopoli uses a board game format to simulate the management of an urban area located in a seismic zone. The game draws upon theoretical and regulatory frameworks from the field of disaster prevention, reinterpreting them within the gameplay as models of territorial intervention. In particular, the game simulates an actual risk prevention initiative currently active in Italy, financed by the National Plan for the Prevention of Seismic Risk (Article 11, Law 77/2009). Since 2012, this initiative has involved over 3,500 Italian municipalities located in medium to high seismic risk zones—making the game an authentic reflection of real-world practice.

A review of 39 risk management games revealed a striking lack of tools that address risk reduction across the full disaster cycle. Very few incorporate urban planning perspectives. Sismopoli aims to fill this gap by offering a comprehensive, planning-based approach to seismic risk.

Initial playability testing across various events showed that the game mechanics are intuitive and the gameplay is enjoyable, while still engaging players in achieving risk-related objectives.

The current phase of the research focuses on evaluating the effectiveness of Sismopoli in increasing awareness of seismic risk. A structured educational laboratory was recently implemented at a secondary school in Rome as part of the institutional initiative Roma Scuola Aperta – Mappa della Città Educante 2024–2025, which promotes educational programs across schools. The evaluation was carried out through pre- and post-activity questionnaires, yielding promising results regarding student engagement and learning.

Simultaneously, the game is being disseminated more widely through public outreach efforts, including participation in scientific festivals and communication activities promoted by the National Research Council (CNR). These efforts aim to bring the game into classrooms, communities, and broader public settings.

The ultimate goal of Sismopoli is to initiate a broader path of public awareness, starting from simplified, engaging experiences that introduce the complex issue of seismic risk reduction in urban environments. The next phase will involve integrating the simulation into citizen science initiatives, allowing participants to apply the knowledge gained from the game in real-world contexts, directly within their own territories.

Epistemological Uncertainties in Planning Education: The Transformative Role of Studio Pedagogy

Begüm Eser, T.Kerem Koramaz
Istanbul Technical University
eserb18@itu.edu.tr; koramaz@itu.edu.tr

Abstract
Planning education faces a persistent challenge: equipping planners with the knowledge and skills to navigate an increasingly uncertain and complex world. As Ferreira, Sykes and Batey (2009) metaphorically describe it, planning theory resembles the mythical multi-headed creature, the Hydra, in that it lacks a single dominant paradigm and is made up of multiple paradigms that coexist.The evolving nature of planning theory raises critical questions: This paper argues that studio pedagogy is a critical tool in equipping students with the necessary skills to respond to contemporary urban challenges. By repositioning studio pedagogy as a transformative learning environment, this study contributes to the debate on how planning education can better respond to contemporary socio-spatial challenges. We believe that a pedagogical transformation that goes beyond theoretical teaching and actively prepares students for the uncertainties and ethical complexities of professional planning practice is essential.

Keywords: planning theory; planning education; studio pedagogy; transformative learning

1. INTRODUCTION

Planning theory has been shaped by the successive and intertwined coexistence of different paradigms. The rationalist and technocratic approaches of the modernist era have gradually been criticised and replaced by more pluralistic and interpretive perspectives. In the postmodern condition, planning theory no longer adheres to a single dominant framework; instead, it has developed into a multi-paradigmatic structure marked by ongoing transformation. As Ferreira, Sykes and Batey (2009) metaphorically describe it, planning theory resembles the mythical multi-headed creature, the Hydra, in that it lacks a single dominant paradigm and is made up of multiple paradigms that coexist.

Rather than resting on a singular body of knowledge or method, planning exhibits a contextual, relational, and layered epistemological structure. This inherent diversity gives rise to a fundamental question: what types of knowledge should planning prioritise? Davoudi & Pendlebury (2010, p. 638) identify three key areas: (1) space as the core object of inquiry; (2) the nature of integrative knowledge; and (3) the interface between knowledge and action. It is precisely through the infusion of disciplinary and experiential knowledge that planning has carved out a distinctive position within the family of social sciences. What distinguishes planners from, for instance, geographers, is not only their critical thinking about space and place, but their aspiration to transform them (Davoudi, 2009). Planning is thus a mode of doing—an epistemic field grounded in action and interaction, in which knowledge becomes operative in shaping spatial futures .

This dynamic, practice-oriented nature of planning inevitably finds reflection in its educational practices and pedagogical structures. Planning education is a site of reflexive engagement with the evolving paradigms of planning theory. Jane Rendell (2013) states that disciplinary uncertainties and boundaries create a productive transitional space. In this spirit, this text rethinks the uncertainties at the boundaries of the planning discipline not as deficits or dilemmas, but as spaces of strategic potential and intellectual creativity.

Yet it is precisely this multidimensional character of the discipline that perpetuates a sense of crisis in planning education. As Kunzmann (Kunzmann, 1985, p. 442) notes, planning education has been in crisis since its inception and will continue to be so, but this should not be seen as a weakness. The inherent complexity of planning demands a pedagogical approach that is reflective, adaptive, and dynamic. To better understand how these transformations have shaped planning education, one must revisit the changing role of the studio, which was foundational to the discipline's early formation.

In this context, understanding the transformation of planning education is critical for assessing today's spatial, political, and ecological crises and building an effective pedagogical framework for the future. This study explores the following research question: How can studio pedagogy be used as a transformative learning environment to equip planning students with the knowledge and skills necessary to navigate contemporary socio-spatial challenges and epistemological uncertainties in planning education? In line with this question, the research will employ reflexive and situated learning methods.

2. PARADIGMATIC SHIFTS IN PLANNING EDUCATION AND THE EVOLUTION OF STUDIO PEDAGOGY

The planning discipline, unlike empirical sciences, deals with wicked problems that require a specific type of (scientific) approach (Rittel and Webber, 1973, p. 160). Because of this complexity, planning necessitates a comprehensive and integrative educational model that operates independently from the disciplines it is traditionally associated with Rooij and Frank, 2016, p. 483).

One of the most significant shifts in planning education emerged during the "social turn," when the discipline began to embrace a social science orientation. The evolution of studio pedagogy has been shaped by broader paradigm shifts in planning education. In response to urban issues of the late 1960s and early 1970s, planning discipline adopted a social science orientation, which changed planning education in a broad way, and in particular the definition of 'studio' as a pedagogical approach (Wetmore and Heumann, 1988). As planning education reoriented itself, studio courses in planning curricula were gradually reduced in some curricula, and in some planning schools they are only offered in the last semester. This reorientation in planning education can be described as a hidden curriculum (Baum, 1997) that transforms practice-oriented teaching.

A similar transformation can be observed in the context of Turkey. With the first planning department established in 1961, planning education was initially carried out with a more physical design-oriented approach. However, over time, the influence of social sciences has increased and the direction of planning education has changed, especially after 1980 with the impact of neoliberal policies. Despite this, studios have continued to exist as an essential component of practice-based pedagogy.

Whether planning is primarily understood as a social science or a design discipline, both traditions remain integral to the field; however, there may still be differences in focus and priorities (Biggs and Büchler, 2011). By the late 1990s and early 2000s—what (Anacker, 2024) refers to as the fourth era of planning—the studio once again became a subject of planning education research, reflecting a renewed interest in practice-based education and studio-based learning.

To respond to the complexities of contemporary urban life, we argue that studio pedagogy must be repositioned as a critical and transformative site of learning. By repositioning studio pedagogy as a transformative learning environment, this study contributes to the debate on how planning education can better respond to contemporary socio-spatial challenges. We believe that a pedagogical transformation that goes beyond theoretical teaching and actively prepares students for the uncertainties and ethical complexities of professional planning practice is essential.

3. THE RETURN OF THE STUDIO: PEDAGOGICAL POTENTIALS IN TIMES OF CRISIS

We argue that two key dynamics triggered the return of the studio in planning schools: (1) The Rise of Neoliberalism and the Importance of Space and (2) Ecological Thresholds and Social Inequalities. The strength of studio pedagogy lies not only in its capacity as a medium in which theoretical knowledge is transmitted and practice is learnt, but also in its capacity to encourage students to question the way they think when making ethical and political decisions.

1. The Rise of Neoliberalism and the Importance of Space: Davoudi (2017) argues that the resurgence of spatial planning in the 2000s was a response to an awareness of the importance of space. She links this to two theoretical developments: (1) relational space and (2) communicative action.

2. Ecological Thresholds and Social Inequalities: Increasing income inequality, housing problems, social exclusion, and crises related to food and water rights directly affect the content of planning. It is crucial to acknowledge that neoliberal policies not only exacerbate spatial inequalities, ecological crises, and social vulnerabilities but also utilise planning tools in the process.

In this context, understanding the transformation of planning education is critical for assessing today's spatial, political, and ecological crises and building an effective pedagogical framework for the future. By examining how planning theory translates into pedagogy, this study offers a framework for integrating equity and sustainability into planning education, ensuring that studio pedagogy evolves in response to contemporary crises. To make this evolution meaningful, it is necessary to understand not only what issues studios address, but how they function as environments for learning and transformation. In this regard, the studio's pedagogical structure becomes as important as its thematic content.

Studio teaching methods typically follow a "learning by doing" pedagogy (Schon, 1985). Studios are environments where students actively engage in place-based problem solving (Neuman, 2016), negotiating semi-structured and open-ended real-world problems situated within a physical and social context (Alizadeh, Tomerini and Colbran, 2017). One of the most influential studies on design education, Nigel Cross's Designerly Ways of Knowing (Cross, 1982), argues that much of what designers know about their own problem-solving processes remains as "tacit knowledge," which they struggle to externalise—thus leading design education to rely heavily on an apprenticeship model. Therefore, it is essential to investigate this tacit knowledge within studio courses: how it is produced, and how students discover and engage with it. It is crucial to articulate the specific learning characteristics associated with studio pedagogy and to evaluate its potential and limitations in addressing contemporary challenges in urban and regional planning education.

4. THE CASE OF "BAŞKA TÜRLÜ STÜDYO" IN PLANNING EDUCATION

As discussed in previous sections, the contemporary return of the planning studio demands not only a reconsideration of pedagogical form, but also a reimagining of the kinds of knowledge and practices that planning education should cultivate. To explore this further, this section presents a pedagogical experiment conducted in the third-semester undergraduate planning studio at Istanbul Technical University (ITU) during the 2022–2023 fall term. Titled Başka Türlü Stüdyo (Another Kind of Studio), this studio engaged cinematic techniques as a tool for spatial inquiry, offering a concrete example of how epistemological uncertainty and multidimensional knowledge can be translated into pedagogical method.

The studio was designed as a method-oriented inquiry into housing site planning and design, focused on the city of Gömeç in Balıkesir, located in western Türkiye. Drawing from site visits and grounded in everyday life observations, the studio was structured around the use of cinematographic products and techniques as a method for tracing spatial knowledge. The pedagogical intention was to reverse the traditional shift from upper-scale planning to design and execution, instead shifting from life scale to upper scale, based on human experiences and the immediate environment. Although this may seem very challenging for second-year students at the beginning of their planning education, they were able to adapt to this shift in scale while also benefiting from their first-year interdisciplinary studio experience. This intentional disruption of scalar hierarchy functioned as part of the studio's hidden curriculum (Purpel, 1983), fostering a transition from top-down planning approaches to bottom-up, situated spatial exploration.

The Başka Türlü Stüdyo unfolded through a carefully sequenced structure designed to foster a shift in how students perceive and represent space. The studio's workflow was structured in three key phases: (1) Field-Based cognitive mapping:, (2) Cinematic representation and analysis, and (3) Site-specific planning and design proposals. Each phase was underpinned by a different mode of inquiry—experiential, visual, and design-based—integrated into a broader pedagogical narrative.

1. Field-Based cognitive mapping: In the first phase, students conducted fieldwork in Gömeç and collected qualitative data on urban, ecological, and social dynamics. Their observations were translated into cognitive mappings enriched by direct quotes, personal impressions, everyday life images, and informal material evidence. The goal was to generate layered and situated understandings of space through lived experiences and affective readings of the site.

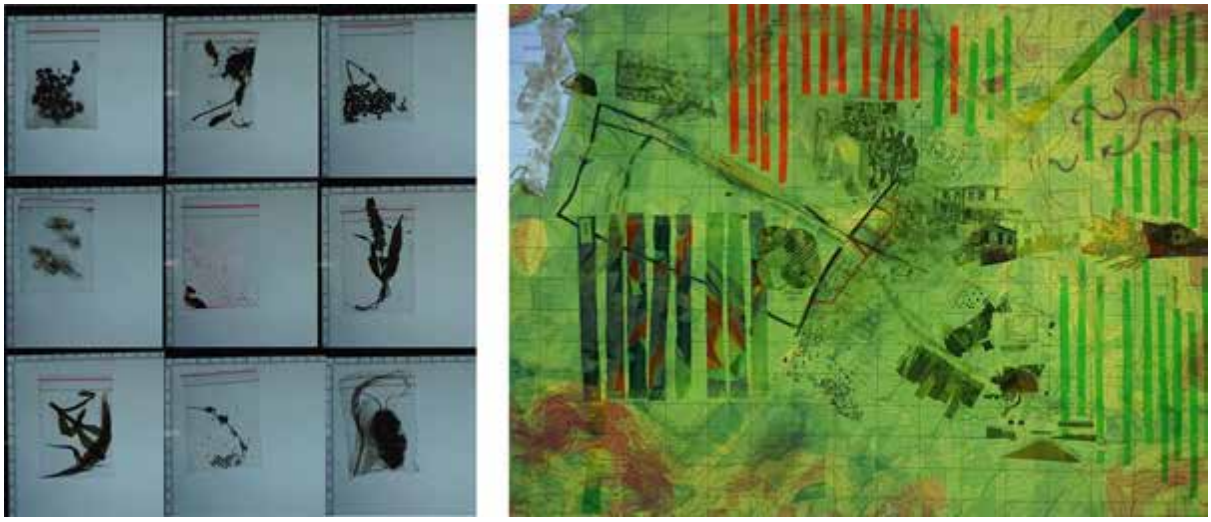

Figure1: Field-Based Cognitive Mapping

2. Cinematic representation and analysis: The second phase introduced cinema as a speculative research method. Students were asked to select a film of their choice—without genre or region constraints—provided that the film depicted domestic life and housing environments. They produced hand-drawn storyboards of key scenes, analysed the everyday rituals within domestic settings, and speculated on spatial organisation by drawing plans and sections. These interpretations were then transformed into scaled urban plan and physical models representing the film's spatial universe. This pedagogical strategy reversed the conventional scalar logic of planning education. Instead of beginning with macro-level planning frameworks, students started from the micro-scale of the dwelling unit and gradually expanded their focus to the neighborhood and settlement scale.

Figure2: Cinematic Representation and Analysis

Through this process, they were encouraged to develop a critical awareness of scale, perception, and material representation. By interpreting cinematic environments and transforming them into planning proposals, students navigated the relationship between imagination, representation, and spatial thinking.

Figure3: Models and Material Representation

3. Site-specific planning and design proposals: Drawing on insights from fieldwork and cinematic analysis, students developed comprehensive housing site plans for Gömeç. This phase involved a gradual scalar transition from interior to settlement level, enabling students to grasp the cognitive and practical challenges of spatial scaling. Students produced 1/1000 scale plans that responded to the ecological landscape and local social needs, proposing innovative, context-sensitive, and materially informed housing typologies. The use of experimental materials and model-making techniques encouraged tactile engagement with scale, form, and spatial organisation.

Figure4: Exhibition of The Başka Türlü Stüdyo

The use of cinematic tools in Başka Türlü Stüdyo served as a valuable medium for enriching the creative studio experience and facilitating students' perception of urban space across multiple scales. This approach enabled students to transition from an embodied, human-centered perspective to a more analytical, planning-oriented gaze. Through this pedagogical journey, cinema functioned not only as a representational technique but also as a cognitive device that guided students in navigating scalar complexities and engaging critically with spatial transformation.

5. CONCLUSION

This paper has explored how planning education can respond to the epistemological multiplicity of planning theory and the pressing crises of our time by rethinking the pedagogical potential of the studio. Beginning with the recognition that planning is a multi-paradigmatic and action-oriented field of knowledge, we examined how educational practices, particularly studio pedagogy, have evolved in tandem with shifts in the discipline's theoretical foundations.

Through a critical review of historical and contemporary developments, we argued that the studio must be repositioned—not merely as a site for practicing technical skills, but as a generative space for ethical reflection, creative speculation, and spatial imagination. Amidst ecological thresholds, deepening inequalities, and the instrumentalisation of planning under neoliberal regimes, the studio offers a unique pedagogical environment for confronting complex realities.

The Başka Türlü Stüdyo case study illustrated how reversing scalar hierarchies and integrating cinematic tools can enable students to navigate between lived experience and planning logic. By centering embodied perception, relational spatial thinking, and visual research, the studio functioned as a performative and reflexive learning environment, opening up new epistemic pathways for planning education.

More broadly, Başka Türlü Stüdyo exemplifies how visual culture and cinematic representation can be embedded into planning education as both an epistemic and creative practice. By positioning cinema as a planning tool, the studio facilitated students' transition from human-scale spatial perception to rational, studio-based thinking. This process enabled them to connect subjective experience with analytical inquiry. Through experimental techniques, the studio fostered critical engagement with issues such as ecological vulnerability, housing, and social inequality. This pedagogical experiment not only expanded the scope of studio-based learning but also cultivated a socially responsive and ecologically aware planning mindset. It reaffirmed the potential of studio pedagogy to operate as a dynamic interface between narrative imagination, empirical research, and spatial design.

Ultimately, reimagining the studio as a site of uncertainty, experimentation, and learning space the way for a more situated, inclusive, and resilient planning education that is capable of confronting the unknown and cultivating new imaginaries for spatial futures. In this context, understanding the transformation of planning education is critical for assessing today's spatial, political, and ecological crises and building an effective pedagogical framework for the future.

AI + Geospatial Models for Engagement and Performance Measures in the Pedagogy of Sustainable Planning Studio

Azza Kamal
University of Colorado Boulder

Abstract
The emergence of the 15-minute city concept is linked to the climate crisis. Research on streamlining decisions in the planning practice to respond to this crisis shows that technology integration guides better decisions and strengthens citizen engagement. This paper focuses on two questions; will the use of AI tools help make public engagement truly meaningful? and how can technology platforms in urban planning curriculum enhance students' experience? I utilized an Artificial Intelligence tool to examine engagement and integrated mixed reality to develop neighbourhood scenario models in an undergraduate studio. Feedback from student assessment and peer's input yielded an effective engagement, appreciation for technology, geospatial platforms, and role play tools. Quantitative measures using campus standard surveys were utilized to measure the impact of the revised curriculum.

Key Words: AI, GIS, XR, Immersive Environment, Planning Studio

Cutting-edge Technologies & Urban Planning Practice

Research on the planning practice and automation shows that integration of cutting-edge technologies can inform decision making, enhance resource allocation, predict trends, and mobilize citizen engagement (Ghisleni, 2024). With the rapid economic growth and urbanization, cities are challenged with a myriad of problems (i.e. traffic congestion, noise, air and water pollution). City officials are rethinking their decision process through various scenario simulation and spatiotemporal analysis that examines socio-spatial inequalities and prepares for sustainable urban development (Wang et al., 2021). Both the planning education and practice have encountered an enormous transformation through integrating technology at various levels and scopes in the pedagogy and processing and implementation of projects. In recent years, researchers explored the attributes defining the ideal plans that correspond to the "15-minute city" concept by training an automated system using previous human-designed projects and factors that are predictive of positive outcomes (Ghisleni, 2024). Urban planning practice is also seeing revolutionary changes by relying on algorithms, automation, and artificial intelligence (AI) to predict scenarios and decisions (Sanchez, 2025). Curriculum revisions in planning schools now aim to integrate structured methodology for aligning academic goals, learning outcomes, and accreditation with the recent trends and technology to advance the planning profession.

In this paper, I review a case study for integrating multiple technology platforms including AI speech recognition tool and geospatial modelling for redevelopment of four neighbourhoods (Cherry Creek, Highland, Lincoln Park, and South Park Hill) in Denver Colorado. The case study is part of a core undergraduate planning studio in the University of Colorado Boulder.

AI is defined by the Council of Europe Framework Convention on AI and Human Rights, Democracy and the Rule of Law as:

"a machine-based system that, for explicit or implicit objectives, infers, from the input it receives, how to generate outputs such as predictions, content, recommendations or decisions that may influence physical or virtual environments. Different artificial intelligence systems vary in their levels of autonomy and adaptiveness after deployment." (European Center for Not-for-Profit Law, 2024)

With the rising concerns about cities growth, climate crises, and migration, a shift in urban planning is growing by adopting automation and AI in land use and transportation planning. According to a study by Zeng et al. (2023), this shift is driven by the unreliable and intuition of human capacity in optimizing multiple metrics in large datasets. For instance, to estimate the optimal distance between various services and residential areas in the 15-minute city concept, AI or geospatial tools for processing large datasets is utilized to create visuals to help in decision making. These visual and quantifiable metrics are processed by computational AI tools, which are

trained based on millions of previous trials (Zeng et al., 2023). Another example is developed by a team in Tsinghua University in China, where urban planners and scientists developed an AI tool that surpassed the performance of humans. The research team utilized attributes of the 15-minute city concept. In their automation approach, the team trained the system using variables described as positive characteristics of the city in formerly human-developed projects (i.e. parks, bike lanes, and entertainment spaces). The system, which was tested in a 3x3 grid, revealed that its project outputs have the same -or more- quality of those created by planning experts, while saving an ample time in processing (Ghisleni, 2024).

In an article on the popular planning platform, Planetizen, Sanchez (2025) discussed some of the fundamentals of planning practices that benefit from AI integration in their workflow. These include:

1) As planning relies on extensive data analysis, AI tools enhance planners' ability to process large datasets and help with output interpretation.
2) AI is not a substitute for human judgment. Since planners are taking a critical role in shaping AI's impact, the power of integrating AI workflows is to identify unseen patterns, and evaluate complex scenarios, and thus support planners' decisions.
3) Transformation of planning practice started when hand-drawn maps switched to Geographic Information Systems (GIS) generated maps, or when windshield surveys transitioned to computer vision. As such, AI is a continuation evolution of the practice, which offers a toolkit for planners to extend their capabilities as well as their possibilities.
4)Skillsets to run and customize AI tool are attainable for planners without prior knowledge in coding or a degree in computer science.

With its capabilities and versatility, AI can assist local governments in responding to the impact of climate change. Using predictive modelling, risk assessment, and early warning systems enable planners to address extreme weather events through resilient planning (Ghisleni, 2024). As an example, Google's Tree Canopy tool, powered by AI and shown in Figure 1 helps to mitigate the impact of extreme heat waves. As an integrative part of Google's Environmental Insights Explorer (EIE), the tool combines AI with aerial images of cities. AI literacy is soon becoming essential knowledge for practitioners and researchers alike. Thus, developing AI knowledge as a primary component of planning curriculum is now equal to understanding budgets, zoning, land use, and citizen engagement. AI Knowledge helps planners to be key players in decisions about how AI is used and regulated. If they did not participate in regulating such use, their voices and insights could be excluded (Sanches, 2025).

Climate Crisis and the Emergence of the 15-Minute City

History of City Planning

The city planning vision that Le Corbusier's approach created was centred on rationalizing and organizing urban space to improve residents' quality of life. Stimmed from a functionalist and rationalist zoning approach, his vision prioritized the efficiency and separation of land use activities, while maintaining modern aesthetics and orderly building forms (Moreno, 2024).

In the 1960th, the construction industry in the United States underwent a boast in expansion and transformation. Accompanied by considerable economic growth and cities transformation, this decade resulted in a massive scale of new buildings construction and expressways that traversed the city's urban fabric. As a result, the decades that followed 1960s suffered from damaged urban landscape and fragmentation and segregation of the neighbourhoods that were encroached by the multilane expressways. Physical barriers between communities and increasing air and noise pollution were the utmost anticipated result of such damage. Movements to urbanize and reconnect neighbourhoods arose in the following decades including new urbanism, which responded to the need to address proximity, community cohesion, and the traditional activities of city life (i.e. local markets, walkability, and urban nature), (Moreno, 2024).

City's Urbanization and Climate Crisis

As a result of the fragmentation of the city structure in the 1960s and 1970s, movements to transform the city into a city of proximity, where basic goods and services are available at short distances within 15 minutes of one's residence, evolved. The new approach envisioned the city as an urban environment that would not only eliminate reliance on traffic, but also encourages a daily happy lifestyle (Moreno, 2024). In 2015, the Paris agreement recognized this vision and supported actions to invest in the built environment of cities to reduce greenhouse gas emissions and strengthen society's resilience. Using nationally determined contributions (NDCs), the agreement tailors its action plans to reduce greenhouse gas emissions and adapt to climate change for each member city. The 15-minute city concept developed by Moreno (2024), which aligns urban growth and city plans with the anticipated response to climate crisis, emphasized promoting more frequent and meaningful social interactions through prioritizing human interactions and social networks traffic jams. Municipalities that adopted the 15-minute city concept promote cleaner, more renewable energy sources. They support the 15-minute city's holistic approach through creating more sustainable, resilient, and liveable cities for present and future generations. This is attained through electrifying the building sector and infrastructure by relying on sustainable energy systems and the use of electric or hydrogen-powered public transportation. This concept also aspires to create a more balanced infrastructure, where uses are harmoniously integrated in areas where residents can live, work, play, and connect easily. Adopting a land use system -comprising mixed-use neighbourhoods- is essential for executing this concept and to ensure adequate living spaces that support community interaction, strengthen social cohesion, and promote a better quality of life (Moreno, 2024). Inspired by the matrix developed by Professor Muhammad Yunus as well as premises of sustainable development goals (SDGs); this concept in broad and open, while focusing on an array of detailed plans to improve the quality of life in towns and cities.

While addressing proximity, liveable spaces, and community cohesion, the 15-minute city, shown in Figure 2, is also centred on climate action. It supports the creation of a naturally linked system of ecological, economic, and social dimensions. The transition to this concept requires thoughtful changes and a commitment to transform one's lifestyle and the urban landscape of the cities and towns into a system of neighbourhoods that create living spaces that are attractive, welcoming, and conducive to interaction. This means designing neighbourhoods where the use of public spaces for cultural, economic, and social activities, as well as the relocation of local shops and services are intermingled. Moreno (2024) also re-envisioned a 30-minute territory concept for medium and sparsely populated areas (Moreno, 2024).

Rethinking The Sustainable Planning Curriculum

Transformation of urban planning training for undergraduate students using advanced technology for planning scenarios and placemaking helps prepare students for the job market and be ready for the shift in planning practice discusses in Sanchez's (2025) article. A revised design for the planning curriculum helps to equip students with a mix of skills including technological know-how to tackle complex and technically challenging problems that require processing large datasets (i.e. climate adaptation, resilient planning, zoning reform). Continuous improvement of our pedagogical approaches in the 21st century is a necessity not a luxury. I see a value in dynamic instruction tools that regularly change and adapt to align with the needs of decisions and support changes in the planning practice. Designing innovative pedagogies helps to tailor technology platforms to student capability and align digital applications with the project and course needs. Instructional methods also need to be enhanced through integrating methods that best reach students of diverse backgrounds and ability, so we can prepare our students for the future. At the University of Colorado Boulder, Arts and Sciences Support of Education Through Technology (ASSETT) program provides support for integrating technology with pedagogy to promote impactful learning for all faculty. Through a two-semester workshops and reflection meetings, the program helps faculty to engage in a discourse with fellow faculty members from other disciplines and coaches to address the best practices and lessons learned from technology integration into instructional methods. It helps to emphasize the importance of continuous improvement of studio instructions, enhance active learning, and infuse technology where it could best align with the scope of work and the learning outcomes.

After completing this program, a proposal for instructional revision is proposed and tested in course instruction or a program of study.

Considerations and Risks of AI Adoption

Although AI tools might steer a fast pace of data processing and lead to radical efficiencies and deeper connections with the public, one must be aware that these tools need to be responsibly adopted. Concerns arose among practitioners on the use of AI and thus, the leading international corporation, Deloitte (2025), addressed the following considerations and risks, shown in Figure 3, related to the best practices in the adoption of AI-assisted outreach and engagement:

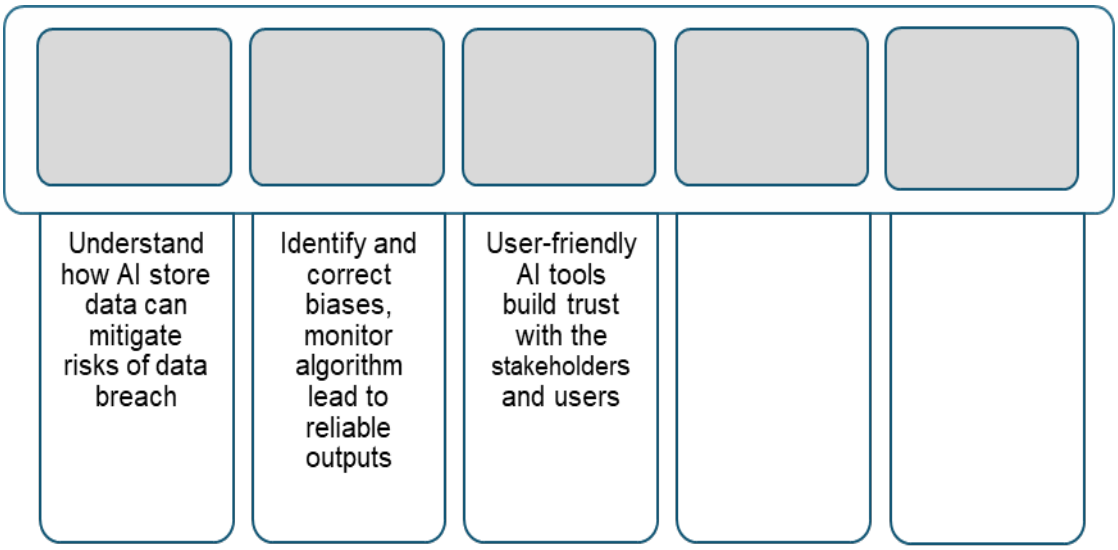

Figure 3: Deloitte's key considerations and risks for AI adoption in outreach and engagement.

Technology Integration in Sustainable Planning Studio

In the academic year 2024/2025, the program helped to support the revised course instructions for an undergraduate planning studio that I led at the Program in Environmental Design. Carefully revised modules, shown in Table 1 and Figure 4, in partnership with two campus institutions, helped to advance course and project content, enhance student engagement, and equip students with technical and communications skills through hands-on learning and experimenting.

The optimal goal was to equip students with technical skills included focusing on geospatial tools and mapping and using different Geographic Information Systems apps and online tools for 2D, 3D mapping and data visualization apps for interactive data visualization (Esri, 2024). In this paper, I discuss the pedagogical innovations that included collaboration with the Immersive Media Lab, where students utilized VR/AR devices and the Sketchup Software (Trimble, 2024) to develop intervention models of the pre-post retrofit scenarios of Denver neighbourhoods. I also analyse the results of quantifiable use of an AI tool to measure a week-long Role-Play workshop series, led by students to emulate the roles of stakeholders and their -often- conflicting interests. This Co-Design CoBI AI tool was a collaboration with the campus Institute of Cognitive Science, which has tested the tool in different secondary education classrooms.

Table 1: Revised planning studio curriculum using advanced technology and AI tools.

Module	Tool	Weeks	Modality
Research on Denver neighbourhoods and planning reports	Policy analysis	Three	Individuals
Case study research	Reports review	One	Individuals
City & neighbourhood resilience	Environmental and sociodemographic analysis	One	Individuals
Experiential learning through role play	CoBI AI	One	Randomly assigned groups

Retrofit planning proposal	GIS Pro + StoryMap	Three	Self-assigned groups
Immersive environment for scenario modelling	XR devices Trimble Connect	Four	
Final development proposal	All tools	Two	

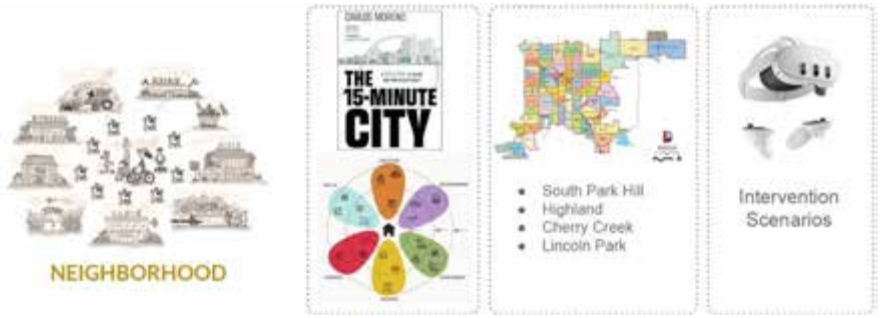

Figure 4: Revised planning studio; research and immersive environment integration

Denver as an Open Lab

Wang et al. (2021) examines research trends and the usefulness of urban scenario modelling. Their approach focused on global planning practices, urban planners, and politicians who should draw up suitable frameworks to implement sustainable urban development policies. Based on their systematic and quantitative review of 126 articles, they concluded that utilizing scenario modelling to help achieve sustainable development goals (SDGs).

In this undergraduate studio, the City of Denver, Colorado, US, was the open urban lab, where students were tasked with exploring, analysing, and redesigning four neighbourhoods (Cherry Creek, Highland, Lincoln Park, and South Park Hill) using the 15-minute city principles and local zoning and sustainability plans. In addition to site visits and visual analysis using site images for critical areas, students reviewed the existing zoning codes, newly adopted ordinances for minimizing parking requirement, and resiliency and climate action initiatives. In this studio 19 undergraduate students were introduced to sustainability and resilience measures, and contemporary urban design to examine urban growth as well as the development regulations on four prototype neighbourhoods. The neighbourhood characteristics entail different building typologies and density in order to propose a retrofit plan for each within the framework of the 15-minute neighbourhood concept. As an undergraduate studio, pedagogy challenges them to think through a multi-faceted and complex lens that intertwines environmental and equity measures.

After individual analysis of the City of Denver zoning, environmental and resiliency metrics, students were organized in four -randomly assigned- groups to undertake AI engagement workshops. The goal of the engagement module, shown in Table 1, was to engage students in a series of research activities, and to let them acquire research knowledge through engaging in small-group discussion and analysis. Students worked in groups of four to five students each to analyse each neighbourhood and its context.

AI for Community Engagement

The challenges of community engagement that the government sector faces are largely due to the need to establish trust with the populations they serve (Deloitte, 2025). Cities and public sector organizations don't have to re-invent the wheel — they can advance their existing outreach and engagement practices using AI platforms. According to Deloitte (2025) guidelines, AI offers new opportunities for public sector communicators at each step of the marketing and outreach process. AI-powered analytics can uncover behaviour patterns and preferences

with precision in real-time, Generative AI (GenAI) tools can produce hundreds of tailored content options, and Machine Learning (ML) technologies can now make real-time data-driven decisions to maximize every dollar (Deloitte, 2025).

Hurley's (2024) article questions the ability of urban planners to use AI to support their public engagement work. Centred on AI for public engagement, the article discussed ways that planners have proposed or adopted AI for public engagement. These ideas include the utilization of tools such as Chat GPT, Claude, or Microsoft Bing, and include the following possibilities:

Writing Support Uses

• Edit text to convert planner terminologies to everyday language at a 6th grade reading level: as Hurley explained, planners and related professionals such as engineers, architects, and landscape architects have higher levels of education than the population at large. The jargons of each of these professions could be very challenging to be understood by the general public. This shorthand makes it easier and more accurate to talk amongst peers, but it can be a barrier when communicating with the public. It is also a challenge to write for a reading level lower than one's own. Hurley assures that AI is great at adjusting a short piece of text to a particular reading level.

• Expand the options to consider: Planners are often asked to give an overview of policy options for a particular problem or analyse a possible solution for pros and cons. Due to the broad scope of planning expertise; not all planners are qualified to provide information in an area where they are not an expert. Even if the planner is familiar with the topic, it may require further research to ensure an accurate response. In situations like this, AI can help furnish some options for planners or provide a few examples to support their policy (Hurley, 2024).

• Convert one form of writing into another: Plans often have text to describe the graphic and analysis content to the public. In many occasions, AI could help create the first draft of the goals based on the vision or to support the intended goals (Hurley. 2024).

Meeting Support Uses

• Convert handwritten notes to text: It is very common for planning practitioners to use markers and flip charts for meeting notes. Visibility of the notes helps keep people focused, the messiness of the handwriting reinforces the idea that this is a work in progress and change is possible. I tis -however- time consuming to transcribe all those handwritten notes into a word document or presentation slides. AI could help with the transcribing task.

• Develop slides from text: despite lack of complete accuracy when putting together the text for a presentation and importing into an AI tool, this could be a first draft and save planners time to create the full presentation. With minor editing, the presentation could be enhanced in accuracy and visual content.

• Provide ideas for meeting activities or a draft agenda to meet meeting goals: AI tools could help planners and facilitators develop scenario of activities that could take place during the meeting to help achieve the goals for that meeting.

The Power of Role Play & AI

The terms "role play" and "simulation" are sometimes used interchangeably. yet, the two have some differences. While simulations can incorporate role play, leading to the term "role-playing simulation", they often involve instances where each participant may not have a prominent role. By contrast, in a role play exercise, the focus is more on the interaction between participants (or the characters students emulate), hence each participant role is a primary (UNSW, 2025). Role play is a form of experiential learning (Russell & Shepherd, 2010). In a role play scenario, students take on assigned roles and act out those roles through a scripted play. The role play can be carried out one-to-one (individual role play) or as a group role play with each member in the group taking on a role/character. In the script provided by instructors, roles and rules for the role play exercise are clearly defined

to help students prepare for effective engagement and enhance the quality of the output. Role plays can provide very powerful learning experiences for students by immersing them in simulated real-world situations, where they act out a particular role/character in a safe -and often fun- environment.

As today's global education policies address the benefits of problem-based, and active learning models, which further reflects curricula contents for achieving twenty-first century skills (Darling-Hammond, 2006; Vincent-Lancrin et al., 2014). Role play and simulation are becoming critical in enhancing student engagement and immersing them in an environment for real problem-solving scenarios. Role plays and simulations function as learning tools for groups or individuals in an online or in-person environment. They shift the power and autonomy in teaching and learning processes between students and educators, as students learn through their explorations and the viewpoints of the character or personality they are emulating in the environment (Aura et al., 2023). As a powerful student-centred space, role plays can enable learner-oriented assessment, where the design of the task is created for active student learning. Students are actively involved in both self- and peer-assessment, where they both give and receive feedback, and thus feel they contributed to the teaching pedagogy. In role-play exercise, students adopt different characters and work through a given scenario together, interacting in their assumed roles. Role-play is particularly effective for learning about complex social/human systems (Russell & Shepherd, 2010).

In this studio and in collaboration with the leadership team in the Institute of Cognitive Science at the University of Colorado Boulder, I was able to examine the NSF-funded tool Community Building [CoBI] tool that utilizes Artificial Intelligence [AI] Automated Speech Recognition [ASR]. The tool is designed to help researchers measure effective engagement through capturing and analysing the conversation during the engagement workshops. I conducted a role play in a well-structured one-week module that focused on enhancing student collaboration through emulating public participation in planning and design process. The activities encompassed in this week enabled students to fully represent a unique stakeholder's persona, where they can address the stakeholder's interests and concerns through addressing the SWOT analysis for each neighbourhood and the neighbourhoods' re-envisioning ideas. The activities throughout the week included workshops that took place during studio meeting time on Monday and Wednesday. The output of which were reconfigured and presented -using a visual and analytical collage of manually rendered maps and infographics and presented in class on Friday.

Utilizing an active learning jigsaw approach, students from each neighbourhood group I randomly assigned a different role, and students from all groups with similar roles formed a new group to represent matching stakeholders' interest. The Jigsaw active learning technique ensured that a person from each neighbourhood will be participating with three new students to envision the neighbourhood plan from a specific interest perspective that represents the stakeholder they were assigned:

- Environmental specialists (advocacy)
- Residents (Social + Cultural)
- Real estate (developers)
- City planners/public officials (Zoning/Land use)

The workshops were organized to engage the newly formed groups of stakeholder's mutual interests in a sequence of short exercises to conduct a Strengths, Weaknesses, Opportunities, and Threats [SWOT] Analysis and develop a visioning plan for the four assigned neighbourhoods. The short exercises were designed to empower students to take actions and address the -often-conflicting- stakeholder's interests. SWOT analysis workshops for each of the four neighbourhoods assigned to student groups. Figure 5 shows the workshop and its outputs including an engagement tree that measures effective use of languages associated with each attribute during the workshop, a comparison radar that uses pie-wedges to compare the three attributes of the engagement session (being committed to community, moving thinking forward, and being respectful) and measures and examples of thinking critically using specific algorithm-based wording from students speeches and the level of confidence in this analysis.

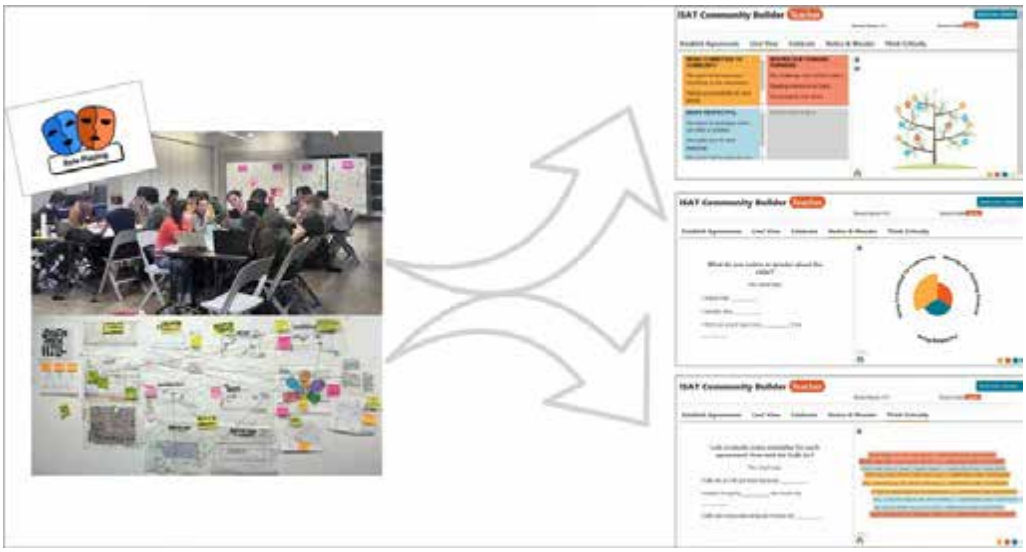

Figure 5: Role play workshops using CoBI AI tool and output [1. engagement tree (top), 2. a comparation radar (middle), and 3. examples of statistical confidence (bottom)].

Following the one-week workshops, students developed a preliminary and a final plan for sustainable neighbourhood's and analysed proximity of basic services using geospatial GIS models and the 15-minute city concept. Part of their analysis was proceeded with lab tutorial, where they attained hands-on instructions on using GIS for proximity analysis and data clipping and reporting (see Figure 6 for an example of students work). A final neighbourhood model was developed using Trimble Sketchup and a revised model was cast on Trimble Connect and navigated through an immersive environment using mixed-reality (XR) device.

Figure 6 shows the outputs of the geospatial scenario models created in GIS by Cherry Creek student team, which was later then integrated into Trimble Connect and visualized by the XR headset.

Discussion

There are multiple technological platforms that can be used to provide decision support to urban planners to obtain useful information and provide effective support (Anthony et. al., 2006, and Ning-rui and Yuan, 2005). Planning Support System (PSS) was proposed by the American scholar B. Harris in 1989. The system has been developed primarily to support planning processes (Geertman, 2002), based on the assumption that an increase in access to relevant information will lead to a greater number of alternative scenarios and, thus, a better-

informed public debate (Shiffer, 1995; Gerrit and Ligtenberg, 2007). Harris's proposed idea was to combine information technology with urban planning methods to provide decision-making assistance during every step of the planning process (Mao et al., 2008). PSS not only covers the ultimate act of decision making, but also the discovery, analysis, and evaluation stages of planning; it has been applied to urban-rural planning for the past 20 years. DSS also furnishes a process for analysing problems, establishing models, and simulating decision-making alternatives and results, all of which help improve decisions. The most significant area where spatial planning can be used in planning is to integrate it into decision making on various different scales. In the Netherlands the National Environmental Policy Plan (Ministry of VROM, 2001) emphasized the responsibility local authorities have for creating a sustainable environment, stressing that spatial planning at the local level has a direct impact on both urban and rural environments. This requires an area-specific planning approach at the local level.

The benefits of incorporating interactive forms of decision-making using GIS applications have developed beyond an operational support system and into a strategic decision-making support system (Grothe, 1994, and Cornelius and Medyckyj-Scott, 1991). AI-powered tools can facilitate communication between urban planners and the community. Applications of virtual reality (VR) or augmented reality (AR) can assist residents in visualizing proposed changes and provide feedback, promoting a more participatory planning process (Ghisleni, 2024). Comparing the results of engagement effectiveness will inform future pedagogies and assignment structure for next years. The results of student assessment, integration of AI and geospatial tools and other online environmental performance platforms utilized in this studio, serve as an opportunity to discuss and reimagine planning education as a critical change agent for enhancing student experience. Curriculum enhancement and partnerships with the Institute for Cognitive Science and the Immersive Media Lab helped to align faculty interests while advancing student experience and increasing their access to campus resources without adding any financial burden on their tuition and fees. Student evaluation is discussed in the conclusions section.

Conclusion and Recommendations

Planners are crucial contributors to the conversation on AI applications in urban planning practice and education. According to Sanchez (2025), planners have a long-term perspective, a commitment to public participation, and a thorough understanding of the intersection of policy, infrastructure, and daily life. These strengths are exactly what is needed to ensure that AI supports a sustainable and equitably built environment. Through a revised studio pedagogy using the capacities and support of University of Colorado's ASSETT program, I developed a curriculum for an undergraduate sophomore planning studio to respond to two primary questions. In the curriculum modules, I employed technology tools and geospatial platforms to support the learning objectives and to align student learning with the shift in the planning practice. Collaboration with two campus institutions yielded great success and supported student access to multiple technologies at no additional cost. The responses to these questions showed a positive and effective impact on students learning experience, measured through the campus administrative survey, peer-feedback, and unstructured observations of group performance.

Question 1: Will the use of AI tools help make public engagement truly meaningful? In the case study of this undergraduate -sophomore- studio, the students reported excitement and full autonomy of the engagement process including the decision making and their views of the SWOT elements of each neighbourhood. Role play exercise helped to maintain clarity of stakeholder's interest in each part of the exercise and students were able to immerse themselves in their assigned roles. One of the students' feedbacks is shown here:

"*I enjoyed the stakeholder workshop and the different formats of the class periods.*"

Question 2: How can technology platforms in urban planning curriculum enhance students' experience? Since the studio integrated multiple platforms including Esri and Trimble products and XR device developed by Metaverse, it was challenging to measure the effective use of each tool or platform separately. However, unstructured observations showed that students were more committed to learning Esri products (ArcGIS Pro and StoryMap) than applying what they learned in the analysis of their neighbourhood. Some students utilized ArcGIS Pro to analyse proximity of goods and services to the residential areas in their assigned neighbourhood,

while others utilized Adobe Illustrator to draw proximity buffers. Further tutorial sessions are needed to ensure that students will apply all tools. The most remarkable part of student interactions with technology was when they were introduced to AR/VR and XR as they started to navigate through their developed neighbourhood models. The following quote from students' feedback is related to technology use in this studio:

"The VR thing is so cool, I really do love it. Thanks for the great studio!"

Using in-class tutorials to train students on applying geospatial technology and AI tools in their projects is essential to ensure that students graduating can conduct neighbourhood proximity and flower of opportunity analyses. Students are also prepared to tackle real world problems related to mixed use and residential neighbourhoods. Future tools for assessing studio outcomes could be developed in the form of structured and systematic survey.

Acknowledgements
The studio revision and travel funds were made possible by an award from the Centre for Teaching and Learning (CTL)/ Arts & Sciences Support of Education Through Technology (ASSETT) Fellow Program at the University of Colorado Boulder, United states. I would like to thank Kirk Ambrose, Professor and Director of CTL, and Amanda Seal McAndrew, Associate Director of CTL for their support and leadership of the Faculty Fellow Program and their suggestions and feedback on the revised curriculum proposal. I would like also to thank Patrick Clark, Assistant Professor and Director of the CU Boulder Immersive Media Lab, and Thomas Breideband, Associate Director of the Institute for Cognitive Science at the University of Colorado Boulder.

Abstract
This study focuses on circular maker spaces as catalysts, integrating new technologies and creative industries within Circular Economy (CE) strategies at a local neighbourhood scale in cities within the embedded narratives of equity and just future. The research develops a Local Appropriation Model (LAM) to guide site selection and integration, combining (1) the Local Communities Comprehension Tool (LCCT) to assess local expectations and a GIS-based multi-criteria spatial analysis for site selection. By analysing local dynamics, the study developed the core structure of the Local Appropriation Model based on common findings from six pilot neighbourhoods. Ultimately, it offers an inclusive and holistic framework, serving as a vital roadmap for integrating Circular Economy (CE) strategies into urban environments through CMSs.

Keywords; Circular Economy, Circular Maker Spaces, Sustainable Development, Local Appropriation, Neighbourhood Scale, Just Future

01. Circular Economy & Circular Maker Spaces – Why is it necessary?

The rapid consumption of natural resources and ongoing urbanization have led to various socio-economic and environmental challenges around the World. In response, the concept of a circular economy (CE) emerging from debates on sustainability and sustainable development has gained increasing importance and is continuously evolving through academic and policy research.

Unlike the dominant linear economy model, which follows a make-use-dispose trajectory, the circular economy emphasizes reuse, durability, and recycling. Here, the Ellen MacArthur Foundation, which provided one of the first and most widely accepted definitions of the circular economy, describes it as follows:

> "A circular economy is an industrial system that is restorative or regenerative by intention and design. It replaces the end-of-life concept with restoration, shifts towards the use of renewable energy, eliminates the use of toxic chemicals, which impair reuse, and aims to eliminate waste through the superior design of materials, products, systems, and business models." (Ellen MacArthur Foundation, 2013, p. 7)

Over time, the circular economy has evolved beyond its initial focus on recycling to encompass a broader range of strategies to minimize resource use and environmental impact. In this context, many countries have developed different approaches and policies related to the circular economy. For instance, early frameworks such as Japan's 3R Initiative (reduce, reuse, recycle, 2004) and the EU Waste Framework Directive (2008) laid the foundation for this shift by introducing basic "R" strategies (Ekins et al., 2019).

By 2017, this framework was expanded into the 9R strategy, introducing a more comprehensive and hierarchical approach to circularity (Potting et al., 2017; Kirchherr et al., 2017; Ekins et al., 2019). This framework targets smarter product use and circularity by prioritizing sustainability. Among the approaches developed in this context, the most important and primary strategies are rejection, rethinking, and reduction (R0–R2). It focuses on reducing overconsumption through innovative technology, product design, and organizational change. The second most important strategies are reuse, repair, refurbishment, remanufacturing, and repurposing (R3–R7); It contributes to resource efficiency by extending product life. The last and third most important strategies include recycling and recovery (R8–R9), material processing and energy recovery processes, and are closer to traditional linear

economic applications. This expanded R-framework supports a more sustainable future by promoting the transition from end-of-life waste management to systemic design and socio-technical transformation (Potting et al., 2017; Kirchherr et al., 2017; Ekins et al., 2019).

Followingly, the circular economy is operationally examined under 3 main scales in this context. These are respectively: It is defined as the micro level (products, companies, consumers), meso level (eco-industrial parks), and macro level (city, region, nation, and beyond) (Ekins et al., 2019). This provides an important framework for understanding the scope of potential future circular economic activities at different levels.

Furthermore, many researchers highlight that the circular economy will likely drive major changes in the labour market, which will affect the operations in different levels. New employment opportunities are expected to emerge in sectors such as repair, maintenance, remanufacturing, and reuse, as well as in digital technologies and sustainable design. In line with this, the European Commission (2020) predicts that over 700,000 new jobs could be created across the EU by 2030 as a result of new circular economy policies in the EU. The Ellen MacArthur Foundation (2015) also emphasizes that circular models stimulate growth in labour-intensive sectors, thereby supporting local employment. Cities will play a pivotal role in this transformation, as they not only host a large share of the global population but also account for 60–80% of global energy consumption and 75% of carbon emissions (Chen & Chen, 2012; Environment, 2017; Coskun et al., 2022).

On the other hand, the circular economy serves as an alternative economic model that promotes social and environmental sustainability while seeking a balanced relationship among the three pillars of sustainable development: environmental protection, social equity, and economic growth (Coşkun et al., 2022). At this point, while cities face various socio-economic and environmental challenges, questions arise regarding how circular economy strategies can be scaled and implemented within urban environments.

In line with this, it is crucial to recognize that urban space is a collective value and that all city residents have equal rights to its production (Lefebvre, 1996). Harvey (2008) emphasizes that residents have a collective right to access existing urban resources and engage in urban transformation, which are essential principles for fostering an inclusive and just transition in the cities. Accordingly, implementing circular economy practices in cities must be diverse, democratic, and equitable (Fainstein, 2010). Ensuring both a just transition and justice in emerging urban structures is essential.

Here, CMSs, which have the potential to advance sustainable development goals (SDGs) through circular-making activities such as reusing, repairing, refurbishing, and recycling (Galleguillos et al., 2023), emerge as a key mechanism for accelerating the just transition to a circular economy in urban spaces. Makerspaces provide an opportunity for individuals from diverse backgrounds to connect, exchange knowledge, and collaborate on creative projects (Einarsson & Hertzum, 2021). At the same time, these maker spaces serve as key focal points for building a sense of community and engagement, facilitating the adoption and implementation of circular economy principles within society. (Galleguillos et al., 2023, Kohtala & Bosqué, 2014). Moreover, they will function as platforms for social empowerment and social justice in the city.

As a result, the circular economy, which has emerged as part of the concept of sustainability in the face of various socio-economic problems that arise in a rapidly depletion and urbanization of the world, is seen as an important model that will reverse or slow down this situation due to its scope and capacity. In this context, CMSs appear as an important tool to implement the principles of the circular economy in cities, both environmentally and socially, and to ensure a just transition.

In this context, the local-scale implementation of circular production spaces, as tools for applying circular economy (CE) principles at the urban scale, will play a significant role in accelerating the process and promoting its wider integration at the grassroots level. In this regard, the next phases of this study explore how CMSs can be integrated at a local neighbourhood scale in cities within the embedded narratives of equity and a just future.

02. Local Appropriation of Circular Maker Spaces (CMS) – How Can CMSs Be Integrated at the Local Scale?
The concept of appropriation, based on Lefebvre's discussions on the production and construction of space, has been used by architects, planners, and designers since the 1960s and 70s in line with various discourses and policies in urban planning and development. Due to the multi-layered and complex nature of urban space, appropriation is shaped and realised not only physically, but also through socio-political, cultural, and environmental processes. (Lefevbre, 1991). Therefore, appropriation refers to the sum of all the actions we take to transform our environment for a specific purpose, while the individual's motivation is essential to initiate this transformation (Noschis, 1978).

On the other hand, the urban space that surrounds us can encourage or restrict us from this transformation. In the process of appropriation of space, understanding local elements is also an important factor in terms of sustainability and ownership of the space. In this context, the research seeks to provide a framework for the appropriation of circular maker spaces in urban space in line with CE principles.

While makerspaces serve as platforms for sharing knowledge, ideas, skills, and equipment by prioritizing sharing and learning over commercial gain (Kuznetsov & Paulos, 2010; Peppler et al., 2016; Galleguillos et al., 2023), they also foster community building. Additionally, makerspaces act as structures that promote local economic development through the use of digital technologies and traditional methods. In this context, circular makerspaces have the potential to support and transform existing local networks within the city. As social and inclusive spaces, they enhance the well-being of city residents and contribute to sustainability (Taylor et al., 2016; Galleguillos et al., 2023). (Taylor et al., 2016; Galleguillos et al., 2023).

The adoption of CMSs in urban areas is important for implementing CE principles locally and accelerating the transition. This study aims to provide a framework for integrating CMSs at this level. In this context, the study focuses on 6 different neighbourhoods of Bayrampasa district in Istanbul, which include different groups and have various application bases for CE applications. The selected neighbourhoods within the district borders, respectively, are Yıldırım, Kartaltepe, Cevatpasa, Muratpasa, Kocatepe, and Altıntepsi. The studies conducted in these neighbourhoods have been supported by qualitative and quantitative research methods to understand how urban residents perceive CMSs and where they place them in future scenarios. In addition, analyses have been conducted to determine how these spaces will be physically integrated into the urban space, in order to select an appropriate location.

Subsequently, a Local Community Comprehension Tool was developed through a survey conducted with neighbourhood residents and an examination of studies that will serve as a foundation for the municipality's CE applications. The Local Communities Comprehension Tool (LCCT) aims to understand local communities and authorities' expectations, their perception of the CE and its implementation on the local scale.

To ensure sustainable implementation, criteria for site selection were subsequently developed and tested through pilot applications using a Multi-Criteria Decision Analysis method based on GIS (Geographic Information Systems) that supports spatial decision-making. The site selection criteria included several important factors, such as accessibility for local residents. Additionally, detailed descriptions of related facilities and networks were considered, enabling discussion on the physical integration of these spaces into neighbourhoods.

02.1. Local Community Comprehension Tool (LCCT)
The Local Community Comprehension Tool consists of 3 stages. These intertwining phases aim to understand how the circular economy and circular production spaces are perceived in the local context, and what applications they have.

These phases are as follows:
(1) Understanding how local residents perceive the circular economy and maker spaces.
(2) Reviewing the local government's approaches and implementations regarding the circular economy and circular production.

(3) Understanding how city residents perceive the local government's implementations regarding circular production and CMSs. (Figure 01).

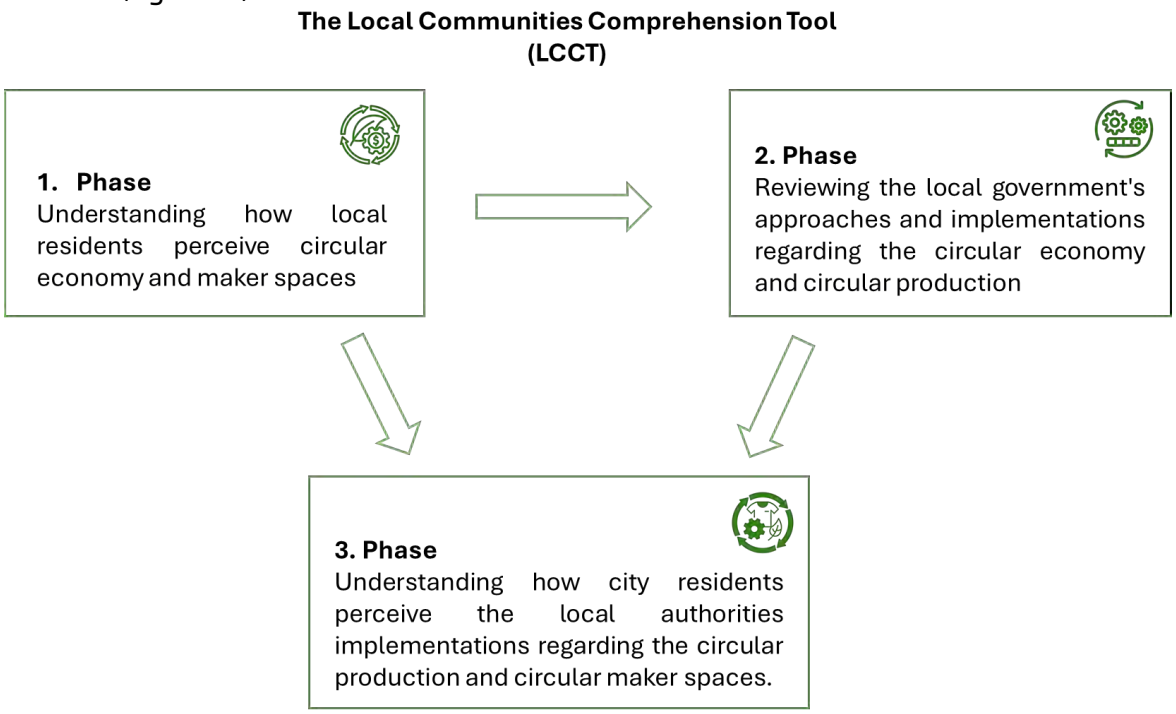

Figure 01. The Local Communities Comprehension Tool (LCCT)

Phase 1 contains survey data about the circular economy and maker spaces. Phase 2 contains a review of the implementations of the Bayrampasa Local Municipality related to the circular economy. Phase 3 contains survey data to understand the local authorities' perceptions of their implementations and their expectations of CMSs.

Phase 1: Understanding How Local Residents Perceive the Circular Economy and Maker Spaces

The survey on the circular economy and production spaces was conducted online. The survey questions were directed at city residents and were organised under five main headings. These were: 'Circular Economy', 'Circular Production Spaces', 'Circular Production Spaces and the Municipality', 'Circular Production Spaces and Participation', 'Circular Economy and the Future of the City', and 'Circular Production Spaces and Social Impacts'.

A total of 66 people participated in the survey. Of these, 30 were male and 36 were female. Therefore, men accounted for 45% of the total participants, while women accounted for 55%. (Table 01)

Table 01. Participants' Age Ratios

Age Range	Number of Participants	Participant Ratio (%)
18-25	15	23
26-35	25	38
36-45	11	17
46-55	6	9
55>	9	13
Total	66	100

The participants are divided into six age categories. These are the 18–25 age range, the 26–35 age range, the 36–45 age range, the 46–55 age range and the over-55s. The proportion of participants in the survey is as follows: 23% are in the 18–25 age range, 38% are in the 26–35 age range, 17% are in the 36–45 age range, 9% are in the 46–55

age range, and 14% are in the over-55 age range. These values show that the majority of participants are young. (Table 02).

The section measuring the participants' level of education is divided into five categories. These are: primary school (compulsory education); high school, vocational school, university; and graduate education.

Table 02. Participants' Educational Background

Educational Background	Number of Participants	Participant Ratio (%)
Primary School – Compulsory Education	6	9
High School	10	15
Vocational School	9	14
University	35	53
Master's Degree	9	9
Total	66	100

Nine per cent of the respondents have completed compulsory education (primary school). Their education levels are as follows: high school (15%), vocational school (14%), university (53%) and master's degree (9%). The survey data shows that the majority of participants have a higher level of education. (Table 02).

The proportion of survey participants from the sample neighbourhoods selected for the study in the Bayrampaşa district are as follows: Yıldırım District (26%), Kartaltepe District (20%), Cevatpaşa District (15%), Muratpaşa District (15%), Kocatepe District (13%) and Altıntepsi District (11%).

According to the survey data, 33% of participants said they had heard of the circular economy, while 67% said they had not. Of those who had heard of the concept, 26% associated the circular economy with the efficient use of resources, while 74% associated it with the reuse and recycling of waste.

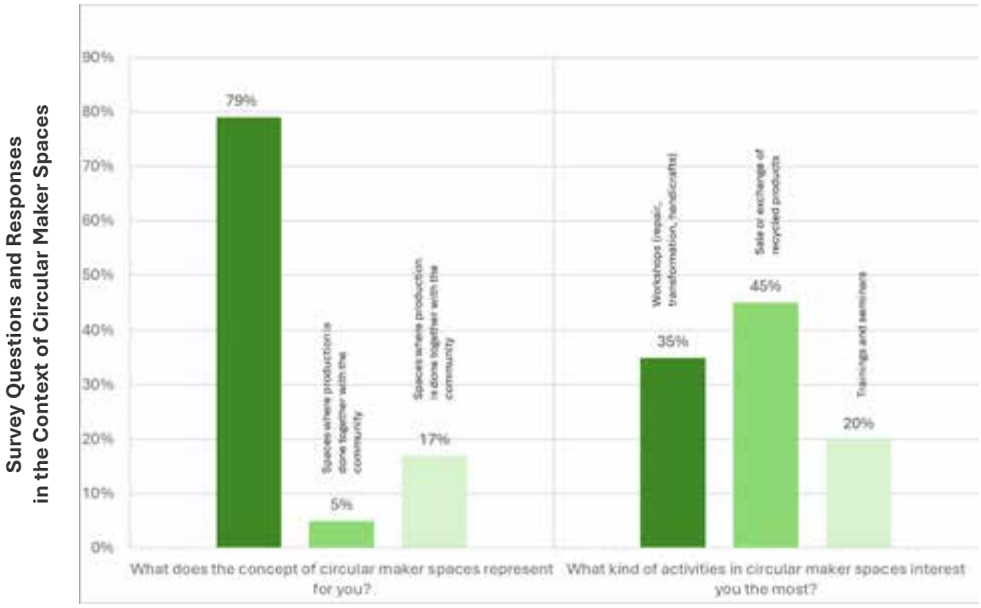

Figure 02. Survey Q&R in the context of Circular Maker Spaces

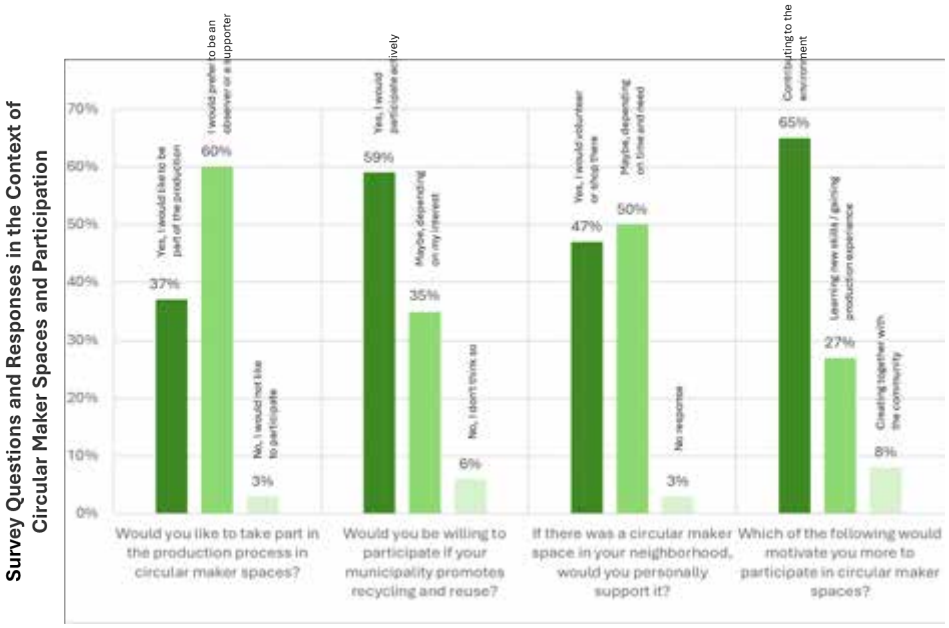

Figure 03. Survey Q&R in the context of CMS and Participation

Participants defined circular production spaces as places where new products are made from waste, with 79% defining them as such. Meanwhile, 17% defined them as places focused on repair, transformation, and sharing, and 5% as areas where production is carried out with society. On the other hand, when asked what activities they would like to take part in at circular production spaces, 35% replied workshops (e.g., repair, conversion, and handicrafts), 40% replied selling or exchanging recycled products, and 20% said training and seminars. As a result, it illustrates that the participants support activities that produce new added value from existing waste products. (Figure 2).

When asked about the municipalities' CMSs, 41% of participants stated that they were familiar with the municipalities' practices regarding CMSs, while 58% stated that they were not. One percent did not answer this question. Following this, when asked about participation, 37% of participants stated that they wanted to be involved in the production in circular maker spaces, while 60% stated that they just wanted to be observers or supporters. Three per cent of participants said they did not want to be involved in the production process.

This result shows that, although the participants have reservations about the production process, they still support it. This can be considered a positive development for the production of CMSs (Figure 03).

Another question about the participation process is whether municipalities promoting recycling and reuse should be allowed to participate. While 59% of participants said they would actively participate in recycling and reuse practices if encouraged by municipalities, 35% said they might participate depending on their interest, and 6% said they would not participate. This result shows that most participants support waste recycling and reuse and want to be involved in the process (Figure 03).

While 47% of participants said they would volunteer or shop individually if there were a circular production space in their neighbourhood, 50% said they might support it, depending on their schedule and needs. Consequently, it is assumed that participants will support the implementation of CMSs or applications at the neighbourhood scale at a high rate. In the following question, when asked what would motivate them the most to participate in CMSs, 65% of the participants said contributing to the environment, 27% said learning new skills or gaining production experience, and 8% said producing with the community. This reveals that environmental concerns are the most important factor encouraging participants to engage with CMSs. (Figure 03).

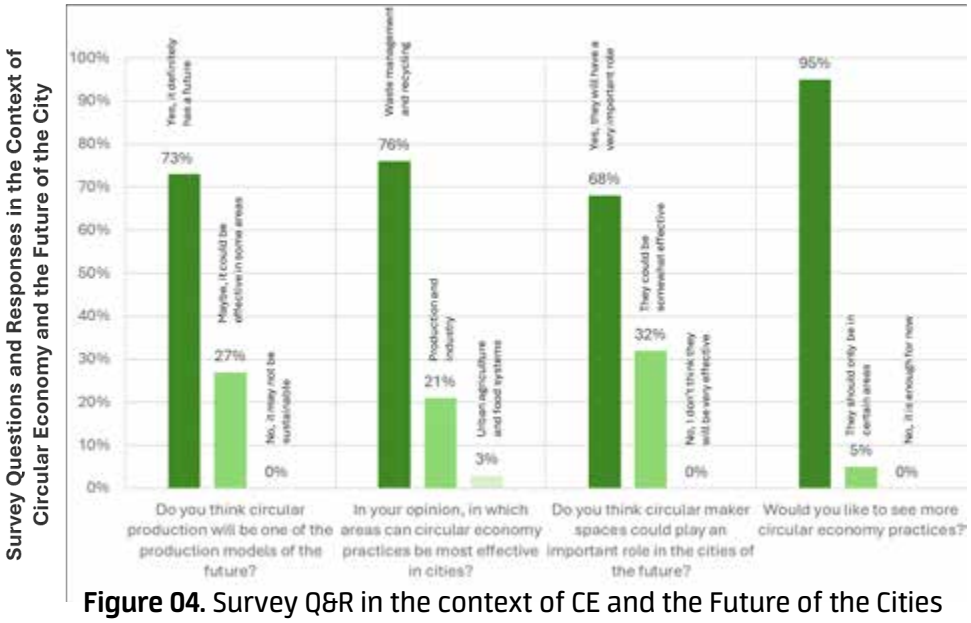

Figure 04. Survey Q&R in the context of CE and the Future of the Cities

While 73% of participants said that circular production would be one of the dominant production models in the future, 27% said that it might only be effective in certain areas. All of the participants agree that circular production will be one of the dominant production models of the future. Therefore, based on the survey data, we can conclude that the participants firmly believe that circular production will be one of the dominant production models in the future (Figure 04). When asked which areas of the city could benefit most from circular economy practices, 76% of participants answered waste management and recycling, 21% replied production and industry, and 3% responded urban agriculture and food systems. This question supports the above answers and reveals that participants are concerned about environmental and waste issues (Figure 04).

In answer to the question of whether CMSs will play an important role in the future of cities, 68% said that they would be very important, while 32% said that they might be partially effective. None of the participants said that they did not think it would be effective. This question's outcome reflects participants' belief that CMSs will play an important role in future scenarios. Additionally, 95% of participants supported the implementation of circular economy practices throughout the city, while 5% favoured a more targeted approach. None of the participants considered existing circular economy practices to be sufficient (Figure 04).

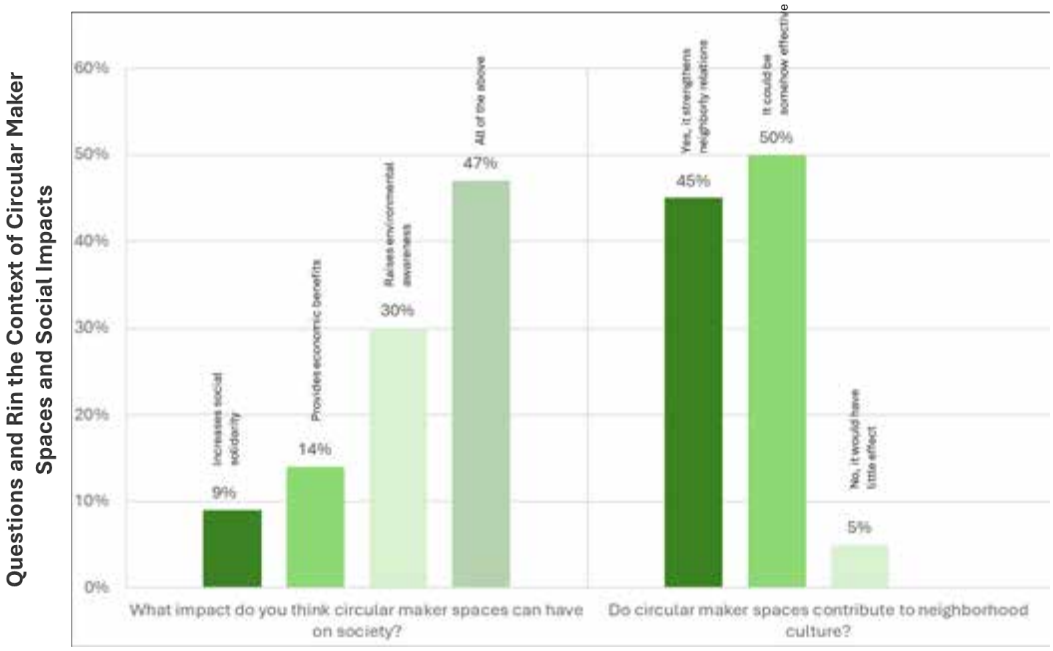

Figure 05. Survey Q&R in the context of CMS and Social Impact

Figure 05 shows the responses given by participants when asked what impact maker spaces can have on society in the context of CMSs and their social impacts. The responses were as follows: 9% increased social solidarity, 14% provided economic benefits, 30% increased environmental awareness, and 47% all ticked. Examining the survey data for this question reveals that participants believe circular maker spaces will have a positive social, economic, and environmental impact on society. This demonstrates that participants view CMSs as socially sustainable. In response to the question regarding the contribution of CMSs to neighbourhood culture, 45% of participants agreed that they strengthen neighbourhood relations, while 50% believed they could be partially effective. Five percent of participants believe that CMSs will not contribute to neighbourhood culture (Figure 05).

As a result of this phase, the survey revealed that participants were sensitive to environmental issues and found solutions and waste management practices to be insufficient. Furthermore, they believe that CE practices will be crucial in addressing these problems, particularly the promotion of CMSs. Although the survey data emphasizes that municipalities should support these practices, it also shows that participants are quite willing to support circular maker spaces on their own. Lastly, participants responded very positively to questions about the future social impact of circular production spaces, stressing that these spaces would be socially sustainable.

Phase 2: A review of Bayrampasa Local Municipality's Implementations related to CE

Although the Bayrampasa Municipality does not officially adopt the principles of the circular economy, it has implemented numerous projects of various sizes and scopes related to this concept. These projects aimed to encourage waste separation at source, promote recycling and energy efficiency, and foster sustainable environmental awareness. In addition, the Istanbul Provincial Zero Waste Management System Plan (2020), published by the Ministry of Environment, Urbanisation and Climate Change, states that the Zero Waste Management and Practices, which have been in active implementation since 2018, were started by the Bayrampasa Municipality in 2019 (URL 01).

Figure 08 shows the municipality's practices related to CE principles and supporting the transition to CE. These include the Bayrampasa Recycling Mobilisation, the Collection of Recyclable Waste, the Zero Waste Project Containers, the Recycling Education Programme, the Zero Waste Children's Play Area, the Pasakart and the Solar-Powered Lighting. (Table 03).

Table 03. Implementations of the Bayrampasa Municipality

Implementations that are related to Circular Economy	
Implementations	**Purpose**
Bayrampaşa Recycling Mobilization	Raising Public Awareness
Collection of Recyclable Waste – Distribution of Blue Waste Bags	Promoting Recycling
Zero Waste Project – Recycling Waste Collection Containers (glass, clothing, batteries, oil, etc.)	Promoting Recycling
Recycling Education in Schools	Raising Public Awareness & Education
Zero Waste Children's Play Performance	Raising Public Awareness & Education
Paşakart (point accumulation within the scope of the Zero Waste Project)	Raising Public Awareness & Economic Development
Solar-Energy Lighting in Parks and Squares	Promoting Energy Efficiency

These applications have various purposes, including raising public awareness, education, local economic development, and improving energy efficiency. In this context, some of them stand out. The Zero Waste Project, initiated and supported by the ministry, is particularly well known among city residents. Conversely, these practices are concrete examples of the environmentally friendly policies and approach of Bayrampasa Municipality, which will form the basis for a circular economy. Incorporating waste into the economy, raising environmental awareness, and taking steps towards a sustainable future demonstrate the municipality's engagement with this issue.

Another application, Pasakart, is a recycling initiative introduced by the municipality. Thanks to this project, citizens can take recyclable waste, such as paper, plastic, glass, and metal, accumulated in their homes to waste collection points in their neighborhood on certain days. 'Money Points' are loaded onto the Pasakart according to the weight of waste measured by digital scales. These points can be used by citizens at contracted markets and restaurants within the borders of Bayrampasa. According to data from 2023, over 1,300 people became Pasakart holders, and a total of 13,437 kg of recyclable waste and 350 litres of waste oil were collected. As a result of these recycling activities, citizens received a total of 22,638 TL worth of Money Points. Additionally, approximately 24,000 trees were saved from being cut down, and millions of litres of water were saved from pollution by collecting 50 tonnes of waste vegetable oil. In addition, approximately 24,000 trees were saved from being cut down, and millions of litres of water were saved from becoming polluted by collecting 50 tons of waste vegetable oil (URL 02). This project, which protects the environment while providing economic benefits to citizens, is an important step towards a sustainable future and CE practices.

As part of the Bayrampasa Recycling Mobilisation initiative, teams from the Municipality's Climate Change and Zero Waste Directorate visited 8,063 households in the Kocatepe district. They informed citizens about the importance of recycling and distributed brochures and household waste bags for recycling. This event is important in terms of both community empowerment and raising public awareness. It supports the transition to recycling, which is one of the principles of the CE. (URL 03).

Phase 3: Understanding the Perception of the Local authorities' Implementations and Expectations from CMSs
In this phase of the study, an online survey on circular maker spaces was conducted with city residents living in six selected neighbourhoods in the Bayrampasa district of Istanbul. The survey aimed to understand urban residents' perspectives on CMSs in different neighbourhoods. In this context, the survey includes a total of 14 questions, organised under the following headings: the municipality's zero waste management and practices;

the use and operation of circular production spaces; the settlement preference of CMSs at neighbourhood level; the individual impact of CMSs at neighbourhood level; and how city residents imagine the context of CMSs. Thirteen of these questions are multiple-choice and one is open-ended.

A total of 53 people took part in the study. Of these, 30 identified as female and 23 identified as male. This equates to 43% male and 57% female participants. The participants' ages were divided into five categories. These were 18–25 years old, 26–35 years old, 36–45 years old, 46–55 years old, and over 55 years old. The proportion of respondents in each age range who participated in the survey is as follows: 18-25 years old (13%), 26-35 years old (42%), 36-45 years old (21%), 46-55 years old (13%), and over 55 years old (11%). These values reveal that the majority of participants are young people (Table 04).

Table 04. Participants aga range

Age Range	Number of Participants	Participant Ratio (%)
18-25	7	13
26-35	22	42
36-45	11	21
46-55	7	13
55>	6	11
Total	53	100

The section measuring the participants' level of education is divided into six categories. These are: primary school (compulsory education), high school, vocational school, university, and graduate education. 9% of respondents have completed compulsory education (primary school). The respective education levels of the participants are as follows: high school (14%), vocational school (6%), university (51%), and master's degree (8%). The survey data shows that the majority of participants have a higher level of education. (Table 05).

Table 05. Participants educational background

Educational Background	Number of Participants	Participant Ratio (%)
Primary School – Compulsory Education	5	9
High School	14	26
Vocational School	3	6
University	27	51
Master's Degree	4	8
Total	53	100

The participant rates from the six selected sample neighbourhoods are as follows: Yıldırım Neighborhood (17%), Kartaltepe Neighbourhood (25%), Cevatpasa Neighbourhood (6%), Muratpasa Neighbourhood (11%), Kocatepe Neighbourhood (34%), and Altıntepsi Neighbourhood (8%).

The survey questions and answers are divided into four groups according to their context. The questions were designed to understand the municipality's participation in the zero-waste project since 2018, the communication between the municipality and city residents, and the effectiveness of the project's practices. The results revealed that 66% of participants were aware of the project, while 34% were not.

In response to the question about Bayrampasa Municipality's practices within the scope of the Zero Waste Project, based on information from the municipality's website, it emerged that participants were less familiar with the municipality's practices in neighbourhoods beyond routine activities such as the collection of recycling waste and the provision of recycling waste containers.

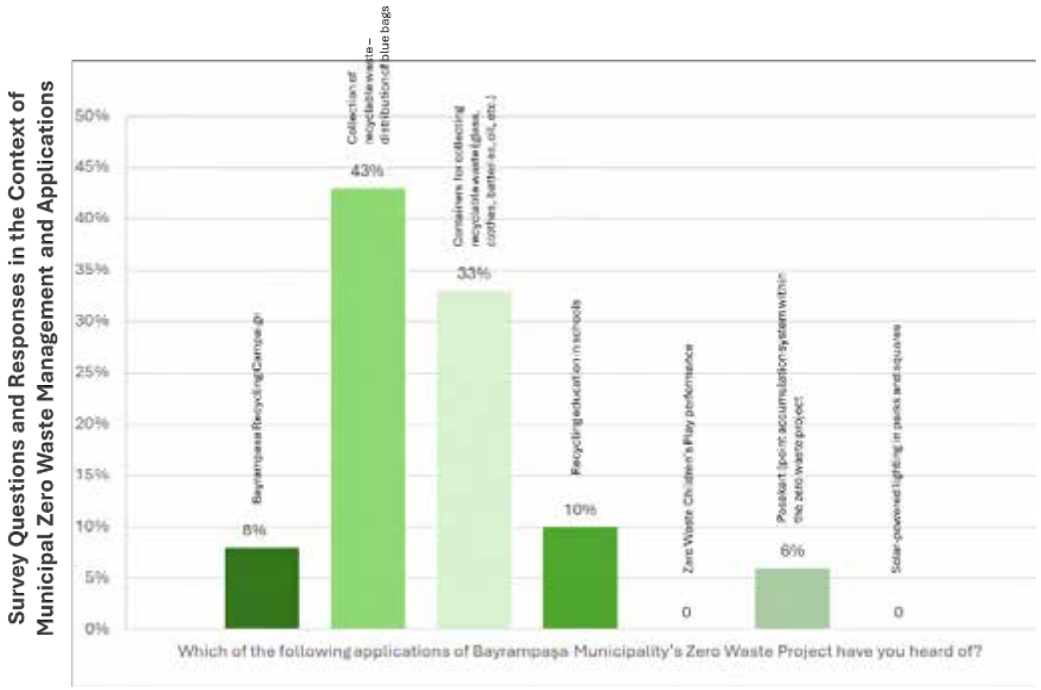

Figure 06. Survey Q&R in the context of Municipal Zero Waste Management and Applications

As an act and routine practice of the municipality in neighbourhoods, the collection of recycling waste (the distribution of blue bags) is recognised by 43%, as are recyclable waste collection containers (33%). The Bayrampasa recycling mobilisation is known by 8% of participants, the recycling education programme in schools by 10%, and the Pasakart scheme (which involves accumulating points within the scope of the zero-waste project) by 6% (Figure 06). The Zero Waste Children's Play Demonstration held at the municipal cultural centre and the solar-powered lighting projects in parks and squares are not known to the participants.

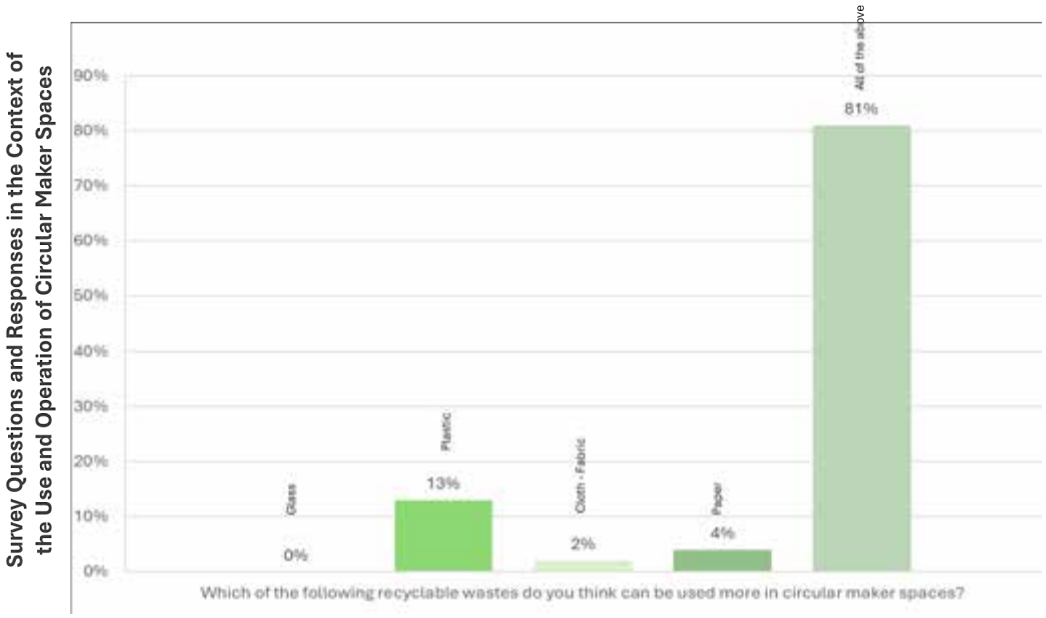

Figure 07. Survey Q&R in the context of the Use and Operations of CMS

Various questions were asked about the materials to be used in circular production spaces, as well as how these spaces would function and be governed. These questions aimed to measure participants' perceptions of circular production spaces. The aim of the questions prepared for those considering materials that can be used in CMSs as part of the zero-waste project is to provide participants with an insight into the production models that will exist in these spaces. The majority of participants (81%) stated that all products (glass, plastic, clothing, and paper) will be used together in these production areas. In addition, 13% of participants only selected plastic, 12% only selected clothes, and 4% only selected paper, saying that these items could be recycled in these places. Nobody marked the glass as recyclable. (Figure 07).

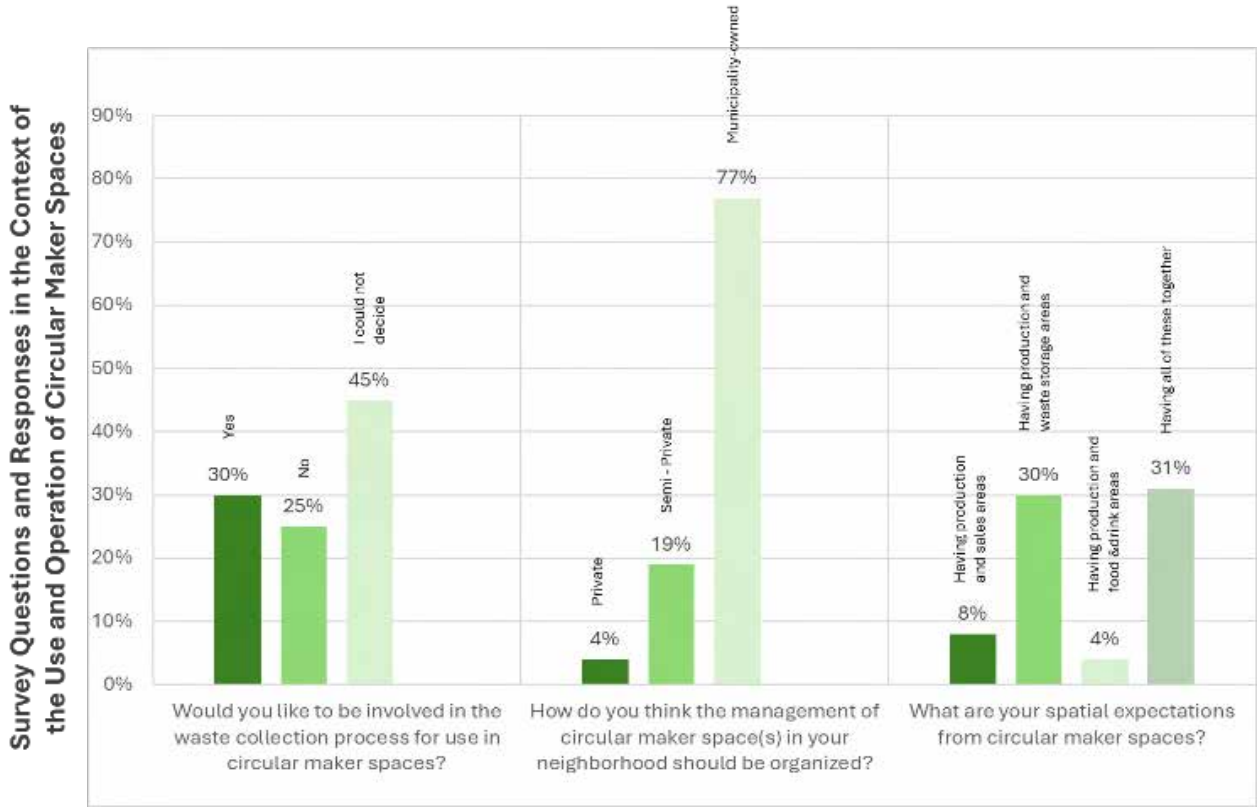

Figure 08. Survey Q&R in the context of the Use and Operations of CMS

In response to the question about participation in the waste collection process, 30% of respondents agreed, 25% disagreed, and 45% were undecided. This shows us that participants tend to act after seeing the process. (Graphic .07) Regarding the question about the management of CMSs, the majority (77%) indicated that the municipality should own them. Meanwhile, 19% of respondents thought that semi-private management would be good, while 4% supported private management. This result shows that urban residents want the municipality to initiate or carry out the expansion process of CMSs. (Figure 08)

In another question, participants were asked about their spatial expectations for CMSs. Eighty percent stated that there should be a production and sales area only, 30 percent stated that there should be a production and waste storage area only, and 4 percent stated that there should be a production and food and beverage area only. Thirty-one percent of the participants stated that all these areas should coexist. Regarding the preference for the spatial organization of circular maker spaces, the majority (31%) thought that different functions should be together. The other majority (30%) stated that these spaces should be used only for production and waste storage (Figure 08).

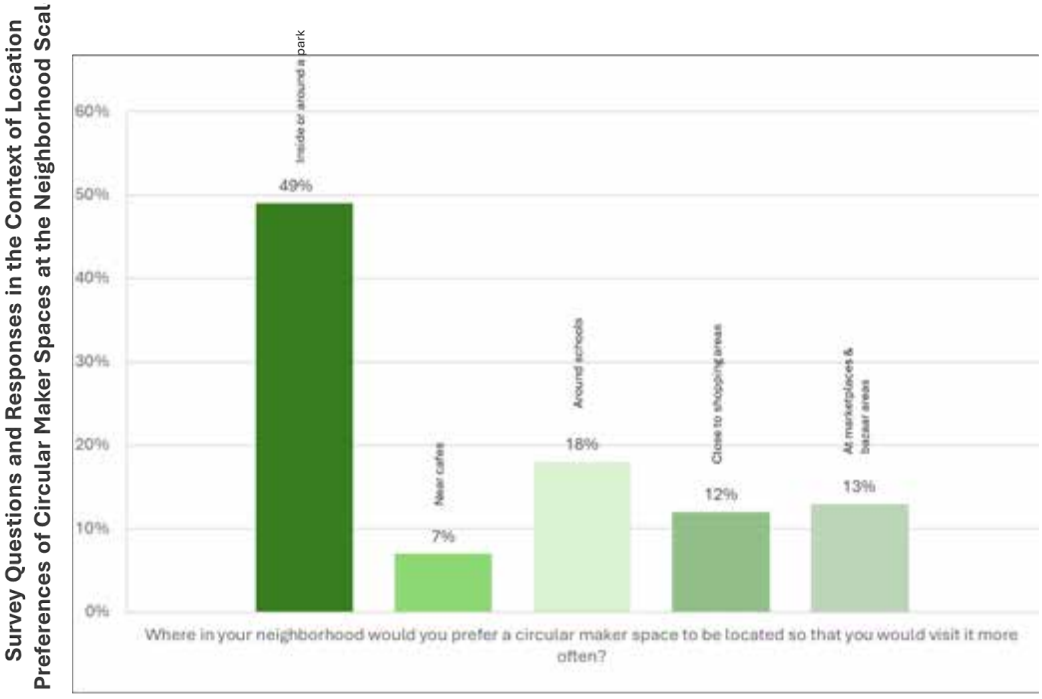

Figure 09. Survey Q&R in the context of Location Preferences of CMS at the Neighbourhood Scale

When asked about their preferred location for CMSs, 49% of participants said they should be in or around the park. The next highest responses were around schools (18%), in marketplaces (local bazaar areas) (13%), near shopping areas (12%), and near cafes (7%). These answers indicated that, while participants imagined circular production spaces alongside the green infrastructure of cities, they also believed these spaces should be combined with social activities (Figure 09).

When asked how neighbourhood-scale circular production spaces could affect their lives, most participants (60%) indicated positive effects, and 25% said they would have a very positive effect. This shows that the presence of CMSs in neighbourhood design is viewed positively. Additionally, 14% of respondents said it would have no impact, while only 1% said it would have a negative impact. Participants did not select the option that a circular maker space would have a "very negative impact" (Figure 10).

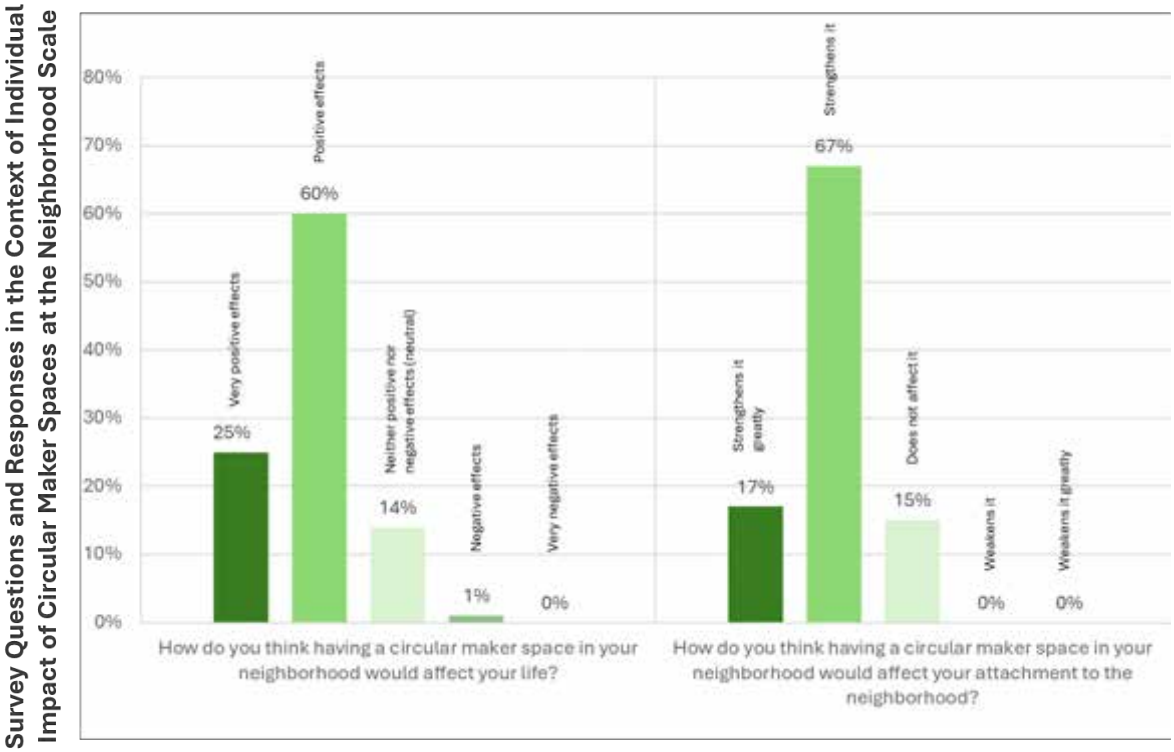

Figure 10. Survey Q&R in the context of Individual Impact of CMS at the Neighbourhood Scale

Additionally, participants stated that a circular maker space in their neighbourhood would have a mostly positive effect on the bond they have established with the neighbourhood. They stated that their bond with the neighbourhood would strengthen by 17%, and 67% said it would strengthen. Fifteen percent of participants think that CMSs will not affect the bond they establish with the place. None of the participants expressed a negative opinion on this issue. This demonstrates that CMSs can foster relationships and a sense of belonging in the neighbourhood (Figure 10).

As a result, the participants perceive circular production spaces as a tool that can strengthen existing socioeconomic and environmental factors in neighbourhoods. In this context, the local government is expected to play an active role in these areas. Lastly, it was revealed that the participants were not sufficiently informed about zero waste projects that could contribute to the municipality's circular economy practices and circular production spaces.

As part of the qualitative research, neighbourhood residents were asked to describe their vision for the circular maker space. A wide variety of responses were received. Analysis of the responses indicated that participants exhibited varying levels of awareness, interest, and imagination regarding the concept of circular production. The responses were associated with six different concepts. These concepts are safe and environmentally friendly, environmental sustainability, social interaction, location of the space, management and organization, uncertainty, and hesitation, respectively. (Figure 11)

Many participants emphasized that CMSs should adapt to their environment. They stressed the importance of avoiding environmental harm. This shows that a circular maker space is perceived as both a technical process and a social value that raises ecological awareness. However, participants had different opinions about the location and structure of CMSs. Some argued that this type of building should be located independently and safely.

Others imagined it as an aesthetically pleasing, well-maintained open space in public areas such as parks. While some participants described circular production spaces on a mesoscale, most envisioned them as part of the neighbourhood's urban space on a microscale.

Open-Ended Questions and Responses in the Context of How City Residents Envision Circular Maker Spaces

	Scope	Number of Responses	Short Definition
	Safe and Environmentally Friendly	1	The expectation for the space to be independent, safe, and isolated from environment
	Enviromental Sustainability	2	Zero-waste managment and environmentally sustainable facility concept
	Social Interaction	3	Spaces for co-production, solidarity, and social interaction
	Location of the Space	3	Located inside the park or in public spaces with an aesthetic design
	Managment and Organisation	2	Serious management attitude and awareness-raising information
	Uncertainty and Hesitation	2	Participants who have no idea or have a negative perception

Figure 11. Open Ended Survey Q&R in the context of How City Residents Envision Circular Maker Spaces

Furthermore, some participants described CMSs as places where not only waste is collected or recycled, but people also come together, work together, and produce social benefits. They also emphasized the importance of incorporating sales spaces into CMSs. This perspective demonstrates that society can develop and embrace a socio-economic perspective, along with circular economy practices and circular production spaces. Some participants emphasized the importance of promoting CMSs and highlighted their educational function and potential to raise public awareness. These responses reveal that communication strategies and physical design are integral to the process.

Some participants were unfamiliar with the concept of circular maker space, could not visualize the space, or thought it was not suitable for their neighbourhood. This shows that society has not yet embraced the concept. Various communication strategies are needed to improve this situation.

The results of the open-ended survey question illustrate that awareness of CMSs varies at the neighbourhood level. These spaces are considered not only physical structures but also spaces for social interaction and environmental awareness. In this context, it has become clear that a holistic strategic planning approach focused on design, education, social participation, and awareness is needed to implement circular production practices at the neighbourhood scale.

02.2. GIS-based Multi-Criteria Analysis (MCDA) for Site Selection

Multi-criteria decision analysis (MCDA) helps decision makers analyse possible actions or alternatives based on multiple, often incomparable, factors or criteria. Geographic information system (GIS)-based MCDA provides a powerful tool by enabling the evaluation of objective and subjective criteria together in decision-making processes. This type of analysis uses decision rules to combine criteria and rate or rank alternatives (Eastman, 2009; Figueira et al., 2005; Malczewski, 1999a; Greene et al., 2011). According to the literature, the main factors affecting the selection of multi-criteria decision analysis methods are the effects of elements such as the number of decision makers, stage of the decision process, number of targets and alternatives, level of uncertainty, risk toler-

ance, measurement scales, experience level, and technical resources on method selection (Greene et al., 2011).

The summary table provides an explanation of each factor in relation to the relevant literature and is structured to guide the selection of methods in decision-support processes. This method was developed to increase the contextual sensitivity of decision analysis, evaluate the suitability of techniques, and ensure transparency and repeatability in analytical processes. It also enables one to perceive the difficulties related to location selection from a broad perspective. (Figure 12).

This study developed a multi-criteria decision analysis (MCDA) evaluation framework of the Analytic Hierarchy Process Table (AHP) to help select locations for circular production spaces. The AHP Table comprises various factors grouped under three main headings.

1. Natural factors: This group evaluates topographic features and suitability for settlement, such as dominant areas and landslide risk areas, as well as distance to water resources and slope.
2. Social and Economic Factors: This group discusses distances to local economic activities, residences, public spaces, and buildings.
3. Access factors: This group includes distances to pedestrian paths, green spaces, public transportation networks, and main transportation axes.

Each factor and subfactor is graded by dividing it into distance-based suitability classes. During the analysis process, the weight of each factor on the total decision is expressed as a percentage. (Figure 14).

Factor	Explanation	Key References
Number of Decision Makers	MCDA techniques designed for individual decision-making can be modified for group settings, typically requiring consensus-building through negotiation or aggregation strategies.	Malczewski (1999b, 2006a); Hwang & Lin (1987); Balram & Dragicevic (2006); Joerin et al. (2009); Rinner (2001)
Decision Phase	Decision-making generally consists of two key phases: problem structuring and evaluation/recommendation, each demanding specialized tools and methodologies.	Anderson et al. (2003); Bouyssou et al. (2006); Turban & Aronson (2001)
Number of Objectives	Single-objective problems are addressed through methods like MCE or MADM, whereas multi-objective decision making (MODM) involves recognizing conflicts or synergies among objectives and organizing criteria accordingly.	Jankowski (1995); Malczewski (1999a, 2004); Eastman et al. (1995)
Number of Alternatives	When alternatives are few, the problem is discrete; when options are numerous or continuous, such as all possible land parcels, it falls within a screening or suitability analysis framework.	Chakhar & Mousseau (2007); Eastman (2009); Malczewski (1999a)

Existence of Constraints	Constraints can limit available options or impose minimum requirements, such as ensuring contiguity or connectivity in spatial analysis.	Eastman (2009); Chakhar & Mousseau (2008)
Risk Tolerance	Risk-tolerant decision makers might optimise for alternatives that satisfy fewer criteria, whereas risk-averse individuals tend to favor options that meet all specified conditions	Eastman (2005, 2009); Chen et al. (2001)
Uncertainty	Decision models can process criteria and weight assignments using a deterministic approach or incorporate uncertainty through probabilistic methods or fuzzy logic techniques.	Jiang & Eastman (2000); Malczewski (1999a); Shepard (2005)
Measurement Scales and Units	The feasibility of normalizing heterogeneous criteria such as monetary values and qualitative data onto a unified scale depends on methodological approaches and the comfort level of decision makers with numerical representation.	Chakhar & Mousseau (2008); Joerin et al. (2001)
Experience	The methodological choices in decision-making are shaped by the expertise and background of the decision maker and the analyst, particularly due to the varied assumptions embedded in MCDA approaches.	Belton & Stewart (2002)
Computational Resources	The choice of methodological approaches can be influenced or constrained by the availability of suitable software and hardware, and financial limitations.	Malczewski (1999a); Weistroffer et al. (2005)
Direction of Problem Solving	Most issues are examined with a forward-thinking mindset, but analyzing past choices through preference disaggregation provides insight into underlying value judgments.	Jacquet-Lagrèze & Siskos (2001); Siskos (2005)

Figure 14. AHP (Analytic Hierarchy Process) Table for GIS-Based Site Selection for CMS in Bayrampasa

Figure. 15 GIS Based MCDA Analysis - Overlay Analysis for Highly Suitable Areas for CMSs in Bayrampasa / Istanbul

These factors were determined using sustainable strategic planning principles. The goal is to make them accessible to different groups and support sustainable transportation methods. GIS allows MCDA to support complex land-use planning, site selection, and resource management decisions. (Malczewski, 1999, p. 1).

In addition, the analysis included the main axes in the district and their surroundings, taking into account the importance of adapting cyclical production spaces to economic activities and local elements in the neighbourhoods. Public spaces and buildings accessible to city residents were prioritized during the analysis process. Then, all these layers were overlapped according to the determined sub-factors, and suitable and highly suitable areas were identified for the site selection analysis. The analysis revealed that the yellow areas shown in Figure 13 are highly suitable. These areas are located 100 m away from green transportation networks, 150 m away from the main axes, and at the intersection of public spaces and buildings. (Figure 15)

As a result, the analyses consider the importance of taking a holistic approach to evaluating environmental, social, and economic factors when choosing the location of circular production spaces. Using the superimposed layers in line with the determined sub-factors, it was determined that the yellow zones, located 100 meters away from green transportation networks, 150 meters away from main roads, and at the intersections of public areas, are highly suitable for such production activities (Figure 15). These findings demonstrate the effectiveness of data-driven, multi-criteria decision support systems in sustainable urban planning.

03. Discussion – What are the possibilities for LAM?

The circular maker spaces discussed in the study are believed to be vital instruments in spreading the CE model during the transition process, helping to accelerate it. The results of the surveys conducted in this context sup-

port this hypothesis. Here, an important question arises: how can CMSs be appropriated into urban spaces on a local scale? This section discusses the potentials and constraints of the appropriation process.

The qualitative and quantitative data presented in this empirical study reveal many potentials for the development of local appropriation models for CMSs, but also constraints at different scales.

Firstly, the expectations of local residents regarding CMSs and the current practices of the municipality were examined as part of the empirical research conducted in the context of the Local Community Comprehensive Tool (LCCT). According to the survey data, CMSs are perceived as environmentally sensitive spaces that support green transformation. In parallel, the findings revealed that in future urban scenarios, CMSs are envisioned as spaces that merge with urban space, are easily accessible, are dominated by technology, and will create added value for neighborhoods and residents while implementing CE principles. These expectations demonstrate that CMSs are seen as potential spaces to support local economic development in neighborhoods.

On the other hand, the municipality's existing practices (Pasakart, etc.) promote waste recycling and support residents to gain added value from it, but are not well known by residents. This highlights various constraints that will occur in the process of transition to CE while highlighting various failures in the governance forms of local government. In general terms, these constraints point to a lack of cooperation and communication between local government and residents.

Furthermore, residents' expectations from the municipality regarding CE implementations and the management of CMSs reveal that local government is one of the most important actors in meeting expectations in this process. The presence of the local government as a mediator is an important element as the process of finding a place for CMSs in urban space will be a multi-actor process. Indeed, issues such as inequality, power relations, accountability, and adaptation to changing needs over time are important in the governance process. In this context, these concerns of local residents have also revealed the importance of the unity of management models and implementations in the integration of CMSs at the local scale. This highlights the importance of shaping these practices within a framework of just city understanding, equality, diversity, and democracy (Fainstein, 2010) in order to gain social acceptance.

Conversely, the fact that residents perceive CMSs as a means of strengthening their sense of belonging to the neighbourhood suggests that these spaces could be supported locally. It is important to consider the nature of space, which is defined by the idea that 'space is permeated with social relations; it is not only supported by social relations, but also produced by, and produces, social relations' (Lefebvre, 1991: 286, cited in Hayden, 1995: 31; Low, 1996). Apart from the physical production process of CMSs, integrating these spaces into the urban landscape through participatory processes is important for redefining the meaning of urban spaces for residents. Additionally, this process fosters place attachment and the perception of CMSs as places that transcend urban spaces.

This is because place attachment emphasises the emotional relationship that people develop with specific places. In this case, it significantly affects how urban residents experience, perceive and engage with these spaces, shaping their identities and well-being. Strong place attachment plays an important role in protecting and maintaining these places (Scannel & Gifford, 2010). At the same time, residents must see CMSs as social empowerment platforms that go beyond spaces focusing on CE principles. The process must also be transparent and diverse to support social well-being.The presence of CMSs in neighbourhoods is the most important factor in ensuring their sustainability in urban spaces.

As supported by the survey results, it is clear that these places will support social empowerment and contain possibilities for a diverse and just future. The location of CMSs, their easy accessibility, support from green city networks, and enabling activity for different socio-economic groups also support local implementation in this regard. The second part of the study is a GIS-based, multi-criteria analysis that considers the suitability of CMSs for urban spaces. Taking a holistic and analytical approach, this analysis provides important findings on these spaces within the framework of strategic, sustainable urban planning. Supported by qualitative data, this offers possibilities for achieving the ideal result in terms of site selection.

Developing existing applications in line with CE principles and integrating CMSs with local government will initially help these spaces flourish on a local scale. Understanding these principles, ensuring their adoption by society, and managing this process are important for the success of the applications. Additionally, the different functions of these spaces encourage residents to use them more frequently. These CMSs support local appropriation at the neighbourhood level. At the same time, this situation also demonstrates the different potential of CMSs.

04. Result

In a nutshell, the acceleration and dissemination of CMSs in cities regarding the implementation of CE principles process should be managed through bottom-up, transparent, and democratic methods by local authorities. This process should be able to create added value in neighbourhoods and enable various functions and spaces to be combined within the context of local appropriation. The study concluded that the local appropriation process of CMSs has the potential to support socio-economic empowerment and environmental improvement. As a result, the study revealed that the local appropriation process of CMSs has the potential to support socio-economic empowerment and environmental improvement. This result is a significant finding in terms of supporting the sustainable development of future cities.

In the context of the study, it provides an important roadmap for integrating circular economy (CE) strategies in cities, offering an inclusive and holistic perspective. Ultimately, it aims to address the lack of literature on the subject by offering insights into future scenarios for the sustainable development of cities in terms of the implementation of circular economy (CE) principles.

Unveiling Hidden Potential. A Typological Approach for the Underground Landscape.

Caterina Juric
Affiliation: Department of Architecture and Design,
Politecnico di Torino, 10125 Torino (Italy)
Email: caterina.juric@polito.it

Abstract
Urbanization and environmental challenges underscore the importance of utilizing underground spaces as strategic resources for future cities. However, a systematic framework for analysing the complexity of these spaces is missing. This research proposes a typological analysis of underground environments, categorizing them into four layers: surface, medium, deep, and ultra-deep—each with distinct functionalities. While the underground is recognized for its potential in stabilizing temperatures and reducing energy consumption, it remains fragmented mainly in analysis. The article proposes an underground taxonomy generating a hierarchy of configurations, divided into geometrical and topological, and networks, divided into vertical, nodal and horizontal, helping to understand better how underground layers influence above-ground development and emphasizing the need for a robust urban planning theory.

Keywords: Underground Urbanism, Typological approach, Subterranean Taxonomy, Three-dimensional city, Layered Urban Landscape.

Introduction

The city should be considered a unique entity defined by combining different objects and (Hillier, 1984) considering a three-dimensional perspective, the connection between the above and below-ground realm. However, even if these two spaces have a different structure and forms, their point of connection defines the relationship between them. The encounter between the superficial city and the ground is usually reduced to a simple line, while it is a thick object container of activities and transformations (Berlanda, 2014). This complex object is the catalyser of motion, transforming the horizontal movement to the vertical and again to the horizontal in a continuous circle. Already, this concept divides the city into three principal stratus: the city above the ground, the one below it, and what we find in the middle, the ground itself. This last term does not refer to a static plane but a negotiable, permeable membrane that can be traversed, penetrated, and reinterpreted. Therefore, today's subterranean realm cannot be considered only a tunnel network or utility corridor but a complex system answering to the urban metabolism.

The lack of understanding of how the underground landscape is structured prevents us from projecting its coherent and strategic management into the future. As a result, planning below the surface tends to be treated as a subordinate extension of what is planned above ground. The absence of a holistic vision capable of harmonising design between ground-level and underground areas limits the functional and ecological potential of these spaces and reflects a short-term vision. This article analyses the subterranean landscape as a component of urban morphology that has not been explored due to its difficulty in extending the above-ground analysis to the underground realm.

Methodology

The article is structured in two phases: one theoretical, where the underground realm is analysed in its urban development, and one practical, classified in its possible typological components.

Firstly, the theoretical background defines a historical excursus of how the underground realm has been considered from the birth of modern cities until now. From the chronological analysis, the subterranean results as a non-liu, unconnected to the superficial space and, therefore, not easy to analyse. That brings the author to the first classification of the below-ground layers, described by the depth, the location of the activities and the actual use of the underground realm in today's urban planning. Then, a typological approach is provided after describing Henry Beck's Diagram and understanding a new abstraction method for defining the subterranean which is analysed in terms of its taxonomy, spatial, and network configuration.

The outcome mirrors how the underground realm can be described and classified.

State of the Art

Ground Strata

Although the Earth's complex structure extends deep below the surface, human activities have primarily focused on the upper layers for urban development. This preference is mainly due to the temperature and material conditions in these shallow strata (Admiraal, 2018). As one descends closer to the Earth's core, temperatures increase significantly, complicating infrastructure construction and costs. The soil consists of several horizontal layers, and its structure and quality depend on the climate, temperature, geological, and hydrographic local conditions. The most superficial layer is the litter of undecomposed or partially decomposed organic plant and animal residues. Beneath this lies humus, rich in organic matter that is actively decomposing, where intense biological and chemical activity occurs to transform the soil. Further down, the layers become increasingly solid, consisting of silt, sand, and clay, with the deepest layer being inert rock, often referred to as the mother rock (Parisi, 2019).

Therefore, this article will concentrate on the top forty meters below ground level. As we explore underground layers, the characteristics of each stratum, the infrastructure and activities present within them, and the geological and structural factors that shape their development will be examined. This analysis aims to enhance our understanding of subterranean environments by proposing a classification system with five distinct strata, each typically linked to particular urban activities.

- The Surface and Shallow Layer, extend up to 10 meters deep, crucial for building construction and underground basements, as it maintains surface integrity. It supports underground parking, shopping malls, sewer systems, utility facilities, and service tunnels, which are affected by weather and urban activities.
- The Mid-depth Layer, 10 to 40 meters underground, contains more complex security and environmental protection infrastructure. It supports metropolitan transport networks, rail tunnels, underground warehouses, power distribution networks, and environmental control systems.
- The Deep Layer, from 40 to 100 meters deep, features denser and more stable soil with increased temperature and pressure. It supports specialized infrastructure, such as rail and road tunnels, geothermal plants, underground storage facilities, research laboratories, and water treatment systems.
- Finally, extending beyond 100 meters, the Ultra-deep Layer presents extreme geological and environmental challenges. At such depths, temperature and pressure are significant, complicating access. This layer is utilized for specialized activities, including mining, oil and gas storage, seismic monitoring, and communication networks.

It is essential to note that these divisions are not rigid; various processes can overlap within the same layer, leading to a mixture of different infrastructures existing together in a single space.

Surface-Subsurface Representation

Today, the architectural approach considered the division of what was happening above and below as a fixed object, simple to analyse due to its minimal dimension. The way of representing the vertical city led to three main methods. The section (Figure 1) is the most used solution[1], where the city is presented as an iceberg, and what we see above and below is divided by a simple linear object without form (Berlanda, 2014). The result emphasises the division between the two elements that define the city: what lies above and below. Then, the axonometry[2] (Figure 2) creates a more holistic overview of the city (Frampton et al., 2012). This solution creates a three-dimensional perspective of the metropolis but needs a fundamental comprehension of how the space is made. The result is a unique, indistinct object.

Finally, the scheme[3] (Figure 3) is a representation method that synthesises concepts and helps comprehension

1 Representations in the book: Berlanda, T., (2014). Architectural Topographies. A graphic lexicon of how buildings touch the ground, Routledge: New York.

2 Representations in the book: Frampton, A., Solomon, J. D., Wong C., (2012). Cities Without Ground. A Hong Kong Guidebook, ORO.

3 Representations in the book: Reynolds, E., (2020). Underground Urbanism, Routledge.

(Reynolds, 2019).

Figure 1 (left): Section of J. M. Tjibaou Cultural centre in Noumea (New Caledonia) by Renzo Piano 1991-1998 (Source: Berlanda, 2014)
Figure 2 (centre): Axonometry of the city of Hong Kong (Source: Framptonet al., 2012).
Figure 3 (right): Schematic representation of the underground (Source: Reynolds, 2019).

To understand correctly the transition between above and below urban landscapes, we have to start from its role in the urban composition. The shift from below ground to above ground connects two distinct urban flows: one that moves through a horizontal underground city layout and the other that aligns with a horizontal aboveground city layout, traversing a substantial element known as the groundline. Furthermore, this element defines the vertical relationship between different parts of the three-dimensional city and can be analysed by three variables:

- Altimetry, which considers the different heights it has to connect;
- Orography, which defines the natural conformation of the environment under study;
- and Topography, which represents the form and movement of the earth's surface.

This space's final design can create separation or promote inclusion among different city areas, enhancing accessibility, reducing barriers, or potentially leading to the opposite outcomes (Berlanda, 2014).

Another essential role of this transition is determined by its social effect in the city and can be classified as invisible (or passive) or visible (or active).

The passive purpose addresses the practical requirements for constructing the city: it is essential to consider the transition layers as key areas shaped by the foundation technology. The deeper the foundations are for the structures above ground, the stronger the connection between the surface and underground environments. These layers define how dependent different parts of the city are on one another. This solution is also described as invisible since we do not consider it in everyday life but instead create the structural basis for the city itself.

On the other hand, the visible transition emphasises vertical layering in the metropolis and determines how we move around it. This solution is well represented in the axonometric views of Hong Kong by Frampton et al. (2012), who creates an actual layering in the city according to the different activities. Taking these drawings as a reference, the metropolis can be organized into three distinct movement levels: a lower level for vehicles, a middle level for pedestrian pathways, and an upper level for high-speed public transport. In this design, the traditional concept of the ground takes on new significance as individuals primarily navigate one of these three layers, depending on their roles in transportation. With this in mind, the ground moves up or down with the user and its needs.

When we look at technology, the lines between physical infrastructure and digital interfaces are becoming less distinct, creating a seamless technological environment. Underground spaces are becoming vital technological hubs that significantly change how we experience urban areas. They are more than just physical structures; they function as dynamic systems facilitating communication, movement, and social interaction. As technology influences our understanding of urban spaces, underground infrastructure has shifted from a passive element to an active part of urban life. It engages with us, changes our experiences, and continually shapes our interactions with technology. In this new perspective, the underground is not just below the city. Again, what 'ground' means shifts depending on the user's experience (Kim, 2016).

The division between private and public spaces becomes essential in the active transitions. This separation clarifies the level of accessibility in space, defining what is reachable and what is not and to who (Admiral et al., 2018). The result is a different perception among inhabitants of the city's depth, and again, the ground level moves according to this perception.

Michel Foucault's idea of heterotopia is relevant here, as it helps explain the complex interactions within urban spaces (Foucault, 1967). These spaces are not fixed or stable. They are dynamic environments where social and technological factors continuously reshape our experiences. The ground transforms into a lively realm where various spatial principles coexist and interact. This perspective challenges our fundamental beliefs about city dimensions, influencing urban dynamics and morphology: architectural forms, infrastructure, and human experiences are blended into a complex, 3D system that defines the city. In this context, every urban layer influences the metropolitan dynamics.

Subsurface Conceptualization

In the early years of the nineteenth century, navigating the underground city was challenging due to its lack of design planning. The first underground maps, introduced in 1908 (Figure 4), were created for the London subways to aid travellers in finding their way to address this issue and make them orientate in a space without an apparent coherent form.

The English maps of the 20s were folded and sold in shops, railway stations, or companies as an orientation device. The standard dimensions were 14,7x22,1 cm, and the paper was folded twice to obtain a pocket size. All provided the 'Underground Map of London' title (Burwood et al., 1982).

Figure 4 - Underground Map of London, 1908 (Source: Garland, 1994)

Figure 5 - Underground Map of London, 1923 (Source: Garland, 1994).

While the first maps did not directly guide users, they were essential in connecting the above-ground and underground public transport networks. They helped create a sense of unity among the different layers of the city by

illustrating concurrent activities both on the surface and underground. Additionally, the maps aligned the transport routes with the city's geography, allowing users to quickly understand the relationship between the station locations and the city's overall layout. However, looking carefully, the geographical coordinates also needed to be more precise to guarantee the integration of the above-below network, resulting in the distortion of some lines: few maps were accurate to scale (Toor, 2013).

The first colours used distinguished only the surface network (red) from the subterranean one (blue) as visible in the map of 1923 (Figure 5): different palettes were used in the various editions. As visible in the image, the lettering needed to be more precise, overlapping, or directly omitted (Gerland, 1994).

As the city grew, the public transport network became more complicated, making it harder for people to read the map and find their way around. In an attempt to address this issue, symbols were added to the map in 1927, but more was needed to improve the situation significantly.

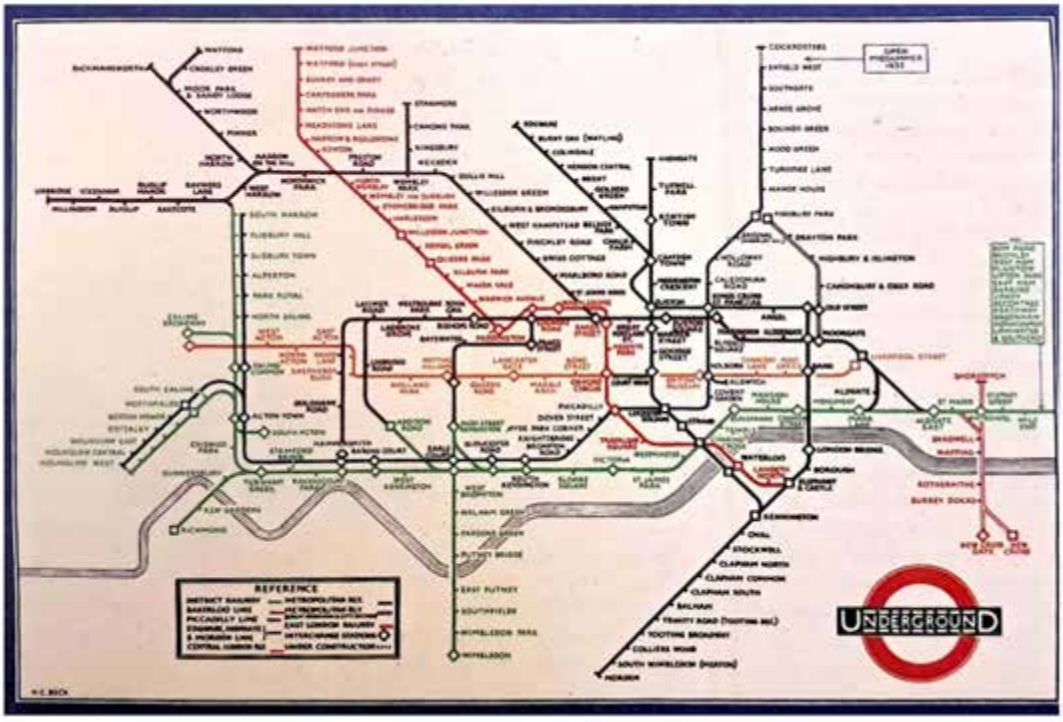

Figure 6 - Underground Map of London, January 1933 (Source: Garland, 1994).

The chaotic, incomprehensible reality of the modern underground city was simplified by the design of the Diagram (Figure 6), the new map of the London Underground network published in 1933. In the previous editions, the geographical approach created difficulty in comprehending the devices, which entailed concerns about orientation in the subterranean network. Therefore, it is no coincidence that Beck's Map was so highly appreciated in its foldable, pocket-sized form and practical use. The defined colours, orderly lines, rational rigor, and structural grid stayed within a reasonable conceptual distance from those of Mondrian, so beloved at the time. All these elements helped to define the Diagram, one of the great modernist aesthetics inventions of the London Subways (Ashford, 2013).

> "Looking at the old map of the Underground railways, it occurred to me that it might be possible to tidy it up by straightening the lines, experimenting with diagonals and evening out the distance between stations. The more I thought about it the more convinced I become that the idea was worth trying, so, selecting the Central London Railways as my horizontal base line I made a rough sketch. I tried to image that I was using a

> convex lens or mirror, so as to present the central area on a large scale. This, I thought, would give a needed clarity to interchange information." (Ashford, 2013)

From these assumptions, he decided to convert the old 'vermicelli' (what he used to call the previous geographic network setting) into a new solution.

When he designed the first proposal, Henry Beck was a 29-year-old engineer of the London Underground Railway who remained impressed by the complexity of the maps published before and wanted to get involved to create a more effective solution (Gerland, 1994).

Already in the first sketches and the first map from 1931, the background usually used in the previous editions disappeared, and only the River Themes remained as an orientation reference. The colours were the same as the Stingemore solution, while the map structure was defined by horizontal, vertical, and 45- or 90-degree diagonal lines (Garland, 1994).

A new non-lieu

What emerges is an underground realm analysed in its forms of abstraction and an undefined entity, which seems unconnected to the surroundings and the city as a whole. In fact, before Henry Beck's Diagram, the first underground experience in the nineteenth century was noisy, chaotic, and confusing. The fear of the first travellers in the underground was the perception of being compared to goods where passengers were left or picked up at the stations in what was instead shown by the government of all of Europe as the most revolutionary discovery of the century. In the environment, contact with the landscape was lost, and without a map, only those familiar with the lines and underground structure could orientate themselves below ground (Ashford, 2013).

Marc Augè (1992) defined a non-place as a space lacking connection to the surrounding landscape, where it is difficult to move without signals or indicators. Based on this definition, the subterranean realm can be considered a non-lieu. Its complex structure and distinct characteristics compared to the surface require guides—such as colours, lighting, and design elements—to help individuals orient themselves within this environment.

We analyse our space at three levels that, little by little, help us understand and experience it. The first level is perceived space, representing what is captured from the outside. This space is not conveyed by reason; our senses determine it, and it is innate. Once inserted into an environment, our body automatically perceives temperature, colours, and lights and transforms them into physical or mental sensations. Then there is the second layer, defined by society and the need to live in the same space governed and determined by rules and ways of behaving: the conceived space. It is abstract, presupposes knowledge of basic concepts of representation (symbols, signs, colours to which a meaning is associated), and is structured according to the logic of the dominant social power. The conceived space is built by specialists (engineers, architects, artists, etc.) who, with their representations of space, try to reduce the environment to rational and geometrical solutions, thinking technically and logically, creating a standardisation of the space. Finally, the lived space is chaotic and full of personal memories and conflicts. This space escapes social rules and constraints, preserving a more authentic and personal dimension of human experience. Here, the imagination plays a fundamental role in creating representational spaces, images of reality, then transformed by the human mind to appropriate and personify them (Lefebvre, 1974).

In the first forty years of the subway, the subterranean realm was not understood by travellers and was considered abstract and not comprehensible by the majority. They needed to wait at least two decades after the opening of the first line for the first station interiors and the first underground map in 1933 designed in the UK. Advertisements were not immediately all around, and the first solutions were provided in case of emergency (escape exits or personal support) (Ashford, 2013).

Results

How it has emerged, the city is usually analysed without connecting what lies below the ground layer with the su-

perficial realm, with consequent difficulty in understanding the city as a whole. Moreover, the approach is usually typographical since it is considered the point of departure and the one of arrival, not the space between them. Harry Charles Beck introduced this method in 1908 to help Londoners navigate the city's underground transit system more effectively. His approach made it easier for users to understand the network quickly and logically. It improved subway navigation and provided a clearer overall view of the city, allowing people to describe the urban morphology from perspectives beyond just the surface.

Although the underground is integrated into the urban environment through its four layers of stratification, which create a vital foundation for surface functioning, capturing it as a cohesive entity remains challenging. The concept of the underground revolves around human experiences related to what lies beneath our feet. This contrasts the idea of landscape, which evokes a sense of frontality and represents everything within our line of sight. The subterranean, however, is largely hidden; it can only be imagined or described metaphorically. As a result, a clear opposition exists between landscape and underground: the landscape encompasses the spaces we can immediately perceive and articulate, while the underground necessitates time and exploration to uncover. Therefore, it is essential to consider how underground spaces can be classified and described to ensure their connection to the city as a whole system.

Discussion

Typological Analysis of Underground Spaces

The following paragraph explores the typological characteristics of the space beneath us, trying to encompass the previous studies for the subterranean landscape: architectural planning often overlooks the complexity of the underground realm, focusing on engineering and geological assessments. This approach creates a disconnect between the subterranean and the surface, leading to a predominantly two-dimensional perspective on urban design. The following classification will categorise underground spaces to enhance our understanding.

Typological Taxonomy

The urban underground represents a complex and multifaceted spatial realm that goes far beyond the stereotypical image of dark, damp tunnels. Delving into this subterranean dimension reveals a diverse tapestry of spaces, each shaped by distinct functional, architectural, and experiential characteristics. Drawing from the taxonomic framework, the first categorization of the underground world that immediately results in our mind is the division between what can be considered a mere excavation in the underground and what needs a more structured architectural and engine eristic background. Starting from this point, we can examine three primary typologies that encapsulate the richness of the urban subsurface.

The first category will be the excavated spaces - subterranean environments carved out through deliberate human intervention or natural geological processes. These solutions range from ancient underground cities, such as the remarkable Uchisar complex in Cappadocia, Turkey, to more contemporary forms of spontaneous, adaptive reuse. Excavated spaces demonstrate the noteworthy adaptability of the urban underground, as well as its ability to accommodate alternative modes of inhabitation. The Cappadocia region is characterized by lava material solidified after an eruption, creating interesting plastic objects called "fairy chimney" that differ in depth, dimensions, and colour. Initially, these spaces were used for shelter, but then, thanks to the handwork of the area's inhabitants, it was transformed into an actual caved city where all the natural rocks called 'fairy chimney' were converted into churches, houses, or collective spaces simulating stone houses with decorations, columns, vaults, and arches. These spaces, which could not contain more than 15-20 people at a time, guaranteed isolation and protection for other civilizations surviving during the time. According to the architectural elements used for the construction, the fairy chimney was used for different purposes, as seen in the image below (Erdem, 2008).

Then, there are the infrastructure spaces that represent the critical technological arteries that sustain the functional operations of the city above. These spaces include extensive transportation networks, such as the renowned subway systems of global metropolises and intricate utility distribution systems for water, electricity, telecommunications, and other essential services. These infrastructure spaces facilitate the efficient flow of peo-

ple, resources, and information, incorporating advanced engineering solutions and cutting-edge technologies. They transcend their purely utilitarian role, becoming integral to the urban experience. Even if these spaces are used only for the flow of utilities (water pipes, gas pipes, electricity pipes, etc.) or people and can be defined as places of movement, they are characterized by designed features mostly in spaces where citizens can walk. The Moscow Metropolitan Line, for example, was designed not only to exhibit the city's technological development but also as a manifesto of traditional socialism aesthetics. The stations should be attractive for those who pass through them with long corridors with vaulting breakthroughs, recesses, coffers, false skylights, projecting cornices, dividing piers into orders, creating niches, and blind windows (Toson, 2024).

The third type of underground space includes architectural spaces designed for human use in subterranean environments. These solutions are intentionally created to support various activities, such as recreation, commerce, education, and cultural exchange. Unlike infrastructure spaces, which are characterized by a continuous flow of movement, these architectural spaces focus on specific activities within the underground environment. Infrastructure spaces serve as pathways to these architectural areas, aiming to enhance the environmental qualities of the surface and offering experiences that reflect traditional urban layouts. They also differ from excavated spaces because they need a more structured and planned to characterize today's cities.

As urban populations grow and land use becomes more intense, many cities are exploring innovative solutions to meet the basic needs of their residents. In Beijing, for instance, some individuals live underground to stay close to the city centre while keeping costs manageable[4] (Kim, 2016). The city contains over 10,000 bunkers initially built during the Cold War for protection against bombings: these bunkers have now been repurposed as homes. It is estimated that around 1 million residents in Beijing live underground. Typically, these apartments are small, averaging about 10 square meters, and often shared by multiple occupants. Residents have access to shared bathrooms, centralized heating, gas air conditioning, internet services, and some retail spaces below ground. To foster a sense of community, those living underground have formed groups like the "Rat Tube" and Digua Shequ ("Sweet Potato"). These communities provide shared amenities such as gyms, cinemas, theatres, and cafes, enhancing the living experience for their residents. The spaces are intentionally designed with colourful decor, specific lighting, and materials that aim to minimize a cave-like atmosphere (Reynolds, 2018).

In **Table 1**, the principal activities that can located underground are defined.

Table 1 – Underground principal activities

Commercial	***Civic & Public***	***Industrial***	***Specialised Environment***	***Technological Interfaces***
Shopping Complexes	Cultural Spaces	Data Centres	Military Installations	Communication Networks
Retail Arcades	Government Facilities	Manufacturing Spaces	Scientific Research Facilities	Sensor and Monitoring Systems
Commercial Galleries	Emergency Shelters	Research Laboratories	Archaeological Preservation Zones	Automation Infrastructure
Service Tunnels	Public Amenities	Utility Management Zones	Climate-Controlled Repositories	Energy Management
Storage Facilities	Educational Complexes	Technical Infrastructure Hubs	Secure Storage Facilities	Smart Control Systems

Spatial Configuration

The underground landscape has yet to be analysed from a morphological point of view, creating difficulty in defining, describing, and understanding it. Many solutions have been brought to the catalogue between objects

4 Distance to the centre is the principal element that creates the price of these spaces, and the data provided by the www.ganji.com website show that depth is not a factor influencing the value of the apartment.

and networks, otherwise defined as containers of activities and connections between receptacles. In addition, it is also possible to distinguish between private and public spaces according to the ownership of the space it is looked at (Admiral et al., 2018). Specifically, objects are all spaces that represent an area of being, while networks represent movement (what was divided between architectural spaces and infrastructure space before).

Even if it is easy to understand and describe, this definition still needs to tell the form of the underground and the possible configuration it can assume according to the city and the environment analysed. In the following chapter, the analysis will consider the possible morphological arrangements the underground can acquire. The metropolitan network will be used as an example to make the study more comprehensible and connected to reality. The same considerations can be repurposed to people, vehicle flows, networks, utilities, and fluid movement.

The analysis will start with a division between geometrical and topological configurations. The first ones refer to structures' physical form and spatial disposition, and their measurable characteristics define them. These solutions find linear, radial, or grid patterns following precise geometrical roles, explaining the physical organization of space and its proposition and dimension. The topological configurations refer to how spaces are connected and related: connection networks, hierarchy, functional relations, flow and way of movement through space, and logical and relational organization between different systems.

If we take the metropolitan line as an example, its geometrical configuration will explain the tunnels' physical layout, dimensions, and forms. At the same time, the topological characteristics will analyse how different lines are connecting, which are the principal nodes, and how people are moving inside.

This distinction is fundamental to understanding the underground landscape's physical form and how it functions as an interconnected system of spaces and relations.

The geometrical configuration can be divided into three subcategories.

The linear configuration represents the simplest type of metropolitan configuration, defined by main routes connecting to the nodal points of the city. This solution may represent the first stage in constructing an underground network, thus symbolizing a city in the development process or not too large to need a more articulated network. This simple solution guarantees rapid movement around the metropolis without the need for other intermediate connections.

The second configuration is the radial one. It develops from a centre outwards, creating a radial structure. This configuration is particularly effective in the historic centres of European cities, where a central core serves as a distribution hub and aims to keep the landmark centre as intact as possible. This solution also had a significant following during the post-war period because, through a well-known external connection for all lines, it was possible to keep the underground city well-connected and ensure a greater connection between the various lines.

Underground grids often reflect the surface urban structure, creating an ordered system of interconnections, the grid configuration. They are solutions that require careful and orderly planning at the base and, therefore, were not found in early metro solutions, where it was essential to combine planning with technologies and construction methods that had never been applied before. These solutions are seen again in often very extensive underground landscapes related to metropolises of considerable size. The underground grid facilitates orientation and navigation by creating a simple and intuitive movement logic.

Lastly, the interconnected configuration is the most complex solution, requiring different systems to overlap at various levels. This solution is mainly found in vastly expanded metropolises where the flow of people is so high that parallel paths connected at other levels are required. We are primarily talking about solutions that have developed over time, requiring a continuous adaptation of the underground space to the surface space and, in some cases, modifying the initial rigor with solutions capable of extending the underground route to the entire urban fabric.

There is then the topological configuration which can be divided into three subcategories.

The nested spatial arrangement describes how underground spaces fit into each other, creating layers of depth and connection. The hierarchy envisages central bodies as centres of activity and hubs from which pathways, in turn, branch off to other central cores. The result is a highly dynamic and quickly developed structure of nodes and axes that concentrate urban sprawl in the poles that become social, economic, housing, and resource catalysts for the entire city.

The ramified network system represents a diffuse net of connections where all the central stations have the principal role. The configuration has an inward-looking development; the historical centre is the most preserved and connected area. This solution results from a historical city that wants to maintain the city centre from extended metropolises and guarantee a strong identity in each neighbourhood.

The decentralised distributed system is the opposite solution before described. It represents a diffuse net of connections where all the stations assume the same hierarchy. The configuration has an outward-looking development and guarantees a quick reach of peripherical areas still well connected to the historical centre. This solution usually needs both a superficial and underground development and results from an extended metropolis that guarantees a strong identity in each neighbourhood.

Network Configuration
The network structure of underground environments can be analysed in various ways, starting with the concept of hierarchies, which is essential. When planning a network, it's crucial to establish a hierarchy to ensure an organized layout throughout the city. Typically, the lines are categorized into primary, secondary, tertiary, etc., which allows for quick connections between areas, while less critical lines intersect with these to reach different parts of the city.

This categorization serves multiple purposes. Firstly, it helps facilitate smoother navigation through the city, reducing congestion in high-traffic areas where a fast flow is necessary. Additionally, different levels of connectivity can highlight various characteristics of the network. Underground connections often link to surface networks, varying depths affecting how elements connect and what (or who) they transport.

Another important aspect of this hierarchy is accessibility. Not all underground areas are available to everyone due to their natural layout or urban needs. As a result, spaces are typically divided into public, semi-public, and private zones. Public zones like the metropolitan line are open for general use, allowing people to move freely across the city. Semi-public zones are accessible only to particular groups, like companies or institutions with limited access. Private zones are restricted to a select few who own or have permission to enter those areas.

Lastly, networks can also be divided based on security levels for military considerations. For example, in Moscow, the metropolitan line is categorized into first-grade and second-grade lines, indicating which can withstand bomb attacks and which cannot (Toson, 2024).

Another possible classification of the network can be done from a geometric point of view, considering the disposition of the spaces and how they are disposed of in the space. Considering this perspective, we can talk about horizontal systems that are the subject of the underground landscape and represent all the networks, lines, and pipes we can find underground. Then, vertical systems connect between the above-ground level and the underground realm. Lastly, the nodal connections represent the junction between different levels in the subterranean realm and help move from one horizontal system to another or reach the vertical exit/entrance.

The underground landscape "is defined by a world usually described as cylindric, cones, cube-piped, connected, or overlapped," as Christian Toson defines in his book Memorie del sottosuolo. La metropolitana di Mosca (2024).

From a horizontal perspective, tunnels play a crucial role in the city's management and operations by facilitating the underground movement of people, goods, and services. They can be categorized based on their purpose and construction, and each type serves a specific function contributing to the city's efficiency and safety. They include the following types. Firstly, there are the transportation Tunnels. These are essential for public mobility, such as subway lines connecting different city parts. Another type is the Service Tunnel, which houses utilities like electrical systems, sewage lines, and telecommunication networks. Finally, the escape tunnels are designed to allow rapid emergency evacuation.

The list should also include the Transit platform located in elevated areas within the station, facilitating passengers' movement along the line. Occasionally, service personnel utilize these spaces to maintain the lines. The English engineers who designed the first underground line in 1863 implemented a solution that involved placing trains in a central area, supported by platforms on both sides, to effectively manage passenger flow.

Additionally, different technologies were adopted by Moscow stations based on the expected passenger volume. Stations designed with shorter depths that featured columns, a floor slab, and a central platform, allowing trains to operate on either side, hosted a small flow of people. In contrast, deeper stations were designed to accommodate larger crowds, with three interconnected tunnels and various entry points (Toson, 2024).

The passage between the surface and the subsurface should not be perceived as a simple line but as a thick object, a receptacle of the transition between these two parts of the city and the vehicle for moving vertically (Berlanda, 2014; Frampton, Solomon & Wong, 2012): what is going to be called the transition strata. The descent into the underground realm represents a vertical travel between urban time and space (Graham, 2016). Access to the subterranean landscape can be categorised into four primary types: standard entrances typically marked by staircases, entrances enhancing accessibility for individuals or linking to additional stations, entries from public spaces, and entries from private properties.

- *Standard Transitions.* Stairs are the usual way to access the subway, while ladder stairs provide a straightforward way to access the unseen underground, symbolising an immediate shift from the surface to a mysterious, hidden world (Manaugh, 2012). Descending a ladder is viewed as a transformative action, shifting from the familiar and routine to the unexplored and concealed. This movement requires effort and can foster a sense of vulnerability and reflection. These accesses are usually used for maintenance and access to critical infrastructure such as sewer systems and underground power lines (Graham, 2016).
- *Transitions Enhancing Accessibility or Linking to Stations.* The issue of accessibility is crucial when it comes to vertical movement. In 2018, just 25% of New York's subway stations were accessible to people with disabilities who could not use stairs to move between levels. The situation has improved with enhancements such as elevators, access ramps, handrails, tactile indicators on ramps and stairs, and accessible service entry gates[5]. Similarly, in Hong Kong, the Island Line constructed in 2014 features high-speed elevators with high capacity, ensuring easy movement around the city and providing access for people with disabilities, guaranteeing benefits in the use of underground utilities (Chan, Lai-Chi, Mansoor & Chen, 2022). Furthermore, the introduction of the PATH signage program in the 1980s in Toronto by Paul Arthur facilitated orientation below ground level and, more generally, in public spaces in other metropolises (Bélanger, 2007).
- *Transitions from Public Spaces.* The entrance to the subway is designed to facilitate access from the local area to the underground realm. Therefore, the design of Hector Guimard's projected metropolitan accesses in Paris serves an aesthetic purpose and guarantees better orientation, facilitating pedestrian flow (Reynolds, 2020).

- *Transitions from Private Properties.* In Hong Kong, some skyscrapers offer direct access to subway stations, seamlessly integrating public transportation with commercial buildings and enhancing the efficiency of daily commutes. These private spaces are strictly regulated, prohibiting noisy activities, smoking, or animal walking (Frampton, Solomon & Wong, 2018). An opposite example is the structure of Toronto's underground landscape:

5 Inclusive City Makers (last access 30/07/2024)
Source from: https://www.inclusivecitymaker.com/innovation-accessibility-new-york-city-subway/

its logical axes-nodes structure ensures a direct connection to more than fifty buildings, six hotels, two department stores, and 20 underground parking lots. Those underground tunnels guarantee better climate conditions yearly (Bélanger, 2007) and such a straightforward structure facilitates the movement of pedestrians and their orientation below ground level.

Finally, the nodal connection represents an architectonical system complex where different space typologies converge in a unique fulcrum where all different characteristics must be combined. Two leading solutions can be considered, and one is the evolution of the other. The design plays a fundamental role in all these solutions, and all the possible issues need to be addressed to avoid segregation situations.

Firstly, there are the transfer zones, complex areas where different forms of movement intersect and interact. Designing these spaces requires careful consideration of their functionality and dimensions and how individuals perceive and experience them. These zones must accommodate various movement types, including pedestrians, vehicles, and public transit systems. The primary objective is to create a hub as a crossing point and a social and economic activity centre.

Transfer zones must seamlessly link different transportation systems, such as trains, metro lines, and other vehicles, to effectively manage the simultaneous and varying traffic flows. A clear and easy-to-navigate layout enhances efficiency, allowing these areas to handle different speeds and absorb peak traffic volumes effectively. Designing transfer zones necessitates a multidimensional approach. It's not enough to focus solely on functional connections; the movement through these spaces should also be engaging and inviting. Elements such as lighting, materials, spatial configurations, and wayfinding strategies are essential for guiding individuals and creating a sense of continuity as they navigate different levels and areas.

Additionally, these spaces must be adaptable to change, with designs that anticipate future developments. A flexible, implementable, and regenerative layout accommodates ongoing transformations over time.

The other typology is represented by the Central Hubs, zones of transfer that are big catalysers of people and are defined not only by the movement of people (infrastructural spaces) but also by place of being (architectural spaces). They developed and increased their connecting role until becoming a destination point where activities and social interactions happen. Here, movement and permanence coexist. Together with the characteristics of the transfer zones, they also need to offer complementary services, create a social environment, and dispose of the flows of movement directed to another point of the city (Admiraal et al., 2018).

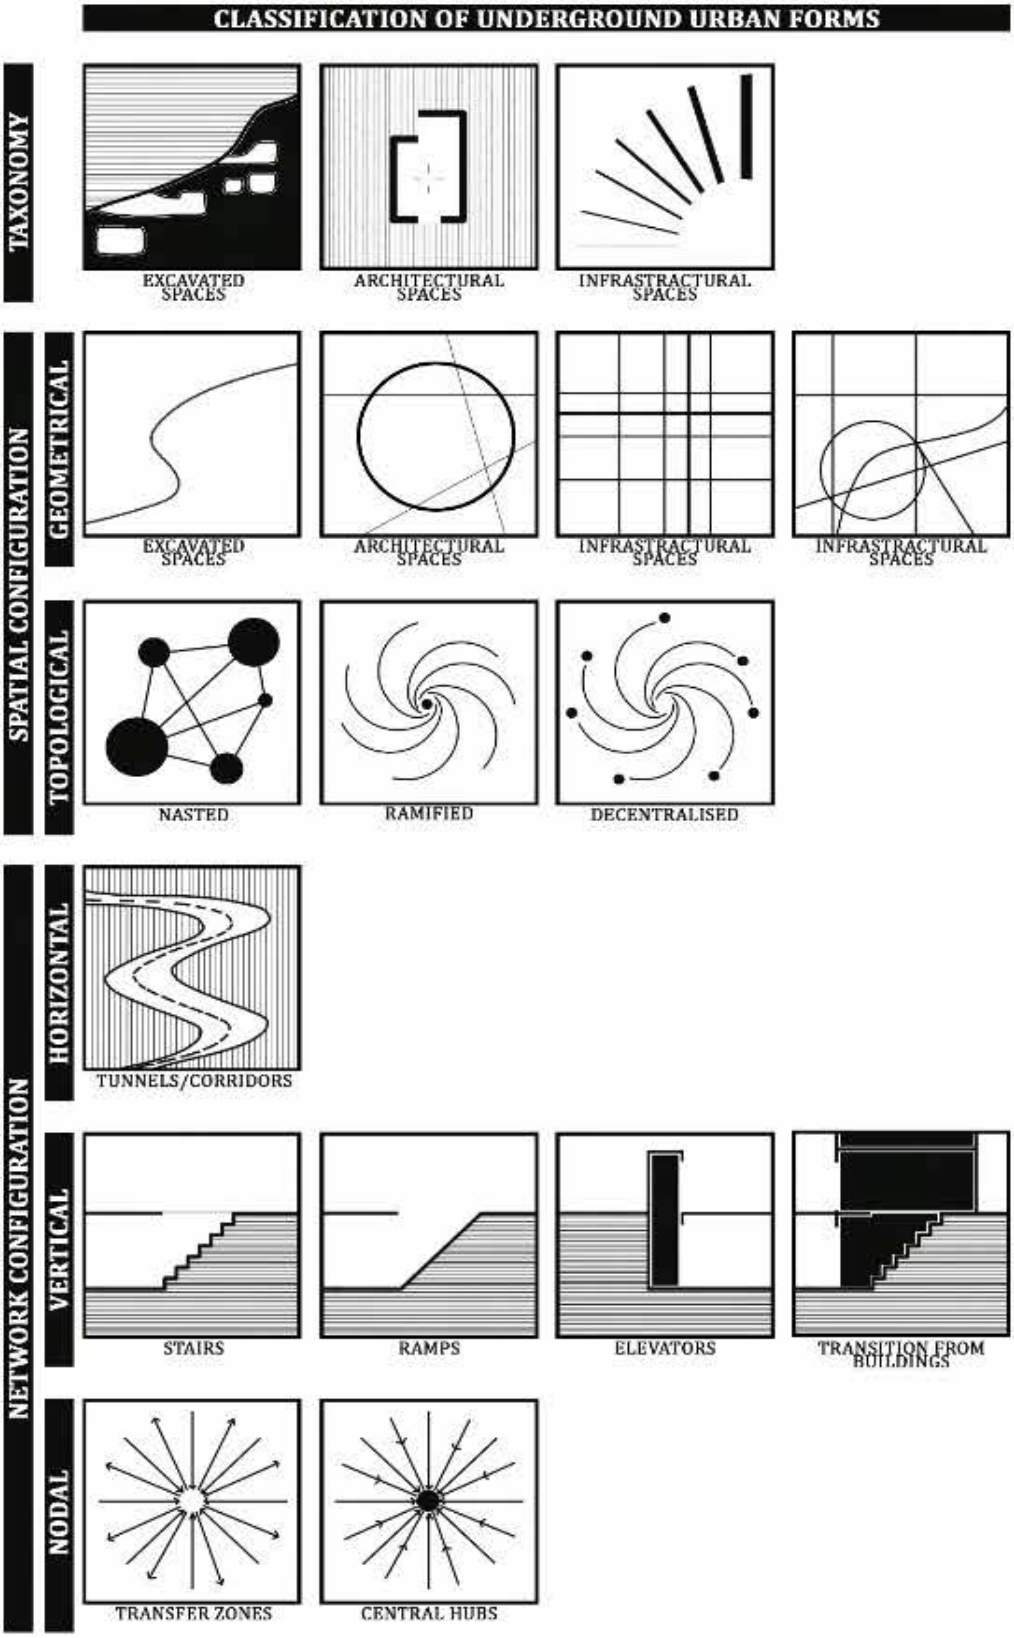

Figure 7 – Classification of underground urban taxonomy

Conclusion

This study has explored the urban underground landscape by proposing a typological and morphological framework capable of interpreting its complexity and overcoming the traditional separation between surface and subsurface realms. Through stratigraphic analysis, the classification of spatial configurations, and the examination of connective networks, a theoretical model has been outlined that recognizes the underground landscape as both an autonomous entity and a deeply interconnected component of urban metabolism. This research highlights the need to develop specific analytical and design tools for the subterranean environment, fostering a three-dimensional vision of the city. However, in order for the underground landscape to be fully integrated into contemporary urban practices, it will be essential to advance interdisciplinary studies that also address the social, technological, and ecological dimensions of subterranean spaces, consolidating their role as an active and strategic part of urban morphology.

Reimagining the future of peri-urban spaces: planning narratives for the sustainability of these areas. The case study of "Stena tou Nestou" in Xanthi, Greece

Alexandros Mpantogias
Affiliation: School of Architecture, AUTH, Greece

Abstract
Despite the appearance at international level of planning narratives regarding the equal growth of urban areas, whether they are economically strong or not, we note significant differences in the development of small and big urban areas. Considering the need for inclusive and resilient communities, the paper tries to envisage the future of peri-urban spaces, particularly the visions and models that lead to the economic, social and environmental sustainability of these areas. The choice of the case study the Thrace region in Northern Greece and the 'Stena tou Nestou' area was based on the necessity to reflect and change old narratives in the planning processes for poor urban and peri-urban areas and to propose a safe and equitable living environment for the inhabitants of these areas.

Key words: planning narratives, sustainability, peri-urban areas, social and economic injustice, Xanthi (Greece)

Introduction

In the last four decades and especially during the 21st century we observe a strong interest in discourses, strategies and norms regarding the form and functions of urban areas in a sustainable way (Michalina and al, 2021). Concepts like the compact city, the 15 minutes city or the smart city try to give responds to issues such as population increase, demanding human needs as well as environmental degradation related to human activities (Allam and al, 2022, Bibri and al, 2020, Shafiri and al, 2024). Sustainability is not only a solution to increasing environmental pollution and cities' environmental footprint, but also to questions related to the social and economic structure of cities like high unemployment rate, discriminations and closure of local enterprises and shops (Eizenberg and Jabareen, 2017). It is important to mention the role of sustainability in big agglomerations where there are issues related to the relationship between the city and its suburbs (connection, dependency of suburbs from the activities inside the city) (Riffat and al, 2016) as well as with its surrounding peri-urban area which is usually not built and there is always the risk for urban sprawl towards this area (Geneletti and al, 2017). Urban sustainability as a concept has two distinctive dimensions; internal and external sustainability (Wamsler and al, 2021). While the first one refers to an equitable and inclusive development of all cities' districts and activities (Bhatia and al, 2024), the second one refers to the relationship between the city and its surrounding environment particularly natural environment (Zucaro and Agostinho, 2025). The external sustainability is a critical issue in contemporary urban and strategic planning. The protection and equitable and inclusive development of peri-urban areas have positive effects on cities' internal organisation and functions as the two units (city and its peri-urban areas) do not depend on each other but rather collaborate on issues they cannot work alone such as environmental protection and economic development (Marmo and al, 2025).

Even though in documents of international organisations, such as the Agenda 2030, the notion of sustainability is linked to a strong commitment for the equal growth of urban areas despite their economic growth and their geographical position (UN, 2015), we note significant differences in the development of small and big urban areas, urban and rural areas as well as areas of the Global North and Global South (Nagendra and al, 2018). Cities of the Global South and their surrounding peri-urban areas are affected by population increase inside cities' limits and the consequent exploitation of natural resources that are found in peri-urban areas (Follmann, 2022). The main problem is the absence of urban planning regulations that allow cities to expand towards their periphery without taking into consideration issues such as the protection of the natural environment (Venter and al, 2021). Population increase in cities and urban sprawl are also observed in cities of the Global North as cities' functions

and organisation seem to attract people from small cities and rural areas. Despite this point in common, we should underline that in cities of the Global North we observe policies and tools for the protection of peri-urban areas such as land uses (for example agricultural activities) and green belts that fit to the more natural character of these areas (Klimczuk-Kochańska and Klimczuk, 2023). Small urban areas as well as rural areas suffer in many cases by economic difficulties and the loss of local population due to changes in production systems that shift industrial and agricultural activities outside big agglomerations or to other countries (Castellano-Álvarez and al, 2024). The result is that these areas progressively lose their urban identity and role at regional and national level (from active economic zones they are transformed to inactive spaces) and in cases of urban sprawl they become part of nearby big urban areas.

Considering the framework of the Sustainable Development Agenda and the need for equitable, inclusive and resilient communities, the main question of the paper is which narratives that is to say which tactics and models lead to the economic, social and environmental sustainability of peri-urban areas? Peri-urban areas are spaces outside the cities' limits which are not fully urbanised, there are houses and small-scale economic activities, but the most part of these areas are either agricultural lands or natural spaces (Sahana and al, 2023). These areas are considered as a supplement to the cities' activities and functions, and their relationship is based on dependency; cities' inhabitants need the products and the resources of peri-urban areas while the economic activity and prosperity of peri-urban areas depends on the exchange links between themselves and the cities (Ravetz and Sahana, 2024). This close relationship between cities and their surrounding areas has an impact on the development model of peri-urban areas as in many cases they lack the necessary infrastructure, equipment, facilities and services (schools, small health care centres, post offices) and they cannot function independently from the cities (Ravetz and al, 2012). In other cases, the geographical proximity of cities and their surrounding peri-urban areas lead to the progressive urbanisation of the latter as the cost of buying land is lower compared to the cities' urbanised districts and there are many vacant lands (Tione and Holden, 2020). It is clear that existing planning strategies for the development of these areas like urbanisation policies and economic dependency between the cities and their surrounding areas do not lead to the creation of sustainability conditions as peri-urban areas cannot be considered as equitable, inclusive and resilient communities. Furthermore, car dependency in peri-urban areas in order to have access to necessary facilities and services on a daily basis deteriorates the air quality and leads to environmental degradation and not to sustainability.

In this context, it is important to question the appearance of new planning policies for areas outside the cities' limits, which are not fully urbanised and maintain the traces of their past (physical and social). These new narratives seem to be closer to the main axes of sustainability (environmental protection, economic development, social cohesion) and to be different from the existing development strategies resulting from the capitalist economic development model. The basic idea is to take into consideration and to put forward the particular local characteristics and existing power dynamics in order to propose a development scenario for peri-urban areas that responds to inhabitants needs, reduces the dependence between peri-urban areas and cities while at the same time agricultural land and natural resources outside cities' limits are protected from exploitation (Fanfani and al, 2024). Even though the economic development of these areas is a critical point to be considered due to existing conditions of population decrease and economic recession, two equally important parameters for their development are the creation of social cohesion conditions and environmental sustainability. Social cohesion refers to the ties developed between the inhabitants of a certain area due to common goals and beliefs that progressively transform them into communities (Moustakas, 2023). This dimension of sustainability is particularly important to peri-urban areas facing socio-economic difficulties and have a population with different ethnic origins due to the need to create community ties in order to respond to the challenges posed by cities' functions and activities. Environmental sustainability refers to the capacity of existing natural resources to be able to exist in the future (Powe, 2020) in order to create an equitable and inclusive environment for all, for both cities and peri-urban areas population. Development models and strategies that equally manage these three main questions seem to create sustainability conditions in peri-urban areas that were considered for many years as cities satellites.

By taking into consideration the previous narratives regarding the sustainability of peri-urban areas, our research tries to investigate and critically think of the ways which potentially could lead to the economic, social, and environmental sustainability of peri-urban areas. A critical point is to recommend through our research planning methods and tools which could be used as narratives for the development of a specific category of peri-urban areas, the ones that face either economic or social difficulties as economic growth and social equity are, together with environmental protection, the three pillars of sustainable development. Under these unfavourable conditions, where the lack of financial means seems to deteriorate the future development of peri-urban areas, it is important to base the development of these areas according to their internal strengths and power dynamics as well as to search for external opportunities at regional and national level. Which are the strategies, policies and tools to develop these areas and which people should be involved in the procedures of their development? The development of peri-urban areas concerns not only the inhabitants of these areas but also the inhabitants and local authorities of neighbouring cities as their functions and activities in certain cases (for example a peri-urban area could be a Natura Zone and a National Park) affect the development of bigger administrative areas such as regions. In our methodology we identified planning policies for peri-urban areas based on the toolkits of international organisations such as the United Nations (UN, 2015), regional scientists (Spyra and al, 2021) and groups of academics working on the internal strengths and characteristics of urban areas (Kamalipour and al, 2023) in order to analyse the processes that lead to the sustainability of peri-urban areas facing economic and social difficulties.

Methodology

The research method used was the descriptive-analytic. The descriptive method was used in order to define planning narratives for the development of peri-urban areas. Our main hypothesis is that the development of peri-urban areas in a sustainable way, based on their particular characteristics should be the basis for the development of such areas and particularly of those facing socio-economic and environmental difficulties, as in several cases these areas have an ecological interest (national and regional parks, Natura zones) and gather activities of regional and national interest (for example tourism). At the same time, in contemporary city and regional planning policies (urban and peri-urban ecology, environmental urban and regional planning) peri-urban areas are designed as zones that protect natural resources due to the fact that they are protected by national and international legislation. This means that in these areas we can find a significant number of indigenous trees and plants, which in certain cases act as filters to the cities' high pollution levels (air and water pollution). The same areas try to reconcile cities with nature as many indigenous animals (birds and mammals) find shelter in these areas. Peri-urban areas, especially the ones that are part of big environmental zones that are divided between different countries (such is the case of several Natura zones), seem to solve environmental problems which cannot be handled by one country such as rivers and seas water pollution and forests protection as they foster international co-operation in the field of environmental sustainability. This means that these areas can act as places of experimentation of environmental policies and tools with the participation of researchers, practitioners and politicians from different countries.

Peri-urban areas near cities that face significant economic and social difficulties due to deindustrialisation, or the closure of local enterprises seem to bear the effects of this negative context as there are not sufficient funds for their environmental protection and economic development. Areas resulting from deindustrialisation such as former industrial lands, they are heavily polluted and struggle with economic recession. In certain cases, we observe informal settlements in these areas (small houses and warehouses) whose presence in these areas deteriorates the environmental degradation, while contractors, investors and local authorities show a particular interest to build them in order to boost the local economy of neighbouring cities facing social and economic difficulties. In this context the development of peri-urban areas in a sustainable way that takes into consideration the needs of the local population and proposes economic activities in accordance with the local characteristics offers a second life to places that were underdeveloped and neglected for several years due to socio-economic problems. Our hypothesis is that the development of neglected peri-urban areas in a sustainable way and their subsequent integration into the regional and national economic channels fabric is not only a measure towards environmental and economic sustainability and resilience, but it can also serve as a measure to solve social

conflicts as underdeveloped peri-urban areas are places for activities of regional and national interest such as research labs and tourism facilities.

Another point to underline in contemporary practices for the strategic development of peri-urban areas, related to cultural geography and to the protection of peri-urban and cultural landscapes, is the planning of a certain category of these areas, the ones that have a significant number of historical landmarks and natural landscapes, as a measure that protects small communities with particular ethnological characteristics. In areas where the cities' limits are expanded towards their surrounding peri-urban spaces historical landmarks and natural landscapes cannot be usually identified as they seem to be part of the urban fabric, while the bad connection of these spaces with the national road network and the absence of signage creates disconnection conditions. Peri-urban spaces like small villages and communities as well as regional and national environmental parks which have a significant historical and ethnological value (presence in the area of minorities and historical buildings and monuments) and which are not easily reachable by car, train and bus, seem to improve the inhabitants and visitors experience in understanding the different historical eras of cities and their surrounding spaces. Taking this into consideration, our third hypothesis is that the development of peri-urban spaces in areas characterised by their unique historical, cultural, ethnological and environmental identities could act as a measure for a new regional branding, when they are well connected with the national road network, and thus lead to the discovery of unknown areas that have a significant importance in the development of their regions.

The analytic method was used in order to identify first the reasons that lead to economic decline and social injustice in several small and medium-sized cities and make the necessary correlation between environmental sustainability, economic growth and social equity for the development of these areas. In second place we developed our strategy and model for the development of peri-urban areas near small and medium-sized cities facing socio-economic difficulties based on their transformation in a sustainable way which takes into consideration the local social, economic, environmental and cultural characteristics. The method proposes an experimental approach in the planning of peri-urban areas and their relationship with the surrounding cities based on the case study of "Stena tou Nestou", (which in English could be translated as narrow pathway near the Nestos River) a peri-urban area located near the city of Xanthi in Northern Greece. Our proposal was developed during an urban and landscape design studio named 'Landscape and Architecture' at the School of Architecture of Democritus University of Thrace. The studio emphasises on the development of peri-urban natural spaces, located near small and medium-sized cities with important social and ethnological characteristics, through small-scale economic activities such as tourism, culture and research activities that lead to sustainability and resilience conditions. At the same time semi-structured interviews were conducted with local elected officials and inhabitants in order to take into consideration their needs and expectations for the development of these peri-urban spaces. We suggested a development scenario for the peri-urban space 'Stena tou Nestou' located near the city of Xanthi, based on the principles of sustainable development (environmental protection, social cohesion, economic development) and the local cultural and ethnological landscape (presence of ethnic minorities and important historical elements from antiquity to present time). The development scenario focuses on measures such as: 1) the protection of the natural resources of peri-urban areas as a means to reduce the cities ecological footprint, 2) the revalorisation of significant cultural and natural landscapes such as regional parks and historical buildings and monuments as a means to protect and show the identity of these spaces, 3) the connection of peri-urban spaces with the national road network as a means to facilitate mobility and reduce disconnection as well as 4) the development of small-scale economic activities to boost tourism, recreation, sports practice and research as a means to reduce local unemployment rate and to lead to economic resilience and sustainability.

For the development of our scenario for the peri-urban area outside the city of Xanthi we took into consideration existing power dynamics of the city and its surrounding area as well as of the region of East Macedonia and Thrace in which administratively is part the city of Xanthi. It is important to mention that the region of East Macedonia and Thrace is among the less developed at national (Greek) level and is characterised by deindustrialisation and the closure of local enterprises. Despite the above weaknesses of the region, the presence of Democritus University of Thrace (DUTH) in six cities of the region (Drama, Kavala, Xanthi, Komotini, Alexandroupoli, Orestiada),

including Xanthi, is among the strong points of the area as it brings people from other cities in a region affected by deindustrialisation and population decline. The presence of small-scale enterprises of regional interest in the sectors of agriculture and food products create the conditions for a development based on the local characteristics. The ports in the city of Alexandroupoli and Keramoti, a small town in the outskirts of the city of Kavala, the airports in the city of Alexandroupoli and Xrisoupoli, a small town in the outskirts of the city of Kavala, as well as Egnatia Odos, a highway that connects the north part of Greece with neighbouring countries (Bulgaria, Turkey) create the conditions for the development of the cities of the region based on commercial and retail activities. At the same time, peri-urban areas of the region are used as spaces for tourism facilities and research labs due to the environmental characteristics of the area. We should also mention the presence of important natural parks inside the region, including three Natura Zones in Evros, Rodopi and Xanthi (Nestos river delta whose part is 'Stena tou Nestou') which consist of its internal dynamics, and the presence of the Greek Muslim Community in the cities of Xanthi and Komotini posing challenges regarding the support of ethnic minorities and the enhancement of social cohesion through the development of peri-urban areas.

The case study: the city of Xanthi in the region of East Macedonia and Thrace in Northern Greece and the 'Stena tou Nestou' area

The choice of the case study was based on the necessity to reflect and change old narratives and discourses in the planning processes for poor urban and peri-urban areas and to propose a safe and equitable living environment for the inhabitants of these areas.

The city of Xanthi is located in the north part of Greece, in the region of East Macedonia and Thrace, with an area of 495.01 square kilometres (Greek Statistical Institute, 2015). It is built on the foot of Rhodope Mountain chain, close to the Nestos River (Figure 1). Based on the 2021 population census, the Municipality of Xanthi has 58,760 inhabitants (Greek Statistical Institute, 2021).

Figure 1. Xanthi's location on the map of Greece. In detail the cities of the Xanthi regional unit, whose capital is the city of Xanthi, and the neighboring regional units. Source: Greece-map.net

As most of the cities of the region of East Macedonia and Thrace, Xanthi is characterised by the diversity of its urban fabric combining neighbourhoods with a historical significance and architectural cultural value such as the Old Town (Figure 2) with contemporary city's expansions built during the 19th and 20th century (Figure 3). At the same time, we should note the continuity between the city and its neighbouring peri-urban areas as they are neighbourhoods inside the city's limits that are not fully urbanised, which have significant natural elements such as a small river and forests. Xanthi is characterised by its dense urban fabric especially in the neighbourhoods that were built during the Ottoman era while the rest of the city follows contemporary urban planning policies (presence of public spaces, tall buildings and large streets with pavements).

Figure 2. Xanthi's old town. In the photo we can see the neoclassical mansions of Greek merchants from the 18th and 19th centuries that characterise the old town of Xanthi. In the same city neighbourhood, we can find elements from the presence of the Greek Muslim Community in the area such as Ottoman-Era mosques. Source: www.flickr.com

In this panoramic view of the city, we can distinguish in the front part of the photo the Old Town from the contemporary city that appears in the photo's background. At the right side of the photo, we can see the surrounding peri-urban spaces of Xanthi characterised by the presence of natural elements. Source: www.newsbreak.gr

After the Greek Turkish War of 1919–1922, the city of Xanthi entered a new era of prosperity and development due to the industrial, commercial and agricultural activities (Archaeology Newsroom, 2012). Xanthi became greatly involved and developed further in the processing and trading of tobacco mainly with European countries (Lantitsou, 2015). Many buildings related to the storage and processing of tobacco from that era are preserved in the city and act as landmarks of the city's past. During the last decades, tourism has also increased, especially during the period of the "Old Town Festival". As most of the Greek cities, especially small and medium-sized, Xanthi faces in the 21st century the consequences of deindustrialisation and the closure of local enterprises, despite the fact that the presence of university departments in the area increases the local inhabitants' incomes due to apartments' rentals.

"Stena tou Nestou" (in English it could be translated as narrow pathway alongside Nestos River) is a peri-urban area located near the city of Xanthi in the region of East Macedonia and Thrace in Northern Greece, an area that maintains its physical and social characteristics since the 20th century and which is nowadays used as a space for leisure and sports (natural regional park). It is important to underline the particular characteristics of the region of East Macedonia and Thrace as it is among the less developed at national (Greek) level, while at the same time the presence in the region of the Greek Muslim Community poses challenges regarding the just and peaceful transition towards a safe and equitable living environment for all despite their ethnic and cultural background. Our case study is located in a place with particular natural and historical characteristics and is part of the Nestos River delta, a Natura zone, while Nestos River is protected by International Water Law. The narrow pathway that crosses the peri-urban space 'Stena tou Nestou' was created in the 19th century to serve the workers who built the railway line connecting West European countries with the Ottoman Empire (Orient Express). The natural landscape is dominated by the river itself through the presence of water, the steep rock inclination, and the small sandy shores (Figure 4). The space has access by the small city of Toxotes while the hiking route inside this area connects the city of Toxotes with the city of Stavroupoli.

Figure 4. Natural and cultural characteristics of the 'Stena tou Nestou' peri-urban space. In the photo they are represented constructive elements of the particular landscape of 'Stena tou Nestou' such as the railway, which was part of the Orient Express, the pathway which is still used as part of a hiking route, Nestos River and the mountains of the region of East Macedonia and Thrace. Source: Varvara Toura

During our field research in the city of Xanthi and its surrounding areas and particularly in the 'Stena tou Nestou' peri-urban space we observed that the access to the 'Stena tou Nestou' area was only possible through the local road network that connects the city of Xanthi with small cities and villages of the Regional Unit of Xanthi. At the same time, vehicles are not allowed inside the 'Stena tou Nestou' area as it is a Natura Zone and there is a parking lot at the entrance of the park. Inside the park the only activities allowed are connected to recreation and sports practice while at the entrance of the park there is a small open-air café and restaurant (Figure 5).

Figure 5. The entrance to 'Stena tou Nestou' peri-urban space. The photo shows the first landscape unit of the park where recreation and sports facilities are found while at the left corner in the background is the area of the park where the café, the restaurant and the parking lot are located. Outcomes-Results

The study of the region of East Macedonia and Thrace, of the city of Xanthi and its surrounding peri-urban spaces especially the 'Stena tou Nestou' area revealed areas with different characteristics. While the main cities of the region, the capitals of regional units, have a rather dense urban fabric and are well connected to the national road network, the peri-urban spaces are disconnected and have many unbuilt spaces. The main economic activities, such as commercial and retail activities as well as activities related to research and development, are located in the main cities of the region, leaving peri-urban spaces with activities related to agriculture and small-scale commerce. We can do the same remark regarding the revalorisation of the significant landscapes of the region, cultural and natural, as the ones located in the main cities of the region they are preserved and restored (for example the Old Town of Xanthi), while similar landscapes in peri-urban spaces are neglected (for example the train stations serving several of peri-urban areas) and not integrated in the development plans of these spaces. Despite this problem of abandonment and neglect of significant local cultural elements, we should highlight the fact that many peri-urban spaces of the region that have a significant environmental interest such as Nestos River delta and the 'Stena tou Nestou' peri-urban space are protected by International Environmental Law by being defined as Natura Zones. The expansion of the main cities of the region into the natural peri-urban spaces (we already described the urban development system of the city of Xanthi) due to the high demand for new housing poses problems in the protection of the natural resources of peri-urban areas and requires actions to reverse this phenomenon. The analysis of the interviews with local elected officials and inhabitants of peri-urban spaces of the region revealed the necessity to reconsider these spaces according to sustainability and resilience criteria as they are spaces with particular characteristics (there are still unbuilt spaces inside them and have significant natural and cultural elements) that could be developed through a model that takes into consideration the three parameters of sustainability (environmental protection, economic development, social cohesion) as well as the local cultural and ethnological identity (presence of ethnic minorities in the area).

Our proposal for the development of peri-urban areas located near small and medium-sized cities, focusing on the case study of the 'Stena tou Nestou' peri-urban space located near the city of Xanthi, was based on policies and tools to improve the main problems identified in the region. These policies focused on a development scenario of the Natura zone located inside the 'Stena tou nestou' peri-urban space which will be transformed into a research and recreation area, combing the existing facilities for sports practice and dining with new ones. These new facilities will host a small-scale research centre where researchers of the local Democritus University of Thrace and Athena research centre will work on issues related to biodiversity and environmental sustainability. The proposed facilities, which are located close to the pathway serving the visitors, will have spaces for the researchers (library and working spaces) as well as spaces for the visitors of the area such as a small café and living room, WC and a souvenir shop as a means to boost small-scale economic activities in an area facing socio-economic difficulties. The development plan for the 'Stena tou Nestou' peri-urban space as well as the activ-

ities and buildings inside its perimeter were decided together with the inhabitants of the area in order to foster the dialogue between professionals and citizens and to create the conditions for the public acceptance of our development plan for the peri-urban spaces near the city of Xanthi. The basic idea was to propose rather simple solutions, respecting the local identity and landscapes that could be easily adopted and implemented by the Region of East Macedonia and Thrace and the local Municipalities and to avoid complicated and expensive policies and tools. The economic activities proposed are linked to the local economic activities network and take into consideration the internal power dynamics of the region while the materials and the vegetation that were proposed in the new building inside the 'Stena tou Nestou' peri-urban space (wood, stone, ceramic tiles, pine trees) are all local in order to reduce the cost of the project in an area facing significant socio-economic difficulties.

Concerning measures for the connection of the 'Stena tou Nestou' peri-urban space with other areas of the region of East Macedonia and Thrace, we have already mentioned that the area is not connected to the national road network (Figure 6). In our development plan we considered important to facilitate the travels of the area's inhabitants and to make it accessible to visitors and people working on this area in order to facilitate mobility and reduce disconnection. Our proposal suggested the connection of the peri-urban space with the national road network (exit on Egnatia Odos towards the 'Stena tou Nestou' area) as well as signage boards on local and national road network especially for people who come to region for the first time.

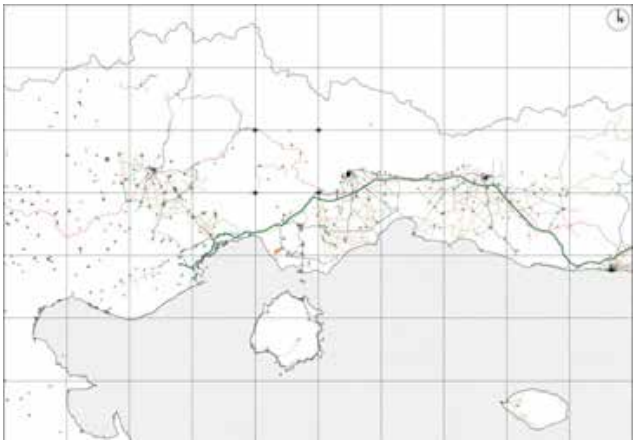

Figure 6. The main road network serving the region of East Macedonia and Thrace. The national road network serves mainly the cities of the region while peri-urban spaces are served by the local road network that connects cities with their surrounding spaces. Source: Alexandros Mpantogias

The 'Stena tou Nestou' peri-urban space is nowadays a space for recreation and sports practice (canoe kayak, hiking) in its area defined as Natura Zone, while the economic activities in villages and small cities in its perimeter such as Toxotes and Stavroupoli are primarily agricultural and commercial (Figure 7). As we have previously mentioned the region of East Macedonia and Thrace and particularly its peri-urban spaces struggle with the consequences of deindustrialisation and closure of local enterprises.

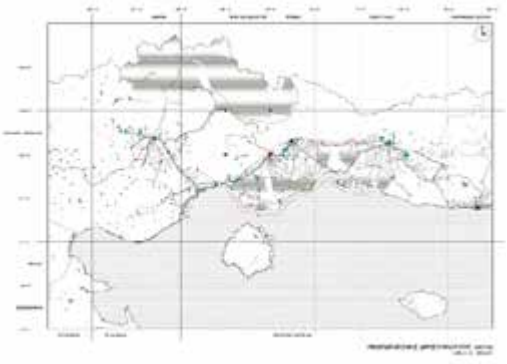

Figure 7. The main economic activities developed in the region of East Macedonia and Thrace. The areas marked in grey colour are protected areas such as Natura Zones while the industrial activities in blue colour are located near the national road network (Egnatia Odos). It is clear that the region struggles with the effects of deindustrialisation while in the interior of protected areas we can find a small number of houses. Source: Alexandros Mpantogias

In our development plan for the 'Stena tou Nestou' peri-urban space we emphasised on the development of small-scale economic activities to boost tourism, recreation, sports practice and research as a means to reduce local unemployment rate and to lead to economic resilience and sustainability. The small research and recreation centre located inside the Natura Zone of the peri-urban space (Figure 8) highlights the importance of proposing economic activities that fit to the local cultural, social and economic landscape and create sustainability conditions based on the existing power dynamics of the area (the presence of Democritus University of Thrace).

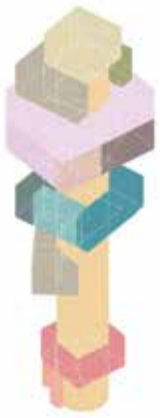

Figure 8. The functions of the new research and recreation centre proposed inside the perimeter of the Natura Zone of the 'Stena tou Nestou' peri-urban space. In purple and red colour are the spaces for recreation, in blue the small souvenir shop for the visitors and an exhibition space while in green colour are the spaces that will be used by the researchers. Source: Alexandros Mpantogias

As we have previously mentioned the region of East Macedonia and Thrace is characterised by the dense urban fabric of the main cities of the region while there are many natural landscapes and environmental protected areas located in peri-urban areas (Figure 9). The cities' organisation and the land uses in their peri-urban spaces resulted from the arrival in the region of East Macedonia and Thrace of refugees from Anatolia region after 1923 (end of Greek-Turkish war) which had as a result the increase of housing needs inside cities and the use of peri-urban spaces as agricultural lands. In the years following the Second World War (1950 and 1960) and especially in the late 1970s several industrial units were built inside the perimeter of peri-urban spaces thus affecting their natural characteristics. In our strategy for the development of the 'Stena tou Nestou' peri-urban space

we emphasised on the protection of the natural resources of peri-urban areas as a means to reduce the cities ecological footprint. For this reason, we proposed the increase of vegetation around new buildings and in deindustrialised areas where in previous years there were active industrial units in order to restore the relationship between the natural and the built environment (Figure 10).

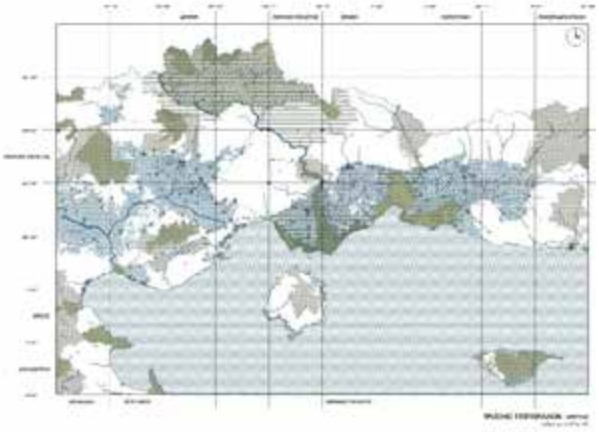

Figure 9. The natural landscapes in the region of East Macedonia and Thrace. The region is characterised by a significant number of natural landscapes including Natura Zones and zones protected by International Environmental Law. Source: Alexandros Mpantogias

The proposed and existing vegetation (plants and trees) around the new research and recreation centre proposed inside the perimeter of the Natura Zone of the 'Stena tou Nestou' peri-urban space. Plants and trees around the new building are proposed as a means to restore the relationship between the natural and the built environment. Source: Alexandros Mpantogias

In our strategy for the development of peri-urban spaces we considered that the notions of sustainability and resilience are connected to peri-urban landscape where all phases of the region's cultural and natural history are present and repurposed alongside contemporary needs (small size economic activities) (Figure 11). The inscription of new buildings in these areas which host economic activities, is based on the understanding of the structural elements of the space and the protection of the natural and cultural landscapes. For this reason in our development scenario we proposed the co-existence on the same space of different elements (cultural, natural, contemporary architecture) which are connected through suitable vegetation (tall trees) and urban equipment (pergolas and benches) that highlight the unique historical characteristics of the above spaces and offer a different experience in the discovery of these peri-urban spaces (Figure 12).

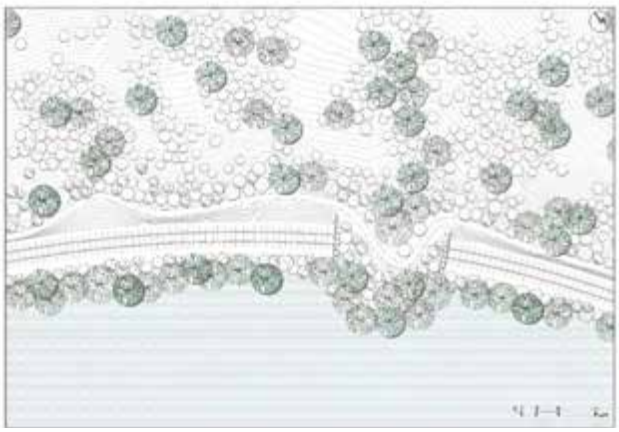

Figure 11. Significant cultural and natural landscapes inside the perimeter of the Natura Zone of the 'Stena tou Nestou' peri-urban space. The revalorisation of significant cultural and natural landscapes such as regional parks and historical buildings and monuments acts as a means to protect and show the identity of peri-urban spaces. Discussion

The study of a real-world setting and its particular characteristics (socio-economic difficulties, environmental protected peri-urban space) revealed the necessity to consider planning in poor peri-urban areas as a transformative action which seeks to achieve sustainability goals through strategies and tools at different governance levels (national, regional, municipal) and in different sectors (economic, environmental, social, cultural). The development of peri-urban spaces in a sustainable way could act as a new narrative for inclusive urban and peri-urban transformations when local elected officials and inhabitants work together with researchers and practitioners in their planning processes and try to find solutions that fit not only to technical and legislative norms but also to the needs of communities. It is important to mention that this democratic procedure, which can sometimes take the form of co-decision and co-planning and not only inhabitants' consultation, in small-

scale development projects acts as a planning laboratory for the strategic design and testing of solutions that could later be implemented at regional level (the planning methodology and tools in a development project of a peri-urban space could also be used in development projects at regional level concerning housing policies, environmental policies and socio-economic policies). The cost of development projects in peri-urban spaces is an issue to consider when proposing development scenarios in small and medium-sized areas facing socio-economic difficulties. The discussions with local authorities and especially with the inhabitants allow to propose policies and measures that are closer to their expectations and needs, while the socio-economic analysis of the local regional, urban and peri-urban context allows to adjust these policies and measures to the economic dynamics of the area. Good strategies for the development of peri-urban spaces do not mean expensive and complicated technical solutions but rather proposals inscribed in the local social, economic, environmental and cultural peri-urban context.

Another issue to further consider through the planning of peri-urban spaces and their role in regions' development is the preservation of the local cultural and natural landscapes. We saw in the analysis of the case study and the subsequent development scenario for 'Stena tou Nestou' peri-urban space that the particular characteristics of the local landscapes are reflected in the planning of the peri-urban space. Landmarks from the previous land uses of the space (train stations), monuments and natural landscapes (mountains and rivers) that have shaped the region's history are not only living memorials of the different eras of the cities and peri-urban spaces but are also vital elements for contemporary strategic planning as they are often inscribed in national and regional development plans. Their integration on the development plans of peri-urban spaces, by giving an emphasis on the protection of the local cultural and natural landscapes, could lead to a new regional branding, especially when these spaces are well connected with the national road network (accessibility criteria), and to the discovery of unknown areas that had a significant importance in the development of their regions. Through these planning policies on peri-urban spaces, they could be identified significant landscapes, both cultural and natural, and define them as protection zones in order to protect them from mass-tourism and overscale construction projects that seem to not respond to the cultural and historical characteristics of these peri-urban areas. On the contrary small-scale economic activities such as recreation activities and research centres in accordance with the existing power dynamics of the areas could be found inside these spaces as they serve as measures for facing socio-economic difficulties (high unemployment rate).

To go further on the field of urban sustainability and resilience and the relationship between urban spaces and peri-urban spaces we should underline that measures and policies in favour of nature's protection in peri-urban spaces, such as the planning of national and regional parks and the definition of Natura zones in spaces with a particular ecological interest, should be proposed and implemented in peri-urban spaces close to dense urban areas based on the local characteristics of each area (cultural, environmental, social, economic). These measures and policies should put forward the relationship between the urban environment and its surrounding peri-urban spaces and try to find a balance between them in order to improve socio-economic and environmental conditions. At the same time urban planners and local authorities should carefully consider that the protection of the natural resources in the planning of peri-urban spaces could have positive effects on the cities functions as well as to water and air quality. Peri-urban spaces planning, organisation and functions based on environmental sustainability criteria could reshape urban and peripheral areas of the Mediterranean region that are exposed to extreme weather conditions (heat waves) during summer. For this reason, it is important to consider the planning of peri-urban spaces as a process inscribed in the fields of urban sustainability and resilience as peri-urban spaces like Natura zones and national and regional parks serve also as places for social encounters that boost citizens' health and well-being and solve social problems.

In many cases of neglected peri-urban spaces located near cities facing population shrinkage due to the swift in their economic model (former industrial cities), social problems appear after this swift related to the high unemployment rate. This local economic context combined with the loss of local population who moves in other areas in order to find work has as a result the recession of certain urban and peri-urban areas who are trying to find a new identity (social, economic, cultural) in order to increase their population and improve the living conditions

of the local population. Peri-urban spaces could play a key role in the development strategy of these areas, as we have previously seen in the case study of 'Stena tou nestou' peri-urban space located near the city of Xanthi a medium-sized city affected by deindustrialisation and the loss of local population. The creation of community conditions (people who have the same goals and needs), in urban and peri-urban spaces affected by economic recession, could be achieved through the planning of peri-urban spaces as these spaces act as places for social encounters where people with different social and ethnic backgrounds gather and spend time with other people. Research activities in these spaces focusing on the study of the local natural and cultural landscapes as well as activities related to sports practice and recreation bond the relationships between the inhabitants and their living environments and help them to act together as a group in issues related to social, economic and environmental policies of their municipalities and regions.

Spatiotemporal Evolution Characteristics and Planning Strategies of Population and Construction Land in Shrinking Chinese Counties

Weiping Cao, Su Wang, Han Tao
College of Architecture and Urban Planning, Tongji University
529788416@qq.com

Abstract:
This study focuses on the contradiction between population loss and construction land expansion in China's shrinking counties. It explores the spatiotemporal change patterns of permanent population, urban population and construction land through three time sections: 2000, 2010 and 2020. On this basis, the decoupling model is used to further analyze the degree of coordinated development of population and construction land in shrinking counties, summarize its characteristics and causes, and compare them with international shrinking cities. Planning strategy recommendations are proposed to optimize the human-land relationship and promote coordinated and sustainable development.

Keywords
population and construction land relationship;urban shrinkage;spatial-temporal evolution;coordinated development; Planning strategy

1. Introduction

1.1 Research background

1.1.1 The universality and challenges of the shrinking county phenomenon in China

Against the backdrop of accelerating global urbanization and cities entering the post-growth era, China is experiencing extensive population mobility and reconstruction of spatial development. Due to factors such as unbalanced regional development, in sharp contrast to the continued expansion of large cities, the shrinking of China's counties is gradually becoming an undeniable reality in the process of new urbanization. According to the China County Statistical Yearbook, between 2010 and 2020, many of the country's counties (cities) experienced a continuous loss of permanent population, with the Northeast and central mountainous areas being particularly significant. This shrinking phenomenon not only reflects the objective law of population agglomeration in developed coastal areas and high-level cities, but also exposes the deep-seated contradiction between the county development pattern and spatial resource allocation(Wu and Sun,2017).

1.1.2 The particularity of China's county shrinkage phenomenon compared with international shrinking cities

The phenomenon of urban shrinkage is common in Western developed countries, but China's urban shrinkage phenomenon is significantly different from that of Western developed countries. On the one hand, unlike Western developed countries, urban shrinkage occurs in the mature stage of urbanization development. For example, in developed countries such as the United Kingdom and the United States, the shrinkage of population and idle housing land are developing in the process of urban deindustrialization and suburbanization.(Yang,Wu Wang etc,2021) China's urban shrinkage phenomenon occurs in the rapid urbanization development cycle. A large number of people flow out of county towns and move to large cities, resulting in widespread shrinkage of county towns. The slowdown in China's urbanization growth in recent years will further aggravate the phenomenon of urban shrinkage(Yang,Long,Yang etc 2015). On the other hand, the shrinkage phenomenon in Western developed countries is the "double shrinkage" of population and construction land, while China has a more widespread contradiction between population shrinkage and construction land growth(Sang,Pan,Zhang etc,2024). The transfer and flow of population and the corresponding changes in construction land continue to affect the allocation efficiency of urban construction resources. To achieve high-quality urbanization development, it is necessary to coordinate the evolution and coordination relationship between population and construction land, and promote the rational use of resources and sustainable development.

1.2 Research Questions

Many scholars have conducted research on the phenomenon of urban shrinkage in China, but most of them focus on the prefecture-level cities in some regions, with few nationwide studies and insufficient long-term analysis of county-level units. At the same time, most studies focus more on the phenomenon of population shrinkage

itself, ignoring the contradiction between population decline and increase in construction land, and insufficient analysis of the spatiotemporal heterogeneity of the response to human-land relations. Relevant planning strategies do not make targeted distinctions between shrinking cities in different regions and development types across the country. Therefore, based on the above contradictions and gaps, this study takes the spatiotemporal evolution pattern of population and construction land in shrinking county-level cities in China, the analysis of coordination degree, and the analysis of classified planning strategies as the main research issues.

1.3 Research framework and technical route

This study first clarifies the universality of the development of shrinking cities in China and its uniqueness from the Western country. Then, it takes county-level cities in China with shrinking population as the research object, selects three time sections of 2000, 2010 and 2020, uses spatial statistical tools to deeply analyze the spatial characteristics of the evolution of their population and construction land, and comprehensively analyzes their development coordination. It classifies and summarizes the coordination types and development trends of the relationship between people and land in shrinking counties in different regions, analyzes their influencing factors by category, and proposes planning optimization strategies based on international shrinking cities comparisons.

2. Research area and methods

2.1 Research area

More than 1,848 county-level units (excluding urban districts) with available data across China were selected as the research scope, and county-level cities that had a county-level permanent population and whose permanent population increased by no more than 20,000 people between 2000 and 2020 were defined as “county-level shrinking cities shrinking counties”. A total of 280 research objects were selected. They are distributed throughout the country.

2.2 Data Source

The county population data comes from the fifth, sixth and seventh national census data in 2000, 2010 and 2020, and the construction land data comes from the China Urban Land Cover Remote Sensing Monitoring Dataset (CNLUCC) produced and released by The Data Center for Resources and Environmental Sciences, Chinese Academy of Sciences (RESDC) (Xu,Liu,Zhang etc,2018)

2.3 Research Methods

2.3.1 Standard Deviation Ellipse

Standard deviation ellipse is a spatial statistical method widely used to describe the spatial distribution characteristics of geographical elements, and depicts the centrality, spread, directionality and other spatial morphological characteristics of geographical elements. This study constructs the standard deviation ellipse of urban construction land in shrinking cities in counties across the country from 2000 to 2010 and from 2010 to 2020 to analyze the spatiotemporal evolution pattern of construction land.

2.3.2 Change coupling mode measurement

This study constructs a decoupling model of shrinking cities in counties based on the elasticity coefficients of urban population and urban construction land area in counties from 2010 to 2020.

$$F=\triangle P/\triangle L$$

Where F is the elasticity coefficient, $\triangle P$ and $\triangle L$ are the ratios of the change rate of urban population to the change rate of urban construction land in a certain period, reflecting the coordinated relationship between urban population change and construction land change. According to the positive and negative change rates of urban population and construction land(Yi,Wang,Zhang etc,2023), as well as the value of the elasticity coefficient, the decoupling type of human-land relationship can be further established to judge the current status and trend of human-land relationship.

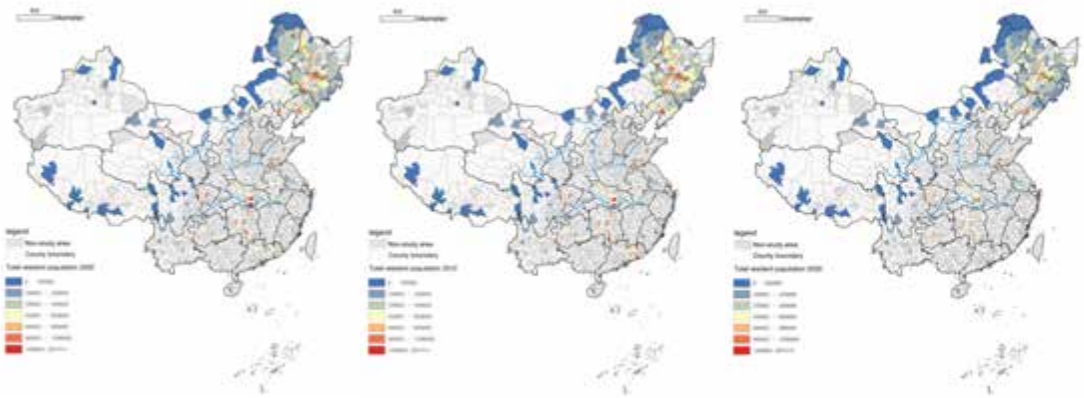
3. Characteristics of the spatiotemporal evolution of population and construction land in shrinking counties

3.1 Characteristics of population shrinkage

3.1.1 Spatial distribution pattern of total population in counties

As can be seen from the figure 1, the shrinking counties development in China are mainly concentrated in the Northeast, Sichuan Province, Hubei Province, Hunan Province in the upper and middle reaches of the Yangtze River, and Fujian Province and Guangdong Province in the southeast coast.

In terms of total volume, the total population of shrinking counties showed a straight-line downward trend in the two decades from 2000 to 2020, with the total population dropping from 110.665 million in 2000 to 86.232 million, which was significantly reduced in all regions of the country. Among them, the total population base of shrinking counties in the Northeast, Central and Western regions is large, and the reduction is the largest. The total population in the Northeast region has decreased by more than 10 million in 20 years. It is the region where the urban shrinkage phenomenon in my country has occurred most profoundly and extensively, and is experiencing a large-scale population outflow; the total population of shrinking counties in the eastern region is small. Due to the high level of economic development and small county gaps, the population mobility changes are relatively slow. Overall, the total population of shrinking counties in all regions of the country showed a more obvious decrease between 2010 and 2020, and the population shrinkage phenomenon further intensified.



(a)2000 (b)2010 (c)2020

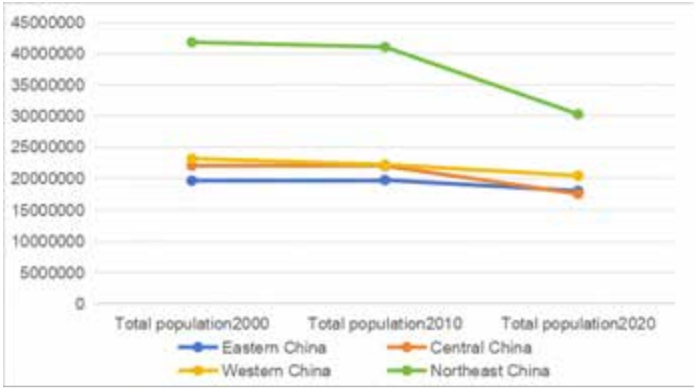


Figure 1 Spatial and Temporal Pattern of Total Population Changes in Shrinking Counties in China

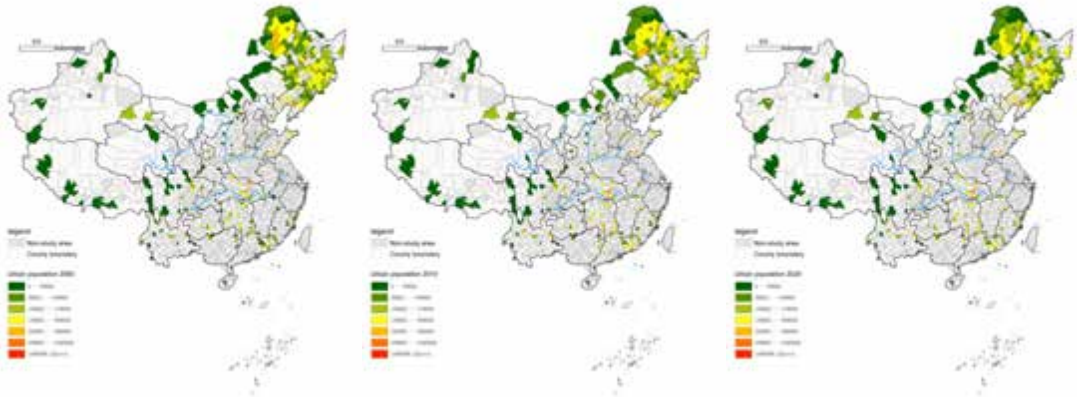
3.1.2 Spatial distribution pattern of urban population

The figure 2 shows that from 2000 to 2020, the urban population of shrinking counties in China first increased and then decreased. The total urban population eventually increased from 33.806 million in 2000 to 40.231 million in 2020, and the changes in various regions across the country were different. Among them, the number of urban residents in the Northeast and Central regions first increased and then decreased, showing an overall downward trend. The urban population in shrinking counties decreased significantly, and the population loss was more serious. It is the most important shrinking development region in China. The urban population in the western and eastern regions continued to increase. The growth rate of the urban population in shrinking counties in the eastern region gradually slowed down after 2010. The urban population in the western region continued to increase. This is largely due to the fact that the economic and urbanization development in the western region lags behind other regions. It is still in the stage of converting rural population into urban population on the spot, which has led to a certain increase in the urban population.



(a)2000 (b)2010 (c)2020

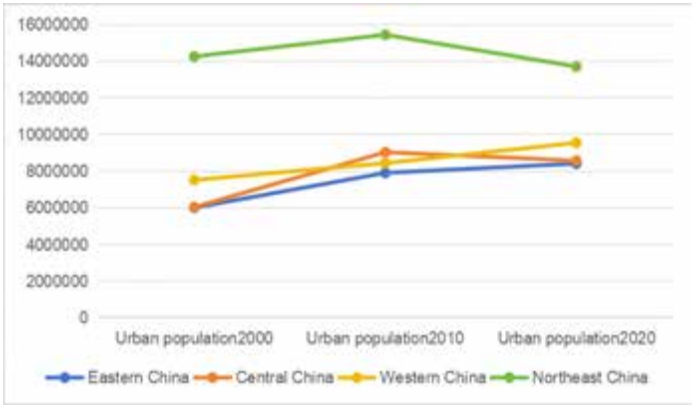


Figure 2 Spatial and Temporal Pattern of Urban Population Changes in Shrinking Counties in China

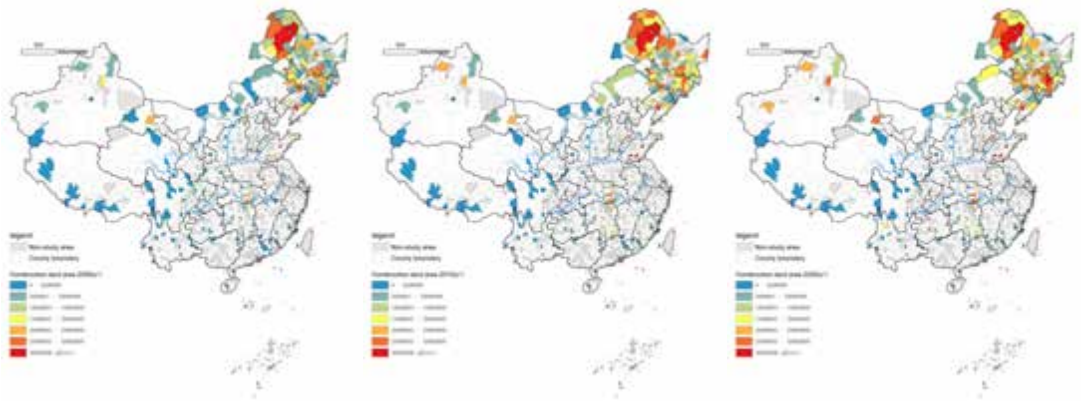
3.2 Changes in construction land

3.2.1 Dynamic changes in the total amount of urban construction land

In terms of total amount, the area of urban construction land in shrinking counties across the country increased from 2584.21 square kilometers in 2000 to 3949.86 square kilometers in 2020, with a growth rate of 52.8%. The changes in the area of construction land in shrinking counties in different regions of the country vary greatly (Figure 3). Except for the western region, the growth rate of construction land in other regions has slowed down after 2010. The slowdown in the growth rate of construction land in the northeast region may be related to the transformation and development of industry, the slowdown of urban economic growth, and the large-scale population loss; the counties in the more developed eastern and central regions may gradually enter the stock development period, and the speed of urban land construction and development will slow down. The western

region is still in the process of accelerated development, and the area of urban construction land is accelerating. The large-scale growth of urban construction land has formed a paradox with the shrinking population, and it presents an unbalanced and contradictory development state in different regions.



(a)2000 (b)2010 (c)2020

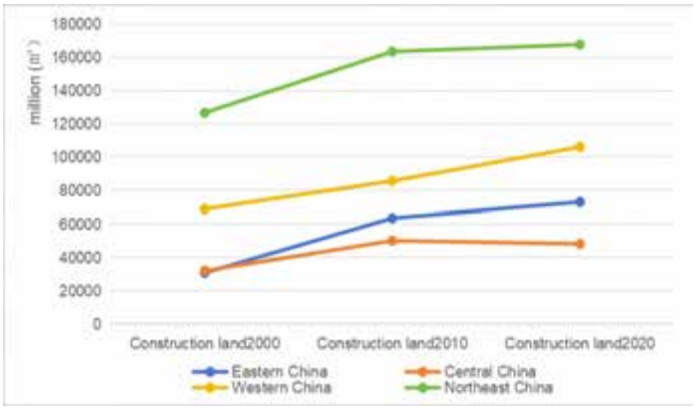


Figure 3 Spatial and Temporal Pattern of Urban Construction Land Changes in Shrinking Counties in China

3.1.2 Dynamic changes in the average amount of urban construction land

As can be seen from the figure 4, the per capita construction land in shrinking counties across the country has been growing over the past 20 years, with the average value increasing from 76.4 square meters per person in 2000 to 98.2 square meters per person in 2020. This is related to the continued growth of construction land while the population in shrinking counties is declining. It can be seen that the uncoordinated development of the relationship between people and land in shrinking counties is likely to cause resource waste and unsustainable development problems. During this period, the centre of gravity of urban per capita construction land area continued to move toward the central and western regions. The northeast region with vast land and sparse population is the main area of population loss. The per capita construction land area is large, and there is obvious waste of resources. The change direction of construction land and urban population in the central region is relatively consistent, but the growth rate of construction land is still faster than the growth rate of population, resulting in an increase in per capita construction land area. The western region is still in a rapid urbanization development stage, and the construction land area is increasing rapidly. In addition, the local towns have limited attraction to the population, and the population growth lags behind the growth of county construction land. The per capita construction land area continues to expand. The eastern region is densely populated, construction land is tight, and the per capita construction land area is growing slowly. There is a spatial mismatch between the per capita construction land area in county towns and the economically developed and more densely populated regions in China. The problem of uncoordinated development of population and construction land needs to be optimized and solved urgently.

(d)standard deviation ellipse of per captia construction land area

Figure 4 The Spatiotemporal Evolution of Per Capita Construction Land Area

4 Analysis of the coordinated relationship between shrinking county population and construction land

4.1 Construction of a decoupling model for human-land relationship

Based on the analysis of the spatiotemporal evolution of shrinking urban population and construction land in the previous study, the changes in population and construction land during 2010-2020 are more diverse, which can better reflect the dislocation and disharmony of human-land relationship. In order to further measure the mismatch relationship between shrinking urban population and construction land, this time period is selected to analyze the decoupling relationship between shrinking county population and construction land changes. According to the provisions of China's "Urban Land Classification and Planning Construction Land Standards" on per capita construction land indicators and related research by other scholars, the types and trend standards of the decoupling relationship between urban population and construction land are formulated as follows.

Figure 5. Types of the Decoupling Relationship Between Urban Population and Construction Land

decoupling type		△P	△L	F	human land relationship status
decoupling	strong decoupling	△P<0	△L>0	F<0	Population decreases, land use increases
	weak decoupling	△P>0	△L>0	0<F<0.8	increase at the same time, the growth rate of land use is greater than the growth rate of population
	weakening decoupling	△P<0	△L<0	F>1.2	decrease at the same time, the land use slowdown is smaller than the population slowdown
negative decoupling	strong negative decoupling	△P>0	△L<0	F<0	Population increases, land reduction decreases
	expansion negative decoupling	△P>0	△L>0	F>1.2	increase at the same time, the land use growth rate is lower than the population growth rate
	weak negative decoupling	△P<0	△L<0	0<F<0.8	decrease at the same time, land use slowdown is greater than population slowdown
connection	expansion Connection	△P>0	△L>0	0.8<F<1.2	Relatively synchronous increase
	declining Connection	△P<0	△L<0	0.8<F<1.2	Relatively synchronous decrease

A corresponding analysis of shrinking counties across the country found that there is a clear correlation between the shrinkage of counties and the decoupling development of the relationship between people and land, resulting in three types of decoupling of the relationship between people and land: negative decoupling type, connection type and decoupling type (Figure 6). The negative decoupling type includes a strong negative decoupling mode with population growth and reduction in construction land, an expansion negative decoupling mode with both urban population and construction land increasing, and the growth rate of construction land being lower than the growth rate of urban population, and a weak negative decoupling mode with both urban population and construction land decreasing, and the deceleration of construction land being higher than the deceleration of population. From 2010 to 2020, county units of this type of decoupling accounted for about 31.7% of the total, and nearly half of the counties' urban construction land area exceeded the national standard. Under the trend of population shrinkage, these areas should continue to maintain slow growth and negative growth in construction land to further optimize and coordinate the relationship between people and land.The connection type includes a pattern of relatively synchronous growth and decrease of urban population and construction land, which is a type of relatively harmonious human-land relationship. From 2010 to 2020, such county units accounted for about 5.2% of the total. Only very few counties were in such a good state of human-land relationship. More than half of the shrinking counties were in the third decoupling type of unharmonious human-land relationship, indicating that the human-land relationship in shrinking county units is more likely to be out of balance.

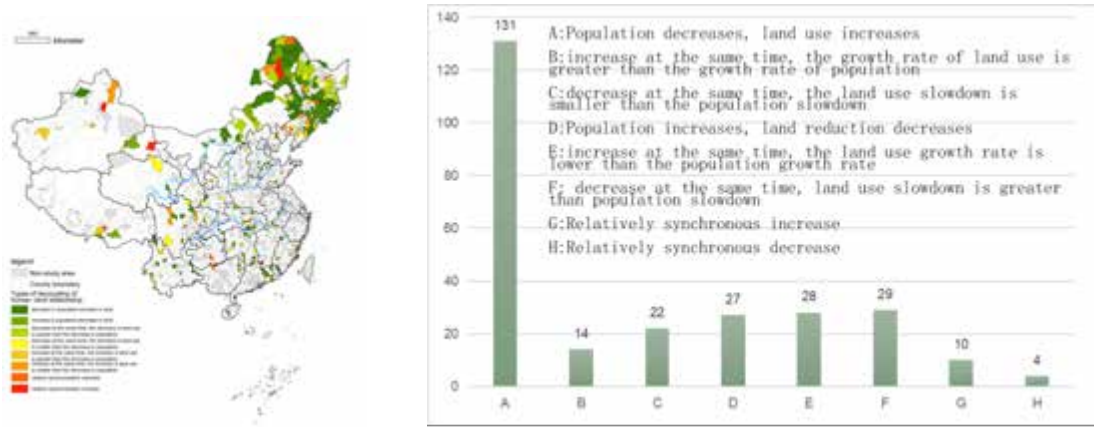

Figure 6. Space distribution of the decoupling relationship between urban population and construction land

4.2 Analysis of the uncoordinated human-land relationship of "decreasing population and increasing construction land" in shrinking counties

In the decoupling type of human-land relationship presented by most shrinking counties, three different development models have been formed according to the different rates of change of urban population and construction land: the first is the strong decoupling model with decreasing population and increasing construction land area. From 2010 to 2020, this type of shrinking county units has the largest number, accounting for 49.3% of the total, and is widely distributed. It is more concentrated in the three northeastern provinces, Hebei Province, Hunan Province, Sichuan Province, Yunnan Province and Guangdong Province. These areas are the main areas facing population shrinkage problems. Among them, the development gap between counties in Hebei Province, Hunan Province and Sichuan Province is large. The counties with strong decoupling of human-land relationship in these areas are mostly in the "depression area around the provincial capital". The urban population in shrinking counties is continuously transferred to large cities in the province or larger cities around them due to the siphon effect, resulting in the continuous loss of urban population in counties. At the same time, compared with the developed eastern coastal areas, these regions are still in the process of accelerated urbanization and have a strong driving force for construction and development. Some government-oriented investments have led to the continued expansion of construction land, resulting in a resource contradiction of reduced population and increased land. The three northeastern provinces are the areas with the most concentrated shrinking counties in China. They are facing the pain of transformation and development of traditional resource-based industries. Many counties still retain a large amount of inefficient industrial land, which has formed a driving force for population outflow. The lag in industrial transformation has caused a mismatch in land space. At the same time, the phenomenon of "reduced population and increased land" is common in counties with shrinking populations, and is also affected to a certain extent by land finance and local administrative management factors. With the loss of county population and the continuous reduction of tax revenue, many governments tend to expand land transfer to maintain finances, and then ignore the current population situation and continue to accelerate infrastructure investment, which has led to the continuous expansion of land use, becoming an institutional cause of the contradiction between people and land in shrinking counties.

This type of county should correctly deal with the current situation of its own population outflow, accelerate the transformation of development mode, reduce population outflow and attract population return by improving competitiveness; make full use of existing construction land and stock land, reduce large-scale development of construction land, and avoid waste of resources(Figure 7).

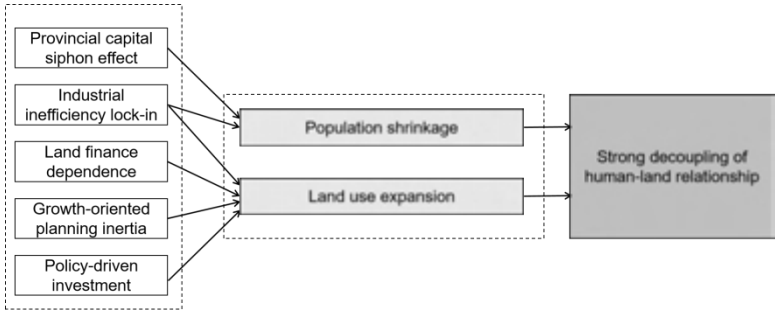

Figure 7. Space Distribution of the Decoupling Relationship Between Urban Population and Construction Land .

The second is the weak decoupling mode in which both urban population and construction land grow, and the growth rate of construction land is greater than the growth rate of urban population. From 2010 to 2020, the number of shrinking county units of this type accounted for about 5.28% of the total, mainly distributed in the eastern part of Liaoning Province, Yunnan Province, Xinjiang and Tibet Autonomous Region. These counties are mostly located in frontier border areas and ecologically fragile areas, and are prone to passive urbanization. Ecological immigration and poverty alleviation relocation have brought a certain increase in population and construction land, and the failure of related supporting facilities and industries to follow up simultaneously can easily lead to vacant new homes. Counties in these areas should strictly abide by the ecological red line, reduce the ecological damage caused by construction and development, and reasonably determine and implement construction indicators in immigration and relocation to avoid waste of resources.

The third is the weakening decoupling model in which both the urban population and construction land are reduced, and the deceleration of construction land is less than the deceleration of population. From 2010 to 2020, the number of shrinking county units of this type accounted for about 8.3% of the total, mainly distributed in Heilongjiang Province, Sichuan Province and Shaanxi Province. These regions are relatively backward in economy, lack of self-development, and show a clear shrinking trend. It is necessary to further optimize the use of construction land and reduce resource waste. The above three development models are all facing the spatial mismatch problem of "more land and fewer people". It is urgent to change their own economic development mode, reduce extensive construction and development, vacate some inefficient land according to the current population situation, and promote the efficient and intensive use of construction land.

5. International Experience and Planning Strategies

5.1 Differences in Shrinking Characteristics

Based on the development characteristics and causes of shrinking cities in county levels in China, there are significant differences compared with other shrinking cities in the world, mainly reflected in the three aspects of economic structure, policy orientation and spatial characteristics.

(1) Differences in Economic Structure

Shrinking cities in European and American countries are mostly due to the process of "deindustrialization". For example, the relocation of manufacturing industries in the "Rust Belt" cities in the United States has led to a sharp decline in jobs and a continuous loss of population; after the reunification of the two Germanys, the East German region of Germany suffered a structural recession due to insufficient industrial competitiveness. In contrast, the shrinking of Chinese counties is more manifested as a "gradient shrinkage" under the background of "semi-urbanization" - the siphon effect of large cities has led to the outflow of population from counties, but the counties as the outflow of population are still making up for the shortcomings in infrastructure construction, expanding the investment in construction land, and forming a decoupling phenomenon of "reducing population and increasing land".

(2) Differences in Policy Orientation
European and American countries generally adopt a market-oriented regulation model. For example, the United States acquires abandoned properties for redevelopment through the "Land Bank", and Germany promotes the spatial reorganization of East Germany through federal fiscal transfer payments. The shrinking of Chinese counties is more subject to administrative intervention. The inertia of past growth-oriented planning is likely to lead to continued infrastructure investment. Some local governments still rely on land finance to maintain development.

(3) Differences in spatial characteristics
In terms of macro-spatial distribution, foreign shrinking cities are mainly distributed in industrial urban areas where local resources are exhausted or industries are undergoing transformation. Shrinking counties in China are more widely distributed, including resource-based counties in the northeast, agricultural counties in the central region, and border counties in the west. In terms of micro-spatial shrinkage characteristics, international shrinking cities generally show "hollowing out of central urban areas"; while Chinese urban shrinkage has the characteristics of "decentralized shrinkage": large cities and regional central cities are plump, surrounding counties are shrinking, and the population is moving to provincial capitals and regional central cities. Regional development differences may further aggravate the shrinkage of counties around large cities.

5.2 Planning strategies discussion
By summarizing the international experience in shrinking city governance and the national conditions of China, we can summarize the following planning strategies to deal with the uncoordinated development of the relationship between people and land in shrinking counties.

(1) Change in planning approach
The planning approach should shift from incremental expansion to stock optimization, establish a dynamic linkage mechanism of "population-land use", adjust the construction land indicators according to the elasticity of permanent population changes, optimize the economic construction and development assessment mechanism, and avoid the influence of the inertia of past growth-oriented planning. At the same time, it is necessary to shift from rigid planning control to flexible governance, promote the mixed use of industrial land, and improve the efficiency of construction land use.

(2) Differentiated governance
Based on the different types of county-level shrinkage, differentiated governance should be carried out, and smart shrinkage should be implemented by drawing on international experience. In the face of resource-declining counties in Northeast China, inefficient industrial areas should be "closed, stopped, merged and transferred", and space and construction land resources should be integrated and utilized. Follow-up industries, such as industrial heritage tourism, should be fully developed to inject new momentum into regional development and avoid continued decline. In the face of the population loss in the central provinces, we should shift from the homogeneous layout of construction land and public service facilities to precise allocation, learn from Japan's bus-oriented development to reasonably compress the radius of public services and reduce duplication and excessive construction.

(3) Regional coordinated development
To deal with the problem of county shrinkage through regional coordination and build a "core-contraction" matching mechanism for urban agglomerations, we can achieve complementary development through land quota transactions and regional function decentralization. At the same time, we should also improve the regional infrastructure sharing belt. Ultimately, through smart contraction and transformation, regional coordinated optimization, and the comprehensive construction of a full-chain governance system of "institutional constraints-market regulation-spatial optimization", we can further coordinate the matching of population and construction land and achieve high-efficiency and high-quality sustainable development.

Abstract
The concept of a "play-friendly city" has gained prominence in urban planning, highlighting the essential role of play in children's development and well-being. This paper investigates global frameworks promoting children's right to play and examines how cities interpret and implement these principles in diverse local contexts. It first reviews the theoretical foundations of play-focused urban planning, underscoring its importance in creating inclusive environments that support children's physical, cognitive, and social growth. It then analyzes international policy narratives and city-level strategies, identifying shared objectives and local adaptations. Finally, Istanbul is examined as a case study, with a particular focus on the Istanbul Play initiative, which seeks to embed play into the city's planning processes through holistic, participatory, and community-driven approaches. The study forms part of ongoing doctoral research aimed at developing decision-making tools to guide local authorities in planning for play-friendly urban environments.

Keywords: play-friendly city; urban development; local adaptation; strategic planning; decision-making

1. Theoretical and Practical Dimensions of Planning for Children and Play

Play is widely recognized as a fundamental aspect of children's physical, emotional, social, and cognitive development. Through play, children develop creativity, problem-solving abilities, social skills, and resilience, all of which contribute to their overall well-being and healthy growth (Ginsburg, 2007; Lester & Russell, 2010). Urban environments have a profound influence on the quality and quantity of opportunities children have to engage in play. Thoughtfully designed cities can offer safe, stimulating, and accessible spaces that encourage children to explore, interact with peers, and connect with nature, which supports not only individual development but also community cohesion (Hart, 1997; Fjørtoft, 2004). In contrast, poorly planned urban areas often restrict such opportunities, limiting children's physical activity and social interactions, which may negatively affect their health and well-being (Veitch, Bagley, Ball, & Salmon, 2006).

Designing child-friendly cities involves integrating specific principles into urban planning and development to prioritize children's diverse needs and rights. Among the most essential principles is ensuring mobility and accessibility, which means providing safe pedestrian pathways, dedicated cycling lanes, and proximity to essential services such as schools, parks, and healthcare facilities (Llewellyn & Wheeler, 2013). Safety and security are also crucial components; implementing traffic-calming measures, ensuring adequate lighting, and creating well-supervised, welcoming play areas are necessary to allow children to play independently with minimal risk (Hillman, Adams, & Whitelegg, 1990; Moore, 1986). Furthermore, urban environments should support play and learning by offering ample green spaces, interactive installations, and flexible public areas that stimulate children's cognitive, emotional, and social development. These spaces function as informal "third places," facilitating learning, creativity, and community engagement outside of home and school contexts (Worpole, 2000; Malone & Tranter, 2003). Equally important is community engagement in the design and planning processes. Involving children, parents, educators, and other local stakeholders helps ensure that play spaces meet the actual needs and desires of users, promoting ownership, inclusivity, and sustainability (Hart, 1992; Burke & Grosvenor, 2008).

Increasingly, urban planners and policymakers recognize children as active agents in shaping their environments rather than passive recipients of adult decisions. Participatory planning approaches that involve children directly in decision-making processes empower them to express their experiences, preferences, and ideas regarding urban spaces (Chawla, 2002; Skelton, 2007). Techniques such as guided neighborhood tours, creative workshops, drawing exercises, and storytelling have proven effective in eliciting children's perspectives, often

highlighting needs and opportunities that adults might overlook (Filler, 2007). This participatory approach aligns with the United Nations Convention on the Rights of the Child, which emphasizes children's rights to be heard in matters affecting their lives (UNCRC, 1989). Embedding participatory methods within urban governance not only enhances democratic decision-making but also leads to more responsive, inclusive urban environments that better support children's rights and well-being (Tremblay, 2014).

2. Global Narratives and Planning Frameworks for Child-Friendly Urban Environments

Urban planning increasingly acknowledges the essential role of play and recreation in shaping inclusive, healthy, and vibrant cities. Across the globe, municipal strategies and international policies converge in emphasizing children's rights to safe and accessible play as fundamental to sustainable urban development. This chapter synthesizes the guiding global frameworks alongside pioneering city plans from Barcelona, London, Dublin, Nottingham, Berlin, and Australia, illustrating a shared commitment to embedding play within urban design.

2.1 International Policy Foundations

The cornerstone of the global movement toward child-friendly cities is the United Nations Convention on the Rights of the Child (UNCRC), Article 31, which guarantees every child the right to rest, leisure, play, recreational activities, and participation in cultural life. Building on this, the UN Committee on the Rights of the Child General Comment No. 17 (2013) elaborates on the significance of play in children's development and urban environments. The Sustainable Development Goals (SDGs), particularly Goal 11 (Sustainable Cities and Communities), emphasize inclusive, safe, and accessible green and public spaces that promote well-being and social cohesion. These global mandates set the normative framework urging cities worldwide to prioritize play infrastructure and policies.

2.2 City Plans as Expressions of Global Commitments

The examined city plans operationalize international principles within localized contexts, offering concrete frameworks, strategies, and actions that reflect and advance global aspirations. City authorities increasingly integrate play into urban planning approaches as a means to enhance the quality of life, promote social cohesion, and foster healthier, more inclusive environments for all residents.

Barcelona's Public Space Play Plan Horizon 2030 integrates play within a broader sustainability agenda aligned with the Sustainable Development Goals (SDGs), emphasizing well-being, inclusion, and environmental quality. The plan positions outdoor play and physical activity as core policy priorities for a healthier urban life. It reflects UNCRC principles by aiming for universal access to diverse, accessible play spaces and promoting inclusive environments for all ages, genders, and abilities. The interdisciplinary drafting process and comprehensive implementation strategy illustrate how global norms can be translated into actionable urban policies. (Barcelona City, 2019)

Through its Good Growth Plan and Supplementary Planning Guidance (2011), London aligns with the UNCRC and SDG frameworks by embedding children's rights into urban design, prioritizing independent mobility and safe access to play. The London Play Plan advances the concept of a "child-friendly city" by shifting focus from isolated playgrounds to integrated neighborhood play ecosystems. Its emphasis on safe routes and pollution reduction through initiatives like Ultra Low Emission Zones demonstrates the intersection of environmental health and play, consistent with international sustainability goals (London City, 2012).

Dublin's City Play Strategy 2022–2027 explicitly references international legal instruments such as the UNCRC and General Comment No. 17, grounding its vision in children's rights. The strategy promotes a coordinated, cross-departmental approach to ensuring equitable access to quality play opportunities, reflecting the global narrative of inclusive urban environments. The city's commitment to participation and inclusive design further embodies the principles of meaningful child involvement advocated in international frameworks. (Dublin City, 2022)

Nottingham's Play Strategy 2008–2020 aligns with international policies by defining play as a right and emphasizing inclusion, safety, and community engagement. It promotes accessible, well-maintained play spaces

throughout the city, supporting social inclusion and well-being—key themes within the SDGs and the UNCRC. The strategy's emphasis on sustainable, inter-agency collaboration reflects global calls for integrated governance in child-friendly urban planning. (Nottingham City, 2008)

Berlin's Urban Development Concept Berlin 2030 offers a holistic vision that integrates play and recreation within broader goals of sustainable and inclusive development. Its focus on public participation, including engagement with future generations, mirrors international calls for child participation and community inclusion. The city's approach to balancing urban density with green spaces fosters livability, social cohesion, and environmental sustainability—central pillars of global urban development agendas. (Berlin City, 2015)

Australia's Play Strategic Plan 2020–2025 embeds play within national frameworks of public health and urban design, recognizing it as a fundamental human right. The plan's alignment with UNCRC Article 31 and SDG goals reinforces the global priority of accessible play for all children. Through legislative and urban design reforms, and grassroots initiatives such as the 1000 Play Streets Movement, Australia demonstrates a multi-level approach to implementing international play frameworks. (Australia Play, 2020)

2.3 Synthesis of Global and Local Frameworks

Together, these city plans and international policies articulate a shared vision: urban environments must be designed and managed to facilitate daily, meaningful play opportunities for children. The global policy frameworks provide normative guidance, emphasizing children's rights, equity, and sustainability, while city plans translate these ideals into concrete commitments and strategies tailored to local contexts. A key convergence across these documents is the recognition of play as a fundamental right, grounded in Article 31 of the United Nations Convention on the Rights of the Child (UNCRC), which frames play as essential not only to children's development but also to their active citizenship. Additionally, inclusivity and accessibility are central concerns; universal design principles and cross-sector collaboration ensure that play opportunities are available to children of all abilities, genders, and socioeconomic backgrounds. Furthermore, play is increasingly understood as an integrated element within broader urban systems, embedded not only in designated playgrounds but throughout transport networks, green spaces, and community facilities—promoting independent mobility, environmental health, and seamless access. This vision is complemented by a strong emphasis on participation and co-design, with children and communities actively engaged throughout planning and implementation processes, thereby reflecting the principle of meaningful involvement and agency. Finally, the role of play is linked to wider urban objectives such as environmental sustainability, public health, and social cohesion, recognizing that fostering playful, inclusive environments contributes to the well-being of the entire city. Despite these advances, challenges persist in scaling up the integration of play within diverse urban contexts and ensuring equitable access for all children. Emerging innovative approaches, such as London's "Slow Build" model and Australia's digital Playground Finder, illustrate the potential for responsive, adaptive play planning that can better meet the needs of rapidly changing cities. Looking forward, continued alignment with evolving international frameworks and the strengthening of inclusive governance mechanisms will be crucial to advancing child-friendly urban futures that fully embed play as a vital element of city life.

3. Istanbul's Journey Towards Becoming a Playable City

Istanbul's vast and complex urban fabric presents both significant challenges and unique opportunities for embedding play within the city's evolving landscape. As a city that straddles continents and cultures, with sprawling metropolitan dimensions and diverse socio-economic realities, Istanbul's pursuit of becoming a "playable city" illustrates how global narratives on child-friendly urbanism adapt to local specificities.

3.1 Overview of the Istanbul Play Initiative

Istanbul's journey toward becoming a "playable city" reflects an ambitious and contextually nuanced effort to embed play within a highly complex and diverse urban environment. As a sprawling metropolis bridging two continents, Istanbul's urban fabric is characterized by vast dimensions, diverse socio-economic realities, and multifaceted spatial patterns. These factors distinguish Istanbul from many other cities undertaking similar

child-friendly urban initiatives, making its approach to play deeply rooted in local interpretations while still engaging with global narratives. (IMM, 2022)

The Istanbul Play initiative, anchored by the Istanbul Play Master Plan, represents a comprehensive framework aiming to integrate play into the very fabric of the city beyond conventional playgrounds. It embraces a holistic planning vision that seeks to incorporate play opportunities throughout the urban environment—whether in streetscapes, parks, community centers, or informal spaces—ensuring play becomes a seamless part of everyday urban life. This shift towards a "playable city" is guided by the recognition that children's right to play is not limited to designated areas but must be interwoven into the broader urban experience. (IMM, 2022)

A fundamental aspect of this initiative is its strong emphasis on community engagement. Given Istanbul's cultural diversity and complex social dynamics, the planning process prioritizes collaboration with local residents, families, and children to create public and play spaces that resonate with their specific needs and cultural contexts. This participatory approach fosters local ownership and encourages sustainable use of public areas. Moreover, the initiative seeks to align urban planning policies with international frameworks such as the United Nations Convention on the Rights of the Child (UNCRC) and the Sustainable Development Goals (SDGs), ensuring that play is integrated into wider municipal policies that promote children's well-being and rights. Efforts to strengthen institutional coordination and embed play considerations into broader urban development policies are critical elements of this policy integration. (IMM, 2022)

3.2 Comparative Analysis with Other Cities

While Istanbul's play initiative shares many foundational principles with global examples of child-friendly cities—such as London, Barcelona, and Dublin—the city's unique characteristics present distinct challenges and opportunities (Meier and Thiel, 2014; IPA, 2017). Unlike these relatively compact European cities, Istanbul's enormous size and sprawling urbanization extend far beyond the boundaries of formally controlled urban patterns (Yardımcı and Şenol, 2020). The city's rapid expansion includes large informal settlements and irregular development that complicate efforts to provide equitable access to safe, inclusive play environments across all neighborhoods (Akkaya, 2015; UNICEF, 2018). This complexity stands in contrast to cities with more uniform urban governance where play infrastructure can be coordinated more systematically (Karaman, 2018).

Furthermore, Istanbul's urban fabric is extraordinarily heterogeneous, ranging from dense historic districts and tightly knit neighborhoods to sprawling suburban zones and informal settlements (Çelik, 2019). Such diversity demands adaptable and context-specific play solutions that accommodate varying spatial conditions—from intimate courtyard spaces in compact areas to expansive green parks in suburban localities. This variety differs significantly from cities where the urban form is more homogeneous, requiring less tailored interventions (Dover and Daly, 2021).

The socio-cultural dimensions of Istanbul also shape its approach to play. Traditional attitudes, family structures, and concerns about safety influence how public spaces and play are perceived and used (Dover and Daly, 2021). Unlike cities with long-standing traditions of public child-friendly design, Istanbul's initiative places particular emphasis on cultural sensitivity and community engagement to foster acceptance and participation in public play (Hart, 1992). This cultural dimension adds a layer of complexity to the planning process, necessitating thoughtful dialogue and inclusive design.

Institutionally, Istanbul continues to develop its governance mechanisms to better facilitate children's participation and cross-sector collaboration in urban planning (Karaman, 2018). While some cities have established mature interdepartmental frameworks dedicated to child-friendly urbanism, Istanbul is still evolving these structures to enhance accountability and effectiveness (UNICEF, 2018).

3.3 Outcomes and Future Directions

Istanbul's play initiative aligns closely with global aspirations to recognize play as a fundamental right and essential component of children's health, well-being, and social inclusion. The city adopts a rights-based framework that draws from international commitments while tailoring implementation to local realities. (IMM, 2022)

Since its inception, the Istanbul Play initiative has achieved promising outcomes. Innovative play environments have been introduced, showcasing a range of approaches such as natural playgrounds, interactive installations, and the creative reuse of public spaces that reflect Istanbul's unique cultural and environmental context. The initiative has also succeeded in raising awareness among policymakers, urban planners, and the general public about the importance of play as a core urban function. (IMM, 2022)

Looking forward, Istanbul's efforts focus on strengthening mechanisms for monitoring and evaluating the impact of play spaces on children's well-being and community life. There is a clear commitment to continuously refine policies, incorporating new insights and feedback from stakeholders to improve the quality and inclusivity of play provision. Scaling up successful pilot projects to reach Istanbul's diverse neighborhoods, including informal areas, remains a central priority. Embedding play within broader urban strategies—such as transportation planning, housing development, and green infrastructure—will be essential for sustaining progress. (IMM, 2022)

Crucially, the city aims to deepen participatory frameworks, ensuring children and communities have a meaningful voice throughout planning, implementation, and evaluation processes. Istanbul's experience demonstrates how global principles of child-friendly urbanism can be interpreted and adapted to address the specific challenges of a sprawling, diverse metropolis. This adaptive process offers valuable lessons for other large, rapidly growing cities seeking to make play an integral part of urban life.

4. Conclusion

This study, situated within the broader framework of doctoral research, has explored the complex interplay between global narratives of child-friendly urbanism and their localized interpretations in the context of Istanbul's ambitious journey toward becoming a play-friendly city. By examining international policy frameworks alongside the specific urban, social, and cultural realities of Istanbul, this research highlights both the universal principles and the distinctive challenges that shape how play is integrated into city planning.

Play is increasingly recognized not only as a fundamental right of children but also as a critical component of healthy, inclusive, and vibrant urban environments. Integrating play into urban planning contributes significantly to the physical, social, emotional, and cognitive development of children, while fostering community cohesion and enhancing the overall quality of public spaces for people of all ages. Embedding play in urban design challenges planners to move beyond isolated playgrounds and instead create interconnected, accessible, and diverse play opportunities that respond to the varied needs of children and families within complex cityscapes.

The comparative analysis of international city plans reveals several prominent principles that underpin successful play-friendly urban strategies. These include ensuring accessibility and inclusivity for all children regardless of age, gender, ability, or background; promoting independent mobility and safe routes within neighborhoods; embedding play within broader sustainability and public health agendas; and fostering meaningful participation of children and communities in planning processes. Plans from cities like Barcelona, London, Dublin, and Berlin consistently emphasize the importance of cross-sectoral collaboration, adaptive design approaches, and ongoing monitoring and evaluation to sustain play infrastructure that evolves with changing community needs.

The comparative analysis with other global cities underscores Istanbul's unique position as a vast, diverse metropolis with sprawling urbanization patterns that extend beyond conventional regulatory boundaries. This complexity necessitates adaptive, context-sensitive approaches that go beyond replicating international models, emphasizing community engagement, cultural inclusivity, and flexible planning strategies. The Istanbul Play initiative and Master Plan exemplify this localized interpretation by embedding play into a wide range of urban

spaces and fostering collaboration between policymakers, communities, and children.

Importantly, this research contributes to a deeper understanding of how play can be systematically incorporated into public services and urban planning processes, moving beyond ad hoc interventions to more holistic, sustainable frameworks. As part of an ongoing doctoral study, the insights gained here aim to inform the development of a decision-making tool for local authorities. This tool is intended to support strategic planning for play, ensuring that children's rights and needs are at the core of urban development policies and practices.

Ultimately, the study reinforces that fostering play-friendly cities requires both a commitment to global child rights frameworks and a nuanced appreciation of local urban realities. Istanbul's experience serves as a valuable case study, demonstrating how cities with complex, rapidly evolving urban fabrics can successfully integrate play into their public spaces and policies. The findings offer practical guidance for policymakers and urban planners seeking to create inclusive, vibrant, and equitable environments where children can thrive.

Research on the Distribution and Typological Characteristics of Urban Office Centres from a Fine-Grained Perspective: A Case Study of Yangpu District in Shanghai, China

Chen Gongda
Affiliation: Tongji University, Shanghai
Email: 2330157@tongji.edu.cn

Abstract
IT maturity has transformed business operations and the preferences for office space, altering urban office distribution. This study uses geospatial data to map fine-scale office space patterns in Yangpu District, Shanghai, identifying office centres, exploring their typologies and relationships with nearby facilities. Key findings: (1) Offices are dispersing from central CBDs and re-aggregating spatially forming new centres. (2) These centres feature high-density, mixed-use surroundings, good subway access, and proximity to residences/universities. Five spatial types emerge: TOD Developments in Peripheral Location, University-linked Mini Industrial Clusters, Small-scale Creative Parks in urban renewal, We-work space based on Multiple-Functional Community Complexes, and CBD Zones. This study enhances understanding of internet-era office spaces and provide theoretical support for the refined organisation and optimisation of urban employment spaces.

Key words: urban office centres; facilities in the environment; clustering analysis; decentralisation

1. Introduction

Residence and work are considered two fundamental urban functions by Le Corbusier, and the jobs-housing relationship – the spatial layout relationship between employment and residential areas – has long been a classic and critical topic in urban planning. Since the late 19th century, shifts in policy thinking and advancements in transportation and communication technologies have continuously presented new opportunities and challenges for this relationship, giving rise to numerous urban theoretical models addressing it. In China, abundant job opportunities and higher wages continue to attract populations towards cities, with urban population size projected to grow further. By the end of 2023, China's permanent urbanisation rate reached 66.16%, and it is expected that the urban population will surpass one billion for the first time by 2030. Where to live and where to work are two core questions urban residents inevitably face. Over the past decade, rapid regional and urban economic development has driven continuous global industrial upgrading. Modern service industries, particularly producer services, have gradually become pillar industries in major cities. Office spaces, primarily comprised of commercial office buildings, provide urban residents with substantial employment opportunities and high-quality work environments, exerting a significant influence on the urban jobs-housing relationship. Optimizing the spatial organisation of office space is thus a major research focus in global geography and urban planning disciplines.

The maturity of information technology (IT) has seen information connectivity gradually replace traditional transportation connectivity, revolutionizing office models in the internet era. During the Third Industrial Revolution, the proliferation of digital infrastructure and remote collaboration tools enabled cross-spatiotemporal communication. Online office forms like video conferencing, web-based training, and mobile working became widely adopted, even partially replacing face-to-face interaction. By the end of 2021, the number of online office users in China reached 469 million (Sun Bindong, 2021). Devices like mobile workstations became new carriers for resources and information, diminishing the external gravitational pull and spatial effects of industrial clusters, thereby reducing the physical scale of industrial spatial agglomeration (Castells, 1989, 1996). Advances in communication technology and online interaction tools liberated people from geographical and physical office constraints, enabling work from virtually anywhere. Concurrently, digitisation and knowledge-intensive activities transformed the nature of work itself, making flexible employment models like remote work and freelancing increasingly important, leading to the virtualisation and decentralisation of workspaces (Long Ying, 2022). Many companies are transitioning towards networked, distributed management models. Progress in office organisation methods has greatly enhanced flexibility. Driven by factors such as rent, resource availability, and environmental quality, office functions are gradually detaching from traditional industrial cluster areas and dispersing spatially (Yang Dejin, 2012). Against this backdrop, office space is developing in a decentralised manner within cities, with significant

emergence outside traditional urban cores, showcasing diverse urban office scenarios and vibrant economic activity.

Theoretically, academia widely agrees that breaking the "agglomerated yet separate" polarised development pattern of employment centres and residential centres, and enhancing urban functional mix, is one pathway to optimizing the jobs-housing relationship. Urban planning concepts like Smart Growth and New Urbanism also endorse this view. Building on the "Neighbourhood Unit" concept, China has further developed the "Community Life Circle" concept based on "15-Minute City" theory. This serves as a spatial carrier for residential life, aiming to meet residents' diverse activity needs. Localizing employment opportunities is a key aspect of building 15-Minute Cities. Shanghai's community renewal practices explicitly include "Suitable for Employment" as one of its "Five Amenity Goals" (Wu Yi), advocating for ample job opportunities within or near communities to reduce commute times and pressure. Current research on urban office spaces often focuses on the agglomeration patterns of high-level employment centres at a macro scale (e.g., CBDs, sub-centres, polycentric structures). Studies investigating finer-scale, decentralised yet re-agglomerating office centres are relatively scarce, and the pathways to achieve localised employment opportunities within the "15-Minute City" framework remain unclear. Therefore, addressing this gap, this paper focuses on fine-scale office centres. We propose the hypothesis: "Office space is dispersing from the urban CBD and re-agglomerating spatially on a smaller scale to form new office centres." After validating this hypothesis, we explore the characteristics of these office centres to decipher the mechanisms behind employment decentralisation and localisation. This analysis may offer insights for optimizing urban spatial layouts under constrained land development conditions. The structure of this paper is as follows: Section 2 presents a literature review on office space research, establishing the necessity and innovation of this study. Section 3 details the methodology for hypothesis validation and subsequent analysis. Sections 4 and 5 present systematic empirical research. Conclusions are summarised in Section 6.

2. Literature Review

Reviewing research themes on office space structure both domestically and internationally, collecting relevant literature through searches in Science Direct and the CNKI helps establish a relatively comprehensive literature database system on office space research. Searches were conducted based on keywords such as "producer services," "office space," "office centres," "urban spatial structure," "influencing factors," "evolutionary trends," and "dispersed distribution." encompassing research themes including CBDs, business offices, business districts, office buildings, urban design, layout characteristics, spatial structure, and evolutionary features.

Early research on office spaces in Western countries was not an independent topic but appeared within economic studies. Based on classical economic methods, core theories such as Thünen's Agricultural Location Theory, Weber's Industrial Location Theory, and the Market Location Theories of Scheffler, Christaller, and Lösch were formed, primarily focusing on economic activities in urban centres and their spatial carriers. In the 1920s, alongside the transition from secondary to tertiary industries, the Central Business District (CBD) emerged as a typical spatial carrier, prompting specialised research on office spaces in western planning academia. From the 1920s to 1940s, research focused on the characteristics and causes of the centripetal agglomeration of office activities. The classic urban spatial structure theories proposed by the Chicago School—Burgess's Concentric Zone (1923), Hoyt's Sector (1939), and Harris and Ullman's Multiple Nuclei (1939)—all indicated that office space should be highly concentrated in urban centres. After the 1950s, the office industry became a pillar industry in major Western cities, and related research became increasingly systematic. Guided by Location Theory, Urban Spatial Structure Theory, Central Place Theory, theories of office decentralisation, and stage development models, academia conducted extensive theoretical and empirical research on office activities, the office industry, and office spaces, leading to a maturing theoretical system. Research subjects were concentrated in three main fields: urban economics, financial economics, and urban geography. Content covered office space location, spatial structure, types of agglomeration distribution, morphological structure, formation mechanisms, and increasingly, research on layout evolution under suburbanisation and informatisation.

Research on office spaces in China began in the 1990s, approximately 70 years later than in the West. Relying

on theories such as Office Space Location Theory, Agglomeration-Diffusion Structure Theory, and Enterprise Behavioral Decision Theory, research mainly focused on the concept of the office industry, office location theory, headquarters economy space, urban CBDs, and the interaction between office space and urban development. In recent years, improved research capabilities and data informatisation have significantly expanded data coverage and reduced acquisition difficulty. Using GIS technology to analyse the agglomeration characteristics of urban functional spaces has become a trend. Concurrently, transformations in office models have spawned various new forms of office spaces such as co-working spaces, SOHO, and renovated industrial buildings, enriching the typology of office architecture.

2.1 Research on Factors Influencing Office Space Distribution

Western office location theory takes corporate autonomous site selection as its basic premise, viewing it as the intrinsic driver shaping office spatial patterns. Since the mature development of Central Business Districts (CBDs) in the 1980s, academia has gradually revealed the formation mechanisms and influencing factors of office space agglomeration structures through empirical case studies. As an emerging industrial space characterised by low land occupancy and low transportation costs, its site selection is primarily dominated by non-production cost factors, encompassing multidimensional influences such as agglomeration economies, face-to-face communication needs, information technology advancements, changes in corporate organisational structures, urban cultural environments, and market environments. These factors can be categorised into three levels: economic-market, technological-social, and organisational-institutional.

The spatial agglomeration distribution of office spaces at the urban scale can essentially be seen as a product of the co-evolution of the city's multifunctional systems, shaped by both the active force system (office districts, residential areas, commercial districts, transportation hubs, etc.) and the environmental constraint system (natural ecology, green spaces, built environment, etc.). Agglomeration scale reflects the level of development of urban functional spaces, agglomeration characteristics reveal endogenous development laws, and the uneven distribution of spatial elements leads to heterogeneous effects of the same influencing factor in different regions, exhibiting significant non-stationary characteristics. For instance, a specific factor might strengthen agglomeration in the centre while potentially triggering dispersion in the suburbs. This is the particularity of this complex mechanism within the Chinese context. The three-dimensional driving framework proposed by XUE Dongqian et al. (2011) for Xi'an's producer services confirms this: market orientation creates demand pull, locational factors trigger spatial competition, and government guidance implements policy intervention. Together, these three aspects explain the evolutionary logic of office spaces during the transition period.

2.2 Research on Trends of Concentration and Dispersion in Office Spaces

The agglomeration and dispersion, equilibrium and disequilibrium of office spaces within cities are core topics in geographical research. Agglomeration is considered a fundamental characteristic of office space. Studies show that regardless of changes in urban structure, the Central Business District (CBD), centreed on office functions, typically maintains its core position, with office buildings generally tending to locate in relatively central urban areas. This pattern has been confirmed in the urbanisation processes of Western countries (Kee Boim Nahm, 1999). However, although the agglomeration trend has not fundamentally changed, office space layouts in developed metropolitan areas in recent years have shown a tendency towards dispersion, gradually spreading to sub-regional urban centres. Large companies, in particular, are increasingly likely to relocate some operations to lower-cost peripheral areas, forming localised office functions. This dispersion pattern first appeared at the national urban system level, accompanying the shift from centralised to dispersed regional development models. Simultaneously, dispersion also occurs within cities. For example, research in Toronto shows that non-central urban areas can also become new office centres to reduce communication costs.

Accompanying the maturation of CBDs and the localisation of office space, academia has gradually identified typical layout patterns such as "Cluster" and "Net of mixed beads." Integrating the research of Erickson and Hart, Masu proposed a universal four-stage localisation evolution framework: 1) Spillover and Specialisation; 2) Dispersion and Diversification; 3) Polycentricity (Filling Nuclei / Diffusing Nuclei); 4) Three forms of suburban office space

(Loop Centres, Radial Road Centres, Unstructured Expansion). Castells argued that concentration and dispersion often coexist rather than being absolute, both at the regional and urban levels, categorizing office space distribution states into four types: Agglomeration, Dispersion, Concentrated Agglomeration, and Concentrated Dispersion. Similarly, ZHANG Jingqiu et al. (2011) quantitatively analysed Beijing's office building distribution, extracting three industry-specific agglomeration types: "Large Dispersion - Small Agglomeration," "Large Dispersion - Large Agglomeration," and "Small Dispersion - Large Agglomeration," noting their spatial coupling with major transportation arteries. Scholars such as WANG Yang (2016), WANG Junrong (2017), ZHANG Zhibin (2019), and YE Qiang (2022) subsequently conducted empirical studies in cities like Guangzhou, Zhengzhou, Lanzhou, and Changsha, further enriching regional case support. This stage saw the extensive application of mathematical statistical analysis methods.

The existing literature review indicates that international research has recognised the trend of office space decentralisation, theoretically explained the process, and dialectically analysed the two spatial organisation modes—agglomeration and dispersion—from macro perspectives of regions or cities. However, relevant research still exhibits relative gaps: First, the research objects mostly focus on traditional commercial office buildings, with less identification and differentiation of new office space types from spatial or industrial perspectives. Second, there is a scarcity of in-depth studies targeting dispersed office centre entities at the meso-micro scale and a lack of systematic exploration into the characteristic typologies of new office spaces.

3. Research Design

This study is divided into two main parts. The first part describes the evolving characteristics of office space distribution within the study area and verifies the hypothesis. The second part identifies office centres within the study area at a fine scale and conducts an exploratory analysis of their characteristic typologies. This research utilises Point of Interest (POI) data and Location-Based Service (LBS) data as the basis for identifying office spaces and office centres. Open geographic information data from OSM, Baidu Maps, and AMap are employed for spatial calculations to describe the fundamental characteristics of the office centres. The study adopts spatial analysis methods such as Standard Deviational Ellipse Analysis and Spatial Autocorrelation Analysis, alongside quantitative analytical methods like Principal Component Analysis (PCA) and Hierarchical Cluster Analysis (HCA) for induction and interpretation.

3.1 Research Approach

To address the hypothesis proposed in this paper – "Office space is dispersing from the urban CBD and re-agglomerating spatially on a smaller scale to form new office centres" – this study primarily utilises multi-temporal POI data for the study area obtained from online sources. First, data pre-processing is performed in ArcGIS to filter business office POI point data exhibiting characteristics of producer services. Facilities within the jurisdiction capable of providing employment are treated as individual discrete points. The Standard Deviational Ellipse (SDE) method is used to determine the overall distribution characteristics of office space within the study area. Based on planning documents, the study area is divided into central urban areas and non-central areas. Spatial grid statistics are employed to count office spaces. Data visualisation and spatial analysis methods, including spatial autocorrelation analysis, are then used to intuitively present the spatial clustering distribution characteristics of office spaces in different years within the study area, describe their evolutionary trends, and thereby verify the hypothesis.

For the exploration of the spatial patterns and typological characteristics of office centres, the process is as follows: First, POI data and LBS data are used to identify office centres within the study area. Basic geographic data, including POI data, AOI data, and road network data, are utilised in spatial calculations to obtain proxy descriptive parametres representing the locational, morphological, and functional environmental attributes of the identified office centres. Subsequently, the PCA method is applied to reduce the dimensionality of these parametres to extract the most critical feature elements. Finally, the HCA method is employed to classify the identified office centres and analyse their groupings.

3.2 Research Method

(1) Standard Deviational Ellipse Analysis

This study uses standard deviational ellipse to summarise the spatial characteristics of geographic features, including central tendency, dispersion, and directional tendency. The ellipse represents the spatial distribution direction and range of employment position data.

(2) Spatial Autocorrelation Analysis

Spatial autocorrelation analysis can examine whether the attribute values of elements with spatial locations are correlated with the attribute values at neighbouring spatial points, including global spatial autocorrelation and local spatial autocorrelation. The global Moran's I index is used to analyse the overall spatial correlation and spatial differentiation of the region, and then the Getis-Ord Gi* statistics are used to create hotspot and cold spot maps with statistical significance.

(3) Principal Component Analysis (PCA)

Principal Component Analysis (PCA) is a commonly used dimensionality reduction method that transforms a large number of complex linearly correlated variables into a smaller number of linearly independent principal components through orthogonal transformation, while preserving the main characteristics of the data and reducing its dimensionality. It effectively eliminates redundant information and extracts key features, thereby simplifying complex datasets. PCA projects high-dimensional data into a low-dimensional space by maximizing variance retention, and these principal components can be used for data visualisation, classification, clustering, and other applications.

(4) Hierarchical Cluster Analysis (HCA)

Hierarchical Cluster Analysis (HCA) is a method for grouping samples based on the similarity of their characteristic data. This method constructs a hierarchical clustering dendrogram by iteratively merging or splitting the most similar samples or clusters. The clustering process is conducted according to specific linkage criteria (such as nearest neighbour, farthest neighbour, and average linkage between groups). Ultimately, by analysing the hierarchical structure of the dendrogram, the optimal number of clusters and grouping schemes are determined based on research needs, revealing the inherent natural grouping patterns within the sample data.

3.3 Research Case

The case, Yangpu District (Figure 1), is located in the northeast part of Shanghai's central urban area, on the northwest bank of the lower reaches of the Huangpu River, covering an area of 60.61 square kilometres. It has jurisdiction over 12 sub-districts (the smallest administrative division in China). As of December 2024, Yangpu District has a population of 1.1997 million, with a density approaching 20,000 people per square kilometre. In the 2023 "15-minute community life circle" initiative in Shanghai, Yangpu District has delineated 33 15-minute community living circles, each with a population of approximately 36,000 and covering an area of about 1.8 square kilometres.

Yangpu District is located on the outskirts of the traditional work centre and has undergone industrialisation, rapid urbanisation, and urban renewal since its establishment as a district in 1960. Some areas of WJC Sub-district were planned as a sub-centre of Shanghai in 1991, while some areas of JPL Sub-district were planned as a regional centre in 2004. Additionally, the district is rich in educational and scientific resources, with 14 various types of higher education institutions, which accounts for more than one-third of the total number of higher education institutions in Shanghai. Therefore, there are various types of urban spaces present, including urban centres, new and old residential areas, remnants of industrial factories, and knowledge-intensive areas around universities. In terms of industry and economy, by 2024, the added value of the tertiary sector will account for 90.0% of the district's GDP, with traditional and emerging office industries such as new media, the internet, technological innovation, and finance being the key development targets for Yangpu District. In summary, Yangpu District is an excellent case study for researching office spaces and office centres.

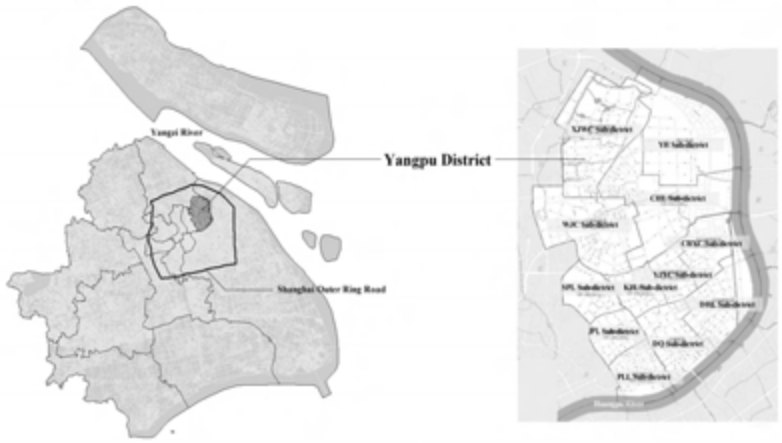

Figure 1. The location of Yangpu District

3.4 Data Description

In the hypothesis verification section, this study adopts a grid with a side length of 300 metres to describe the evolution trend phenomenon of the macroscopic office space distribution in Yangpu District, in order to lay the research foundation. By analysing the aggregation characteristics, characterisation accuracy and computational efficiency of employment facilities using spatial units of 100 metres, 300 metres, 500 metres and 1000 metres, it is found that the 300-metre grid can better represent the spatial distribution within Yangpu District.

Considering that this study mainly focuses on the distribution of office space and the identification of office centre locations at a more refined scale, although using the regular grid cutting base map as the analysis unit can effectively unify the research scale, this method has the following significant drawbacks: (1) Spatial fragmentation: The regular grid ignores the natural boundaries of the urban texture and may cut the complete functional areas into different grids; (2) Scale untruthfulness: Fixed grids are difficult to reflect the spatial heterogeneity between the dense road network in the central urban area and the sparse road network in the suburbs. Therefore, in the feature research section, an attempt is made to adopt the logic of "natural demarcation - functional integration" to divide the research units. The office centre land units are specifically delineated mainly through road and land use functions. The plots (different land use function sections) within the blocks (units enclosed and demarcated by urban public roads) are taken as the basic research units. The specific methods are as follows: By adopting the OSM open map to obtain the vector data of the entire road network in Shanghai, the four-level road network (expressways, main roads, secondary roads, and important branch roads) within Shanghai was extracted, and extract the centre line of the road network to simplify the road network into a single line. Reconstruct the topological network model again to eliminate redundant nodes and hanging points (node spacing) 50m automatic merge. The generated network model is used to cut the blocks to obtain the initial block units, and then the plot within the block are divided by referring to the land resource survey and unit planning of Yangpu District. Finally, inspect the plots and eliminate the area. For 200m^2 of fragmented patches, reduce the number of cracked plots and inspect the hard boundaries with expressways and major water systems. Cross-plot consolidation is prohibited. Finally, the area of Yangpu District was divided into 2,002 research units (Figure 2).

The point of interest (POI) data used in this study comes from Amap and is updated to 2024. Integrating the research of other scholars and the 20 major industry categories in the "National Economic Industry Classification Standard (GB/T 4754-2017)," this study selects the following data as categories related to the business office industry (Table 1), covering five major categories: life services, finance and insurance, automotive services, science and education culture, and corporate enterprises from the POI data accessed through Amap. To ensure the consistency between industry classification standards and POI data, this study cleaned the POI data for Yangpu District from 2014, 2019, and 2024, filtering to include key information such as company name, address, type, and geographical coordinates. The dataset contained 2,425 points in 2014, 3,975 in 2019, and 2,982 in 2024, leading to

the establishment of a GIS spatial database for subsequent research.

In addition, the LBS data used to identify office centres comes from the Baidu Huiyan data platform, covering the period from November 11 to 17, 2024, with data selected from weekdays at 10, 11, 14, 15, 16 and 17 o'clock. The rest of the spatial data is sourced from the Amap, Baidu Map, and OSM. Considered that some indicators involve descriptions of the surrounding environment of plots, this study uses a 300-metre buffer zone around each plot as the calculation range. Specific data descriptions detailed in Table 2.

Figure 2. Research unit on Plot Accuracy in Yangpu District

Table 1. Office POI Types

Industry Type	POI Data Content
E - Construction industry	Construction companies, architectural firms
K - Real Estate Industry	Real estate companies, sales centres, real estate agencies, property management companies
P - Education Industry	Cultural and educational companies, training institutions
R - Culture, Sports, and Entertainment Industry	Cultural media companies, animation design companies
I - Information Transmission, Software, and Information Technology Service Industry	Telecommunication business halls, graphic and text advertising companies, postal services, information technology service companies
M - Scientific Research and Technical Service Industry	Technology companies, high-tech companies, research institutes

J - Financial Industry	Banks, securities companies, trading companies, insurance companies, futures companies
L - Leasing and Business Service Industry	Car rental companies, machinery rental companies, daily necessities rental companies, advertising companies, management consulting companies, law firms, accounting firms, assessment firms, certification firms, patent firms, talent markets

Table 2. Spatial data sources

Data Name	Data Description	Data Source	Data update time
Office function - Point Data	Data points that describe the distribution of office functions. Obtained based on the classification and screening of Amap POI.	Amap API https://lbs.amap.com/api	2014 -2019-2024
Behavioural activity heat - Point Data	Vitality statistics of urban at different times based on "mobile device location services".	Baidu Huiyan https://huiyan.baidu.com	2024. Sep.11-17
Urban road network – Polyline Data	Urban road network information, including road classification	Open Street Map https://openstreetmap.org	2024
Urban architecture - Polygon Data	Urban completed building data, including location, area, and height, number of floor.	Baidu Map	2024
Urban functional area - Polygon Data	Urban functional zone data, including functional classification, location and area.	Amap API https://lbs.amap.com/api	2024
Urban public/commercial service - Point Data	Data points that describe the distribution of public/commercial service. Obtained based on the classification and screening of Amap POI.	Amap API https://lbs.amap.com/api	2024

4 Distribution Characteristics of Office Spaces in Yangpu District

4.1 Overall Distribution Exhibits a Trend of Decentralisation

Using the standard deviation ellipse analysis method, we visually compare the spatial distribution of POI data for business office enterprises in Yangpu District for the years 2014, 2019, and 2024. In this analysis, the first-order standard deviation ellipse covered 63% of the point elements within the study area. Specifically, the standard deviation ellipse for 2014 had a long axis of 2710.14 metres and a short axis of 1902.63 metres(Figure 3a); in 2019, the long axis was 3041.61 metres and the short axis was 2055.78 metres(Figure 3b); and in 2024, the long axis measured 3306.87 metres and the short axis was 2013.33 metres(Figure 3c). The standard deviation ellipses from 2014

to 2019 show significant expansion in both the long axis and short axis, with the area also increasing, indicating a trend from concentration to decentralisation in the distribution of business office enterprises in Yangpu District over these five years. From 2019 to 2024, the changes in the standard deviation ellipse are minimal, suggesting that on a macro scale, the decentralised characteristics relative to 2014 have been maintained, while potential adjustments in the distribution structure at the micro level are occurring, which is a topic for further research.

Figure 3a, 3b, 3c. The standard deviation ellipse of office space distribution in 2014, 2019 and 2024

4.2. Evolutionary Pattern of "First Dispersal, Then Re-aggregation" Forms Hierarchical Office Centres

Quantitative visualisations of the POI data of business offices in Yangpu District for the years 2014, 2019, and 2024 were conducted, utilizing the local spatial autocorrelation Getis-Ord G* statistic to identify hotspots and describe the aggregation characteristics of business office functions over different periods. According to the illustrations, in 2014(Figure 4a, 5a), the business office functions in Yangpu District were primarily aggregated around important urban functional areas, including the WJC urban sub-centre and the JPL regional centre. By 2019(Figure 4b, 5b), the area of business office function hotspots significantly increased in the WJC sub-centre and JPL regional centre, with a few point-like and linear business office hotspots emerging in the central hinterland outside the urban core. In 2024(Figure 4c, 5c), the planned urban sub-centres and regional centre business office functions continued to enhance; additionally, more business office functions concentrated in the central hinterland and certain areas in the northern suburbs, forming point-like decentralised office centres.

Figure 4a, 4b, 4c. Statistical description of office POI distribution (Jenks) in 2014, 2019 and 2024

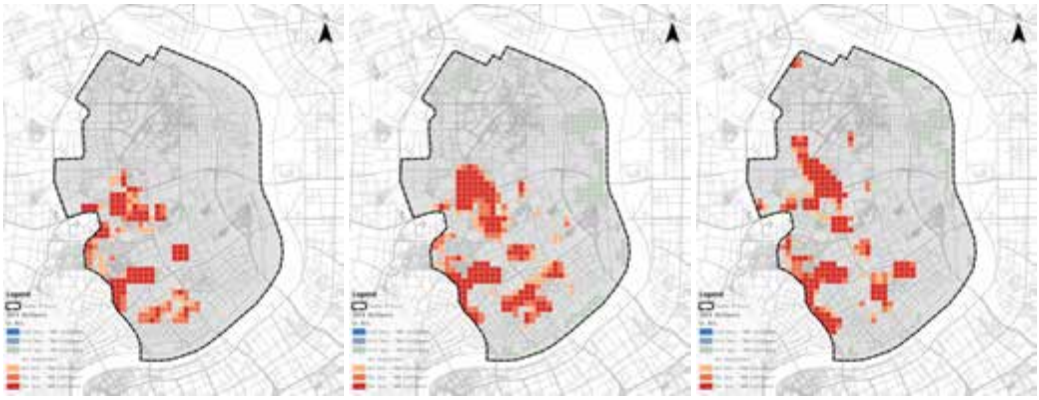

Figure 5a, 5b, 5c. Identification of Office Hotspots in 2014, 2019, and 2024

Quantitative visualisation of the changes in the number of business office POIs within the grid from 2014 to 2019 and from 2019 to 2024 was conducted to explore the evolutionary pattern of the distribution of business office functions in Yangpu District. The chart reveals that between 2014 and 2019(Figure 6a), most areas in Yangpu District, including some hinterland regions primarily characterised by residential functions, showed an increasing trend in the number of office enterprises. The area with the largest increase was the rapidly developing WJC urban sub-centre. During this period, the number of office POIs in the central urban area of Shanghai, including traditional business office centres like People's Square and Lujiazui, was sharply declining. From 2019 to 2024(Figure 6b), there was a decrease in the number of business office enterprises in most residentially dominated areas in Yangpu District, while a few grids within the reduction area showed significant increases. Specific sectors that saw growth included the WJC urban sub-centre, KIC Space, the National University Science Park of SUFE, Changyang Innovation Valley, and Yangpu Riverside.

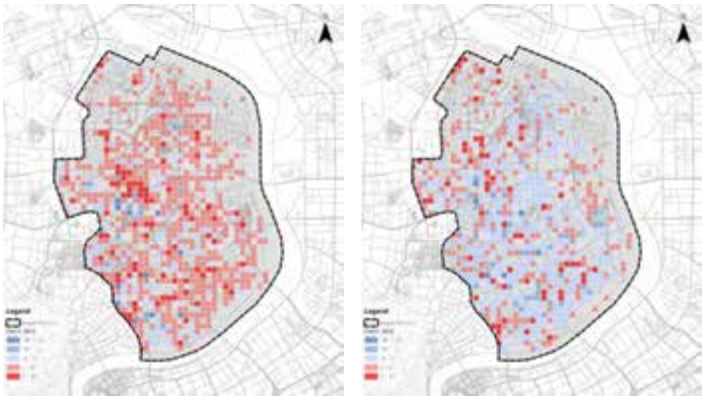

Figure 6a, 6b. Changes from 2014 to 2019 and from 2019 to 2024

Overall, the preliminary description of the evolutionary pattern during the 2014-2019 phase is that office functions dispersed significantly from the urban office centres of Shanghai to the emerging urban sub-centres and residential blocks outside the urban core in Yangpu District. In the 2019-2024 phase, the business office functions that surged in Yangpu District during the previous five years began to re-aggregate at a microscopic scale in localised areas. While the urban sub-centres and regional centres continue to develop, the functionality of secondary point-like office centres outside the urban core is also steadily enhancing.

5. Exploration of the Spatial Patterns and Typological Characteristics of Office Centres in Yangpu District

5.1 Identification of Office Centres

The identification of office centres in Yangpu District employs a "function-heat" dual-verification method. The data used consists of cleaned 2024 office POIs in Yangpu District and 2024 LBS data. Utilizing ArcGIS software, spatial overlay statistics were conducted on the density of office POI points within plots (research units), and

natural breaks were applied for visualisation (Figure 7a). Additionally, kernel density calculations were performed on 100-metre precision point LBS data to conduct overlay statistics of crowd activity heat during office hours for each research unit from November 11 to 17, 2024, with natural breaks again used for visualisation (Figure 7b). Ultimately, research units exhibiting significantly high values in both office function and activity density were selected, resulting in the identification of 197 office centres in Yangpu District.

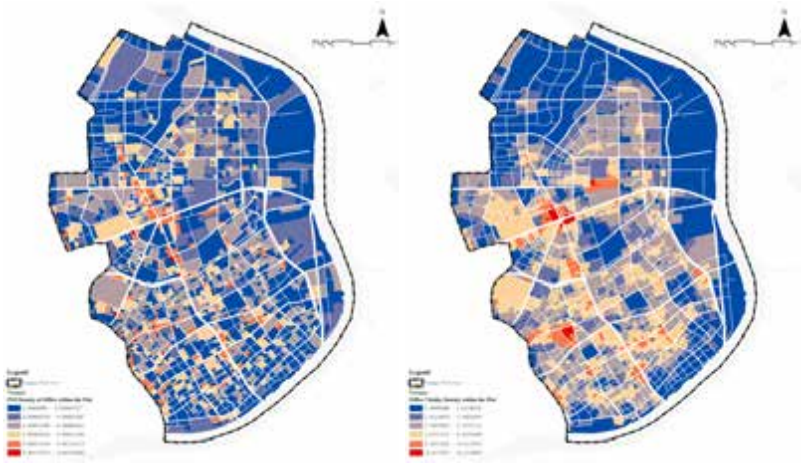

Figure 7a. Office centre identified based on functional data
Figure 7b. Office centre identified based on behavioural activity data

5.2 Spatial Pattern Analysis Framework and Key Factor Extraction

The formation and evolution of office centres are the results of the synergistic effects of multiple factors. To systematically deconstruct the spatial organisational logic of office centres in Yangpu District, this section extracts spatial pattern characteristic analysis factors from multiple dimensions, aiming to transcend the limitations of traditional one-dimensional research by incorporating the locational potential, material carriers, and functional environments of office centres into a unified analytical system. In the end, 17 key influencing factors were summarised and extracted for research, forming a dynamic and multidimensional spatial analysis system. The extraction logic for core factors across various dimensions is described in Table 3.

Table 3: Key Characteristic Factors and Descriptions of the Spatial Patterns of Office Centres

Dimension	Indicator		Description
Location	Loop Location	virtual variable	The location relationship of office centres in the city (within the inner ring, from the inner ring to the Middle ring, from the Middle ring to the Outer Ring)
	Transportation Location	km	The distance from the office centre to the main and secondary roads of the city
	Public Transportation Location	km	The distance from the office centre to the subway station
Form	Spatial Density	m^2/km^2	The ratio of the total base area of buildings to the total area of the plot
	Floor Area Ratio	Score	The ratio of the total floor area of all buildings within the plot to the total area of the plot
	Maximum Building Height	m	The maximum building height within the plot
	Road Network Density	km/km^2	The ratio of the total length of the road network around the office centre to the total area of the buffer zone
Function and environment	Educational Density	pcs/km^2	The POI density of schools, training institutions, etc. around the office centre
	Traffic Density	pcs/km^2	The POI density of subway stations and bus stops around the office centre
	Medical Density	pcs/km^2	The POI density of hospitals, clinics, etc. around the office centre
	Catering Density	pcs/km^2	The POI density of restaurants, cafes and other facilities around the office centre
	Culture, Sports And Entertainment Density	pcs/km^2	The POI density of museums, theaters, gyms, etc. around the office centre
	Poi Shannon Index	Score	Measure the diversity and degree of mixture of different types of POIs around the office centre
	Proportion Of Residential Land	km^2/km^2	The proportion of residential land area around the office centre
	Resource Distance	km	The distance from the office centre to universities and research institutions
	Central Distance	km	The distance from the office centre to the city centre
	Green Space Distance	km	The distance from the office centre to the public park

5.3 Principal Component Analysis

After collecting all the indicators, a preliminary data quality check was conducted to eliminate indicators with severe missing data or insufficient variability. Then, Z-Score standardisation was applied to different dimensions and data types to create a standardised data matrix, eliminating weight shifts caused by numerical differences. During this process, dummy variable elements were also standardised through methods such as feature multiplication, resulting in a matrix with only 0 and 1. The variable "ring location" was split into three variables: "within the inner ring," "between the inner and middle rings," and "between the middle and outer rings."

The final summary results are shown in Appendix Figure x1-x17. Subsequently, the SPSS tool was utilised to perform PCA on the 17 indicators based on the correlation coefficient matrix for dimensionality reduction analysis, yielding a total of 12 principal components (PC1-PC12). According to the Total Variance Explained in Table 4 and the scree plot shown in Figure 8, the cumulative explanation rate of the first 5 principal components is approximately 80.2%, with a notable gap compared to the subsequent eigenvalues. Therefore, considering spatial complexity and interpretability, this study comprehensively uses the first five principal components to characterise the spatial patterns of office centres.

Table 4. Total Variance Explained

	Initial Eigenvalues			Extraction Sums of Squared Loadings		
Component	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	3.348	28.900	28.900	3.348	28.900	28.900
2	1.748	15.567	44.466	1.748	15.567	44.466
3	1.547	13.888	58.355	1.547	13.888	58.355
4	1.230	11.250	69.605	1.230	11.250	69.605

Extraction Method: Principal Component Analysis.
a 5 components extracted.

(1) PC1 (explanation rate 28.9%): Urban centrality, comprehensive support intensity, and transportation accessibility. From the loading matrix, we can see that the indicators with a large positive loading in PC1 include: density of dining POIs (0.816), density of cultural, sports, and entertainment POIs (0.820), and density of educational POIs (0.799), as well as the density of public services and commercial facilities. Additionally, road density (0.436), maximum building height (0.297), and floor area ratio (0.247) also contribute positively. The corresponding indicators with significant negative loadings include: distance to the central area (-0.676), distance to the subway station (-0.530), and proportion of residential land nearby (-0.415). Overall, combining the two significant negative loadings of "distance to the central area" and "distance to the subway station" (-0.530), along with the high density of various public services/commercial facilities (dining, cultural entertainment, education, etc.), PC1 represents a gradient from high-support, high-function mixed-use in the city centre to low-support, low-mix in the outer ring and suburbs. It reflects the characteristics of the urban core area, manifested as high-density public service facilities, central location advantages, and high-rise, high-intensity building layouts. Higher scores indicate proximity to the core urban area, with convenient public transportation and comprehensive facilities, as well as a high degree of spatial mixing in functional layouts.

(2) PC2 (explanation rate 15.6%): Emerging areas outside the centre and high-intensity TOD development. In PC2, the indicators with a significant positive loading include: floor area ratio (0.650), building height (0.574), and road density (0.374) related to public services and commercial facilities. Moreover, road density (0.436), maximum building height (0.297), and floor area ratio (0.247) contribute positively as well. The corresponding indicators with significant negative loadings include: densities of various public services/commercial facilities, distance to the subway station (-0.257), and distance to the central area (-0.117). PC2 reflects development characteristics of high-intensity urban expansion areas around subway stations from the city centre. Higher scores indicate areas near the city centre that are well-serviced by public transportation, primarily focusing on business office functions, with high road network density, small plot sizes, and high building development intensity, embodying the features of emerging urban functional areas.

(3) PC3 (explanation rate 13.95%): Old city renewal. In PC3, the primary positively loaded variables include: road density (0.600) and distance to universities/research institutions (0.608), while the main negatively loaded variables are floor area ratio (-0.511) and maximum building height (-0.670). Overall, combined with the high road density reflecting a mature road network foundation and significantly lower-than-average development intensity (with floor area ratio and building height as strong negative loadings) and density of public/commercial services, PC3 characterises areas of old city renewal where spatial forms are constrained by historical textures, following a gradual renewal model. It is characterised by a high-density road network post-renewal, dominated by low-rise, high-density large-scale buildings, markedly lower development intensity than emerging business districts, and spatial separation from core higher education and residential areas.

(4) PC4 (explanation rate 11.3%): Island effect of scientific and educational resource concentration. In PC4, the main positively loaded variable is distance to the subway station (0.416), while the significant negatively loaded variable is distance to universities/research institutions (-0.457). This loading combination indicates that areas with higher PC4 scores are closer to universities/research institutions but have significantly poorer accessibility to the subway. Overall, PC4 reveals the spatial mismatch between areas of high concentration of scientific and educational resources and public transportation infrastructure (especially rail transportation), reflecting typical characteristics of traditional cultural and educational districts or emerging scientific and educational parks (such as university towns without subway access) — despite the high concentration of educational functions and substantial knowledge spill over, they form relatively isolated "office enclaves" due to insufficient rail coverage.

(5) PC5 (explanation rate 10.6%): Centrality of residential communities. In PC5, the main positively loaded variables include: proportion of surrounding residential land (0.732), density of educational POIs (0.421), distance to the central area (0.347), and distance to main roads (0.452). This combination points to urban peripheral residential communities dominated by residential function and educational service: a high proportion of residential land and dense educational facilities drive community functionalities, while the positive loading for distance from the city centre (0.347) further reinforces its spatial location characteristics. Therefore, PC5 represents community service centres in the urban fringe or suburbs, centred on residential functions, supported by education-related facilities. Higher scores indicate greater distance from the city centre and main roads, reflecting the characteristics of peripheral residential community service centres.

5.4 Hierarchical Cluster Analysis

This study primarily references the HCA methods and parametre designs used by Dibble et al. in urban morphology research. Euclidean distance is employed as the measure of similarity between observation points (office centres). The linkage method selected is Ward's linkage, which tends to generate clusters with minimised variance and higher homogeneity within groups, making it widely used in urban morphology studies. In terms of selecting the number of clusters, this research tested various group numbers (k=3, 4, 5, etc.) and found that the clustering effect is optimal when k=5. The HCA clustering operations were completed using SPSS.

Based on the results of HCA, this study categorises office centres into 5 different spatial patterns (Figure 9) each exhibiting unique location characteristics, spatial forms, and functional environments. The arithmetic averages of PC1 to PC6 by cluster were calculated to characterise the results and features of each specific cluster (Table 6).

Table 6. HCA clustering results and Characteristic Interpretation of Office Centres in Yangpu District

	PC1	PC2	PC3	PC4	PC5
Cluster1	0.1779	1.0025	-2.3231	0.5437	-0.5773
Cluster2	-1.5839	-0.8558	-0.0114	0.4277	-0.5464
Cluster3	0.5596	1.5005	1.6086	-0.9275	-0.4962
Cluster4	-1.7495	0.1151	-0.1886	-0.3148	1.5482
Cluster5	6.6383	-1.6928	0.149	0.3588	0.5753

Among them, Cluster 1 (East Shanghai Lehoo Square, Sanhaowan Plaza, Yangpu Technology Building, China (Shanghai) Entrepreneur Public Training Base, Baodi Square, etc.) exhibits typical characteristics of newly built Transit-Oriented Development (TOD) commercial buildings that overflow from the central area, with a core focus on high-rise office buildings located near the urban centre and subway stations. Cluster 2 (Huantongji Industrial Circle, East Shanghai Technology Park, Fudan University South Campus, Shanghai University of Finance and Economics Science and Technology Park, etc.) is characterised by knowledge spillover around universities and the re-use of existing land to form industrial clusters. It leverages university resources and research institutions, possessing strong capabilities for technology promotion and application. Some areas are developed or updated based on existing plots around the universities, creating diverse spatial forms that support the development of knowledge-intensive industries. Cluster 3 (Interlink Baodi, Changyang Innovation Valley, Dongfanggu Creative Park): This cluster includes a combination of industrial relics from the old city and newly built commercial buildings forming comprehensive industrial parks, showcasing the integration of traditional urban renewal and creative industries. These areas, despite having a high historical background and urban hinterland advantages, utilise industrial buildings to concentrate technology promotion, professional technical services, and creative cultural industries, resulting in a more diversified industrial structure and significant urban renewal demands. Cluster 4 (Xuhui Plaza, Core Area of Xinfengcheng Residential District, Guohe 1000 Community Commercial Centre, etc.): This cluster features small-scale decentralised community service centres and office We-work spaces, located within areas primarily designated for residential functions, mixing with newly built large public buildings such as apartment buildings, community commercial centres, and community clubhouses. These spaces are typically smaller in scale, possess a certain degree of transportation convenience, and generally serve as office spaces preferred by small and micro-enterprises and start-ups. Cluster 5 (WJC Urban Sub-Centre): This cluster demonstrates characteristics typical of a high-energy urban CBD core area.

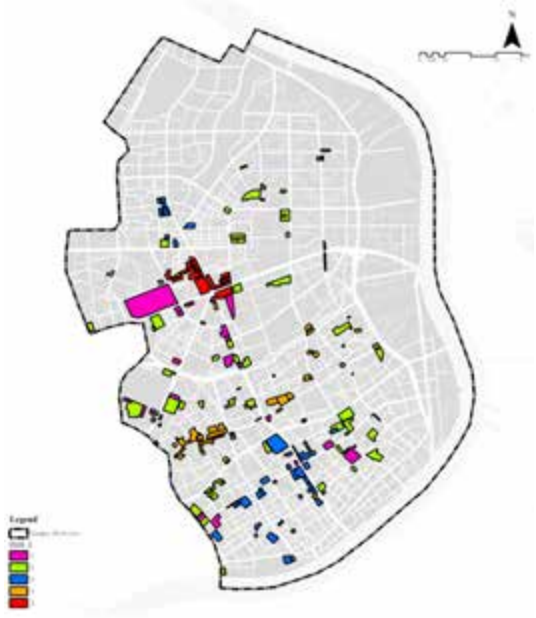

Figure 9. HCA clustering results

6 Conclusions

The main purpose of this study is to explore the distribution patterns and typological characteristics of urban office spaces and office centres in Yangpu District, Shanghai, at a fine scale. Through the integration of geographic information big data and field research, a series of important conclusions have been drawn.

Firstly, the study found a significant phenomenon of dispersion and re-aggregation in office spaces. This indicates that, with the rapid development of information technology, office spaces have gradually expanded from traditional Central Business Districts (CBDs) to peripheral areas, forming several small-scale office centres between specific locations. This trend reflects the ongoing evolution of the work-residence relationship in cities, as the advancement of communication technology and changes in office patterns have led to a demand for flexibility and diversity in the working environment, particularly among the younger generation.

Secondly, the analysis shows that office centres are typically located in areas with a mixture of urban functions, urban centrality, convenient public transportation, and close proximity to residential communities and universities. This finding emphasises the importance of integrating office spaces with urban functions.

Furthermore, through hierarchical cluster analysis, the study identified five types of office centres in Yangpu District: newly constructed TOD commercial buildings that overflow from the central area, mini industrial clusters formed by knowledge spillover and re-use of existing land around universities, comprehensive industrial parks that result from the renewal of industrial relics in the old city and newly built commercial buildings, decentralised small-scale office We-work spaces in community service centres by function multiply used, and high-energy urban CBD core areas.

This research contributes to a deeper understanding of urban office spaces in the internet era and provides theoretical support and practical guidance for the development and refined organisation of business office functions and employment spaces in Shanghai and other megacities in China.

Abstract
Small and medium-sized towns and cities represent the very important elements of the polycentric urban structure and have a crucial role in regional economic development and social well-being. The aim of this work is to emphasize the importance of the scenario method in planning the future development of small and medium-sized towns and cities that is used in the education of future spatial planners. Within the Spatial Planning Workshop, the integral vision for the development of Labin and Raša were propose as the result of the elaboration of five different possible scenario - Karbona, Kulturizam, Koza Nostra, Dystopia and Dispersion, and their valorisation. For vision realisation, necessary activities in the form of different development projects for a period of 25 years were proposed.

Keywords: development vision; former industrial towns; scenarios; tourism

1. Introduction

Spatial planning involves different professionals and actors in complex processes. Primary it focuses on the interests of society, the settlement or the region as an entity, and the longer-term future.

In the "Torremolinos Charter" (1983) it is pointed out that "Regional/spatial planning gives geographical expression to the economic, social, cultural and ecological policies of society. It is at the same time scientific discipline, an administrative technique and a policy developed as an interdisciplinary and comprehensive approach directed towards balanced regional development and the physical organization of space according to an overall strategy." (CEMAT, 1983: 3)

Spatial planners are serving and protecting the general interest and local democracy. Their key role is to be leaders of change in society towards a more sustainable future. According to the ECTP-CEU (2013) the planner's role responds to developments in society, planning laws and policies. Depending on different political and social frameworks, the planners are engaged as visionaries, technocrats, managers, advisors, mentors or instructors. So spatial planners deal with different scales and specific challenges that characterise different entities in space and their interconnection. Those entities are interlinked and linked with their surrounding environment. A systemic approach is needed to understand their specificities, interconnections, and above all processes that happen.

Small and medium-sized towns and cities represent the very important elements of the polycentric urban structure of the European Union. They have a crucial role in regional economic development and social well-being while providing jobs and sustaining local and regional services. Those entities have the possibility to offer good living and working conditions, helping the local community to attain a good quality of life. They demonstrate in-

trinsic value for European environmental and cultural heritage. Research on small and medium-sized towns provides insight into unexplored potential for shaping sustainable urban-rural relations. Based on comprehensive spatial planning different integrated and place-based policy measures should be suggested to make the most of their development assets. (ESPON, 2024)

In order to choose the most suitable development direction for small and medium-sized towns, it is necessary to consider, besides regional development plans, the possibilities and potential of the area at the local level considering the long-term needs of the inhabitants.

The aim of this work is to emphasize the importance of the scenario method in planning the future development of small and medium-sized towns and cities that is used in the education of future spatial planners in order to be able to choose the best possible scenario for long-term development of the selected area.

2. Planning of small and medium sized towns based on the scenario method

2.1 Small and medium sized towns and cities in the EU context

At the European level, the ESPON project TOWN (ESPON, 2014) has set a framework for considering the topic of small and medium-sized towns (SMSTC) by providing their definition based on the work of the OECD and DG Regio on the degree of urbanization. Small and medium-sized towns are defined as urban settlements of 5,000 to 50,000 inhabitants with a population density of 300–1,500 inhabitants/km2. For studying small and medium-sized towns three approaches have been identified: morphological, administrative and functional. Since they represent an unexplored potential for achieving sustainable urban-rural relations, this requires policy intervention in the form of integrated and place-based territorial support measures. The strategic potential of small and medium-sized towns for achieving further development is the role of their cooperation with the environment, their regional position and their ability to mobilize civil society and establish PPPs.

Territorial agenda 2030 points out that SMSTC have different development potential and challenges, as well as demographic and societal imbalances, which particularly applies to remote areas but also inner peripheries lacking access to public services, and adequate economic and social opportunities.
Over the years, the processes of metropolitanisation led to different directions of development of small and medium-sized cities, which largely depended on the proximity of large cities. Some gained importance when they were integrated into functional urban areas profiting from common transport systems, some thanks to their location on a high-speed transport corridor benefited from providing travel opportunities, and some due to their peripherality failed because they could not provide resources to maintain services for the surrounding areas or to be poles of growth.

In rural and peripheral regions, SMSTCs are often assigned the role of territorial anchor centres, thanks to their service and labour market functions, but they face various constraints such as limited capacities, smaller public budgets and more difficult access to private financing. Therefore, strengthening such SMSTCs becomes a key policy objective at all levels of planning, from local to European.

The processes of depopulation of small towns and the aging of their populations are widespread in most European countries. The negative ecological consequences of urbanisation and the gradual changes in rural-urban relations over time have led to an increase in awareness of the importance of small towns (Nesticò et al., 2019), as indicated by the research of numerous authors dealing with the topic of small towns, emphasizing their importance in the urban system. As early as Christaller's central place theory (1933), great emphasis was placed on small towns as centres of goods and services for the rural hinterland. Although there have been significant socio-economic changes in the area (Courtney et al., 2007), small towns continue to provide the surrounding area with various services such as education, healthcare, trade, banking, etc. (Vaishar and Zapletalová, 2009).

De Rossi (2018) points out that small towns are recently seen as an opportunity, rather than a spatial problem, and that their reactivation opens an opportunity for sustainable territorial development, the renewal of local

and regional identity, and the reduction of further land occupation. Zawadzka (2017; 2021) points out that despite the lower accessibility and service provision of small towns, it is precisely their "smallness", their human scale of development, and their unique urban-architectural structure that represent their particular value. In addition, unlike large cities, residents in small towns have valuable social capital characterized by a deep sense of belonging to the place of residence with strong social ties and the ability to cooperate. This results in a synergistic effect, influencing and strengthening the mutual relations of residents and contributing to the improvement of the quality of life of communities in small towns.

The negative consequences of socio-economic processes in the space of small towns, especially in peripheral areas, have led to the need to consider their recovery and possible further development. D'Andria et al. (2021) address the issue of recovery and valorisation of small towns through multi-criteria analysis schemes that encompass the relationships of small municipalities with the territory and with neighbouring medium/large cities or other surrounding small towns, forming a city-village network or a network of small municipalities. The results of their research represent an important tool for determining the priorities for the implementation of interventions based on public and private investments according to the principles of sustainable development with an emphasis on economic policy.

In their work, Somoza Medina and Relea Fernández (2024) deal with the evolution of five cases of small towns in the interior of Spain that a few decades ago invested in culture as a strategy to maintain the population and increase the quality of life of their residents. The results of the conducted research indicate the possibilities of developing cultural policies for small towns in Europe and the world.

Rural peripheral development strategies can be based on traditional activities (Saxena, 2007). In such strategies, tourism has a dual role as a means of strengthening local development processes (Lopez and Ivona, 2018) and as a means of diversifying and regenerating traditional lifestyles (Jackson and Murphy, 2006). In their work, García-Delgado et al. (2020) explore the possibilities of revitalising areas based on tourism and promoting heritage as an opportunity for local development. The research resulted in an analysis of the process of heritage and increasing its tourist value and its impact on local development in rural areas of Portugal, indicating a significant correlation between heritage, rural tourism and local development.

2.2 Importance of small and medium sized towns and cities in Croatia

The Report on the Spatial Situation in the Republic of Croatia for the Period 2013 – 2019 (2021) highlights that the Republic of Croatia is characterized by numerous small settlements. Although four largest cities in the Republic of Croatia (Zagreb, Split, Rijeka and Osijek) are relatively evenly distributed spatially and represent a good foundation for the country's polycentric development, the rest of the settlement system in Croatia has asymmetrical hierarchical and spatial characteristics. According to data from the Register of Spatial Units from 2019, there were 6,755 settlements in the Republic of Croatia. There were 150 settlements without inhabitants, and small settlements stand out in number: as many as 80.2% of them had fewer than 500 inhabitants, and 14.3% had 501 to 2,000 inhabitants, or 38.9% of the population lived in settlements of up to 2,000 inhabitants. Furthermore, 2.7% of settlements had between 2,001 and 10,000 inhabitants, and only 0.5% had between 10,001 and 35,000 inhabitants. There were 10 settlements with more than 35,000 inhabitants. Almost half of the population (48.9%) live in settlements with less than 5,000 inhabitants.

Marinović Uzelac (1999) points out that a small town is an urban agglomeration that meets the minimum population requirements (in the Republic of Croatia in 2000), with the absence of a primary sector of activity within the urban corpus, and which has at least a minimal gravitational influence on its immediate rural surroundings in terms of commercial and financial services, entertainment and culture, and local government and health care.

The polycentric concept of development of the Republic of Croatia, set out in the *Physical Planning Strategy of the Republic of Croatia* from 1997, was based on the then existing structure and system of settlements. In the polycentric concept of development, the focus is on advocating for a careful distribution of residents, activities,

central and other functions and infrastructure systems. Although the planned polycentric concept of development did not fully succeed, due to the too short time foreseen for its implementation, partly due to the sectoral inconsistency of development plans, and partly due to the lack of a system for monitoring implementation, in the Spatial Development Strategy of the Republic of Croatia it still has the leading role.

The spatial distribution of central settlements of all degrees of centrality in the Republic of Croatia shows unevenness, and is the rarest in areas with numerous development constraints and poor availability of higher-level services (hilly-mountainous and border parts of the Republic of Croatia and on some islands), while it is the most developed in the northern and northwestern parts of central Croatia and in the far eastern part of Croatia.

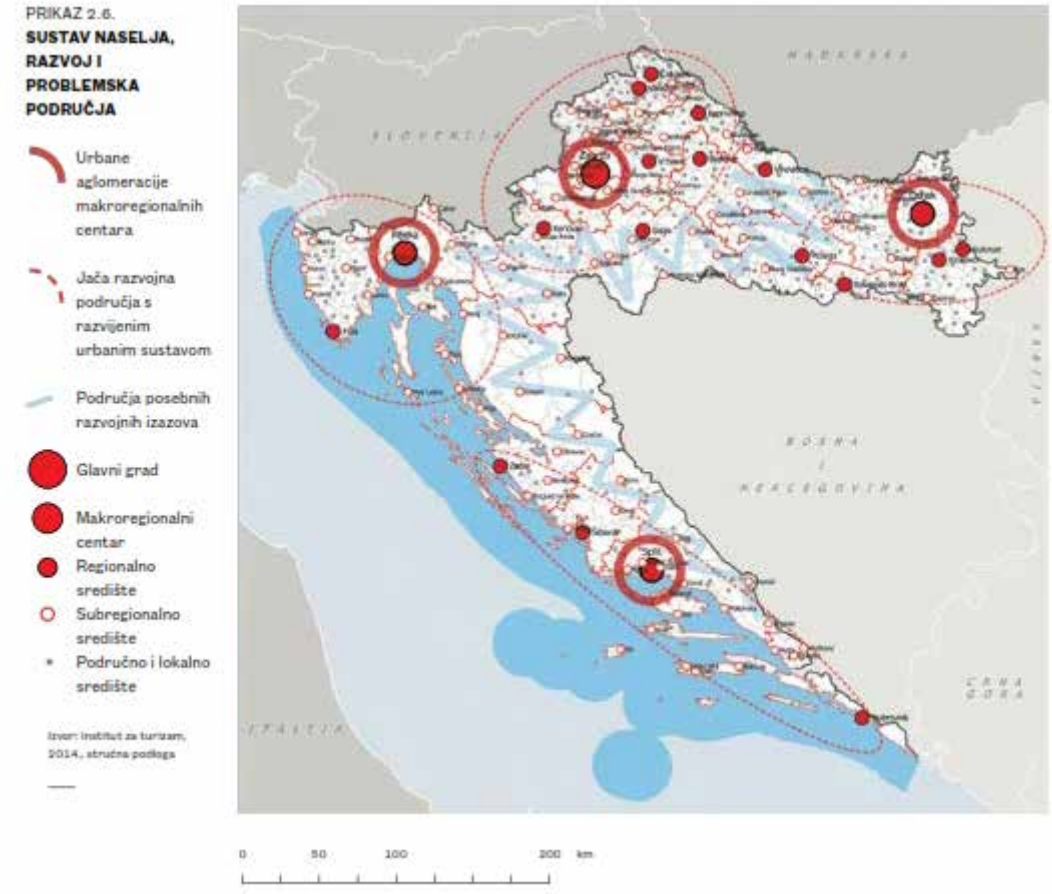

Fig.1: Settlement system, development and problem areas of the Republic of Croatia. Source: Ministry of the Construction and Physical Planning, 2017.

The distant planning of the network of central settlements complicates the trend of reducing (the number of) public facilities. Municipalities and cities located near macro-regional and regional centres are becoming new trade and business zones, while less densely populated areas do not attract investments.

The Spatial Development Strategy of the Republic of Croatia (2017) states that the sustainability of spatial organization should continue to be based on the polycentric model of development, since it has been accepted as the optimal model of spatial development in the EU and has been determined as a key element for achieving territorial cohesion.

By promoting such territorial development, polarisation between the capital, metropolitan areas and medium-sized cities at the national level is avoided. The document emphasizes that medium-sized and small cities should play a key role at the regional level, and represent a link between larger urban areas and rural areas.

The following elements are listed as possible approaches to revitalising the economic role of medium-sized and small towns:

• business based on the use of information technologies
• processing industry related to locally grown agricultural products
• tourism based on the attractiveness of cultural heritage (including industrial heritage), on landscape features, traditional religious sanctuaries, health and spa tradition (untapped or underutilized geothermal water potential), regionally designed tourist routes, traditional local festivals and innovative cultural products, and on gastronomy.

Furthermore, the preservation of historical fabric and the restoration of identity elements are important for increasing tourist attractiveness, economic development and investment, as well as preserving the number of the existing population and attracting new ones.

2.3. Scenario method and education of future spatial planners

Spatial planning is a profession that has its own areas of expertise in territorial development processes. According to the Charter of European Planning (ECTP-CEU, 2013) the planners' key commitments include research and analysis, advocacy and mediation, the ability to envision, evaluate and promote potential future options for urban, spatial, and territorial development. Therefore, future spatial planners should learn how to combine scientific and creative conceptual thinking with practical approaches to be able to define future vision of the city or region.

During the education process and in practical application, students as future spatial planners are directed to think strategically and to use the scenario method as a par excellence tool to articulate future development vision of study area. Scenario methods are research subjects of many authors, especially related to the field of spatial planning that encourages strategic thinking and comprehensive planning. In the education process besides the application of theoretical knowledge, the intention is to encourage the students' creativity. The scenario planning, based on the Intuitive logics school (Stanford Research Institute International) stimulates students' creativity and intuition. As Huss and Honton (1987) pointed out, the advantage of the SRI approach is the development of flexible, internally consistent scenarios from an intuition and logical perspective. In defining the preferred model and creating a common development vision it is important to be able to have an open discussion regarding different actors' interests, so Vogelij (2010) pointed out that there is a need to conceive at least four development scenarios for the study area.

During the spatial planners' education at the Faculty of Architecture of the University of Zagreb students have the possibility to gather theoretical and practical knowledge about the scenario method in spatial planning. On the third semester of the Master Study in Architecture and Urbanism students choose between fourteen workshops led by professors from the Faculty of Architecture. The Workshop 3 - Spatial planning is one of three workshops led by professors of the Department of Urban Planning, Spatial Planning and Landscape Architecture. The main goal of the course is to propose a vision for the spatial development of the chosen area (region or city) based on the principles of sustainability using the scenario method. The work on the course is adapted to the student and takes place in three main stages. The first stage of students' work includes a consideration of theoretical starting points and a detailed analysis of the existing situation and spatial planning documentation, which ends with a SWOT analysis. Students are guided to perceive spatial strengths, weaknesses, opportunities, and threats from different perspectives, that is, to immerse themselves in the different roles played by various actors in space. In addition, they are encouraged to use questionnaires to determine the key issues and needs of residents and users of the study area. In the second phase, based on the previous conclusions, students conceive different development scenarios for the chosen area, considering complex systems and numerous processes in space. In this phase they conceive their assessment tool based on the set criteria in order to choose the most appropriate development scenario and propose a development vision and conceptual solution. In the third phase, a more detailed elaboration of the program for the selected location and the proposal for strategic and development projects are made. Finally, for their designed strategic projects to be realised, they review and propose, if neces-

sary, changes to the actual spatial planning documentation on the local level.

3. Case studies: City of Labin and Municipality of Raša in Istria

Cities Labin and Raša in Istrian Peninsula were chosen as case studies for this research because of their historical significance in the economy of the region and rich potential for future development. The project was made within the Workshop 3 – Spatial Planning in the Academic year 2024 / 2025 (student: Teodora Jelić, mentor: Associate Professor Lea Petrović Krajnik, PhD). The goal of the project was to set up an optimal shared vision for two administrative entities, that once were treated as one unit due to their regional economic role and their spatial characteristics.

3.1 Spatial specificities and urban development

The city of Labin and the municipality of Raša are located in the eastern part of Istria between Plomin and Raša bays covering the area of 152,7 km2 with a population of 13 233 inhabitants (2021). The administrative area of the city of Labin (72,3 km2 with a population of 10 424 inhabitants) today includes the central settlement of Labin and 16 other settlements, and the municipality of Raša (80,4 km2 with a population of 2 809 inhabitants), along with the central settlement of Raša includes another 22 settlements. The settlements are characterised by a variety of spatial, cultural and socio-economic specificities.

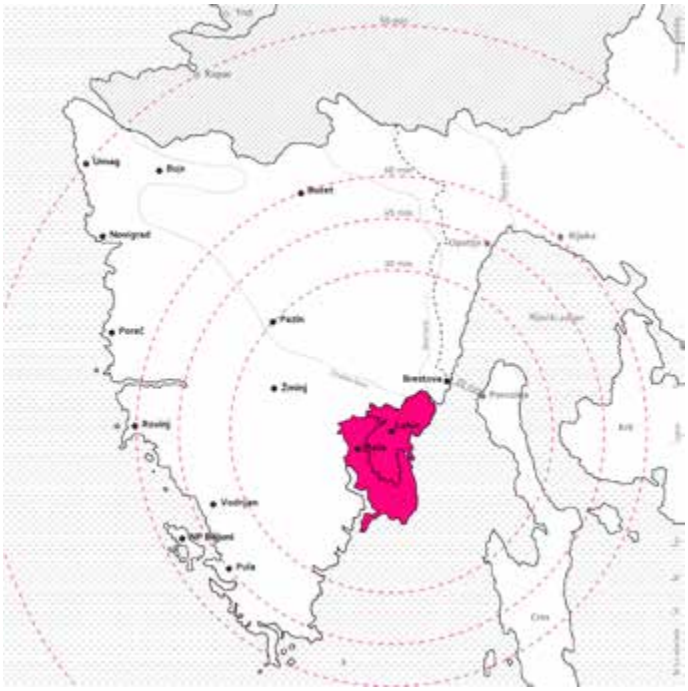

Fig.2: Position of City of Labin and Municipality of Raša in Istria. Source: Jelić, 2025.

In the 19th and 20th century the area was known for its mining activities as a basis for its economy. In the 1930s the greatest economic and infrastructural development of the Labin mining basin took place. As part of the then policy of the Italian government of the time to establish the so-called »città di fondazione« on new premises of urbanism and architecture in the area, planned mining settlements were built: Arsia - Liburnia (today Raša) in 1936/1937, designed by the Trieste architect Gustavo Pulitzer Finali, and Pozzo Littorio (today Podlabin) as a suburb of the historic core of Labin, built in 1940-1942, designed by the Roman architect Eugenio Montuori. (Karač 2010)

Thanks to the melioration works on the former marshland and the undeveloped mouth of the Raša River and its tributary the Krapan Creek, favourable conditions for the development of the settlement along the Rijeka-Pula road and the undeveloped green hills have been ensured.

In order to ensure optimal living conditions for the mine workers, the Italian architect Gustavo Pulitzer Finali prepared the basis for the urban unit of Raša (Arsia, designed under the name Liburnia) in 1935 and the architectural projects (1935-1937). The settlement, designed according to the principles of a garden city, was planned for 3,000 inhabitants. The longitudinal settlement is characterized by a clear functional and social division. Two-thirds of the settlement consists of workers' houses, which are separated from the apartments of the managers and the villas of the managers by an urban centre. South of the creek is an industrial zone with the mine administration building, power plant and other buildings.

Particular attention was paid to the design of the central area around which buildings with public facilities were placed (the church of St. Barbara - the patron saint of miners, the municipal headquarters, a hotel with a café on the ground floor, a complex multi-purpose building with shops, leisure halls and rooms for various associations, a post office, etc.). The central area was designed as a connection between the large *Piazza dell Impero* and the small *Piazzetta del Mercato*, which are connected by "triumphal" doors from the building set to the very edge and open porticos with deep shadows. (Radović Mahečić, 2000)

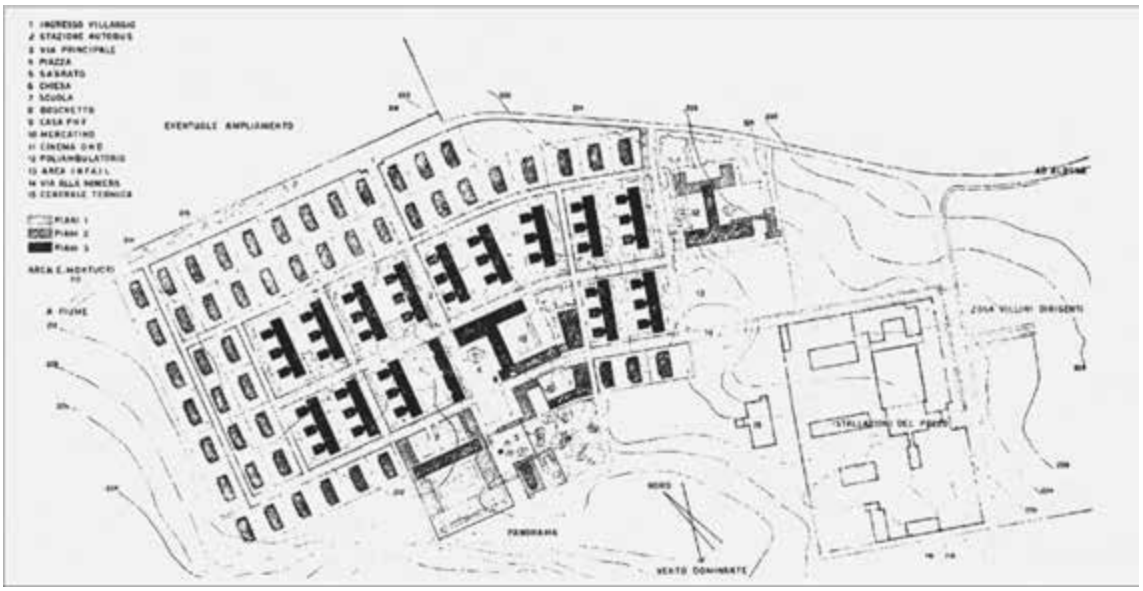

Fig.3: Regulatory basis Pozzo Albona, Eugenio Montuori, 1938. Source: Braun at al., 2019.

The mining and industrial complex of Pozzo Littorio, located north of the old town of Labin, was the reason for the construction of the urban unit of Podlabin *(Pozzo Littorio, Pozzo Littorio d'Arsia or Pozzo Albona)*. In 1938, the Italian architect Eugenio Montuori designed the regulatory basis for a new settlement with 3,000 inhabitants, as well as the projects of all residential and public buildings. The construction of the settlement took place in the period from 1939 to 1942. The main town square of the settlement was designed on a Roman forum model and was divided into a sacral and profane part (with the administration, cinema, sports hall, post office and other buildings of social standard). The spatial accents of the square are the bell tower of the church of St. Francis of Assisi in the axis of the central street and the massive *Torre Littorio* on the Ceva house. The residential part of the settlement is divided into parts intended for the residence of workers, civil servants, engineers and managers, the division of which can be read both by the different typology of construction and the size of the plots. (Braun et al., 2019)

When planning Podlabin, a holistic approach was applied, taking into account the climate, sunlight, dominant winds, views, pedestrian paths, and the author incorporated the existing greenery into the urban design of the settlement. (Laginja, 2024)

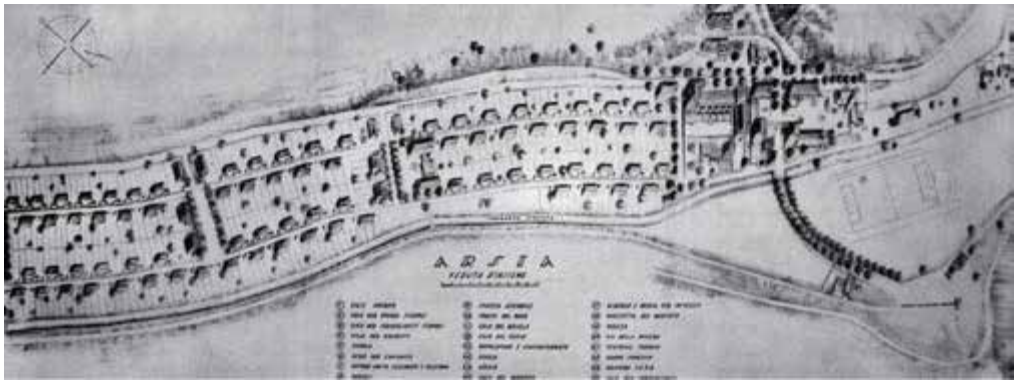

Fig.4: Axonometry of Arsia, 1937. Source: Arsia, il villagio per il minatori della S.A. Carbonifera Arsa, Trieste: Editrice Libraria, 1937.

At the end of the 20th century, all coal mines were closed, which led to the need for economic orientation shift. The city of Labin has focused on small and medium-sized enterprises, the opening of economic zones and tourism, while the municipality of Raša sees its potential, besides the cement factory in Koromačno, in agriculture especially in the Raša valley, in fishing, and in tourism thanks to two camps and large number of private accommodations.

3.2 Strategic and Spatial planning documentation

In 2017, the Government of the Republic of Croatia initiated a reform of strategic planning and development management in order to implement improved public policies and projects at all levels for achieving synergistic links between Croatian and European development policies. Strategic planning and development management on the national level and the adoption of legislative and institutional framework for its optimal arrangement have the aim to ensure social progress, enhanced and more focused territorial development. The strategic planning system is regulated by the *Law on the System of Strategic Planning and Development Management of the Republic of Croatia* (Official Gazette, 123/17, 151/22). The strategic framework of strategic planning system and development management of the Republic of Croatia is based on defined principles and includes acts of strategic planning of national significance, acts of strategic planning on local and regional level, strategic planning acts related to the EU economic management framework.

The spatial planning system, which ensures the conditions for the use, protection and management of space in the Republic of Croatia as a particularly valuable national asset, is the result of long-standing practice and tradition of spatial planning. It is based on the Constitution and the territorial organization of the state determined by a special law, the authority and jurisdiction of the Croatian Parliament, regional units and other public law bodies. The spatial planning system is regulated by the Physical Planning Act (Official Gazette 153/13, 65/17, 114/18, 39/19, 98/19, 67/23) and the basic principles are harmonized with EU regulations.

Below is a brief overview of the valid Spatial Planning documentation, i.e. the spatial planning plan of the city and municipality, the basic spatial planning documents of the local self-government unit, and the implementation programs of the local self-government units as short-term strategic planning acts.

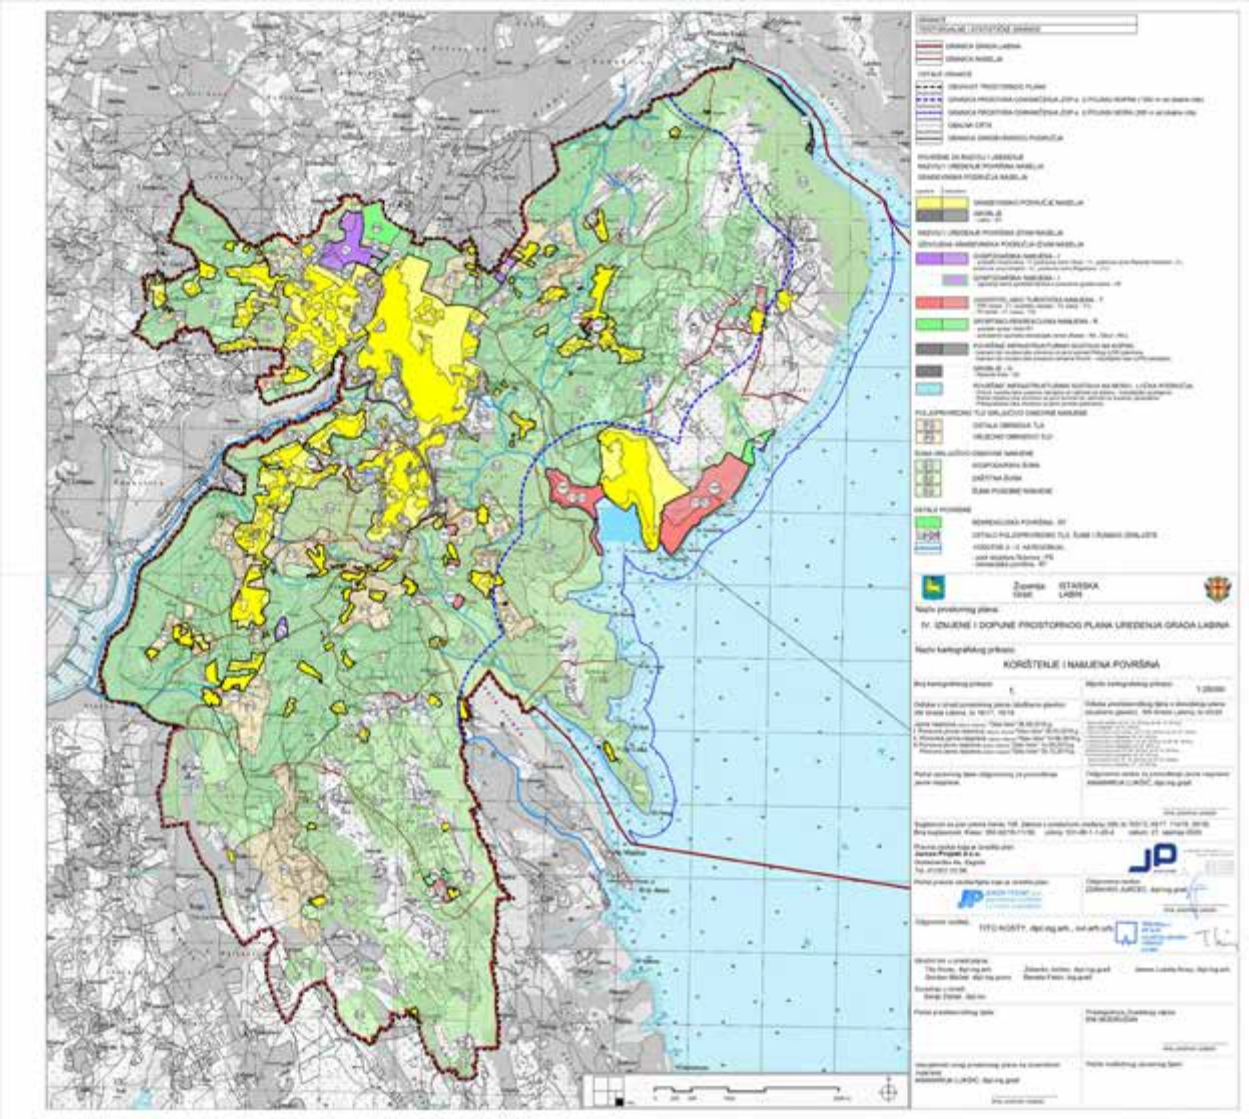

Fig.5: Spatial Development Plan of the City of Labin. Source: City of Labin, 2025.

The Spatial Plan of the City of *Labin* stipulates that the City's space will be developed and renovated in parallel and in interdependence with the balanced and even development of both the Istrian County and the Republic of Croatia.

The law envisages the rational use and preservation of spatial resources along with the development of the City of Labin as a recognizable smaller regional centre and the development of the Istrian County's space, creating prerequisites for the renewal of the economy and strengthening tertiary and quaternary functions. The development of urban and rural settlements is planned through the spatial development structure and space use, while preserving the traditional and ambient values. The infrastructure network is planned in accordance with the transport connections of the Istrian County, and settlements are connected within the City, establishing a rational transport structure. The distribution of economic activities in the existing partially built economic zone and the planned economic zone is planned, as well as the arrangement of tourist development areas and tourist areas in accordance with the Spatial Plan of the Istrian County.

A specific goal set by this development plan is the functional addition of central, public and social facilities, as well as the expansion and development of sports and recreational zones. (City of Labin, 2025)

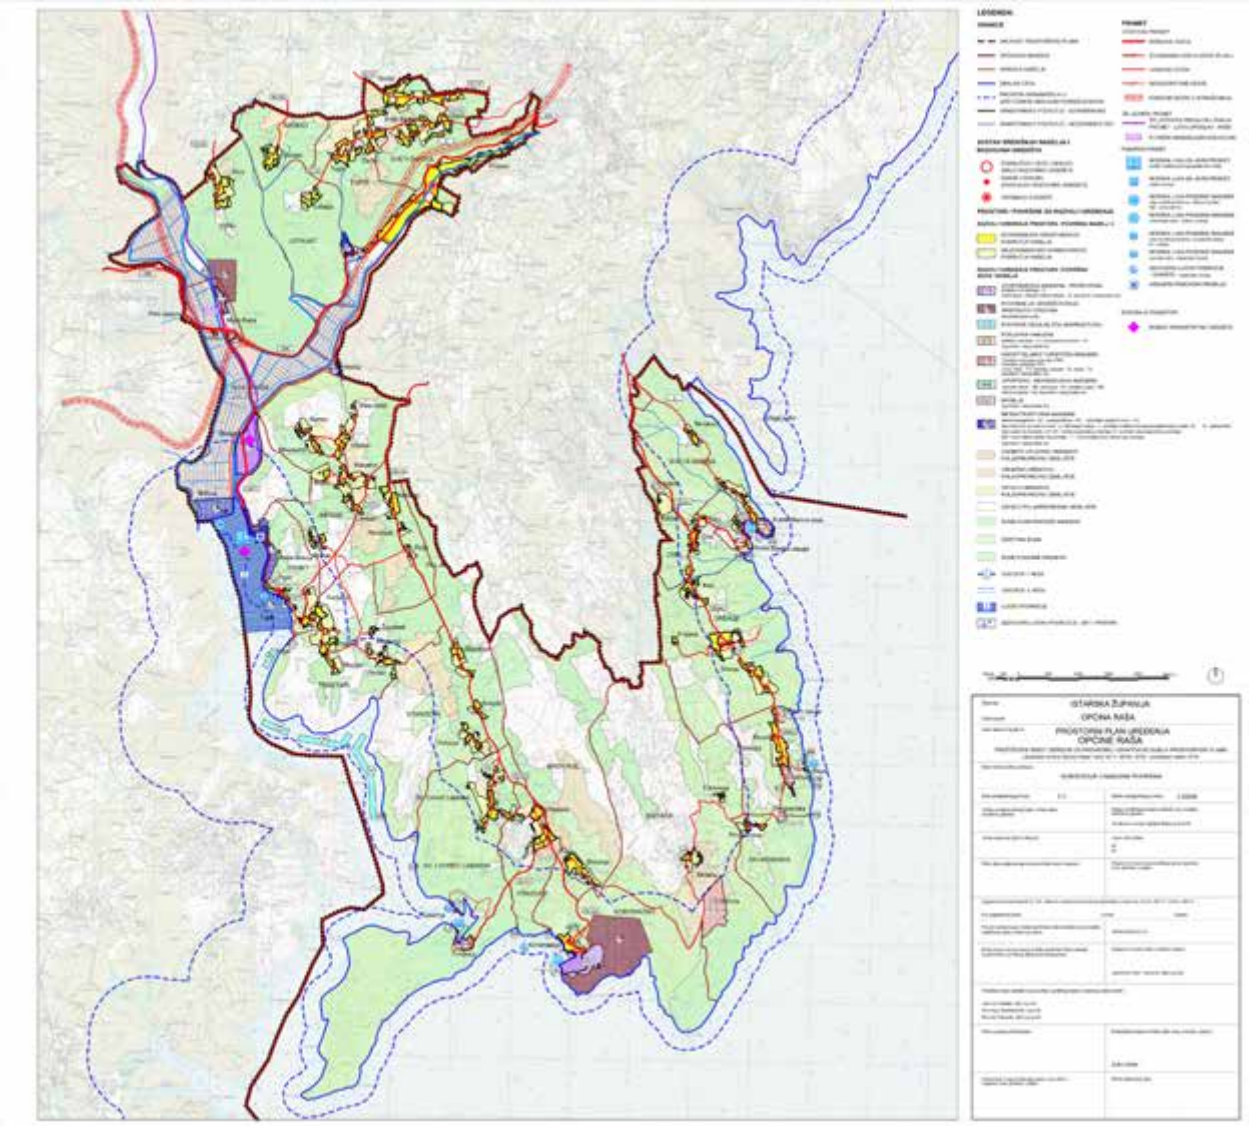

Fig.6: Spatial Development Plan of the Municipality of Raša. Source: Municipality of Raša, 2025.

The Spatial Development Plan of the Municipality of Raša, as a long-term and coordinating planning document, establishes the conditions for development, determines the purposeful use, design, renovation and rehabilitation of building stock, environmental protection and protection of cultural monuments and particularly valuable parts of nature.

The plan provides measures to direct development with the aim of better use of natural and anthropogenic values (especially coastline and cultural heritage) of individual spatial units, determining the size, structure, quality and capacity of the tourist offer in accordance with the permissible load limit of the coast, and in accordance with the provisions of the Act relating to the development and protection of the protected coastal sea area (ZOP), rationalization of the construction area, determination of the water protection regime, forests, other particularly valuable parts of nature, agricultural soils, architectural heritage, and all natural and cultural values.

One of the basic starting points is to subordinate development to improve the quality of life. In further economic development and use of space, natural and other fundamentals of life must not be compromised, nor must the already partially achieved standard and quality of life be compromised.

The plan determines the system of central settlements related to the planned central functions and expected development of residential and economic activities. (Municipality of Raša, 2025)

In accordance with the development directions of the *National Development Strategy of the Republic of Croatia* until 2030, the *Implementation Program*[1] of the City of Labin for the period 2021-2025 has set the following priorities:
1. "Digital transformation and transparency" which is based on the digitalization of processes at the city administration level
2. "Development and diversification of the economy" through which measures are defined with the ultimate goal of economic progress (in line with national development direction 1 - "Sustainable economy and society")
3. "Progress in the quality of life of citizens" which refers to increasing the quality of life in the City through several aspects (in line with national development directions 1 "Sustainable economy and society" and 2 "Strengthening resilience to crises")
4. "Strengthening infrastructure and environmental protection" - which focuses on green and sustainability (in line with national development directions 3 "Green and digital transition" and 4 "Balanced regional development").

The Implementation Program of the Municipality of Raša for the period 2021-2025 sets the direction for economic and social development of settlements in the municipality, taking into account all development needs and potentials, as well as limitations.

Thus, the Program establishes priorities for future development contained in the following priority areas:
1. "Development of a competitive and sustainable economy",
2. "Improvement of infrastructure, environmental protection and improvement of the quality of life of citizens", and
3. "Protection and sustainable valorisation of mining, industrial, cultural and natural heritage". (Municipality of Raša, 2025)

3.3 Considering future development of Labin and Raša: Beneath - Beyond Labin & Raša

Project made within the Spatial Planning Workshop at the master's Study of Architecture and Urbanism proposed the vision for the future development of Labin and Raša. The development vision is the result of the elaboration of five different possible scenarios - *Koza Nostra, Karbona, Kulturizam, Dispersion and Dystopia* and their valorisation according to the set development goals and related criteria. For the purposes of vision realisation, necessary activities in the form of different development project for a period of 25 years were proposed.

Based on the analysis of the existing situation, spatial planning documentation, strategic documents, and SWOT analysis, general goals for the further development of Labin and Raša were set, covering four specific topics: society and community, nature and environment, economy and tourism, and transport.

Using the scenario method, five possible scenarios for the further development of the Labina and Raša area with reference to the 4 main themes were proposed.

The first scenario, *Koza* nostra, is aimed at creating a community that cherishes the tradition, history and cultural identity of Labin and Raša. The development of agritourism is encouraged as a sustainable alternative to mass tourism, which allows the preservation of local customs, gastronomy and authentic lifestyles. The scenario plans to establish a college for education in agriculture, livestock farming and renewable energy sources, as well as

1 The implementation program is a short-term act of strategic planning. The implementation program of a local government describes and ensures the implementation of specific objectives set out in the local government development plan (if one has been drawn up), or the implementation of specific objectives set out in the development plan of a public utility, as well as the link between measures and the corresponding items in the local government budget (activities and projects) for which funds for implementation need to be planned.

an innovation incubator, providing opportunities for young entrepreneurs. The planned collection of rainwater for irrigation and the use of renewable energy sources contributes to the preservation of the natural environment. In order to protect the landscape and natural resources, the expansion of construction area is limited. The scenario plans to revitalize the primary sector through the cultivation of indigenous crops, sustainable fisheries and local processing of products. The construction of modern markets and the development of agritourism creates a sustainable local economy, while educational programs and innovation centres enable the application of modern techniques and employment. The scenario envisages the reactivation of the railway for the transport of local products, reducing pressure on road infrastructure. The construction of new ports in Rabac and Trget settlements enable wider distribution of products and development of fisheries.

The second scenario, called *Karbona*, proposes revitalisation of Labin and Raša industrial heritage by converting mining buildings into sport, education and cultural facilities. The plan is to rebuild Raša according to the original concept, restoring facilities of cinema and the city pool, while industrial buildings are transformed into museums and educational institutions. Industrial heritage becomes a driver of development through new tourist and educational facilities. The scenario's focus on cultural and historical tourism reduces pressure on coastal areas, which contributes to nature conservation. This focus encourages the influx of visitors throughout the year. Revitalization encourages the creation of new jobs, which also strengthens the local economy. The renovated mining tunnels serve as a high-speed railway connecting Raša, Labin and Rabac, while the mining shaft is reactivated as an elevator.

The third scenario, *Kulturizam*, emphasizes cultural sites connected by cable cars, tunnels, and bike paths, allowing locals and visitors to experience the area in a unique and comprehensive way. The preservation of natural resources is achieved through a sustainable approach to tourism, using cable cars and bike paths that allow visitors to explore natural beauty without harming the environment. The preservation of cultural heritage creates new economic opportunities through ecotourism and cultural tourism. Developed infrastructure of cable cars, public transport and bike paths will attract visitors throughout the year, extending the season creating new jobs in tourism, and as sustainable transport solutions relieve road traffic.

The fourth scenario, called *Disperzija*, focuses on the decentralization of the city and the strengthening of smaller, rural settlements. The focus is on creating a network of settlements that interconnect social, cultural and educational facilities, thereby enabling more balanced development and a better quality of life in rural areas. Strengthening rural settlements reduces the need for further urban expansion while protecting natural areas. Rural areas become key for food production, reducing the need for imports. The scenario enables more balanced economic development by strengthening rural settlements that become centres of agricultural production, thereby contributing to self-sufficiency and sustainability. Decentralization contributes to the creation of new jobs and entrepreneurial opportunities. The main element of the scenario is the improvement of transport infrastructure, including roads, railways and sea connections, and the establishment of efficient public transport. These links enable better connectivity of smaller settlements with urban areas, facilitating the distribution of resources.

The fifth scenario, titled *Distopija*, is based on organizing shelters in underground tunnels under Labin and Raša, so that the local population, in the event of natural disasters or other crisis situations, could find haven. These shelters would include sleeping areas, medical stations, survival and training education centres. It is planned to establish environmentally friendly systems for food production and water filtration. The area would be self-sufficient. Underground laboratories and food production systems would provide a basic food supply for the population. The underground tunnels would also house transport infrastructure, such as underground trains or transportation systems which would enable the rapid and safe movement of people and resources within the "survival system".

In order to choose the optimal scenario for the further development of the Labin and Raša area, the valorisation of the scenario was carried out based on the set criteria. 4 main themes and 20 sub-themes were selected for the valorisation and subsequent comparison of the scenarios. The evaluation of the elements is graded as a strong

positive effect, as a positive effect, and elements that have neither a positive nor a negative effect. All scenarios are designed to have a positive impact on the subject area, with some scenarios being rated better than others. By comparing the evaluations of the elements of the scenario, it follows that the scenarios complement each other, and for the vision of further development, it is proposed to combine the three scenarios Cosa Nostra, Carbon and Culture into a single scenario called 3K_Beneath & Beyond.

Fig.7: Valorisation of five scenarios and merging three scenarios into a development vision 3K_Beneath & Beyond. Source: Jelić, 2025.

The selected scenario, or vision for the further development of *3K_Beneath & Beyond*, achieves a positive rating in all topics and subtopics, which means that it has fulfilled the condition in each of the listed fields, or has a significant impact on the development of the selected area. The vision is planned for a period of 25 years with 22 development projects.

In order to reduce the demographic challenges of depopulation, the vision is focused on creating conditions that would encourage young people to stay in their hometowns and thus stimulate population growth. In the centre of the city of Labin, the construction of new cohousing communities and residential buildings according to the POS model is planned, which would ensure affordable and sustainable forms of housing, as well as transformation of industrial heritage buildings into social facilities. The large bathroom on the Piazzale is being revitalized and converted into a cinema. In Raša, the renovation of the former city swimming pool is proposed. The building of the former Mine Directorate becomes part of the Open University and Innovation Centre.

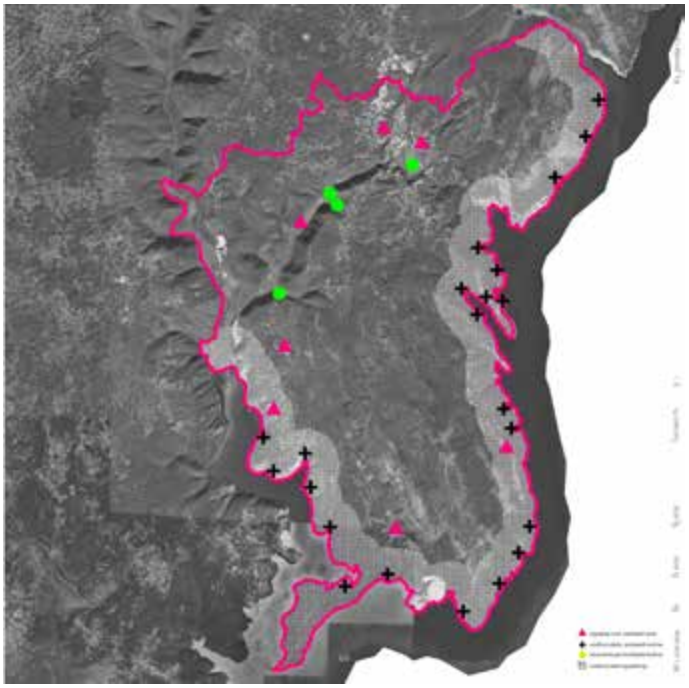

Fig.8: K1_ nature and society in the development vision 3K_Beneath & Beyond. Source: Jelić, 2025.

Particular attention is paid to the coastal area. Development of new public beaches in the Raša Bay (Škvaranska, Crna Punta, Koromačno, Šebešnica and Prtlog), through minimal interventions, ensuring accessibility, is planned to relieve overcrowded coastal area.

The construction of bicycle paths and lanes through the centre of the city of Labin as well as setting up points for electric bicycles and scooters rental is planned to encourage the use of sustainable means of transport and reduce traffic congestion during the tourist season. The introduction of new public transport lines would improve the mobility of residents and visitors, which would also result in reduction of private car traffic the need for parking spaces. The vision proposes the activation of former underground mining tunnels that would serve for occasional traffic and as a part of tourist tours and attractions. Panoramic cable cars on the stretch between Raša, Labin and Rabac, and Skitača and Škvaranska are planned for public transport and as a tourist attraction. In order to increase traffic flow and reduce congestion, the construction of a city bypass from the settlement of Vozilići to the tourist settlement of Rabac is planned, while the reactivation of the railway infrastructure will have a dual role - supporting the industrial sector and the function of public transport. In order to strengthen maritime transport, interventions that enable the distribution of locally produced food by sea and increase the tourist connections of the region with the islands of Kvarner, Dalmatia and the eastern coast of neighbouring Italy are planned.

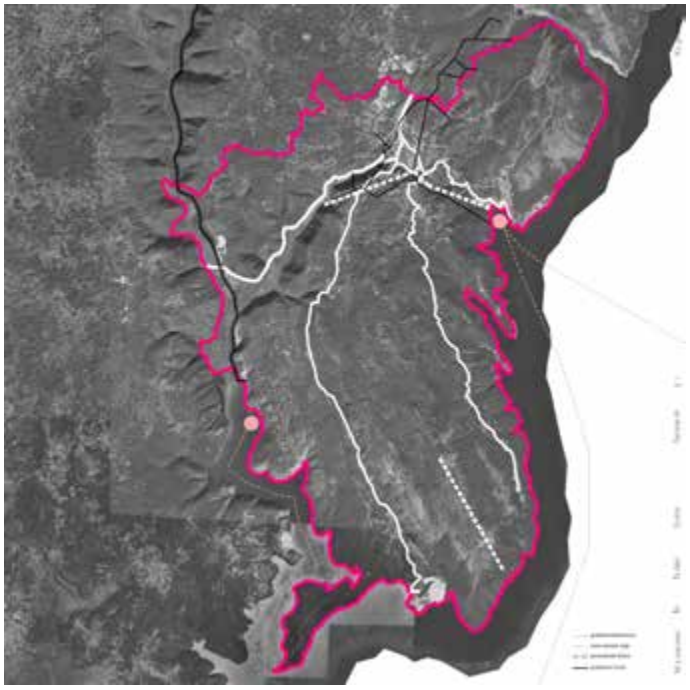

Fig.9: K2_ traffic in the vision development 3K_Beneath & Beyond. Source: Jelić, 2025.

The planned interventions should encourage the creation of new jobs, the development of primary and service activities, with a controlled expansion of tourist settlements to preserve the natural and cultural heritage. One of the goals of the vision is the preservation of industrial heritage and the expansion of the tourist offer. The opening of new public facilities (museums, social and cultural centres) would contribute to the quality of life of the local population and the overall attractiveness of the area. Agriculture production encouragement with a focus on growing crops characteristic of eastern Istria (olives, vines, root vegetables, fruits and lavender). Fishing, shellfish farming and livestock farming - breeding of indigenous animals (goats, sheep, Boškarini, donkeys and horses) is also planned. One of the main goals is to encourage the development of agritourism and marine tourism in order to valorise natural resources and enrich the tourist offer. In order to strengthen local production and sustainable development, the establishment of family farms, markets with locally produced food, new incubators and educational centres that will serve as areas for retraining and professional training of the population for work in sectors such as agriculture, livestock, fishing and tourism are planned.

4. Discussion

European organizations conduct various research and develop projects related to the development of urban systems. One of the current topics is the development of small and medium-sized cities, which represent a still insufficiently explored potential, especially in the context of European urban systems and the achievement of sustainable urban-rural relations.

European documents emphasize that such entities of the urban system are characterized by various demographic and social inequalities, especially those located in remote areas or inner peripheries, since they lack access to public facilities and appropriate economic and social opportunities.

Over the years, the processes of metropolitanisation have led to different directions of growth and development of small and medium-sized cities depending on their position in relation to large cities, profiting from integration into functional urban areas or development along fast transport corridors, while some have stagnated or even declined due to their peripherality and insufficient services.

At the national level, *the Spatial Development Strategy of the Republic of Croatia* from 2017, modelled on European documents on spatial development, states that the sustainability of the spatial organization of the state should be based on a polycentric model of development, which is a key element for achieving territorial cohesion. The document states that medium-sized and small cities should play a key role at the regional level and represent a link between larger urban areas and rural areas. The revitalization of the economic role of medium-sized and small cities should be based on business, processing industry and various forms of tourism.

Conceiving the further development of cities and regions is a very important process that Architecture and Urbanism students have the opportunity to learn at Workshop 3 - Spatial planning. The education of future planners is based on a combination of the collection of additional theoretical knowledge, such as the method of scenario planning and the process of valorisation, and the practical application of knowledge related to research, analysis, design, valorisation, and the selection and elaboration of a development vision. The practical application of the scenario planning method in the education process is particularly important for encouraging the use of planning intuition and strategic thinking.

The analysis of the existing situation, spatial planning documentation and strategic plans for further development at the local level enables the collection of information about the area and its possibilities and represents the basis for designing development goals and applying the scenario planning method. Determining the criteria and implementing the valorisation of the proposed scenarios gives future planners the opportunity to practice making decisions as objectively as possible. In addition to graphic representations that follow the planning steps, models are also created in the planning process so that future planners can better present and communicate their ideas with the public.

Fig.11: Model of the development vision of Labin and Raša - 3K_ Beneath & Beyond. Source: Jelić, 2025.

In this case study, five possible scenarios for future development of Labin and Raša were proposed. In this project, two local self-government units, the city of Labin and the municipality of Raša, were considered together as a whole due to their spatial, economic and social specificities and historical economic significance.

The realization of 22 designed development projects (8 related to the topic of nature and society, 8 related to the topic of transport and 6 related to the topic of economy and tourism) in accordance with the proposed vision of *3K_Beneath & Beyond* in a period of 25 years would lead to the revitalization and improvement of the quality of life at the local level, the revitalization of economic activities in the region, contributing at the same time to the objectives of the Spatial Development Strategy of the Republic of Croatia, i.e. strengthening the polycentric model of development and territorial cohesion.

Conceiving development scenarios and development projects based on the sustainability goals indicates an awareness of the importance of global trends, which by planning at the local level contribute to the achievement of global goals.

5. Conclusion

Research on the possibilities of further development of an area and the prediction of possible development scenarios is a very important topic in professional circles. In addition to the theoretical knowledge in the field of spatial planning and urbanism, which is collected during the studies, the practical application of the collected knowledge and skills on different scales is possible towards the end of the master's study within the framework of Workshop 3 - Spatial planning.

On different scales, future planners can practice research, analysis, synthesis, strategic and critical thinking, forecasting, modelling evaluation tools and decision-making process while planning the future development of selected area. The ability to choose the area further encourages future planners to go through the comprehensive process themselves in just 15 weeks with joy and a special interest in the space.

During the education process, considering the space in a broader context and considering its significance at the regional level can provide additional impetus for planning in a broader context, i.e. crossing the administrative boundaries of local self-government, which was agreed upon by the city of Labin and the municipality of Raša in this case. We can say that this work has set a new model of approach, i.e. that a new entity has been formed, formally composed of two local self-government units, and through comprehensive consideration, a proposal for a vision of future joint development has been given based on historical elements, recognized potentials and possibilities of space in the context of sustainable development, while maintaining the specificities of individual elements in the space.

Towards transformative actions through perceptions research: Q-methodology as a tool for identifying ideological dimensions of planning problems

Aida Arik
Univ. Grenoble-Alpes, INRAE, LESSEM, Grenoble, France
aida.arik@inrae.fr

Abstract
Addressing complex planning problems requires being able to respond to a diverse spectrum of perceptions and ideas. However, capturing nuanced perspectives to develop transformative actions remains difficult in research and planning processes. This paper explores Q-methodology as a tool to analyse ideological dimensions in planning problems. By combining qualitative and quantitative analytical techniques, Q-methodology is a useful tool for studying subjectivity, revealing consensus and divergence among perspectives. Here, I reflect on five diverse applications of Q-methodology—to inform or analyse stormwater and flood risk policy, ease water conflict tensions, and assess co-creation's role in shifting perceptions of transdisciplinarity in climate change adaptation. While acknowledging that there are limitations, these studies illustrate the method's capacity to uncover narratives, foster dialogue, and study transformative processes.

Keywords: Q-methodology, subjectivities research, narratives analysis, communicative planning

1. Introduction

Urban planning presents various "wicked" problems that are complex, multifaceted, and pervasive throughout social systems (Rittel and Webber, 1973). These problems are challenging to manage because they involve several interrelated and co-evolving processes, each with its own counterbalancing forces, making a single best solution impossible. Collaborative planning emerged as a postmodern framework for addressing wicked problems by engaging with diverse viewpoints and fostering inclusive decision-making (Innes and Booher, 2016). Despite planning being largely government-led, postmodern theories advocate for bottom-up approaches that centre inhabitant and user perspectives, recognising that scientific analyses offer only a partial understanding, often overlooking the social, cultural, and ideological forces shaping decisions (Allmendinger, 2002; Innes and Booher, 2010; Irving, 1993). Since its emergence as a dominant postmodern theory, collaborative planning has evolved to address the complexities of power, communication, and governance, challenging modernist assumptions of order and predictability in planning processes (Healey, 2003, 1997). As a result, communicative planning scholarship promotes leveraging communication and collaboration not just as mechanisms for problem-solving, but as essential tools for identifying challenges, negotiating competing interests, and fostering collective capacity to navigate the uncertainties of urban design in dynamic socio-political contexts.

Capturing nuanced viewpoints in planning is a significant challenge due to the inherent complexity of subjective experiences and power dynamics that shape decision-making processes. Similarly, studying wicked problems has multiple modes of entry and requires drawing wieldy boundaries around an inherently complex system (Holling, 2001; Hou et al., 2022). Studying wicked urban planning problems and deciding necessary research priorities is, by definition, reductive even when attempting to cast the widest possible net. Because of the complex nature of wicked problems, mixed-methods approaches offer a means to look at multiple aspects of a problem (Mertens, 2015). One mixed-method technique increasingly used to study wicked problems subjectively is Q-methodology (QM). It uses data reduction techniques to condense multi-dimensional subjectivities into a practical set of perspectives regarding a particular subject. William Stephenson is credited with founding this research method within psychology (Stephenson, 1936, 1935), and it has since been incorporated as a valuable tool in many human research disciplines (Ramlo, 2016a).

In this paper, I reflect on the use of QM as a tool in collaborative urban design. The methodology offers a means to identify multi-dimensional subjective views of various planning problems. This paper is structured as follows. In section 2, I give an overview of QM and how the studies are designed, implemented, and analysed. In section 3, I give a summary of the five QM studies from which this reflection is based. In section 4, I provide insights in the positive aspects of using the QM in planning applications and some of the limitations. Finally, I close the paper with brief concluding remarks.

2. Understanding Q-Methodology

The Q-method (QM) recognises that an individual's subjectivity is better understood in a sociocultural context with respect to the perspective of others. William Stephen developed the methodology out of the idea of an inverted factor analysis (Stephenson, 1953, 1935). Indeed, QM inverts the traditional factor analysis by having m subjects react to n tests rather than performing m tests on n subjects. In other words, QM enables individuals to define themselves through the relative ranking of a set of ideas, and is thus a useful tool for studying subjectivity on a topic of interest (Brown, 1980; Robbins and Krueger, 2000; Stephenson, 1953). The method distinguishes itself from pure quantitative methods as a technique to make discoveries rather than test theories (Stephenson, 1953; Watts and Stenner, 2005). QM is also distinct from purely qualitative methods in that it uses quantitative techniques to articulate these discoveries. Although the method developed in the field of psychology, it has expanded into many different academic and professional fields over the decades (Ramlo, 2016a), for example, human geography (Eden et al., 2005; Robbins and Krueger, 2000), environmental sustainability and conservation (Sneegas et al., 2021; Webler et al., 2009; Zabala et al., 2018), healthcare research and education (Churruca et al., 2021; Hensel et al., 2022)the methodological variations, and the major implications to inform best practices. Design: Scoping review design using the Preferred Reporting Items for Systematic Reviews Extension for Scoping Reviews. Data sources: Academic Search Complete, CINAHL Complete, Education Research Complete, Embase, ERIC, Proquest Nursing and Allied Health, PubMed, PsycInfo, SocINDEX, and the Web of Science Core Collection. Review methods: A comprehensive search of English language journal articles was conducted for Q methodology studies published between 2015 and 2020 that used undergraduate nursing students or nursing faculty as participants. Data were extracted using a modified version of the Assessment Review Instrument for Q Methodology. Results: Eighteen studies from five countries met inclusion criteria. The majority were single-site studies and used nursing students as participants. The number of stimuli for sorting in the Q sample ranged from 21 to 60. Study aims fell into three broad domains: attitudes about patient populations or settings (N = 7, and educational research (Lundberg et al., 2020).

Generally, a QM study proceeds in four major phases: developing a concourse, Q-sampling and Q-set finalisation, collecting Q-sorts and interviewing participants, and data analysis and interpretation. In addition to systematic literature reviews (Dieteren et al., 2023; Sneegas et al., 2021), several primers offer detailed theory and instructions for carrying out a QM study (Brown, 1993; McKeown and Thomas, 2013; Watts and Stenner, 2005). For reference, Table 1 provides a guide to terminology used in QM studies and their meanings.

Table 1. Terminology specific to a QM study.

Term	Meaning
Concourse	A collection of stimuli, usually statements, often numbering in the hundreds, that pertain to a specific topic of interest. The concept of a concourse is that it is the collection of all ideas possible, and therefore can never truly be complete.
Q-sampling	The process of selecting the stimuli that will comprise the Q-set.
Q-set or Q-sample	The final set of stimuli (e.g., statements that are not provable) used for the QM study.
P-set	The set of participants participating in the QM study.
Q-sort	The sorted set of stimuli ranked by each participant according to the pre-defined semi-normal grid.

Phase 1: Building the Concourse. A concourse is created to represent the body of thoughts on the subject of inquiry. While QM studies typically use statements, other stimuli like images, poems, and words can also be used. The concourse, drawn from sources such as interviews, forums, literature or media, provides subjective stimuli for an eventual Q-set selection. Though in theory never exhaustive (Stephenson, 1986), ideas are added to the concourse until the 'point of saturation' when no new ideas are emerging.

Phase 2: Q-Sampling and Q-Set Selection. Once saturated, Q-sampling selects a subset of statements, the Q-set, from the concourse often guided by a structured framework (Brown et al., 2019). To enhance clarity, pilot tests help refine the Q-set, reducing and refining the statements as needed. Statements should be ideas that cannot be readily tested. In environmental sustainability research studies, Sneegas et al. (2021) found the number of statements in the Q-set range from 9 to 69, with a mode of 36. Across other disciplines, the average number may be higher (Dieteren et al., 2023). The appropriate number depends on the ability to capture the breadth of the concourse while considering interview time constraints and participant fatigue.

Phase 3: Participant Selection and Q-Sorts. Study participants are then asked to rank the Q-set based on a pre-defined grid. QM studies focus on identifying the perspectives present among a group rather the central tendencies of a population. Therefore, there are no hard and fast rules on sample sizes, which vary in most studies between 20 and 50 participants (Dieteren et al., 2023). Principally, the number of participants should reflect the amount needed to address the research question at hand (McKeown and Thomas, 2013). Each participant creates a Q-sort—participant-ranked statements based on the pre-defined grid—which are collectively analysed and often complemented by semi-structured interviews for deeper interpretation. While traditionally in-person, use of online Q-sort platforms have expanded in the wake of the COVID-19 pandemic.

Phase 4: Data Analysis and Interpretation. Collected Q-sorts undergo factor analysis. There is an active debate among QM researchers regarding the most appropriate analytical tools and choices at this step (Akhtar-Danesh, 2017, 2016). For instance, QM traditionally used centroid factor analysis and manual rotation, which were largely necessitated by computational constraints in its early development; however, modern studies favour Principal Component Analysis (PCA) and varimax rotation as the prevalent techniques for analysis (Dieteren et al., 2023; Zabala et al., 2018). Nevertheless, since these analytical tools are generally designed for large datasets and QM studies use smaller datasets, careful interpretation is crucial to choosing an analytical path that reflects viewpoints collected. The process reduces the full collection of Q-sorts down to a handful of key perspectives, reconstructed Q-sorts based on the weight of participant correlations to factors. After analysis and interpretation, many researchers suggest this as the starting point of a deeper conversation with the participants, informed by the findings.

3. Example Studies Illustrating the Application of Q-Methodology in Planning

This reflection paper pulls from 5 diverse QM studies employed to different ends related to contemporary planning issues. A summary of the studies is provided in Table 2. Among all studies, a forced grid was used for data collection with ranking statements on a scale from most disagree (-) to most agree (+), and analysed using PCA and varimax rotation to identify the factors. Online interviews were conducted using Q-Tip without a pre-sort step (https://qtip.geography.wisc.edu/) or EQ Web Sort (Banasick, 2023) with a pre-sort step. Data were analysed using Ken-Q Analysis (https://shawnbanasick.github.io/ken-q-analysis/).

Table 2. Summary of various applications of the Q-method

Study: Context and research objective	Study design	Study application	Q-sort design
Study 1 (Honolulu study): Honolulu, Hawaii. A study on stormwater management priorities amid community-government tensions over a US Army Corps flood project	Concourse built from comments taken from media, public forums, and semi-structured interviews. Participants included stakeholders and experts from the community, academia, and government	Online only (Q-Tip) Q-set: 25 P-set: 18 Factors: 4 (3 with one bipolar split into two)	±4: 1 ±3: 2 ±2: 3 ±1: 4 0: 5

Study 2 (Maui study): Lahaina, Maui fire (Hawaii). A study exploring agreement and disagreement on water management strategies after the Lahaina Fire	Concourse built from post-fire press articles. Participants were part of a closed advisory group that guides water management strategies for Hawaii	Online only (Q-Tip) Q-set: 22 P-set: 12 Factors: 3	±4: 1 ±3: 2 ±2: 3 ±1: 3 0: 4
Study 3 (GAM study): Grenoble-Alpes Métropole (GAM), France. A study to understand tensions in flood risk management	Concourse built from semi-structured interviews. Participants were part of a public advisory committee on flood risk management, including managers, experts, and elected officials	Majority in-person (online: EQ Web Sort) Q-set: 32 P-set: 55 Factors: 3	±5: 2 ±4: 2 ±3: 3 ±2: 3 ±1: 4 0: 4
Study 4 (TAA study): Trentino-Alto Adige (TAA), Italy. A comparison study with Study 3 to understand how the EU's principle of subsidiarity plays out in flood risk management	Same study design as Study 3. Participants were flood risk managers or experts. Comparative stats analysed ranking differences among 26 similar GAM and TAA participants	Majority in-person (online: EQ Web Sort) Q-set: 32 P-set: 31 Factors: N/A	Same as study 3
Study 5 (TD-assess study): International. A study to assess the changes in ideas about transdisciplinarity in climate services for climate action	Concourse drawn from semi-structured interviews with international climate service experts. Young professionals from various countries attended a two-week transdisciplinarity school in Arusha, Tanzania, completing a Q-sort before and after the program	Online only (EQ Web Sort) Q-set: 23 P-set: 25 (16 before, 9 after, 7 repeats) Factors: 4 (3 including one bipolar split into two)	±3: 2 ±2: 3 ±1: 4 0: 5

The first application, the Honolulu study conducted in 2020, explored the expectations of stormwater management prompted by a flood risk management project framed in the press as a community-versus-government issue. The QM revealed tensions existed over the role of the government in planning and financing stormwater management, whereas everyone was in agreement to move towards green infrastructure and away from grey solutions. Further details can be found in Arik (2022).

The Maui study was conducted among a non-public stakeholder group in the wake of the Lahaina fire in 2023 which decimated the entire town. Decisions about water releases made during the unfolding disaster prompted a battle that played out over national newspaper outlets—a unusual occurrence for Hawaii-related issues. The conflict stemmed from a decades-long struggle to secure in-stream water rights for indigenous Hawaiian practices, against a deep-rooted legacy of colonial-era water diversion. The purpose of using the QM was to start a conversation between some of the parties at the heart of this conflict—as a means to acknowledge with data the differences of opinion and move quickly to productive conversation.

The GAM study and TAA study are twin studies conducted in 2022 and 2023, in two similar urban settings in France and Italy to understand how flood risk management decisions are made. They both used the same study de-

sign with statements and interviews conducted in French and Italian respectively. Further details about the GAM study can be found in Arik et al. (2023). For the GAM study, an additional judgmental rotation was employed based on one participant who had a leading role in flood risk management. The study was conducted among affiliates of a democratically structured flood risk management steering committee. However, QM revealed that this structure tended to suppress marginal issues—those significantly affecting local communities but not severe enough to become watershed-level priorities. The TAA revealed somewhat of an opposite problem that voices of change were often externalised from flood risk management decision, and that flood risk management decisions remained insular. To compare the GAM and TAA data, comparative statistics were used on the raw Q-sort ranking data. In this case, the PCA was not applied for the comparison.

The TD-assess study explored how participants in a two-week climate services school that took place in 2024 shifted their views on transdisciplinarity in climate action (Vigna et al., forthcoming). To measure this change, they were asked to complete a Q-sort before and after the program. Participants were young professionals from diverse disciplines, working or studying worldwide, but primarily based in Europe or Africa. Unlike the other studies described, which included one-on-one interviews, the TD-assess study gathered perspectives through commentaries in a post-sort survey. The QM revealed a growing recognition of the value of transdisciplinary collaboration.

4. Reflections on the Use of the Q-method in Planning

The QM is a valuable tool for analysing discourse, systematically categorising subjectivities to reveal patterns of agreement and divergence. By bringing clarity to complex planning issues, it helps uncover underlying perspectives that shape decisions and guide deeper discussions. While its effectiveness depends on thoughtful design and interpretation, QM offers a structured approach to fostering more inclusive and informed decision-making in planning. Here, I elaborate on some of its strengths and limitations based on the applications described in the previous section.

4.1. Strengths and Impacts

Understanding the Roots of Conflict. The QM offers a structured approach to analysing discourse, helping to uncover the underlying factors driving disagreements in planning and policy decisions. By identifying viewpoints present among participants, it highlights sources of friction—whether stemming from miscommunication, competing priorities, or deeply held values. This ability to clarify tensions provides a useful lens for understanding how conflicts emerge and where opportunities for dialogue exist. Mapping diverse perspectives can help planners recognise not only points of consensus but also areas of divergence that require negotiation. The Honolulu study illustrates this dynamic, showing that even though stakeholders broadly supported green infrastructure, disagreements about governmental roles in planning and funding fragmented overall alignment. This suggests that consensus on solutions sets alone does not guarantee cooperation—governance structures and expectations around responsibility play a critical role in shaping stakeholder engagement.

The Maui study further demonstrates how structured discourse analysis can facilitate dialogue in deeply rooted conflicts. The Lahaina fire brought long-standing tensions over water rights into national focus, underscoring the historical struggle between indigenous Hawaiian practices and colonial-era water diversion policies. By framing perspectives in a structured way, QM served as a tool to initiate conversations among a critical stakeholder group, offering data-driven recognition of differing viewpoints to move discussions toward more productive outcomes. These studies highlight that understanding stakeholder perspectives is not just about identifying agreement and disagreement, but about recognising the governance, historical context, and discourse structures that shape how conflicts evolve, where QM can help define how they may be navigated.

Amplifying Underrepresented Voices. Dominant narratives in planning often shape decision-making processes in ways that overshadow minority perspectives, limiting the inclusion of diverse viewpoints. Unlike survey instruments that aim to measure consensus or central tendencies, QM provides a structured approach to identifying distinct perspectives among participants, making it particularly useful in highlighting overlooked priorities. The

GAM and TAA studies demonstrate how flood risk management decisions are shaped not only by technical assessments but also by institutional structures. In the GAM study, conducted within a democratically structured steering committee, QM revealed that while decisions reflected majority preferences, they tended to suppress marginal concerns—issues significant at the community level but too localised to influence watershed-scale priorities. Conversely, the TAA study exposed a different issue: voices advocating for change were largely externalised from decision-making, reinforcing an insular approach to flood risk governance. These findings illustrate that participatory structures do not always guarantee inclusivity, emphasising the need for tools that can expose both dominant and marginalised viewpoints.

By systematically categorising viewpoints, QM helps uncover underlying patterns that might otherwise be concealed within governance processes. The comparative analysis between the GAM and TAA studies highlights how flood risk decisions are shaped not just by technical assessments but also by institutional dynamics that determine whose voices are amplified and whose are excluded. In GAM, a structured democratic process inadvertently side-lined concerns that did not meet broader strategic priorities, while in TAA, exclusionary decision-making reinforced internal confidence at the cost of external perspectives. Together, these studies reveal that different governance structures produce distinct challenges in integrating diverse viewpoints into planning processes. QM's ability to illuminate such discursive patterns makes it a useful tool for analysing how decision-making frameworks operate, and how they may be adapted to foster more inclusive engagement.

Facilitating Collaborative Solutions. In complex policy and planning contexts, productive dialogue is often hindered by competing interests, conflicting priorities, and the sheer diversity of perspectives involved. QM helps structure these discussions by reducing the dimensionality of viewpoints, revealing nuanced patterns in stakeholder perceptions rather than treating opinions as isolated and competing. By clustering perspectives, identifying consensus, and highlighting points of divergence, QM enables planners to navigate discourse with greater clarity, offering a structured framework for untangling dense debates and facilitating more effective negotiation. This was evident in the Maui study, where QM findings were used to initiate dialogue, allowing acknowledgement of differences without dwelling on them in a discussion. Similarly, the TD-assess study demonstrated QM's ability to track shifts in participants' perceptions of transdisciplinarity, illustrating how structured discourse analysis can reveal changing attitudes within collaborative settings. These examples highlight QM's potential to bring coherence to complex discussions, ensuring that planning processes account for both areas of alignment and persistent tensions.

4.2. Challenges and Considerations

Dependence on a Well-Designed Q-Set. The effectiveness of QM relies heavily on a carefully constructed Q-set that accurately captures the breadth of perspectives relevant to the study. A poorly designed Q-set can limit the insights derived from the method, restricting the ability to identify meaningful clusters of viewpoints. For example, in the GAM and TAA studies, the statement set attempted to incorporate ideas that were not necessarily central to all participants, leading to many consensus statements around neutral positions that were not very insightful because they reflected a non-positionality. Moreover, since the study was initially designed for GAM and later deployed in TAA, certain statements did not align as well with the TAA context, illustrating the challenges of adapting a Q-set across different governance structures. This underscores the importance of tailoring statement selection to the specific decision-making environment to ensure meaningful insights, which can limit its usefulness to the context. Finding the right balance between participation and the validity of the Q-set can also be tricky. In the case of the TD-assess study, we faced challenges related to participation rates, prompting us to reduce in the number of statements in an effort to increase engagement in the study for future iterations of the program, but preventing us from using the first dataset to compare to future studies. These examples highlight the need for careful Q-set construction, keeping in mind the participants, and ensuring that statements will be effective in capturing the nuances of the participant perspectives while remaining relevant to the study's context.

Complexity in Explanation and Lack of Visualisation Tools. The method itself and its findings can be challenging to communicate effectively due to its complexity and lack of conventional numerical summaries, making

interpretation less intuitive for broader audiences. To date, visualisation tools to communicate QM finding are underdeveloped as well. In the Honolulu and GAM studies, findings were shared openly through reports with opportunity for reactions, with no feedback given. Similarly, a presentation was given to the stakeholder group in the GAM study with no substantive follow-up. This highlights the importance of carefully considering how its results are presented to enhance engagement in planning processes. In contrast, the Maui study demonstrated a more effective approach—using QM as a tool to initiate dialogue among key stakeholders, helping structure conversations around conflicting perspectives because it was conceived as a tool to enhance the discussion. These examples suggest that QM's effectiveness depends not only on its methodological rigor and the ability to communicate the method and findings effectively, but also on its integration in planning processes to foster meaningful discussion.

Context-Specific Nature and Limited Generalisability. The QM is highly context-dependent, meaning its findings often cannot be directly transferred across different studies or planning environments. This is evident in the Honolulu and GAM/TAA studies, which both focus on flood risk management yet show minimal overlap due to their distinct governance structures and local dynamics. While Honolulu study of identifying priorities in stormwater management which revealed underlying tensions, the GAM/TAA studies deployed a Q-set to test potential tensions as hypotheses and revealed governance dynamics. Similarly, the TAA study particularly underscored the importance of designing the Q-set to fit its specific context, as transferring statements from GAM resulted in misalignment of certain statements in the Q-set with local context. Meanwhile, the TD-assess study took a different approach by designing its Q-set with broader applicability in mind—allowing its framework to be potentially redeployed to measure shifts in transdisciplinary collaboration in climate services and adaptation planning. These examples emphasise the need for careful Q-set construction tailored to the study's objectives while considering ahead of time whether the potential for adaptability across similar research domains is a goal or not.

5. Concluding Remarks

Addressing complex planning problems requires approaches that can engage with a diverse spectrum of perceptions and ideas. However, translating subjective viewpoints into actionable strategies remains a fundamental challenge in research and policy-making. Q-methodology can be a valuable tool for analysing ideological dimensions in planning, offering a structured way to assess areas of consensus and divergence. By combining qualitative and quantitative techniques, QM facilitates the study of subjectivity in decision-making contexts, uncovering narratives that influence planning outcomes. This paper examined five distinct applications of QM—from informing stormwater and flood risk policy to navigating water conflicts and assessing co-creation's role in shifting perspectives on transdisciplinarity in climate adaptation. While QM is not a universal solution, its use in these cases demonstrates its ability to highlight discursive patterns, foster dialogue, and provide a structured approach to understanding differing viewpoints.

At the same time, employing QM in planning comes with important considerations. The method's effectiveness relies on a well-designed Q-set and thoughtful implementation, requiring careful framing to ensure meaningful insights. Additionally, its context-specific nature means that findings from one study may not be broadly generalisable, limiting direct application across different cases. Furthermore, QM's complexity can make it challenging to communicate results to diverse audiences, especially given the lack of visualisation tools. Despite these limitations, QM remains a useful mixed-method approach to studying subjective perspectives in planning. When used appropriately, it can offer decision-makers a clearer view of ideological tensions, highlight voices that might otherwise go unheard, and contribute to more informed and inclusive planning processes.

Acknowledgements

The research referred to in this article was conducted by the author and colleagues while affiliated with the Department of Urban and Regional Planning of the University of Hawaii at Manoa (Honolulu, Hawaii, US), One World One Water LLC (Honolulu, Hawaii, US), and l'Institut des Géosciences de l'Environnement (Grenoble, France). The GAM and TAA studies were conducted as part of the Climat-Métro project and the TD-assess study as part of the CATER schools project.

From Masdar City, Abu Dhabi to Florya, Istanbul: What Can We Learn from Smart Cities?

Abstract
Masdar City is one of the first smart city models that emerged as an ambitious project, aiming to become the world's first zero-carbon, zero-waste city, weaving technology into its urban fabric. Today, the project remains unfinished and is largely a ghost town, neglecting the most crucial component of a city: people. Learning from Masdar City, how can we design more people-centric smart cities? This paper proposes a future city model for a site in Florya, Istanbul. We explore how urban planning can benefit from "smart" initiatives that promote social connection through volunteering, supporting local production, and prioritising pedestrian-friendly mobility. Future cities do not have to be technological utopias but offer a reasonable interpretation of community needs to build a just and equitable future.

Keywords: Masdar City; Florya, Istanbul; Urbanisation; Future Cities; Community Development

1. Introduction

In light of the world's rapid technological development and increased environmental consciousness, future cities, often called smart cities or eco-cities, emerge as an initiative to leverage technology for sustainable development. Sustainable development, composed of the social, economic, and environmental pillars (United Nations, 2002), has become a pressing global concern, and balancing these pillars is a significant challenge in our capitalist-driven world. This dilemma has been particularly evident in future cities as the vision drifts away from a people-centric approach to a revenue-driven, profit-oriented urban model.

Masdar City is no stranger to the aforementioned urban challenge. Located in Abu Dhabi, United Arab Emirates (UAE), Masdar City came to life as the world's first city with a zero-carbon, zero-waste goal. Considering the UAE's oil-based economy and future resource scarcity, it became essential for the UAE to explore potential urban solutions and alternative economic models. Launched in 2006 as a subsidiary of the Mubadala Investment Company, the 640-hectare city is a testing ground for innovative renewable energy solutions and diverse sustainability-oriented technologies within the UAE's challenging context (Foster + Partners, n.d.), particularly its harsh climate and the Emirati society's lavish lifestyle (Fattah, 2007). Thus, one of Masdar City's main goals is to show that achieving a high quality of life with minimal environmental impact is possible (D'Eramo, 2021).

Masdar supports Abu Dhabi's transition to a knowledge-based economy as part of the Abu Dhabi Economic Vision 2030 (Masdar, 2020), and its goal as a zero-carbon, zero-waste city further creates a positive incentive towards technological and economic development. Foster and Partners, the design firm that dealt with Masdar City's master plan, introduced design solutions and strategies that aim to reduce energy consumption while fostering Masdar's desire for technological innovation, including narrow shaded streets inspired by traditional Emirati architecture (Ibrahim, 2016), "wind and photovoltaic farms, research fields, plantations" (Foster + Partners, n.d.), and an electric personal rapid transport system (Cugurullo, 2013). The city also attracted major companies, including Siemens and General Electric, reflecting its power as a business hub. These companies play an integral role in Masdar's economic model as their innovations are promoted and displayed in Masdar City as a living portfolio (Cugurullo, 2013; Cugurullo, 2016).

While the master plan of Masdar City is still not fully implemented, the analysis in this paper discusses how the city has a business-oriented model focusing on the economic pillar of sustainability, rendering the social component of the city neglected. Furthermore, it highlights how the integrated technologies resulted in more shortcomings than advantages. Thus, this study envisions what prioritising social sustainability while benefiting from technology could look like. To explore this concept, this paper proposes an experimental approach entitled "The Social City" in Florya, Istanbul. "The Social City" aspires to integrate urban planning and design decisions along with technology to create a lively city that fosters community bonds and encourages people to socialise and interact with each other.

2. To What Extent Is Masdar City What It Claims to Be?

The current reality of Masdar City has not aligned with its initial vision. After the 2008 financial crisis, the UAE's economy was highly affected, and ever since, the plans and reality of Masdar City have changed significantly (Griffiths and Sovacool, 2019). The original goal was to become a zero-carbon, zero-waste city with 40,000 residents by 2016 (Premalatha et al., 2013). Masdar City's reports indicate that the current sustainability efforts have been modified to decarbonisation initiatives, and the original net-zero goal is to be reached by 2050 (ESG 2023, 2023). However, the multiple delays and changes in defining the goal (Figure 1) and the budget cut from 22 billion dollars to 18 billion dollars may reflect some scepticism about the vision's attainability and feasibility.

Figure 1: The Construction Progress of Masdar City since 2009

While integrating technology into future cities can be beneficial, multiple technologies adopted in Masdar City failed in terms of efficiency, application, and utilisation. For example, the photovoltaic plants, which were expected to generate approximately 17,500 megawatt-hours of clean energy (masdar.ae, n.d.), face the issue of excessive dust accumulation, which significantly decreases their efficiency, and cleaning them is a resource-intensive solution (Omar, 2018). Another example is the idea of the Ergos energy-based currency that replaces traditional money with kilowatt-hours to monitor household consumption (Günel, 2014). Each citizen is given an energy budget, helping Masdar reach its energy and zero-carbon goals. However, while the solution appeared to be a promising tech-based innovation, the idea was disregarded due to the cost and financial considerations of installing the necessary monitoring systems, the solution's heavy reliance on educating the human actors in the system, and the fear of data exploitation (Günel, 2014; D'Eramo, 2021). Such examples reflect how some of the tech and innovation-based solutions adopted in the city were rendered inefficient due to the cost needed to maintain them or their requirement of a significant paradigm shift in citizen lifestyles and governance. This highlights the paradox that excessive dependence on technology in a smart city may, in practice, be "unsmart."

Another primary concern is Masdar City's reliance on the UAE's conventional oil-based economy for sustenance since the renewable energy solutions adopted were insufficient to power the city (Cugurullo, 2016). As Masdar City was supposed to be the world's first zero-carbon city, such an approach defeats the entire raison d'être of Masdar City. Furthermore, its reliance on oil raises an important question: If the existing infrastructure is inadequate to sustain a partially built city, how can we be sure that Masdar City will truly achieve its net-zero goals

once fully developed? While this reality may change once the master plan is complete, it still highlights the drawbacks of an overly ambitious vision, often fuelled by the smart city concept.

While Masdar City claims to aim for a well-rounded sustainable approach, the city, which operates as a living portfolio for companies that produce green technologies, is, in reality, a research and development-based business model that aims to attract developers, investors, and potential buyers (Cugurullo, 2013; Cugurullo, 2016). These companies play an integral role in Masdar's economic model as their innovations are promoted and displayed in Masdar City as a marketing and business strategy for both parties. While this is not necessarily a negative approach, it prioritises economic sustainability over the other pillars. Furthermore, environmental sustainability in Masdar City is primarily attained by supporting green technology companies and working towards sustainability certifications. While a good start, it still reflects a limited interpretation of the pillar and its complexity. Social sustainability, however, remains largely neglected. A city's main living component is its people; however, Masdar City is deemed a "ghost town" (Goldenberg, 2016). Even though the project was designed for around 50,000 people, the almost-empty city's main users are those associated with Masdar City's research university or company employees. The reasons go back to multiple factors, mainly the high living costs. Masdar City's design focused more on titles, numbers, catchy marketing ideas, and futuristic innovations rather than the actual needs of the users. Furthermore, considering its approach as a business city, it innately appeals to social elites rather than people of diverse backgrounds and social classes (Cugurullo, 2016).

Upon examining the initial vision of Masdar City, it was primarily meant to be an investment company that aims to create a new model of economy motivated by climate change and resource scarcity in the form of a techno-city (masdar.ae, 2019; Cugurullo, 2016). This goal boasts a commercial incentive instead of truly targeting sustainability and all its pillars. Thus, sustainability is approached more as a business strategy than a holistic urban practice, and social sustainability remains fundamentally unaddressed.

3. Background

As smart cities like Masdar City emerge, analysing their implications is necessary for a more conscious, well-informed approach to urban planning. Some leading voices in the study of smart cities include Carlo Ratti, Anthony Townsend, Adam Greenfield, and Ben Green, who present their varying ideas, thoughts, and concerns about integrating smart solutions into our urban fabric.

Ratti affirms the potential of technology in creating more efficient and adaptive urban systems through the power of data and citizen interaction (Ratti and Claudel, 2016). In his book "The City of Tomorrow: Sensors, Networks, Hackers, and the Future of Urban Life" with Matthew Claudel, he discusses how more mobile phones with active service exist than people, showing the potential of sharing services in a way that has never been done before. With this potential unlocked, Ratti envisions the transformation of urban dynamics with the Internet of Things to improve quality of life and make our lives more efficient and practical. For example, he discusses a scenario where self-driving cars and other modes of transportation could be shared and moved where needed based on a model that predicts demand (Ratti and Claudel, 2016). His views are relatively optimistic about the potential of technological integration in our cities; however, his thoughts are more exploratory, lacking solid grounds for how people would interact and come together considering this new movement. In addition, the potential he discusses is only relevant in the developed world or places where sufficient funding is available for this technological leap (Evans-Cowley, 2016).

On the other hand, Townsend highlights how our transition to smart cities is inevitable; however, he finds that our response to technology is a critical challenge (Townsend, 2013). In his book "Smart Cities Big Data, Civic Hackers, and the Quest for a New Utopia", Townsend (2013) discusses how "smart cities need to be efficient but also preserve opportunities for spontaneity, serendipity, and sociability." He believes that our current cities are the "smartest cities" and that envisioning utopian smart cities does not necessarily mean addressing the problems we currently face. He also acknowledges that each city and society is unique, meaning no tech-based solutions will be the same everywhere (Townsend, 2013). Thus, involving citizens in the planning and implementation pro-

cess of smart cities is crucial to ensure that technology serves the public.

Greenfield, in his book "Against the Smart City", criticises the conception of a top-down smart city approach that reduces people, their complexities, and interactions with the built environments to mere algorithms, warning against the dangers of treating technological systems as a universal solution (Greenfield, 2013). Greenfield (2013) also depicts how efficiency cannot be the only "metric by which urban processes ought to be judged," emphasising how this approach resembles the views of modernist planning approaches, which ultimately failed. His views also shed light on people as the smart component of the city, reflecting how urban technology should aim to support human activity instead of overpowering them and treating humans as mere sources of data. This is crucial since he regards technology as non-neutral, with each technology "encoding a hypothesis about human behaviour" (Greenfield, 2013).

Finally, Green, the author of "The Smart Enough City: Putting Technology in Its Place to Reclaim Our Urban Future," advocates for the concept of the smart enough city, reflecting how too much technology can have significant drawbacks on the city and public life. Green (2019) introduces the term "tech goggles", which "warp behaviours, priorities, and policies according to the logic of technology." Like Greenfield, he describes the risk of oversimplifying people and the city's concerns, which often results in inadequate tech solutions that do not address root causes. One serious risk of utilising technology in governance is that it may reproduce social, institutional, and racial biases in its outcomes, as the data used to train algorithms often reflects these existing biases (Green, 2019). Therefore, technology must not be the driving force in a city's political and social reforms but rather a supporting tool. This indicates that participatory design is essential in shaping a future city's tech innovations. Furthermore, Green (2019) emphasises the importance of understanding the limitations of technology to protect our cities from its potentially detrimental effects.

4. Research Question and Methodology

While the discussion highlights some of Masdar City's shortcomings, it is important to note that the city is a work in progress. The analysis does not attempt to undermine the city's accomplishments but instead aspires to learn from the city's development process as an essential part of this project's methodology. Thus, upon examining Masdar City, several lessons can be derived. Primarily, experimenting on a large-scale means spending larger budgets to prove a concept that may not work in the first place. This reflects that working on smaller-scale research and development projects, perhaps on the neighbourhood scale, could be more efficient. Secondly, while technological development is inevitable, balancing technological interventions in the urban fabric is crucial, as Townsend, Greenfield, and Green highlight. Therefore, selecting and implementing reasonable tech solutions can be more sustainable and cost-efficient than developing full-scale innovations. Furthermore, Masdar City's business-oriented approach shows that focusing on economic sustainability is insufficient for a city to succeed; a more people-centric approach ensures a well-rounded interpretation of sustainability and its varying pillars.

Considering these lessons, we pose a significant question: How can we design a city that integrates technology into its urban fabric to promote and foster community values and connectivity?

To answer this question, a framework was developed as part of "MBL 537E: Architectural Design Futures", a graduate course at Istanbul Technical University. It consisted of analysing a case study of a future city, which in this paper is Masdar City, understanding its implications and features, and then implementing a design strategy on the grounds of a site in Florya, Istanbul. As Istanbul is no stranger to the effects of urbanisation, experimenting on its grounds could provide valuable insights. The comparison of Masdar City and Florya, Istanbul, allows us to envision and implement strategies to create a more inclusive city. The design framework for Florya is entitled "The Social City" and comprises four main approaches focused on public spaces, walkability, supporting local production and initiatives, and volunteering. Each approach consists of detailed, actionable goals that are comprehensively outlined.

5. "The Social City" for Florya, Istanbul

The project site, located in proximity to Florya's residential area and public transportation facilities—namely the Marmaray train, the Metrobus line, and bus routes—is approximately 0.6 km² in size, which is ten times smaller than Masdar City (Figure 2). The site's manageable scale and strategic location make it a reasonable experimentation spot, reducing the need for building entirely from scratch (Figure 3).

Figure 2: Florya and Masdar City's Scale Difference

Figure 3: The Selected Site in Florya, Istanbul

The Social City is a response to urbanisation and its negative consequences on community life to promote community and citizen well-being. The Social City aspires to strengthen community bonds and revitalise the sense of community and civic responsibility that has faded due to rapid urbanisation. It proposes a shift in urban thinking by transforming cities into smaller "smart villages," promoting a model that fosters community engagement, social connection, healthier lifestyles, innovation, and community identity. Investing in a stronger, well-connected community helps support social sustainability, one of the often-neglected dimensions of sustainability, and positions it as a foundation for environmental and economic development. The Social City model aspires to put

people at the heart of urban planning while developing platforms and regulatory frameworks that ensure long-term sustainable living. Through people-centric, scalable technological interventions, The Social City provides an opportunity to explore how technology and urban design can work towards social sustainability in a city like Istanbul.

In metropolitan cities like Istanbul, scale and distance often form significant mobility and infrastructural challenges, which are reflected in the social dimensions of urban life and citizen well-being. This research proposes a smaller-scale urban model to address these challenges and create a more liveable and inclusive environment. The project aspires to develop a well-connected, walkable city by making all essential services and destinations accessible within walking distance. This way, the proposed model encourages walking and cycling, promoting healthy lifestyles.

This structure also strengthens the role of public squares and spaces as accessible community zones where different civic and cultural activities can be planned and organised through a digital citizen event-planning platform. Furthermore, the city is envisioned to be connected to the broader Istanbul metropolitan area via an integrated transportation system complemented by a digital mobility application that informs citizens of public transportation schedules and bus locations.

In addition, supporting local and small businesses is a primary goal in The Social City, where residents are provided with a platform that helps connect these community-based initiatives. This structure enables small businesses to flourish and provides revenue opportunities for underrepresented or economically disadvantaged groups through increased access to work and business potential.

To foster community engagement and promote civic responsibility, the model includes a volunteer-based platform where youth and residents can offer their time to support local needs. In return, participants are awarded social points to recognise their contribution. This system not only supports participants' educational and financial needs but also strengthens intergenerational ties and reinforces community identity.

The Social City is structured around four main approaches and strategies: **i. Dynamic Community-Centric Public Spaces, ii. The Walkable Grid for Green Mobility, iii. Local Business Empowerment Through Community, iv. Volunteering as a Bridge to Stronger Communities.**

5.1 Dynamic Community-Centric Public Spaces

Public spaces are paramount in connecting people; without such spaces, people cannot meet and socialise. As part of fostering community ties, providing well-located, well-designed public spaces that promote citizen interactions is essential to encourage people to socialise and interact with one another. Furthermore, by allowing citizens to play an active role in choosing and developing events of their interest, The Social City model can ensure that its public spaces are used effectively and inclusively. The key goals are designing central public spaces and city squares that are user-attractive and user-friendly and developing an app that provides citizens with the chance to be part of city events to promote citizen activity and interaction.

5.1.1 Designing central public spaces and city squares that are user-attractive and user-friendly

The city square serves as the city's main event and gathering space (Figure 4). As a well-serviced, accessible space with a central location within the heart of the city, everyone can participate in local events and enjoy the city spirit. Public spaces like walkways and courtyard spaces are meant to be green, walkable spaces where people can meet and socialise while hosting smaller-scale events at the neighbourhood scale (Figure 5).

Figure 4: The Social City's Main Public Square

Figure 5: The Social City's Open Spaces

5.1.2 Creating *The Social City* Platform, an app that provides citizens the chance to be part of city events, to promote citizen activity and interaction

Through The Social City Platform, citizens can suggest, organise, and vote for events of their interest (Figure 6). For large-scale events in the city square, citizens can share their ideas, which are later organised by the municipality. For small-scale events in local neighbourhoods, such as having a picnic, citizens can send a public invitation to a specific category. For example, an old lady wants to meet other women her age in her block. She can send an invitation to this category asking them to meet for tea in a specific public location. Furthermore, health-oriented events that promote socialising and connection, such as marathons, walking events, and sports activities, are to be highly promoted and encouraged. Citizens are encouraged to participate in these events and engage with one another through digital awards.

Figure 6: The Social City's Event App

5.2 The Walkable Grid for Green Mobility

This approach aims to provide a safe, green environment that promotes walking and cycling activities. Through a grid organisation and well-served central city artery, users are almost 5-15 minutes away from everything they could need. In addition, to promote the safe, social, and well-connected city model, the city is organised in a car-free grid with the peripheries and a main artery designed to serve as service and transportation zones. The key goals include creating a walkable city through a grid organisation, providing car-free lanes that encourage walking and cycling, and creating a mobility application for the city.

5.2.1 The walkable city through a grid organisation

The city is designed in a grid at a reasonable scale to enable users to navigate their surroundings easily while having different locations and target destinations within less than 15 minutes (Figure 7).

Figure 7: The Social City's Organisation & Dimensions

5.2.2 Providing car-free lanes and promoting cycling and walking activities while managing the peripheries and the city's main artery for a functional city model

The grid organisation and the scale of the city facilitate moving around and allow the grid's intersections to be car-free (Figure 8). The peripheries of the city, represented by the perimeter of the rectangular grid and its main central curved artery, allow vehicular access as part of the transportation strategy. While the city's policies do not promote private car ownership, users with cars or taxis can move around the grid's perimeter and central axis with one main parking space to the northern part of the master plan (Figure 9). The interior roads are designed to be utilised as service roads when necessary.

Figure 8: The Social City's Lanes

Figure 9: The Social City's Access Points

5.2.3 A mobility application to organise vehicular movement and public transportation with a regular schedule for demand-based supply

A mobility application will track people's movement patterns, their varying transportation activities, and the city's rush hours to tailor and provide transportation services accordingly. The app also allows users to track nearby buses' locations and The Social City's minibuses to plan their movement accordingly (Figure 10). The mini-buses within The Social City provide access points to the surrounding neighbourhoods and Istanbul's public transportation, like Marmaray.

Figure 10: The Social City's Mobility App

5.3 Local Business Empowerment Through Community

The Social City aspires to empower citizens with small businesses or services. The "Thrive Local" platform is a local business platform that allows those with small businesses to operate via an e-store where they can sell their services. Users looking for a specific product or service may search for it and find locals who can provide it. This model encourages local production and strengthens social bonds by fostering the values of supporting small business owners and community empowerment. The key goals include creating the "Thrive Local" app and marketing the platform to support its usage.

5.3.1 The "Thrive Local" App

The "Thrive Local" app is a platform that aims to connect local business owners with local consumers to encourage local production and consumption. Thus, the app acts as a digital marketplace where users can browse different online businesses, search for various products or services, and talk to business owners for special requests and orders. Quality control is maintained through community rating and with the value of trust that the city aims to foster (Figure 11).

Figure 11: The Thrive Local App Model

5.3.2 Marketing the platform to encourage users to support local

To encourage users to support this socially empowering business model, citizens can receive coupons, discounts, and gifts based on how frequently they use the app and engage with online businesses (Figure 12).

Figure 12: The Thrive Local App's Marketing and Economic Sustainability Strategy
(This diagram was created with the help of Napkin AI)

5.4 Volunteering as a Bridge to Stronger Communities

Different social and age groups may need help from others. Whether you need help carrying some heavy groceries or moving around your furniture, The Responsible City Platform connects those who need help with available volunteers who are rewarded with social points and develop a good citizen score, which provides them with education and financial benefits. This promotes volunteering as an essential social value while rewarding citizens dedicated to social good. The key goals include creating "The Responsible City" volunteering platform, establishing the citizen score system, and ensuring safety measures for the volunteering system.

5.4.1 *The Responsible City Volunteering Platform*: Connecting those who need help with volunteers

Through The Responsible City Volunteering Platform, people in need of help can request the aid of a volunteer through the platform, which connects them to an available volunteer (Figure 13). This ensures that people who need help will have support from people who want to be active community members.

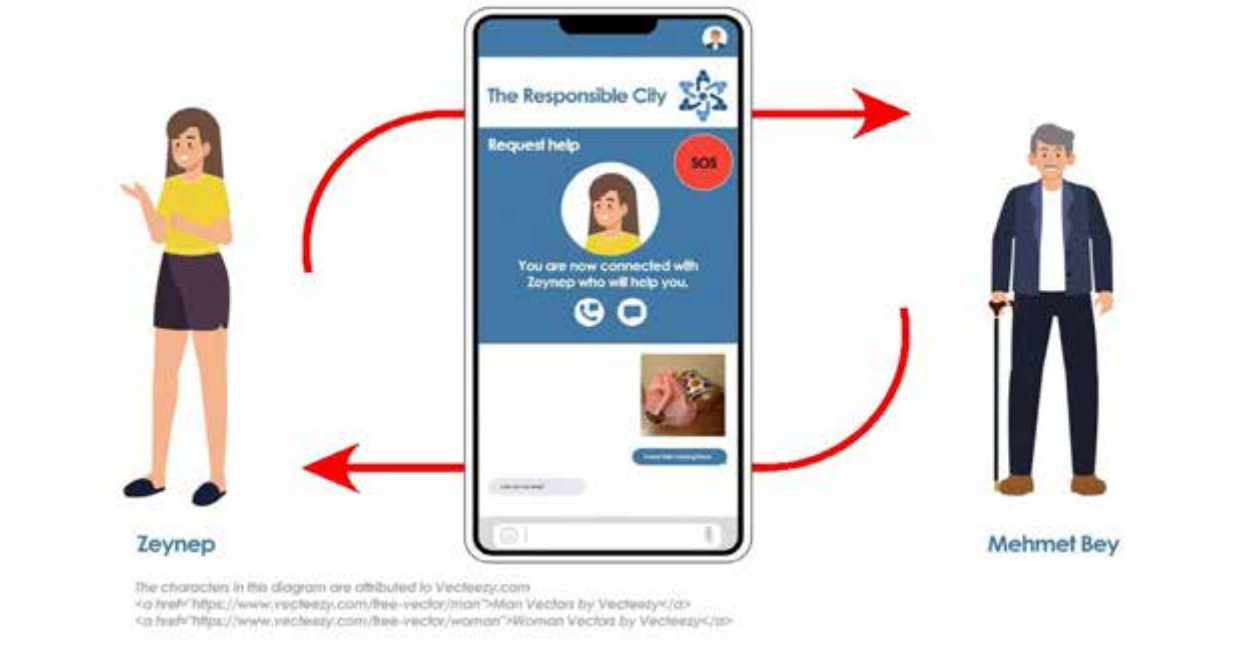

Figure 13: The Responsible City Volunteering Platform Model

5.4.2 The Good Citizen Score as a measure of volunteering activity

Citizens who actively engage as volunteers are rewarded with a good citizen score. The higher the score, the more benefits a citizen can acquire, ranging from financial support to educational fee support, discounts, and volunteering certificates (Figure 14). Furthermore, those who obtain high citizen scores can receive further training to "climb up" the social work and volunteering ladder and have a more effective social role and impact, potentially as a profession or with increased benefits. This fosters a volunteering environment that promotes civic responsibility, which enhances social bonds and connects people.

Figure 14: The Responsible City App Citizen Score and Benefits

5.4.3 Implement safety measures through volunteer training, user feedback, a point system, and tracking

To ensure the model's safety, interested individuals must attend training sessions to learn how to deal with different social and age groups before starting as volunteers. Furthermore, the Responsible City Volunteering app allows both volunteers and help recipients to offer feedback and explain their experiences. Users, whether volunteers or help recipients, acquire a score that reflects their honesty and integrity, and any users with questionable activity can be blocked from the app as a safety measure. Users are also tracked, and the app provides an emergency button if they feel unsafe and want to request help from a third party. Lastly, users may specify certain traits they seek in a volunteer, including gender and age (Figure 15).

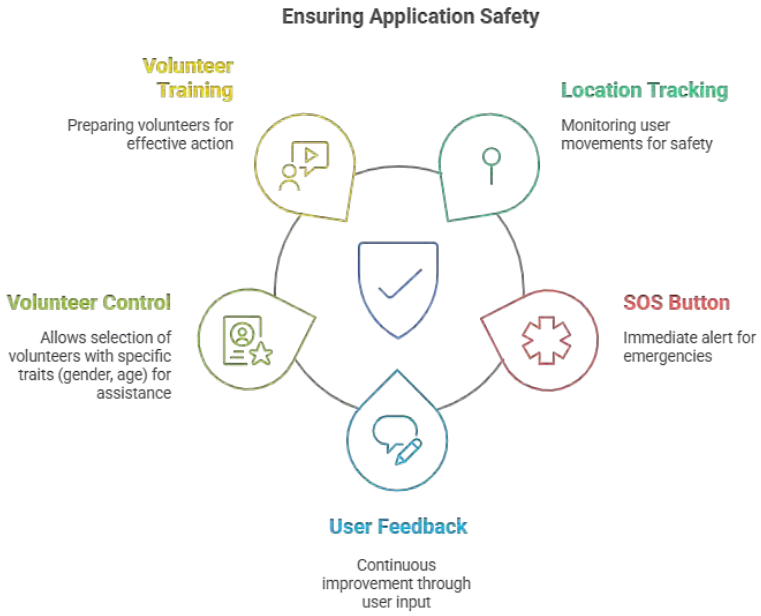

Figure 15: The Responsible City App Safety Precautions and Measures (This diagram was created with the help of Napkin AI)

6. Conclusion

Through an experimental approach, this paper aims to propose a potential smart city model for the selected site in Florya, Istanbul, based on a thorough examination of one of the most prominent examples of a smart city: Masdar City. Taking into consideration the views of influential scholars like Green and Greenfield, the proposed model aims to focus on people and their varying needs while utilising technology to foster community bonds. At the same time, it seeks to adopt simple urban planning and design decisions to render the city more liveable and functional. The Social City helps envision a smart city without heavy technological infrastructure, with a focus on using mobile phones, which are highly available (Figure 16).

Figure 16: A Summary of The Social City's Approach (This diagram was created with Napkin AI)

As this project's approach was more exploratory and experimental, more attention was given to the ideation and innovation process. Thus, a more thorough investigation of the social construct in Florya is required to modify and tailor the proposed solutions accordingly. Further studies should revolve around understanding the community of Florya and their needs and concerns in the form of a participatory process to better understand how the proposed ideas could be integrated with the existing neighbourhood and society.

Initiatives like the "Thrive Local" app and "The Responsible City" volunteering platform advocate for a shift towards participatory and inclusive urbanism; however, potential obstacles, including safety and trust-related concerns, could hinder their progress or render them inefficient. Predicting how people would engage with new ideas is challenging; thus, testing such solutions before their full implementation is essential, and developing efficient and accurate testing methodologies for the proposed ideas could take "The Social City" a step further. Ultimately, The Social City in Florya, Istanbul sets the foundation for an approach that focuses on serving people and meeting community needs with technology.

Co-Producing the Future: Imaginaries at Work in Spatial Planning Practice

Jan Schreurs
KU Leuven (Belgium)
jan.schreurs@kuleuven.be

Abstract
Two emblematic products of imagination reflect contrasting attitudes toward the future. The film Back to the Future evokes a nostalgic longing for a 'good world', while Paul Klee's Angelus Novus embodies the inevitable trail of destruction left by progress. Such tensions are inherent in collaborative spatial planning, where stakeholders are often guided – consciously or not – by divergent imaginaries. Co-producing a shared future requires the alignment of these imaginaries. Generative metaphors can serve as catalysts for convergence. This paper presents a case study that explores how such metaphors can be used to strengthen coherence among fragmented projects and different stakeholder perspectives. While this experimental attempt yielded mixed results, the concept of 'correspondence' – supported by evocative 'thought-images' – emerges as a promising avenue for enhancing collective spatial imagination.

Keywords: imaginary; co-production; metaphor; correspondence; thought-image

Introduction: Imagining Imaginaries

Planning is fuelled by imaginaries. In his comprehensive critical introduction The Urban Planning Imagination, Nicholas Phelps defines this imagination as: '[...] the faculty of forming ideas, images or concepts relevant to the task of city building where these need not be entirely new but instead are the products of an historical stream and geographical diversity of ideas, images and concepts.' (Phelps, 2021:1) Considering that imagination is defined as a faculty or capacity, and images are but one of the results of this faculty at work, we are tempted to define imaginary as the mental construction of a more or less coherent set of ideas, images, concepts, narratives, fantasies, symbols, ... This realm of imaginative representation can vary according to the socio-geographical context and can change over time.

Imaginaries can be individual and collective. Using the terms 'image of the world' and 'universe of discourse', Kenneth Boulding describes a vivid picture of the rich and complex content of individual and shared or public imaginaries. Their multiple dimensions are coined as a complex of 'images': spatial, temporal, relational, personal, value-related, affectional or emotional. These images are modulated by scalar meta-dimensional images: certainty-uncertainty, reality-unreality, public-private, conscious-unconscious-subconscious. His 'organic theory of knowledge' (Boulding, 1977:16) opens ways to 'develop a really adequate theory of behavior' (Boulding, 1977:18). Those imaginaries are necessary for people to understand themselves and their position and role in a context. It means that imaginaries play a crucial role in human behaviour. This proposition is central to our argument: changing imaginaries implies influencing behaviours. And vice versa.

Persistent crises can be the result of ingrained behaviour. Daily, we experience the results from massively spoiling water, sealing the ground, dumping garbage, thoughtless car-driving, ... Stimulating alternative attitudes, knowledge, and practices can be influenced by changing existing imaginaries. Consciously or not, that is what planning processes realise when they are designed to install new conceptual frames, e.g. sustainable development, robustness, degrowth, soft mobility, ...

In this paper, not a world crisis is calling for alternative imaginaries, but a more modest upheaval in a former mining town. A clash about the way industrial heritage is being developed, urged the Municipal Government to appoint a project director and install a quality platform (Schreurs, 2024). From firsthand experience, as project director, I describe the context and condition of this case before embarking on a metaphorical imaginary, which was created to help change the mindsets of the principal actors and stakeholders. Next an assessment analyses the positive results, as well as some setbacks of the initiated process. Thinking ahead towards improving this situation, the concluding reflections concerning correspondence, refer back to the first part, which problematises

co-production from the perspective of imagining futures, and the power of though-images.

1 Co-Production And The Future

1.1 The Future Caught In Imaginaries

1.1.1 A Lot Of Small Actions (Can) Make The Future

The number of challenges calling up spatial planning for transformative actions is dazzling and increasing: climate, water, biodiversity, neocolonialism, (anti)globalisation, degrowth, social injustice, migration, ... In planning literature 'crises' fight for focus. What would be the 'best' way to tackle this planetary crisis? What kind of spatial planning might help to resolve those big issues?

A picture in a street - a sentence on the wall of the UGent rectorial building - hit my imagination: 'The next big thing will be a lot of small things.' For many years, I have cultivated a sensibility to bottom-linked and bottom-up initiatives (e.g. Kuhk, et al., 2019). This explicit formulation on the façade of the university of Ghent's academic seat fueled my imagination ànd my hope for a potentially successful distributed and collaborative planning approach. Could 'many small things' mean: ideas and actions from many people (inhabitants, organisations, ...)? Could the sentence thus mean: ideas and actions from a large number of acting subjects can make a big difference? Then the message 'the next big thing is a lot of small things' means intrinsically the same as: our future is the result of a lot of small actions. But, how can it lead us to a better future? How to organise those many small actions as contributions to shared ambitions and aims? How to reach an immense transformative result, even without a predefined, integral plan in the 'major key' (Stengers, 2005)?

1.1.2 Expecting The Unexpected?

The future is a central issue in planning. On a regular basis, planning literature is harking back to future's uncertainty (e.g. Hillier and Healey, 2010). The character 'future' is indeed ambivalent. How drastically diverging the imaginaries about the future can be is illustrated by Jacques Derrida's witty reflection on the difference between two common French words for 'future': 'There's a future that is predictable, programmed, scheduled, foreseeable. But there is a future, l'avenir (to come), which refers to someone who comes, whose arrival is totally unexpected. For me, that is the real future.' (White, 2007:407) Such differences often stay unnoticed, while tacitly playing an immense role both while making plans and while discussing or implementing those plans.

1.1.3 'Back To The Future' As Imaginary

How important it is to be aware of the differences between contextual imaginaries can be illustrated by two emblematic narratives: a movie and a painting. Both implicitly value 'what comes' and the relevance of change, while they stage two different attitudes towards the future. Robert Zemeckis' movie Back to the future cultivates the longing for flying back from the past world of 1955 to the 'good world' of 1985. Paul Klee's Angelus Novus captures the catastrophe of progress, inevitably driving him forward into the future. Adolescent and Angel both stand with their back to the future, however, with diametrically opposite attitudes. Marty knows the future and wants to go back, but cannot because his car needs the power of plutonium, not yet available in 1955. The Angel does not know the future but is frightened to go there because it only sees the devastation of 'progress'. For one, 'future' is a brilliant destination; for the other, 'future' is leading away from paradise.

A similar ambivalence concerning the future is looming into spatial planning. With their back to the future, planners cannot 'see' the future, but have to deal with the present, using assembled knowledge and experiences from the past. Past and present are fueling imagination. Now, imagine planning initiatives for a 'better future' when some actors around the table believe in gradual improvement (e.g. thanks to technology), while others only see further degradation (e.g. also due to technology)! How to bring them into the same imaginary? How to change their attitude?

This insight about tacit imaginaries, which are potentially contradictory, results from Walter Benjamin's interpretation of the Angelus Novus. This critical analysis of history's presumed linearity of progress, offers a clear example of his famous 'Denkbilder' (Richter, 2007). Interpreted as 'thought-image', Gerhard Richter not only uses

this concept as a critical lens, but also acknowledges its 'formal site for singular and unpredictable – but not arbitrary or facile – acts of conceptual creation' (Richter, 2007:18) It illustrates both the richness and the power of (tacit) imaginaries. Imaginaries help think complex issues in coherent ways, and are instruments for innovation. This touches upon the focus of this paper: how to influence or create imaginaries for the sake of a better common future?

1.2 Co-Producing A Future

1.2.1 Challenging Co-Production

During the complex quest for concepts, strategies and instruments, collaboration is a crucial factor in spatial planning. Rightfully, it is promoted by many scholars and professionals. The circulation of a multitude of terms collaboration is dealt with in literature (e.g. co-creation, co-production, collaborative, coalition, collective...) is an indication of some confusion concerning meaning, relevance, and applicability of this concept. These span from normative (e.g. Albrechts, 2012) to functional (e.g. Medina-Garcia, 2024). Multi-actor collaboration is a major condition within planning situations, not limited to analysis, research and design, but extending into operational aspects such as action programs, communication, and implementation. In this paper, such situations will be labelled as co-production.

The practice of collaboration is not obvious. 'Co-creation and co-production [...] relate to the broader challenge of combining different types of knowledge and experiences in collective learning trajectories' (Medina-Garcia, 2024:14). Actors then have to work in processes of joint problematisation and building shared meanings (De Blust, Devisch and Schreurs, 2019). Many stakeholders need to be informed, motivated and mobilised while they are preparing to invest their creativity, time, and money in realising a project. The always present diversity in values, knowledge, experience, and means does not help to bring and keep stakeholders easily on the same track. Moreover, the actual turbulences urge planners to include and integrate knowledge and goals from an increasing number of specialist fields of research and practice: climate, biodiversity, water, energy, health, food, justice... . In addition, within participatory processes, stakeholders arrive with diverging models and imaginaries of what it means 'to collaborate': some 'take part' while others 'take a share'; some work in a complementary way while others invest (care) in a common project. Different attitudes, aims, interests and means only reinforce tensions between those images. It means that collaboration is co-laborious. How to deal with those frictions? How to create coherence?

1.2.3 Metaphors As A Medium For Changing Interaction

Metaphors are an intrinsic part of our language, shape our thoughts, and influence actions (Lakoff and Johnson, 1980). Evidence from research learns e.g. that people who think about crime as a beast or as a virus defend different remedies: more police and severe penalties versus better education and more jobs (Dekeyser, 2018). Within a context where collaboration between diverse actors with divergent backgrounds is essential, metaphors can play an important role. As creative device, metaphors produce similarity. They can make actors see sameness notwithstanding difference (e.g. 'argument is war', 'ideas are objects'). Thus, metaphors integrate by making connections between unlikely ideas, aspects or objects, often in a novel and unexpected way, creating new understanding. As framing device, metaphors can serve to reframe thoughts and practices (e.g. learn to see 'argument as dance' and not 'as war'), thus offering a similar perspective to different actors in a co-ordinated way. As epistemological device, metaphors can work integrative because of the unifying meaning of their 'vehicle' or referent that conveys the comparison (e.g. 'love is a collaborative work of art'). Metaphors' emotive character (Schön, 1979) helps to engage persons into such shifts. Thus, by introducing a well-tuned mix of metaphors, the ideas of different actors can be stimulated to shift from their evident meanings towards referents with a collective or/and integrative character.

For the case analysed in the paper, three referents played a role as generative metaphors (Schön, 1979). Ship, beacon and wayfaring were metaphorically mobilised to help look in a systematic way at the 'planning ecology' at stake (Schreurs, 2024). They were introduced to respectively frame the intended change of the character of the planning process, to guide diverse projects towards coherence, and to offer a medium for the co-ordination of ideas and activities.

1.2.4 An Experimental Co-Productive Setting

This paper analyses a specific planning practice where collaboration is a structural condition. In Beringen-Mijn, a public-private-partnership (PPP) is responsible for the urban renewal of an extensive former industrial coal mining site. As project director and chair of a multi-disciplinary quality platform, I am expected to help pilot the planning process towards a high level of spatial qualities and coherence. It is my privilege to observe and assess what is happening in a real-life instance of intense collaboration among a multitude of actors.

Within each project, steps can be intentionally induced due to my responsibilities. Whenever appropriate, transformational imaginaries (e.g. 'mine-landscape'[i]) or co-creative actions (e.g. research by design) could be introduced to generate changes in ideas or practices. The resulting dynamics are at least partially motivated by such steps in the projects. Linking those effects to infused imaginaries and actions allows to learn for next (steps in) planning processes. Although this local situation is not comparable to the more global crises often referred to, I see this case and the lessons learned as a modest experimental action research concerning the power of imaginaries in strategic spatial planning.

2. How To Co-Produce In Beringen-Mijn?

2.1 A Case Of Structural Co-Production

2.1.1 A Partnership With A Vocation

One possible way of grasping the accuracy of imaginaries in a critical way, is to learn from cases. The case is 'Beringen-Mijn', a district in a mid-sized Belgian city, developed out of a huge coal mining plant. From motor of prosperity, this miner's district became a monumental burden when the mine closed down. On October 28th, 1989, status, conditions and perspectives of the historical mine site gradually tilted in terms of physical problems (large derelict land, empty impressive industrial buildings, abandoned heritage, a worn-out garden city, ...), social tensions (spatially isolated and socially divided communities of migrants and newcomers, ...), and mental disruption (loss of work and collective ethos, traumatic history, emptied signifiers, ...).

Its enormous heritage became a heavy financial burden for the central government, which had to take care of the social passive, as well as of buildings and infrastructures. Dwellings in the 'cité', the miners' garden district, were sold rather cheaply, preferentially to renting inhabitants. The empty industrial buildings and warehouses deteriorated while being 'mined' by copper thieves and urban explorers.
Typically, such burdens also have a huge potential for new developments.

2.1.2 Heritage As A Field For Development

From dynamic productive machine, the mine turned into a complex of massive heritage, which was listed in 1993 and 1994. Considerable amounts of subsidies became available for these protected buildings, but this came with an ambitious vocation. Being listed implied conserving a coherent image of a complete mining plant, enabling to demonstrate, to explain, and to experience its former role and functioning. This huge expectation was motivated by the production unit's representativity and grandeur, its age, completeness of buildings and installations, architectural and technical value, state of preservation, compactness, clarity, present complementary activities, the presence and location of two slag heaps (Team Vlaams Bouwmeester, [2019]). The immense coal washing plant was the main reason for this entrusted vocation. With its four parts, it was formally and functionally the heart of the industrial complex (Figure 1, 2), and Beringen was the only place of preservation of such plant in the mining region of Limburg.

To implement this vocation, a public-private-partnership (PPP) was founded in 2009. This was formalised as a public limited company, named NV be-MINE, with the goal to restore, renovate, and repurpose the former mining site. A reconversion plan was made in which the destination of the mine site was seen as a touristic-recreational project. It had to comply with a new local legally binding plan (Bongaerts, 2000) that defined the location as a

i In this paper, I introduce the term 'mine-landscape' to denote a dual perspective: it refers to the physical landscape shaped by extractive coal mining; it also evokes a personal, subjective relationship to that space. The hyphenated form intentionally plays on the possessive pronoun 'mine', suggesting both territorial belonging and emotional or mnemonic attachment.

zone for urban development. The restoration and re-use of the plant was gradually implemented.

When the NV be-MINE asked the responsible minister to drop the heritage label for two of the four parts of the coal washing plant, the project took a dramatic turn in December 2018. The entailed compulsory public investigation provoked a gulf of national and international protest and pressure, and resulted in 1.311 notices of objections. Instead of coming to a head using legal procedures, the minister preferred to find common sense amongst the development consortium and heritage associations.

Figure 1. Painting (1957) of mine site with huge coal washing plants in the centre
Figure 2. Condition (2021) of coal washing plant

2.1.3 Problematising The Case

Looking for a way out of the conflict, the Flemish Government Architect was asked to mediate between the stakeholders. Reporting optimistic principles for a constructive consensus, he ventilated severe criticism as well of the way the PPP was managed. His report identifies a lack of coherence and co-ordination between stakeholders and their initiatives as one of the major objectionable aspects of the ongoing development on the mine site (Team Vlaams Bouwmeester, [2019]). Precisely this argument convinced the Municipal Executive (board of mayor and aldermen, in Dutch: College van Burgemeester en Schepenen or CBS) of the city of Beringen to take bold measures in 2020. Enlarging and re-qualifying drastically the former 'quality chamber' (kwaliteitskamer) and installing a project director (projectregisseur) explicitly aimed at fully integrated development in co-production (CB&S, 2020a). In line with the advice of the Government Architect, success was expected from two goals. Synergy and added value had to be found within an overall long-term vision on a larger scale; coherence between projects should be steered systematically and supported by all relevant actors. It would be the project director's responsibility to guard sufficient coherence and co-ordination among all current and future projects, both content- and time-wise, while pursuing cross-pollination and societal added value (CB&S, 2020b). This decision of the Municipal Executive launched a trajectory of redirection, and the direction was clear. A vision would focus on a much broader work field than the coal washing plants and was even extended towards the complete mining site. At the same time the Executive enumerated a list of at least 15 projects that waited for co-ordination, in co-production with the many partners involved: private developers and their architects, city government and administration, provincial government and administration, Flemish Government Architect, Flemish Heritage Agency, local and regional heritage associations, organized local stakeholders, and individual inhabitants.

2.1.4 Development By Bits And Pieces

The Government Architect's evaluation quite precisely assessed the situation on the field. The ex-mining territory had been compartmentalised into lots, and the fragments were declutched under separate ownerships. About 11 ha. were split off to realise 'Houtpark', a new housing district. On newly created plots between the listed historic buildings, a private swimming pool, a restaurant, and a shopping boulevard had been constructed. Besides the existing tourist reception and small mine museum, parts of the old mine buildings had been reused for nursery classes, a climbing hall, a banquet hall, a bike shop, and offices. The former thickener of the coal-washing process had been transformed into a diving centre. The largest part of the listed buildings was still empty. However, plans

were already on the table. The main spaces would be used for an experiential museum, focusing on the 'path of the miner', to be run by the province of Limburg. The technically worst part would be partly opened up to invite trees, light and rain, and partly be transformed into a casco, to be sold piecemeal.
Ownership of the partial project on the site was already given to separate stakeholders: NV be-MINE, province of Limburg, city of Beringen, region of Flanders, social housing company, school community, private families, and investors. Only NV be-MINE had a clear development model: restore listed buildings supported by subsidies, find a new, fitting program, transmit (part of) the building to third parties, by selling or establishing a long-term right in rem (e.g. long lease). Without intervention, the demonstration of a complete and coherent coal-mining history, as the minister was expecting when listing the building, would obviously not be the result of the ongoing development.

2.2 Creating An Imaginary By Images And Metaphors

2.2.1 A Working Program Fitted For Change

From the previous section we learn that levers for easily steering the coherence between projects were already gone when the project director could start to remedy. Because of the distributed 'ownership', the situation was an amalgam of collective and individual actors, each with their 'own' goals, means and trajectories. To cope with this situation, the Municipal Executive of Beringen approved my proposal for a twofold approach: conceptual and process-oriented (CB&S, 2020b). It combined Maarten Hajer's conviction that socio-spatial transitions need a shared 'imaginary' ('denkbeeld') (Hajer, 2016), with George Brugmans' three-step approach for a 'sabbatical detour' (Brugmans, 2016). In my proposal for the working program (Schreurs, 2020), the suggestion of the Government Architect to instrumentalise the 'power of designerly research' (Team Vlaams Bouwmeester, [2019]) would find a productive 'locus' in three successive workshops with the crucial stakeholders. Each workshop would deal with one of three cohesive questions. First: What do we aim at? How do we collectively look at the city-district Beringen-Mijn (including the ex-mining site)? Second: What can we aim at? How can we together articulate and discuss the desired qualities for Beringen-Mijn? Third: What will we do? How will we work conjointly while developing Beringen-Mijn?

Content-wise, the essence of each question was illuminated by supporting images. Making or choosing inspiring paintings or pictures was suggested as a guiding beacon for stakeholders' later designs. Collectively developing a 'language for quality' could eventually function as a metaphor for both understanding each other's aims and for agreeing on appropriate manners. Collectively planting and caring for a tree was foregrounded as a conceptual image for 'growing' a collaboration.

2.2.2 Becoming A Fleet

The overarching metaphor of the text was 'becoming a fleet'. The collective search for a common perspective on both the socio-physical context and the collaboration was explicitly framed within the metaphor of 'projects as ships'. Inspired by the actual, fragmented situation, I conceptualised the ongoing diverging projects as individual 'ships' with autonomous commanding officers, following a singular route towards their predefined destinations. However, to attend to coherence between these projects, captains should start thinking and acting as a collective, as a 'fleet' heading for a common destination: to realise, each for her or his part, the vocation of the ex-mine site. To reach out for that destination would demand a decisive tack, a specific twist in each ship's course. Ships' noses needed to be redirected, sometimes drastically. Imagining how wind or weight can influence the course of a ship makes us aware of the careful manoeuvre needed, but also of the energy, time and risks involved.

Since no predefined goals in terms of form and program were available, a 'beacon' for the new directions had yet to be defined collectively. And since that beacon would become defined en cour de route, a co-creative process of collective learning seemed an appropriate image to frame the future trajectories of the captains, to be defined and redefined continuously and collectively.

2.3 From A Nautical Imaginary To A Territorial Practice

2.3.1 Mine-Landscape As Common Beacon

The working program proposed to the CB&S conceptualised the quality platform as 'locus of co-production'. This platform was not only meant to be the 'place' where actors would meet to find out why and how to co-produce the different projects, but also as 'moments' of effectively co-producing a collective.
During the first meeting of the quality platform, developing shared imaginaries as 'beacons' to co-orient the 'noses' of 'ships' was presented and discussed as a success factor for co-production. As guide for qualitative development of Beringen-Mijn, the quality platform formulated a mission-and-vision statement concerning the expedient rectification of ongoing courses of the projects (Kwaliteitskamer Beringen-Mijn, 2021). In line with the Government Architect's suggestions, this text expresses enduring concerns about a mutual attuning of projects, in space and time. That mission is taken up by a vision which promotes working within interdisciplinary, integrating frameworks. The basis of their articulation is the explicit ambition to work towards sustainable development and socio-spatial qualities, but first and foremost towards a coherent mijnlandschap (mining landscape, or mine-landscape), articulated at different levels of scale. Within this perspective, open spaces, heritage and community are foregrounded as its most important facets. The focus of the vision is on links amongst, and within these facets, both on the short term (masterplan, project) and on the long term (strategy, management).

The choice for 'mine-landscape' as beacon may seem obvious, but has a fourfold motivation. First mijnlandschap is a common name in Beringen-Mijn, known and used by most stakeholders. This term does not sound far-fetched or strange, and mentally covers the territory in need of coherence. Second, 'landscape' is a concept most people can attach to easily. Everyone has an image of landscape and sees making a landscape most of the time as a positive action. Third, because of its common and positive connotations, inhabitants feel attached to the process because the term landscape – and even more: mine-landscape – makes them feel it is about 'their' habitat. Finally, because the concept is understood by most participants, but is also sufficiently plastic, landscape can work as a bridge between different individual or social imaginaries. It can be interpreted differently across social worlds, but with enough immutable content to maintain integrity. Therefore, mijnlandschap can function as a 'boundary object' (Star & Griesemer, 1989), a means of translation to help sustain coherence within the imaginaries in progress.

Figure 4. Design presentation and dialogue during design week

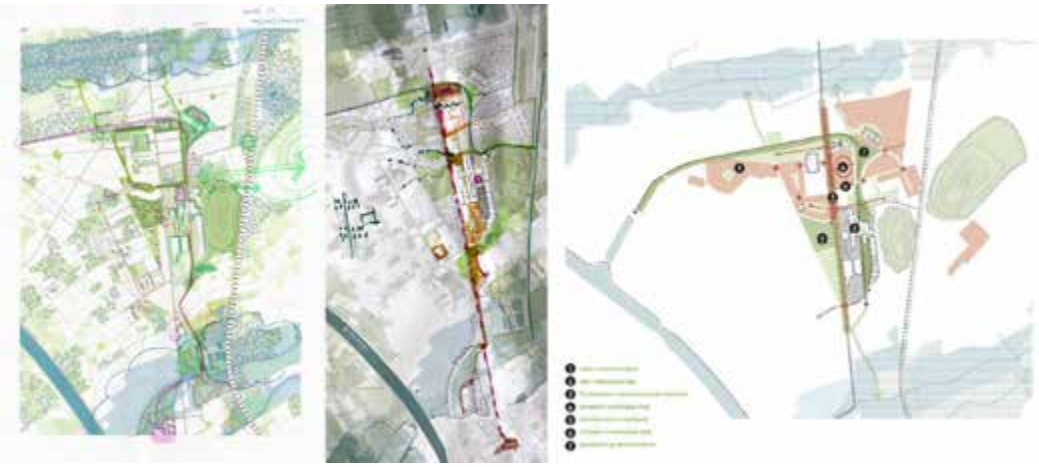

Figure 5. Strategic project interpreted by the quality platform
Figure 6. Designerly researching with the Flemish Government Architect
Figure 7. Structure sketch for Beringen-Mijn (© BUUR PoS)

2.3.2 Wayfaring Through Design-Based Workshops

An always compromising practice of priorities and agendas was responsible for a less strict working scheme than the setup of the 'sabbatical detour'. The trajectory of the projected 'tacks' involved more than three steps. Rather than rolling out a clear-cut route ahead, the pioneering search for a common definition of 'mine-landscape' turned into adventurous wayfaring. Although aims did not change, partners did fluctuate, depending on evolving dossiers, progressing insights, and personal affinities. In practice, the three thematic questions – concerning exploring aims, articulations, and actions – intertwined iteratively. This was not completely unexpected: both gradually articulating qualities more clearly and reshuffling coalitions of practice can lead to shifting ways of seeing the territory and its vocation, as well as each other's ambitions and attitudes. Nevertheless, two factors were kept constant: the middle of the table was always occupied by maps, plans, pencils and pens, and the idea of 'landscape' was never obliterated (Figures 3 and 4).

During the first 'internal workshop' of the quality platform, external experts and civil servants of the city administration prepared a new vision framework. Inspiration was found in a situation scan published by the team of the Flemish Government Architect (BUUR, 2021). This tool is offering a socio-spatial diagnosis to local governing bodies, highlighting spatial and executive strongholds and weaknesses concerning the communal territory. Stimulating a local agenda-setting of projects and policies, the scan articulates potential strategic projects. One of these projects – 'Augmenting living quality and improving the spatial structure of Beringen-Mijn' – was assessed and evaluated by the participants. Collective brainstorming produced alternative design ideas suggesting new green connectors at the scale of Beringen-Mijn. These would also strengthen cohesion between green and blue open space structures to the East and West of the central nucleus (Figure 5).

As a next step, a 'week of design and dialogue' was organised. Developers, associated designers, inhabitants, external experts, administrations, and aldermen collectively contributed by offering ideas for and comments upon the strategic project (Figure 6). Simultaneously, designerly imaginations produced a first version of what would be elaborated later into a spatial structure sketch for Beringen-Mijn. The central figure is a landscape structure of two parallel north-south axes: a functional city boulevard lined with urban services, and a recreational green connector for soft mobility. This idea was complemented by a set of seven possible actions to interconnect these axes and the surrounding cité (Figure 7).

Next, an extensive series of 'advisory design workshops' was organised, bringing together NV be-MINE, city ad-

ministrators and representatives of the quality platform. Spread over several months, this group discussed and designed innovative but feasible proposals for the use and layout of coal washing plants 1 and 3. Breaking away the worst parts of the structure should enable incorporating nature and enjoying it while growing. Although spatially invasive, this intervention was going to serve as a flag and symbol for a 're-nature' strategy, ambitiously framed as philosophy and essence of the whole redeveloped ex-mining site, and gradually applied as landscaping strategy.

In parallel, intensive 'research by design' played a decisive role in an extensive trajectory of meetings and workshops, aiming to complete the necessary plans for receiving a building permit for the new living quarter, 'Houtpark'. Starting with a declaration of intent, signed by NV be-MINE and the city of Beringen, these partners launched a steering committee, also incorporating members of the quality platform. After ten months of co-production, the result was 'Houtparkboek', an abundantly illustrated quality guideline, stimulating future designs beyond building regulations (SWECO, 2023). With its qualifying descriptions and visual references, this book gives designers and administrators tools to grasp the desired qualities of buildings and generous landscape connectors between the existing cité and the new quarter.

2.3.3 A Meshwork Of Interactions As Armature Of Co-Production

In line with favouring effective co-production, the mission-and-vision text expresses a clear intention: 'The quality platform's way of working should lead to incorporating this vision as an evident dimension of ideas and practices of crucial stakeholders and actors' (Kwaliteitskamer Beringen-Mijn, 2021; my translation). This ambition to structurally enrich the stakeholders' imaginaries was intended to be realised within a process of co-productive trajectories: during numerous conversations and dialogues, while constructing narratives about interaction, coherence and co-ordination, and during designerly research, while drawing and representing imaginative mine-landscapes.

The series of workshops already described is a good example of such trajectories. Those ran simultaneously with numerous meetings of the quality platform (hosting external experts with different backgrounds, major and aldermen, civil servants; inviting developers and designers related to the project discussed) and project-related or thematic mixed working groups. Depending on the project at stake, its character, importance, and timing, either the quality platform or ad hoc working groups (including some representatives of the quality platform) discussed intermediate proposals or engaged in more intensive dialogues with partners and stakeholders.

Gradually, the frame set during the 'week of design and dialogue' was enriched. Spatially, the structure scheme served as reference for a following series of projects on the agenda: a lightning plan for the public space on the mine site, renovation of the park surrounding the former mine director's villa, new building regulations for the garden-district mine cité, urban role of the listed former football-stadium, defining principles for the destination and development of the former water-tower, extension of the logistic park at the former coal-harbour, new policy for development and access of the southern hinge of Beringen-Mijn, destination of the restored coal-washing plant, landscape plan for Houtpark and design of the first phase of the housing-development, trajectory for a regional cycling-path, building plans for a kindergarten, renewing the school playground, ...

Analogous to the idea of 'landscape', throughout the whole process, elements were systematically situated within their context, and not given meaning without that larger picture. E.g. inspired by their original way of functioning, each coal washing plant was systematically valued in terms of complement to the three others. E.g. the relevance of building new dwellings was explained in terms of what the housing quarter will receive from, and what it will offer to the larger environment. E.g. the water tower was evaluated in terms of potential local facility, generous entrance to the park, historic demarcation, and visual signal.

All these wayfaring trajectories entangle, because – often – the same actors were meeting about many projects, in different constellations, on several occasions. Even without intersecting in conclusions or clashes, their ideas, arguments and suggestions nevertheless were influencing each other, similar to how the lines walked by pedes-

trians on a footpath develop along and with each other. Together, the bundles of narrative and designerly lines weaved a co-productive meshwork of actors, intentions and actions, into a potential armature for continuing development.

3. Evaluation And Reflections

3.1 Flourishing Development

Although turbulent at times, everyone structurally involved agrees about the positive results of four years of work. Two projects, formerly heavily criticised, were given formal permission to start implementing: the reconversion of two listed coal-washing plants and the development of a new housing quarter. Meanwhile, aspects of social and spatial sustainability improved throughout the site: re-nature became the main principle for the landscape design; stocks and infiltration of water are reinforced by new WADI's; substantial open space on the mining site is safeguarded; relationships between inhabitants and developers relaxed; collective heating is discussed and calculated for feasibility; experiments with timber frame construction are on the way to implementation; cycling and car sharing are systematically put at the agenda.

An evaluation of the process is promising. The design-and-dialogue week was emblematic of the planned approach. A co-created structure sketch shows opportunities for strengthening spatial and functional coherence between the new projects, the urban facilities and the housing district of Beringen-Mijn. Actions needed to operationalise those opportunities were identified. Moreover, designing the structure sketch staged formerly 'tacit' elements of the new 'mine-landscape': infrastructure, suburbanisation, centrality, mixed use ... and the open heath landscape where this all settled. Innovative ways of interaction between developers, the city, external experts, and inhabitants established intensive exchanges, especially during the design week, participatory dialogues, collective biking, co-visiting coal washing plants and relevant external projects. As a result, mutual understanding grew between planners, developers and inhabitants.

3.2 Flagging Imaginary

However, ambition and trust amongst the quadruple helix involved (PPP-developer, city government, social actors, external experts) gradually lost track. Looking back, several contextual reasons influenced this loss. Two key actors of the 'first hour' – the strategic manager 'environment and city development', and the director of NV be-MINE – left the scene and were replaced by less experienced and poorly networked newcomers, lacking precious contextual knowledge. As time went by, the developer gradually became more nervous about the increasing imbalance between cost and gain. Consequently economy of means burdened discussions about spatial qualities of the public space. Expenses for designers were cut, and design workshops were no longer organised.

Moreover, the option to collectively shape the beacon mijnlandschap (mine-landscape) during the wayfaring process, together with its metaphorical expression, probably led to an unthought-of flou artistique. Indeed, this option implied instrumentalising only a short description of the nautical imaginary, conveyed to the quality platform when starting, with no showing off to the public. While its facets and principles functioned as a source of inspiration during dialogues, the mission-and-vision text of the platform was never published. Probably more important was the absence of a figuration of the proclaimed beacon. The 'content' of the pursued mine-landscape was not addressed in a tangible way, other than stories. As a result, the beacon loomed up as a rather foggy silhouette. Moreover, the short narrative of ships tacking to a collective beacon might have generated a rather one-dimensional imaginary of projects with one final destination, to be reached within a limited time frame, one project at a time. The continuous and collective care, which will be needed to keep the mine-landscape in good shape, leached from the image. The time necessary for creative wayfaring, as well.

3.3 Strengthening The Landscape Of Correspondence

Regarding this situation, the motivation to hark 'back to the future' is growing. Implied questions are: How to construct a performative shared perspective on the world, that spurs a commonly supported goal-orientation and enables enduring practices? What kind of imaginary (as imagined representation of the future) can help to make the beacon 'mine-landscape' stand out of the fog?

3.3.1 Correspondence Needs A Language For Quality

Co-production is primarily social interaction, as demonstrated in the case description. Interestingly, Tim Ingold spells out two modalities of relationship among acting subjects: 'between' and 'in-between' (Ingold, 2015). For instance, communicating by letters, people bridge the distance in space and time between them by informing each other about matters of interest. These letters are written with an intention. But in sending, waiting for an answer, reading, answering, expecting, ... respondents also generate a flow of in-betweenness. 'Thus while letters may go back and forth, the correspondence has no starting point or end point. It simply carries on.' (Ingold, 2013:105) And, importantly, this 'midstream' of correspondence, this movement is sentient. 'To read a letter is not just to read about one's respondent, but to read with him or her.' (ibidem) Writing and answering embody a flow of attention.

Ingold frames continually answering to one another as a 'correspondence of lines'. According to him, this concept is relevant for many areas of human relationships, such as kinship, economy, religion and politics (Ingold, 2015). I see no reason to exclude spatial planning. To get an implementation-oriented design made, authors with diverse disciplinary backgrounds need to create occasions to communicate, with the intention to exchange ideas, test them designerly, critically discuss proposals, and translate them into decisions. In Beringen-Mijn, many such connecting moments were established between actors during every project. Those interactions served the articulation of matters of interest: functional intentions such as making timelines or setting agendas; or qualitative intentions such as goal-setting, discussing referential projects or enriching successive sketches.

The importance of an attentional 'ecology of correspondence' (Ingold, 2015:155) is, however, highly undervalued, though crucial for long-term success. City development is more than delivering enrolled projects. Upcoming projects to anchor and strengthen still vulnerable societal aims, need to be welcomed. Management and enduring care are necessary to keep results in good shape. Actions of inhabitants and builders should capture the guiding imaginary, and carry this on. To ensure this ongoing correspondence continuity, a language to articulate matters of concern becomes a crucial condition. Let's call it a 'language for quality'. Mastering and continually enriching such an in-betweening language will be necessary to capture and convey crucial interpersonal aspects of affect, such as building trust.

3.3.2 Correspondence Needs Translation

Considering some hindrances of the co-production in Beringen-Mijn (different actors depending on projects, personal changes, more projects to go, ...), it seems important to strengthen the long-term dynamic of correspondence.

Co-producing a beacon was expected from wayfaring through a collective mental landscape. During the numerous meetings, words and images of many participants were reassembled by dialogue and design along imaginative lines of thought. Often, those were open ideas and reflections, not necessarily meeting in a final design. Usually, they developed along and with each other, as entwining lines, sometimes interweaving, sometimes knotting. Together, they form a meshwork of mental paths, as memory of collective learning. This imaginative memory was, however, never grounded in a synthetic representation, e.g. an inspiring landscape design.

Within the quality platform, the idea is looming that this memory for the future might be backed up by a contextual thought-image. To make developing lines of thought of engaged actors enduringly tally with the overall vocation of a coherent mine-landscape, a 'transducer' (Ingold, 2013) will be useful. Such representation could help to translate the flow of ideas about 'mine-landscape' from the register of actors' ideas (concepts, values, engagements, interests, ...) to the register of actions (designing, qualifying, calculating, constructing, ...). Gradually, the concept for such a thought-image is being developed already by synthesising and enriching existing maps, projects and images of the mine-landscape. As a start-up, a first attempt was included in the evaluation report (Schreurs, 2024b). A collage of projects-in-the-making on the map of actual Beringen-Mijn hints at a future-to-be-made of the evolving mine-landscape: a 'landscape of landscapes' (Figure 8).

Figure 8. Future Beringen-Mijn: a landscape of landscapes (collage of 3 plans)

Prospect
Co-producing an open, more artistic visual representation could probably be a well-functioning and richer planning method (Phelps, 2021) to seduce or persuade actors into an engaging correspondence. Inspired by two examples from Richter (2007) – Benjamin's staging of the Angelus Novus, and the structure of Baroque emblems – the format of a three-fold thought-image seems promising.

First, the name mijnlandschap (mine-landscape) can be transformed into a conceptual 'motto' by 'estranging' the word into mijn|land|schap. In Dutch, this decomposition evokes both mine-land-scape and my-land-scape. Each component carries layered meanings: mijn (mine) refers to personal perception and appropriation, land (land) to the geological and biophysical characteristics of a place, and schap (scape) to the collective ownership and care of a shared environment. This linguistic and conceptual shift opens up the notion of landscape: from primarily optical to haptic, from individual to collective, and from static to dynamic.

Second, a triadic lens may help to articulate this broadened perspective in three dimensions: zien & zijn & zorgen (seeing & being & caring). An interpretive commentary or 'epigram' can highlight the interplay of engaging personal experiencing, social living and timely caring. These dimensions capture the mine-landscape as 'the sum total of actions that people and groups undertake to build and shape their environment' (Oles, 2014:22).
Finally, a layered 'icon' can function as an 'eidetic' image (Corner, 2014), expressing those dimensions in terms of place, meaning and use (Figure 9). As an open collage, with changeable pictures, this is an artistic/poetic invitation to 'a way of thinking that is neither instrumental nor representational but simultaneously both' (Corner, 2014:250).

This emblem or thought-image for the mine-landscape, is a potential canvas for a 'language for quality'. The combination of a vocation (motto), a grammar (epigram) and a vocabulary (icon) allows stakeholders to explore the landscape of common concerns. By collaboratively layering (representations of) place, meaning and use, they can discuss how the mine-landscape will not only be materially transformed but also personally and culturally inhabited.

Acknowledgments
I would like to express my sincere gratitude to all individuals and institutions who contributed to the successful completion of this paper. In particular the members of the quality platform (Peter Douven, Benjamin Hens, Maarten Horemans, Liesbeth Huybrechts, Werner Janssen, Adriaan Linters, Marc Martens, Willy Miermans, An Moons, Ganaël Vanlokeren, Sylvie Van Damme, Thomas Vints, Oda Walpot), the critical readers of the first evaluation report

(Thomas Vints (Mayor of Beringen), Karolien Sas (NV be-MINE), Koen Nulens (LRM), Guy Vanderlinden (Beringen)) and all designers, developers, stakeholders, inhabitants... who contributed with presentations, dialogues, proposals and critique to the work of the quality platform.

Sensemaking In Urban Experiments: The Case of Barcelona's Superblocks

Manuel Caldeira
Affiliation: HHL Leipzig Graduate School of Management
Email: manuel.caldeira@hhl.de

Keywords: Sensemaking, Urban Experimentation, Enactment, Learning, Complexity

Abstract
This research analyses the Superblocks initiative in Barcelona within the broader context of urban experimentation. It assesses whether the participatory process adopted aligns with the constructs formulated within Weick's (1988) concept of enacted sensemaking. The research uses a thematic analysis of the minutes from 11 participatory meetings that took place before, during and after the project. The results emphasise the importance of considering the overlooked identity dimension when planning future projects, as this can promote social learning. This study addresses the current lack of literature bridging the gap between urban experimentation and organisational change theories.

1. Introduction

Recently, a substantial body of literature on urban experimentation has emerged, offering a relevant, inclusive and practical approach to system innovation and structural change in contexts of urban uncertainty and ambiguity (Raven et al., 2019; Sengers et al., 2018, 2019). By promoting piecemeal interventions and gradual changes to the urban landscape, urban experimentation enables deep-rooted transitions and adaptations to urban reforms, encouraging support and legitimization of these measures (Evans et al., 2021). Consequently, urban experimentation has become a central concept in sustainability transition literature, with urban and transition studies scholars exploring these processes and how urban experimentation can influence broader transformational processes (Raven et al., 2019).

Urban experimentation has also been situated in the context of complex systems (Sengers et al., 2018) and thus in the context of complexity theories. Rittel & Webber (1973) first developed the concept of 'wicked' or complex problems in planning, conceptualised as issues shared by multiple stakeholders with competing perspectives, conflicting interests, different types of uncertainty and significant intangibles. Urban structures tend to evolve through cooperation rather than being dictated by a central planner (Rittel & Webber, 1973). Portugali, one of the most relevant authors on complexity in urban contexts, has elaborated on the concept of urban self-organisation (Portugali, 1997), derived from Haken's (1980, 1985) synergetics, to describe urban structures. The call for a trial-and-error, as found in complexity theories of cities (CTC), makes planners participants in a 'huge self-organising process' (Portugali, 1997). This approach helps to connect complexity theory with the exploratory nature of urban experimentation.

The concept of learning is central to both urban experimentation and complexity (Sengers et al., 2019). Approaches to urban experimentation that are relevant to this focus on the learning processes initiated by these experiments, such as transition-oriented experimentation (van den Bosch & Rotmans, 2008) or strategic niche management (Seyfang & Haxeltine, 2012). Meanwhile, concepts such as double-loop learning (Sterman, 1994) and adaptive and generative learning (Senge, 2003) frame learning in terms of complexity, locating it at the level of assumptions, behaviours, norms, and interpretative frameworks.

Yet, despite the clear link between urban experimentation and complexity, there has been no systematic interaction between the former concept and relevant complexity-related organisational theories. These theories encompass a broad range of research, including Lewin's action research (Lewin, 1946, 1947), systems approaches (Checkland, 2000; Ulrich & Reynolds, 2010) and enacted sensemaking (Weick, 1988, 1995).

This research aims to demonstrate the undeniable utility of organisational theory, particularly Weick's (1988,

1995) seminal work on enacted sensemaking, in the context of the uncertainty and ambiguity of urban experimentation (Sengers et al., 2019). Sensemaking is the process of interpreting cues about reality to create knowledge about a given situation (Weick, 1988). In short, sensemaking involves placing an input within a framework (Weick, 1995). Understanding these concepts enables better control of appropriate enactment strategies, which can facilitate new approaches to urban experimentation.

This paper uses a framework drawn from Weick's work (Maitlis & Sonenshein, 2010; Weick, 1988, 1995) to investigate perhaps the most iconic case of urban experimentation: Barcelona's Superblocks. The aim is to determine whether the Superblock project addressed the principles of enacted sensemaking, and to explore the potential benefits of doing so.

The paper is structured as follows. The 'Context' section provides an overview of the Superblock project with a focus on Sant Antoni and offers a brief summary of the concept of sensemaking. The 'Research Framework' section adapts the three meanings of sensemaking to the research framework used. The 'Research Methodology' section details the principles of the thematic analysis performed and outlines the documents used. The 'Results' section explains the objective outputs of the analysis and presents categorisation examples for each analysis topic. The 'Discussion' section presents the research's key arguments, linking the discussion of sensemaking to urban experimentation and learning. Finally, the 'Conclusion' section summarises the key findings and suggests avenues for future research.

2. Context

2.1 The Experimentation of the Superblocks

The Superblocks Project is a flagship initiative launched by Barcelona's city council in 2015. The project involved creating clusters of traditional grid-shaped city blocks with car-free public spaces within them. Implementing these superblocks required severely restricting car access to pedestrianised areas and changing traffic flow, with main car traffic being diverted to neighbouring streets. The project aimed to create urban spaces that are more pedestrian-friendly and suitable for children and other vulnerable groups, while promoting more sustainable mobility.

The first superblock was introduced in the Poblenou neighbourhood in 2016, with further projects implemented in other districts until 2023. The implementation of the superblocks was associated with the government of Ada Colau, who achieved an unexpected victory in the 2015 municipal elections. Although a preliminary policy had been approved and included in the Urban Mobility Plan by the previous centre-right mayor (Estruch-Garcia et al., 2024), it was under Colau's leadership that the city adopted the superblocks as a signature project, linking them to other initiatives aimed at reducing car use through pedestrianisation and expanding cycle lanes. From the outset, the city has used the 'superblock' label for various operations across the territory, even reframing earlier, unrelated interventions under the same heading, such as those in Gràcia or Passeig Sant Joan (Boeck, 2021).

The first Superblock Project implementation in Poblenou was met with criticism. A group of citizens organised a non-legally binding referendum, which resulted in the project being discontinued. However, the referendum had a low turnout, raising doubts about its representativeness. The city council proceeded with the Superblock project without adequately informing the public, prompting opposition (Versigghel et al., 2023). According to the same authors, although some opposition to the project persisted, the municipality was able to increase acceptance of the project by undergoing more participatory processes and intensifying consultation rounds after the initial implementation. The Sant Antoni Superblock followed, and the Municipality's strategy was reportedly more cautious, slowing down the intervention stages and actively consulting local residents and workers.

The Sant Antoni Superblock was the first to feature a participatory process from the start. The first meeting with the Steering Group took place in February 2017, and a further ten were held until April 2022 (Supermanzana de Sant Antoni, 2017).

Despite its international success, the project was controversial in the city and polarised political parties during Colau's government (Boeck, 2021; Estruch-Garcia et al., 2024). In the 2023 elections, Ada Colau lost votes and went into opposition. During the campaign, differing positions on the Superblock were set the stage for a reward-punishment dynamic in voter behaviour, and residents directly impacted by the project were likely to either reward or punish the incumbent party (Estruch-Garcia et al., 2024) Although different studies have shown an increase in the tendency to vote for Ada Colau in the Superblock districts (Estruch-Garcia et al., 2024; Marquet et al., 2024), these studies have some limitations. Firstly, they do not guarantee the same population measurements and may overlook events such as the gentrification of districts, which is one of the concerns associated with the measure. Secondly, they only test the localised effects of the superblocks in their immediate vicinity and do not consider how the wider public perceives the actions (Marquet et al., 2024).

Conversely, the media's opposition to the measure often focused on issues such as Barcelona's alleged disorder and decadence, the 'war on cars', and strangulation of the city (Nello-Deakin, 2022). Although the Municipality repeatedly expressed its intention to implement the measure systematically across the whole city rather than in certain neighbourhoods only (Versigghel et al., 2023), by 2023, the affected districts were mainly in central locations (e.g. Poblenou, Sant Antoni and Eixample), raising concerns about gentrification and the promotion of tourism.

The potential challenges of the Superblocks concept are consistent with recent studies that have focused on the limitations of urban experiments, particularly with regard to their ability to promote learning, legitimacy, and the alignment of social goals (Eneqvist et al., 2022; Scholl & Kraker, 2021). Additionally, Colantone et al. (2024) have demonstrated how the implementation of comparable green initiatives has resulted in mounting public dissatisfaction and electoral repercussions. Their study found that residents affected by a car ban in Milan were significantly more likely to vote for the far-right Lega party, which opposed the ban, in subsequent elections. These findings highlight the need for a more in-depth discussion and understanding of the real impact of urban experimentation on urban transitions.

2.2 Enacted Sensemaking

Enacted sensemaking involves a process of forming a coherent worldview by interpreting cues, as well as contributing to the worldviews of others through a sense-giving process (Maitlis & Christianson, 2014a). Therefore, sensemaking involves actively creating environments through one's actions and interpretations (Weick, 1988). This "two-pronged" process of learning and acting relates to Lewin's (1946) action-evaluation interactive process and to Checkland's (2000) conception of an ever-changing problematic situation. This means that action not only proceeds cognition – meaning that one cannot understand a system without trying to change it (Schein, 1996) –, but also that any action upon a problematic situation is immediately followed by a change in the problem itself, requiring constant adaptation to the situation. These core concepts help to explain how urban experimentation shapes broader processes of transformation (Raven et al., 2019).

These authors' emphasis on process-oriented strategies, human-centred approaches, and the tentative nature of change renders their work relevant to the literature on urban experimentation. It should also be noted that all of the literature highlights the risks associated with failure in collective learning processes. Failure to enact sensemaking can negatively impact the life of an organisation. Lewin's three-step model — unfreeze, move and refreeze — can be used to illustrate the importance of ensuring that the sensemaking process freezes in the final stage, rather than returning to the previous status quo and becoming just a 'shot in the arm' for the problem (Lewin, 1947). Failure to refreeze the organisation leads to a process of disconfirmation, resulting in a counter-productive contribution to change (Schein, 1996). Better control over appropriate enactment strategies could empower urban experimentation.

This research builds on Weick's three basic constructs of enactment, namely commitment, capacity and expectations (Weick, 1988). It also builds on the update made by Maitlis & Sonenshein (2010) , relating it to turbulent organisational contexts and renaming the concept of capacity 'identity'. This concept of identity is consistent with

other relevant literature (see Weick, 1995). These three concepts enable us to understand the activities involved in creating a shared worldview, which is present in both crisis and change management literature. These concepts serve as building blocks for analysing the enactment process in urban experiments, acting as both enablers and barriers to the sensemaking process (Weick, 1988, Maitlis & Sonenshein, 2010).

Commitment reflects the extent to which we recognise the need for change, and is foundational to sensemaking (Maitlis & Sonenshein, 2010). However, it can be both productive and unproductive to associate commitment with a previous state of affairs, as individuals tend to generate retrospective explanations to justify a position they have already committed to (Weick, 1995).

Capacity, which Maitlis & Sonenshein (2010) also refer to as 'identity' (a term adopted for the purposes of this study), is the way in which we understand our role and agency within a given context. People tend to pay attention to what they believe they are capable of acting upon (Weick, 1988). Identity is usually most evident when it is threatened; therefore, it is necessary to create an environment in which our identity is adequately challenged. Our perception of identity is never free of preconceptions and can easily be influenced by salience. During organisational change, identities are often completely replaced (Corley & Gioia, 2004).

Expectations, combined with contextual cues, create meanings which are then used to filter subsequent cues, building confidence in a definition of the situation (Maitlis & Sonenshein, 2010, p. 564). Undermining or exaggerating the impact of urban change can have significant implications for its implementation and acceptance by the population. Table 1 displays different examples of the conditions of enacted sensemaking.

Table 1 – Applied constructs of enacted sensemaking

	Context	**Commitment**	**Identity**	**Expectation**
Mann Gulch Fire	Weick's (2009) analysis of a fire incident in which several smoke jumpers were killed after choosing not to leave their tools behind	Firefighters are committed to a set of meticulously rehearsed procedures for extinguishing fires	Firefighters told 'drop your tools' immediately feel as losing their identity to one of people fleeing the fire	Hopeful expectations were created by labelling the fire as routine and relatively easy to manage
Alps' Lost Soldiers	Weick's (1979, in Maitlis & Sonenshein, 2010) tale of a group of soldiers who safely find their way through the Alps using a map that later turns out to be of the Pyrenees	Tenacious commitment to a plan to escape from the mountains helped keeping the group moving	Soldiers believing that escaping was within their capabilities helped keeping the plan	Setting hopeful expectations on the plan helped keeping panic at bay and keep moving
Bhopal Disaster	Weick's (1988) analysis of a disaster in a plant whose symptoms were overlooked by everyone (e.g. alarms were shut off and refrigeration equipment was disconnected).	Lack of commitment to safety and commitment to other opposing values – commitment to secrecy and cost cutting	Employees readily grant the supervisor's claim to authority and the implied capacity to act, taking any responsibility away from them	Low regard for the tasks at hand led to sloppy procedures and inattention to details from every worker and manager in the factory

3. Research Framework

This research adapts Weick's (1988) framework to the context of urban experimentation. Each construct – commitment, identity and expectations – has specific implications for the population and different ways of addressing. This section briefly adapts these three dimensions to an urban setting, providing clear definitions and outlining the framework used in this analysis. The intention is to create a roadmap for analysing the minutes, providing possible examples found within them. The role of each dimension is extensively explored in the discus-

sion section, as well as the concrete cases found and the links to other relevant discussions.

In an urban experimentation setting, the commitment shared by all people should be to the idea of sustainable transition. Common problems arise when faced with divergent opposing commitments, for example a shopkeeper who sees pedestrianisation as a barrier to their business, which can lead to resistance to the transition and retrospective justifications. Therefore, the person presenting the policy should seek to present the case and emphasise the need for deep commitment to the experimentation. At the identity level, the focus is on understanding the scope of action as broadly as possible in order to encompass actions that will meet the need for experimentation. In an urban context, the problem often lies in abandoning an old identity rather than finding a new one – for example, adopting a new way of commuting. An individual's choice of commute (e.g. using a car) may become part of their identity. Expectations relate to a person's understanding of how a given transformation will impact their life at any given moment. In an urban setting, clearly stating the consequences of interventions, providing good descriptions of them and promoting population engagement from an early stage can help to ensure that expectations are formed correctly. Table 2 shows how the meanings have been adapted to fit this research framework.

Table 2 – The research framework

	Commitment	**Identity**	**Expectations**
Relevant objectives in an urban experimentation, related to each construct	Emphasise the importance of the project for society and future generations. Align the commitment to sustainable transitions with other commitments in one's life. Create a sense of urgency around achieving sustainable transitions.	Demonstrate one's ability to adapt to urban transitions. Facilitate a process of questioning preferences, identifying implicit biases, minimising distractions, reducing certainty and overcoming paradigm blindness. Build a new shared identity around sustainable mobility that is compatible with people's lives and culture.	Address people's anxiety about disruption to their lives by describing the impact of the process and providing a clear picture of how it will play out. Demonstrate one's control over the process.

4. Research Methodology

After an initial enforcement period of the superblocks, the city of Barcelona launched intensive rounds of consultation with citizens and stakeholders (Versigghel et al., 2023). The city council hosted participatory meetings that brought together traders, residents, and other local district entities to propose and co-create the analysis and design of the interventions. The Sant Antoni district was the first to hold these meetings since the beginning of the project.

Considering these meetings as triggers of the sensemaking process, characterised by a confrontation of the status quo and interruption of an ongoing activities (Maitlis & Christianson, 2014b), this research uses the minutes from Santo Antoni district meetings to analyse the three constructs of enacted sensemaking during the participatory process. Thematic and critical analyses of the minutes were carried out. The different documents and meeting minutes were accessed via the Ajuntament de Barcelona website (Supermanzana de Sant Antoni, 2017) (Table 3).

Table 3 – Minutes consulted

Document	Date	Coded Remarks
Minutes of the Session with the Sant Antoni Driver Group	27 Feb 2017	36
Minutes of the Session with the Sant Antoni Driver Group	15 Mar 2017	19
Minutes of the Session with the Sant Antoni Driver Group	13 Jun 2017	43
Minutes of the Session with the Sant Antoni Driver Group	14 Jun 2017	15
Minutes of the Session with the Sant Antoni Driver Group	02 Nov 2017	2
Minutes of the Session with the Sant Antoni Driver Group	12 Dec 2017	80
Minutes of the session of the Driving Group and traders of the Sant Antoni Superblock	09 May 2018	40
Minutes of the session of the Driving Group and traders of the Sant Antoni Superblock	26 Feb 2019	23

Minutes of the expanded Driving Group of the Sant Antoni Superblock	28 Oct 2019	46
Monitoring Session of the Sant Antoni Superblock	26 Apr 2022	52

Files retrieved from: https://ajuntament.barcelona.cat/superilles/es/content/sant-antoni (accessed 16/09/2024)

Braun & Clarke (2006) define thematic analysis as a foundational qualitative research method involving the identification, analysis and reporting of patterns within data. According to the authors, it offers a flexible and accessible approach and allows the organisation and description of qualitative data sets in rich detail, deriving meaningful insights from it. This has made thematic analysis a valuable tool in psychological research and beyond.

The analysis does not aim to cover the content of the initial project presentation or the project's specific details. Rather, it aims to understand the nature and content of the discussion held during the meeting segment dedicated to the participatory exchange of ideas with the public (i.e. the question-and-answer session). The analysis of the minutes was conducted at a participation level, meaning that each entry point in the dataset was a remark made by an individual, which was divided into different parts when covering different ideas. This approach was adopted both to achieve a reasonable level of segmentation and because the way the minutes were typed changed throughout the project, resulting in inconsistent data structure and necessitating adaptation of the thematic analysis.

Each entry point was coded according to three main themes: 'Remarks type', whether the remark was voiced by a project proponent or participant and whether it was a positive, negative or neutral comment, request or question; 'Remarks subject', depending on the main subject covered in the remark, which was coded as public space, automobiles, public transport, bicycles, motorcycles or logistics; and 'Remarks nature', that varies according to the construct, i.e. commitment, identity, expectation or the group 'others'. Each remark was coded according to the most salient category concerning its 'type' and 'nature', while the 'subject' was coded according to specific keywords that featured in the text.

5. Results

This section presents the results of the thematic analysis of the minutes. The website of the Ajuntament de Barcelona states that the work carried out in Sant Antoni is the result of a debate process involving neighbours, business owners and other local associations, who constituted the steering group (Supermanzana de Sant Antoni, 2017).

The first meeting was held on February 17th 2017 and the last one on April 26th 2022, with a total of 11 meetings listed on the Ajuntament de Barcelona website (Supermanzana de Sant Antoni, 2017). Work on implementing the

Superblock began in September 2017 and was divided into three phases, extending until October 2019 (Ajuntament de Barcelona, 2019c).

The meetings always followed a similar format. First, there was an opening session with an introduction to the agenda and an overview of the superblock framework, along with some remarks about previous sessions. Then, there was a question-and-answer session about the project or specific issues regarding the intervention. For example, the meeting held in February 2019 focused specifically on loading and unloading logistics, while the meeting held in June 2019 focused specifically on the construction process and timings.

5.1 Remarks Type

The type of remark was coded into two main groups: proponents and participants. These two groups represent a clear distinction between the people participating in these sessions: the Ajuntament representatives, who were on the side of those proposing the superblocks, and the civic society entities participating in the process. This clear differentiation is evident throughout all the analysed minutes.

The remarks from civic society entities and individuals were categorised according to the type of participation they represented: questions, neutral comments, negative comments, or positive comments. This categorisation provides a brief insight into the views of these entities (Table 3).

Table 4 – Type of remarks

Row Labels	Remarks
Participant	178
Neg Comment	41
Neutral Comment	42
Pos Comment	9
Question	86
Proponent	205
Proposal	205
Grand Total	383

The balance of remarks from participants (178) and proponents (205) indicates a participatory process. Within the group of participants' remarks, a prevalence of questions (86) is visible, followed by a nearly equivalent number of neutral comments/requests (42), negative comments (41), and lastly, positive comments (9).

Questions were mainly asked for two reasons. The first was related to the project's operational characteristics, e.g. requests for information on unloading and street parking, or specific points such as the Ferran Sunyer School exit (Ajuntament de Barcelona, 2017b) , the location of motorcycle parking spaces (Ajuntament de Barcelona, 2017a), the location of logistics unloading bays or cycle lanes (Ajuntament de Barcelona, 2018), or issues related to the construction site (Ajuntament de Barcelona, 2019a). The second category of questions was related to the outcome of the project. It was asked whether the project was the same as that implemented in Poble Nou (Ajuntament de Barcelona, 2017b), . Other questions related to forecasts for an increase in traffic looking for parking, specifically on Viladomat Street (Ajuntament de Barcelona, 2017a), whether there would be a gentrifying effect on the neighbourhood (Ajuntament de Barcelona, 2017e), and whether there were studies proving that the project would reduce pollution, given that it would cause vehicles to slow down and turn more (Ajuntament de Barcelona, 2017d).

Neutral comments/requests are usually remarks that describe the participants' needs without making any direct positive or negative judgements about the project. Examples include requests for traffic management, such as

improving neighbourhood access (Ajuntament de Barcelona, 2017b) or reducing traffic speed with the help of speed cameras (Ajuntament de Barcelona, 2017e), managing parking by creating new parking areas or changing from blue to green parking zones (Ajuntament de Barcelona, 2017e), and deciding on furniture locations, such as placing benches outside a school (Ajuntament de Barcelona, 2017a), and expressing opinions on newly created or grown bar terraces (Ajuntament de Barcelona, 2019b).

Negative comments encompass negative opinions on various topics, such as the outcome of the project – e.g. the idea that the neighbourhood would become a maze (Ajuntament de Barcelona, 2017b) –, the fainess of the project – e.g. illustrating that some streets will be improved but others will worsen their current situation (Ajuntament de Barcelona, 2017c) –, or general complains – e.g. complains from Shopkeepers on Calabria Street and Viladomat expressing being "left out" of the action (Ajuntament de Barcelona, 2019a), or the idea that Sant Antoni is tired of being a testing area for Barcelona (Ajuntament de Barcelona, 2022) –; and even complains about specific operational characteristics – e.g. complaints about the loss of parking spaces (Ajuntament de Barcelona, 2018), complaints about two-way cycle lanes (Ajuntament de Barcelona, 2017d), and specific traffic management in certain areas, such as next to the Cotxeres Civic Centre (Ajuntament de Barcelona, 2017c), as well as the lack of cleaning and maintenance of the new spaces created (Ajuntament de Barcelona, 2019b).

Positive comments are usually expressed in support of the project. For example, AMPA Ferran Sunyer School appreciates the work done (Ajuntament de Barcelona, 2017b), Vicenç Gasca values input, consensus and support for the measure (Ajuntament de Barcelona, 2017e), requests for the expansion of the measure (Ajuntament de Barcelona, 2017a), or the great satisfaction with the project demonstrated by the Ferran Sunyer Primary School (Ajuntament de Barcelona, 2019b).

5.2 Remarks Subject

The subject of the remark is divided into the six most common topics: public space, automobiles, public transport, bicycles, motorcycles and logistics. Each remark was attributed to one of these categories when a keyword related to the concept was found. This means that each remark may cover different subjects (Table 3).

Table 5 – Remarks subject

Public Space	Automobile	Public Transport	Bicycle	Motorcycle	Logistics
92	76	12	21	6	54

The subject of 'public space' was the most frequently addressed topic (92), relating to street furniture, greenery and shop terraces. This was followed by 'automobiles' (76) and logistics (54). Further down the ranking were 'bicycle' (21), 'public transport' (12) and 'motorcycle' (6). Different topics arose in different meetings. Different topics arose in different meetings. Figure 1 shows the proportion of topics covered in each meeting.

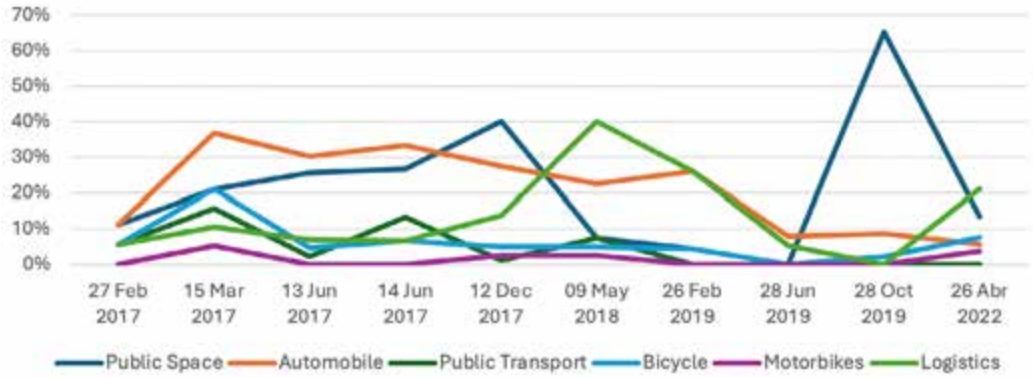

Figure 1 – Proportion of remarks attributed to each subject per minute[1]

1 The minute of the meeting held on November 2017 was excluded from the graph due to lack of substantial content

5.3 Remarks Nature

The nature of the remarks was coded according to the main themes addressed in the research framework, which draws on Weick's (1988) and Maitlis & Sonenshein's (2010) three constructs of enacted sensemaking: commitment, identity and expectations. A fourth group, 'Others', was included, encompassing remarks dedicated to overall project details and operational information on how the participatory process will proceed. Similarly to what happened with the type of remark, the nature theme is coded based on the most salient category for each one. The results are shown in Table 3.

Table 6 – Remarks nature

Remarks nature	Nr of remarks
Commitment	29
Expectation	228
Identity	7
Others	111
Grand Total	375

The results clearly show a higher propensity for remarks to fall within the realm of 'expectations' (228), with a significant difference from the other two categories: 'commitment' (29) and 'identity' (7).

Distinguishing between remarks that express the idea of expectation and general enquiries about the project is a complex task, as the line between the two is thin. The general rule applied was as follows: continuation of a given activity versus interest in general details of the plan. For example, asking 'What material is this wall made of?' is different from asking 'Will I be able to hang a frame on this wall?'. The former seems to be a general enquiry about the project (although there may be a hidden intention), while the latter is a direct concern about expectations regarding the outcome of an activity. The categorisation criteria and examples are shown in Table 7.

Table 7 – Categorisation criteria and examples

Nature of remark	Criteria	Examples
Commitment	Questioning or referring to general goals and consequences of the measures	"Will we get safe streets for children to play on?"; "(...) the measures to be taken should generate spaces to avoid sedimentation (...)"; "If bicycles ride next to cars, are they very exposed to pollution?" (Ajuntament de Barcelona, 2017b)
Identity	Questioning or referring to ways of being or one's agency	"(...) citizens have the right to have a car" (Ajuntament de Barcelona, 2017a); "(...) they are used to doing things in a certain way and that they are concerned about change" (Ajuntament de Barcelona, 2018)
Expectations	Questioning or referring to specific tasks or tasks already taking place	"Situation regarding the Ferran Sunyer School exit"; "What about the buses?"; What will Ronda Sant Antoni look like? (Ajuntament de Barcelona, 2017b); "How will you access the Sant Antoni Market?"; "Will there be a reduction in parking for residents?" (Ajuntament de Barcelona, 2017a);
Others	Questioning or referring to general dynamics of the project, the participatory process or specific operational assumptions	"Question: Is this the same idea that has already been implemented in Poble Nou?", "what type of actions will be carried out?" (Ajuntament de Barcelona, 2017b); "Is there a forecast for an increase in traffic on Viladomat Street?" and "Why is Parliament Street considered a civic axis?" (Ajuntament de Barcelona, 2017a)

6. Discussion

6.1 General Conclusions

The initial conclusion to be drawn from the analysis is that the three pillars are not consistently addressed during the Sant Antoni Superblock participatory meetings. The minutes show that the expectation dimension is given more emphasis than commitment and identity (Figure 1). Further elaboration of this preliminary analysis is outlined below.

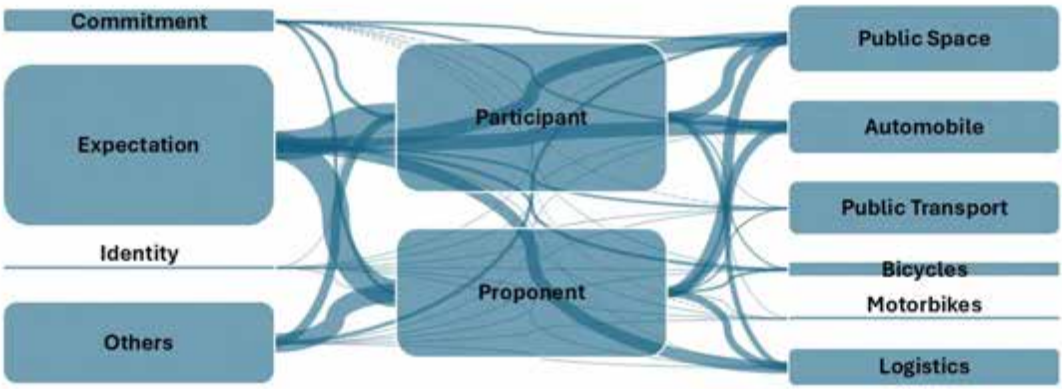

Figure 2 – Cognitive mapping of the type, subject and nature of remarks

Commitment

Commitment is associated with adherence to a specific set of actions. It is a necessary element in providing a sense of value to one's actions and is a vital foundation for keeping individuals moving forward and keeping panic at bay (Maitlis & Sonenshein, 2010). However, the concept of commitment can also be counterproductive when an individual is committed to an opposing worldview. In order to achieve commitment during a process of change, it is necessary to create a clear and compelling vision of successful change; storytelling is generally considered to be an essential part of this process (Weick, 2012).

Although this construct was not explicitly addressed in the minutes, examination of other documents suggests that the Ajuntament de Barcelona endeavoured to emphasise the importance of the project in the introduction to each meeting (Supermanzana de Sant Antoni, 2017). The initial segment of the participatory meetings consisted of a presentation by a municipal representative outlining the Superblocks project's overarching objectives. This presentation addressed the need to reduce greenhouse gas and carbon emissions, as well as the city's gradual pedestrianisation. Furthermore, the documentation reveals the integration of the commitment to sustainable transitions with other commitments, such as promoting healthier lifestyles and enhancing commerce. This integration fosters a sense of urgency for the realisation of sustainable transitions.

Therefore, although commitment was not a common theme in the content analysis of this research, it is a construct that has been considered when implementing Superblocks.

Expectations

Expectations are related to the anticipation of the outcome of certain actions on a problem. Consequently, they are associated with the ability to interpret cues, form a mental image of the problem and decide how to address it (Weick, 1988). Excessively optimistic or pessimistic expectations can influence the outcomes of a given situation. For expectations to align, people must possess a coherent conceptual understanding of the progression of activities.

A thematic analysis of the minutes revealed that remarks concerning expectations were the topic that was addressed most frequently. In most of these meetings, the tangible impact of the transformations on each street is discussed, along with the alternatives and participants' opinions. A key issue in the presented documentation

is the creation of a clear mental image of the planned interventions, which involves presenting visual aids and providing detailed explanations of specific street segments.

In the context of the Superblocks initiative, the municipal authorities placed significant emphasis on establishing consistent communication channels and disseminating information about the project's progress and subsequent implementation phases. Despite potential critiques regarding the extent to which the project was a bottom-up initiative (Boeck, 2021), proximity to the population promoted effective management of expectations.

Identity
Identity refers to how we understand our role and agency within a given context (Maitlis & Sonenshein, 2010; Weick, 1988). As our actions are limited by what we perceive as possible, the larger this scope, the wider the variety of actions we consider. Remarks such as 'citizens have the right to have a car' (Ajuntament de Barcelona, 2017a) and 'they are used to doing things in a certain way and are concerned about change' (Ajuntament de Barcelona, 2018) suggest that some participants were unable to broaden their perception of possible actions beyond the current paradigm.

According to Weick (1988), someone who believes they can adapt to a wide range of situations is open to a variety of inputs because they will always find a way to cope with them. Conversely, a person whose identity is closely linked to the way they currently do things - for instance, driving home - will not be able to consider alternative ways of being.

The Superblocks project challenged the dominant identity of car users. However, the analysed minutes barely addressed the question of identity or attachment to previous ways of doing things before the Superblocks intervention. Had the project encouraged people to broaden their perceptions of what they can do, they might have been more open to accepting changes. The following sections will explore the lack of consideration given to this issue, and its potential impact on urban experimentation.

6.2 Identity Problems and Implications
Due to their promotion of the pacification of streets, the Superblocks were often portrayed by the media as a 'war on cars' (Nello-Deakin, 2022). However, despite a scientific consensus on the need to promote more sustainable modal choices, the reasons behind our natural inclination towards cars is explained by transport behaviour science (Dyson & Sutherland, 2021). Dyson & Sutherland (2021) explain that the preference for the automobile over public transport, for example, can be attributed to convenience, reliability and status, deeply ingrained processes that have a tremendous impact on our subconscious decision-making processes. 90–95% of our daily tasks are performed automatically, and drivers only consider which mode of transport to use for 14% of trips (Dyson & Sutherland, 2021).

The problem stems from the fact that we see the car as an extension of our identity. In his famous analysis of the 1949 Mann Gulch fire in Montana, Weick (1995) reports that the smokejumpers resisted instructions to leave their tools behind in order to sprint to safety more quickly. Those who left their tools behind were reportedly able to run to safety, while those who did not were overtaken by the flames. Some men did not consider leaving their tools behind because they were part of their identity – the idea did not even cross their minds. Identity therefore acts as a filter for potential actions, which become more rigid in a crisis situation when most of us act almost on autopilot. Cars may be seen as tools for fighting fires. Despite the fact that they prevent us from running away from a figurative fire – the climate crisis – we tend to cling onto them.

Our identity shapes our worldview and influences the way we perceive problems. This can result in tenacious justification, blind spots, selective attention, confident action, and self-confirmation (Weick, 1988). Even when the other dimensions of sensemaking — commitment and expectations — are aligned with the change process, these mental processes affect how we interpret information. This can lead to retrospective justifications for certain events, causing commitment to change to fade.

The analysis of the minutes reveals a preoccupation with project parameters that were repeatedly proven to be irrelevant by municipal research and presentations, yet which were still addressed by the population. This may be due to selective attention, such as the preoccupation with increased traffic due to fewer available parking spaces and lower speed limits (e.g. 'Question: Pacifying traffic slows down vehicles and makes them turn more. Has it been well studied whether this reduces pollution?" (Ajuntament de Barcelona, 2017d), "Will there be an increase in traffic looking for parking?" (Ajuntament de Barcelona, 2017a)). Furthermore, during the implementation of the project, there was an increase in problems that were only indirectly related to superblock implementation and derived from deeper roots. These included an increase in robberies in the area during construction (Ajuntament de Barcelona, 2019c), rats appearing in flowerbeds (Ajuntament de Barcelona, 2019c), increased noise on the streets due to more people using them, and groups of skaters using the new pedestrian area (Ajuntament de Barcelona, 2022). The attention dedicated to these issues may be seen as a selective attention bias towards the outcomes of the project.

6.3 Experimentation and Social Learning

The Superblocks project was developed based on the principle of urban experimentation. These experiments are socially inclusive, practice-based and challenge-led projects and initiatives that aim to develop system innovation through social learning, addressing ambiguity and uncertainty (Sengers et al., 2016). The implementation of urban living labs and urban experiments has increased due to municipalities' growing confidence in "government by experiment" (Bulkeley and Castan Bróto, 2013, in Raven et al., 2019, p. 258). The Superblocks project aimed to facilitate urban transitions through small, tactical interventions showcasing the positive impact of street pacification and a gradual rollout across the city (Rueda, 2019).

The primary intention behind urban experimentation is to introduce solutions into limited urban environments to generate objective or empirical evidence of their advantages (Caniglia et al., 2017, in Evans et al., 2021). However, as we have seen, a lack of identity in a project can lead to tenacious justifications and blind spots. Since these justifications influence both perception and action, they often become self-confirming (Weick, 1988). In other words, people will perceive the 'objective evidence' and act unconsciously according to their preconceptions. Physical changes alone will not promote a transition.

The concept of social learning has also been addressed in literature on experimentation (Evans et al., 2021; Raven et al., 2019; Sengers et al., 2019). Experimentation is considered to be characterised by social actors aiming to facilitate social learning in relation to a new socio-technical configuration (Sengers et al., 2019). This type of experimentation requires facilitation to enable systemic learning by doing. This necessitates an inclusive, broad-based and iterative approach to learning with goals that are monitored and evaluated across a series of steps and phases (Sengers et al., 2016).

Identity can then hinder the learning process. According to Weick (1988) , as people only understand their actions after they have taken them, it is inevitable that they and their actions will become part of a crisis. Learning therefore often requires one to admit to being part of the problem and accept that, had people acted differently all along, they would face a 'different set of problems, opportunities and constraints' (Weick, 1988, p. 309). During organisational change, identities are often completely replaced (Corley & Gioia, 2004). We can therefore conclude that learning depends on updating one's identity, making it an essential concept for successful urban experimentation.

6.4 Path Forward

According to Weick, the process of sensemaking is initiated by a trigger event, which he defines as 'a specific event that is identifiable in time and place, and traceable to specific man-made causes' (Shrivastava, 1987, in Weick, 1988, p. 308). In the case of the Bhopal plant, the triggering event was the leakage of toxic gas (Weick, 1988, p. 309). For the purposes of this research, the triggering event is considered to be the meetings that preceded the implementation of the Superblock. These meetings introduced a change in the outside world, altering the way people perceived it and how they thought it behaved. Weick (1995) describes this moment as 'sensebreaking'.

Sensebreaking increases sensemaking activity, since people have to reinterpret external cues in light of new events. According to Maitlis & Sonenshein (2010), two actions associated with wisdom are required to promote an adaptive rather than destructive role for shared meanings: the capacity to update and the capacity to doubt. Updating involves awareness and enables individuals to revise their interpretations based on new information. Doubting involves considering different possibilities, trying them out, and modifying, transforming, or abandoning them as necessary. Various processes can be employed to encourage a sensebreaking and sensemaking dynamic.

This approach aligns with the concepts of double-loop learning (Sterman, 1994) and adaptive and generative learning (Senge, 2003). These are forms of learning that operate at the level of assumptions, behaviours, norms, and interpretative frameworks. Senge has developed group techniques that provide feedback on accepted assumptions and behaviours. These techniques may include visioning processes, scenario building, backcasting exercises and small-scale social-technical experiments/bounded socio-technical experiments (Vergragt & Brown, 2007).

Updating our identity may also involve reassessing the boundaries of our possible actions and expanding our perception of problems. Ulrich & Reynolds (2010) develop the idea of boundary experiences as joint activities that foster a sense of community and lead to boundary judgements through a participatory process.

According to Senge (2003), the role of a leader in a learning organisation should be to: build shared visions by encouraging personal views, communicating and asking for support, consider visioning as an ongoing process, engage in extrinsic and intrinsic visioning and differentiate between positive and negative visioning; bring mental models to the surface and challenge them, help spot leaps of abstraction, balance advocacy and inquiry, differentiate between espoused theory and theory in use; recognise and defuse defensive routines; and, lastly, to engage in systems thinking, seeing interrelationships and processes (not things and snapshots) and understanding dynamic (not detailed) complexity. Methodologies such as soft systems methodologies (Checkland, 2000) and critical systems heuristics (Ulrich & Reynolds, 2010) can be employed to this end.

The goal of the learning process should be to reduce saliency and promote a safe environment in which to question and doubt present preconceptions. This makes it possible to update shared meanings, particularly those relating to identity.

7. Conclusion

Urban experimentation can facilitate meaningful, sustainable transitions in today's cities. However, to promote the necessary learning and deployment of urban solutions, enacted sensemaking must be addressed. The sensemaking process may be hindered by a lack of commitment, conflicting identities or unrealistic expectations. Moreover, given that all sensemaking is provisional and incentivised by the fast pace of the world in which we live, the capacity to update meanings must be permanent.

The results of the thematic analysis of the minutes make it clear that the identity dimension was not adequately addressed during the participatory meetings. The codification used showed a low prevalence of remarks related to this shared meaning. When these were addressed, they tended to demonstrate a limited perception of people's agency. The paper has also explored the problems arising from the lack of proper shared meanings in an urban experimentation. By analysing complexity-related organisational literature, we can understand how a lack of shared identity around a change can affect an organisation.

Although the research was limited to analysing the meeting minutes, considerable findings emerged that will inform future agendas. Future research could extend these findings and test their validity among those affected by the Superblock implementation. Questionnaires and semi-structured interviews with participants and Ajuntament members could shed light on the challenges of not incorporating sensemaking into participatory meetings. Additionally, new research could focus on strategies that encourage doubt and the updating of shared

meanings, particularly with regard to commitment, expectations, and identity. This could involve exploring new participatory processes that promote complex systems thinking.

The fictional municipality of "Zwirgberg" as a model for spatial planning in rural Rhineland-Palatinate

Katharina Mayer - Martin Berchtold
Rheinland-Pfälzische Technische Universität
Email: katharina.mayer@rptu.de , martin.berchtold@rptu.de

Abstract
Rural regions in Germany face significant structural transformations due to climate change, demographic shifts, digitalization, and mobility transitions. The research project "Kommune 2050" addresses the challenge of limited strategic planning capacities in rural municipalities by developing a transferable model framework. Using the fictional collective municipality "Zwirgberg," based on existing municipalities in Rhineland-Palatinate, the project integrates GIS analyses, modular synthesis, and participatory scenario development. Zwirgberg functions as a digital experimental space that combines real data with creative projections. The result is a planning tool that allows municipalities to explore future development paths and translate abstract challenges into spatial strategies. This methodological approach offers an innovative and replicable model for strategic spatial planning in rural areas.

Keywords: Data-Driven, Model Municipality, Scenario Modeling, Rural Development

1. Introduction and theoretical background

The ramifications of the substantial challenges confronting contemporary society, encompassing the climate crisis, demographic shifts, social transformations, the digitalization of numerous domains, and the mobility transition are already exerting an influence on nearly all aspects of municipal endeavors. These repercussions are poised to persist, engendering increasingly disparate (spatial) repercussions on our lives in the forthcoming years. This phenomenon is not merely an abstract concept; it is one that is particularly pertinent to the German state of Rhineland-Palatinate. It presents challenges, opens up new perspectives, offers opportunities for control and highlights areas where action is required. But what will future change look like? Where and how strongly will changes be felt? How can we identify, formulate, visualize, and communicate changes? What conclusions must be drawn and what innovative solutions are available?

The "Kommune 2050 - Die nächste Generation" (English: "Municipality 2050 - The next Generation") research project was concerned with these issues and is developing new planning approaches. The objective of the project was to develop a set of tools with which municipalities - exemplified by the fictional model municipality of "Zwirgberg" – can concisely identify, design, test, and spatially concretize their own futures and development paths, but in particular, possible solutions. In order to develop practical and transferable solutions, it was essential to consider both general future trends and local characteristics. In consideration of the model nature of the fictional "Collective Municipality" (German: "Verbandsgemeinde") it is possible to derive and transfer corresponding conclusions to analogous structures and the entire federal state. These conclusions can then be classified in the context of future (spatial) developments and their control.

In the German administrative system, a Verbandsgemeinde (roughly translated as "collective municipality") is a specific form of local government structure, predominantly found in the federal state of Rhineland-Palatinate. It consists of a group of smaller, municipalities (Ortsgemeinden) that collaborate under a shared administrative body. While each local municipality retains its political autonomy and elected council, key public services - such as urban land-use planning, school administration, infrastructure management, and fire protection - are managed collectively by the Verbandsgemeinde. This structure is designed to improve administrative efficiency and ensure the provision of essential services in sparsely populated areas. Due to the lack of terminology for precisely this form of municipality, the German word Verbandsgemeinde is used in this paper, also the term Hauptort refers to the largest and functionally most central town within the Verbandsgemeinde and the word Nebenort denotes the smaller surrounding villages or localities.

Also used in German are the words Grundzentrum, Mittelzentrum and Oberzentrum. Germany's spatial planning system categorizes settlements into a three-tiered hierarchy of central places to structure public service provision and regional development, where a Grundzentrum (basic center) serves everyday local needs (e.g. primary schools, groceries, basic healthcare), a Mittelzentrum (intermediate center) offers a broader range of services such as secondary education, hospitals, and specialized retail, and an Oberzentrum (major center) provides high-level services and infrastructure, such as universities, major hospitals, and cultural institutions, typically serving large regions (ARL, 2010).

During a preparatory phase, the essential foundations for this were laid: future topics were identified, necessary data sets were analyzed, and methodological approaches were formulated. The development of a realistic yet abstract model that provides a framework for iterative planning processes was a primary focus. The emphasis was placed on interdisciplinary collaboration between students and teachers, who cooperated as part of a 'Masterprojekt' (English: 'master's project' - a final project at the very end of the Master's programme) or as student assistants. The objective of the research project was to employ creative and data-driven methodologies to conceptualize a fictional municipality derived from authentic structural components.

The methodological structure of the project was based on a three-phase process; however, the practical work revealed the necessity for increased iteration. In the initial phase, entitled 'Understanding the Territory' the emphasis was placed on the analysis, categorization, and design of the model community. In the subsequent phase, entitled 'Construction of the Model' the elements of the model community were specified, reconstructed, and digitized. In the third phase, entitled 'Developing Future Visions', scenarios were formulated to illustrate potential future trajectories for the developed Verbandsgemeinde.

The methodological value of fiction is the central aspect under consideration here. Zwirgberg's - the fictional Verbandsgemeinde - model does not represent an arbitrary real community; rather, it is composed of real fragments. This phenomenon gives rise to a reflexive space wherein authentic communities can discern their own identity without the sense of being addressed in a direct manner. In this context, Zwirgberg functions as a projection-open planning tool - as a digital experimental space for exploring realistic yet innovative development paths. The structural modularity enables the flexible composition of fictional community types and targeted transfer of individual components to real contexts.

The project thus demonstrates an innovative approach to planning processes in rural areas based on geodata, creativity, and strategic planning. Working with "Zwirgberg" allows concrete actions and the exploration of potential spatial configurations prior to their implementation in actual planning instruments. This lays the foundation for subsequent development of digital, modular, and participatory tools in municipal planning.

2. Methodical approach

The objective of the project was to develop a fictitious municipality based on existing Verbandsgemeinden in Rhineland-Palatinate. Subsequent to this, the future development visions of several Verbandsgemeinden were to be formulated and presented. During the initial six-month period, a collaborative effort was undertaken with a team of four students enrolled in master's programs specializing in 'Urban and Regional Development' and 'Urban Planning'. As a culminating element of their master's program, students were tasked with the development of the fundamental structures of the fictional municipality and its future vision. These were subsequently elaborated upon by a group of three students, two of whom were in the initial stages of their bachelor's degree program. It was anticipated that they would offer a novel and impartial perspective on the future of the municipalities in Rhineland-Palatinate.

The initial plan was to divide the project into three phases; however, as work progressed, it became evident that this approach was not feasible. Conversely, alternating between task areas (analysis, construction, replication, detailing of previously developed content) and levels of consideration (Verbandsgemeinde and municipalities within the Verbandsgemeinde) has been demonstrated to be a more fruitful approach. Nevertheless, the three

phases remained as a rough framework for the order of processing:

• Phase 1 - "Understanding the Territory"
Reading, analyzing, and understanding: Getting to know and developing the framework of the fictional Verbandsgemeinde
• Phase 2 - "Construction of the Model"
Recreating, assembling, and defining the model municipality; Describing its characteristics or "genetic code"
• Phase 3 - "Developing Future Visions"
Examination of developments and trends at the Verbandsgemeinde level and their manifestation in the individual municipalities

Database and selection of existing Verbandsgemeinden
The research project was commissioned by "Entwicklungsagentur Rheinland-Pfalz e.V." which had already formulated specifications the fictitious Verbandsgemeinde to be developed was to embody. These were as follows:

The Verbandsgemeinde is comparable to a modern-day municipality in Rhineland-Palatinate: The Verbandsgemeinde has approximately 20,000 inhabitants. It consists of a Hauptort (5,000 inhabitants, Grundzentrum with schools) and 15 Nebenorten (150 to 800 inhabitants). All 16 individual towns (Hauptort and Nebenorte) are run on a voluntary basis. The Verbandsgemeinde has a full-time administrative head who is responsible for all 16 municipalities. It has its own independent administration. The Verbandsgemeinde is situated in the rural area of Rhineland-Palatinate. The property is located approximately 30 kilometers from the nearest Oberzentrum.

According to these criteria, all Verbandsgemeinden in Rhineland-Palatinate with 18,000 to 22,000 inhabitants that are also more than about 30 km from the nearest Oberzentrum were selected for inclusion in the study: Aar-Einrich, Bad Marienberg (Westerwald), Birkenfeld, Brohltahl, Cochem, Kirchberg (Hunsrück), Kirchheimbolanden, Linz am Rhein, Prüm, Südeifel (northern half), and Wirges.

The Verbandsgemeinden of Annweiler am Trifels, Edenkoben, and Wonnegau are located approximately 30 kilometers from the nearest Oberzentrum (red circles). However, they are situated within the 20-kilometer catchment areas of a Mittelzentrum with partial functions of a Oberzentrum (Mittelzentren mit Teilfunktionen eines Oberzentrums) (yellow circles). It should be noted that this selection does not yet take into account the number of sub-locations, i.e., "one Hauptort and 15 Nebenorte"

The initial spatial structural studies are summarized in the map below:

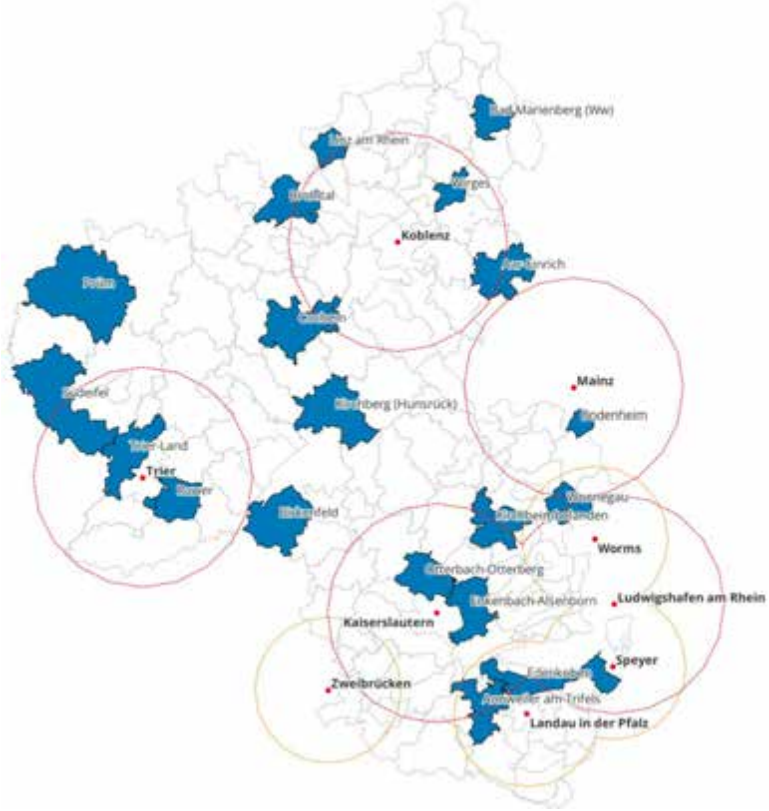

Fig. 1: The map shows the first spatial structure studies. All municipalities with a population of 18,000 to 22,000 are coloured blue, the red circles show the 30-kilometre radius around the Oberzentren, the yellow circles around the Mittelzentren with partial functions of a Oberzentrum. Source: Authors 2024.

Role of students and didactic format

A central feature of the methodological design is the involvement of students in various stages of their education: Master's students provided initial drafts and structural concepts as part of project-based work and developed the fictional Verbandsgemeinde in its entirety. Bachelor's students then took over the further elaboration, reflection, and critical development—their impartiality proved to be particularly productive. This interdisciplinary and multi-stage process enabled a deep understanding of both systemic relationships and the challenges of concrete municipal development.

3. Phase 1: Understanding the Territory

Following the methodological foundation of the project, an empirical analysis of existing Verbandsgemeinden in Rhineland-Palatinate was conducted. This analysis forms the backbone for the subsequent construction of the model Verbandsgemeinde "Zwirgberg." The analysis can be divided into three sections.

In the initial phase, profiles were created for the eleven selected Verbandsgemeinden. The objective of this stage was to acquire a comprehensive understanding of them. In the subsequent phase, the land distribution of the Verbandsgemeinden was examined and classified into categories so that comparable or similar structures could be grouped together. The third and final step of the analysis entailed the creation of a modular system that would serve as the foundation for establishing the fictional association of municipalities.

The objective was to identify the typical structural characteristics, development potential, and spatial functional patterns of the Verbandsgemeinden in Rhineland-Palatinate. These characteristics were then used as the basis for building the fictional association of municipalities.

Profiles and comparison criteria
The initial phase of the study centered on eleven selected Verbandsgemeinden of comparable size (18,000–22,000 inhabitants) and remote location (more than 30 km from the regional center). For each of these Verbandsgemeinden, structured profiles were created, reflecting the following criteria:
- Demographic structure: age distribution, population development,
- Household sizes
- Settlement structure: density, types of centers, types of urban development
- Land use: proportions of settlement, vegetation, traffic areas
- Accessibility: distance to medium-sized and larger centers, public transport connections
- Infrastructure: education, health, and administrative services

Comparability was ensured by a standardized profile template that combines both quantitative data and qualitative assessments.

Spatial analyses of similar existing Verbandsgemeinden in Rhineland-Palatinate
In order to gain a more nuanced understanding of the selected Verbandsgemeinden's spatial characteristics, a range of structural elements were subjected to analysis, including boundaries, settlement patterns, primary access routes, the location of the primary urban center, agriculture, topographical features, water bodies, green spaces and points of interest.

To this end, cartographic representations were developed through the utilization of a geographic information system (GIS) and hand sketches, which were made based on such maps. Infrastructure aspects such as interregional connections, public transportation, and bicycle paths were also considered. During this phase, statistical data was also processed and subsequently compared with the data from the other Verbandsgemeinden.

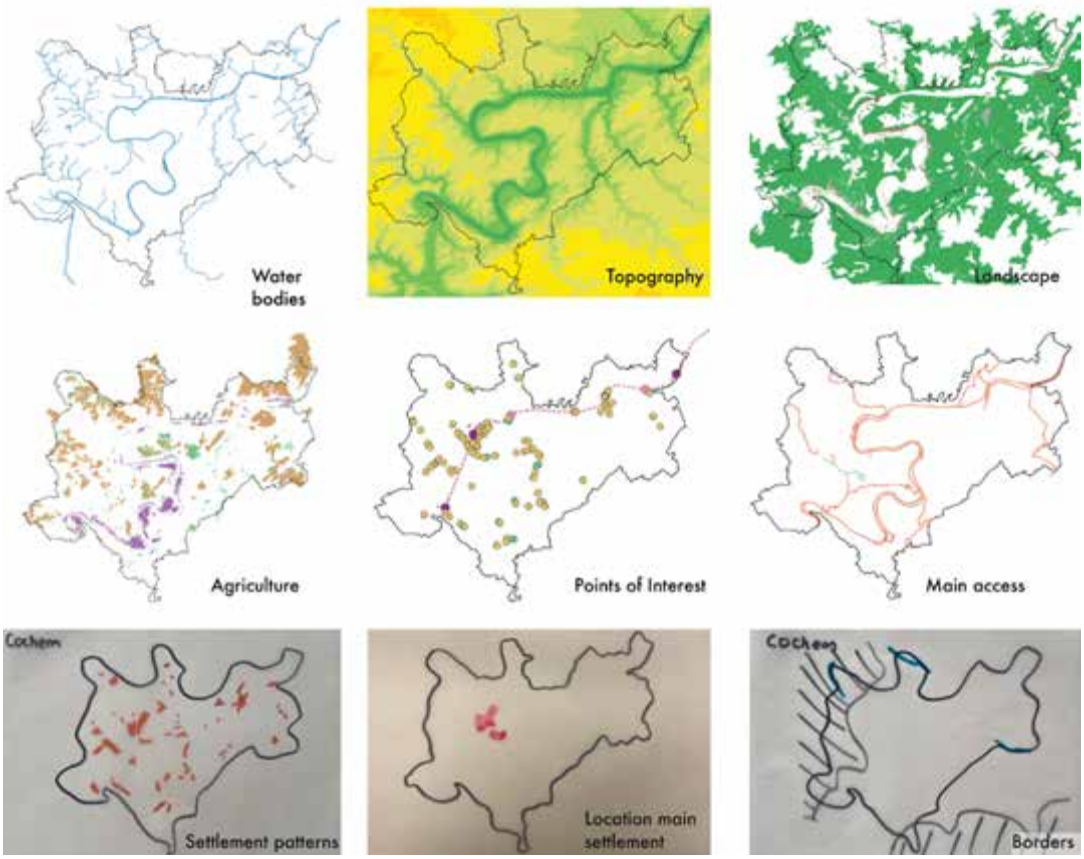

Fig. 2: The structures of the municipalities examined using the example of Cochem. Source: Authors 2024.

Following the examination of the Verbandsgemeinden individually, the results were compared with the analysis results of all the other considered Verbandsgemeinden. Based on these comparisons, categories were developed for each analysis topic into which the eleven municipalities could be classified (even though transitions can be fluid).

The following example illustrates the investigation of all subject areas, as evidenced by the presentation of the various settlement patterns. A distinction was made between:

• Cow spots:
Large-scale settlement structures are dispersed in a seemingly random manner.
• Drops:
The settlement structures under consideration are of a smaller nature, with some larger drops situated between them.
• Sprinkles:
The settlement structures are diminutive in size and dispersed in a seemingly random manner.

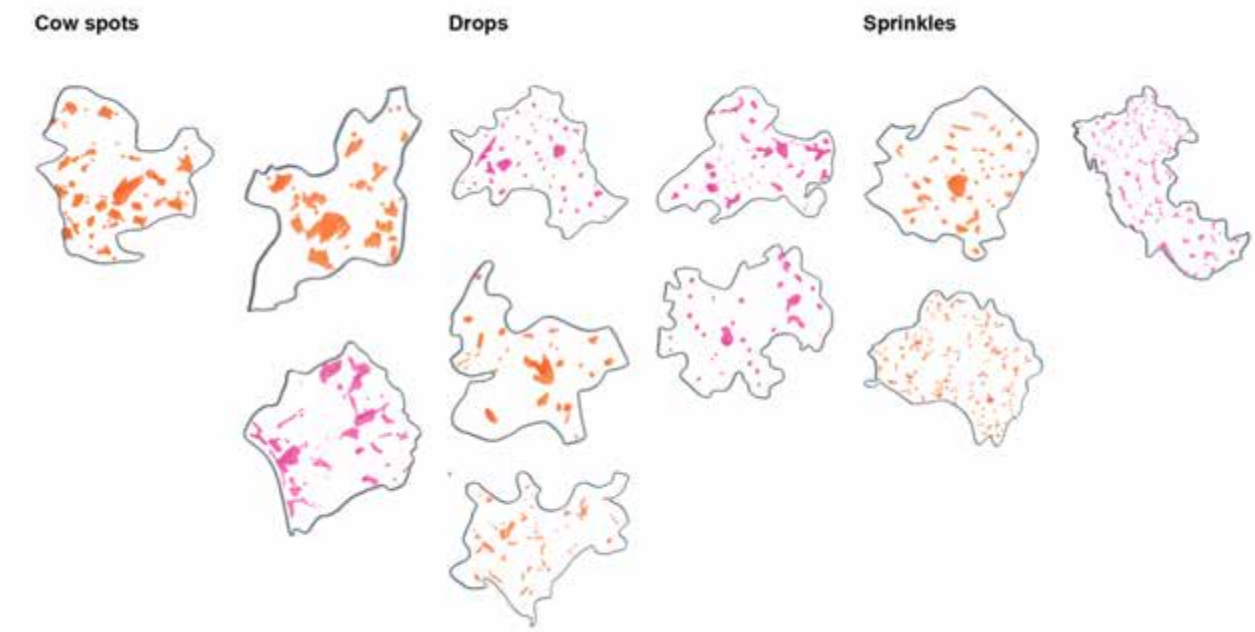

Fig. 3: The settlement structures of the eleven municipalities divided into the categories of cow spots, drops and sprinkles. Source: Authors 2024.

Derivation of a modular system of similar existing municipalities
A modular system was created by analysing and categorizing the structures. Based on this, the fictitious Verbandsgemeinde was to be designed and built in the next phase. A distinction was made between two categories:

• Fundamentals: The foundational elements of the municipal framework such as topography and settlement structure
• Infrastructure: Encompasses elements such as public transportation and bicycle pathways.

The following presents an overview of the components of the modular system. These modules can be flexibly combined in further planning to develop structurally similar municipalities in a differentiated manner. This approach facilitates the synthesis of empirical evidence and planning creativity.

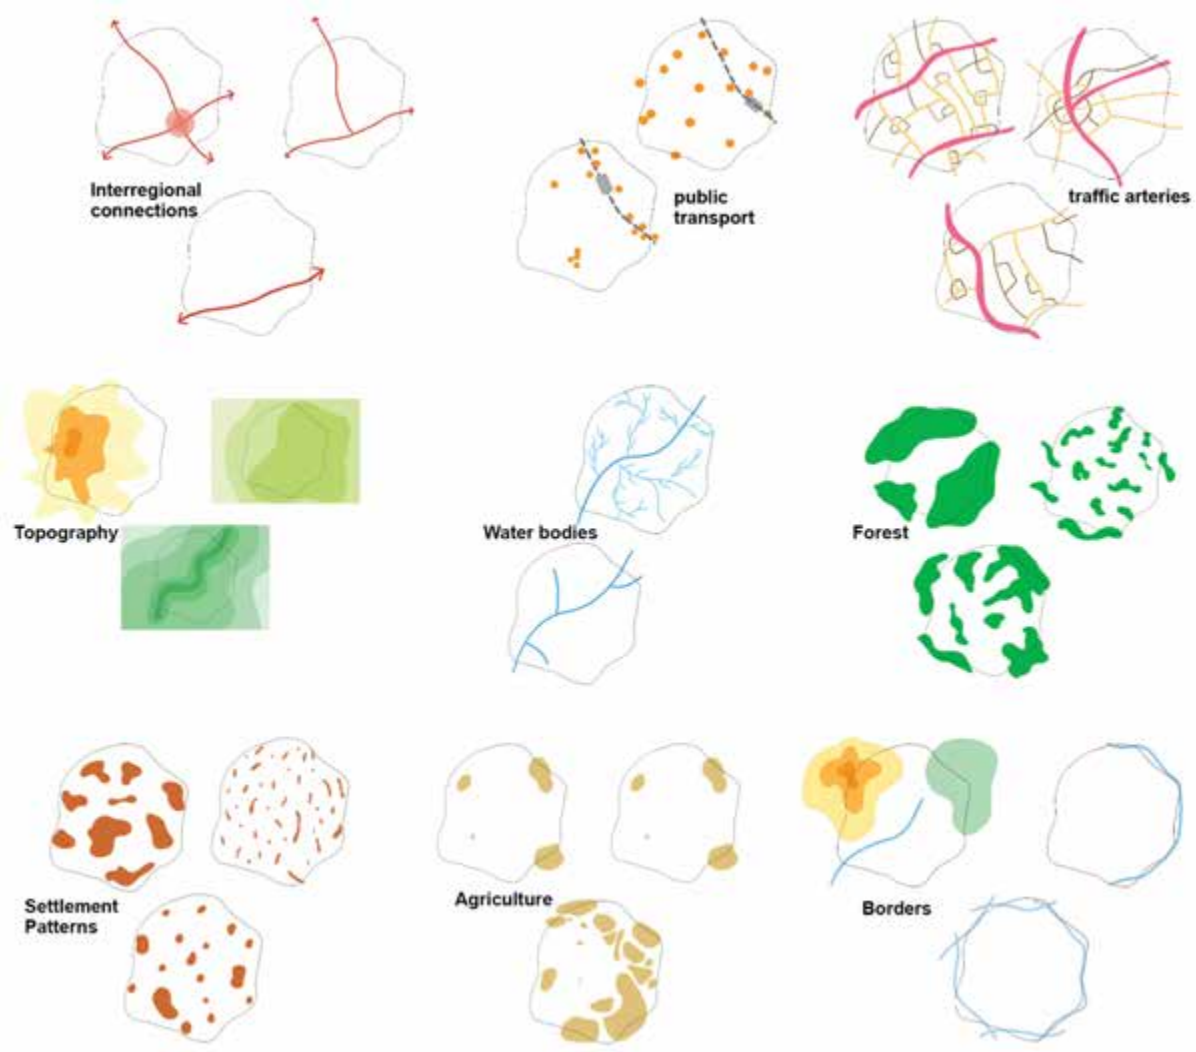

Fig. 4: Characteristics of the municipalities within the Verbandsgemeinde in accordance to the modular system. Source: Authors 2024.

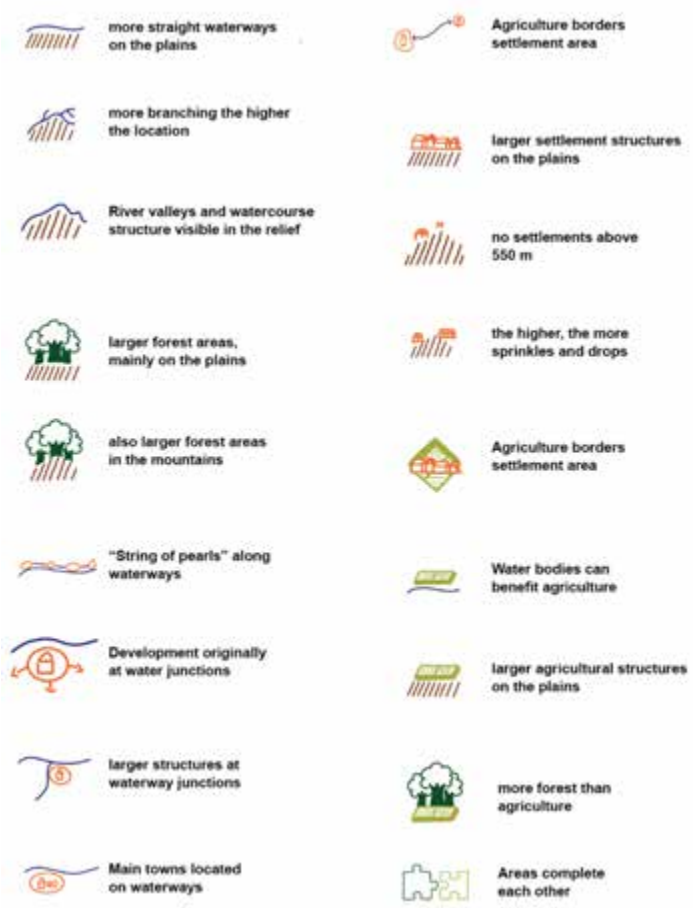
Identification of correlations between the categories considered in the analysis

In order to be able to derive initial design guidelines for the fictitious Verbandsgemeinde from the results of the analysis, it was investigated whether the categories analysed were somehow mutually dependent.

Depending on the constellation, there are varying numbers of connections and mutual conditions. For example, four relationships could be identified between settlement structure and water bodies, but only one between water bodies and agriculture. No conclusions about mutual conditions could be drawn from other constellations, such as forests and settlements.



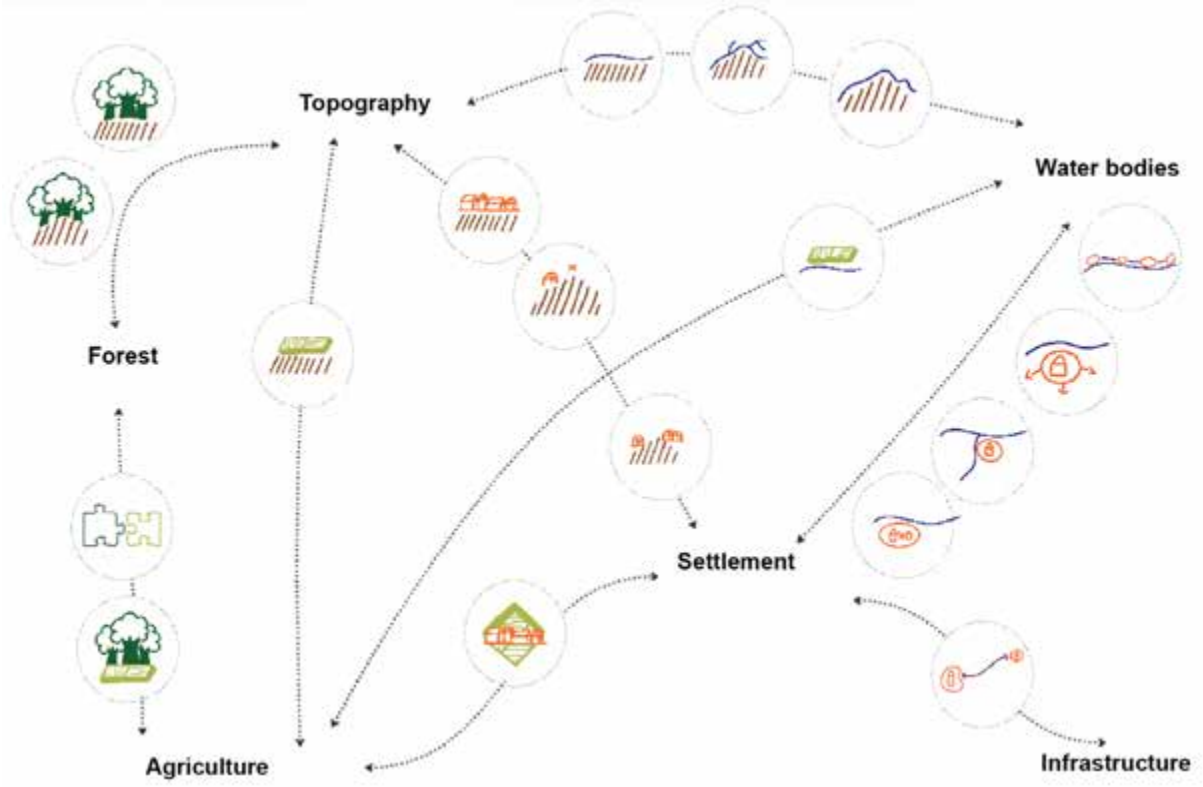


Fig. 5: The diagram shown illustrates the relationships between the categories, the legend above provides explanations of the symbols within the diagram. Source: Authors 2024.

4. Phase 2 - Construction of the Model

During the preceding analysis phase, the modular system was developed and the overarching relationships were examined. In the subsequent design phase, the current status of a fictitious Verbandsgemeinde was determined.

The fictitious Verbandsgemeinde of Zwirgberg was designed by first developing two types of Verbandsgemeinden from four basic designs. These were then combined into one type. Using hand drawn sketches, the individual layers were digitized with the help of a geographic information system (GIS), so that the basic structure of the Verbandsgemeinde became visible.

In further steps, the relationships within the settlements were analyzed. In the present study, sprinkles in higher topographical levels, pearl chains along waterways, cow spots, and even drops in the landscape were analyzed. The results were used to reconstruct fictional municipalities from fragments of real local communities before these were digitally reconstructed in the GIS using the corresponding census data.

Impromptu design

The construction of the fictitious Verbandsgemeinde began based on the analysis. As part of the project, each participating student carried out an individual “basic impromptu design”. The aim was to develop their own design for the municipality based on the knowledge gained.

Fig. 6: Basic impromptu designs for the fictional municipality. Source: Authors 2024.

On closer inspection of the drafts produced, two types of draft could be identified.
• Many smaller villages at higher altitudes and branched water structures
• Larger villages in lower, flatter locations and straighter watercourse structures
Therefore two new drafts were produced, each resembling one of the distinct types.

Fig. 7: The two types of designs for the fictional municipality. Source: Authors 2024.

The fictitious Verbandsgemeinde of Zwirgberg was ultimately developed from these variants. The derivation of the individual layers and the entire Verbandsgemeinde was based on the previously developed modular system and the identified correlations between the categories of the superordinate structures. The aim was to integrate as many special features of the previously considered existing Verbandsgemeinden in Zwirgberg as possible. This duality also allows the exemplary treatment of central areas of tension - such as between the formation of centers and peripheralization - in the model. Furthermore the choice of these types reflects the demographic, infrastructural and functional heterogeneity of many real Verbandsgemeinden.

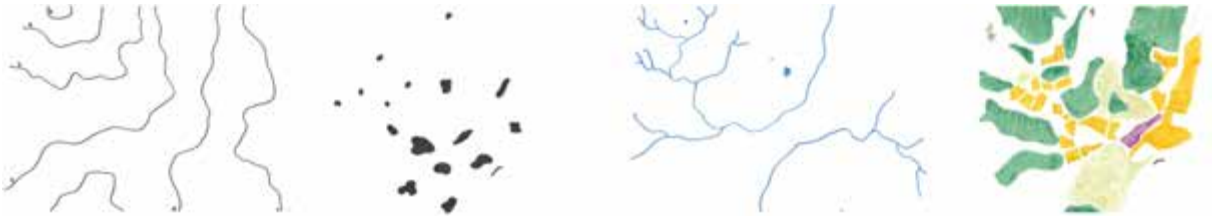

Fig. 8: The municipality of Zwirgberg and its layers: topography, settlement structure, water bodies, and land use. Source: Authors 2024.

Several points were relevant in the development process. The boundaries were to be defined as the final element of the process in order to avoid a limited and therefore incorrect alignment of the subsequent steps from the outset. In addition, it should be noted that the category of open spaces is not limited exclusively to forest and agricultural areas but also includes green spaces to which no specific function is ascribed. In view of these findings,

the corresponding work steps in the previous phases were modified and carried out again until a satisfactory result was achieved.

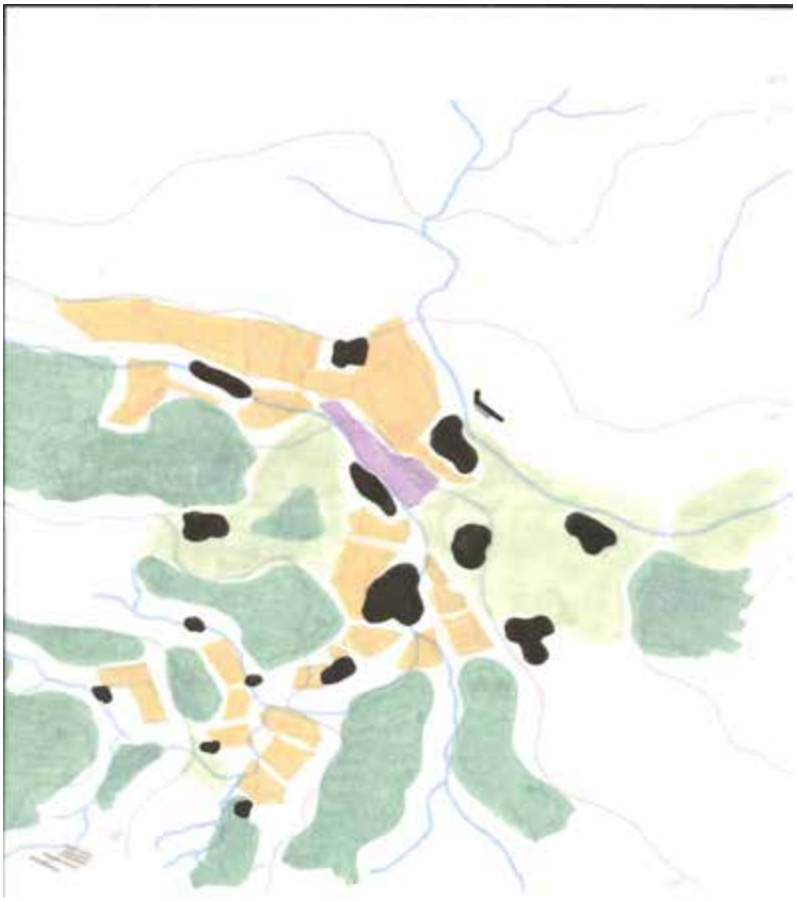

Fig. 9: Overlay of the hand drawn layers of the Verbandsgemeinde of Zwirgberg. Source: Authors 2024.

Transfer and reproduction of the fictitious municipality in a Geographic Information System (GIS)

After developing a joint design for the fictitious Verbandsgemeinde, it was transferred to a GIS. As part of the topographical incorporation, a structural simplification was carried out in which the topographical levels were numbered from one to five and assigned specific properties without a detailed GIS representation. Level 1 represents the lowest level, while level 5 indicates the highest elevation. Subsequently, the other levels of the municipality are successively transferred to the GIS. These are settlements, forest, agriculture, waterways, meadows, vineyards and a quarry.

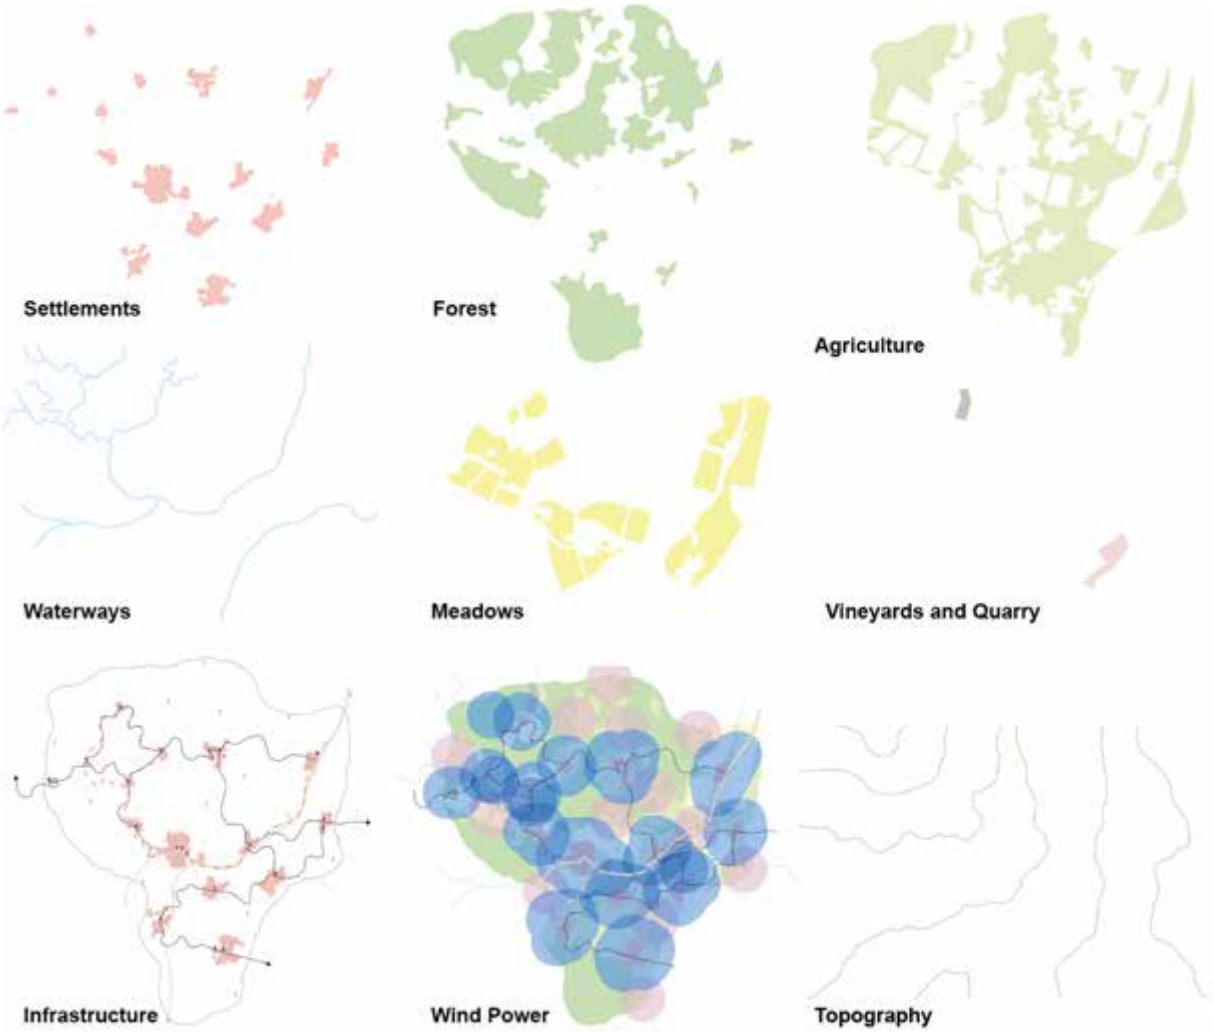

Fig. 10: The digital layers of the Verbandsgemeinde of Zwirgberg. Source: Authors 2024.

Once the relevant layers had been recorded, the infrastructure could be added. In the present context, a hierarchy with main roads, connecting roads and residential roads was selected for traffic, which was supplemented by active and disused railroad tracks and bus stops. Due to the fact that an average of eleven wind turbines are installed in the previously considered municipalities, this number of wind turbines should also be placed in Zwirgberg.

According to the applicable guidelines, wind turbines must be installed at a distance of at least 900 meters from residential areas. In addition, a minimum distance of around 1,000 meters between individual turbines must be ensured. Furthermore, positioning in bird or nature conservation areas is not permitted and they must not impair the appearance of the landscape (Vhw - Bundesverband für Wohnen und Stadtent-wicklung e.V. 2023). Following corresponding analyses, the areas marked in blue were excluded as locations so that the turbines could be positioned in the remaining areas.

Settlement structures and their characteristics - Territory categories
In order to create realistic local structures based on settlement areas, it is first important to identify connections between settlement structures within the localities. To this end, the 15 localities are first divided into three "Territory categories":

• Territory category 1
Sprinkles to Drops in topographically higher locations
• Territory category 2
Cow spots as a string of pearls
• Territory category 3
Cow spots surrounded by agriculture or meadows

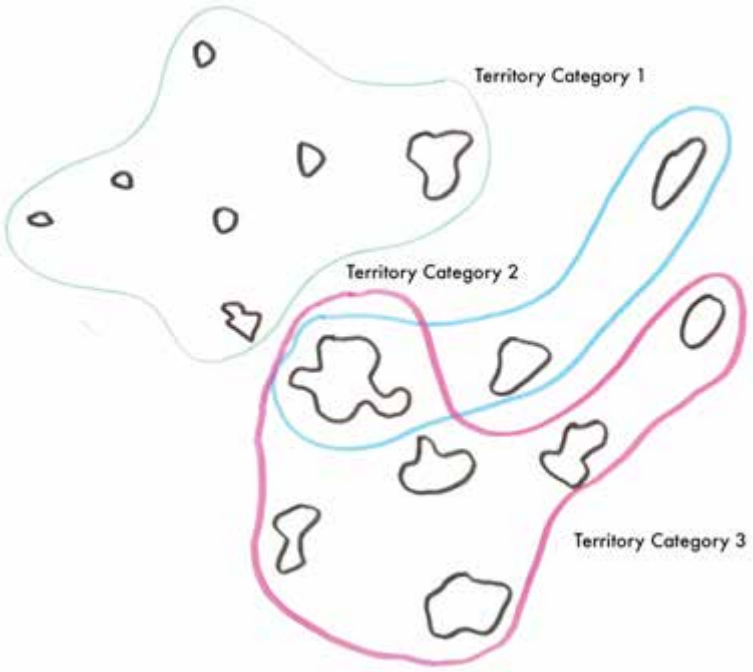

Fig. 12: Division of Territory Categories in the municipality of Zwirgberg. Source: Authors 2024.

Based on these categories, the eleven existing Verbandsgemeinden were analysed and examined for their local characteristics. Particular attention is paid to the town centre, the boundaries to the surrounding area, how the town has grown, how the single-family home areas are arranged, where waterways run, what typologies are present, how the transportation infrastructure runs and what uses are located where and how.

Furthermore, the analysis examines how local structures have grown along waterways, surrounded by vineyards or surrounded by agriculture and to what extent they differ from one another. The analysis also distinguishes between main towns and secondary towns. Since the scattered settlements in the higher-lying areas of the analysed existing Verbandsgemeinden do not contain any Hauptorte, only Nebenorte can be analysed for Territory category 1.

Tab. 1: Settlement structures and their characteristics divided into the three Territory Categories and their respective characteristics in the areas town center, typology, traffic, infrastructure and waterways. Source: Authors 2024.

				Territory Category 1	**Territory Category 2**	
	Nebenorte	**Hauptorte**	**Nebenorte**
Town Center	Type 1: denser town center with a street village character, directly on the main road Type 2: looser town center, characterized by several groups of farms	Town center along the intersection of a state road Retail and supply along the town center	Compare with Hauptort
Typology	Single-family houses on both sides of the main road, which runs through the center of town. Mostly, there are no large single-family house areas in the smaller drops, but several (usually two) smaller ones	Single-family home areas border directly on the town center, without transition If commercial or industrial areas are present, they are located along major roads, railway lines, or bodies of water	Commercial enterprises are often located on the outskirts. Denser local structures can be seen along the main roads. Agricultural farms are often found on the outskirts. Type 1: The town develops elongated along the water. Type 2: The town developed as a cluster across the water.
Traffic	Mostly arranged in T-junctions Main road runs through the town center or directly past it	T-junctions Roads often run parallel to the watercourse	A country road or federal highway runs through the town. District roads connect the neighboring towns. The towns are partially divided and split in two by major roads.
Infra-structure	Sports fields are mainly located on the outskirts of town	Sports fields mainly on the outskirts of town School facilities available Market square near church and water, surrounded by main road	Compare with Hauptort

Waterways	Often run parallel to the roads	Type 1: Flows through the main town Type 2: Borders one side of the development Type 3: Recognizable branch of the water in the main town	Compare with Hauptort
			
	Territory Category 3		
	Hauptorte	**Nebenorte**	
Town Center	The town center stretches along the main roads. It is partially surrounded by waterways.	Along the main road in some cases, no clearly recognizable town center, but denser structures along the larger roads and less dense structures away from the main roads	
Typology	Commercial enterprises are located along the main roads or important transport links and mostly on the outskirts. Single-family residential areas adjacent to the town center are mostly laid out in a grid pattern.	Commercial enterprises on the outskirts along transport routes Agricultural farms are located slightly outside or adjacent to the outskirts of the town	
Traffic	Star-shaped traffic axes: State, federal, or district roads often converge at a roundabout.	Compare with Hauptort	
Infra-structure	Some isolated green spaces in the town. Educational institutions are often grouped together in one location in connection with a sports field and clubhouse. Most main towns have a hospital adjacent to the single-family home areas, which is often located on the outskirts of the town.	Volunteer fire department in the town center or on the outskirts	

Development of fictional municipalities

An analysis of settlement structure interdependencies was conducted and suitable structures were first sought from the eleven existing Verbandsgemeinden with the help of a GIS. The structures were color-coded according to their use: town centers, single-family home areas, multi-family homes, educational institutions, healthcare facilities, industry, commerce and agricultural farms.

In the subsequent phase, the GIS snippets were extracted and integrated to generate new settlements. This was done by printing them out, cutting them into smaller sections and "puzzling" them into new settlements. The composition of the locations was based on the identified connections and findings from the analysis phase. Following the integration of the snippets, they were transferred back to the GIS, along with the raster-based census data (as of 2011, the newest data available to this date) corresponding to the building structures. The existing street layouts were adopted and adjusted or expanded as needed.

Fig. 14: Exemplary representation of three municipalities of the Verbandsgemeinde of Zwirgberg, once in their raw form consisting of snippets of different thematic categories and once integrated into the GIS. Source: Authors 2024.

Zwirgberg's Profiles

Following the completion of the digitization process for all 16 municipalities (15 Nebenorte and the Hauptort Zwirgberg), the subsequent phase involved the consolidation of the individual localities' identities. Since the local communities that had been developed only existed in their current state in the present, the first concern was to underpin them with a historic background to be able to better shape the future of the localities on this basis.

Based on the structure of the municipalities, open questions were formulated that could find their answers in the history of the places: Questions have been raised regarding the rationale behind the location of Strempelfeld, which is situated in a forested area, and the relative size of the town Zwirgberg in relation to the broader municipality.

In order to address these inquiries, a comparative analysis was conducted on the historical functions and origins of the eleven existing Verbandsgemeinden, which revealed a variety of patterns. The majority of the local communities were characterized by agricultural use, although there were also some forest clearing and craft settlements, mining and wine-growing villages, as well as industrial sites, mayoralties, trading centers, and monasteries or castles. In accordance with the categories delineated above, the fictional local communities are allocated to one of these categories, contingent on their geographical location and settlement structure.

Fig. 15: Characteristics. Source: Authors 2024.

In addition to the historical background of the fictional municipalities, further information was assigned to them (based, among other things, on the census data on file). This additional information included the following:
- Size of the settlement area and
- Population
- Local and regional connections
- Individual distribution of land use
- Distribution of open space and
- Leisure activities

This information can be found in respective profiles, such as the one shown below for the Verbandsgemeinde and the Hauptort Zwirgberg. The location of the municipality in the Verbandsgemeinde can also be seen in the illustration next to the name of the town. The illustrations appended to the profiles offer insight into the specific spatial configuration of the municipality.

5. Phase 3 - Developing Future Visions 2050

The development of scenarios is a central aspect of strategic future planning. As part of the "Kommune 2050" project, they were used to design different plausible development paths up to the year 2050 based on the fictional model community of Zwirgberg. The objective was not to provide exact forecasts, but rather to present a range of possibilities that existing Verbangsgemeinden in Rhineland-Palatinate can use as a guide. The scenarios are based on trends such as climate change, demographic change, digitalization, and the mobility transition. These developments have a profound impact on rural areas. The fictional Verbandsgemeinde of Zwirgberg is the result of a synthesis of the existing Verbandsgemeinden that were reviewed during the analysis. As a result, many of the ideas and visions realized in this fictional Verbandsgemeinde can also be transferred to the existing ones. This approach enables these Verbandsgemeinde to gather ideas or find inspiration without being subjected to specific criticism of their shortcomings.

Methodological approach to the scenario development

The scenarios were developed in close coordination with the previous phases of analysis, construction, and vision. Based on Zwirgberg's structures, three consistent futures were developed using narrative elements, trend syntheses, and graphic sketches. Using the GIS model, which contained real demographic and morphological data, iterative feedback enabled the scenarios to be precisely anchored in space. Participatory elements and critical reflections - such as those concerning the plausibility or scope of visionary proposals - complemented the methodological process.

To ease the transition into developing visions of the future, three phases were completed as part of a "Future Workshop" (Zukunftswerkstatt). During the 15-minute criticism phase, the municipality's weaknesses and risks were identified and noted. Next came a 20-minute utopia phase, during which future developments were designed without restrictions due to practical constraints to capture all wishes, dreams, and utopias. The concluding 25-minute implementation phase reviewed the utopian designs for feasibility and translated them into concrete, realizable projects.

Fig. 17: Characteristics. Source: Authors 2024.

Three Scenarios for Zwirgberg in 2050

Based on current trends, the results of the 'Future Workshop', and Zwirgberg's existing potential, three visions of Zwirgberg's future were developed.

These visions are interconnected and mutually dependent. The visions 'Net Zero Tourism', 'Climate-Positive Zwirgberg', and 'Interconnected Community' contain core building blocks that can be implemented with the help of the developed tools. The cross-cutting themes of digitalization and mobility are reflected in all three.

A conceptual image was created for all three future visons, and corresponding areas of action and associated measures were developed for each. The conceptual image is provided for all visions; the detailed version, which includes the fields of action and measures, is only shown as an exemplary model in the case of vision a, but was also developed for the other visions.

The scenarios were not only designed as thought models, but systematically translated into concrete action paths. These include: the reactivation of vacant properties, the transformation of mobility infrastructure, the promotion of civic energy projects and digital inclusion. Thanks to the modular structure of Zwirgberg, these building blocks can be transferred directly to existing Verbandsgemeinden. Each Verbandsgemeinde can select the components from the Zwirgberg toolbox that suit its starting point and objectives.

A. Net-Zero Tourism

The future vision is predicated on the trends of mobility and climate change. The region's potential for hiking and cycling trails, the distinctive characteristics of the surrounding villages, and viticulture will be fully utilized. The Verbandsgemeindes distinctive selling point is its commitment to net-zero tourism. It is hypothesized that Zwirgberg will become an oasis for climate tourism. Measures such as the renaturation of the Meerbach stream, the introduction of new forms of mobility (autonomous shuttle buses, mobility stations, mobility on demand), and the expansion of the cycle path network will improve accessibility. The implementation of additional measures is expected to enhance the appeal of the towns and the broader municipality.

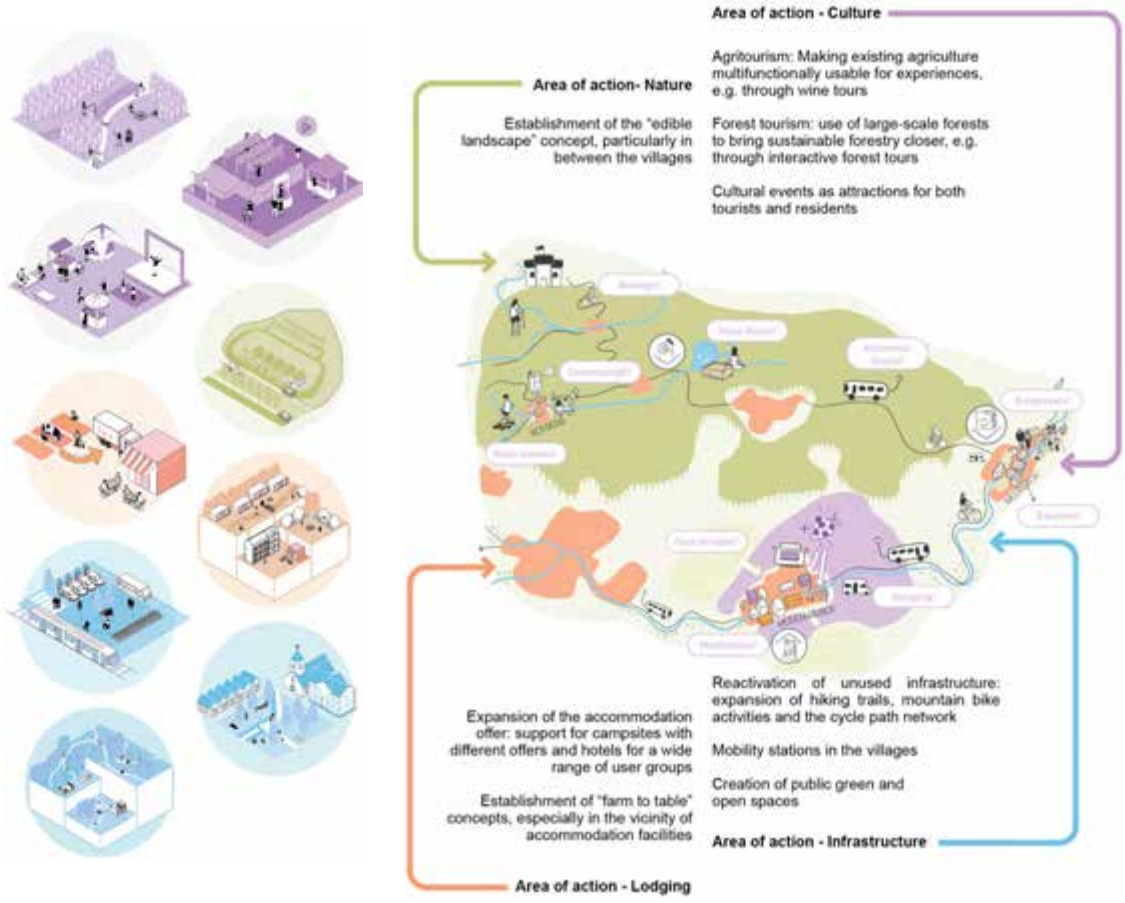

Fig. 18: Areas of action and the according catalogue of measures of the future vision 'Net-Zero Tourism'. Source: Authors 2024.

B. Climate-Positive Zwirgberg

This vision focuses on climate change, particularly extreme weather events, changes in biodiversity, the energy supply, and sustainable mobility. Forest structures, agriculture, wind turbines, and places such as Niederkalm are characterized by climate-adapted development. Zwirgberg aims to become climate-positive by 2050, surpassing the goal of merely achieving climate neutrality. This proactive approach to climate change is included in the vision for the future. The measures cover construction and housing, forestry, and agriculture.

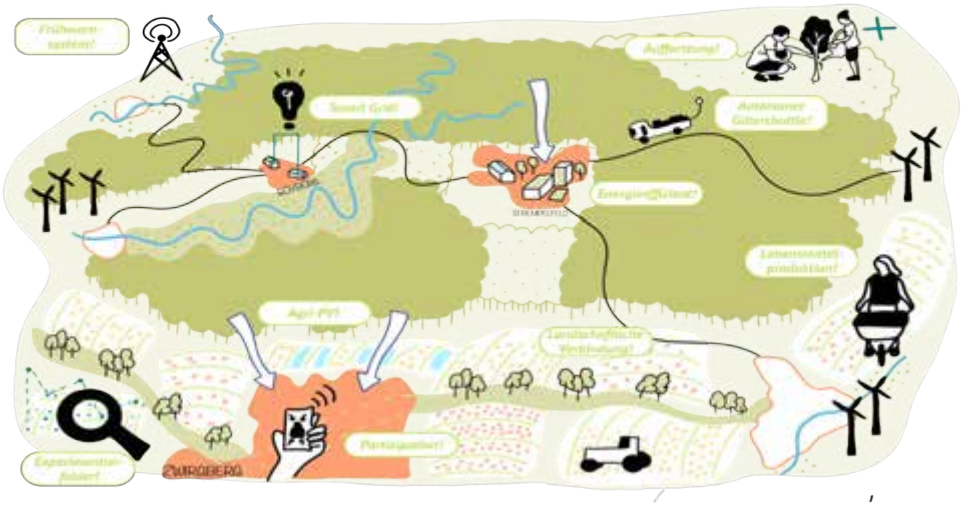

Fig. 19: The conceptual image of the future vision 'Climate-Positive Zwirgberg'. Source: Authors 2024.

C. Interconnected Community

Central to this vision is the reorganization of the administrative and supply structure. Zwirgberg becomes a federally cooperating community in which administration, social services, mobility, and education are networked via a digital platform. Shared infrastructure, shared resources, and hybrid co-working spaces form the basis of a new municipal governance model. Smaller local units retain their autonomy but benefit from the network character of the overall community.

Fig. 20: The conceptual image of the future vision 'Interconnected Community'. Source: Authors 2024.

6. Discussion and conclusion

The 'Municipality 2050 - The next Generation' research project demonstrates the potential of an experimental approach using digital, creative and analytical methods. The chosen approach of using a fictitious but realistic model municipality as a projection surface for future issues has proven to be a viable basis for reflecting on real development challenges.

The combined methods proved to be particularly effective: the combination of GIS-based analysis, modular settlement structuring, participatory scenarios and narrative elements enabled a high degree of reflection and connectivity. The creative and analytical work with real settlement fragments strengthened the transferability to real contexts. At the same time, the fictional nature of the model allowed for a certain degree of non-bindingness, which opened up scope for the municipal actors to selectively explore possible future options without political pitfalls.

Nevertheless, it is important to acknowledge the limitations of this approach: Transferability depends largely on the willingness of local authorities to embrace new ways of thinking. Methodologically, the approach also requires a certain degree of planning and data expertise in order to be able to interpret and use models, scenarios and spatial analyses. Collaboration with students proved to be a strength in this context, as their perspectives provided creative impetus, but also required a substantial degree of guidance and structuring.

The central realisation is that it is less about a 'right model' and more about a comprehensible and well-structured process of self-assurance and perspective building. Zwirgberg as a fictional but realistic model space offers a versatile framework for this. The further development now lies in transferring the reflection into real practice - with the Verbandsgemeinden, for which Zwirgberg can also be a mirror.

Next Generation EU The Case of Rome, two strategic actions within a list of projects

Giovanni Caudo
Roma Tre University, Department of Architecture
Email: giovanni.caudo@uniroma3.it

Abstract
This paper examines the implementation of the Italian National Recovery and Resilience Plan (PNRR) in Rome, with a particular focus on its urban dimension. It analyses how city governance, through the creation of a dedicated department and a Special Council Commission, has responded to structural deficiencies by strategically integrating extraordinary resources with long-term urban planning goals. Special attention is given to the Integrated Urban Programs (PUI) of Corviale, Tor Bella Monaca, and Santa Maria della Pietà, highlighting their transformative potential as nodes of innovation and inclusion. The case of Rome exemplifies a shift from top-down emergency planning to territorially grounded governance strategies.

Keywords: Urban regeneration; PNRR; Rome; Integrated Urban Programs (PUI); Living Labs; Urban governance

1. Introduction

In recent years, cities have emerged as crucial actors in responding to major global transitions — from climate adaptation to social resilience and digital innovation. However, this urban protagonism has often clashed with the rigidity of national frameworks and the inertia of institutional systems. The COVID-19 pandemic accelerated this tension, exposing not only the fragilities of public infrastructure and governance but also the untapped capacity of cities to act as laboratories of policy innovation.

In this context, the European Union launched Next Generation EU, a historic recovery instrument endowed with €750 billion to support Member States in addressing the post-pandemic crisis. The Italian National Recovery and Resilience Plan (PNRR), the most extensive national plan in the EU with over €190 billion allocated, represents a once-in-a-generation opportunity to reshape public investment, institutional capacity, and territorial development.

Despite its transformative potential, the Italian PNRR has been repeatedly criticised for lacking an overall vision — a "plan without a plan" — with limited coordination, a top-down allocation of resources, and little attention to territorial specificities. Especially in urban areas, this disconnect has often resulted in a mismatch between funding opportunities and actual urban needs.

The city of Rome, Italy's capital and largest metropolis exemplified this contradiction (De Leo, 2022). Initially receiving only two projects within the national strategy — Caput Mundi (focused on tourism) and Cinecittà (media infrastructure) — Rome found itself relegated to a marginal role despite its scale, complexity, and governance challenges.

However, Rome did not remain passive. The change in municipal leadership in late 2021, with the election of Mayor Roberto Gualtieri, marked a decisive turning point. The new administration implemented an ambitious institutional framework to realign the city's strategic vision with the fragmented architecture of the PNRR. It established a dedicated Department for Strategic Planning and PNRR (DPSP) and created a Special City Council Commission (CS PNRR), facilitating interdepartmental coordination and participatory oversight.

This paper examines how Rome utilised the PNRR not only as a financial opportunity but also as a catalyst for strategic urban governance. Through a detailed analysis of the Integrated Urban Programs (PUI), particularly those of Corviale, Tor Bella Monaca, and Santa Maria della Pietà, this study aims to understand how cities can transform emergency funding into long-term urban development.

The aim is twofold: first, to identify the institutional, spatial, and participatory mechanisms that have enabled

Rome to reclaim agency within a nationally constrained framework; second, to reflect on how this experience aligns with the principles of the evolving Urban Agenda for the EU, proposing a path toward institutionalising such practices beyond 2026.

2. The PNRR in Rome: Context, Governance, and Actors

Rome's relationship with national investment programs has historically been complex and ambivalent. As the capital city, Rome is burdened with both symbolic and administrative functions, but it lacks the financial and institutional autonomy typical of European metropolises. The PNRR has made this contradiction even more evident.

Rome's National Recovery and Resilience Plan (PNRR) was developed in two distinct phases. The first phase, conducted in parallel with national planning, was led by the municipal administration under Mayor Virginia Raggi (Five Star Movement), in office until the end of October 2021. The second phase commenced with the inauguration of the new administration, headed by Mayor Roberto Gualtieri (centre-left), on 3 November 2021, marking the start of the PNRR's operational implementation in the city.

During the initial phase, the City Council focused on drafting a "Resilient and Sustainable Development Plan" (Autumn 2020), incorporating 159 projects proposed by various departments of Roma Capitale. The total value of this plan amounted to €25 billion, intended to be financed through the Recovery Fund. The proposals addressed strategic domains for the city's recovery and growth: social inclusion and urban regeneration, sustainable and integrated mobility, safe and efficient infrastructure, ecological transition, and digital innovation. However, this strategic vision and the projects it comprised were not included in the national PNRR approved by the European Commission in July 2021. In that version, Rome was represented only through two national projects of relevance: Caput Mundi and Cinecittà. Nevertheless, parts of Raggi's proposal, especially those related to the tram lines and the enhancement of the city's archaeological and historical heritage, were later reabsorbed into national programs.

With the arrival of the Gualtieri administration, the launch of the first national funding calls marked a turning point. To successfully participate and secure funding, Roma Capitale signed cooperation agreements with universities in the Lazio region, ensuring a high level of scientific and technical support in the preparation of project proposals. Simultaneously, based on a national agreement between the government and **Invitalia**, the city coordinated its departments to prepare tenders for the design and/or implementation of works (Caudo G., Baioni M., Celata F., De Leo D., Fava, F., Piselli E., Tomasello P. (2024).

A pivotal agreement was also signed with the **Metropolitan City of Rome (CM)** to jointly participate in the call for **Integrated Urban Programs (PUI)**, which allocated €300 million to the CM. This agreement established a collaborative framework between Roma Capitale, the CM, and its municipalities, reserving approximately €200 million for Rome and the remaining funds for other municipalities within the metropolitan area.

In 2022, the majority of the PNRR-related calls were issued, and the city engaged in negotiation procedures with the respective ministries. In June 2022, Mayor Gualtieri, acting as Government Commissioner for the Jubilee, signed an agreement with the Ministry of Tourism (the lead authority for Caput Mundi) to transfer its governance to Roma Capitale. Following this agreement, some of the projects were integrated into the Jubilee framework, while others remained under the direct responsibility of Roma Capitale or were managed by the Ministry of Culture through its Special Superintendency for Rome.

Roma Capitale and the CM participated in nearly all available calls for which they were eligible. In addition, they engaged in "negotiated procedures" with central government entities for strategic, non-competitive projects, such as Caput Mundi, the bicycle lane network, tram and electric bus infrastructure. Some initiatives already financed through other programs (e.g. **PINQuA** — the National Innovative Program for Urban Quality of Living) were also integrated into the implementation framework.

Rome's participation rate in national calls approached 100%, and the city succeeded in securing approximately **90% of the total resources requested**, resulting in an allocation of **€1.15 billion** (excluding additional co-funding from the Ministry for tramways and municipal contributions for PINQuA and cinema/theatre projects). However, one principal exclusion concerned funding for **waste treatment infrastructure** under Mission 2, Component 1, Investment 1.1 (lines A and B), totalling €191.4 million. This rejection was due to selection criteria established by the Ministry for the environment, which prioritised projects in small- and medium-sized cities based on expected impact, thus penalising large metropolitan areas such as Rome.

At the end of the funding acquisition phase, the scope of PNRR investments in Rome had expanded significantly, covering a wide range of strategic sectors (e.g. mobility, digitalisation, culture, and inclusion). From an initial allocation of just under €230 million for Caput Mundi, the city's direct management of resources grew to nearly **€1.2 billion**. Despite several critical issues, the formation phase of Rome's PNRR can, therefore, be regarded as a **successful institutional response** to a challenging national framework.

This paper adopts the perspective of those who view the PNRR not simply as a disbursement mechanism but as an **opportunity to be amplified through the introduction of new tools, methods, and institutional arrangements**. These mechanisms — although shaped by exceptional and complex circumstances — can serve as catalysts for long-term transformation.

While maintaining a critical eye on the structural weaknesses of the PNRR — such as the excessive emphasis on the **quantitative volume of resources** as the dominant evaluative criterion — this contribution argues for a broader and more qualitative understanding of its governance implications. The prevailing narrative has obscured the **absence of strategic planning** and reinforced the impression of a "plan without a plan" (Pizzo, 2022). Furthermore, the national government's interpretation of Rome's role has appeared **anachronistic**, limiting the capital's potential to two symbolic areas — **Cinema and Ancient Rome** — as though the city still belonged to the era of La Dolce Vita. Such a reductive vision fails to grasp the complexity of contemporary Rome and its need for integrated, future-oriented planning.

3. Urban Regeneration Strategies: The Integrated Urban Programs (PUI)

The PUIs, funded under **Mission 5** of the PNRR (Cohesion and Inclusion), represent the most territorially grounded and socially complex component of the plan. In Rome, three priority areas were selected: **Corviale**, **Tor Bella Monaca**, and **Santa Maria della Pietà** — each a symbol of spatial marginality and socio-economic fragmentation. The regeneration model adopted goes beyond physical upgrading. It involves:

- Multi-level coordination (City, Region, ATER, third sector)
- Activation of **30 Civic and Cultural Hubs**
- Integration of **immaterial actions**, such as job activation, education, and care services
- Strong emphasis on **participation and proximity governance**

This integrated approach aims to shift the paradigm from housing-centric redevelopment to **neighbourhood-based regeneration**, embedding welfare, culture, and active citizenship into the very structure of public space.

3.1 Corviale and Tor Bella Monaca, two peripheral icons

Corviale and Tor Bella Monaca are among the most emblematic cases of public housing estates in Rome and, more broadly, in Italy. Both represent the architectural and social outcomes of large-scale, modernist planning in the post-war period. Over time, however, these projects became spatial containers of structural inequality — synonymous with marginalisation, physical decay, and institutional neglect.

However, these same spaces have also become laboratories for resilience, experimentation, and urban innovation. The PNRR's Integrated Urban Programs (PUI) did not impose regeneration from above but built upon years of local action, community work, and territorial knowledge.

3.1.1 Corviale: From Architectural Symbol to Regenerative Ecosystem

Corviale is one of the most iconic urban structures in Italy — a monolithic, one-kilometre-long residential block built between the late 1970s and early 1980s in the southwestern quadrant of Rome. Originally conceived as a "linear city" capable of self-sufficiency, with housing, services, commerce, and leisure integrated within a single continuous structure, Corviale soon fell short of its utopian vision.

Only 80% of the complex was completed, and the entire fourth floor, designed for public and commercial use, remained empty. Over time, this space was informally occupied by families in need of housing, reinforcing the area's stigma. Corviale became a symbol of both architectural excess and public policy failure.

However, since 2014, a new phase began with the launch of the Laboratorio di Città Corviale, coordinated by Roma Capitale, the Lazio Region, ATER (the public housing agency), and multiple academic and social actors. The Laboratorio operates as a place-based institutional infrastructure, combining participatory design, public deliberation, and technical planning.

Thanks to this groundwork, when the PNRR was launched, Corviale was already equipped with a governance platform capable of channelling new investments. The €43 million allocated through the PUI was not a starting point but an accelerator of an ongoing process.

The core objective of the PUI in Corviale is the **completion and functional reactivation of the fourth floor** — the so-called piano libero. This space, once a void and a site of informal appropriation, will be transformed into a **linear public infrastructure** housing:

- Social and cultural services
- Spaces for education and training
- Job creation hubs and co-working areas
- Healthcare and psychological support facilities

The project explicitly adopts the principles of **proximity urbanism**, aiming to restore access to rights and services within walking distance. It is not only a physical intervention but an **institutional reconfiguration** of space — converting a zone of abandonment into a civic backbone.

Parallel to the physical works, a package of **"immaterial" actions** has been activated, encompassing educational support, health services, and employment pathways tailored to the residents' skills and needs. These programs are implemented in cooperation with third-sector organisations selected through public calls.

3.1.2 The Role of the Laboratory

The **Laboratorio di Città Corviale** plays a central role in ensuring the continuity and coherence of the regenera-

tion process. It serves as:
- A **platform for co-design** involving residents, schools, cultural associations, and local businesses
- A **mechanism of coordination** among city departments, ATER, the Lazio Region, and technical offices
- A **monitoring and learning space** where policies are assessed, adapted, and scaled

This multi-actor configuration ensures that regeneration is not only planned "for" Corviale but "with" Corviale. Moreover, the Laboratory maintains a **public presence within the building itself**, operating from offices located inside the complex — a deliberate choice to **reduce institutional distance** and promote trust.

Intervento Cavea - ante e post-operam.

Intervento Parco Est (rimozione delle barriere visive e accesso al Centro Polivalente Campanella)- ante e post-operam.

Fig. 4 – Corviale's pojects

What emerges in Corviale is more than a redevelopment project. It is a **shift in urban policy** from isolated, short-term interventions to **systemic, cross-sectoral governance** rooted in place. The integration of PNRR resources into a pre-existing strategic trajectory demonstrates how **extraordinary funding can reinforce, rather than distort, local priorities**.

This model challenges traditional notions of urban renewal, which often treat physical upgrading as sufficient. In Corviale, **social infrastructure and public institutions are considered integral components of the regeneration strategy**, not add-ons.

In that sense, Corviale is not only a case study but a **prototype** — offering insights into how European cities can manage complexity through adaptive, participatory, and spatially grounded urban governance (Nevens, F., Frantzeskaki, N., Gorissen, L., & Loorbach, D. (2013).

3.1.3 The Laboratory as a Living Lab: Participatory Urbanism in Practice
The Laboratorio di Città Corviale can be interpreted through the conceptual lens of the **Urban Living Lab** (ULL) — a model of urban experimentation that combines **multi-stakeholder engagement, place-based co-creation, and iterative learning cycles** to address complex challenges in real-life settings (Schliwa & McCormick, 2016; Steen & van Bueren, 2017).

Living Labs are increasingly recognised in urban studies and innovation policy as **arenas for collaborative experimentation**, where public institutions, residents, researchers, and civil society actors engage in the co-production of knowledge, policies, and services. They aim not only to test solutions but to transform institutional relationships and build new capacities for governance.

In this light, the Laboratorio di Città Corviale functions as a **territorially embedded Living Lab** with distinctive characteristics (Nevens et al., 2013; Marvin et al., 2018):
• **Spatial anchoring**: The Laboratory is physically located within the Corviale complex, reducing the symbolic and operational distance between the administration and residents.
• **Actor plurality**: It engages a broad coalition of stakeholders — including Roma Capitale, the Lazio Region, ATER, universities (e.g., Sapienza, Roma Tre), local associations, and informal groups — operating under a shared, negotiated framework.
• **Iterative co-design**: Project development unfolds through **cycles of consultation, feedback, and redesign**, echoing the iterative logic of Living Labs. This is particularly evident in the reprogramming of the "piano libero" and the tailoring of social services to residents' expressed needs.
• **Learning infrastructure**: The Laboratory not only implements but also **documents and reflects on processes**, producing governance knowledge that can be transferred or scaled to other contexts (e.g., the Lab is now in dialogue with similar initiatives in Tor Bella Monaca and Santa Maria della Pietà).

In contrast to traditional participatory mechanisms, which are often limited to public hearings or consultative boards, the Laboratory adopts a **model of embedded co-governance**. This means that citizens are not merely external observers but **co-producers of planning decisions**, contributing both their lived experiences and social knowledge.

This approach aligns with recent scholarship that frames Urban Living Labs as **transitional governance spaces** (Bulkeley et al., 2016) capable of mediating between formal institutions and grassroots innovation. The Laboratory acts as an **intermediary arena** where diverse rationalities — bureaucratic, political, civic — are negotiated and recomposed into shared actions.

Moreover, the Laboratory has become a **site of institutional learning**, allowing Roma Capitale to experiment with regulatory flexibility, cross-sectoral coordination, and capacity-building in a low-risk, high-feedback environment — precisely the conditions recommended in the literature for successful ULL implementation (Nevens et al., 2013; Marvin et al., 2018).

Perhaps the most important legacy of the Laboratory is cultural: it fosters an alternative narrative about Corviale, moving beyond stigma toward a **collective re-imagining of the city**. Demonstrating that collaborative processes can be compelling, legitimate, and inclusive contributes to a shift in the institutional mindset of public administration.

As Rome looks to scale similar approaches to other neighbourhoods — including Tor Bella Monaca and Santa Maria della Pietà — the Corviale experience offers a **blueprint for cultivating a city-wide Living Lab ecosystem**, where regeneration is understood not as an intervention **in** the territory but **with** and **through** it.

4. **Toward a Strategic Description of the Plan: PUI and the Monumental Archaeological Center**
Currently, two coordinated efforts can be identified in Rome as attempts to develop a more strategic reading of the National Recovery and Resilience Plan (PNRR): the **Integrated Urban Programs (PUI)** and the **Fori Project**, specifically, the projects related to the **Monumental Archaeological Centre of Rome** (CArMe).

The three PUI initiatives are described as **innovation hubs** that combine interventions on the built environment and the creation of public spaces with the ambition of integrating **immaterial (social and relational) projects** aimed at supporting physical redevelopment through responses to the **real needs of the local communities**.

This aspect has been strongly emphasised by the work of the **Special Commission on the PNRR (CS PNRR)**, which has held a series of hearings on the implementation of the PUIs. These meetings have involved actors from the **third sector**, **trade unions**, and **neighbourhood associations**, all engaged in building paths toward meaningful integration. One concrete result of these participatory processes has been the **issuance of calls for expressions of interest** by the Department of Social Affairs for the **co-design of interventions** within the PUIs, which will also benefit from additional resources — approximately **€10 million** from the PON Metro fund (currently being finalised).

Among the **immaterial projects** included in the PUIs is the **experimental adoption of active labour policies**, inspired by the French model of Territoires zéro chômeur de longue durée ("Territories with Zero Unemployment"). The PUIs are further reinforced by the development of **30 Civic Hubs (Poli Civici)**, which together create a **strategic framework for the urban periphery** of Rome, structured around three principal axes (Corviale, Tor Bella Monaca, and Santa Maria della Pietà) and thirty civic nodes distributed across the city.

What is meant by "Civic Hub" is, in fact, a central question being addressed through these projects. For example, the transformation of a local library into a **Civic Hub** provides an opportunity to design a **context-sensitive offering of proximity services** tailored to the specific characteristics and needs of each neighbourhood. The Civic Hub thus becomes a flexible infrastructure, adaptable to local differences and a vehicle for redefining the scale and nature of urban welfare.

The **Monumental Archaeological Centre of Rome (CArMe)** is a project currently under development by **Walter Tocci**, whom the Mayor has appointed to coordinate interventions in the areas of the **Imperial Fora, the Colosseum Park, the Circus Maximus, the Celio Hill**, and the **Archaeological Promenade** (Passeggiata Archeologica).

This initiative builds upon the vast set of investments launched under the Caput Mundi programme — not only those developed by Roma Capitale but also those promoted by the Ministry of Culture — with the objective of delineating a **comprehensive and unified strategy** for the archaeological heart of the city.

Naturally, the project is also being developed in alignment with the **Jubilee 2025**. It revives the conceptual thread of long-term reflection, dating back to Leonardo Benevolo's **Progetto Fori** (1985), reactivating the ambition to make the monumental core of ancient Rome **more accessible, integrated, and coherent**, both in terms of urban form and cultural function.

5. Conclusion – Beyond the PNRR: Strategic Futures and the Urban Agenda for the EU
The implementation of the PNRR in Rome offers not just a case study in urban resilience under extraordinary conditions but a window into the possible futures of urban governance in Europe. While the PNRR was born as a crisis-driven funding mechanism, its unintended consequence has been to expose both the latent capacities and systemic shortcomings of local administrations. In Rome, this stress test has produced a response that is

not only reactive but, in many respects, structurally transformative (Viesti, 2023).

The introduction of dedicated institutional frameworks (DPSP PNRR and CS PNRR), the successful engagement of civil society, and the embedding of participatory practices in the design of public investment all point to a more mature, place-based model of urban policymaking. These developments contrast sharply with Italy's traditional model of urban governance, which has long been characterised by fragmentation and limited strategic capacity at the local level.

As the 2026 deadline approaches, the sustainability of this transformation is far from guaranteed. The risk is that institutional innovations may be dismantled once the extraordinary funding cycle ends — a step backwards when cities must act as frontline actors in addressing climate, social, and digital challenges.

In this context, the Urban Agenda for the EU is crucial. Since its launch in 2016, it has evolved to give cities a role in shaping EU policies. The New Leipzig Charter and Ljubljana Agreement promote integrated, place-based, multi-level governance — principles Rome has already put into practice.

Italy now faces the task of institutionalising these practices. The PNRR has been a stress test; now, it must become a foundation. The Urban Agenda should guide ordinary planning, supported by:
- Long-term funding for cities;
- Stronger inter-municipal governance;
- Enhanced capacity building and civic participation.

Rome can become a living laboratory for the Urban Agenda — not just reacting to emergencies but planning its future. The real goal is not merely to administer funds but to institutionalise the capacity for continuous, democratic, and inclusive urban change.

Should planning and policy gather around the concept of "community of disagreement"?

Abstract
The planning field tends to have consensus building as a guiding inspiration. Politics, on the other hand, is an activity characterised by disagreement and competition over ideology, values, knowledge, and planning solutions.

Since, or if, we in the planning field today are concerned with giving politicians a leading position, we must recognise the need for politicians to highlight disagreement. Only then will planning become a tool for political governance and for strengthen democracy.

We will in this paper present some main positions in the field of planning theory regarding handling professional and political disagreements, and then introduce the concept «communities of disagreement», as it is defined and discussed in the book Communities of disagreement: perspectives on democratic interaction[1] (Iversen, 2014).

Key words: Community of disagreement, politics in planning, disagreement in planning

Introduction

This text is more of a reflection than a conclusive answer. to the question "Should planning and policy gather around the concept of 'community of disagreement?" I will argue that this concept, with its theoretical foundation and practice, will be fruitful to use in the debate on how societal planning has dealt with and should deal with disagreement. The field of planning, both in theory and practice, often has consensus as its guiding star for normative theory and practice development. Politics, on the other hand, is an activity characterised by disagreement and competition over ideology, values and what constitutes legitimate knowledge. In politics the goal may be to cultivate disagreement, rather than to reach an agreement. If, or when, we in the planning field are concerned about that politicians should take the leadership position that planning legislation[2] emphasises they should do, the planning field must both recognise and make room for politicians' need to highlight disagreement, also in planning processes. Only then will societal planning become a tool for both political leadership and for strengthening democracy.

I stumbled upon the concept a couple of years ago at the Nansen Center for Peace and Dialogue in Lillehammer (https://peace.no/), which uses the concept in its dialogue work, e.g. in the New handbook: A practical approach to public dialogue NEW HANDBOOK: A practical approach to public dialogue https://peace.no/en/new-handbook-a-practical-approach-to-public-dialogue/

For a number of years, I have followed and admired this dialogue work that takes place primarily in other countries other countries i.a. the Balkan countries, Ukraine, Chile, Afghanistan, Poland, but also in Norway. The core of their work is to build trust and communities in societies with strong opposing interests and high levels of conflict. The ambition is to increase the understanding and respect for disagreement, to be able to better live with, rather than resolve, such disagreements.

Disagreement is normal within organisations and societies. It is important in a democracy to accept disagreement, to consider it as something inevitable. Disagreements can be both problematic, action-paralysing, and destructive, while also engaging, and have the potential for new thoughts and actions, for innovations.

In this paper, I primarily focus on how the field of planning over the years has given attention to disagreement with emphasis on the place of politics and politicians in the planning field. I delve into some Norwegian and

1 Own translation from Norwegian
2 At least in Norway

international planning theory texts, Norwegian planning research, government planning guidelines, and apply experiences from my own planning research, teaching, student guidance and lecturing activities. I will also draw on experiences from 40 years as a political activist, 25 years as an elected official at local, regional, and national levels, and as an active member of a political party, various organisations, and trade union movements. Politics, however, is not my academic field, just my field of practice, cf. the book Planners in Politics: Do they make å difference (Albrechts ed., 2020) where I have written the chapter 'Forty years as a politician with a background in planning. How did this affect me as politician and as a planner?' (Hagen, 2020).

Concluding opinion

My concluding opinion is that (i) politics and politicians are given too little attention in the field of planning. When attention is given, it is more that politics and politicians are part of the problem rather than part of the solution. The dominant narrative is that politicians come late into the process and often politically tear up thoroughly prepared comprehensive planning proposals. (ii) The field of planning, with its focus on striving for agreement and consensus, finds it difficult to incorporate politics' inherent need to highlight disagreement with other politicians and political parties, and to compete for perception of reality, goals and means of action. I believe that this normative pressure to achieve consensus weakens both planning's and politics' place in societies and organisations by making the activities less interesting and relevant for people - citizens and voters. This is unfortunate and pity, especially because part of the purpose of planning should be to sustain and refine an engaged and vibrant democracy.

Politics as a theme in the field of planning – ideals and realities.

Planning is an inevitable activity. "We are constantly thinking about the future and how to control it. Man is therefore a planning animal. ... Planning is as old as man." says José L. Ramírez (Ramírez, 1995:24). The public sector is planning like never before, at least in Norway - the Nordic countries. One of the many reasons is that politicians increasingly see planning as a tool for putting their own political issues on the agenda.

Planning theorists and practitioners who aim to make planning as comprehensive as possible often describe planning as a stepwise activity with four main phases: 1) Basis for decision-making: Interpretations of current situation, likely and desirable futures and means to get there. 2) Decisions: Determination of what we want to achieve in the future, in what way. 3)Implementation: From 'words to action'. 4) Evaluations: Output and outcome, what happened, with which results and why.

Traditionally, planning theorists and practitioners have limited planning to be only phase 1. For others phase 2, is defined as part of the planning process, making planning contain two main elements (Kleven ed. 1998:12): Element no 1 - using some form of scientific, knowledge-based analysis method. Element no 2 - making decisions about future actions based on this methodological analysis foundation. Politicians have traditionally been relegated to phases no 2 and element no 2. Politicians are decision makers, not planners.

This brings us to a core question within planning: To what extent can organisations and societies be scientifically, or shall we say professionally, observed, cf. phase no 1? Traditional planning processes are often characterised by professionals, primarily planners and consultants, producing and informing about facts of the present and forecasting both possible and professionally recommended futures. Then, elected politicians, 'lay people,' signal which of these futures with associated means they desire.

Tha planning field have both theoretically and practically developed away from this position in recent decades. However, the growth of participatory and co-creation theories and methods in recent decades has not decisively changed this basic culture and practice of division of labor between disciplines/administration/planners and politics/politicians. For example, it is preferably professionals, and professionals alone without participation and political involvement, who prepare the "knowledge base" in municipal and regional planning documents.
An alternative approach involves a rejection of the fact that facts about the present and expected future unambiguously exist, and a rejection of the fact that correct action comes as an automatic consequence of

being aware of specific, selected facts. Organisations and societies must be "read", understood, interpreted like text in a book, more than unambiguously registered, investigated and researched using statistical methods. It is also impossible to make certain forecasts for the future development of open systems such as municipal organisation and municipal/county society. My experience as a politician over many years is that there are often greater disagreements about what the current situation is in a society or a thematic area such as climate change or inequality, than about what are good future situations and good planning solutions.

This gives us a situation where neither politicians (lay people), planners (the scholars) nor researchers (the super-scholars) can objectively or adequately capture the past or present, i.e., describe the situation unambiguously as it was and as it is. The cognitive basis is that facts and truth, right and wrong, good, and bad can be fleeting, situational, deeply individual, i.e., something that fundamentally belongs to politics. Then it is problematic when/if the planning field has agreement as a guiding star, when politics undeniably has competing disagreements as an inherent feature.

Planning theory – A glimpse into historical main positions

Most of the leading planning theorists from the 1960s have focused primarily on developing the normative aspects of planning. This one-sided focus on improving and refining the normative approach has tended to go beyond understanding the planning activity that takes place. This has led much theoretical development away from practice rather than attempts to understand and respect practice. The theoretical contributions have become of little practical use; even misleading with all their heavily normative expectations for both the planning process and the planning product.

Here follows a brief introduction to a few theoretical contributions that, for me, stand out as most relevant in the discussion of the place of politics in societal planning. Such brief glimpses do not do justice to the planning theory debate - most contributors and perspectives are not mentioned.

It seems that Edvard C. Banfield in the 1950s gave us the recipe for a normative ideal for planning: First, present a normative model ideal and then analyse various means to achieve the goal, choosing the means that professionally ensure the best goal achievement (Banfield, 1959:149).

The rationalist planning theory and method are born. The normative guiding star becomes consensus because of unequivocal knowledge produced by experts. One must then expect that politicians will loyally listen to the experts when they are invited to make the formal planning decisions.

However, Charles Lindblom immediately responded with the following criticism (Lindblom, 1959, 1973, 1979): It is both useless and unproductive to operate with an ideal that is completely impossible to achieve, which lies in "The range of impossibilities."

In a reality characterised by uncertainty and disagreement about what constitutes valid knowledge, by conflict of interests and political disagreement, we should choose what is possible, what can be politically implemented given the prevailing power relations. Incremental planning therefore prescribes a step-by-step approach where you try, occasionally fail, and learn during the processes, and where you do not waste time identifying all workable solutions and consequences.

Incremental planning provides a greater room and need for politics than Banfield's rationalist planning ideal. Lindblom argues that consensus about goals and means in societal planning is often unrealistic, not achievable, and not politically rational. Lindblom warns against unrealistic ideals:

"What kind of aspiration, norm, or ideal gives direction and other specific guidance to a body builder - his hope to have the strength of a gorilla or his attention to exceed Arnold Schwarzenegger? For a soprano, the impossible aspiration to hit a note six octaves above the highest note ever sung, or the resolve to reach A above high-C?"

(Lindblom, 1979: 518)

Practice must seek to achieve what is possible, what can be achieved, a consensus on minor ("incremental") changes that occur without the resistance becoming too noisy and paralysing. This gives a greater degree of both room for and need for politics than in Banfield's rationalist planning ideal. Politicians must develop solutions that at least a majority of elected officials in, for example, a municipal or county council can support.

Later, throughout the 70s and 80s, and up to the present day, other theories became more visible, especially the communicative approach. Where Banfield's normative ideal has professional analysis as a key concept, and Lindblom relies on incremental changes, reestablishes the communicative position the idea of consensus. Achieving agreement should be possible thanks to the 'force of the best argument' (Pløger, 1998). Pløger writes in the research report «Communicative Planning: Between Communication and Rhetoric" (Pløger, 1998) that there are two research perspectives dominating the 80s and 90s; the communicative planning theory inspired by Jürgen Habermas and "the perhaps less known research that views planning as a 'rhetorical activity' and exercise of power (Pløger, 1998:3), inspired by, among others, Michel Foucault. Consensus is neither possible nor desirable as a planning ideal.

Inspired by the communicative turn, much planning practice in the seventies, also in Norway, was genuinely concerned with active participation, and that this could result in unified planning solutions (e.g., "Arbeidsbokmetoden"[3] Orhaug, 1988). What is new in this communicative turn lies in the fact that influential planning theorists to a particular extent focused on the dialogue itself, the dialog in practice: How to get dialogue to promote understanding, how to get it to be as "dominant-free" as possible, so that it ensures that always "the best argument" wins.

The process becomes central. It becomes important to involve, in the planning dialogue, as many as possible of those affected by the planning work. Direct participation is more appropriate and better for so-called weak groups than being represented by spokespersons and "radical" planners, respectively "Advocacy Planning" and Radical Planning (Pløger, 1998:11). While incrementalism heavily relies on the assumption of a functioning representative democracy, the communicative position focuses on more people engaging in dialogical processes where it becomes paramount to promote mutual understanding of each other's positions in dialogue and develop new, agreed-upon positions.

Patsy Healey writes in her article "Planning through debate. The communicative turn in planning theory" (Healey, 1992) that planning is a child of modernity. By using scientific knowledge and reason, people/organisations/societies are liberated from the "tyranny of thought" that can follow from religious regimes and political/military dictatorships. One of the main challenges to this planning paradigm is related to the criticism of the idea of the scientifically based reason's superior position, in relation to local, tacit, or experience-based knowledge. The salvation for the planning project lies in developing the communicative aspects of planning. By moving from individual reason to reason that emerges because of intersubjective communication, one avoids "destructive relativism." The good and right is what we can develop together through communication and simultaneously agree upon. The dialogue should be informed by knowledge; the communicative position does not reject scientific knowledge, cf. Banfield's normative planning ideal – it is just not seen as superior. For all the planning theorists who lean heavily on Habermas, the dialog-based consensus often becomes a requirement that we can and should make for planning. The pursuit of consensus becomes a central content in the very understanding of normativity.

Bent Flyvbjerg argues in his doctoral dissertation Rationality and Power (Flyvbjerg, 1991) that Habermas's discourse ethics are based on the following thinking: If the rules in this discourse ethics are followed, the result will be rational and acceptable actions. But for Flyvbjerg, it makes little sense to separate power and communication as much as he believes Habermas does by composing such process ideals. He aligns himself

3 The Workbook Method – my translation

with Richard Rorty, who claims that communicative rationality almost has a religious status in Habermas's thinking (Rorty,1985). Habermas's optimism about reason is problematic in relation to what happens in actual communication processes. Communication will be characterised by interest preservation, not by domination-free and consensus-seeking (Ramírez, 1995). Flyvbjerg argues that Habermas's work for more democracy diverts attention away from fundamental power relations. This is unfortunate because attention to power relations is precisely a first prerequisite for more democracy.

In this sense, Flyvbjerg's criticism of Habermas and all the planning theorists inspired by him has much in common with Lindblom's criticism of Banfield's normativity. Both Flyvbjerg and Lindblom ask us not to overlook, or develop theories away from, power games and politics.

Månson gives us an additional argument about politics that is relevant for societal planning when he points out that a dialogue will always contain a "... flow of power relations that envelop and condition the discourse[4]" (Månson, 1989:326). It is unreasonable, "irrational," to be communicatively rational if one wants to gain support for their viewpoints. This was emphasised by Davidoff, the father of advocacy planning, already in the mid-60s: "... it may be simpler for professionals, politicians, or lobbyists to make deals if they have not laid their cards on the table" (Davidoff, 1965:287).

Research, development work, guidance booklets

What attention is given to politics and politicians in research, development work, and guides in planning from national ministries and KS - The Norwegian Association of Local and Regional Authorities? The main picture, up until 2018, is that politics and politicians have been given little attention. Where politics is given attention, it is usually under the theme of participation and involvement: Inhabitants, landowners, users of public services, civil society representatives, businesses should be involved early in all planning processes. Politicians are hardly mentioned in connection with participation in, and/or management of planning processes.

'Program Plan 2017-2024 Democratic and Effective Governance, Planning and Administration'[5] (DEMOS) (Forskningsrådet, 2018) is a typical example where politicians are mentioned, but mostly as one of several groups that planning must include - "... residents and users, local politicians ..." (page 17). Another clear feature is that research is to be conducted on and about politicians and then communicated to politicians. It is not conducted together with politicians. There are no co-research ambitions in this research program.

The research project 'Evaluation of the Planning and Building Act' (EVAPLAN) (NIBR, 2014) aimed, among other things, to find out to what extent broad participation and political governance are the basis for planning. When we search for the words 'politics' and 'politicians' in the two books presenting findings from the research project (Hanssen & Aarsæther a and b ed., 2018), we find that only one of the 47 chapters has the word politics in the title, namely the chapter on Planning Strategy (Kvalvik 2018). There is some writing about political leadership (pages 34 and 192), politician training (page 48), and politicised problems (page 229). The researchers have interviewed mayors but have hardly talked to part-time politicians about, for example, how to help/support/encourage part-time politicians to take the lead in planning work or to use plans/planning as a political tool.

The guidance booklet 'Municipal planning process' (Miljøverndepartementet, 2012) hardly mentions politicians. The same applies to the guidance booklet 'Participation in the planning process' (Kommunal- og distriktsdepartementet, 2014) and '10 pieces of advice for a well-functioning and effective planning system'[6](KS, 2016). None of the three addresses politicians about leading planning processes, even though we have a planning law that precisely assumes that societal local and regional planning is a fundamentally political activity.

4 My translation
5 My translation
6 My translation

However, 'Let's do it together! Handbook in local co-creative social innovation'[7] (KS, 2018) addresses the role of politicians in the co-creative municipality. It emphasises that politicians must use time for policy development together with inhabitants in various workshops, working groups, and open thematic meetings, and not spend all their time preparing for and attending meetings - with piles of ready-made documents with proposals for decisions.

Community of disagreement – introduction and theoretical foundation

The concept of "community of disagreement" is used in various areas in Norway, especially related to democracy, education, and culture. In the book "Uenighetsfellesskap: blikk på demokratisk samhandling,", "Community of Disagreement: A Look at Democratic Interaction"[8] Lars Laird Iversen writes that the term can refer to a group of people who come together around a common theme, problem, or goal but have different or conflicting views on how this theme, problem, or goal should be handled (Iversen, 2014).

In my search for the use of this concept, I have come across a bunch of texts, none of them planning texts. I therefore in this paper rely heavily on this book (Iversen 2014) and Trond Solhaug's review in the Journal of Social Research (Solhaug, 2015).

The first sentence in the first chapter titled 'Community of Disagreement' sets the tone: "Norge er et uenighetsfellesskap, og har alltid vært det" (Norway is a community of disagreements and always has been[9].) (Iversen, 2014:11). Norwegians share problems and arenas for discussion, but we share values to a much lesser extent. Our democratic communities are communities of disagreement, which he which he defines as follows:

"Et uenighetsfellesskap er en gruppe mennesker med ulike meninger, som er i en felles prosess for å løse et problem eller en utfordring" (A community of disagreement is a group of people with different opinions, who are engaged in a common process to solve a problem or challenge[10]) (Iversen, 2014:12).

For me, this goes directly to the core of what community planning is, namely solving problems and challenges together in a democracy. With this book, Iversen aims to create greater insight and debate about managing disagreement, creating consensus on critical issues, and, importantly, living with diversity (Solhaug, 2015:251). Iversen mentions school classes, religious communities, and institutions as examples of community, and in what he refers to as 'public sphere of democratic nations'[11] (Iversen, 2014:18). That must mean, in my view, that we can also include local and regional communities, as well as communities such as municipal planning committees, city councils, neighborhood associations, county councils, and civil society organisations.

Iversen is concerned with several ways to normalise and demystify disagreement, including value disagreement, so that individually and collectively, we become better at living with all this disagreement. Iversen claims that behind much perceived agreement, there is much disagreement, from the internal disagreement within the individual to disagreement in several types of communities. We must be aware that agreeing as well as disagreeing is about relationships, strategies, politics, and conventions. (Solhaug 2015:251). This reminds me of the discussion we have within planning regarding wicked problems (Rittel and Webber, 1973). The point is that 'living with' is often a wiser strategy for practice than seeking to solve these types of problems, which is precisely why they are labeled 'wicked.'

Iversen is focused on revitalising and expanding democratic processes. Influence must be genuine. We need to take more decisions back to real democratic bodies "– and away from experts, bureaucrats, markets, and

11 My translation

regional enterprises"[12] (Iversen, 2014:135). He argues that disagreement stimulates creativity (Iversen, 2014:52–58). Freedom of expression, free debates, and a positive approach to disagreement stimulate new thinking.

Iversen discusses Habermas' argument for a power-free conversation, where only the rational value of arguments is emphasised, where everyone has a real opportunity to participate. Iversen disagrees with Habermas on the view of rationality:

"Habermas argues for freedom from power in public discourse because the best arguments will then prevail. This is not necessarily the case in a community of disagreement"[13] (Iversen, 2014:138). Within the community of disagreement, the arguments for open, free, real discussions are that multiple voices provide a greater diversity of ideas, more innovation.

In the end of the book, Iversen points out that the community of disagreement closely resembles Chantal Mouffe's theory of political leadership and agonistic politics (Mouffe, 2000 and 2005, in Iversen 2014:145-156). What Iversen presents here are the same arguments found in definitions and discussions of agonistic planning theory. This is an approach to planning that has recently emerged as a critique of and alternative to communicative planning theory. The agonistic perspective recognises that conflict is an inevitable part of democracy. Therefore, the idea that the goal of democracy is to achieve consensus among society members is rejected. On the contrary, disagreement is somewhat of an inherent necessity in a lively, engaging democracy. In an agonistic model, both for politics and planning, the conflicting parties acknowledge each other as legitimate, even though they disagree. They accept common premises and procedures for political struggle and planning discussions, enabling a more constructive form of conflict, and increasing the likelihood of innovation.

Community of disagreement – implications for planning practice

Planning literature is dominated by arguments that agreement is preferable, a prerequisite for successful planning. It is about, among other things, creating legitimacy for a plan, preventing frequent rematches, and showing outwardly that one stands united. Overall societal plans, such as municipal plans and regional plans, should preferably give a positive picture, that it is attractive to live and work in this local/regional society. It is therefore important to show optimistic agreement, not to expose disagreement and conflict.

However, such a consensus ambition also has negative consequences. Firstly, it can weaken party politics and thus engagement among party members and voters. The consensus ambition can suppress political debate, as it encourages compromise and agreement rather than highlighting and addressing political divides and ideological differences. Furthermore, it risks overlooking or smoothing over fundamental differences and conflicts in society. This can make it harder for voters to see clear differences between parties, thereby weakening parties' ability to profile themselves and mobilise voters based on clear political alternatives. Without clear conflict and debate, voters may also feel that democracy is not functioning properly because the planning documents do not contain disagreements and conflicts.

Secondly, consensus gives increased attention to planners, administrative staff, and experts. Consensus-oriented planning is often characterised by a heavy emphasis on inputs from planners, administrative staff, consultants, and researchers. This marginalises the political dimension, where different values and interests compete. It reduces the space for political discussion and influence from political parties. Voters might get the impression that politicians do not have real power over the most important decisions. Likewise, it can marginalise participation from civil society and inhabitants. Processes become more ritualistic and characterised by information dissemination and feedback rather than real discussions where participants can draw on their own experiences and values.

12 My translation
13 My translation

Thirdly, consensus can suppress political innovation. Consensus-driven planning processes can also hinder political innovation, as compromises often lead to radical or new ideas being toned down to achieve broad agreement. This can reduce the dynamics of party politics and lead political parties to be more cautious in their political programs. When consensus is the goal, it can be tempting for parties to avoid promoting new or controversial ideas that might disrupt the established agreement. This can lead to stagnation in political development and prevent parties from challenging the status quo, which in turn weakens parties' ability to represent the interests of different voter groups and ability to promote real political change.

Flyvbjerg argued (Flyvbjerg, 1991) that heavily normative planning theories, both the classic rationalist approach (Banfield, 1959) and the classic communicative ones (e.g. Healey, 1992,1997, Harper and Stein, 2012, Innes, 2004, Sager, 1994) would soon appear as a historical phenomenon because they will not survive all the attacks that will eventually come against them. They will fail the practice criterion (Flyvbjerg, 1991). I believe, mostly hope, that this is now about to happen. The rational planning model and the communicative planning models are not two extreme positions. They represent a common mindset that only the normative ideal, the maximum, is good enough as an ideal. In this sense, they are both located in "The range of impossibilities" (Lindblom, 1959, 1973, 1979). They overlook realities on the ground such as power imbalances, the inherent communicative limitations of language, ideological and value-based conflicts of interest, disagreements, and uncertainties in knowledge, and therefore, fundamentally, politics as well.

Three planning Theories – relevant for community of disagreement

I will briefly point out three theoretical positions that support the argument for community of disagreement as a concept and ambition for planning in organisations and society. These three are not independent planning methods but rather approaches that can appear in collaboration or be integrated into other planning methods and processes. What all three have in common is that they have internalised that planning is fundamentally political, and therefore must provide understanding for, respect for and relevant room for action for politicians, for the exercise of their political rationality.

Planning as rhetorical exercise of power - as previously mentioned, Pløger argues that two research perspectives dominate planning in the 80s and 90s; communicative planning theory and the perspective that views planning as a "rhetorical activity" and exercise of power (Pløger, 1998:3). A key point in this latter perspective is that planning is about communicating successfully (Hellspong, 1995: 2), not about finding or jointly developing objectively correct answers. Rhetoric is a practical logic, not a descriptive model, not a normative model, but a prescriptive model. It gives advice, it points out approaches in planning processes. (Hellspong, 1995).

James A. Throgmorton is one of the most visible planning theorists in the USA working with rhetoric. He argues like Hellspong when he claims that planners should work in the following way:

"Planners should strive, not to be good and be right and get things done, but to create, sustain and participate in a public, democratic discourse that enables them (and others) to argue persuasively and coherently about contestable views of what is good, right, and feasible" (Throgmorton, 1996:54).

Throgmorton sees planning as a form of storytelling about the future in which one seeks to convince and constitute the perception of the situation (Throgmorton, 1996:250,251). He compares society to a weave that lacks objective structure or meaning (Throgmorton, 1996:253). What we see depends on where we are placed in the weave. The same applies to what we plan, how we plan, and how we participate in the planning process. Sometimes this leads to agreed positions/consensus, other times to clarified disagreement. In this perspective, the planning text (text – images – maps and figures – design) and speech/conversation become important. Not least, politicians would like to activate their political project, their political ambitions, in such planning processes. It is then important for all those participating in such processes to be good at "storytelling." This is a well-known acknowledgment for politicians.

Innovative planning - increasingly, planning theorists argued throughout the nineties that creativity and innovation are restricted, even hindered, by planning theories and methods that rely heavily on either the analysis perspective (Hillier, 2008) or the communicative perspective (Mäntysalo, 2002). Mäntysalo (2002) argues that Habermas's concept for dialogue is too narrow, too static, and not creative enough. Others claim that planning theory with communicative ideals does not allow and can even stifle creativity and innovation (Stein & Harper, 2012).

Regardless of this specific planning theoretical discussion, we know that planning practice has already benefited from being inspired by innovation theory and practice for many years. No matter what planning theorists may think about the power of various theoretical positions, planners and politicians have increasingly appreciated theoretical and practical contributions from the field of innovation. Arguments that frequently appear in texts about innovative planning is that planning must encourage the development of innovative and liberating planning practices, stimulate innovation, and value and refine disagreement (Hagen and Higdem, 2023). Politicians who want change can therefore be inspired by innovative thinking and practice. The fact that this perspective also celebrates disagreement inspires many politicians to engage in planning processes. Planning that accepts and values disagreement is far more politically relevant than traditional consensus-seeking planning (Hagen and Higdem, 2023).

Agonistic planning - recognises and embraces conflict as an inevitable and productive part of democratic politics. This comes from the political theory of agonism, already mentioned (Mouffe, 2000, 2005, 2013), which emphasises the importance of political competition and disagreement within a democratic society. Instead of resolving or minimising conflicts, agonistic community planning views conflicts as an opportunity to promote democratic participation and innovation. Agonistic community planning acknowledges that groups in society have different interests and values and that these differences can be both legitimate and productive. This is precisely what politics is all about.

Agonistic theories aim to open and provide a new approach to democracy, where the rules of democracy are always open to questioning, competition, disagreement, discussion, negotiation, and changes over time. The same ambitions must also be used as a basis in planning processes. It is important that planning reflects the diversity of today's society in terms of opinions and interests. A central element then becomes how to develop methods and cultures for planning practice characterised by such contradictions, which can still result in accepted decisions (Pløger, 2004, 2012, 2018). The agonistic approach is less focused on achieving consensus as in communicative planning theory. It is more concerned with how to make decisions in planning processes (Pløger, 2018: 265), which can later be accepted and implemented in the community, even though there is disagreement.

Conclusion

It is fundamentally important to both take care of and seek to refine disagreement in planning processes and planning documents. Both planning theorists and practitioners must realise that disagreement is an inherent reality that one cannot theorise away from – neither within the field of planning theory nor within the field of practice. If planning theory should be able to follow up on its ambitions to both describe and prescribe practice, disagreement must at least be accepted, preferably treated as something potentially positive. It represents a potential for change.

Further, acceptance of disagreement by planning professionals is necessary to make planning interesting, relevant, and effective for organisations and society. Acceptance of disagreement by planning professionals is also necessary if planning want to contribute to preserving and building democracy.

Of course, we will continue to seek to reduce disagreement in planning processes, when the participants involved in the planning process, including politicians, see this as possible and appropriate. In other situations, however, it may be wise to do the opposite, to make visible, communicate and explain disagreements that often do not come up in analyses, debates, and the public. Accepting, exploring, and refining disagreements can also be positive in

stimulating innovative thinking, and in recruiting new people and environments into planning processes.

Developing good processes and procedures for voting, and how to work further afterwards in situations with winners and losers, also needs more and better attention in research and practice development.

Good, safe, trusting communities of disagreement are likely to promote individual and collective well-being, innovation, and democracy (Iversen, 2014). We must realise that we cannot plan our way out of many disagreements, only hide them by, for example by forcing a minority to remain silent. This is ethically and democratically reprehensible, and overall, simply counterproductive, or simply stupid.

The question in the title of the paper is: "Should planning and politics gather around the concept of 'community of disagreement'?" My answer is 'yes' and a call to both the planning field and the politic field, theoreticians as well as practitioners, to cultivate and refine theories – models – methods based on 'communities of disagreement.

Progressive Urbanism

Chandrima Mukhopadhyay

Abstract
It is time to better understand how despite numerous constrains innovative, equitable practices that lead to progress have emerged in cities in the global south and east, especially acknowledging new development pathways which are different than how cities in the developed countries had evolved. This essay proposes a new understanding of "progress" and "urbanism" building on recent research on development- and urbanism-literature. The term 'progressive' is meant to signify an advancement of and a convergence towards a new form of economic development which leads to climate-friendly urbanism, in line with the global urban agenda, which calls for an inclusive built environment for the majority. Cities and regions in the Global South are the best places to understand about progressive urbanism right now.

1. Introduction: Progressive Urbanism

The term "progressive" in the development literature has been used in multiple ways. I take two main works into consideration here, to criticize and build on a "progressive urbanism" that emerged from the Global South and East: first, Walt Rostow's stages of growth (Rostow, 1960) and the Stiglitz Commission's report (2008) on Measurement of Economic Performance and Social Progress. I argue that based on a broader understanding of progress and human well-being, including environmental concerns, the global urban agenda like the Paris Agreement, UN's Sustainable Development Goals, and New Urban Agenda were formulated. And the essay conceptualizes the "Progressive urbanism" term grounded in a context where such global urban agenda are being localized and implemented. In doing so, it accumulates new meaning as well, such as, incremental development.

India, being rapidly urbanizing now, and being known for large share of informality (e.g. around 90% jobs are in informal sector), it would be important to understand how these components could be captured in the "progressive urbanism" concept. Census of India defines "urban" by population, density and share of non-agricultural jobs. This is quite unique way of defining. A World Bank Report published in 2015 called India's urbanization as messy and hidden, along with other South Asian countries. It is called "hidden" as based on a different methodology like Agglomeration Index, India's urbanization rate was found to be around 55%, when by the census it was found to be 33%. It's called "messy" as a major part of urbanization is informal and unplanned. In India, 65 million people live in unplanned settlements. 40% of South Asia's urbanization lives in slum. The essay aims to understand what sort of changes could define "urban" in Indian context as progressive, in the contemporary times, including a combination of economic growth and social progress. There is need to critically look into whether Indian cities are truly urban, as Mukhopadhyay (2021)[1] does based on social emancipation, political agency, and economic progress or engines of growth. "Unplanned urbanisation" has become a buzz word. Planning may not be a single step intervention, it could be a step by step process. One recommendation could be at least defining a sub-level of "progressive urban" category.

There is a large share of jobs, housing and other infrastructure sectors in informal sector. In Indian context, informality and/or unorganized sector is defined quite broadly. It is important to focus on informal sector due to its large contribution towards the nation's GDP (around 45%), its relevance with social equity, and hence, social progress for all. In South Asia, informal sectors contribute towards 40%-60% of GDP. As prescribed by multiple civil organizations that directly work with the vulnerable population on the ground, and as recommended by academics, a progressive and differentiated formalization is the way out. We would like to cite some examples showing how such "progressive and differentiated" formalization are already taking place on the ground, including the acknowledgement of "informal spaces" needed in the formal spatial plans.

•The link between progressive urbanism and the Informal Sector could be:
o **Initial Growth:** During the early stages of urbanization, the informal sector often experiences rapid growth, fuelled by migration from rural areas and the need for basic services.
o **Challenges of Informality:** Rapid urbanization can also lead to challenges for informal workers, including low

wages, lack of social security, limited access to finance, and precarious working conditions.
o **Potential for Formalization:** Some argue that progressive urbanization should focus on supporting the formalization of the informal sector, providing more stable employment and better working conditions for workers.

One of the predominant understandings of "progress" in development literature has been measuring the economic development, and meeting the western standard, not only in terms of economy, but also in the development sector. In the essay, this popular meaning of "progress" is contested. As explained in the essay, the term can potentially capture the need to measure qualitative (social) growth including fulfilling the aspiration of the majoritarian or pluriverse, in addition to an inclusive economic growth, and yet drastic reduction of wasteful resource uses in cities of the Global South and East. The essay proposes multiple usage of "progress". Although the contested meaning is provoked by the development predominantly taking place in India, many Southern and Eastern countries are going through a similar transition. In many cases, such as India, such transitions come about because of national-level policies (e.g. Make in India), which can remain path dependent to some extent, and influenced by the international agenda (e.g. Paris Agreement, Sustainable Development Goals etc.). "Progressive" here is not used as a drastic transition, rather a step-by-step transition or advancement, an incremental process. I would like to explicitly point out the difference here between Global South and East. Global South and East is specific geographical and cultural context. 'International' as a term involves more than two countries. I use certain concepts and terms below that originated from international organizations. However, I consider them relevant here as these international organizations are operative in large numbers of emerging countries or Global South and East countries as well. The essay brings a critical understanding of "progressive" (based on two works as mentioned above), the changing meaning of "urbanism" including behavioral changes, supporting the majoritarian ideology, and based on innovative practices emerging mainly from the Global South and East context together.

Urbanism is defined as a way of life. "Progressive urbanism" is a form of urbanism that converges or synergizes every interest groups' (mainstream, marginalised and subaltern groups') interests or the interests of the pluriversal actors (e.g. heterogenous onto-epistemological positions), including meeting the need of both built environment and ecology/environment (referring to ecological priorities); it is progressive for all groups that allows socio-economic mobility, along with achieving economic development, while respecting the environment/ ecology. The way Wirth (1938) mentions that the urban mode of life is not confined to cities, similarly, the urban mode of life is not confined to the concrete jungle/built environment either in "progressive urbanism". Nature is brought into the city/built environment in the form of nature-based solutions, nature-based infrastructures, green infrastructure as an integral component of "urban" to take climate action and to be sustainable in the long run. Urban farming, green and blue infrastructures, roof gardens, vertical gardens are increasingly becoming part of urban life. Climate-friendly urbanism also promotes the lifestyle change for all, which is essential to deliver climate actions. Low-carbon urbanism (Bulkeley et al., 2012); Climate urbanism (Long and Rice, 2019). In addition, circular economy/ circular urbanism (ICLEI, no date) adds new dimension to the "way of life" through behavioural changes. The idea aligns with the majoritarian view, which is a political philosophy or ideology with an agenda asserting that a majority, whether based on a religion, language, social class, or other category of the population, is entitled to a certain degree of primacy in society, and has the right to make decisions that affect the society. "Majoritarian urbanism" is a term that has been used in explaining the neoliberalism, informality, resistance and well-being in Mumbai (Patel et al., 2022).

The term "progressive urbanism", in a nutshell, means the way of life that is progressive, in terms of delivering socio-economic mobility over generations, economic development, prioritising ecology, progressive for the "pluriversal" (Moreno-Tabarez et al., 2023), including mainstreamed, marginalised, subaltern, and externalised groups, progressive for "where many worlds fit in", for multiple elsewhere (Gandy, 2022), and has an emerging meaning of "urbanism" which is not confined to the concrete jungle/built environment, encourages behavioural changes for circularity, and explains the neoliberalism, informality, and resistance for the sake of the majoritarianism. The essay argues that such "progressive urbanism" has emerged being inspired from the

complexities and dynamics in the southern and eastern contexts, and originated by the Global South and East.

2. Progressive in what sense? : A new definition

For unplanned and hidden urbanization, progressive in the sense of combined impact of economic growth or engine and social progress. Progress in terms of improving the quality of urbanisation.

For informality and messy urbanization, progressive formalization in terms of slowly or step-by-step formalization.

I take two major works on "progress" in the development literature, to criticize and build the new meaning. Following Rostow (1960), there are five stages in Walt Rostow's stages of growth (Rostow, 1960): Traditional society, Preconditions for take-off, Take-off, Drive to maturity, and Age of High mass consumption. Rostow's (1960) view on development in the South has been closely linked to the World Bank and International Monetary Fund's politics of progress, where 'progress' means becoming like the West. Based on this understanding, the term "progressive" is highly critiqued within the Global South and East in the essay. The essay develops the concept of "progressive urbanism", which is considered "progression" by the Global South and East.

The second work I focus on is the Stiglitz Commission-published report on "Measurement of Economic performance and Social Progress" in 2008, authored by Stiglitz, Sen and Fitoussi, which was a French initiative. Their report provided an opportunity to redefine the meaning of human progress. Instead of relying on a one-dimensional measure of success, i.e., the gross domestic product (GDP), the Stiglitz Commission argued that societies should insist on a broader understanding of their achievements and predicaments. Besides social progress, the component of environmental and/or ecological crisis was added as an urgent issue. The central message of the report was that human wellbeing is far more than the sum of the economic resources. Wellbeing also depends upon health, education, environment, housing, access to information, the ability to communicate, and the overall quality of life experience. Sen's capability approach explains how provision of basic services and infrastructure improves the communities' capability for socio-economic mobility (Sen, 1993). Instead of measuring the performance of national economies, the activities and experiences of households should also be considered to understand progress. Rather than absolute levels of wealth, the distribution of income and the extent of inequality should be deciding factors. Kanbur et al (2016) including Joseph Stiglitz as one of the authors draws a link between the Sustainable Development Goals (SDGs) introduced by the UN with a number of goals and targets going beyond GDP, with a focus on developing countries, and the logic behind defining "progress" in the Stiglitz Commission Report (2008). The essay builds on its definition of "progress" depending on this idea.

The term Global North and South are basically defined based on economic well-being, and the term East-West is defined based on cultural identity (Yiftachel, 2006). In the essay, in order to define "progressive" for Global South-East, the proposed use of the term is NOT limited to economic progress, however, it includes economic growth as well (explained below in relation to degrowth literature). It indicates technological, financial, institutional innovative pathways and practices taking place in the cities in Global South and East, with converging positive outcomes including economic progress, synergic relationship between (economic) development, climate action and poverty alleviation, towards a better, liveable, and healthy urban life. For instance, the Deep Decarbonisation Pathway Program[1] that aims to deliver GreenHouse Gas (GHG) emission mitigation and economic development while promoting socio-economic mobility of all interest groups. The essay defines this approach as progressive, in the sense of progressing towards both socio-economic and ecologic progression for all or the pluriversal[2]. On the ground, planners are working towards delivering both the Paris agreement and United Nation's (UN's) Sustainable Development Goals in synergy. The essay argues that in the southern theory literature, it is timely to start theorizing about the innovative approaches, and re-define the term "progressive" for the South and

1 Accessed at https://www.iddri.org/en/initiative/deep-decarbonization-pathways.

2 Pluriversal indicates the existence of many worlds somehow inter-connected, including the human world is connected to the natural world and to the spiritual world.

East. Synergic[3] urbanism or converging[4] urbanism could be alternative terms. Converging cities, as already used, indicate to decreasing gap between the rich and poor, however, in Europe. Similarly, progressive urbanism will finally lead to decreasing inequality.

Conceptualising Progressive Urbanism

Figure 1. A conceptual diagram on conceptualising Progressive urbanism
Source: Kroll (2011) and Author

Unlike the traditional use of the word "progressive" in development sector, in the essay, "progress" or "progressive" has multiple meanings as follows:

• Example 1: Deep Decarbonisation Pathway as progressive:

The Deep Decarbonization Pathways[5] initiative helps global and national decision-makers take actions towards a deeply decarbonized world with drastically reduced inequalities. The program aims at keeping the global warming well below +2°C, which requires immediate changes, through choices that will lead economies towards a carbon-neutral world by the second half of the century. The program aims to deliver both economic development and GHG emission mitigation in synergy. They ground their national and international engagement on the principles of being country-driven, country-led, country-owned. DDPP's partners are both from the developed and emerging economies. The emerging economies or Global South and East countries are South Africa, Indonesia, Argentina, Nigeria, Senegal, Mexico, India, China, Brazil etc. Comparing the pathways adopted by the developed economies and emerging economies, and specially considering the pathway developed by India, the essay argues that

3 Accessed at https://www.degruyter.com/document/doi/10.1515/9783035606867-028/html.

4 Accessed at https://www.conted.ox.ac.uk/news/converging-cities.

5 Initiative on Deep Decarbonisation Pathway Program (2017): https://www.iddri.org/en/initiative/deep-decarbonization-pathways.

India is following a complicated pathway in order to deliver both economic development and global urban agenda including the Paris Agreement through innovation in a context with complexities that the developed economies did not have to do while becoming a developed economy. With economic development and socio-economic mobility, one's lifestyle would improve along with their economic activity, therefore there are chances of increased GHG emission. The program takes a progressive approach in terms of innovative pathway through which socio-economic mobility over generations is achieved while delivering climate action in synergy.

There are some recent studies that have already attempted to develop a link between the Stiglitz report and climate action based on IPCC report. For instance, Tokimatsu et al.'s (2019) "Tackling the Stiglitz Report: Measuring Social Progress and Economic Performance under **Various Climate Policy Scenarios"**, connects the measurement of social progress from the Stiglitz report and climate change mitigation (CCM) by the Intergovernmental Panel on Climate Change (IPCC) assessment reports. They operationalize this in terms of various climate policy scenarios ranging from business as usual to economically efficient, CO_2 double stabilization, and targeting two degrees Celsius (DC).

Another example to be considered through the lens of deep decarbonisation pathway program in India would be to understand the planning and implementation of the economic and industrial corridors, where business induced scenarios increase or improve manufacturing sector production, output and export, while still achieving deep decarbonization. The national government's vision is to achieve economic development through rapid urbanization using these corridors as tools; hence, it is imperative to understand what "progressive" pathway would be taken to implement these corridors, achieve economic development, and yet deliver deep decarbonisation.

• Example 2: Localising and implementing multiple Global urban agenda as "progressive":

Cities across the globe aim to implement multiple global urban agenda such as the Paris Agreement, Sustainable Development Goals, and New Urban Agenda. In this regard, Global South could be used in an analytical way to address how these agenda are localised and implemented in an inclusive way to address the need of the vulnerable groups. It is progressive in terms of delivering multiple global urban agenda through minimal interventions.

Here are some examples from the various sectors of infrastructure. For instance, in urban transport sector, accessible and affordable electric public transports are sourced by renewable energy. Low-carbon public transport modes are both climate-friendly and healthy. For instance, the use of electric three-wheelers or e-rickshaws both achieve GHG emission mitigation and deliver multiple SDGs such as SDG1 on reducing poverty, SDG3 on health and well-being, SDG5 on gender equality, SDG11 on inclusive cities. Planners and designer make decisions as providers, and industry and individuals as consumers.

Within water supply and the sanitation sector, which is a nature-built environment interface, nature-based infrastructures deliver both mitigation and adaptation strategies in climate action, and implement relevant SDGs as well at a lower cost. For the Solid Waste Management (SWM) sector, segregation of waste at source imparts public awareness about what is waste, how it is related to one's consumption pattern, what waste that can be recycled. A sense of responsibility amongst the public that the pre-capitalism era had is reviving. This also delivers economic development, climate action, and UN's SDGs in synergy.

• Example 3: Post-growth or de-growth in the South

Post growth or degrowth is a northern concept that aims to create a sustainable and equitable society by reducing economic output and throughput. While the southern scholars aim to apply this in a southern context, the use has been limited so far. Economic development remains a priority for the Southern countries unlike the northern context. Hence, even though the concept is originated from a northern context, its application in

the south shows that 'growth' in the south (and eastern) part of the world, will still incur economic growth as a priority. [Why would this be progressive?]

• Example 4: Using new vocabularies in Planning as "progressive":

Bhan's (2019) list of new vocabularies for planning in southern cities is progressive. Acknowledging informality, accepting activism for planners is progressive. Progressive in terms of developing new vocabulary in planning practice that fits into a context, repairing, squatting, organising etc. [This is South specific.]

• Example 5: Decentralisation and hybridisation of infrastructure as problem-solving and progressive

With rapid unplanned urbanisation process, it is a challenge to provide basic services such as water supply and sanitation, and solid waste management towards the periphery of the cities and regions specially in the low-income areas. Decentralised and hybridised infrastructures are the solution with incremental investment in a step-by-step manner depending on resources and in an inclusive manner, and to upgrade the infrastructure or development in the future. Such infrastructures are mainly provided in the global South context. For instance, city-wide inclusive sanitation is a great example.

- Two synonymous terms with added meaning:

a. Synergetic urbanism: A combination of top-down and bottom-up planning.[6] Progressive in terms of democratic decision making within built environment. Participatory democracy.
b. Converging urbanism/cities: Reducing inequality.[7] Progressive in terms of reducing inequality. Stiglitz's "progress" includes reducing inequality.

3. Urbanism: What is new about the way of life?
Wirth (1938) defines urbanism as a way of life. "Progressive urbanism" introduces the new meanings of way of life within an urban area:

a. Definition of urbanism/urbanisation:
Over-defined: Need to modify the definition

Messy: informal settlements. With economic growth, social progress, also concern about public health.

Hidden: urbanisation rate is actually higher than calculated.

b. Shift to non-western & traditional behaviour to deliver climate action:
In order to effectively implement climate actions, both behavioural change and change of life style are integral to the process. For instance, such urban way of life is about:

-Growing own food in on your roof or within a plot in cities: urban farming, roof garden.
-Creating lesser waste- consumption pattern change, and recycling your own waste.

c. Way of life as urbanism is not confined to the concrete jungle/ built environment:
Nature is brought into urban life. Green and blue infrastructure is brought in within the city fabric at different scale: Urban farming, roof garden, bioswales, lakes, Vertical green. (IUCN)

d. Circularity as a urban way of life (traditionally non-western):
Circular urbanism is becoming a way of life, such as, using biogas produced from municipal waste and wastewater

6 Accessed at https://www.archdaily.com/1005567/top-down-and-bottom-up-urban-planning-a-synergetic-approach.
7 Accessed at https://www.conted.ox.ac.uk/news/converging-cities.

in running buses. Many of such projects are delivered at the community level, and require public awareness and public acceptance.

e. Synergetic urbanism:
The term synergetic urbanism is already in use, which indicates a combination of top-down and bottom-up approach. Improved public participation and democratic decision making in planning- Way of urban life is about participating in democratic decision-making in urban decisions with trust.

f. Converging urbanism:
Converging urbanism is also a term already in use, which indicates reduced inequality. Increasing equality for all- way of life is in not discriminating between various income groups, which is also reflected in built environment and in actions.

4. Representative Spatial imaginaries for Progressive Urbanism
Spatial imaginaries are deeply grounded, widely circulated collective understanding of socio-spatial relations that are performed by, give sense to, make possible and change collective socio-spatial practices (Davoudi et al., 2018). They are produced through political struggles over the conceptions, perceptions and lived experiences of a place. They are circulated and propagated through images, stories, texts, data, algorithms, and performances. This section attempts to offer spatial imaginaries on what "Progressive urbanism" could be. Although it is not usual to use actual pictures to represent spatial imaginaries, and more focus is on the narratives, I attempt to use both images and narratives below to establish how spatial imaginaries could represent "progressive urbanism". For each example, there is one component of "progressive", in a way moving towards sustainability, and an associated component on "way of life" or lifestyle.

Spatial imagery 1. Is there an urban form for inequality? Reduced inequality can be represented through urban form in terms of individual land holding.

Figure 1. Aerial view of Dharavi housing in Mumbai showing inequality
Source: https://qz.com/india/1396785/drone-photos-capture-the-staggering-inequality-in-mumbai

Spatial imagery 2. Sponge cities as spatial imaginaries of bringing nature into the urban way of life, which is progressive in terms of climate action. Climate urbanism. Stated in China in 2014. China is considered to be the Global East.

Figure 2. Representing Sponge City in China
Source: https://earth.org/sponge-cities-could-be-the-answer-to-impending-water-crisis-in-china/

Spatial imagery 3. Decentralisation and hybridisation of infrastructure as form of circular urbanism.

In developing countries or emerging economies, as an innovation to serve the informal sector with low income at the periphery.

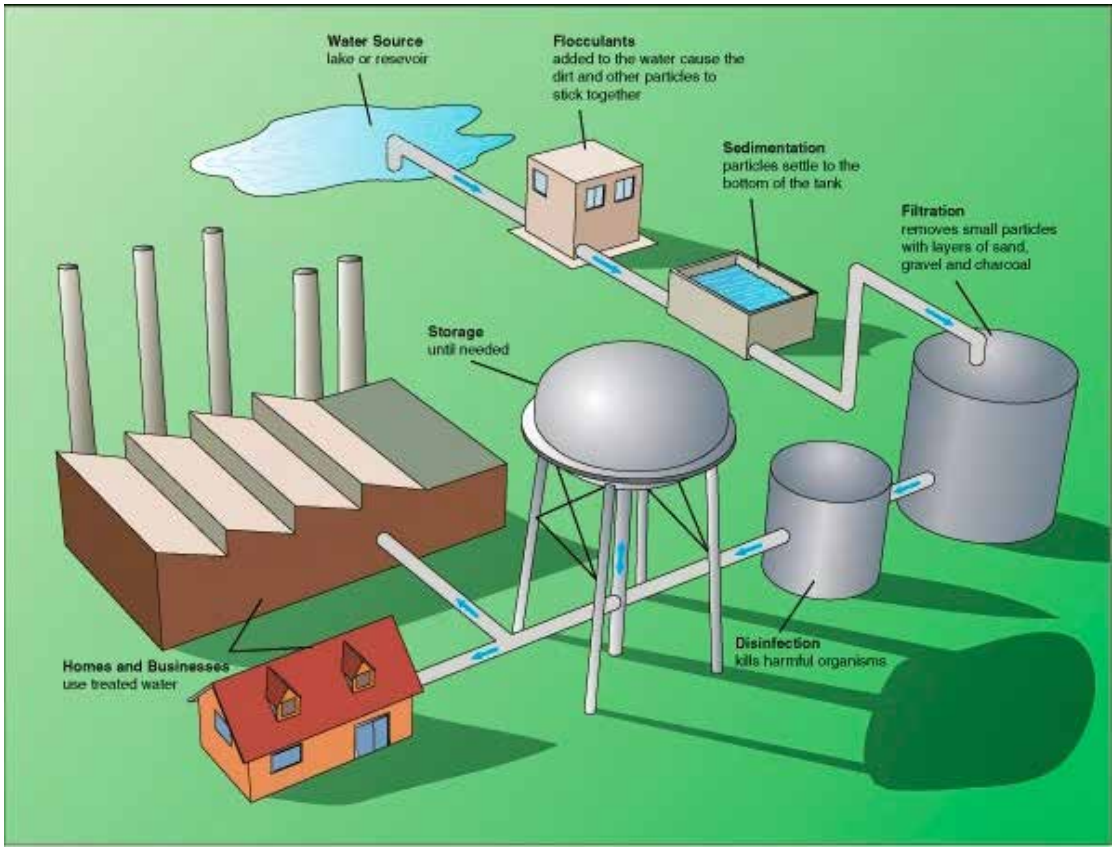

Figure 3. Decentralised wastewater system

Spatial imagery 4. Participatory budgeting

Participatory budgeting could provide a narrative for "progressive urbanism", where "progress" is about participatory decision-making within built environment, and a new way of life where it is usual to participate in decision-making about the urban. Originated in Brazil in 1989.

Figure 4. Women-led participatory budgeting in Penang, Malaysia
Source: https://www.socdemasia.com/latest/news/gender-responsive-and-participatory-budgeting-programme-penang

5. Conclusion: Towards an emerging form of "progressive urbanism"

Progressive urbanism is not a large drastic transition; it is the summation of many little transitions in day-to-day activities. It is about the incremental day-to-day decisions made by all socio-economic groups, not only by the marginalised, subordinates, and externalised ones today, but even those who are in power, physically, wealth-wise, politically, as a society, towards a more equal, economically well-off, healthy future for tomorrow, for the next generation. This equal society, economically progressed than what it was before, healthier and climate-friendly urban for all, indicates the "progress" here, decided by those who are working as academics, scholars, practitioners, policy makers, based in the South-East. This generation is optimistic of delivering a better and competitive future.

Localization and Application of Scene Theory in the Context of Historic Town Preservation in China: A Case Study of Shannxi Mizhi Ancient Town

Liangwei Du Xinwen Wang
Affiliation: School of Architecture, Xi 'an University of Architecture and Technology, Xi' an, China
Email: 921806860@qq.com

Abstract
Under the discourse of value inheritance in Chinese historic towns, the dual challenge of preserving cultural heritage and revitalizing urban vitality has emerged as a pivotal issue in contemporary urban studies. Clark's scene theory, with its innovative theoretical framework and quantitative analytical methodology for assessing cultural values, has stimulated extensive interdisciplinary research and academic discussions. This study employs Mizhi County as a representative case to establish a localized interpretation and analytical framework of scene theory within the Chinese context. The findings reveal that creative scenescapes serve as crucial catalysts for heritage conservation and vitality regeneration. Furthermore, scene measurement proves effective in quantifying value orientation transmission and public perception patterns, providing empirical evidence that cultural spaces function as dynamic mediators between historical continuity and contemporary urban development.

Key words: Value Transmission; Historic Town Conservation; Scene Theory Contextual Adaptation;

1 introduction

Cultural destiny intertwines with national fortune, and cultural lineage connects with national vitality (Xu Zhong, 2023). As Lewis Mumford noted, "Complex civilizations require stable historical urban containers." President Xi Jinping has repeatedly emphasized strengthening cultural confidence and enhancing the protection of historical heritage. The 19th CPC National Congress highlighted that preserving cultural relics and inheriting cultural heritage are crucial components in building cultural confidence and promoting socialist cultural prosperity, requiring continuous advancement in the "creative transformation and innovative development" of traditional Chinese culture. Sun Jing's (2024) analysis of Operational Guidelines revisions reveals an epistemological breakthrough: historic towns are now recognized as dynamic human ecosystems, transcending traditional monument-centric conservation frameworks. ICCROM defines living heritage sites as "places continuously shaped by historical actors, maintaining both physical structures and socio-cultural practices, with core communities inhabiting or adjacent to these sites" (Zhao Xiaomei, 2016). As inhabited heritage, they differ fundamentally from conventional monuments by preserving not only material artifacts but also unique socio-cultural ecosystems formed through centuries of evolution. However, current conservation practices often prioritize physical preservation over humanistic dimensions while lacking methodologies to measure communities' spiritual perception of heritage values. This study therefore investigates scene theory's applicability in addressing value transmission and vitality regeneration in Chinese historic towns.

2 Literature review: The Evolution of Historic Town Conservation and Theoretical Research in China

2.1 Review of the Development and Research on Historic Town Conservation in China

Historic town conservation in China began later than in Western countries. By integrating Western conservation philosophies with local practices, China has gradually developed a context-specific heritage protection system. The enactment of the Cultural Relics Protection Law in 1982 marked a significant milestone by initiating state-level rescue protection for heritage sites and introducing the concept of "historical and cultural cities." In 1986, the idea of "historical and cultural protection zones" was officially proposed. The 2002 revision of the same law integrated "historical and cultural blocks" and "villages and towns" into urban master planning. The 2008 "Regulations on the Protection of Famous Historical and Cultural Cities, Towns and Villages" established a tiered national conservation framework, comprising three levels: cities, blocks, and cultural relics. In 2010, the Ministry of Housing and Urban-Rural Development introduced management guidelines that emphasized not only authenticity and integrity but also the continuity of social life.

Since the 18th CPC National Congress, cultural heritage "revitalization" has gained prominence, with strategic policies accelerating the construction of integrated urban-rural heritage protection and transmission systems. A value-oriented approach to cultural conservation has gradually taken shape.

Recent research has shifted from the authenticity of heritage objects to system integrity and sustainable cultural transmission. Some scholars have revisited traditional Chinese urban philosophies. Wang Shusheng (2019) conceptualized the "landscape-cultural spatial pattern," proposing that landscape serves as a natural axis and culture as a spiritual axis. Based on this, Gao Yuan (2023) and others constructed a regional network in the Guanzhong region; Liu Shuhu (2024) analyzed visual connectivity in ancient Quanzhou; and Yan Pei (2024) examined the spatial logic of towns along the upper Han River by interpreting their geomorphic settings.

Additionally, scholars are increasingly focused on the spiritual heritage and activation of historic towns. At the macro level, Chen Shuangchen (2022) proposed a heritage value system rooted in the evolution of Chinese civilization. Zhang Huan (2022) developed a collaborative protection framework emphasizing full-element and full-spatial coordination. Wang Kai (2022) explored systemic models for urban-rural heritage transmission. At the meso level, Zhang Guanghan (2023) designed a cultural transmission path for the Grand Canal, and Li Heping (2022) employed scene theory to address the holistic, dynamic, and multi-dimensional characteristics of historic towns.

At the micro level, models have been developed to assess residents' cultural sustainability through dimensions such as cognition, emotion, and practice (Li Lu et al.,2022); and to decode landscape and cultural "genes" to capture spatial vitality (Xiao Jing et al.,2021). Quantitative frameworks have also been proposed to evaluate cultural inheritance (Yang Liguo et al.,2017), liveliness (Zou Jun et al.,2020), and rurality (Liu Peilin et al.,2012), identifying areas of weakness in the preservation process.

In conclusion, China's historic town conservation has transitioned from static protection under a relic-oriented paradigm to dynamic strategies emphasizing social and cultural continuity. The current core of conservation practice lies in addressing how to effectively transmit heritage values and achieve cultural revitalization.

2.2 Literature Review of Scene Theory

Scene theory, pioneered by Terry N. Clark of the New Chicago School, emphasizes cultural consumption as the foundation for urban revitalization. It views urban space not merely as a functional environment but as a cultural amalgam of consumption symbols, with convenience and comfort as essential preconditions (Wu Jun, 2014). Clark's theory argues for fostering urban regeneration through the integration of creative scenes, and subsequent studies have highlighted the role of "amenities" as drivers of population concentration and urban economic growth (Wu Jun et al., 2022; Wang & Wu, 2011). At its core, scene theory evaluates space from the perspectives of aesthetics and lifestyle, focusing on its embedded values, cultural meanings, and aesthetic qualities (Wu Jun, 2022).

Unlike "place," which emphasizes rooted identity through kinship and geography, the concept of "scene" stresses constructed identity within diverse social groups. Bian Lanchun et al. (2024) argue that creative districts function as a synthesis of site, place, and scene, integrating spatial forms, cultural narratives, and social activities.

In applied research, the theory has been extended in various ways. Zhang Ye et al. (2024) proposed a cultural framework for national cultural parks based on the triad of "cultural genes–cultural elements–cultural scenes." Chen Mingkun et al. (2024) introduced micro-renewal strategies for park cities based on holistic assessment and feature recognition. He Xiaorong et al. (2023) explored how nostalgic consumer spaces, such as the Super Wenheyou project in Changsha, are constructed and perceived under scene theory.

Further local adaptations have emerged to align the theory with Chinese contexts. Xia Shu (2019) emphasized reconstructing scenes' spatial-temporal dimensions and emotional content in the digital era. Guo Chen et al. (2022) proposed six elements and four levels for scene planning in metropolitan coordination. Xu Wanting et al. (2024) retranslated the concepts of authenticity, theatricality, and legitimacy into "cultural authenticity," "cultural consumability," and "cultural balance" to guide heritage renewal. Tang Juan et al. (2023) applied scene theory to develop a cultural value assessment system for Suzhou's historic streets.

Overall, scene theory offers a holistic, pluralistic, and systematic analytical framework, combining culture-driven development strategies with methods that integrate subjective perceptions and objective evaluations. Beyond serving as an effective tool for assessing cultural value transmission, it also provides a strategic pathway for revitalizing urban vitality and restoring the livability of human settlements. Meanwhile, scholars across disciplines have made contextualized adaptations of scene theory to suit their respective domains. In the context of historic town value transmission in China, its emphasis on culture as the core driver, the value–carrier logic of cultural inheritance, and an integrated perspective that spans all regions, elements, and time periods aligns closely with the foundational principles of scene theory. As such, it is both necessary and timely to explore its applicability in this context and to develop a localized theoretical framework tailored to the cultural preservation of historic towns.

3 Theoretical Framework: A Scene-Based Analytical Model for Value Transmission in Historic Towns

3.1 Compatibility between the Context of Value Transmission in Historic Towns and Scene Theory

3.1.1 Applicability Analysis

(1) Scene theory provides a quantitative analytical framework integrating subjective and objective dimensions for the preservation and renewal of historic towns.

Scene theory constructs a dual-dimensional analytical system encompassing both subjective perceptions and objective environmental elements. Through three core dimensions—legitimacy, authenticity, and theatricality—and their corresponding 15 sub-dimensions, it offers a robust theoretical tool for identifying and quantifying scene characteristics in urban spaces. By analyzing combinations of these coded sub-dimensions, researchers can systematically evaluate what types of scenes attract which groups, trigger specific activities, and generate varying socio-economic and cultural impacts. This process ultimately informs strategic decisions regarding scene configuration for specific development goals.

The integration of subjective and objective dimensions enables a comprehensive pathway for linking tangible heritage environments with intangible value perceptions. It offers a theoretical foundation for unifying the "form" of heritage preservation with the "spirit" of cultural transmission, thereby providing a quantifiable and operational approach for guiding value renewal in the context of historic town conservation.

(2) The cultural-driven model in scene theory offers theoretical guidance for the cultural revitalization of historic towns.

Scene theory advocates for a shift from the traditional post-industrial economy-driven paradigm toward a culture-led model of urban development. By strategically supplying and configuring "comfort amenities," it aims to cultivate a livable and culturally vibrant environment that attracts and retains members of the creative class, thereby stimulating urban regeneration.

In the context of historic town conservation, protection strategies that solely emphasize heritage elements—akin to "museum-style" preservation—often overlook the everyday production and living needs of local residents, ultimately weakening the town's livability and vitality.

The culture-driven model thus provides a new developmental logic for revitalizing historic towns: placing traditional culture at the core while integrating emerging contemporary cultural expressions to forge new forms of creative culture. This approach fosters the aggregation of social groups sharing common interests and values, enabling a proliferation of participatory cultural activities. Such a framework not only facilitates the dynamic inheritance of cultural values but also offers a viable theoretical foundation for promoting the integrated economic, social, and cultural revitalization of historic towns.

(3) The amenity system of historic towns contributes to the formation of distinctive scene characteristics

"Amenities" refer to elements that provide comfort and pleasurable experiences for residents, encompassing facilities, activities, and services aimed at improving urban quality of life (McNulty et al., 1985). Early definitions of amenities emphasized their nature as non-market, non-productive public goods (Ullman, 1954; Clark, 2003). Later, Clark expanded the concept to include the spillover effects of private goods, thereby developing a more comprehensive and flexible theoretical framework (Silver & Clark, 2016). Overall, amenities are generally categorized into three types: natural, social, and cultural (Wu Jun et al., 2024).

In the spatial construction of historic towns in China, traditional planning philosophies—particularly the interaction between settlements and natural landscapes—have resulted in the creation of natural amenities. Meanwhile, the integration of rich tangible and intangible heritage resources has fostered a robust cultural amenity system. This, combined with deeply rooted, localized social-cultural amenities, helps form distinctive cultural scenes within historic towns. An emerging academic consensus suggests that the construction of cultural scenes and the conservation of historical heritage are not isolated undertakings but rather interdependent and mutually reinforcing processes (Li Heping et al., 2022).

3.1.2 Inapplicability Analysis

(1) Divergence in Value Orientations under Consumption-Driven Logic

Scene theory is grounded in a logic of cultural consumption. It emphasizes the cultivation of specific urban scenes to attract and retain the creative class, thereby revitalizing urban economies in the post-industrial era. Within this framework, the primary function of scenes lies in stimulating economic growth through consumer-oriented spatial experiences.

In contrast, the contemporary context of historic town conservation in China assigns these spaces a broader set of responsibilities. Beyond supporting the everyday production and living needs of local residents, historic towns are increasingly regarded as key spatial carriers of China's national cultural revitalization strategy. They serve as integral components of the urban-rural cultural heritage system and play a crucial role in reinforcing national and ethnic identity.

Accordingly, the value orientation of historic towns in China extends far beyond that of consumer-driven scenes. These towns must simultaneously support autonomous, daily-life activities of indigenous populations and facilitate the transmission of cultural heritage and collective memory. This dual function—rooted in cultural identity and historical continuity—stands in marked contrast to the economic utility-driven logic embedded in Western scene theory.

(2) Semantic Divergence of Key Elements in the Context of Migration Societies

Scene theory emerged within the sociocultural context of Western immigrant societies, where urban life is shaped by ethnically diverse communities, heterogeneous value systems, and pluralistic cultural practices. Its conceptual foundation assumes a social structure characterized by individual mobility, multicultural coexistence, and high degrees of personal autonomy in spatial and lifestyle choices. Key elements such as "neighborhood," "amenities," and "activities" are thus defined within this framework of diversity and voluntary association.

In contrast, the value transmission of historic towns in China is grounded in a context of cultural continuity, rooted in localized traditions and collective memory. These towns emphasize the dialectical relationship between the national and the local, privileging emotional attachment to place and shared cultural identity. Rather than being shaped by fluid migration patterns or market-driven consumption behaviors, the social relations embedded in Chinese historic towns prioritize authenticity, temporal continuity, and spatial rootedness.

Consequently, the conceptual underpinnings of scene theory—developed in a Western immigrant context—require contextual reinterpretation when applied to Chinese historic towns. A localized reconceptualization of core elements is necessary to address the specific cultural, social, and functional demands of heritage preservation and value transmission in the Chinese context.

In summary, while scene theory offers a systematic analytical framework and valuable methodological tools for understanding the value transmission of historic towns, its foundational concepts—such as the integration of subjective and objective dimensions, the culture-driven development model, and the interaction between amenities and values—resonate well with China's heritage logic that emphasizes both tangible forms and intangible meanings, as well as the mutual construction of carriers and values.

However, the sociocultural context underlying scene theory—rooted in Western post-industrial and immigrant societies—differs significantly from the cultural missions and social structures faced by Chinese historic towns. These divergences are particularly salient in the value orientations and spatial-social logics that inform scene construction.

Therefore, when applying scene theory to the context of China's historic towns, it is essential to adapt and reinterpret its key concepts, structural elements, and value systems. By constructing a localized analytical framework, scholars and planners can more effectively identify cultural scene characteristics and design more contextually appropriate pathways for value transmission and urban revitalization.

3.2 Scene-Based Analytical Framework for Value Transmission in Chinese Historic Towns

3.2.1 Contextual Adaptation of Scene Elements in Chinese Historic Towns

Silver et al. (2010) argue that the essence of urban scenes lies not in isolated elements such as neighborhoods, facilities, or population, but in the combination of these factors and the resulting activities they engender. Grounded in the theory of social dramaturgy, scene theory conceptualizes the city as a symbolic "stage," where amenities form the "set," diverse populations act as "performers," neighborhood relations provide the "social context," and activities function as "scripts" that convey meaning and identity. Within this integrative framework, scene theory underscores the interaction between spatial components and cultural values.

Given the unique cultural lineage and spatial characteristics of Chinese historic towns, this study proposes a localized interpretation of the four core components of scene theory—amenities, population, neighborhood, and activities—as follows:

Amenities: Defined as both tangible and intangible resources that bring pleasure or comfort, amenities in historic towns encompass not only physical heritage, natural landscapes, and public infrastructure, but also symbolic environments and cultural atmospheres shaped by intangible heritage and traditional lifestyles.

Population: The population structure of historic towns typically consists of: (1) indigenous residents deeply embedded in local cultural traditions; (2) tourists attracted by the historic and cultural milieu; and (3) new residents who migrate due to shared cultural values or employment needs. These groups interact and co-shape the dynamics of cultural inheritance.

Neighborhood/Social Networks: In the context of historic towns, neighborhoods refer not just to physical proximity, but also to the embedded social relationships, including kinship- and place-based networks, occupational mobility-based communities, and emerging value-based cultural collectives.

Activities: As the dynamic core of scenes, activities embody the interactions among amenities, populations, and social networks. In historic towns, activities range from traditional cultural expressions such as festivals and rituals, to modern cultural-creative practices and participatory events, as well as the daily practices of life and work that continually animate the space.

This contextualized understanding of scene elements provides a more grounded theoretical and practical basis for identifying cultural values, constructing meaningful scenes, and guiding the conservation and regeneration of historic towns in China.

3.2.2 The Scene Hierarchy of Historical Towns

Historic towns possess dual attributes of historical-cultural significance and contemporary living functions. They are required not only to convey profound cultural values but also to meet the diverse production and living needs of residents, thereby revitalizing the town's vibrancy. As a crucial node within the urban-rural cultural heritage system, historic towns must effectively integrate with territorial spatial planning and cultural inheritance systems to ensure comprehensive spatial coverage and dynamic integration. Due to constructive recognition of diverse lifestyles by multiple stakeholders, the boundaries of scenes in historic towns are often ambiguous and dynamic.

Based on related research (Guo Chen et al., 2022), and centered on cultural inheritance, the scene hierarchy in historic towns can be delineated along both horizontal and vertical dimensions:

Horizontal Dimension: Scenes are categorized into three concentric layers—cultural scenes, creative scenes, and living scenes.

Cultural scenes are spaces of cultural significance formed around key historical nodes, serving as the foundation and source of cultural transmission.

Living scenes focus on facilities and services essential for daily production and life, underpinning residents' everyday existence.

Creative scenes lie between cultural and living scenes, representing the integration of traditional and contemporary cultures, embodying cultural innovation and quality of life enhancement, and acting as the core driver of cultural vitality revival.

Vertical Dimension: Scenes are structured from micro to macro levels, including scene units, scene clusters, scene cluster groups, and scene aggregations. These correspond respectively to specific components of cultural scenes, entire categories of cultural scenes, the historic town's complete scene system, and its position within the broader urban-rural cultural heritage framework.

This hierarchical framework clarifies the internal composition logic of scenes in historic towns and provides a theoretical and practical basis for the organic integration of cultural inheritance and spatial planning.

3.2.3 Value Dimensions of Historic Town Scenes

While scene theory offers robust tools for measuring scene dynamics, the value dimensions it proposes—rooted in Western consumer culture—are not universally applicable, especially in contexts like Chinese historic towns where cultural inheritance plays a central role. Scholars have thus proposed localized reinterpretations of scene value structures. For example, Hou Xueyan (2025), through analysis of 43 rural public cultural spaces, distilled three perception dimensions: locality, consumer orientation, and cultural depth. Similarly, Chen Bo (2025), drawing on the triadic dialectic of spatial production and historical town value systems, identified local expressiveness, symbolic perception, and social integration as key dimensions.

In contrast, Clark's formulation, developed within the framework of Western cultural consumption, identifies three primary value layers: Dramaturgy – the emotional expressiveness of a scene; Legitimacy – the behavioral norms and regulations embedded within the scene; Authenticity – the degree to which individuals can derive identity and belonging.

These three dimensions effectively address how scenes evoke emotions, structure behavior, and foster identification. They also reflect the capacity of space to guide cultural meaning and social conduct.

For this study, these are consolidated into three analytical layers: Emotional Layer (linked to dramaturgy); Behavioral Layer (linked to legitimacy); Identity Layer (linked to authenticity).

This framework is applied to a representative historic town case, and thus the observed value orientations reflect specific characteristics of that locality.

3.2.4 Analytical Framework for Historic Town Scene Typologies
This framework unfolds in four key steps:

Step 1: Constructing a Database of Comfort Amenities. Identify and catalog both cultural and daily-life elements within historic towns. Cultural elements are derived from field surveys and planning documents, including various levels of heritage sites, historic buildings, traditional-style architecture, time-honored commercial entities, and landscape-oriented urban design features. Daily-life elements are extracted primarily through POI (Point of Interest) data mining, including public services and cultural industry facilities.

Step 2: Scene Typology and Hierarchical Structuring. Based on the dual nature of historic towns—cultural heritage and everyday life—this step identifies cultural scenes and living scenes. The creative scene serves as a dynamic link between the two, offering pathways for cultural innovation and revitalization. From the perspective of integrated heritage systems, scene typologies are structured hierarchically as follows: Scene Units: constituent elements of cultural scenes; Scene Clusters: typological groupings of cultural scenes; Scene Cluster Groups: aggregations of scenes across a town; Scene Aggregations: macro-level systems aligning with the national cultural heritage framework.

Step 3: Scene-Based Diagnosis through Measurement. This involves two diagnostic approaches: Scene Cluster Value Assessment—quantifying the cultural value supply by comparing actual scene characteristics with expected symbolic representations. Scene Cluster Group Value Diagnosis—evaluating the integrity of the value system at the emotional, behavioral, and identity levels.

Step 4: Integrated Scene Analysis and Strategic Response. Using a holistic approach, this step synthesizes comfort amenities, user groups, social network structures, activities, and value orientations to analyze cultural transmission bottlenecks and formulate adaptive planning strategies for historic towns.

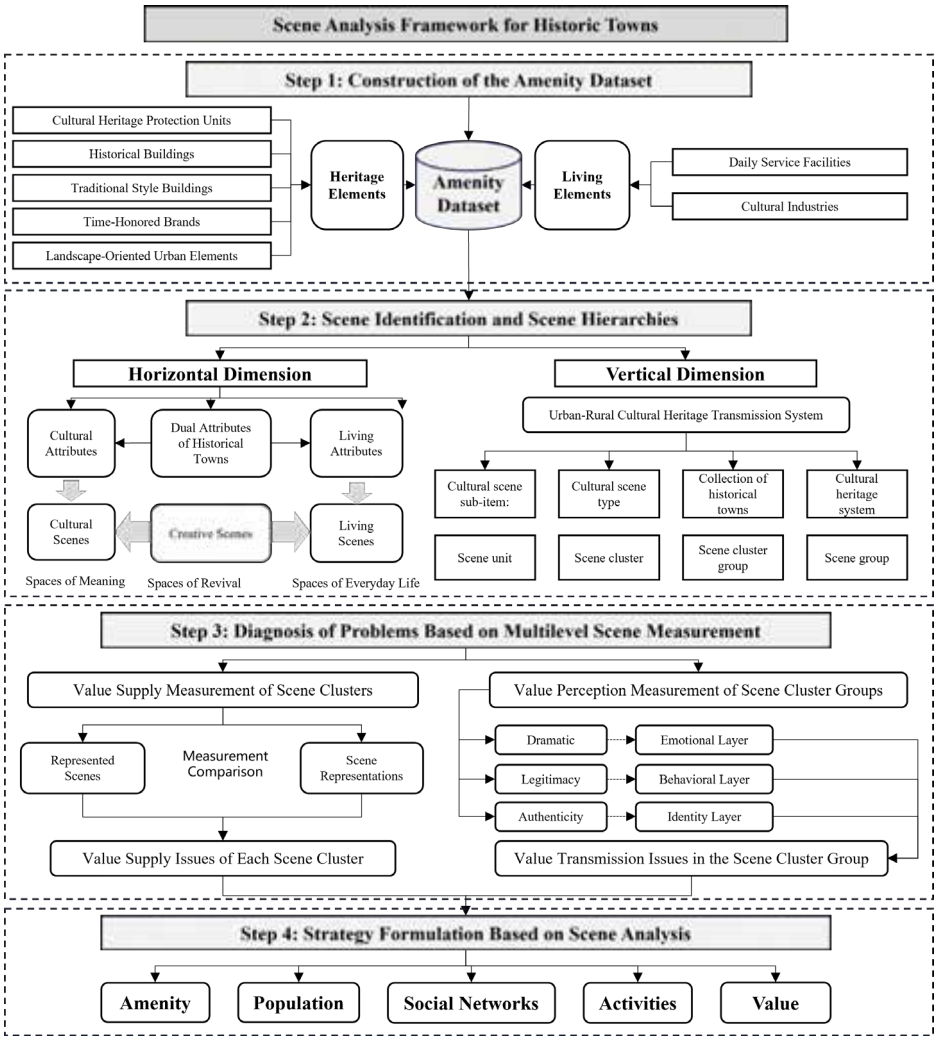

Fig1 Analysis framework of historical town scenes

4. Empirical Study: Scene Analysis of Mizhi Historic Town

4.1 Overview of Mizhi Historic Town

Mizhi, historically known as "Yinzhou," derives its name from the saying, "the land yields golden streams and fertile soil; its rice juice is as smooth as fat." In 2023, it was designated as the sixth batch of provincial-level historic and cultural cities by the Shaanxi Provincial Government. Located in the Wuding River Basin in eastern Yulin City, Shaanxi Province, Mizhi lies in the transitional zone between agriculture and pastoralism in the middle reaches of the Yellow River. It has long served as a cultural intersection between farming and nomadic civilizations, fostering a rich and diverse heritage that remains vibrant today through numerous forms of intangible cultural heritage.

On one hand, Mizhi boasts abundant historical and cultural resources, including 50 officially protected heritage sites, 59 historic buildings, and 64 items of intangible cultural heritage at or above the county level. On the other hand, situated in the heart of the Loess Plateau, the town faces significant challenges due to its fragile ecological environment, the demographic siphon effect of the Xi'an metropolitan area, and a resource-dependent industrial structure. These factors have led to a reconfiguration of the local social structure and hindered the transformation of rich historical resources into drivers of urban revitalization. As such, Mizhi represents a typical case among China's historical towns, highlighting the developmental constraints faced by many similar locales.

Fig2 satellite image of Mizhi historic town

Fig3 The landscape layout map in the county annals

(Source: Mizhi County Annals)

4.2 Research Setting and Data Source

This article takes "Mizhi" as the keyword, and searches on websites such as Weibo, Douyin, and Ctrip. Through Python programming, 785 pieces of online text data were crawled. After data cleaning, 512 online review data related to Mizhi were obtained.

Then, through a Python program connected to an AI large model, multimodal analysis was conducted on the online text data. It obtained keyword strength and keyword information based on the comprehensive number of likes, reposts, and comments, as well as the emotional tendency attached to the online texts.

4.3 Cultural Scene Identification

Based on fieldwork and questionnaire surveys, a "comfort objects" database was constructed for Mizhi Historic Town. Four distinct types of cultural scenes were identified through thematic categorization:

4.3.1 Scholarly Culture Scene

Mizhi is renowned as a cradle of education and literature in northern Shaanxi. It was once said, "Every three steps there's a scholar's courtyard; every five steps, a residence of a successful candidate." During the Ming and Qing dynasties, Mizhi produced 24 military and civil jinshi, a successful candidate in the highest imperial examinations, 105 juren, a successful candidate in the imperial examinations at the provincial level, and 345 tribute students, earning it the name "Cultural District of Shaanxi." Notable figures include Li Jiqian, Li Dingming, Du Bincheng, Du Yuming, Li Jianhou, and Ma Jianling. Comfort objects in this scene include academies, ancestral halls, historic residences, and literary landmarks.

4.3.2 Landscape Culture Scene

The county's majestic topography, marked by hills and gullies, exemplifies classical Chinese geomantic principles. The town is strategically situated "facing mountains and overlooking water," with northern elevation provided by Phoenix Ridge and southern proximity to three rivers: Yinma, Liu Jin, and Wuding. It is surrounded by Panlong, Wenping, and Xiangfeng Mountains, forming a natural defense. Key comfort objects include mountain and river systems, scenic nodes, and culturally resonant landscape features.

4.3.3 Revolutionary Culture Scene

As part of the revolutionary heartland of Shaanxi-Gansu-Ningxia, Mizhi played a pivotal role during the Anti-Japanese War and the Chinese Civil War. It hosted early communist institutions like the Mizhi Party Branch and the County Committee, nurturing significant revolutionary developments. Associated comfort objects include martyrs' memorials, revolutionary heritage sites, and historical signage.

4.3.4 Loess Culture Scene

Situated at the intersection of agrarian and pastoral civilizations, Mizhi developed a unique regional identity blending both traditions. Its rich folk customs and tangible heritage reflect the essence of the Loess Plateau. This category includes intangible cultural heritage like paper cutting, suona music, and folk tales, with comfort objects encompassing cave dwellings, traditional hamlets, and folk performance spaces.

4.4 Measuring Cultural Scenes in Historic Towns

4.4.1 Scene Clusters Based on Representation of Scene

In the context of historic towns, scene representation refers to the projected scenes constructed by governmental bodies and planners under specific ideological and planning frameworks. These representations reflect the top-down expectations for cultural expression and spatial organization.

Scene cluster measurement under this logic relies on policy-based weighting, where cultural assets are scored according to their protection status: National-level protected heritage sites: 50 points; Provincial-level sites: 40 points; Municipal/county-level sites: 30 points; Registered historic buildings: 20 points; Other minor cultural elements: 10 points; Non-contributive points: 5 points. Using this scoring system, comfort objects associated with six previously identified scene types (Scholarly, Landscape, Revolutionary, Loess, Everyday, and Creative) were analyzed. The results were visualized via GIS (see Figure 4).

The analysis reveals several patterns: Scholarly scenes are highly concentrated along West Street, East Street, and around the Palace of Li Zicheng, mainly located in the Ming–Qing Lower Town zone. Landscape scenes align with natural topography, clustering along the town's periphery and in the Song–Yuan Upper Town, while the river-converging Ming–Qing Lower Town shows a notable deficiency. Revolutionary scenes are scattered due to fragmented comfort object distribution, but mainly appear in the Republican New Town and Song–Yuan Upper Town. Loess cultural scenes are shaped by traditional cave dwellings and intangible heritage, concentrated between the Yinma River and Galaxy River, across the upper and lower historical zones. Everyday scenes show a striking vacuum in both major historic zones, indicating insufficient integration of contemporary residential life. Creative scenes, defined by integration of tradition and industry, are sparse and predominantly composed of low-tier education-related facilities, lacking cultural-industrial synergy.

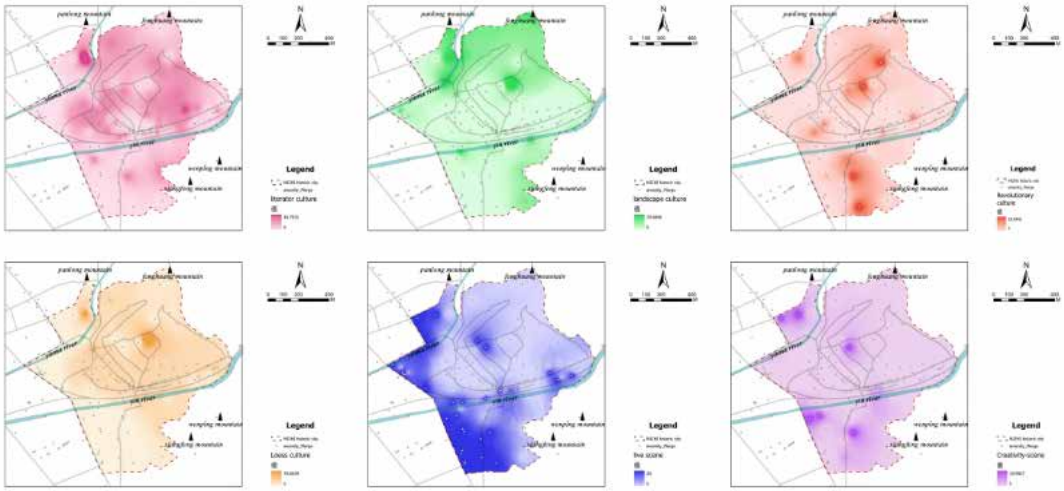

Fig.4 The measure of scene clusters in the representation of scene

4.4.2 Scene Clusters Based on Representational Scene

Representational scenes refer to the meanings assigned to spaces by users such as residents and tourists through symbols, memory, and cultural practices. To evaluate this subjective perception, surveys were conducted with 20 residents and 20 tourists, asking them to rate the contribution of each comfort object to six identified

scene types. A five-point Likert scale was used, and the resulting data were standardized to generate a "Comfort Object–Perceived Intensity Matrix." These data were then integrated into GIS for spatial visualization (Figure 5).

Overall, the distribution of representational perception values shows greater dispersion than the values from the scene representation perspective. There are no clear high-value clusters, suggesting a lack of strong perceptual hotspots. This implies that the current interpretive and display mechanisms in Mizhi Historic Town are underdeveloped, and public cultural perception is fragmented and ambiguous.

However, substantial spatial overlap between perceived scenes and designed scene representations indicates that comfort objects possess strong inherent cultural attributes that are widely recognized across different user groups.

Key spatial patterns include: Scholarly cultural scenes cluster in the northern areas (Song–Yuan Upper Town and Ming–Qing Lower Town); Everyday life scenes concentrate in the southern Republican New Town; Revolutionary scenes are perceived more strongly than their institutional weightings suggest but lack focal centers; Loess and literati cultures are generally perceived north of the Galaxy River; Landscape culture perception focuses on major mountains (Panlong, Fenghuang, Wenping, Xiangfeng), but riverine landscapes are less perceptible; Creative culture has not formed significant or perceptible clusters.

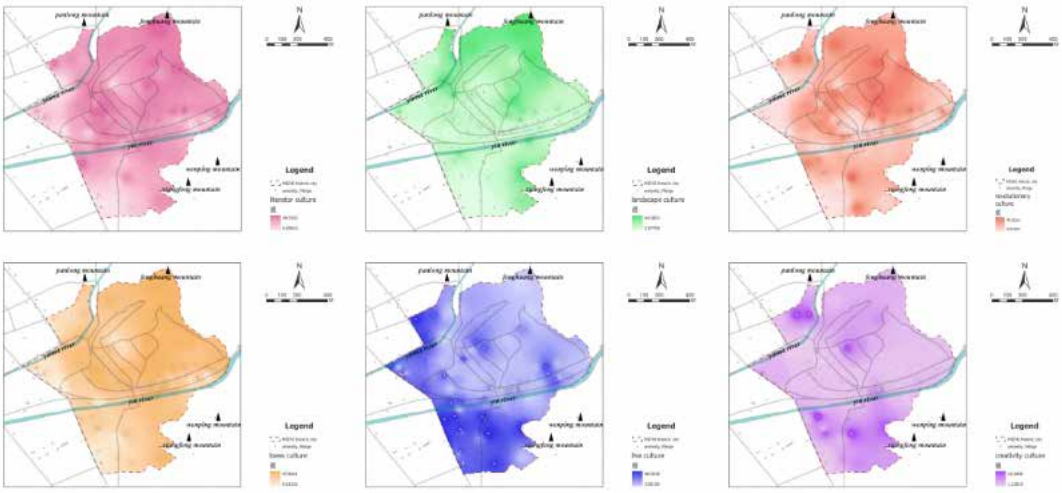

Fig.5 The measure of scene clusters in representational scene

4.4.3 Scene Cluster Value Perception

Based on the web-text data crawled via Python and cleaned accordingly, NVivo 20 was used for word segmentation. The top 60 keywords were selected for coding within the behavioral and identity dimensions. Since emotional inclinations are often implicit in text, Python interfaced with DeepSeek to perform sentiment analysis on individual texts, extracting the top 20 high-frequency emotional words for coding the emotional dimension.

Following grounded theory, a total of 80 keywords and their related texts underwent open coding, axial coding, and selective coding, progressively refining the emotional, behavioral, and identity layers of scene values. This process culminated in the establishment of a value perception framework for the scene clusters of Mizhi Historic Town.

As shown in Table 1 and Figure 6, the emotional layer clusters into five categories: joy, pride, comfort, sadness, and negativity. Positive emotions (joy, pride, comfort) accounted for 67%, indicating that the scene clusters generally evoke significant positive affect. Joy and pride primarily stem from awe and grandeur related to heritage sites, while comfort arises from the town's atmosphere. Sadness accounts for 7.62%, largely reflecting reflections

on historical events; negative emotions comprise 25%, partly due to resentment towards certain negative historical figures and partly due to ecological challenges faced in Northern Shaanxi.

Behaviorally, clusters are categorized as nostalgic, innovative, integrative, and philanthropic. Nostalgic behavior dominates at 45%, demonstrating strong public reminiscence and respect for heritage. Integrative behavior follows at 32.5%, showing a sense of affinity and participatory intention toward the town. Innovative behavior stands at 19.3%, reflecting a strong public interest in new developments. Philanthropic behavior is the least prevalent, mainly driven by official initiatives and lacking spontaneous societal engagement.

The identity layer divides into local, national, ethnic, historical, and fashionable identities. Historical and local identities predominate, reflecting the profound historical and regional cultural significance of Mizhi. National identity ranks next, based more on general patriotism without strong resonance to the town's red heritage. Ethnic and fashionable identities extend from regional ties and contemporary trends.

From score distribution and item concentration analysis (Figure 7), high cohesion in pride and comfort (emotional), philanthropy (behavioral), and fashionable and ethnic identity dimensions are pivotal for optimizing cultural heritage transmission in Mizhi. Attention must also be paid to mitigating concentrated negative sentiments regarding environmental facilities.

Table 1 Value Perception Metrics of Scene Clusters in Mizhi Historic Town

Selective coding	Axial coding	Open coding	Example
Emotion	Delighted	Liked (68), Affirmed (60), Praised (54), Amazed (10), Anticipated (13)	"Visited Li Zicheng's Palace on Panlong Mountain. The architecture towers majestically, exuding imperial grandeur."
	Proud	Shocked (17), Excited (16), Proud (15), Admired (4), Recalled (2)	"The palace appears solemn and majestic, narrating the glory of past dynasties."
	Comfortable	Suitable (20), Romantic (20), Leisurely (12), Refreshing (12), Satisfying (6), Pleasant (7)	"Had lamb offal with Chinese hamburger in Mizhi—absolutely delicious!"
	Sentimental	Regretful (23), Campaigns (10), Sorrowful (4), Disappointed (2)	"Though the rebellion failed, the grandeur of the palace remains a poignant memory."
	Negative	Indifferent (86), Resentful (24), Angry (13), Disgusted (4)	"Dusty winds in Mizhi—feels like eating sand outdoors."
Behavior	Nostalgic	Historical past (83), Transitions (64), Deeds (45), Remembrance (42), Exclamation (30);Nostalgia (6)	"Though Li Zicheng failed, his deeds inspire generations."
	Novelty	North of shaanxi Ballads (52), Cultural Festivals (43), Folk Songs (20)	"A north of shaanxi folk song is now trending in local tourism promos."
	Integrative	Participate (48), Recommend (46), Together (45), Follow (32), Charm (23)	"Joined local folks, danced Mizhi's sky and waters into memory."
	Public	Caring (10), Friendly (5), Warm (2)	"Story-sharing event featuring Mizhi's local role models."

Identity	Regional	Place (413), Mizhi Millet (275), Cave dwellings (97), Mizhi Aunts (91), Hometown (89), Loess (82), Taste (30), Down-to-earth (12), Paper-cutting Art (24), Intangible Cultural Heritage (37), Li Dingming Clinic (6), Iron Flower (20)	With a quick stroke of the knife, cut it into thin shreds and pour it over the simmered minced meat. That's the taste of home.
	Historical	Li Zicheng (314), History (167), Western Xia (145), Ming Dynasty (123), Period (107), Emperor (24), Ancient Times (28), Emperor Xiaowen of Northern Wei (12), Tongwan City (4)	In Chinese history, Li Zicheng is an inescapable figure. This "pioneer" from Mizhi County, Shaanxi Province, led the peasant army to launch a nationwide uprising, eventually overthrowing the Ming Dynasty and establishing the Great Shun.
	National	China (170), the State (138), "Dawn" (24), the Yan 'an Spirit (20), the Eighth Route Army (11), the War of Liberation (6)	Mizhi County held a research and study activity for the "Red Millet" cultivation project. This event closely combined red education, cultural inheritance and knowledge learning, allowing students to receive spiritual cleansing in a variety of rich and colorful activities.
	Fashionable	National Trend (25), Pop-up (20), style (12)	The rice fat in Hayao Miyazaki's paintings is undoubtedly a romantic collision of Oriental rural and fantasy aesthetics
	Ethnic	Ethnicity (74), Military (51), Ancestor (19), Thousand-year-old County (17), Genealogy (10), Descendants (7), Continuation (5), Branch (3)	"The Du clan of Mizhi traces its lineage over 800 years through detailed records."

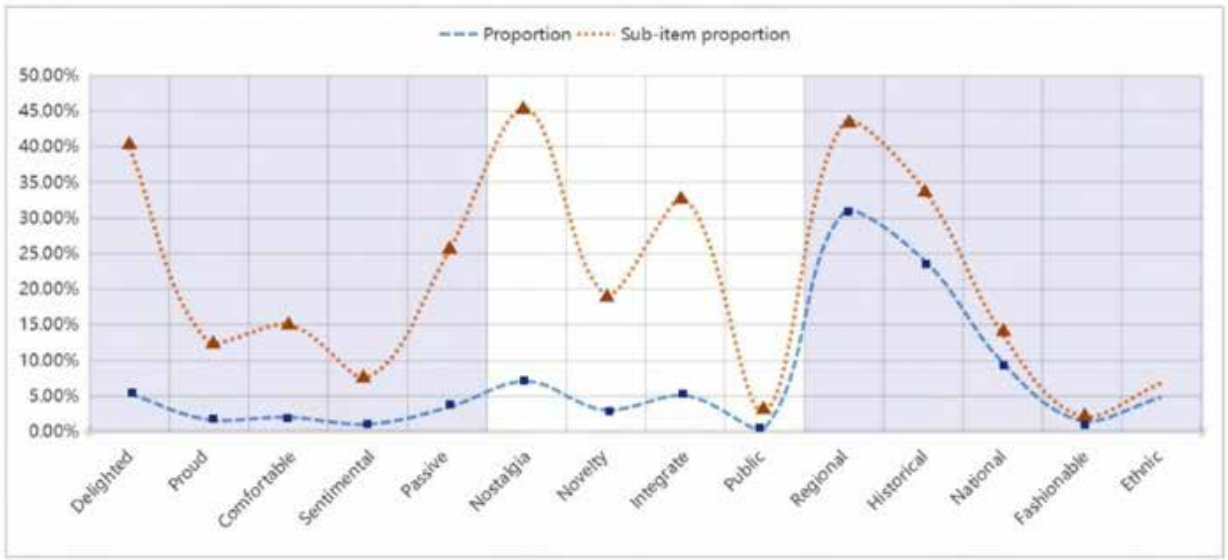

Fig6 The scores and the number of items of the scene cluster values

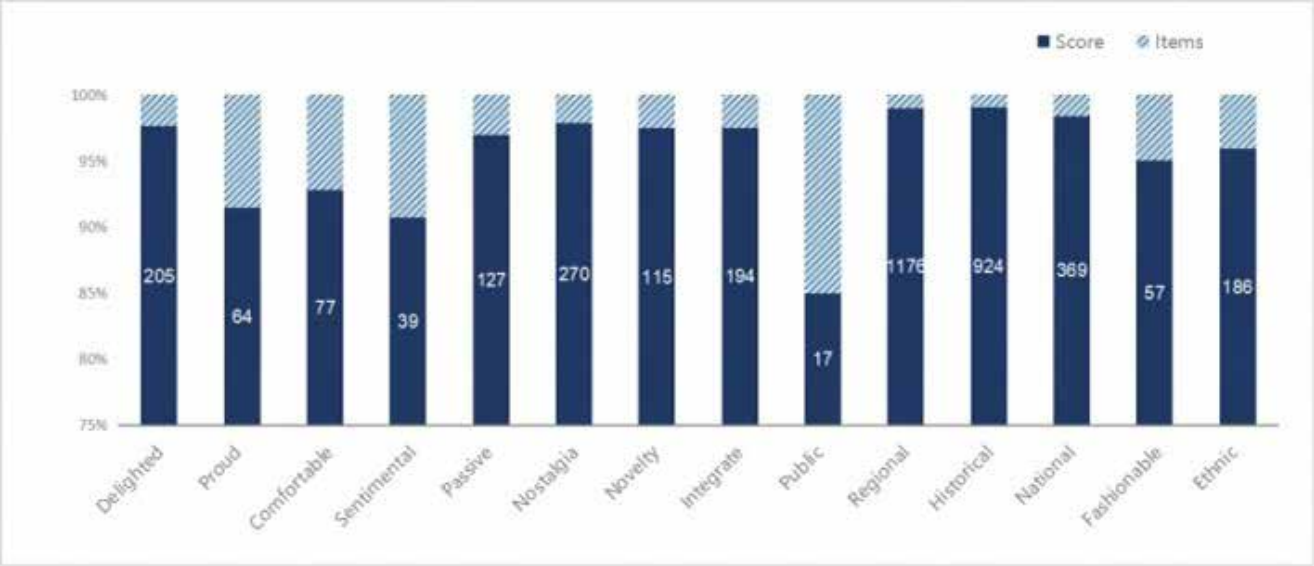

Fig7 The scores and the number of items of the scene cluster values

To conclude, the scene-based evaluation of value transmission in Mizhi Ancient Town reveals three key challenges: First, there is a clear rupture in everyday life scenarios, as local cultural elements have not been effectively transformed into creative or experientially meaningful scenes, leading to a disconnect between daily practices and cultural representation. Second, a structural mismatch exists between the supply of and demand for landscape-oriented and red culture scenes. This has resulted in an unclear, even chaotic, perception of cultural clusters, undermining the coherence of scene-based cultural value. Third, the value perceptions within the scene clusters tend to focus on grand historical and national narratives, or on aesthetic enjoyment derived from historical atmospheres, rather than cultivating targeted cultural transmission or sustaining distinct cultural types embedded in each scene. Notably, there is an emerging enthusiasm for integrating traditional culture with contemporary, trendy expressions. Effectively channeling this momentum to enhance emotional resonance, behavioral engagement, and identity expression will be crucial to realizing the creative transformation and innovative development of traditional Chinese culture.

5 Conclusion

Space in itself holds no inherent meaning. It is through the diverse needs of individuals—manifested in comfort objects, neighborhood interactions, and human activities—that space materializes into scenes and acquires meaning. Responding to the practical challenges of value transmission in China's historical towns, this study constructs a localized scene analysis framework rooted in Clark's scene theory and informed by Lefebvre's theory of spatial production. By incorporating the dual perspectives of "scene representation" and "represented scenes," the framework enables measurement of scene clusters to reveal mismatches in value supply within the spatial production process.

Building on this, the paper evaluates the value transmission of historical town scenes from the perspective of collective value perceptions across scene clusters. It further examines whether the transmission process effectively achieves both spiritual inheritance—from heritage to human consciousness—and living cultural revitalization—from preservation to regeneration.

Creative scenes, as intermediaries between cultural and everyday life scenes, play a critical role in mediating traditional and modern cultural expressions. Using the value dynamics of scene clusters as indicators, this approach provides a viable method to assess the direction and effectiveness of value transmission in historical towns. Moreover, scene connections at varying scales offer a practical pathway for linking different levels and missions

of urban-rural cultural heritage.

Finally, while the scene analysis framework offers a holistic tool for evaluating outcomes and influencing factors of value transmission in historical towns, it remains limited in diagnosing specific combinations of comfort objects, user groups, and activities. Thus, it is imperative to integrate process-based assessments of cultural transmission effectiveness, in order to identify actionable elements and links, and ultimately enhance the overall effectiveness of cultural inheritance in historical towns.

The Role and Value of Theory in Urban Design: Can They Truly Shape the City?

Zhejun Wang
Affiliation: University College London
Email: zhejun.wang.23@ucl.ac.uk

Abstract
This paper critically examines the role and value of planning theory in urban design, using the evolution of the Neighbourhood Unit and its reinterpretation within the 15-minute city model as an analytical lens. It first situates theory within two key debates: urban design as a temporal process of spatial-social change and as a form of activism. The study then explores how the Neighbourhood Unit operates within interdisciplinary frameworks, assessing its theoretical contributions and limitations in the face of socio-spatial complexity and postmodern fragmentation. Ultimately, the paper argues that theory both constructs and contests the order of urban design, marking a shift from static, prescriptive models toward dynamic, adaptive frameworks that reshape how cities are imagined, negotiated, and transformed.

Keywords: urban design, planning theory, neighbourhood unit, proximity-based models, 15-minute city

1 Introduction

The urban fabric and the forms of urban life are being profoundly reshaped by global crises and transformative events. These shifts have triggered new policies and strategies that address social, cultural, and other aspects across multiple dimensions (Longo et al., 2022). In particular, the challenges posed by accelerating urban sprawl and climate change as global issues, together with regulatory failures that have been exacerbated by neoliberal planning environments, have prompted renewed attention to alternative urban models. In response, urban planners, scholars, and policymakers are engaging in renewed discussions on alternative approaches aimed at delivering more sustainable, liveable, and healthy cities (Logan et al., 2022; Walters, 2021). As a result, the way in which urbanisation is conceived has shifted rapidly and significantly over the past few decades, reshuffling the imagination of urban space and transforming the way everyday urban life is experienced. For example, superblocks, low-traffic neighbourhood plans, doughnut models, and hybrids of these have emerged. Among these, the x-minute city model (15-minute city, with its variations) has gained increasing momentum (Di Marino et al., 2023; Moreno et al., 2021; Nieuwenhuijsen, 2021).

This paper adopts Alberti and Radicchi's (2023) study, From the Neighbourhood Unit to the 15-Minute City: Past and Recent Urban Models for Post-COVID Cities, as its primary analytical lens. It examines how the theoretical lineage of the Neighbourhood Unit (NU) continues to inform proximity-based urban models, situating the x-minute city within a broader historical and conceptual continuity. Through this case, the paper critically investigates the role and value of theory in shaping contemporary urban design discourse and practice.

1.1 The Re-emergence of the Neighbourhood Unit

Although the x-minute city is often regarded as a new paradigm, its conceptual foundation rests on well-established precedents (Pozoukidou and Angelidou, 2022). Central to this lineage is the NU, a planning concept introduced by Clarence Perry in 1923, which defined the neighbourhood as the fundamental unit of urban organisation (Mumford, 1954). Despite ongoing critiques and debates surrounding its socio-spatial implications, the NU continues to exert influence in urban planning practice, often in implicit or adapted forms.

In recent decades, the New Urbanism movement has reinterpreted the NU through a contemporary lens, incorporating its core principles of walkability, accessibility, and spatial decentralisation into modern proximity-based planning frameworks, such as the x-minute city (Duany, 2021; Kissfazekas, 2022; Moreno et al., 2021). Consequently, both the NU and the broader notion of the proximity city have re-emerged as focal points in planning theory and urban design practice.

1.2 Case Selection and Analytical Approach

While the 15-minute city and related proximity-based models have been extensively examined in recent academic literature and urban policy discourse, relatively limited attention has been devoted to re-examining the theoretical foundations from which these models originate, particularly the NU. This gap presents a timely opportunity to assess how enduring urban theories are being recontextualised within contemporary planning frameworks.

Within this context, the NU, as the conceptual foundation of the x-minute city, is employed as a lens through which to interpret the underlying principles and intentions of urban design. To address this, the paper draws on Alberti and Radicchi's (2023) study as a case for critical analysis. Their research traces the historical and conceptual evolution of the NU, demonstrating how its spatial logic continues to inform proximity-oriented and decentralised urban models. Furthermore, the study explores how interdisciplinary interpretations of the 15-minute city may provide a framework for addressing the socio-ecological challenges of urban transformation in the post-COVID era. Through this case, the paper interrogates how urban design theory is mobilised, reinterpreted, and contested in shaping future-oriented planning imaginaries.

2 Theoretical Debates in Urban Design

2.1 First Tier: Urban Design as a Temporal Process of Spatial-Social Change

The notion of urban design as a temporal process of spatial-social change responds to the so-called 'spatial turn' (Evans, 2010) and incorporates a temporal dimension into the spatial-social processes that unfold through dynamic interactions (Lefebvre, 2010; Madanipour, 2006). This perspective positions urban design as an ongoing, never-complete process shaped by two interrelated forces: top-down strategies and everyday spontaneous practices (Gańko, 2019). More specifically, it emphasises the role of time in urban design by framing it within the temporalities of "the pace of life and space" and "the historical processes of place" (Carmona, 2014).

Building on this theoretical framework, Alberti and Radicchi (2023) propose that the NU functions as a socio-spatial model and employ it as a historical anchor to illustrate how the concept of urban proximity has evolved across various theoretical paradigms. Their analysis demonstrates an ongoing dialogue in neighbourhood-scale urban design, reflecting a shift from physical spatial forms (isolated units) to social dynamics (interconnected spaces). That is to say, the role of the NU has shifted over time, profoundly influencing the gradual transformation of the concept of neighbourhood in urban design, from a physical space to a carrier of social meaning and identity. This transformation reflects theory as a framework for structuring and organising urban design, sustained through the continuity and repetition of theory within urban processes. Accordingly, theory provides a set of principles that enable urban design to adapt, transform, and reconfigure itself in response to socio-spatial-temporal evolution, thereby contributing to the pursuit of ideal urban visions and supporting the generation of diverse discursive dimensions within urban design.

2.2 Second Tier: Urban Design as a Form of Activism

Urban design as a temporal process of spatial-social change offers a broad conceptual framework that enables challenges to existing urban fabric and social relations. Building on this foundation, urban design as a form of activism reimagines urban space as a site of debate, positioning activism as a key driver in urban transformation (Usubillaga, 2022).

In the recent wave of activism, often undertaken at the neighbourhood or community level, urban activism is increasingly recognised as the seed of transformative change within neoliberal urban contexts (Monno, 2016). Alberti and Radicchi (2023) offer a critical perspective on how the NU theory implicitly contests conventional planning paradigms by re-evaluating urban proximity as a foundational dimension of sustainable cities. Beyond its theoretical role, the NU has contributed to substantial shifts in community lifestyles. By promoting social cohesion, inclusivity, environmental sustainability, and public health, the NU supports a broader transition toward the eco-social urban model.

Most importantly, NU theory has stimulated what has been described as a shift from conventional urban planning to a more integrated form of urban life planning (Allam et al., 2023a; Staricco, 2022). This transition foregrounds the notion of the "right to the city" as a foundational component in the production of spatial, neighbourhood, and social life. In this context, theory functions as a mechanism for structuring urban design by shaping the built environment and envisioning new modes of urban living. It is not only intrinsic, intangible, and embedded in practice, but also operates as a connective framework that aligns physical space, social interaction, and environmental experience. Through this integrative role, theory contributes to the realisation of high-quality urban life.

2.3 Revisiting the Neighbourhood Unit

The evolution of the NU has long been a subject of scholarly debate. Inspired by Ebenezer Howard's (1898) Garden City approach, Perry (1923) introduced the NU as a unit-based spatial method of urban planning (Lawhon, 2014). Notably, this approach was also intended to intervene in existing communities, and is therefore recognised as a tool for urban regeneration (Marchigiani and Bonfantini, 2022). However, the NU has faced severe criticism, particularly for its failure to account for the organic spatial and functional structures embedded within established neighbourhoods (Bauer, 1945; Isaacs, 1948; Pozoukidou and Chatziyiannaki, 2021). Jane Jacobs (1961) critiqued its approach for disregarding the complexity of urban environments and the social fabric embedded within them (Allam et al., 2023b). Similarly, Kevin Lynch (1960) emphasised the need for urban elements to be arranged in a lively and integrated manner that enables people to connect with their localities, rather than be separated by space.

Despite these critiques, modernist planning paradigms have frequently led to spatial fragmentation, reinforcing the need to reconsider neighbourhood planning. In response, Alexander (1962) sought to restore the meaning of the NU as a composition of multiple physical and social units coexisting within the broader urban context. Since then, the neighbourhood principle has continued to be reinterpreted, culminating in the emergence of the x-minute city, which is regarded as the most recent evolution of the NU.

Nevertheless, the NU theory is more than a purely rhetorical statement. A review of its critical reception reveals that the initial controversies stemmed from its perceived role in promoting spatial and social segregation and hindering organic urban regeneration. In response to these criticisms, the x-minute city model seeks to rebuild the connection between spatial form and social function by returning to the fundamental principles of the NU and reaffirming the concept of proximity (Marchigiani and Bonfantini, 2022). This return has resulted in urban design being compressed into a singular and highly localised spatial framework.

In this context, proximity is understood as both a physical and socially relational manifestation of urban space that supports the adaptation and reinforcement of NU theory in contemporary applications. In this way, while the relationship between proximity and neighbourhood planning is ambiguous, the NU theory has become a partial disguise for the complex grammatical characteristics of urban space (D'Onofrio and Trusiani, 2022; Gil Solá and Vilhelmson, 2019; Marchigiani and Bonfantini, 2022). It is tacitly accepted as a representation of urban design's potential to activate new forms of social practice and everyday life (Sennett, 2018). At the same time, an expanding vocabulary of buzzwords related to proximity and community has produced a set of ambiguous terms that are often mechanically repeated in urban discourse. As a result, the NU increasingly appears as a branded concept, detached from its original theoretical foundations.

3 Reinterpreting the Neighbourhood Unit in Postmodern Urban Paradigms

In the late twentieth century, urban planners increasingly shifted their attention to the neighbourhood scale and localised communities, largely in response to the functional-spatial separation and widening socio-spatial divide resulting from modernist planning. Within the context of postmodernism, the NU concept has informed several contemporary urban planning movements (Pozoukidou and Chatziyiannaki, 2021), including Transit-Oriented Development (TOD), New Urbanism, and Smart Growth (Furuseth, 1997). It has also contributed to a range of compact city models aimed at facilitating sustainable urban transformation, such as the compact city, the urban village or transit village, and the x-minute city (Lobner et al., 2021). Postmodern urbanists continue to adopt key principles of NU, including mixed-use, housing and work proximity, human scale, adequate green space, walkability, and

compactness (Wheeler, 2013), and expect this to lead to high-density, walkable, mixed-use, and diverse neighbourhoods, which in turn will promote social interaction and sustainable development (Talen, 2005).

However, physical interventions based on these principles are insufficient to address complex urban challenges such as socio-spatial segregation (Kafkalas et al., 2015). Urban models inspired by the NU often lack the replicability to be adapted to operate effectively across diverse urban environments (Khavarian-Garmsir et al., 2023), particularly in the postmodern era of increased social mobility and pluralistic lifestyles (Al-Khanbashi, 2020). Furthermore, while postmodern models critique and partially move beyond the NU framework, they are frequently criticised for lacking genuine innovation. For instance, New Urbanism is often viewed as an extension of earlier paradigms rather than a truly novel theoretical contribution; it is considered a practice rooted in methodological repetition rather than conceptual advancement (Cuthbert, 2007). Consequently, the persistent ambiguity surrounding the conceptualisation, interpretation, and evolution of the NU theory has contributed to confusion in its application, rendering urban design increasingly contested and theoretically ambiguous.

4 Theoretical Frameworks of the 15-Minute City: A Critical Evaluation

4.1 Framework Composition

Alberti and Radicchi (2023) conceptualise the 15-minute city as a proximity-based framework integrating multiple theoretical strands (see Figure 1). At its core is the NU, complemented by Central Place Theory (service hierarchy and accessibility), Proxemics (human-scale spatial relations), TOD (connectivity through transit), and compact city principles (density and sustainability). This synthesis allows for a multidimensional understanding of urban proximity, bridging spatial, social, and environmental considerations. In the theory of urban planning and design, the NU emphasises the concepts of community-centred facilities and their walkability, which form the basis of urban proximity. The proximity extends its related theories in urban design through interdisciplinary approaches to the Central Place Theory (CPT) and the Proxemics Theory (PT) from geography and anthropology. The CPT develops a hierarchy and mobility of services and facilities to provide the NU with accessibility of facilities in a broader spatial scope. On the other hand, the PT promotes the philosophy of human-scale relationships with distance and space to enhance the interaction between humans and urban spaces for the NU. The TOD, which follows the principles of New Urbanism, further develops proximity by extending the walkability range of the NU to public transport. Additionally, urban proximity is given the concepts of sustainable cities in the Compact City and the Ecocity models. The concepts incorporate the consideration of urban density, mixed-use urban networking, and green areas contributing to the accessibility of urban sustainability to the NU prototype.

The integration of these theories and concepts as a theoretical framework for this research provides the concept of urban proximity and the evolution of the NU's theories to be more comprehensive and adaptable to a wider context. Although the research does not present new theories or unique arguments of its own, through a holistic and critical review and discussion of these existing theories, it makes recommendations for the 15-Minute City within this theoretical framework under urban design and planning research and practice.

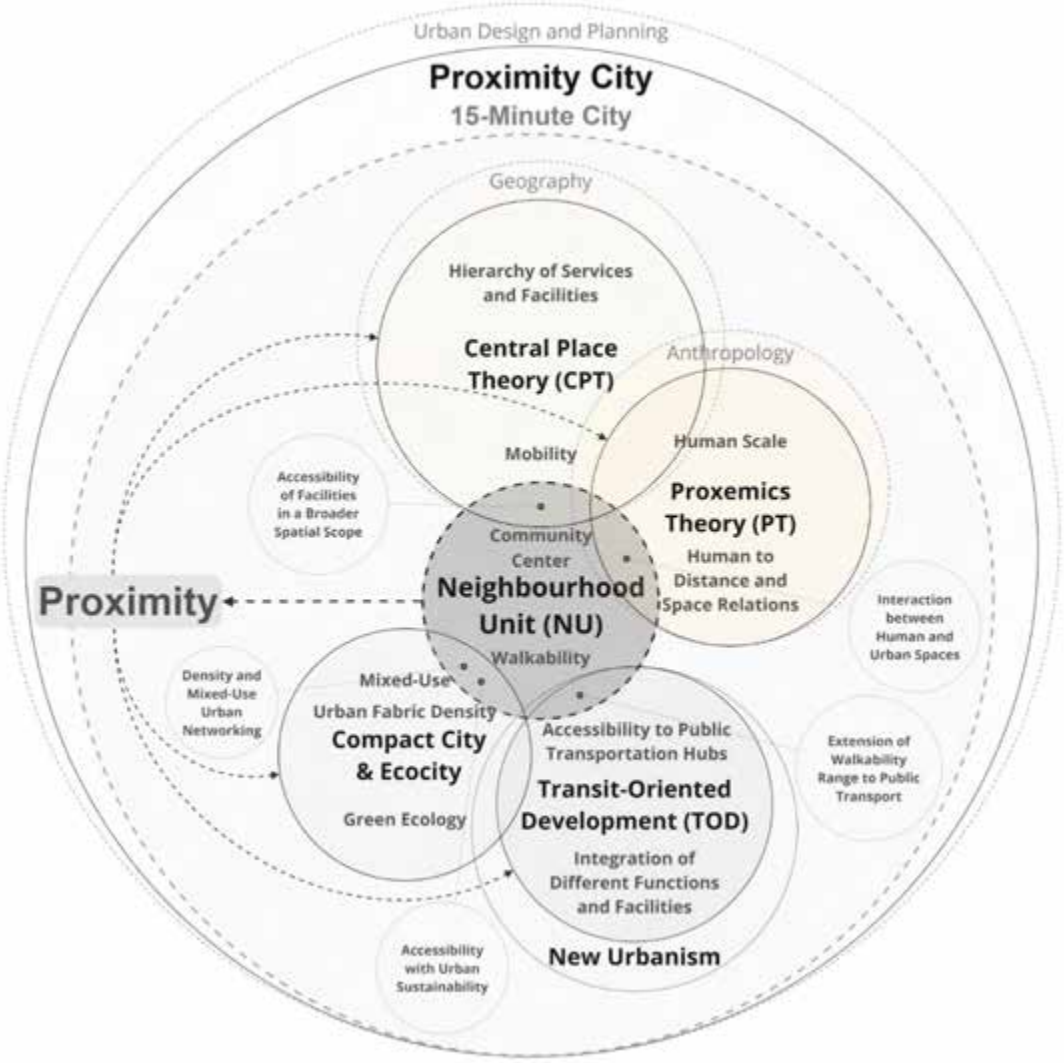

Figure 1: Theories and concepts in the 15-Minute City theoretical framework (made by author)

4.2 Benefits and Limitations

The theoretical framework facilitates the evolution and continuity of urban design in the concept of spatial social change and allows cities to respond to the unpredictability of global challenges, which also significantly addresses the aims of the research project. These benefits derive from the humane accessibility of urban spaces and distances through the comprehensive perspective of proximity across time, as well as the promotion of spontaneous social cohesion and inclusiveness from the neighbourhood order, and the combination of sustainable relevance.

The NU and proximity-centred framework also tend to bring limitations, mainly due to a lack of consideration of social diversity and the challenges of operationalising it in reality. Specifically, the theoretical framework does not adequately consider the social segregation and urban inequalities that may result from the heterogeneity between different socio-economic groups. In addition, its practical implementation in situations where the urban fabric is already relatively fixed will encounter considerable problems in community participation and policy support.

4.3 Integrating and Comparing Alternative Theoretical Frameworks

Among existing theoretical frameworks, the Social-Ecological Model for Physical Activity offers a valuable multilevel structure that emphasises how individual behaviours are shaped by interactions across multiple contextual layers. This model holds considerable potential for integration into the theoretical underpinnings of the 15-minute city.

As illustrated in Figure 2, a comparative analysis of the hierarchical structure of the 15-minute city and the Social-Ecological Model enables the construction of a layered theoretical hierarchy. This hierarchy ranges from the human scale, through neighbourhoods and urban networks, to mixed-use sustainable communities and ultimately the proximity city. Such a structure supports a systematic organisation of urban proximity, beginning with walkability and accessibility at the individual and neighbourhood levels, extending to social interaction and cohesion at the community level, and culminating in spatial deployment and service provision at the urban policy level.

This multilevel approach provides a useful framework for designing urban strategies that simultaneously address the needs of individuals, communities, and governance structures. It facilitates the development of interventions that are both context-specific and scalable. However, the incorporation of multiple layers may introduce analytical complexity and operational challenges in the planning process. Further research is required to understand the interdependencies and dynamics across these levels to ensure effective implementation.

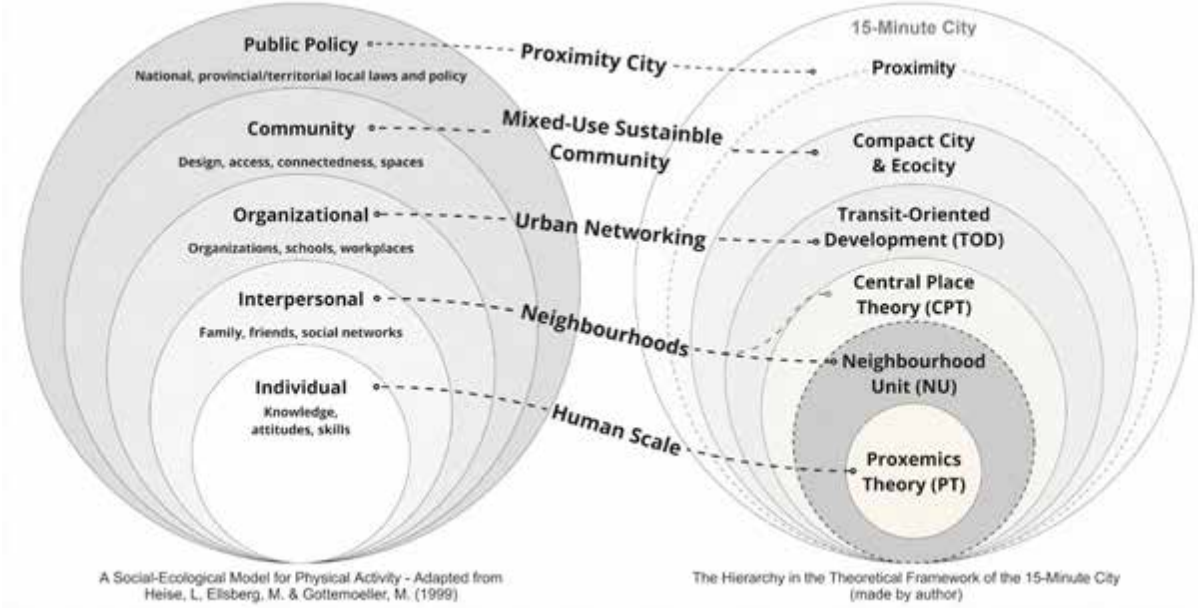

Figure 2: Comparison and adaptation from a Social-Ecological Model theoretical framework to the 15-Minute City theoretical framework (made by author)

5 Conclusion

This study adopted the NU as a dynamic analytical lens to investigate whether theory can truly shape the city. By exploring the evolutionary nature of NU Theory and its progression toward the 15-Minute City, the research reveals the two-fold role and value of theory in urban design. First, theory serves as the order of urban design. Theory, as both a tangible and intangible construct, shapes and reforms the inner principles of urban design, enabling it to adapt to ongoing urban transformation and to stimulate innovation. Second, theory creates an order for urban design that connects the space of place and everyday life. This order is metaphorical and progressive, encouraging urban design to take action in order to reconfigure urban space and enhance the overall quality of urban life.

Although the validity of major urban planning and design theories has been questioned in recent years, largely due to their tendency to oversimplify the complexity of urban design while repeatedly reiterating concepts that have emerged in the past but remain unresolved, this ambiguity has nonetheless stimulated wider critical thinking and urban imagination. Thus, rather than merely serving as a rhetorical gesture, theory acts as and creates the order of urban design. It views the urban as a process and asserts that urban design precipitates and embeds its distinctive historical and practical dimensions into urban space and everyday life.

Acknowledgements
The author would like to thank Dr Filipa Wunderlich and Mr Richard Sobey for their guidance and insightful feedback during the Urban Investigations course at the Bartlett School of Planning, which greatly informed the development of this research.

Rethinking Promethean planning: An epistemological enquiry of technoscientific-centrism in planning theories

Ruggero Signoroni
Department of Architecture and Urban Studies (DAStU), Polytechnic University of Milan
ruggero1.signoroni@polimi.it

Abstract
The paper provides a critical exploration of technoscientific-centrism in planning theory through the lens of the Promethean myth. Considering the prevailing trends of hyper-specialisation, resurgent scientism and the associated risks of depoliticisation, there is a need to unpack the overreliance on techno-scientific rationality within planning disciplinary practices. This can be achieved by drawing upon concepts and analytical categories from outside the discipline. Accordingly, the Promethean myth offers a valuable opportunity to reinterpret the history of planning as 'science of prediction', that is, a field which has been marked since its origins by a conception of 'absolute' space introduced by modern scientific thought. The present paper delineates the paradigm of Promethean Planning, while concomitantly establishing the foundations for a post-Promethean conception of planning.

Key words: Promethean planning, positivist spatiality, scientism, specialisation, technology.

1. Planners, technology, and the never-ending quest for prediction and control

This paper presents an alternative perspective on the evolution of technoscientific-centrism in planning by exploring the myth of Prometheus. Given the apparent distance, in disciplinary terms, of the Promethean myth with respect to urban planning culture and history, a preliminary clarification is necessary. In the subsequent section, the tale of Prometheus, son of Iapetus, will be illustrated and analysed in relation to that of Atlas. A particular focus of this study lies in the relationship between humans and technology, with great emphasis placed on the consequences of this relationship for the domain of urban planning. The primary feature of the Promethean myth that will be examined subsequently is the aspiration for omniscience as the ultimate objective of a techno-centric conception of planning. As will be argued in the fourth section, Promethean planning consists primarily of the combination of prediction and control – in the terms described by John Friedmann (1987) –, the result of which tends precisely to omniscience, ensured by the progressive enhancement of the predictive and modelling apparatus at the disposal of planners starting, at least, from the quantitative revolution.

This vision is deeply rooted in the positivist culture of planning and could be summed up effectively in the expression of George B. Ford (1913), according to which "In the science of city planning the whole city is our laboratory" (p. 551). The concept of an artificial space in which total control is ensured, as will be argued below, is predicated on the notion of 'absolute space' introduced by modern scientific thought (Voegelin, 1948). In such a space, actions and behaviours can be programmed, and therefore, everything can be predicted. The underlying thesis suggests that contemporary planning is characterized by the return of scientism, which insidiously combines the advancement of predictive technologies, based on the extraction of data on an increasingly large scale, and hyper-specialisation. In this regard, it's worth considering that such a trend is particularly striking within planning academe (Signoroni, 2022). As the Promethean myth becomes a way to deconstruct the role of planners as specialists, a key to unpack the origins of the relationship between the planner-specialist and technology might be traced back to early 20th century planning[1]. Notwithstanding the critiques to rationalist planning, and to its

1 Since its inception as both a discipline and a professional practice in the aftermath of the Second Industrial Revolution, urban planning has established what may be considered an enduring overreliance on techno-scientific rationality (Sandercock, 1998). Indeed, the integration of technoscientific rationality into planning theory and practice has profoundly shaped the process of professionalisation and institutionalisation since the early steps of the discipline. For instance, the social reform movement – which was imbued with positivist philosophy – significantly shaped the epistemological foundations of planning (Beauregard, 1990; Fairfield, 1994). The emergence of planning as a distinct field of practice has been extensively documented in scholarly literature (Birch,1980; 2001; Birch and Silver, 2009; Peterson, 2009; Davoudi and Pendlebury, 2009). Notably, the evolution from

overreliance on technoscientific rationality, an in-depth inquiry into technoscientific-centrism in the domain of urban planning has never been undertaken. For this reason, an incursion into the language of myth may prove more beneficial.

Specifically, this study focuses on the Promethean myth. A substantial body of literature exists that examines the myth of Prometheus and its implications for science and technology (see: Kahn, 1970; Calame, 2005). Given the emphasis on the spatial dimension of technoscientific-centrism as the primary focus of this study, a thorough investigation of the Myth's spatial ramifications is envisaged. While drawing upon classical sources, particularly Hesiod (Arrighetti, 1984), the present study primarily draws upon three contributions. Robert Graves' well-known book, The Greek Myths (1960), serves as main reference to introduce the figure of Atlas. Carlo Sini's (1981) appraisal of the myth of Atlas and Prometheus – along with Simona Chiodo's (2020) analysis of the evolution of the relationship between humans and technology – serves to unpack the Promethean legacy, that is, the concept of scientific specialisation that underpins the 'destinal' movement of technology and, accordingly, the quest for prediction and control.

In the domain of planning, a prevailing technoscientific-centrism characterised by the pervasiveness of specialisation as the underlying rationale of the Western faith in technology (see section 3) has evolved into the prime component of what Gabriele Pasqui (2022a) delineates as 'the atmosphere'. Such curtain represents "the set of discourses, traditions, memories within which the practice of urban planning takes form (urban cultures, repertoires, transmission of knowledge, valorisation mechanisms)" (p. 45, translated in English by the author). Accordingly, Pasqui argues, "It is necessary [...] to recognize, together with the transformations of the [disciplinary] field, the concomitant shifts in the atmosphere" (ibidem). The extensive utilization of planning technologies – in the broadest possible sense, yet with specific emphasis on the comprehensive predictive modelling apparatus – has contributed, as Pasqui would assert, to the 'thickening' of the prevailing atmosphere by directing "the operational guidelines, the techniques, the tools" (ibidem). In the absence of "a fertile relationship between the development of tools and techniques for analysing territorial phenomena, also connected to the extraordinary availability of georeferenced data at our disposal [...]" the risk would be that "of supporting a (perhaps presumed) scientisation of urban planning analysis" (ibidem, p. 47). In this sense, examining the past through the lens of myth can offer insights into the present state of the art of the discipline, and potentially inform future theory-building scenarios.

2. Prometheus and Atlas: Symbols of 'technical mediation'

The figure of Prometheus unveils a peculiar reflection on the Western conceptualisation of technology, as it has been extensively discussed in the academic literature (see Kerenyi, 1997). Apart from Prometheus, a compelling parallel can be drawn between the myth of Atlas and the rise of faith in technology. Indeed, the two myths are deeply interrelated. Prometheus' older brother, Atlas "with a violent heart" (Hesiod: 509), is remembered as an inhabitant and lord of the far west, the Land of Atlas: "This land of Atlantis lay beyond the Pillars of Heracles, and a chain of fruit-bearing islands separated it from a farther continent, unconnected with ours. Atlas's people canalized and cultivated an enormous central plain, fed by water from the hills which ringed it completely, except for a seaward gap. They also built palaces, baths, race-courses, great harbour works, and temples; and carried war not only westwards as far as the other continent, but eastward as far as Egypt and Italy" (Graves, 1960: p. 143).

The myth of Atlantis is significant for two reasons. Firstly, it conveys the tale of a potent and technologically sophisticated population whose calamitous destiny is analogous to that of Prometheus. This is because when technological enhancement becomes hubris – that is, when it is employed to challenge the limits imposed by the gods or by fate – it must be stopped. In this regard, the case of Atlantis serves as a paradigmatic example: "The Egyptians say that [...] [Atlas and his brothers] at first [...] were extremely virtuous, bearing with fortitude the burden of their great wealth in gold and silver. But one day greed and cruelty overcame them and, with Zeus's permission, the Athenians defeated them single-handed and destroyed their power. At the same time, the gods

an engineering focus to a planning emphasis within the field resulted in a substantial shift in terms of urban expertise. Traditionally, engineers addressed the ailments of industrial cities (Schultz and McShane, 1978); in contrast, urban planners adopted a more comprehensive and scientific approach in addressing the broader needs of the city as a whole (Karvonen et al., 2021).

sent a deluge which, in one day and one night, overwhelmed all Atlantis, so that the harbour works and temples were buried beneath a waste of mud and the sea became unnavigable" (ibidem).

In contrast to the prominent recognition of Prometheus as the 'ancestor of human beings', Atlas has received comparatively less attention in this regard. The reasons for this discrepancy in treatment, so to speak, are not limited solely to a genealogical question. In the ancient Greek mythos, Prometheus is recognized as the progenitor of Deucalion, who, in collaboration with Pyrrha, is tasked with the responsibility of reestablishing humans in the aftermath of a deluge unleashed by Zeus. However, according to the myth, he is also the deity who oversaw the creation of humankind, shaping it from mud and infusing it with fire. Herein a critical distinction emerges between Prometheus and Atlas. Following the destruction of his kingdom, Atlas aligned himself with Kronos, taking a stance against the Olympic gods (an action that would result in a punishment from Zeus). In contrast, Prometheus chose to support the offspring of the Titans. This decision was met with respect and trust from Zeus. In contrast, Atlas' punishment is regarded as exemplary in that "he is placed on the western edge of the Greek cosmos with the task of holding the sky with his shoulders. Atlas is therefore the one who operates the separation between heaven and earth. The alternation of day and night, or rather the birth of time, is the result of his work" (Sini, 1981: p. 255, translated in English by the author).

Accordingly, Atlas directly operates "the separation between human and divine, being the one who started the relentless flow of time that devours the creatures of a day" (ibidem). This would position him, along with Prometheus, as an alter ego of human beings, thereby serving as a symbol of technical mediation. This reflection is further enriched when considering the subsequent myths associated with the figure of Atlas. According to the 1930 edition of the Treccani Encyclopaedia, "with the diffusion of the euhemeristic interpretation [...] it even goes so far as to make him an astronomer and a mathematician, inventor of the sphere" (translated in English by the author). Accordingly, as a second-generation Titan, Atlas is the brother of Prometheus, the lord of Atlantis, and the rebel ally of Kronos in the Titanomachy. Much more importantly, because of his treason and the consequent punishment, he becomes a mediator between the celestial and terrestrial realms; the originator of time and, in a broader sense, the progenitor of astronomy, to whom we owe the conceptualisation and development of the sphere[2].

What most deserves to be considered here with respect to the myth of Prometheus and Atlas is precisely their being 'mediators'. Atlas creates space by holding up the celestial vault with his own body. It is no longer the Euclidean space – an abstract notion of space (Friedmann, 1993; Graham and Healey, 1999) – but, rather, the space of human life, the space where bodies can breathe, walk, meet, and collide[3]. Moreover, he presides over the alternation of day and night, the natural pace of time. Symbolically placed in the extreme West, to hold up the sky, Atlas is therefore complementary to Prometheus, chained on the Caucasus, in the extreme East – where an eagle sent by Zeus every day devours his liver, destined to grow again in the night, thus perpetuating the torture for eternity (Chiodo, 2020). The two titans are therefore considered ancestors of mankind because they preside over the very first 'technical acts': the invention of time (its scanning, its control) and of fire. Prometheus's actions, in this case the act of stealing fire from the gods, are driven by a desire to assist humanity, whom he had previously endowed with intelligence and memory. However, it is through the agency of fire that men achieve emancipation. It serves as a symbol of technology, that is, techne: "the study and use of techniques, procedures, and advanced technical and scientific knowledge for the solution of practical problems" (Wikipedia). Accordingly, technology

2 It is noteworthy that from the 16th century onwards, the term 'atlas' has traditionally been employed to denote a compendium of graphic works – that is, cartography – which have constituted, and continue to constitute, a primary instrument of graphic communication for planners as well as for geographers and, albeit to a lesser extent, for architects and engineers.

3 In a recent essay, Cristina Bianchetti (2020) examined the relationship between bodies, space, and design. Filled with 'extra disciplinary' references, the contribution enables critical and original readings of the relationship between the body (in its many variations of state and movement) and the space (of the project). Affirming the presence of the body is a political act in itself; however, 'scientific planning' is such in the extent to which it replaces the body (of the subject, of the expert in the field) with pervasive technological mediation – georeferenced data, for example. For further insights into this topic, I refer the reader to Signoroni (2023b).

does not represent an external force; rather, the myth of Prometheus suggests that humans are innately 'technological beings'.

The human being, created with a deficiency due to the fault of Epimetheus (the foolish brother of Prometheus), becomes such when it can handle fire intelligently: "through the fire, jointly with the other Prometheus' gift to the Humans, namely, the intelligence, they can survive animals and atmospheric agents, live under the sun, and even rule the earth. [...] the fire intelligently used is divine in that it is so powerful that humans can rule the earth. Moreover, the fire intelligently used is divine in that it is precisely what makes the humans analogous to the gods" (Chiodo, 2020: p. 212).

3. The Promethean legacy: Specialisation and the civilisation of technology

It is therefore not by chance that human beings are the dominant species on Earth. They are destined for domination precisely because they are technological beings, that is, beings whose actions draw upon (and are informed by) specialisation. In this regard, the concept of specialisation must be understood in its profound meaning, intimately linked to the nature of man and the advent of the 'age of technology':

specialisation means to look at the species. The original Latin meaning of species is 'image', 'appearance', 'spectacle', 'form'. The related verb specere means 'to observe', 'to watch', 'to look at' [...] The species is what lets itself be seen. And in turn, 'it is by virtue of its visibility that the species can be observed, analysed, controlled, measured, desired, feared, refused, shunned [...]. We interpret things as species and enact specialisation, and scientific specialisation is 'the certainty of the difference between things' put into practice in the most coherent and powerful manner: science 'isolates a part (species) of reality; it separates it from the other part in order to be able to observe its configuration and behaviour' (Pitari, 2019: pp. 368-369).

When interpreted in this manner, specialisation can be regarded as anticipating the utilisation of technology by humankind: "Humans can exist as the beings who organise means, realise ends, make decisions and transform the 'world' only in virtue of the prior ontological isolation of all things [...] This is how we define human beings as technological beings" (ibidem: pp. 369-370). Scientific specialisation, therefore, responds to a very specific criterium (isolation of the predetermined field of observation, for purposes of control and manipulation), progressively accentuating it in parallel with technological enhancement. The emergence of the scientist-expert is also a consequence of scientific specialisation. Over the course of a few decades, the modern scientific method was established and with it the figure of the scientist-expert under the influence of astrologists as Johannes Kepler and Galileo Galilei and of philosophers such as Francis Bacon and René Descartes.

All in all, specialisation emerges as "the factual realisation of humankind" (ibidem). Through it, the Western civilisation accomplishes its own destine, becoming a true civilisation of technology. On the 'destinal' character of the event of technology, Carlo Sini (1981) dedicated an insightful reflection which is worth mentioning in this context:

The word 'essence' [...] means 'destiny', both in the sense of the occurrence of a destinal event, and in the sense in which Peirce, in the 'pragmatic maxim', speaks of consequences that are destined. In these two cases a movement (kinesis) is implicit which [...] involves a distinction between 'sense' and 'significance': the interpretant revealing of the present involves a reinterpretation of the sense of the past; it is that which awaits the passage into the future. With the help of an image we can [therefore] depict the destinal movement [...] as a wave which, in its progress, draws away a mobile and expanding circumference. However, the circumference swings in two directions: in the direction of expansion and, also, in the direction of continuous decentralisation. [...] Now, as involved in the movement of this spatially precipitating wave [...] we miss the perception of the propelling center of the circumference that is unfolding, of the movement itself of that center. Similarly, the event of technology, by destining us, drags us along; and thus, also and in a certain way, it directs us towards the driving force of the unfolding movement in which we ourselves are but together it dis-orients us from it (pp. 251-252, translated in English by the author).

Such unfolding movement of technology, therefore, while it destines us, it also compels us to acknowledge that "the present technological configuration of our civilisation may be a recent historical circumstance, but its Weltanschauung is as ancient as humankind" (Pitari, 2019: p. 371). Scientific specialisation, which lies at the heart of the destinal movement of technology, plays a critical role in shaping the direction of technological development and establishes the foundations for subsequent technological progress.

In correspondence with the rise of modern science, the concept of specialisation began to represent the structure of modern thought and accordingly imbued the culture of the 16th and 17th centuries, including the arts. In this regard, a compelling and particularly effective representation of specialisation is that provided by John Marlowe in his Doctor Faustus (1587). As acknowledged in the literature (Watt, 2007), the Faust is a potent 'contemporary' myth. It sheds light on specialisation as the implicit, though well-established, framework of modern thought. In order to exercise dominion over the capricious and uncontrollable forces of nature, it is necessary to acquire profound knowledge, which can be obtained through an 'isolation' process. This is to say, by acknowledging each entity as isolated from the rest. In this sense, the words spoken by Marlowe's Faustus can be interpreted as prophetic.

In the opening scene, as the character of Doctor Faustus is presented to the audience, he goes through all the disciplines in which his studies excel, including logic, medicine, law and theology. While appreciating logic and the law, he harbours a strong aversion to medicine, perceiving it as a discipline that offers no promise of immortality to humankind[4]. Moreover, he expresses disdain for theology, deeming it futile given the inherent propensity of humanity to commit sins[5]. In the domain of magic, a realm that Faustus has not investigated yet, he discerns the potential for greatness and potency[6]. The whole discourse is characterised by a sense of Promethean fashion. This is due to the fact that the "metaphysics of magicians" would bestow upon Faustus omniscience, thereby conferring the ability to foresee the future (hence the meaning of Prometheus: the 'foreseeing'). Though, it is the specialised conception of knowledge that is most striking. The words used by Faustus are indicative of the advent of modern science, as they already embody its fundamental premise, which is to be found in the scientist's essentially manipulative eye.

A second relevant consideration pertains to necromancy. As posited by several works in the field of anthropology (see, for instance: Gell, 1988; Stahl, 1995), magic may be regarded as a rudimentary form of technology. In this regard, Arnold Gehlen's contribution is worthy of mention. In his essay Die Seele im technischen Zeitalter (1957), which was subsequently translated and published in English under the title Man in the Age of Technology (1980), Gehlen discusses the extent to which both primitive and advanced civilisations, such as the Egyptian and the Greco-Roman, relied on magic as a form of proto-technology to bring order in, and equilibrise, the world. Accordingly, magic was performed to ensure predictability, regularity, and order in the face of a chaotic and unpredictable natural environment. In a world perceived as inhospitable to life, the cyclical repetition was assumed to provide a sense of security and stability. Therefore, magic was comprehended as a means to ensure and preserve the automatic, self-regulating, and repetitive character of the natural course. This compelling observation regarding

4 "Be a physician, Faustus, heap up gold, / And be eterniz'd for some wondrous cure. / Summum bonum medicinae sanitas, / The end of physic is our body's health. / Why, Faustus, hast thou not attain'd that end? / Is not thy common talk sound aphorisms?/ Are not thy bills hung up as monuments, / Whereby whole cities have escap'd the plague / And thousand desperate maladies been cur'd? / Yet art thou still but Faustus, and a man. / Couldst thou make men to live eternally/ Or being dead raise them to life again, / Then this profession were to be esteem'd. / Physic, farewell!" (Marlowe, 1616, retrieved from the John D. Jump's 1965 edition).

5 "When all is done, divinity is best. / Jerome's Bible, Faustus, view it well. / Stipendium peccati mars est. Ha! Stipendium, etc. The/ reward of sin is death: that's hard. Si peccasse negamus, / fallimur, et nulla est in nobis veritas. If we say that we / have no sin, we deceive ourselves, and there's no truth in/ us. Why, then, belike we must sin, and so consequently / die. / Ay, we must die an everlasting death. / What doctrine call you this? Che sarà, sarà: / What will be, shall be! Divinity, adieu!" (ibidem).

6 "These metaphysics of magicians / And necromantic books are heavenly; / Lines, circles, letters, and characters: / Ay, these are those that Faustus most desires. / O, what a world of profit and delight, / Of power, of honour, of omnipotence, / Is promis'd to the studious artisan!" (ibidem).

magic as a supernatural technology may become a useful key to understanding the meaning of contemporary technology. If the abovementioned assertion that the ultimate aspiration is to exercise control over the surrounding environment is accurate, then technology – like magic before it – is nothing more than a faith or, at least, a theory – certainly not the absolute truth[7].

The following section will explore the influence of these factors on the Promethean conception of planning, with particular emphasis on the role of planners during the early decades of the 20th century, marking the inception of the planning academe. Particular emphasis shall be placed on the following areas:

- The formation of the concept of expertise in the field of urban planning, as shaped in the light of positivist rationality. That is to say, the combination of prediction and control as a means to achieve a virtual omniscience
- The related conceptualisation of space
- The consolidation of the planners' professional epistemology in the face of older and newer scientistic postures.

4. Theorizing Promethean planning

The distinctive feature of the Promethean conception of planning is the unique combination of predictive capabilities and the exercise of control as a means to achieve virtual omniscience. It is precisely with reference to such characteristics that the definition of Promethean planning is going to be used here, in order to depict the dawn of planning as a professional practice and an institutional activity which was, and still is, imbued with Promethean fashion. However, a comprehensive understanding of Promethean planning necessitates a preliminary clarification regarding the conceptualisation of space, which will constitute the primary focus of this section. As a discipline dealing with socio-spatial dynamics – in terms of theorisation, regulation, and design – planning is inherently concerned with the concepts of 'space' and 'place'. In the context of Promethean planning, it is essential to note that the inclination towards control, which is both facilitated and reinforced by the integration of predictive technologies within planning practices, is underpinned by a distinct conceptualisation of space. The concept of omniscience, which constitutes the unconfessed ambition of planners could not have been achieved in the absence of the idea of space as theorised by Euclid and subsequently by modern scientists, an idea of space which ensures full control.

The interpretation of the myth of Prometheus (and Atlas) suggests a pertinent reflection: the abstract conceptualisation and representation of space paves the way for human domination of the Earth. According to the myth, the rebel titan provided human beings with technology and, in so doing, he set them on the path for domination. The latter is realised primarily and necessarily through the possibility of controlling space and time. It has previously been posited that the creation of space for human life was initiated by the actions of Atlas (Sini,1981). By granting to human beings the measurability of time through the alternation of day and night, Atlas enabled a 'technological' conception of time which complements the representation of space in relation to its manipulability. This combination ensures an unparalleled dominion over nature which has been introjected in planning epistemology. Thus, in the domain of urban planning space has historically been regarded as a 'given'; an a priori condition that has influenced and indeed been instrumental in the development of the discipline during the 19th and 20th centuries. In order to comprehend the genesis of planning as an "art and science" (Birch, 1980), it is necessary to analyse the conditions that determined its professional, institutional and academic structure (as well as its current and future development).

As previously indicated, the positivist paradigm, of Comtean descent, has played a pivotal role in the develop-

7 In this regard, as argued by Paolo Pitari, Emanuele Severino's theoretical endeavour is paramount in that it "invites us to consider that there may be good reason to doubt what we take for granted" (Pitari, 2019: p. 384). In appraising Severino's work on specialisation and technological thinking, Pitari asserts that "We are the Occidens, the West" and that "We pray at the altar of individual freedom, elevating our belief in our power to be technological beings to the ultimate truth" (ibidem). If technology is nothing more than a faith, only "through an interpretation of reality entirely other could one question the ethos of technology (the ethos of power). Only if the technological interpretation of reality is wrong, the ethos of power could and should be questioned" (Pitari, 2019: pp. 384-385).

ment of planning. Of particular interest here is the positivist conception of space, which depends as much on the Euclidean tradition (Friedmann, 1993; Davoudi, 2012) as on what, according to Harari (2017), we could define as the 'myth of Newton'. When considering the genesis of the concept of positivist spatiality, Davoudi (2012) emphasises that "Positivism portrays an absolute view of space which is rooted in Euclidean geometry. Euclid's three-dimensional geometry enjoyed uninterrupted sovereignty until it was challenged in the late 19th century. His ideas were accepted for a long time because 'it had been covertly built into Newtonian physics'" (p. 5). Accordingly, Isaac Newton's contribution as both a scientist and philosopher is paramount in that it established the conceptualisation of space as an "infinite container" (ibidem), characterised by objectivity and measurability, which are also assumed to inform the conceptualisation of place (ibidem). Indeed, according to Davoudi: "Place is considered as objective, bounded, self-contained and measurable [...] [so that positivism] considers space and place as either synonymous or binaries" (Davoudi, 2012: p. 5, italic added).

This conception, firmly anchored in the Euclidean tradition and subsequently confirmed by the scientific revolution, established the foundations for the impulse to control space that is characteristic of Promethean planning. A closer examination reveals that such vision is deeply rooted in the Enlightenment tradition (ibidem), wherein science establishes the epistemic underpinnings of the theory of space. In such a milieu, the role of the scientist-expert attained an unparalleled status, which was established on the basis of a novel 'myth' according to which only by mastering sufficient knowledge heaven on Earth could be achieved (Harari, 2017). The scientific method, therefore, endows humanity (in the role of the scientist-expert) with the will and power to exert control over nature, unravel its mysteries, and establish dominion over creation. This authentic project of conquest is made possible by reducing space to an object, and as such: knowable, measurable, and manipulable. The above-mentioned Euclidean spatiality, which centuries later would become the domain of action for planners (Friedmann, 1993), was hence reinvented and strengthened by modern science – which complemented the Euclidean geometry with Newtonian laws of physics.

Albeit only more recently with respect to the major professions, planning too has joined the ranks of the scientific-technological apparatus devoted to achieving the "technological paradise" (Severino, 2006). Two seminal figures in the field can be regarded as the initiators of the scientific approach to planning: Patrick Geddes and Ebenezer Howard. The contributions of Lewis Mumford, Raymond Unwin and Patrick Abercrombie, even though to a lesser extent, are also worthy of mention. At the turn of century, when planning was not yet institutionalised, the contributions of extraordinary figures such as Geddes and Howard helped shape the core of a disciplinary field strongly focused on social utopianism. The principles of urban planning were already firmly rooted in the positivist model. The notion of the survey (Geddes) and, subsequently, that of the garden city (Howard, Unwin, Abercrombie) were predicated on the ideology of social reformism, which emerged as a response to the squalor of the industrial city (Benevolo,1963).

Indeed, the utopian projects of the first decades of the 20th century played a decisive role in defining planning as an institutional activity. In this regard, Howard's model is exemplificative, as Luigi Mazza contends: "Howard's proposal can be taken as the anticipation of a technocratic planning approach which assumes that it possesses an optimal and progressive model of urban growth and applies it in an almost undifferentiated way throughout the territory. The assumption that the model is excellent and scientifically based is one of the reasons for justifying that it is the state that imposes it. [...] Howard's proposal [...] ends up providing the technical basis for general state intervention in planning and land uses" (Mazza, 2002: p. 27, translated in English by the author). According to this perspective, the first attempts to plan urban growth according to decentralisation models effectively contributed to the subsequent utilisation of planning as an institutional technology, that is, a form of social control pursued through the imposition of specific spatial models (Mazza, 2007, 2009).

However, in that initial phase, the planning techniques and tools that would have facilitated the success of those models were rudimentary, if not yet developed. Moreover, an adequate regulatory framework and the expertise capable of overseeing the complex implementation processes were lacking too. Accordingly, during the 19th and 20th centuries, practitioners engaged in urban planning were, de facto, 'non-experts'. Geddes was a sociologist,

Howard a parliamentary stenographer, and Mumford a historian (just to mention the three most influential). The combination of these two shortcomings – the utilisation of obsolete techniques and a paucity of expertise – profoundly conditioned the origins of the disciplinary field. This condition of precariousness, due to the absence of a shared disciplinary epistemology, decreased significantly in the following decades in conjunction with the institutionalisation process that took place, above all, in the United Kingdom and the United States.

It was in the 1950s that a significant transformation occurred, with planning being recognised as an autonomous discipline and academic field, thus marking the beginning of a period of consolidation (Davoudi and Pendlebury, 2009). Consequently, the role of the planners as 'experts' was considerably strengthened[8]. During this period, specialisation dominated the disciplinary debate, with the assumption that without specialisation, there is no disciplinary epistemology capable of guiding education and professional practices. Harvey Perloff's renowned formula, "A generalist with a specialty" (Perloff, 1956: p. 203), effectively summarise the paradigm that emerged in the mid-century. Such a model fosters the planner as a specialist who also possesses knowledge in a broader range of subjects. Founded upon the rational conception of planning, in continuity with the Enlightenment tradition (Friedmann, 1987; Sandercock, 1998; Allmendinger, 2002; Beauregard, 2020), that disciplinary paradigm also marks a shift with respect to the technocratic, positivistic planning culture of the early 20th century. Indeed, as remarked by Davoudi (2012) the latter is founded upon empiricism: "Positivism refers to an empiricist approach to scientific knowledge which starts from the senses and particulars and gradually rises up to the most general axioms. [...] For empiricists, knowledge is a matter of bottom-up experience (a posteriori)" (p. 3). The rational-comprehensive model, by contrast, is predicated on the conceptual and epistemological foundations of rationalist philosophy. The substantial difference between the two approaches lies in the fact that for the rationalists "knowledge is a matter of top-down underlying theories and laws (a priori)" (ibidem), while for the positivists "it rests on observation as the moment of the truth when hypotheses are tested against the facts of the world" (ibidem).

The transition from the positivist model to the rational-comprehensive one is of crucial significance: it constitutes an unprecedented reversal of perspective on the epistemological level. Prior to the advent of the rational-comprehensive model, technocratic planning was essentially conceived as a form of craft, with a strong association to architecture and engineering. This conception underwent a shift with the introduction of the abovementioned model. Consequently, planners are regarded as comprehensive experts whose actions draw upon a scientific theory of the discipline: "systems analysis and other rational-comprehensive approaches [...] imagine a specific type of planner: a technical expert who draws conclusions and develops advice based on the analysis of scientific evidence [...] Expert knowledge and scientific theories are thus central to how rational planning is to be done" (Beauregard, 2020: p. 23). In the context of the "Systems Revolution", a term coined by Peter Hall (1996), the culmination of Promethean planning is ultimately reached. This development, characterized by the utilisation of computational tools and modelling, enabled unprecedented capabilities, including the previously unattainable control over the development trajectories of urban growth:

The subject changed from a kind of craft, based on personal knowledge of a rudimentary collection of concepts about the city, into an apparently scientific activity, in which vast amounts of precise information were garnered and processed in such a way that the planner could devise very sensitive systems of guidance and control, the effects of which could be monitored and if necessary modified. More precisely, cities and regions were viewed as complex systems [...] while planning was seen as a continuous process of control and monitoring of these systems, derived from the then new science of cybernetics developed by Norbert Wiener (Hall, 1996: p. 327).

Back then, the increase in the predictive capabilities – of a true Promethean fashion – assumed a position of paramount significance. Indeed, the evolution of the scientific-technological apparatus, which began in the early

8 In this regard, Peter Hall observes that "the job of the planners was to make plans, to develop codes to enforce these plans, and then to enforce those codes; relevant planning knowledge was what was needed for that job; planning education existed to convey that knowledge together with the necessary design skills. […] planning was now institutionalized into comprehensive land-use planning" (Hall, 1996: p. 322).

1960s, has been accompanied by a progressive strengthening and extension of urban planners forecasting capabilities. Despite the initial enthusiasm expressed by some planning theorists, the practical application of the systems approach proved to be largely unsuccessful and was criticised accordingly (Goodman, 1972; Rittel and Webber, 1973; Wildavsky, 1973). Among the criticisms that have been raised, some originated from within the community of rational planners themselves, as observed by Beauregard (2020). Accordingly, notwithstanding their technological apparatus and scientific methods, "Planners are poor predictors of the future, never fully cognizant of the consequences that their plans will engender, and are often inattentive to unintended outcomes" (pp. 25-26).

5. Is a post-Promethean conception of planning possible?

The Promethean planning paradigm has endured and thrived to the present day. In the contemporary urban digital era, tools and applications which were formerly unimaginable now appear to have no limits when it comes to their ability to explain, predict, and eventually control urban phenomena. Such boost of scientisation is already re-setting urban planning research agenda globally. A whole new field of study has emerged under the name of 'urban science', which seeks to harness new technologies and enhanced computational power to deliver reliable, accurate scientific knowledge about cities (Karvonen et al., 2021). Differently from the previous attempts to establish a scientific basis for the discipline (Signoroni, 2024), urban science introduces a significant shift. Instead of being incorporated into planning disciplinary practices, it lays the foundations for a competing field aimed to eventually complement planning. Accordingly, the Promethean paradigm would extend its scope far beyond the boundaries of academic and professional planning. Indeed, a number of urban science promoters posit that they can inform scientifically planning decision-making. In contrast to conventional experts such as planners and architects, they claim to address urban challenges in a scientific manner. As specialists in the hard sciences, they provide public decision-makers with something that planners have attempted to provide, albeit unsuccessfully, namely 'bulletproof' scientific evidence.

Returning to the concept of 'atmosphere' (Pasqui, 2022a), as previously introduced, it can be observed that the scientisation of the discipline not only thickens this atmosphere but also dilates it. The applications of digital technology in the urban realm are expanding exponentially. Evidence of this phenomenon can be found in the growing availability of georeferenced datasets and the employment of advanced modelling software and sophisticated sensing technologies for the purpose of harvesting fine-grained data. While this atmosphere thickens and expands rapidly, it is critical for planners to introspect regarding the efficacy of their actions (Balducci, 1991) and the challenges posed by situations of radical uncertainty (Pasqui, 2022b). This introspection must encompass the acknowledgment of two fundamental human uncertainties: the cognitive and the historical (Morin, 2000).

In the current era, characterised by the proliferation of technology, there has been an inevitable rise in complexity (Ceruti, 2015). This phenomenon manifests not only in the magnitude of the prevailing challenges and issues but also in the constraints (and inherent dangers) of hyper-specialisation, which is the true legacy of the Promethean conception. If, as has been suggested, specialisation has underpinned the development of both the hard and social sciences, hyper-specialisation can be considered pernicious. According to Morin, "the disciplinary institution involves [...] a risk of hyper-specialisation of the researcher and a risk of 'cosification' of the studied object, of which we risk forgetting that it is extracted from the context or constructed. The object of the discipline will then be perceived as a self-sufficient thing: the bonds and solidarities of this object with other objects, treated by other disciplines, will be neglected, as will the bonds and solidarities with the universe of which the object is part" (Morin, 2000: p. 112, translated in English by the author). In this context, post-Promethean planning entails acknowledging the intricacies inherent in complex systems, while concurrently eschewing the pitfalls of hyper-specialisation. This represents a considerable challenge that planners are called to take up in that the initial step towards a post-Promethean conception necessarily involves a distancing from hyper-specialisation, intended as the key to virtual omniscience and hence the nucleus of Promethean planning. If it's true that without specialisation there is no technology, then without technology there is no omniscience. Nowadays, planners are confronted with constraints imposed by pervasive disciplinary rhetoric (Palermo, 2022; Signoroni, 2023a),

which is combined with the resurgence of a positivist epistemology of an empiricist nature – as advocated by proponents of urban science. Furthermore, contemporary planners are faced with the dilemma of whether to place their trust in technology – that they hardly acknowledge as an ideology (Habermas, 1972) – or to refuse it.

While it expresses an unwavering confidence in the efficacy of technoscientific rationality in steering the scientific-technological apparatus, thereby governing the transformation processes of the territory, the faith in technology frequently manifests as a scientistic disposition. Akin to a kind of "Mumbo Jumbo" (Scruton, 2011) which serves to address all inquiries and circumvents forms of dissent or conflict, this scientistic attitude fosters a pernicious depoliticisation of planning processes, which are removed from the logic of accountability and public scrutiny. Novel forms of data-driven planning appear to substantiate such hypothesis, notwithstanding prior failures – particularly about effectiveness, but also in terms of participation and inclusion. This drift appears to coincide with, and potentially exacerbate, the tangible risk of the academic expert becoming 'isolated' (Wachs, 2016; Signoroni, 2022, 2023b).

Conversely, it would be imprudent to rely on the opposing faith: the repudiation of any assertion of scientific belief, thus resulting in the pursuit of planning reduced to a mere discursive practice. To overcome the Promethean conception and avoid falling into its opposite, it is necessary to overcome faiths and acknowledge technology as a vision of the world that can be challenged. Because a post-Promethean conception of planning transcends both faith and rhetoric, a first attempt towards alternative theory-building scenarios should be to 'perforate the atmosphere' and thereby pave the way for a meta-disciplinary project that is open to practices of trespassing (Morin, 2000).

What planning needs from theorizing on place in times of global challenges

Abstract
The paper argues for stronger integration of the theoretical notion of place in planning against multiple current challenges. It revisits some established and novel conceptual readings of place and outlines its implications for urban planning, arguing for the theoretically informed use of the place notion as instrumental in planning better cities for people. With its practical focus on shaping physical spaces in cities, urban planning delivers applied results and contributes empiricallydriven insights on the physical setting of cities. Notion of place, on the other hand, allows formalizing diverse social, subjective and intersubjective relations that shape our spatial experience in cities in no less impactful ways than its physical setting. The paper argues that conceptual potential of the term place for urban planning lies in bridging the physical realities of urban spaces with the human dimension of spatial experience at the level of middle range theories connecting empirical application with conceptual premises.

Key words: Urban planning, urban space, place, place-making, human-centered design

Introduction

Cities have undergone dramatic transformations since 'the world's first' city of C¸atalh¨oy¨uk in Konya, T¨urkiye, marked the transition from rural to a new urban type of settlement. Planning strives to respond to constant urban transformations. As any other institutionalized domain, for decades planning faces challenges of institutional inertia, path dependency, and rigidness of established paradigms (Blotevogel et al. 2014; Albrechts 2010) among others, that hinder the responsive potential of planning. At the same time, planning itself acts as a major agent of urban transformation, bringing novel challenges of growth and development that uproot established ways of living. In the age of planetary crisis and accelerating global changes, the responsibility of planning is not only in providing adequate response by leading transformations but in ensuring continuity and upholding a human-centric approach in tackling the above (Good et al. 2017).

Place-based measures are an often-evoked response to the above conditions across many facets of planning. Yet, place is far from being an established conceptual term across planning landscape. While receiving some dedicated theoretical attention on its own (), the most common way for place to feature in planning remains at applied level in an ad hoc or common sense manner without underlying conceptual substantiation (Ellery et al. 2021; Strydom et al. 2018).

Meanwhile the term 'place' is a theoretically loaded notion, albeit no overarching theory of place exists (Cresswell 2015). Place is theorized across a heterogeneous landscape of spatial and social disciplines, spanning from geography, environmental psychology, urban and social studies, humanities, among others. Early systematic theorizing on place in spatial disciplines is attributed to humanistic geography as a critique of the overtly abstract notion of space that dominated the spatial disciplines in the 1960s (Tuan 1979; Relph 1976). Since then, a broad notion of place as space imbued with meaning enters common use. Along with it, the notion of place is being interpreted in many other ways within phenomenological, non-representational, feminist, critical and socio-constructivist veins, relational, post-human philosophies, psychological, cognitive and behavioral models, among many others.

The common conceptual feature to all of the above is a premise underlying a humanistic geographical approach: place changes the mode of our engagement with space. Depending on an adopted theoretical approach, sources, agents, impact and effects of such change can be conceptualized and grasped, entailing different practical

implications and methods to tackle it. Relational readings of place suggest that cities cannot be adequately governed without considering dynamic flows of people, resources and information that all play out on a local scale (Massey 2005). Feminist perspectives on place demonstrate how spatial experience differs along gender lines (Dyck 2005). Phenomenological approach brings forward an embodied and perceived spatialities which are closer to human experience of cities than abstract plans (Seamon 2013).Emergent novel approaches to place building on advances in GIS, data science, and other areas (Wagner et al. 2020; Rossetti et al. 2019; Mocnik 2023) conceptualize the mediating impact of digitalization and pervasive impact of geospatial technologies on human spatial experience.

Being so conceptually versatile, place can equip planners with a fertile framework to understand better a human perspective on space in the city in a multifaceted way. Planning better cities for people contains an underlying but rarely articulated question as to how do we engage with space shaped by and intervened to with planning means:

'The translation of social purposes into space then presupposes that something is known about how patterns of living and working can be affected, for good or ill, by the physical and spatial forms imposed on them. In fact, beyond common-sense and accumulated experience, little is known. p.217 Hillier (Hillier 2008).

Articulating this questioning is pivotal in theorizing on place. Spatial and urban planning as 'knowledge-centered epistemic practices' (Alexander 2016) which link knowledge to organized action towards spatial organization of social relations (Lake 2017), are concerned with theoretically grounded knowledge in no lesser extent than with an empirical realm of action. The present paper argues that theorizing on place falls under both these concerns.

Theoretical body of planning is heterogeneous and subject to long-standing academic debate (Allmendinger 2017; Alexander 2016). Difficulties to determining clear boundaries between theoretical, empirical and applied domains, as well as extensive borrowing from many other disciplines and subjects are recognized as characteristic to planning discourse (Allmendinger 2017). In such state there is a recognition and call for theoretical efforts across different levels, from fundamental theorizing on linking spatial forms to societal processes (L¨ow 2018), to stronger conceptual support for planning actions, and empirical evidence-based planning. While fundamental theories comparable in ambition and grasp to social theory of space (Hillier 2002) might seem as far reaching and distant prospects requiring solid theoretical advancements, the place theory can fulfill the need for middle-range (design-level) theories (Marshall 2012; Hillier and Netto 2002; Cuthbert 2007), bridging conceptual underpinnings with empirical and applied implications at the level of specialized planning domains (such as spatial and urban planning referred to in the present paper).

In what follows, the paper will outline arguments towards more systematic purposeful theorizing on place as a socio-spatial notion from the perspective of spatial and urban planning in its concern of spatial organization of urban space and its physical settings in pursuit of social goals. (In this light, all references to planning in the present paper refer to spatial planning and urban planning insofar as they are preoccupied with urban space and planning cities). First, the paper will sketch out instances of how place features in planning discourse and practice. Then, the paper will proceed with outlining implications for three broad approaches to place in its humanistic, relational, and phenomenological readings, arguing for the latter as instrumental in linking theoretically grounded human perspective on urban settings for planning.

Place of place in planning

While advocating for stronger integration of theoretically grounded notion of place in planning, one faces challenge of theoretical ambiguity of the very notion of place. The elusive nature of place evading a clear definition is a commonplace statement in much of place literature: "Place is a human relation. There is no set of immanent ontological features adhering to a given site that would allow us to define it as a place" (Prieto 2012, p.13). However, complexity of place definition does not have to imply that it is an indeterminate concept bound to ad hoc readings. Rather, it attests that place lends itself to be conceptualized through various approaches leading

towards sometimes remarkably different directions.

In spatial disciplines the starting point for theorizing on place often becomes space. This does not add certainty to understanding of place. Instead, it creates a conceptual state prone for terminological ambiguity, where the terms space and place go hand in hand, as one is being defined through the other, or what the other is not. Widely quoted metaphorical phrase of Yi-Fu Tuan "if we think of space as that which allows movement, then place is pause" (Tuan 1979) illustrates such characteristic vagueness and interlinked thinking about the two notions. Already heterogeneous discourse around geographical space draws the notion of place into self-referential circle: space as fundamental stuff of geography is rarely explicitly talked about in spatial disciplines (Thrift 2003), while place is being commonly defined as 'space imbued with meaning' (Cresswell 2015).

Similar situation appears with usage of the terms 'space' and 'place' in planning (Davoudi and Strange 2009). Fundamental theorizing on the nature of space is not absent, but often carried on higher theoretical levels across other disciplines and discourses (Kühne and Berr 2022), rarely featuring as an explicit issue that requires own planning disciplinary reflection, or a proper conceptual explication from planning practitioners in planning handbooks. It is not uncommon that a table of content from a handbook on urban planning does not feature a chapter or a section on what is urban space that we ought to plan. Instead, the focus could be given to 'making plans', not ordering space, as a main concern of urban planners, as for example (Crane and Weber 2015). Such focus is illustrative of the conceptual position of the two notions in literature which supports planning practice: space as object of intervention remains obscured or hidden within other agendas.

In the context of urban planning and design, both terms acquire adjectives and attached to them wider connotations and definitions. It is common to refer to 'urban space' as space with particular geometrical and aesthetic properties that could only be discerned against the built form (Krier and Rowe 1979). In addition, other terms, such as 'open space', 'public space', 'place', 'public place' and more, are also used, sometimes interchangeably, and sometimes to denote different notions (Abusaada and Elshater 2021). Accepting such varied use, the term 'place' still resonates broadly with the humanistic geographical understanding of place through such distinguishing factors as knowledge, value and quality, lifestyles, experiences and meanings, identity and character, and atmospheres and sense of place (ibid).

In such a state, use of both terms 'place' and 'space' in planning becomes a separate subject of investigation (Davoudi and Strange 2009; Madanipour and Hull 2017; Strydom et al. 2018). Keeping in mind the wider debate on space as important overarching context, the remainder of the paper will refer to uses of the term 'place' in spatial and urban planning discourse on three levels - one of overarching theory, one of middle range theories and conceptual frameworks, and one of applied interventions and empirically driven planning practice. For each level, the paper will suggest concrete contributions that place theory can bring to planning.

On humanistic reading of place in planning

On a higher theoretical level scholars both from within geography (Relph 2015; Good et al. 2017; Bull 2008) and planning itself (Good et al. 2017; Bull 2008) evoke the notion of place towards a humanistic approach to planning. The notion of place serves there a similar critical role as in its humanistic geographical origins against the prevalent current of a positivist turn in geography and spatial disciplines, planning including. A humanistic approach re-orients planning towards a situated perspective onto the lived world as it appears to us in our experience (Lake 2017). Place denotes such turn from abstract objectified space to experiential dimension of spatiality.

Major hindrances appear on the way of such re-orientation. Arguing for fundamental uprooting of primacy of space in favor of place requires ample theoretical efforts to re-work the very way of thinking about the focus and subject of planning, from fundamental underlying premises all the way down to empirical approaches. Along these lines, the above efforts meet limitations and critiques inherent to any attempt at integrating a qualitative paradigm to human-environment relations. These include focus on individual and subjective accounts over patterns and generalizable knowledge in a natural science fashion (Pocock 1983), and incompatibility with quantita-

tive methods and rapidly advancing GIScience (Leszczynski 2009), where planning tend to lean.

Turning to theoretically grounded notion on place, however, is not meant to bring over-individualization of diverse lived experiences, nor to channel planners' attention exclusively onto subjective perceptions of urban milieu by means of qualitative inquiry. On the contrary, place can be a fruitful notion to formalize experiential perspective on space by quantitative means in a way highly relevant and instrumental for planning. Elements of human perception (as in pioneering visibility analysis (Benedikt 1979)), cognition (Penn 2003), and even aesthetic preferences (D'Acci 2019) are already being incorporated in quantitative models of space. Correspondences are drawn between such measures and traditionally qualitative inquiries as in for ex. in phenomenological tradition of place and environmental psychology (Marcus 2018; Seamon 2007, 2013).

Theorizing on place from platial perspective advanced by place-based GIS can contribute to the above direction (the term `platial' is used as the place-based counterpart to the space-based adjective `spatial' (Westerholt et al. 2018)). Place-based GIS works towards operational modeling and representation of places aimed at grasping qualitative characteristics of meaningful spatial units converted into quantifiable variables and accessed through amply available georeferenced data (Tang and Painho 2021).

Among other concerns, the above efforts deal with division of space in the city, which is one of ever-present planning concerns, too. This question underlies not only methodological issues of modifiable areal unit problem, but in many instances can severely affect planning decisions and actions. Administrative census, postal codes, urban structural units, clusters of urban form typologies derived from geometrical plans all have their efficient application for varied planning purposes. However, oftentimes such approaches do not grasp how people organize and divide their space. It is recognized that we differentiate and discriminate urban space: to us it appears in the form of islands of places along undifferentiated space (Zeiher 2003). Conceptual and methodological efforts on spatial footprints of places (Westerholt 2019, 2025), linking geometrical composition of places with functions (Papadakis et al. 2020), grasping fuzzy place boundaries (Gao et al. 2013; Davies 2020) to formalize it for spatial analysis can offer more efficient ways than costly participatory mapping neighborhoods techniques and similar qualitative inquiries into perceived division of space in the city.

On relational reading of place in planning

Place appears in many instances at the level of conceptual frameworks applicable to concrete domains, relation, and areas of planning actions to address manifold crises, from climate change, economic depression, to social fragmentation and migration. Place-based policies to promote local solutions (Barca et al. 2012), place attachment in public participation (Manzo and Perkins 2006), sense of place to foster stewardship of locales (Chapin III and Knapp 2015), place-making initiatives to improve public spaces (Palermo and Ponzini 2014) are among such instances. Place receives dedicated theoretical attention and being reflected upon in such role (Castello 2016; Madanipour and Hull 2017).

Prominent in the above instances are relational interpretations of place. Relational take on space calls for shifting focus from a static view onto dynamic relations among agents, seeing place as a site of complex emergent interrelations across scales in the context of globalization (Massey 2005). Such perspective allows incorporating multi-network actors, complex sets of relations, and non-linear dynamics playing out in spatial dimension, among many others (Graham and Healey 1999; Madanipour and Hull 2017). In this, relational conceptions of space and place support planning practice in setting up frameworks of actions and relations for multiple agents and actors on access to and distribution of material resources (Robertson 2018).

Relational approaches to place speak to a widely theorized tradition of seeing space as socially produced (Lefebvre 2017). This tradition approaches space and place via social praxis at different scales. Critical socio-constructivist school (Lefebvre 2017; Harvey 2012) argues against the objectified and reified totalizing order of space, calling for seeing space as a product of socio-economic relations (i.e. global dynamics of capital (Harvey 2012)). Non-representational approach (Thrift 2008; Anderson 2016) propounds a performative reading of space and

place as being constituted and reconstituted by human actions, or individual tactics of moving through and ordering space in everyday life (De Certeau 1985).

Reading space and place as products of individual human and collective social relations equips us with conceptual lenses to investigate cities as socially produced dynamic entities at higher theoretical and conceptual levels. As such, the above theorizing on place is often not directly applicable to planning and design actions which shape and intervene into cities as built physical entities. High level of abstraction in much of such theorizing, and at times almost exclusive focus on the social risk neglecting "everyday physicality of the spaces in which human beings live". (Hillier 2008, p. 218). Instead of 'humanizing space', place risks abstracting its social meaning from its physical settings.

Meanwhile, a holistic notion of place can allow us to argue that 'meanings of place are not simply attached to places; they are already part of it.' (Muminovic 2015). Place locales, that is, physical settings where everyday-life activities take place, including visible and tangible aspects of a place such as buildings, streets, parks, etc., comprise a constituent element to place, not its mere passive background. Interpretations of place as assemblages ((Latour 2005)) works towards the shift from immaterial relations to material settings (Muminovic 2015; Dovey 2020). The latter are attributed with agency over not only receiving and hosting, but producing place meanings.

Even closer attention to the agency of physical settings on shaping place experience and its meaning is brought by the actor-network theory for architecture and design domains (relevant for the present inquiry on the level of 'urban architecture' in how it shapes our spatial experience on urban scale) (Yaneva 2009, 2022). This approach brings us one step closer to the applied domain of planning where it delivers actual planning solutions and design choices that form place settings in the most immediate and straightforward way of physical shape of locales.

Actor-network approach not only introduces non-human actors to the set of proactive agents shaping and co-creating our lived experiences (Dincer 2020). The approach re-configures the very way of seeing nonhuman material actors, from static material objects to materialized but constantly re-negotiated and re-constituted materialities that themselves are evolving products of socio-material dynamics (Yaneva 2009). Theorizing on place along this direction can not only bring a human perspective on space, but on the entirety of is material settings:

It is not only the architects, his or her clients, de Certeau's pedestrians, Benjamin's flaneurs that do not live in Euclidian space: it is also the buildings themselves! If there is an injustice in "materializing" human embodied experience, there is an even greater injustice in reducing matter to what can be drawn. (Latour and Yaneva 2017) p. 105

Alongside the argument for bringing place for humanizing space from the hold of geometric abstraction place can also 'humanize' built form of the city as shaped by planning and lived by us. Of course, urban space can only be discerned against urban form, as the latter configures the former. In this way, distinction between material settings and urban space could only be drawn to certain extent by formal or conceptual means. Yet, oftentimes this distinction pervasively underlines much of inquiry and theorizing on space and place. Engaging with deeper theorizing on place in a holistic way allows us addressing place meaning, spatial experience and place settings under one conceptual term.

Rounding up the presented argument, in the last part the paper will outline such holistic take on place from a phenomenological perspective as instrumental in humanizing the city for planners from the perspective of place-making as engaged with the city in the most direct empirical way.

On phenomenological reading of place in planning

One of the most noticeable use of the term 'place' in planning appears in place-making. Place-making is a very broad umbrella term that can refer to bottom-up initiatives targeting small improvements at local scale, to top-

down city policies and actions aimed at redevelopment of entire parts of the city. Common for such efforts, regardless of their scale or origins, is their aim at improving quality of life in cities through converting urban space to lively and well-functioning urban places (Ellery et al. 2021).

Place-making engages with the city primarily at the empirical level of practical interventions, policies, projects, and case studies. In-depth theorizing on underlying conceptual understanding of the very notion of place is not common in the above (Strydom et al. 2018). Underlying understandings of place are diverse. Place-making approach draws upon humanistic geographical origins of place in conceiving meaningful engagement with space as premises for creation of places, recognizing place as first and foremost a social and human phenomenon (Strydom et al.2018). Community-bound participatory place-making appears to lean towards relational understanding of place, as it considers relations among actors, stakeholders and social ties as constituents of places (Cilliers and Timmermans 2014). In promoting social events and emphasizing participation as a constant process of community building it taps into performative take on place. Finally, much of place-making efforts are realized via design and direct interventions and changes to physical appearance of urban spaces (Palermo and Ponzini 2014).

At times, place-making debates can appear to refer to a false dichotomy: what is primary, promoting community or delivering good design for places? In practice, however, the question addressed by place-making concerns how the two come together to create places. This demands a holistic concept of place to guide the practice.

Phenomenological reading of place offers a framework towards such holistic reading, as it attempts at discarding a dichotomous understanding of human-environment relations, conceptualizing the two in interconnected instead of juxtaposed way (Locke and McCann 2016; Seamon 2010). The phenomenological school approaches place as a specific category of direct human experience, intrinsic and even formative for human subjectivity. For this reason, it is often viewed as focused on human, subjective domains of place. Place appears deterritorialized and delocalized from its particular site, because the locus of phenomenological inquiry is centered on an inner subjective standpoint.

However, an approach to place grounded in the phenomenological account of human experience in fact opens up a way to integrate material settings of place into a holistic view of body-subjects of perceptual experience (Merleau-Ponty 2012). Physical settings of place in such a view are not abstracted from the perceiving subject into a neutral backdrop, but instead, all merge into a 'perceptual field' (Merleau-Ponty 2012), where subjective perception and objective external world are integral to each other.

Such premises bring important implications for place-making approach. It allows us interpreting an authentic place-making process as "an operation of synthesis' where goods and people are amalgamated to spaces by way of processes of perception, imagination, and memory" (Löw 2016, p.135) from a phenomenological perspective. Such process of synthesis constitutes no less important part of place-making along with actual arrangements of physical objects in space (Löw 2016). We endow a certain arrangement of things and settings in space with unity and meaning attributed to it, conceiving it as a place. Phenomenological inquiry into processes of perception, imagination and memory that synthesize place out of available to us physical settings grasps the lived city in its spatial and physical configuration as experienced by us in a holistic way. In it, the approach is doing justice for physical, material and tangible aspects of places as it brings them from the realm of abstract objective physical city to the actual lived city in the same way as place is meant to bring lived spatiality from the abstract geometrical plane.

Place is conceptualized prominently within the phenomenological approach (Buttimer and Seamon 2015; Relph 2014; Dovey 2009). The phenomenological tradition of place finds a close affinity with a humanistic geographical stance, as it draws into the focus human, subjective, affective, and perceptual dimensions of place. The phenomenological approach also contributes to capturing the embodied aspect of place as expressed in our bodily actions, which create and recreate places in constant flux (as in David Seamon (2015) notion of place-ballet). This

connects the phenomenological reading of place with the non-representational and performative interpretations.

The phenomenological approach has been criticized for its essentialist take on place, while its methods of radical empiricism and interpretative analysis have been associated with compromised objectivity and non-retrievability of results (Murray and Holmes 2014). These, however, do not discard the value of phenomenological approach as argued above, but call for theoretical and methodological efforts towards rigorous and instrumental apparatus. The phenomenological tradition evolves and finds novel interpretations ((Talebian and Uraz 2018)), and not so obvious affinities (such as the above-mentioned parallels with space syntax methods (Seamon 2007, 1994)). In this sense, the phenomenological account of place bears rich potential which translates and feeds into novel platial approaches, reaffirming its potential usefulness on urban grounds (Aravot 2002).

Conclusions

Theoretical, methodological and practical advancements of planning compete against ever increasing complexity of challenges which planning faces. Accelerated crisis dynamics at global and local scales acquire such recurring character that state of multiple crises becomes a new normal of planning as argued by some (Martin et al. 2022). In such a state, calls for more theorizing in planning should not divert planning efforts from pressing agenda, but amplify and support it. Present call for theorizing on place is made towards the above goal.

The paper outlined how the notion of place in humanistic geographical, relational, and phenomenological interpretations appears in planning at higher theoretical, conceptual and empirical levels, amplifying each use by suggesting potential contributions and synergies that are coming from theorizing on place.

The value of place in its humanistic geographical reading is recognized in calls for humanistic planning and planning for people. The paper argued that in addition to that, a humanistic geographical notion of place can offer a robust theoretical framework for operational and instrumental inquiries into human perspective on the city built on advances of quantitative, geo-referenced data and GIS-driven research.

Relational notions of place support planning in organizing and navigating complex relations and actions of multiple agents towards spatial organization of socio-economic relations. In addition to dynamic interactive understanding of planning outcomes as socially produced, the relational approach to space and place opens up a way to introduce novel agents which contribute to production of spatial relation in different ways. In particular, material aspects of our spatial experience become recognized, conceptualized and grasped by planning. Place locales which denote physical settings of places are active contributors, not passive holders of meaning in our engagement with spaces in urban context.

Phenomenological readings of place match empirical place-making efforts concerned with perceived aspects of physical urban features (as in perceived qualities of urban design for ex.). In addition to supporting the above inquiries, further theorizing along phenomenological lines allows integrating all material settings of places as perceived into the construct of spatial experience of the city under the notion of place grounded in a holistic view of human perception and environment. Novel methodological affinities allow phenomenological framework to support models accounting for spatial cognition, perception, psychological and emotional response to urban settings.

Adding the term place to planning vocabulary is not meant to inundate it with yet another vague label of indeterminate use. On the contrary, place as a key word can bring under its conceptual umbrella a wide range of theoretical issues, empirical studies and applied interventions since long carried out by planners towards balanced socio-ecological planning for sustainable cities for people.

Theoretical body of planning is heterogeneous and subject to long-standing academic debate (Allmendinger 2017; Alexander 2016). Difficulties to determining clear boundaries between theoretical, empirical and applied

domains, as well as extensive borrowing from many other disciplines and subjects are recognized as characteristic to planning discourse (Allmendinger 2017). In such state there is a recognition and call for theoretical efforts across different levels, from fundamental theorizing on linking spatial forms to societal processes (Löw 2018), to stronger conceptual support for planning actions, and empirical evidence-based planning. While fundamental theories comparable in ambition and grasp to social theory of space (Hillier 2002) might seem as far reaching and distant prospects requiring solid theoretical advancements, the place theory can fulfil the need for middle-range (design-level) theories (Marshall 2012; Hillier and Netto 2002; Cuthbert 2007), bridging conceptual underpinnings with empirical and applied implications at the level of specialized planning domains (such as spatial and urban planning referred to in the present paper).

Abstract
This paper argues that rental housing is globally growing as a means to access housing in the face of multiple crises and as a financialized real estate frontier of capital accumulation. In Latin America and Brazil, where the homeownership model historically prevailed, households are increasingly renting, the real estate market is incorporating new formats (build-to-rent, multifamily), and professional rental management is spreading in formal and informal markets.

Through a panorama of global and Brazilian cases gathered from a Rental Housing Policies Seminar (2024), we identified different modalities in a wide scope of rental policies worldwide. The paper presents the Brazilian cases analytically organized in three State modulations, understood as incremental processes in which contradictions and variations can coexist: Emergency, Provider and Conceding State.

Key words: Rental housing; housing policy; affordable housing; Latin America; Brazil

Different rental housing policies models and the ongoing difficulty of overcoming the housing crisis

1. The prevailing and increasing importance of rental housing

1.1. Housing as an asset class and rental housing in the global context of financialisation 2.0

Rental housing is on the rise worldwide as multiple crises enhance the role of houses as financial assets, traded not only in formal markets, but also in the informal markets of popular territories.

The financialisation of housing has been widely discussed in its european and north american variations (Fernandez and Aalbers, 2016). In the context of a "rentier capitalism" (Christophers, 2020), houses are properties that as such allow for rent extraction: assets, with projected inflows and expectations of increasing its market value.

More recent literature points out that rental housing is occupying a central role in the expansion of the financial geography of the real estate market (Fields and Ufer, 2016; Fields, 2018). Wijburg et al. (2018) state that there has been a shift from what was deemed financialisation 1.0 - which involved reforms that introduced state subsidised rental housing as assets for "pure speculation" in global investment markets (Idem, p. 1) - to financialisation 2.0, characterised by "long-term investment strategies [...]used by REITs and listed funds in order to release housing into the privatised mainstream of capital accumulation" (Ibidem). The short-term rationale of "buying low and selling high" is not overridden, but relocated to the stock market where the shares of the funds are negotiated (Ibidem).

In the same direction, Aalbers (2019) argues that
"The financialization of real estate is not limited to the rise in household debt, mortgage securitization and international investment in office markets, but increasingly also affects rental housing: private equity, hedge funds and REITs buy up large portfolios of social and private rented housing, while housing associations use derivatives and other financial instruments" (idem, p. 1).

1.2. Rental housing growth in Latin America and Brazil as perceived by its agents

All these research highlights the importance of rental housing in the global landscape of the financialised real estate market. In Latin America, though, this process evolves in a diverse context and assumes new forms. In this region and particularly in Brazil, rental housing is currently on the rise, contradicting its history of social housing policies heavily anchored in the model of home ownership - that fomented the ideal of the casa própria[1] and reinforced the rule of private property (Bonduki, 1998; Cardoso, 2013; Maricato, 2015; Rolnik, 2019). Nowadays, rental housing represents a new frontier for capital accumulation in Latin America (Guerreiro et al., 2022; Marín-Toro, 2024).

The homeownership model has been showing signs of exhaustion over the last years, bringing to question its reign as the exclusive solution for social housing in the region. Centered on the production of new houses destined to subsidised sales, this model is insufficient in the response of a wider set of housing needs, such as that for well located housing - where the land prices are higher - and the inability to validate a steady income, as a great proportion of the brazilian workforce is informally occupied[2]. Even for families that manage to access housing loans, to keep up with the payments is a considerable challenge, along with that of paying the bills and fees that come with the formalization of housing (i.e. water, electricity, taxes - costs that don't necessarily exist in informal living). This picture results in widespread indebtedness and, consequently, in threats and evictions. The recent experience of mass production of social housing prioritised areas of urban expansion, resulting in poorly located dwellings, with no access to any urban facilities and services such as public transport, jobs, education and health care institutions and leisure. In the homeownership paradigm, well located housing becomes inaccessible for the higher land cost must be met by the buyer.

Alternatively to the casa própria model, rental housing is on the rise based on the growing understanding of houses both as dwellings and investment opportunities. This is a variegated process that involves diverse agents and strategies.

Households

In 2022, 20,9% of the Brazilian population, equivalent to 42,2 million people, lived in rental houses, the largest rate since 1980. In 2000, the rate was that of 12,3%, and in 2010, 16,4% (Censos IBGE). Along with this evolution, the num-

1 Casa própria literally means 'owned house', or 'house of my own', but is also commonly used as a metonymy to refer to the ideology of homeownership. The largest housing provision program of Brazil's history, launched in 2009, is named in regards to such ideology: Minha Casa, Minha Vida (My House, My Life).

2 According to the PNAD Contínua research, conducted by the Instituto Brasileiro de Geografia e Estatística (IBGE), the informality rate (proportion of informal workers in the total occupied workforce) is of 37,9% in may 2025. Available at: <https://agenciadenoticias.ibge.gov.br/agencia-noticias/2012-agencia-de-noticias/noticias/43503-no-trimestre-encerrado-em-abril-taxa-de-desocupacao-fica-estavel-e-emprego-com-carteira-bate-recorde> (Accessed: 29 May 2025).

ber of rental houses in Latin America grew 15% between 2000 and 2022 (Cepal Stat - Nações Unidas, 2023 apud Marín Toro, 2024)[3].

The increase in the supply of rental houses does not coincide with a trend of increased accessibility. The excessive burden on urban rent is currently the largest and fastest growing component of the Brazilian housing deficit. In 2022, it represented 52,2% of the total deficit of 6,2 million dwellings (Fundação João Pinheiro, 2024). It is worth noting that households headed by women account for 62% of the Brazilian deficit (3,89 million domiciles) and that non-white headed households are the majority in four of the five regions of the country (the exception is the south, the only region with a white majority[4]).

Possible explanations for this trajectory pose that rent is a flexible tool suited to the instabilities of income and employment. Tenants can more easily move to different neighbourhoods and cities according to work opportunities, which is enhanced by the possibility of short stays or monthly contracts. The purchase of a home, on the other hand, is subject to the fluctuations of inflation and interest rates that determine the cost of housing loans. In that regard, some social groups have structural difficulties in accessing credit for home ownership, such as youths, elders and vulnerable populations.

Real estate market

Rental housing has always been a part of the Brazilian real estate market, even a predominant one, as shown in data from big cities such as São Paulo in the beginning of the 20th century. In this particular case, both entrepreneurs and families explored urban rent as a business and as income supplement or retirement income.

Currently, in the financialised phase of the real estate market, new rental housing models are structuring a new frontier for capital accumulation (Guerreiro et al., 2022; Rolnik et al., 2024) based on the securitisation of inflows captured through rent in certain periods of time. Rental housing ascends as a lucrative investment field motivating new housing products that stem from its financial asset status. Some of the main trends are:

(i) production of new rental housing units financed by international funds and combined with the assetization of rent (debentures and securitization); also with support from government actors through urban and fiscal incentives (as in the case of retrofit incentives in São Paulo) for build-to-rent (Vannuchi, 2020) or multifamily projects found in Santiago do Chile, São Paulo and Mexico City (Marín-Toro, 2024).

(ii) professional management of rent and platformization (depersonified management with increased efficiency in collecting and evicting);

(iii) growth in the temporary rent market, characterised by relatively more expensive rent prices, drawing properties that used to be available for traditional rental contracts (competition between short/medium stay and long stay markets);

(iv) articulation of home ownership and rental policies in the form of leasing, shared ownership and buy to let (Aalbers et al., 2021) models, resulting in individual investors taking public funding to buy property as investment. Moreover, in low liquidity markets, rent is an advantageous destination for the stock of new housing units that haven't found solvable demand at first.

3 The percentual variation of rented houses in selected Latin American countries was: 70% in Chile, 42% in the Dominican Republic, 41% in Colombia, 36% in Brazil and Argentina, 34% in Costa Rica, 21% in Peru and Uruguai, 17% in Mexico, 15% in El Salvador, 9% in Guatemala, 6% in Paraguay, 5% in Panama, 3% in Honduras. Degrowth was only identified in Bolivia and Ecuador (Cepal Stat - Nações Unidas, 2023 apud Marín Toro, 2024).

4 According to the 2022 IBGE census, available at <https://www.ibge.gov.br/estatisticas/sociais/saude/22827-censo-demografico-2022.html>

(v) funding structures involving housing impact bonds[5] based on rent securitization. Such structures are still incipient and supplementary to the public and semi-public fundings (FGTS[6] and SBPE[7]), that are, nonetheless, showing signs of exhaustion. This trend is articulated to the ESG (Environmental, Social and Governance) agenda and retrofit incentive policies in city-centres in Rio de Janeiro, São Paulo, Mexico City (Ciudad de México, 2021) and Buenos Aires (Buenos Aires, 2021).

This "new frontier for capital accumulation" is also set upon markets regardless of its legal formality (Guerreiro et al., 2022; Rolnik et al., 2024) as we watch its expansion through the production of small rental buildings (predinhos) in popular territories (Guerreiro et al., 2022).

Government

The public dimension of housing can be perceived in the State's leading role in different fronts: the building of a financial system for housing production and consumption, the conception of housing both as a public interest theme and an asset class, and the construction of ideological narratives - that are currently shifting from the casa própria paradigm towards more contemporary ways of living compatible with rental housing models.

Governments have recently been studying and testing housing policies centered around rent and, in doing so, are mobilizing different 'State modulations'. Rental policies have never been central in Latin America and Brazil, where housing production policies (for homeownership) had a primary role in economic development plans. Social rent was never really integrated into any kind of housing policy system, constituting at best isolated policies or private market initiatives. Using social politics terms (Geels and Kemp, 2012), home ownership is the historically "dominant regime", and rent is a "niche" undergoing an evolution towards a "subaltern regime" status within the dominant regime that structures the housing policy system[8].

2. Different modalities and arrangements of rental housing policies

In the context of growing importance of rental housing worldwide, it has been possible to put forth a synthetical outlook at modalities and arrangements of rental housing policies based on the review of the international literature and the organisation of an International Seminar on the theme (D'Almeida and Santoro, 2024), as follows:

Rent control

Rent control refers to the regulation of rental relations including rental increase and pricing caps attached or not to the access of public subsidies. Rental control programmes were mainly found in European countries during the post-Second World War period. They responded to a high demand and low supply housing market that demanded State action in order to make houses accessible both by habilitating construction and controlling prices (Harloe, 1995; Kenpen et al., 2005; Ronald, 2013).

In Brazil, there was an unsuccessful experience of rent control implementation with the Lei do Inquilinato (Tenants Law) in 1942. This pioneer measure, not repeated since, consisted of a rent freeze and, although short-lived,

5 Based on the concept of social impact investment and Social Impact Bonds (SIBs), Chiavone (2022) identified those specifically directed to housing issues, deemed "housing impact investment".

6 Fundo de Garantia por Tempo de Serviço (FGTS) is the compulsory savings fund for the brazilian formally employed workers, managed by the public bank Caixa Econômica Federal (CEF). The aforementioned Minha Casa, Minha Vida federal housing program is heavily reliant of this fund, for example.

7 Sistema Brasileiro de Poupança e Empréstimo (SBPE) is the banking system that nationally gathers funds from savings accounts specifically for funding the real estate credit market for the middle classes.

8 The notion of "subaltern/dominant regimes" is borrowed from Gemp and Keels' (2012) approach to mobility transitions. They argue that "there is not just one regime (auto-mobility) but also other regimes (e.g., train, tram, bus, cycling)" and that "It makes no sense to call these transport modes 'niches' in the sense of being radically new and precarious innovations. But these transport modes capture only a small percentage of total mobility (in terms of passenger kilometers) and in that sense occupy small market niches. We propose to call these transport modes subaltern regimes in contrast to the dominant auto-mobility regime" (Gemp and Keels, 2012, p. 56).

had as a main outcome - according to some authors - an stimulus to the growth of favelas and the expansion of the casa própria model by taking down the (no longer lucrative) supply of rental houses (Bonduki, 1998).

Rental assistance[9]
Rental assistance is a financial monthly aid transferred unconditionally to the beneficiaries. Although its intended use, as per its name, is meant for accessing housing, this kind of programme does not attach or supervise the destination of the allowance, resulting that it can be used freely for other purposes. When used for rent, though, it comprises available dispersed housing units, unchecked by the housing authorities and not listed in any housing programme. For that, it can be interpreted as an income-transfer policy, rather than a proper housing policy. Rental assistance is granted to people and households in many contexts, but mostly in emergency scenarios: victims of housing evictions driven by public works or assumption of risk, victims of disasters, women victims of domestic violence, people experiencing homelessness, amongst others.

This is the most disseminated modality of rental policy in Brazil, approximately 55,2% of all the cities offered a similar programme in 2020 (Munic IBGE). From different regions of the country, they are: Florianópolis, Goiânia, Natal, Niterói, Petrópolis, Rio de Janeiro, Sobral, Brumadinho, Belo Horizonte, Campinas, Juiz de Fora, Diadema, Mauá, Ribeirão Pires, Rio Grande da Serra, Santo André, São Bernardo do Campo, São Caetano do Sul and São Paulo (D'Almeida et al., 2024).

Voucher
A voucher is a financial aid attached to the rental of a private house. The properties available are usually registered as part of a private rental housing stock selected by the housing authorities according to some criteria - therefore committed to a housing programme - and with some form of involvement of state actors in the formalization of the rental contracts.

This type of rental policy is often combined with programmes of social rent in privately owned housing stocks and was first implemented in Europe and the United States in the second half of the 20th century, simultaneously to the dismantling of the public housing stocks (Harloe, 1995; Kenpen et al., 2005; Ronald, 2013). The Section 8 programme is one of the most famous cases, funded by the US Federal Government and managed by local governments, it supplements people's capacity of meeting rent prices in private houses.

In Brazil, we identified ongoing formulations of voucher programmes in the municipalities of Recife (Pernambuco State) and Campo Grande (Mato Grosso do Sul State). In Belo Horizonte (centre-east state of Minas Gerais), a programme of social rent in privately owned housing stock combined with a tenant subsidy is already implemented after been regulated by Municipal Decree nº 17.150/2019 (Paolinelli et al., 2025) This experience is inspiring that of the neighbouring municipality of Contagem, which is also been formulated based on the supply of privately owned houses.

Social rental housing
We define social rent as the State operated destination of a publicly or privately owned housing stock to the low income population, through the regular payment of rent, subsidized or not, and without transferring the property to its beneficiary. The management of a social rent programme and stock can be performed by public, private or public-private actors and arrangements.

In the case of a publicly owned and managed stock, rent can be totally or partially met by the beneficiaries, usually with a subsidy calculated according to the household income so as to not burden it with rent. Public management can be temporary or permanent and also articulated with other public services e policies.

In Europe and the United States, welfare state collaborated with the conception of social rent policies in the postwar period. From the 1970's onward, and more intensely in the last couple of decades, processes of dismantling

9 The consecrated term in Brazilian policy is auxílio aluguel, although the names of rental assistance policies vary a lot.

and privatization of public housing stocks took place (Kirchner, 2007; Aalbers and Holm, 2008; Ronald, 2013; Wijburg et al., 2018).

In Brazil, pioneer experiences with social rent are found in the social housing complexes developed by the Popular Housing Department of Rio de Janeiro, that were initially meant to be accessed by rent deducted directly from the worker's salaries (Nascimento, 2004, p. 156). More recently, the São Paulo Social Rent Programme was implemented in 2002 and currently has a housing stock of 937 units divided in seven complexes (Rodrigues et al., 2025).

Another arrangement combines social rent in privately owned stock managed by public authorities, consisting in private units verified and availed by the municipality. This could be deemed as assisted rent.

In Brazil, the aforementioned pilot experience of Belo Horizonte is an example (Paolinelli and Gimenez, 2023), along with the ongoing formulations in Contagem (Paolinelli, 2024), Recife and Campo Grande.

Publicly owned social housing can also be produced and managed in Public-Private Partnerships (PPPs), with the State conceding the building, rental and management rights to a private consortium for a set period of time. This kind of contract is based on a public bidding process where bidders take interest in assessing the project's profitability.

Athought Brazil has experiences with social housing PPPs, none of the implemented cases involve social rent. Two projects of this kind are in the making, though, in Recife and Campo Grande. The first and more advanced one, named Morar no Centro (Live in the Centre) is set to be the country's first social rent PPP. It delegates to a private consortium the construction of six housing complexes and its management throughout 25 years. Out of the 1.128 housing units to be built, 631 (56%) will integrate a social rent programme, and the other 497 (44%) units will be sold to beneficiaries of the Minha Casa, Minha Vida programme. All the urban land involved in the project is publicly owned, by the municipality or the federal government, and will be conceded free of cost for the exploitation by the consortium (Ursini and Santoro, 2025).

Associative management

The management of the housing stock and rental contracts can also be executed by civil society entities, such as hired CSOs and NGOs or even social movements, associations or cooperatives. This arrangement can be combined with subsidised rent and operate in a stock owned by the State or by the managing association. The Housing Associations in the United Kingdom and the Community Land Trusts in New York (Angotti and Jaggu, 2007) are known examples.

The Brazilian examples of associative management are of different types. A first refers to the many experiences of rent management in occupations lead by housing social movements - a theme that receives little attention in the housing literature -, which can be associated with housing and urban policies and the processes of squatts renewal and access to land (Santoro, 2024). Another type comprises recent pilot initiatives that articulate philanthropy with social impact investments, in some cases acting as incubators. A well known example is the FICA Fund, a NGO created in 2015 that rents housing units in São Paulo through a "Social Housing Service" focused on vulnerable households. The fund currently manages 12 properties with a total of 53 housing units acquired through donations or conceded by supporting proprietors. More recently, the NGO created an investment fund, separated from the donations fund, offering an yearly interest rate of 4%[10]. Similarly, the SOMA (Organized System of Accessible Housing) initiative also combines a non-profit entity with social impact investment to offer rental housing for low-income families. The project, headed by the responsible construction and real estate company in association with a securitization company and a law firm, issued a social impact bond (in the form of Certificates of Real Estate Receivables) to fund the construction of a building with 110 units, including the plot acquisition in a central area of São Paulo. An NGO was created specifically to manage the building and the rental contracts that back the certificates.

10 See <https://fundofica.org/>.

Leasing
It refers to contracts of rent or financing that allow for the use of the property during its extension and offers an option to buy at the end of the tenure.

A derived model is that of the shared ownership in England, object of a fomenting state programme in the aftermath of the subprime crisis, that allows the purchase of a quota of a property, requiring the payment of rent corresponding to the remaining property value for the right of living in it.

In Brazil, the Programa de Arrendamento Residencial (PAR) of the federal bank Caixa Econômica Federal, implemented in 1999 by the federal government, consisted in renting houses to families with a maximum total income of six minimum wages for fifteen years with an option to buy at the end of the period. The programme was fairly disseminated in many Brazilian cities and included the creation of an exclusive fund, the Fundo de Arrendamento Residencial (FAR).

3. Housing as service and State modulations in Brazil
Various modalities found use the idea of habitation as a service as justification and as a structural change so that something can be developed as a service. Overlooking the identified set of types and arrangements of rental policies, we initially highlight the dissemination of the understanding of housing as service in Brazilian housing policy. This concept, however, assumes different and often contradictory meanings according to the State modulation to which they associate with.

Recent research on social rental policies in Brazil have used the term 'housing service' or 'housing as service'. Some authors (Balbim, 2015; Cymbalista and Moreira, 2006; Cymbalista, 2024; Costa, 2023) have sought to define it - especially in the realm of public policy conception - demonstrating that the term is key to a narrative dispute involving actors with different interests. Generally, the term is associated with a rental policy conceived by public or private agents or to a set of policies that propose alternatives to homeownership.

The term is also used in urban planning and housing material, such as reports and norms, possibly signaling a dispute for the meanings of housing itself. It is also approached by the critical urban literature interested in the processes of financialisation of housing, that frame 'housing as a service' to the rent concentration dynamics of the real estate financial market - one supported by public policy and urban regulation (Santoro and Chiavone, 2020). Thus, the term appears to be simultaneously defined by different actors guided by different concepts of the role of the State.

4. State Modulations
In that sense, it is crucial to identify the determined State modulations that influence its action and agenda. In the analysed experiences, we identified three modulations preliminarily named as: Emergency State, Provider State, and Conceding State. The first, widespread in Brazil, responds to crises with precarious and temporary solutions, and is widely used throughout the country; the second enforces public governance frameworks, mostly restricted to small scale and pilot initiatives; the third integrates market logics into the production and management of housing and housing services through the advancement of Public-Private Partnerships (PPPs), and to do so they incorporate logics from the financialization of the real estate market.

The use of the term modulation - instead of model - is meant to highlight the understanding of the State as a process in motion, incrementally shifting. Distinct processes of State modulation can coexist, even within the frame of a given location's housing policy. For instance, in São Paulo's municipal housing policy we could identify emergency policies of rental assistance, a (resisting) social rent programme with a publicly owned housing stock - typical of the Provider State - and a housing PPP, aligned with the Conceding modulation. These experiences are not equally institutionalized and implemented; some are more extensively applied while others are embryonary. They reveal, nonetheless, tendencies and enunciate a dispute in the current scenario of social rental policies in Brazil.

3.1. Emergency State

In essence, the Emergency State is one that responds to emergencies and crises with precarious and temporary solutions. This set of experiences comprises different forms of emergency rental assistance; temporary and much disseminated, although lacking a public policy structure of its own. The Emergency State, therefore, is the one that strays most from the idea of a modulation, for it is characterised by the constancy of precarious answers to a permanent crisis of recurrent emergencies.

Rental assistance, the direct transfer of a monthly allowance, is one the most implemented emergency policies on account of its efficacy in supporting evictions in public interest or disaster prone areas. It is limited in terms of a housing response (Guerreiro, 2021; Ximenes, 2023); temporary, with a frequent need for renewal; a palliative for the chronic ineptitude of the State in offering permanent and adequate housing solutions that secure tenure for those in need. It is structural in reproducing the condition of "permanent transitoriness" (Miranda et al., 2019) and keeping "instability, irresolution and temporariness" (Rolnik, 2019). Rental assistance has been granted to households waiting in line for social housing homeownership or home renovation programmes and is commonly introduced in the negotiations around displacement processes. It is the typical (temporary) solution for those that won't accept the State's offers of relocation in distant housing complexes (Fernandes, 2024).

In most cases, the beneficiary households are unassisted by public authorities in the pursuit of a home, which is selected without inspection or technical evaluation. On top of that, rental assistance has a price setting effect over formal or informal housing markets, with the public allowance tending to set the floor for rents in the most seeked after areas. Therefore the granted value often is (or soon becomes) insufficient for accessing rental housing even in popular territories. In that sense, the assistance can be more accurately defined as a supplement of income rather than a means to access housing.

Rental assistance is mostly a fragmented policy, implemented by local governments in an unprogrammed manner, unattached to any encompassing plan in the municipal, state or national level. It needs little management capacity and can be set without integration with other public policies and programmes. As a municipal policy, it can be supplemented with federal resources, as in the recent case of a flood disaster in Porto Alegre (in the southern state of Rio Grande do Sul), in April 2024. In these instances, the resources are contingent to a public calamity situation, and can be taken from different budget rubrics.

A few recent experiences show some degree of policy articulation in the use of rental assistance. In the case of Belo Horizonte, a kind of rental assistance supplements or even overlaps with the municipal social rent programme (Paolinelli, 2023; 2024), as the process of selection of a private housing stock lacks sufficient technical personnel for evaluations. In Sobral (in the northeastern state of Ceará), a rental policy is articulated with income generation programmes (Lessa et al., 2024), and in Brumadinho (in the southwest state of Minas Gerais), it is mobilised as part of the reparative measures pack after the collapse of a dam in the Feijão river (Biasotto, 2024). In the state of São Paulo, rental assistance is granted to women victims of domestic violence and in the city of São Paulo, people experiencing homelessness can also apply for a similar grant.

In that regard, the debate over Housing First policies - pointed as a strategy for dealing with homelessness and drug abuse - is integrated into that of social rent. Pilot experiences that claim the Housing First label were implemented in São Paulo's Reencontro (Reunion) programme. This case has been criticised on the limitations of available housing units and the lack of coordination with care services required by the beneficiaries, demanding an intersectoral integration in the public administration. Calil (2024) gathered research that supports the effectiveness of Housing First programmes and poses that, ideally, rental housing would be seen as a temporary measure, but with no preset time limit: the beneficiary should remain as such until they reach a structured condition of income, social and work reintegration and access to a permanent dwelling (Pinho and Martines, 2024).

Despite being recognised as "emergency responses", these policies are widespread in Brazilian cities and, in some big cities, they occur in more than one type of assistance and exceed all other housing programmes in

number of active beneficiaries. Approximately 55,2% of the Brazilian municipalities had implemented a rental assistance programme in 2020. Among the larger municipalities, with over 500 thousand inhabitants, the percentage goes up to 80% (Munic IBGE 2020; Ximenes, 2024, p. 201). Although temporary, this kind of programme is broader than many other housing policies and responses. In the cities of Rio de Janeiro and São Paulo, for instance, rental assistance reached, respectively, 33 thousand (Ximenes, 2024) and 30 thousand (Guerreiro, 2020) households simultaneously. It is suggested that the emergency state is a permanent one. The increasing challenges of climate change tend to enhance this scenario.

Ximenes (2024) states that this type of policy is actually a resource for managing the housing waiting list (or the "line", as said in the public management lingo), reinforcing instability of tenure specially for those in risk of forced displacement. The city of Rio de Janeiro issued its first decree on "housing assistance" in 1998, updating the term to "temporary housing assistance" in 2013. In the context of Rio's major sports events (specially the 2014 World Cup and the 2016 Olympics) - with its major displacement wave connected to a surge of construction works - the number of households recipient of rental assistance went from 10 thousand in 2009 to 22 thousand in 2016 (Idem, p. 201).

Guerreiro (2020), analysing the experience of São Paulo, goes even further and deems the rental assistance policy as a device for "managing housing insecurity": instead of assuring the right to adequate housing, the policy acts on the regulation of the lack of housing solutions. This response doubles down on the transitoriness of a surplus population and directs resources to the popular housing market. In the form of rent, such resources can be concentrated as financial assets, possibly turning rental allowances into instruments of connection between popular ways of dwelling and the real estate financial capital.

The aforementioned authors highlight a strong correlation between rental assistance and policies of eviction or forced displacements in urbanization and land titling processes in informal settlements. In that sense, rental assistance should not be recognised as a housing policy, but rather its very opposite, as it enables displacement without guaranteeing resettlement. It can even be questioned as a proper policy, as it mostly lacks institutional structuring for its management, funding and articulation to (publicly disclosed) planning, directives and goals. In some cases, though, rental assistance is conceived as a subsidy in the context of a social rental policy.

The expansion of assistencialist policies in Brazil, such as income transfer or minimum income programmes, consolidated on account of its electoral efficacy, has reached the state and municipal levels of politics. Housing policies are incorporating this agenda through policies such as the Aluguel Social provided by the center-west state of Goiás and its capital city of Goiânia. The registration for these programmes is via mobile application. One can quickly download the app and register for an eighteen months allowance of R$350, even with some proof, such as receipts of rent payment every three months.

3.2. Provider State

A Provider State is characterised by mobilizing social rental policies on essentially public arrangements or governance models; a State that claims the responsibility for the production and provision of rental housing. Different from the welfare state model implemented in the central countries after 1945, the Provider State's context is that of peripheral fordism and its limited experiences that have never gone beyond the scale of pilot programmes, with few housing units. These experiences currently resist dismantling efforts relying on a body of engaged civil servants that are willing to face the many challenges of keeping the rental policy accessible to those most in need and guaranteeing their tenure over time. In the peripheral fordism, the paradigm of welfare is experienced as an ideological construct and greatly as frustration.

In general, this State modulation mobilizes municipal social rent policies with public management of a public or private housing stock destined to the low income population through subsidised rent, without possibility of transference of property. These policies are essentially structured in frameworks and governance models centered around the agency of the public sector.

The Provider State seeks to amplify the pilot experiences of State managed social rent by resisting dismantling efforts while also working on improvements in the existing programmes. A sort of militant – although institutional – activity of a mid-level bureaucracy carries out this resistance in the defense of a Provider State. Small scale programmes, managing small housing stocks, are developed in the interstices of the dominant homeownership framework by governments concerned with the public responsibility over housing implied in social rent programmes – capable of reaching specific population groups that are unable to access housing (and maintain tenure) through the formal real estate market. However, the interstices are small, and social rent still hasn't reached a significant scale in the Brazilian housing policy.

Gradually, the Provider State modulation has given way or even reshaped into the Conceding State. The global trend towards managerialism (Harvey, 1989) lands in Brazil initially in its metropolises in, for instance, the outsourcing of services such as housing and social assistance and also of the conception, management and regulation of public policies (Pulhez, 2016). Consultancy agencies, at first hired for specialised services, came to be responsible for public services, replacing and dismantling the established public management structures, resulting in the downsizing of the public servants workforce, in an "unequivocal example of transference of state functions to private agendas" (idem, p. 101). The conception of recent rental housing policies is in tandem with this process. Once hired by the public agent, they become a sort of administrative intermediary, which puts them in a position that is traditionally recognized as State responsibility, controlling the activity of other outsourced parts, conducting execution schedules, setting deadlines, evaluating deliverables etc." (ibidem, p. 100).

3.3. Conceding State[11]

A Conceding State originated in the outsourcing of isolated aspects of housing policies now combined in Public-Private Partnerships that comprise the production of housing and the management of 'housing services' over decades. There are a few initiatives of this sort, formulated in cooperation with international entities such as the Inter American Development Bank (IDB) and in tandem with an agenda for the advancement of the private rental housing market. This State modulation gradually integrates the logics of financialisation into housing policies by: diminishing the State's role in executing policies, relegating it to a regulatory function and to the support of market-oriented projects; destinating public assets (real estate and financial) and tax and urban incentives to stimulate market activity; elaborating and perfecting contract models for PPPs; advancing the concept of social mix in housing developments as a tool for broadening the "social" character associated with public housing.

Romero and Waeywnberge (2020) observed this managing and financing movement as a "private turn" in development finance. They argue that PPP has been a buzzword, with no universally agreed definition, and part of a framework of different typologies and arrangements for engagements between public and private actors for the deliverance of specific infrastructure assets and services (Romero, 2015). According to the authors:

"PPPs, in essence, are one manifestation of State support for the transformation of infrastructure or public services into private assets[12] that often generate revenue streams for asset-holders – with the exception of partnerships with non-for-profit organisations" (Romero and Waeywnberge, 2020, p. 40).

Here, the Conceding State modulation is based on the Housing Public-Private Partnership framework advanced by pilot initiatives on the concession to private entities of the rights of construction and management of housing units over decades, mainly in home ownership arrangements that alienate public land (Bleich, 2025). It is opposed

11 We opted for the most direct translation of Estado Concedente. In portuguese, concedente characterises the part or the power that gives, lends or grants something. For 'Conceding', in english, the same meaning applies, but with an underlying connotation of 'defeating', 'desisting', 'yielding', 'surrendering'. Although involuntary at first, we did not find the double-meaning to be inadequate for our proposition.

12 In this definition they combine the notion of "infrastructure-as-asset" as asset understood as the increasing involvement of the state to engage financialised capital in expanding provision of economic and social infrastructure, but this can take different forms, that they try to exemplify by the existing PPP typologies analysed.

to the original (and residual) framework of the Provider State, that sets to amplify and perfect pilot experiences of social rent in a publicly owned stock managed by public actors.

Some of the experiences in course originated from the federal government's policy of fomenting PPPs. The national structuring of social rental housing policies is conceived inside the federal programme of private partnerships and concessions[13]. The instrument, therefore, appears to be at the root of the housing policies, instead of any analyses of the specific housing needs of the territories. The municipal availability to take the opportunity presented by the federal government seems to have been the main criteria for the selection of Recife and Campo Grande for the implementation of pilot programmes: Brazilian law restricts municipal expenditure with PPPs to 5% of the net current revenue. The housing PPPs are not formulated as responses to housing needs diagnoses, but as investment opportunities to market agents interested in supplying a product - public interest housing - in the framework of "inclusionary housing policies" (Calavita and Malach, 2009; Santoro, 2019). These private partners demand contractual financial models that include the mobilisation of many public assets (Bleich, 2025; Santoro et al., 2018a) and in return, offer a relatively small production of housing units (Santoro et al., 2018b; Romero, 2015).

Critical analysis of the PPP model and its increasing implementation have shown that it "only provides about 15–20 per cent of total infrastructure investment. The lion's share is still provided by the public sector, and this situation is likely to continue", bringing to question why so much focus is placed on the private sector rather than improving public sector capacities (Romero, 2015; Romero, Waeyenberge, 2020). In most cases, it represents the most expensive method of financing, significantly increasing the cost to the public purse, and typically involves complex negotiations and implementation. Additionally, PPPs are high-risk financing operations for public entities, with limited and weak impact, challenging when it comes to reducing poverty, have low transparency and are subject to limited public scrutiny which undermines democratic accountability (Romero, 2015, p. 6-8).

We recently found different formulations in progress: two projects in advanced structuring in Recife[14] and Campo Grande[15], and three in the contracting phase: São José dos Campos/São Paulo State, Santo André/São Paulo State, Maceió/Alagoas[16].
The current formulations of rental policies in Recife and Campo Grande, articulate the modulation of the Conceding State, are pilot programmes, now in final formulation or initial implementation stages, are divided into two types: PPPs for production and management of a public stock of rental housing and voucher policies for subsidised access to private rental housing. They were designed in cooperation with consultancy agencies hired by the federal government as a first result of a broader cooperation with the Inter American Development Bank (BID) that established recommendations for Brazilian housing policies, including guidelines and strategies for a national rental housing policy.

Recife and Campo Grande PPPs actually combine the production of rental housing and market social housing for controlled sale, in the homeownership model. All of the plots for construction (including some existing buildings that will be renovated, in the case of Recife) are public property, municipal or federal. The rental stock will be managed by the private partner for the contractual period of 25 years - after which the property remains public - and the for sale stock will be alienated with no costs related to the concession of the public land. Analysing the financial models of the PPPs, it becomes clear that the cost-free donation of public real estate assets is a crucial element for the composition of attractive return rates for the potential investors. In the same way, the social rent model, one that contemplates a more vulnerable low income public, seems to be subsidised by the traditional homeownership model, that reaches a relatively higher income population (although still classified

13 We are referring to the Partnerships Investments Programme (PPI), created in 2016.

Acess 05 June 2025.

as low-income). The poor subsidise the even poorest, and the implementation of social rent is a burden for the investors relative to the profitability of the for sale production. It is worth noting that the expected return rates for investments in Brazil are typically measured against the basic interest rate set by the Central Bank, one that is always among the highest rates in the world and frequently the highest. The opportunity costs considered in the financial modeling of PPPs is therefore chronically high.

Alongside the PPPs, both municipalities are either formulating (Recife) or already implementing (Campo Grande) a voucher programme that subsidises the access to private rental housing. This model is different from the rental assistance in two key aspects: the policy includes processes of housing stock selection and inspection and the vouchers are paid directly to the proprietors, not the tenants. In Campo Grande, the programme is structured around the outsourcing to local real estate agencies of the management of the housing stock and rental contracts. The coordinating public actor is the municipal housing agency, a public company that manages the municipal real estate assets. In Recife, the implementation of the different rental policies involved different municipal offices, such as housing, social assistance, and one specifically responsible for concession projects.

In this scenario, the challenge of conceiving decommodified alternatives for housing is discarded from the start, as the design of a business opportunity is the primary feature of the framework. There is no consideration for the potential of mobilizing subsidised rent as a means of isolating the use value of housing while taming its exchange value in the public interest. On the contrary, differential and maximised profits captured through rent set a new frontier for the financialisation of housing. One possibility for restructuring the PPP paradigm would be the introduction of non-state and non-profit actors as the partners in the production and management of the rental housing stock, such as cooperatives, Civil Society Organizations (CSOs) and social movements.

5. Final remarks

This paper argues that rental housing is globally growing as a means to access housing in the face of multiple crises and as a financialized real estate frontier of capital accumulation. In Latin America and Brazil, where the homeownership model historically prevailed, households are increasingly renting, the real estate market is incorporating new formats (build-to-rent, multifamily), and professional rental management is spreading in formal and informal markets.

It presents Brazilian cases, analytically organized by three State modulations, understood as the agenda and practices of a State "in progress." An Emergency State, that responds to crises with precarious, temporary solutions. A Provider State, that implements public governance models with pilot programmes. A Conceding State, that incorporates market logics by advancing Public-Private Partnerships in the production and management of housing services.

Through this proposed analytical framework, we observed the evolution of emergency policies, which constitute by far the most disseminated type of rental policy in Brazil. One that seems intended to urgently respond to crises and disasters, but is mostly implemented as an income transfer policy and lacking institutional or programmatic filiations. Through the rental assistance policy, rent is not actually assisted; what is enforced - recycled, recreated and managed - is the precariousness and transitoriness of (the lack of adequate) housing solutions; an anti-policy as such (Guerreiro, 2020).

We also identified a "private turn" in development finance that imposes a PPP agenda, as pointed out by Romero and Waeywnberge (2020), but with regional characteristics. Latin America did not have a welfare state along the lines of the central countries' experience. Here, the Provider State presented pilot-scale projects, and rental policies were never a part of the dominant regime. Recent formulations of rental housing PPPs are aligned to the agenda of international entities and advance the paradigm of inclusive housing policies, where housing is seen as a service and public assets are mobilized to advance investment opportunities.

Furthermore, the three modulations of the State, interacting in processes in progress, enunciate the current dis-

putes surrounding rental policies in Brazil.

Pathways to Urban Resilience: Tactical Urbanism vs. Transdisciplinary Approaches

Esen Gökçe Özdamar
Affiliation: Tekirdağ Namık Kemal University, Türkiye
Email: egozdamar@nku.edu.tr

Abstract
This article explores how tactical urbanism and transdisciplinary approaches intersect in fostering urban resilience within Türkiye's evolving planning context. Tactical urbanism, characterised by small-scale, low-cost, and community-led interventions, promotes rapid adaptation and public engagement. In contrast, transdisciplinary approaches integrate diverse disciplines and stakeholder perspectives to address systemic urban challenges through long-term, collaborative strategies. Drawing on international frameworks and Turkish case studies—including Istanbul's parklet projects and İzmir's public space renewals—the study reveals that combining these two methods can bridge the gap between experimentation and institutional transformation. It argues that fostering synergy between grassroots initiatives and structured collaboration enables adaptive, inclusive, and context-sensitive urban resilience. Ultimately, integrating both approaches supports sustainable, participatory, inclusive and regenerative urban futures.

Keywords: Tactical urbanism, transdisciplinary approach, urban resilience, participatory planning, Türkiye

1. Introduction

The term resilience originates from the Latin word resilientia, referring to the capacity of a substance to return to its original shape after deformation. In the 19th century, Thomas Young and Thomas Tredgold defined resilience as a material's ability to absorb energy and withstand sudden forces, introducing concepts such as the "modulus of resilience" (Rogers, 2017, p. 14). In broader systems theory, resilience is understood as "a measure of the ability of these systems to absorb changes of state variables, driving variables, and parameters, and still persist" (Holling, 1973, p. 17). It has also been defined as "the capacity of a system to absorb disturbance and reorganise while undergoing change" (Walker et al., 2004). Resilience can refer to engineering resilience, which is the time required for a system to return to equilibrium after a disturbance. It also encompasses dynamics far from equilibrium, describing the magnitude of disturbance a system can endure before shifting to a different stable regime with distinct governing variables and structures. In ecological contexts, the terms ecological resilience and ecosystem resilience are often used interchangeably (Brand and Jax, 2007).

Urban resilience refers to the capacity of cities to adapt to both predictable changes and novel conditions, such as population growth, resource scarcity, and climate change. Effective urban resilience planning is essential for cities to anticipate and respond to unexpected shifts (Yaman Galantini, 2020, p. 349). Two key considerations are central to this process. First, a city's ability to cope with change while maintaining stability must be strengthened. Second, resilience strategies need to be context-specific, tailored to the unique characteristics of each city, as the impacts of global challenges vary across local contexts. Given the dynamic nature of urban resilience, cities must periodically reassess their goals and capacities. An effective resilience plan should address three fundamental questions: 1) What are the immediate vulnerabilities? 2) What are the spatial scales for intervention? 3) What are the key components of the planning framework? These components include stakeholders, spatial scale, interdependencies, resilience indicators, planning tools, and policies—all of which together form the foundation for developing context-sensitive, adaptive, and sustainable urban resilience strategies (Yaman Galantini, 2020, pp. 348-349).

"The Urban Resilience Hub," managed by UN-Habitat, is a global platform designed to enhance urban resilience and promote its practical implementation. The hub provides access to research, news, case studies, and best practices, fostering collaboration among local governments, practitioners, researchers, and international organisations. It offers toolkits, guidance documents, and other resources to help cities assess risks and implement resilience strategies, advocating for the integration of resilience thinking into urban planning and policy at local, national, and global levels. Additionally, the hub supports city alignment with global frameworks such as the Sendai Framework for Disaster Risk Reduction, the Paris Agreement, and the Sustainable Development

Goals (Urban Resilience Hub, n.d.). Similarly, "Making Cities Resilient 2030" (MCR2030) is a global initiative led by the United Nations Office for Disaster Risk Reduction (UNDRR). It aims to help cities become safer, more inclusive, and resilient to disasters and climate-related risks, with a target of achieving enhanced urban resilience at the local level by 2030. The initiative contributes to Sustainable Development Goal 11 (SDG11) and other global frameworks, including the Sendai Framework, the Paris Agreement, and the New Urban Agenda, by promoting advocacy, knowledge sharing, learning networks, technical support, coordination among government levels, and the establishment of partnerships (Making Cities Resilient, MCR2030).

Another notable urban resilience initiative is the "New European Bauhaus", launched by the European Commission in 2020, promotes sustainable, inclusive, and human-centered urban living. Bridging the European Green Deal with everyday life, it emphasizes sustainability, aesthetics, and participation, fostering community-driven urban transformation through both commission-led and grassroots projects that support climate goals and social inclusion (New European Bauhaus, n.d.).

A complementary strategy for enhancing urban resilience involves the adoption of tactical urbanism. Recent initiatives that integrate participatory models and tactical urbanism have highlighted both notable progress and persistent systemic challenges. While these approaches aim to democratise decision-making and strengthen resilience, their effectiveness is often limited by fragmented implementation and insufficient transdisciplinary integration.

In the context of Türkiye, the adaptive use of urban open spaces plays a crucial role in enhancing resilience and supporting adaptation to emerging climate conditions. Historically, top-down strategies have dominated urban planning, however, there has been a gradual shift toward participatory practices and project-based policies designed to engage citizens in decision-making processes. Despite these efforts, participatory models have often proven insufficient in effectively addressing urban resilience challenges. Key issues include the sustainability of urban governance, the early-stage implementation of participatory processes, and the tensions between top-down policies and grassroots initiatives.

Conversely, transdisciplinary collaboration and research offer significant potential to manage uncertainties, support adaptation, and drive development in response to emerging challenges, thereby enhancing urban resilience. To address issues of urban sustainability and resilience, architects, planners, and researchers require training and experience in knowledge transfer, with design research recognised as a legitimate method of knowledge generation (Després et al., 2011). In this context, planners can play a pivotal role by raising awareness among local governments and citizens, influencing the outcomes of resilience-building initiatives. Accordingly, this research focuses on strategies for implementing transdisciplinary approaches to strengthen urban resilience. It examines the role of participatory processes in fostering resilience and explores ways to enhance transdisciplinary urban participation within Turkish urban contexts through a theoretical framework.

In light of the theoretical foundations of resilience and its diverse interpretations, this study situates the concept within the specific context of urban resilience and its application to contemporary planning challenges. While global frameworks and initiatives offer valuable guidance, there remains a gap in understanding how tactical urbanism and transdisciplinary approaches can jointly enhance urban resilience, particularly within Türkiye's evolving planning landscape. Accordingly, this research examines how these two approaches—one grounded in grassroots experimentation and the other in integrative, long-term collaboration—can complement one another in addressing systemic urban vulnerabilities. The study argues that bridging the immediacy of tactical interventions with the structural depth of transdisciplinary processes can foster adaptive, inclusive, and context-sensitive models of urban resilience. It seeks to answer the following questions: 1) How can tactical urbanism contribute to strengthening urban resilience through participatory, short-term interventions? 2) In what ways can transdisciplinary collaboration expand these efforts into sustainable, long-term frameworks for urban transformation? By addressing these questions, the study aims to contribute to a more coherent and operational understanding of resilience in urban planning—linking theory, practice, and policy through both bottom-up and

cross-sectoral strategies.

2. Tactical urbanism: A catalyst for active participation

Historically, citizens have modified streets and public spaces—sometimes without formal approval—to address unmet needs, such as improving street safety or creating more open areas. These initiatives are community-led, emerging from the efforts of residents and activists who implement swift, incremental improvements in response to gaps or delays in official action, particularly in areas where municipal authorities are perceived as ineffective or unresponsive. The concept of tactical urbanism draws inspiration from earlier urban experiments, including Paris's pop-up book stalls (les bouquinistes) in the 16th century, Ciclovía in Bogotá, and pedestrian plazas in New York City (Lydon and Garcia, 2015, p. 51). Tactical urbanism arose as a response to the limitations of conventional urban planning methodologies. Its intellectual roots can be traced to the seminal work of Michel de Certeau, The Practice of Everyday Life (1984). De Certeau contrasted the tactical actions of ordinary individuals with the strategic actions of institutions, offering a perspective on social dynamics and the role of individuals in shaping urban environments. He introduced the concept of "making do," a tactical approach employed by urban residents that he described as "invisible." This strategy embodies what he termed an "art of the weak," a means of temporarily subverting hegemonic authority that structures both tangible and intangible urban spaces. Tactics, as de Certeau demonstrated, are structurally shaped by social orders, yet they remain contingent and timeless, adaptable across different contexts (Copeland and Feldman, 2016).

Tactical urbanism has been defined as a "decentralised, bottom-up, extraordinarily agile, networked" and "citizen-led, quick, and affordable" approach to urban planning, characterised by low-cost and low-tech interventions (Mohankumar, 2020, p. 15; Lydon and Garcia, 2015, p. xii). It emphasises the use of short-term, low-cost, and scalable interventions to catalyse long-term change in neighbourhoods and public spaces (Mohankumar, 2020, p. 15). The concept emerged as a grassroots response to the slow, bureaucratic pace of conventional urban planning. Early initiatives included pop-up bike lanes, parklets, and temporary plazas, designed to demonstrate the potential for long-term improvements (Lydon, 2011; Tactical Urbanist's Guide, n.d.; Urban Design Lab, 2023). The approach gained widespread attention during the 2008 financial crisis, when budget constraints prompted cities to adopt cost-effective, community-driven strategies for urban revitalisation.

Tactical urbanism formally coalesced in 2010, at a meeting of the Next Generation of New Urbanist (CNU NextGen) group in New Orleans, convened by Mike Lydon with Anthony Garcia, Lydon authored the influential book Tactical Urbanism: Short-term Action for Long-term Change (2015), which catalyzed collaborative open-source projects and the broader adoption of the approach (Planetizen, n.d.). Their reports documented the experiences of urbanists and activists across the U.S., highlighting practices such as "guerrilla urbanism," "DIY urbanism," "planning-by-doing," "urban acupuncture," and "urban prototyping." These case studies underscored the popularity and potential of tactical urbanism as a method for rapid, community-led change.

By the late 2010s, tactical urbanism gained traction among city governments and grassroots organisations, who implemented pop-up parks, pedestrian plazas, street murals, and other temporary interventions. This period also fostered experimentation with novel public space concepts, alternative street uses, and community-led initiatives such as street art and urban farming. The approach is characterised by its informal, hands-on, and experimental nature, allowing cities to test and evaluate ideas before committing to permanent urban modifications (Tactical Urbanist's Guide, n.d.; Anderson, 2023). The Street Plans Collaborative (2012) defines tactical urbanism as a phased, low-risk approach to urban change that emphasizes local, short-term, and community-driven interventions. It promotes incremental experimentation, context-specific solutions, and the building of social capital through collaboration among citizens, institutions, and organizations (Lydon et al. 2012, pp. 12).

2.1. The role of tactical urbanism in urban resilience

Lydon and Garcia (2015) draw a clear connection between tactical urbanism and broader urban planning movements, particularly emphasising citizen participation and the critical role of residents in shaping their communities. They also promote open-source urbanism, which enables the sharing of ideas and designs,

fostering collaborative problem-solving across communities. Tactical urbanism projects are distinguished by their experimental and adaptive nature, allowing for rapid testing and immediate community feedback. The global pandemic has further increased the appeal of this approach, as it offers flexible, low-cost interventions that can respond to urgent urban needs (Lowe et al., 2024). These initiatives are typically modest and cost-effective, yet they hold the potential to generate significant impacts in creative placemaking, empowering communities to test new concepts and develop a sense of ownership over their surroundings, often led by local residents (CoUrbanize, 2020). The application of tactical urbanism has been shown to enhance adaptability, social cohesion, and environmental sustainability through community-driven interventions such as pop-up parks and street murals (Mohankumar, 2020). As illustrated in Figure 1, tactical urbanism embodies a diverse set of characteristics and practices that collectively support responsive, community-centered urban transformation.

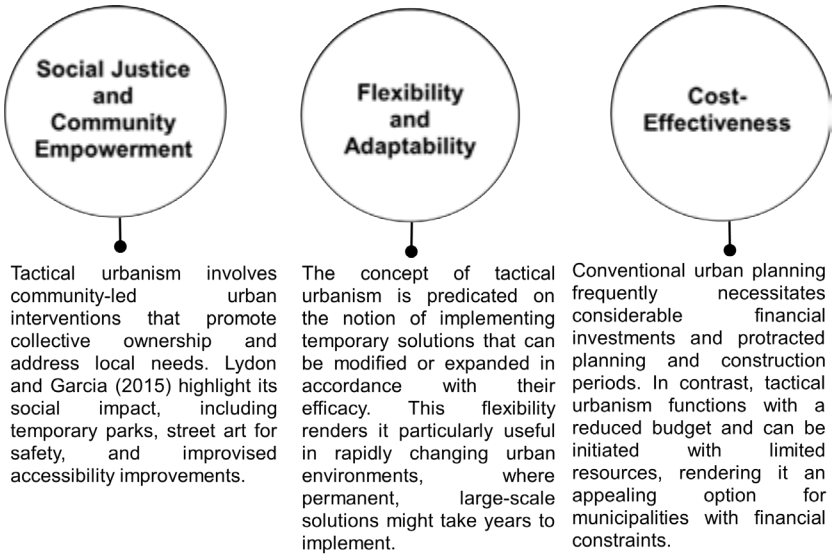

Figure 1. Benefits of tactical urbanism (Derived from Lydon and Garcia (2015)

Table 1 showcases global examples of tactical urbanism, illustrating how temporary, community-led interventions—such as street closures, pop-up parks, and pedestrian zones—can improve public spaces, mobility, and social engagement across diverse urban contexts.

Table 1. Notable Examples of Tactical Urbanism

Project	Year	Location	Description	Impact	Reference
Times Square Pedestrian Plaza	2009	New York City, USA	Pedestrianisation of Times Square using temporary materials; later made permanent.	Improved safety, increased foot traffic, and economic benefits.	Snøhetta (n.d.)
Paris Plages	2002-…	Paris, France	Seasonal transformation of Seine banks into urban beaches since 2002.	Enhanced public access to riverfronts and recreation.	Paris (2022)
Superblocks	2016-…	Barcelona, Spain	Car-free superblocks promoting pedestrian and cyclist priority since 2016.	Reduced traffic, pollution; increased green spaces.	(Iturralde, 2021)

Ciclovía	1970-…	Bogotá, Colombia	Weekly car-free events encouraging cycling and pedestrian use since the 1970s.	Boosted public health and global influence on similar events.	(Lydon et al, 2012)
Park(ing) Day	2005-..	Global (orig. San Francisco (USA)	Temporary conversion of parking spaces into public spaces; annual event since 2005.	Raised awareness on public space use; inspired parklets.	(Bela, 2023)
Better Block Project	2010-…	Dallas, USA	Temporary revitalisation of blighted blocks for urban improvement potential.	Catalysed global community-led urban projects.	Better Block (n.d.)
Play Streets	2019-…	London, UK	Temporary street closures for children's play and community interaction.	Encouraged child-friendly design and community cohesion.	(Sustrans, 2019; Playing Out, 2020)

Despite its successes, tactical urbanism faces several challenges and criticisms, including governance limitations, concerns about inclusivity, and the constraints of temporary interventions in addressing systemic urban vulnerabilities (Mohankumar, 2020). In contrast, participatory approaches to urban planning have demonstrated considerable benefits by fostering collaboration, integrating diverse perspectives, and supporting long-term sustainability and resilience. Such initiatives have been shown to enhance community resilience, strengthen local ownership, and leverage local knowledge to develop context-specific and effective solutions (Özdamar and Önay, 2024). However, challenges persist in contemporary urban transformation practices, particularly in Istanbul. Large-scale projects, such as the planned redevelopment of 600,000 earthquake-prone housing units, often emphasise physical reconstruction over community participation. This prioritisation can lead to community discord and limit opportunities for meaningful engagement in shaping urban outcomes (Gün, Pak, and Demir, 2020).

2.2. Tactical urbanism in Türkiye

The concept of tactical urbanism has gained global recognition, including in Türkiye, where cities have employed temporary, low-cost interventions to address diverse urban challenges and respond to immediate needs. Measures such as street closures, parklets, and pop-up green spaces offer valuable opportunities to enhance public spaces, promote sustainability, and actively engage citizens in urban transformation. Research on tactical urbanism in Türkiye emphasises original processes, participatory engagement, and exemplary case studies (Türkoğlu and Terzi, 2021; Vardı Topal, 2023). These projects primarily focus on improving public spaces, enhancing mobility, and fostering community participation. Notable examples include the Roman Orchard Project in Istanbul and the Transformation of Zümrütevler Square (2019), both of which implemented low-cost, temporary interventions to redesign urban areas. The Zümrütevler Square initiative, led by Maltepe Municipality with support from the Bernard van Leer Foundation, NACTO, and Superpool, aimed to improve pedestrian safety for children and families in the neighbourhood. Interventions included road painting, traffic calming measures, and seating areas, resulting in a 72% increase in square usage (Günç, 2021; Superpool, 2021). Despite these successes, such projects often face limitations in scalability and integration within broader urban planning frameworks, which can constrain their long-term impact on urban resilience. These challenges highlight the importance of linking tactical urbanism initiatives to strategic planning and stakeholder collaboration to ensure lasting benefits for cities.

The "Parklet" Projects in Istanbul (2020), initiated by WRI Türkiye Sustainable Cities as part of the WRI Ross Center for Sustainable Cities' Urban Mobility initiatives, in collaboration with the Istanbul Metropolitan Municipality Transportation Department, transform on-street parking spaces into small, temporary public parks known as parklets. The initiative was supported by the Fund of the "Partnership for Healthy Cities" (PHC), and implemented

in partnership with the World Health Organization. These parklets, deployed across multiple neighbourhoods—particularly in Beyoğlu—feature amenities such as benches, greenery, and public art. The objectives of parklets are threefold: to create pedestrian-friendly spaces, promote social interaction, and enhance public areas. By converting automotive space into pedestrian zones, parklets aim to reduce traffic congestion and increase foot traffic for local businesses. Additionally, these temporary interventions allow communities to assess the potential impacts of long-term urban design changes (Yaman and Yaraç, 2023; IBB, n.d.).

Similarly, the Sokak Bizim Derneği (Street Belongs to Us, 2010), an Istanbul-based NGO, seeks to improve pedestrian infrastructure by temporarily closing streets to cars and reopening them for pedestrians and cyclists (Sokak Bizim Derneği, n.d.) (Table 2). This initiative promotes walking, cycling, and social interaction, raising awareness of sustainable urban mobility and aligning with David Harvey's concept of "the right to the city." While such interventions have the potential to foster more equitable and inclusive urban politics and encourage authentic participatory urbanism, they also carry the risk of failing to generate sustained or comprehensive urban opposition, limiting their long-term transformative impact (Öcal and Erkut, 2019, p. 116).

Table 2. Examples of Tactical Urbanism in Istanbul

Name	Year	Location	Initiated by	Strategy and Description

Several projects in Türkiye illustrate how tactical urbanism can successfully transform public spaces through rapid, low-cost, and participatory interventions. The Tersane Neighbourhood Public Space Renewal Project in İzmir, implemented in collaboration with the United Nations Development Program (UNDP) and Karşıyaka Municipality, aimed to enhance two public spaces through innovative tactical urbanism measures. Engaging neighbourhood residents, the project included improvements such as shelter and health solutions for stray cats and the revitalisation of green areas (UNDP Türkiye, 2022).

In Kadıköy, tactical urbanism initiatives have focused on temporarily converting streets into car-free zones for pedestrians and cyclists, fostering human-centered environments that encourage social interaction and public activity. These interventions also promote alternative transportation modes, such as walking and cycling, reducing reliance on private vehicles. The Boğada Project, a collaborative effort with Herkes için Mimarlık (Architecture for All), Onaranlar Kulübü (Fixer's Club), TAK Kadıköy, and other partners, transformed the area around the Bull statue in Kadıköy. Over ten days, participants conducted field research, generated design ideas, and installed urban furniture, demonstrating the participatory and experimental nature of tactical urbanism (Boğada n.d.; Trak n.d.).

Despite these successes, tactical urbanism faces several challenges. The temporary nature of interventions may limit long-term impact, particularly when projects lack institutional support for permanence. Without a robust planning framework, tactical urbanism initiatives can become fragmented or disconnected, potentially resulting in ineffective outcomes. The approach's emphasis on simplicity and short-term solutions can conflict with broader urban development plans that demand larger-scale investment and long-term vision. Additionally, implementing tactical urbanism in densely populated areas often introduces greater logistical and organisational complexity (Ramos, 2022). These limitations underscore the need to integrate tactical urbanism with strategic planning and stakeholder collaboration to ensure that experimental interventions contribute meaningfully to long-term urban resilience and development.

3. Transdisciplinary methods in urban resilience planning and action

Transdisciplinary approaches originated in the social sciences during the 1970s and were subsequently extended to the physical sciences, including mathematics and quantum physics. They are conceptualised as Mode II knowledge production, referring to knowledge that is socially distributed and accessible to individuals and groups across society. This process-oriented framework facilitates communication beyond traditional institutional boundaries, creating a global network of interconnected nodes (Gibbons et al., 1994). Transdisciplinarity is characterised by its focus on real-world problems, the integration of diverse disciplinary perspectives, and active engagement with stakeholders outside the academic sphere. Through interdisciplinary collaboration and multi-sectoral participation, transdisciplinary approaches are particularly well-suited to addressing the complex, interconnected challenges of urban resilience.

The primary goal of transdisciplinary approaches is to achieve a "unity of knowledge" that transcends disciplinary silos, fostering improvements in the issue under study, the generation of new knowledge, and mutual transformative learning between researchers and participants. This methodology has proven especially effective in tackling sustainability-related challenges, including climate change, poverty, and resource security. The concept of "unity of knowledge" can be traced to early formulations by Jean Piaget (Klein, 2008) and has been further elaborated by scholars such as Hirsch Hadorn (2008), who emphasises the integration of scientific, ethical, and pragmatic knowledge from diverse scientific disciplines and non-academic stakeholders to address complex societal problems. Its primary aim is to co-produce knowledge that enhances understanding (system knowledge), informs decision-making (target knowledge), and guides practical action (transformation knowledge) toward sustainable solutions (Hirsh Hadorn, 2008; OECD, 2020). Similarly, Julie Thompson Klein (2008) highlights the necessity of cross-sectoral cooperation to resolve complex issues and embrace integrative practices that reflect the multidimensional nature of reality. These principles have been institutionalised in frameworks such as those developed by CIRET (Nicolescu, 2002), all of which underscore the importance of combining diverse forms of knowledge to confront complex societal challenges effectively.

Research on transdisciplinary planning demonstrates a paradigm shift in knowledge production and application, moving away from isolated disciplinary approaches toward collaborative, problem-oriented, and socially embedded research practices (OECD, 2020). A growing body of literature highlights the critical role of transdisciplinary approaches in urban planning and urban resilience, showing their effectiveness in addressing multifaceted challenges, including public health, climate change, social vulnerability, and sustainable development. The transdisciplinary approach is a problem-solving methodology specifically designed to address the complex and interconnected societal challenges of the contemporary world. It involves engaging with complexity, acknowledging multiple scientific and societal perspectives, generating actionable knowledge, and bridging the gap between academic understanding and practical application to produce outcomes that are both scholarly and socially relevant (Hirsh Hadorn, 2008). This approach relies on the collaboration of community organisations, private enterprises, and policymakers to co-create knowledge and solutions that are contextually meaningful and implementable. By transcending traditional disciplinary boundaries, transdisciplinarity produces insights that are simultaneously scientifically rigorous and socially applicable.

The transdisciplinary process is iterative and non-linear, requiring the formation of diverse teams that combine disciplinary expertise with practical experience. Engaging relevant stakeholders throughout every stage of research—from the formulation of questions to the integration and evaluation of results—is essential. The process often necessitates negotiation and dialogue among participants with different knowledge bases, assumptions, and interests (OECD, 2020).

Research on transdisciplinary planning has explored a wide range of applications, including urban planning, sustainability, healthier urban environments, and the interaction between Global North and Global South contexts (Després et al., 2011; Pärli, Fischer, and Lieberherr, 2022; Lawrence, 2022). As summarised in Table 3, these studies illustrate key aspects of transdisciplinary planning research, highlighting its capacity to integrate diverse academic disciplines with non-academic stakeholders to collaboratively address complex societal challenges (Table 3).

Table 3. Transdisciplinary Planning Research Focus Areas

- Integrative knowledge production combining academic and non-academic insights
- Collaborative stakeholder engagement as co-producers of knowledge
- Iterative, flexible research processes tailored to complex societal problems
- Development of actionable knowledge that informs policy and practice
- Emphasis on sustainability and societal relevance in research outcomes
- Addressing challenges in research system structures and cultural contexts

3.1. Transdisciplinary approaches in urban resilience

Urban resilience research underscores the critical role of participatory and transdisciplinary approaches in enhancing cities' capacity to respond to social and environmental shocks, such as floods, climate change, and other urban stresses. Central to this is the integration of diverse perspectives and knowledge domains, the promotion of social innovation, and the strengthening of multi-stakeholder collaboration—core components of co-creation and participatory urban planning. These processes enhance both the adaptive capacity and the legitimacy of urban governance. International frameworks, including the United Nations 2030 Sustainable Development Goals, stress the importance of fostering trust, transparent communication, and meaningful participation, particularly among marginalised communities (United Nations Framework Convention on Climate Change, 2015; United Nations, 2015).

However, implementing transdisciplinary research faces several challenges. Disciplinary silos, institutional constraints, and the complexity of integrating heterogeneous knowledge systems can impede progress. Moreover,

methodologies developed in Western contexts are often not directly transferable to developing countries, highlighting the need for context-sensitive approaches (OECD, 2020). Despite these obstacles, transdisciplinary planning is widely regarded as a transformative strategy, capable of overcoming the limitations of fragmented disciplinary work and top-down planning. By integrating diverse stakeholders and knowledge systems, it provides a framework for addressing the complexity and uncertainty inherent in urban environments, including climate-related risks and social inequalities, thereby facilitating more sustainable and equitable urban futures (Karaman, 2022).

Research on transdisciplinary planning in the context of urban planning and resilience highlights its effectiveness in generating inclusive, proactive, and integrated solutions to complex urban challenges. By engaging multiple stakeholders and knowledge domains in collaborative processes, transdisciplinary approaches enhance cities' capacity to promote health, sustainability, and resilience amidst growing urban complexities (Lawrence, 2022; Karaman, 2022). These methods have also been applied in spatial planning education (Van der Knaap, 2022) and in managing collaborations between universities and municipalities (Brink et al., 2018).

The concept of urban resilience requires attention to interrelated dimensions such as social equity, environmental sustainability, and economic stability. Transdisciplinary approaches allow cities to address these dimensions holistically—considering environmental, social, cultural, and economic factors within a unified framework. Incorporating diverse perspectives has been shown to produce more robust and durable solutions. Unlike tactical urbanism, which often focuses on short-term, immediate interventions, transdisciplinary strategies aim for long-term structural change, addressing systemic issues through coordinated planning and sustained action. This enables the creation of comprehensive resilience strategies capable of withstanding future shocks. A key feature of transdisciplinary methods is the emphasis on inclusive stakeholder engagement, ensuring that marginalised communities and non-expert voices are actively involved in decision-making. Such inclusivity is essential for developing equitable solutions that garner broad support, which is critical for the success and legitimacy of urban resilience initiatives (Figure 2).

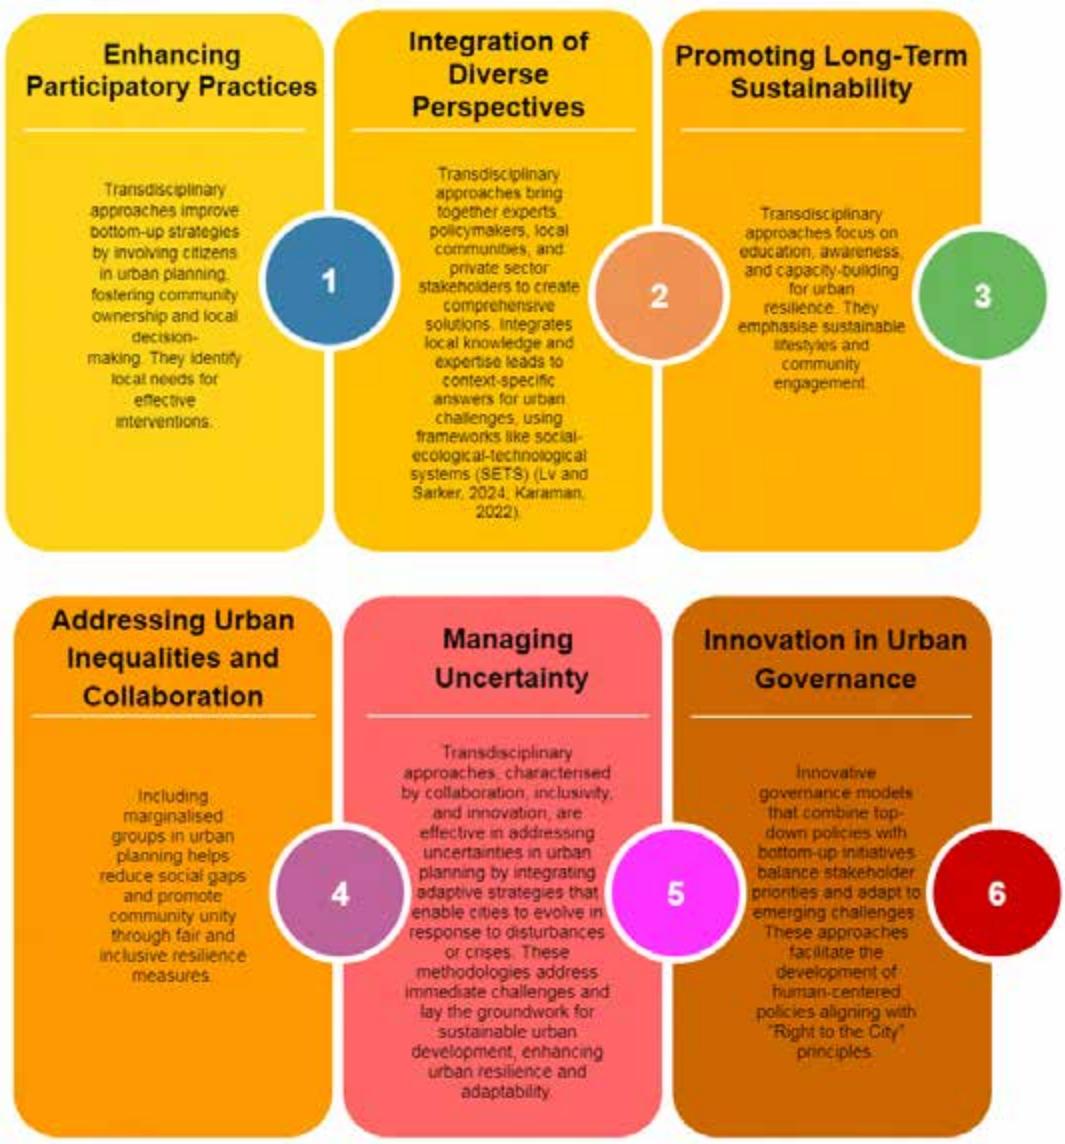

Figure 2. Transdisciplinary approaches promote different dimensions of urban resilience

This figure illustrates how transdisciplinary approaches enhance multiple, interconnected dimensions of urban resilience, including ecological, social, economic, and institutional aspects. By fostering collaboration among diverse stakeholders and integrating knowledge across disciplines, transdisciplinary practices enable cities to:

- Strengthen ecological resilience through sustainable resource management and environmental regeneration;
- Enhance social resilience by empowering communities and encouraging inclusive participation;
- Support economic resilience via innovation, adaptability, and equitable growth; and,
- Bolster institutional resilience through adaptive governance and cross-sectoral cooperation.

Transdisciplinary approaches also encounter several significant challenges. Integrating knowledge across diverse disciplines often proves complex, requiring not only methodological flexibility but also a shared conceptual framework among collaborators. Coordinating multiple stakeholders—each with distinct priorities, institutional constraints, and professional languages—can further complicate the process. Additionally, the substantial time, financial investment, and institutional commitment required for transdisciplinary initiatives may pose considerable barriers, particularly for cities operating with limited budgets or insufficient political support.

3.2. Transdisciplinary practices in Türkiye

Turkish cities have increasingly implemented human-centered policies, participatory practices, and urban rehabilitation initiatives aimed at strengthening both social inclusion and urban competitiveness. These efforts have enabled cities to enhance their global standing while safeguarding citizens' rights and promoting sustainable development. According to the 2014-2023 Istanbul Regional Plan (2016), improving urban resilience requires the integration of interdisciplinary collaboration with bottom-up participation. This plan marked a shift toward a more tailored, inclusive, and locally driven model of regional development. It was developed through the joint efforts of the Ministry of Development, academic institutions, local governments, and non-governmental organisations (NGOs). The plan adopted an interdisciplinary framework, emphasising stakeholder engagement and the co-production of knowledge to generate innovative solutions for sustainability and resilience in Istanbul.

Similarly, the Urban Renewal Project sought to merge bottom-up urban concepts with participatory mechanisms for urban rehabilitation and development. Although the project fell short in meeting the essential needs of local communities, it nonetheless incorporated participatory and community-based strategies into urban transformation processes—addressing challenges such as illegal construction, disaster risk, and uncontrolled urban expansion (Yılmaz Bakır, 2020). However, while interdisciplinary and multidisciplinary frameworks have been widely utilised in Türkiye's planning and development initiatives, transdisciplinary approaches—which move beyond disciplinary boundaries to foster genuine co-creation between experts and communities—have yet to be systematically integrated into these processes (Özdamar and Önay, 2024).

According to Arslan and Kaya Erol (2023), the Turkish planning system lacks a legal framework for participation because it is necessary to create flexible and legal frameworks that incorporate participation arrangements in planning and design to build a knowledge and experience base for participatory-oriented design. The development of comprehensive solutions for complicated problems like disaster preparedness and fair resource allocation is made possible by transdisciplinary approaches, which encourage cooperation between technical specialists, local communities, and legislators. However, the development of cooperative platforms that bring together sociologists, architects, and inhabitants in co-design processes is essential to the success of this approach (Özdamar and Önay, 2024). It has been shown that implementing a transdisciplinary approach is a successful tactic for breaking down silos. A key component of the process is the integration of knowledge. In order to build a resilient neighbourhood, for example, engineering, sociology, ecology, and economics must be integrated (Breaking Down Silos: Collaboration Across Disciplines).

While not specific to a particular city, these examples demonstrate efforts to incorporate transdisciplinary and bottom-up approaches in urban planning and development. The overarching objective of these initiatives is to enhance urban resilience, strengthen local communities, and reduce urban inequalities by promoting collaboration, incorporating multiple perspectives, and involving local communities in decision-making processes (Özdamar and Önay 2024).

While the participatory experiments conducted in Türkiye represent a departure from rigid top-down models, the efficacy of these experiments in building resilience is contingent upon the systemic integration of transdisciplinary collaboration and ICT-enabled inclusivity. It is argued that, by anchoring design-thinking processes in empathy and shared expertise, Istanbul's urban transformation could evolve into a model of adaptive, citizen-centred planning that is globally replicable. Transdisciplinary approaches have the potential to significantly enhance urban resilience in Türkiye by addressing complex urban challenges through integrative, participatory, and innovative strategies.

4. Tactical Urbanism vs. Transdisciplinary Approach

While both tactical urbanism and transdisciplinary approaches play vital roles in advancing urban resilience, they differ markedly in their focus, scale, and methodology. Tactical urbanism is characterised by its immediacy, flexibility, and low-cost implementation—emphasising short-term, community-driven actions that can quickly address local needs and test new ideas. In contrast, transdisciplinary approaches operate at a broader and

more complex level, integrating multiple fields of knowledge and stakeholder perspectives to develop long-term, systemic strategies for sustainable urban transformation (Table 4).

Table 4. Differences Between Tactical Urbanism and Transdisciplinary Urban Approaches

		Tactical urbanism	Transdisciplinary Approaches
1	**Temporary vs. Long-Term Solutions**	Short-term interventions (Karaman, 2022)	Systemic, long-term resilience (Karaman, 2022)
2	**Scalability and Impact**	Hard to scale up Tactical urbanism, like parklets, can be scalable but must be mindful of their limitations in addressing systemic issues in urban areas.	Bigger impact Transdisciplinary initiatives are conceived with the objective of achieving a more substantial impact.
3	**Community Engagement Models Ownership**	Grassroots-driven (Karaman, 2022; Mohankumar, 2020) Value community input. Starts with the community Tactical urbanism, a cost-effective strategy, emphasises community engagement as a fundamental element in its implementation.	Institutional collaboration (Karaman, 2022; Mohankumar, 2020) Value community input. Need to involve community members Although transdisciplinary projects require significant resources, their long-term benefits and transformative potential make such investments highly worthwhile.
4	**Cost-Effectiveness and Resource Allocation**	Cost-effective	Require more resources
5	**Scale and Scope**	Focuses on small, localised Interventions that are swift and cost-effective, often focusing on specific issues in specific neighbourhoods.	Operates on a larger scale, addressing systemic urban challenges and requiring coordination across various sectors and levels of government.
6	**Flexibility vs. Structure**	Thrives on flexibility, experimentation, and immediate action, allowing for rapid adaptation based on real-time feedback, a critical aspect of urban planning and management in dynamic environments.	Prioritises structured collaboration and long-term planning, often requiring more time and resources to develop comprehensive solutions.
7	**Community vs. Expert-Centric**	Primarily driven by community involvement, often with little reliance on experts or formal planning processes.	Integrates expert knowledge across multiple fields, while still emphasising the importance of community participation and inclusivity.
8	**Who Can Use?**	Urban planners can use tactical urbanism to test ideas.	Policymakers can support transdisciplinary projects.
9	**Adaptability to Climate Challenges**	They both address climate change-induced risks like rising water levels and extreme weather events (Lv and Sarker, 2024) (Karaman, 2022).	

Despite the apparent distinction between tactical urbanism and transdisciplinary approaches, these frameworks are not mutually exclusive. When applied together, they can reinforce one another, strengthening urban systems and enhancing their resilience. Both approaches demonstrate their effectiveness through the empowerment of communities: tactical urbanism serves as an experimental platform for testing localised ideas, while transdisciplinary approaches integrate these experiments into broader, long-term strategies for urban sustainability and resilience. Likewise, insights gained from transdisciplinary collaboration can inform and scale tactical interventions, ensuring their coherence with wider resilience objectives.

4.1. Challenges in Türkiye

Despite the increasing emphasis on bottom-up strategies and tactical urbanism in Türkiye, notable shortcomings persist in how these approaches are conceptualised and implemented. A transdisciplinary framework is proposed as a means to enhance their effectiveness by fostering deeper collaboration across sectors and knowledge domains. One of the primary obstacles to active participation in Türkiye is the highly centralised administrative system, which necessitates the development of alternative models to facilitate genuine and continuous collaboration (İzci and Geylani, 2021). Within this context, the participatory democracy model envisions citizens as proactive agents in governance processes (Tekeli, 2012). Although numerous reforms have introduced new mechanisms aimed at promoting openness, transparency, citizen participation, and decentralisation, these efforts often remain procedural rather than transformative. To advance participatory governance, policymakers and public authorities should prioritise establishing platforms that enable sustained, interactive engagement—supported by regulatory frameworks and strategic policy proposals. However, given the limited success of such initiatives to date, it is essential to strengthen citizens' involvement in parliamentary committees and to encourage voluntary collaboration with city councils and civil society organisations. Ultimately, this approach seeks to cultivate sustainable and resilient communities by nurturing open systems of governance grounded in shared responsibility, inclusivity, and collective learning.

4.2. Implementation strategies for synergy between tactical urbanism and transdisciplinary approaches

By adopting these strategies and emphasising participatory processes, Türkiye can cultivate more resilient cities capable of confronting complex urban challenges while advancing long-term sustainability. Empowering local communities, fostering collaboration, and engaging diverse perspectives have proven effective in addressing multifaceted problems and generating more inclusive, context-sensitive solutions. This vision is achieved through strengthening stakeholder cooperation, integrating local knowledge and expertise, and promoting sustainable living practices via community education initiatives. As illustrated in Table 5, the following dimensions are crucial for establishing a productive synergy between tactical urbanism and transdisciplinary approaches.

Table 5. Building synergy between tactical urbanism and transdisciplinary approaches

Balancing Priorities	When implementing both bottom-up and transdisciplinary approaches, it is critical to strike a balance between competing priorities and interests among stakeholders. This requires; • Empowering local communities • Encouraging collaboration • Engaging diverse perspectives
Stakeholder Collaboration	Fostering stakeholder collaboration is essential for addressing complex urban challenges and promoting long-term urban resilience and sustainability. This can be achieved through; • Engaging local knowledge and expertise • Promoting sustainable lifestyles through community education initiatives • Creating awareness among local governments and citizens
Training and Knowledge Transfer	Architects, planners, and researchers need to receive training and experience in knowledge transfer. Design research should be recognised as a legitimate method of knowledge generation to address emerging issues of urban sustainability and resilience (Eker, 2022).

Implementing both bottom-up and transdisciplinary approaches simultaneously requires careful negotiation among diverse stakeholders to balance competing priorities and interests. Empowering local communities, fostering collaboration, and integrating multiple perspectives have consistently proven effective in tackling complex urban challenges and generating inclusive, sustainable solutions. Achieving this necessitates cultivating cross-sectoral cooperation, mobilising local knowledge and expertise, and promoting sustainable lifestyles through community education initiatives. Such an integrated approach enables the formulation of adaptive strategies that respond to immediate needs while fostering long-term urban resilience and sustainability.

A promising pathway for combining these methodologies lies in participatory planning, which actively engages communities, experts, and institutions in shaping urban interventions. Tactical urbanism can act as a catalyst for community engagement—creating opportunities for experimentation and collective learning—while transdisciplinary approaches provide the overarching framework that aligns these small-scale actions within a coherent, strategic vision for the city's future.

The synergy between tactical urbanism and transdisciplinary approaches merits further study. For instance, in a flood-prone city, temporary rain gardens could serve as tactical interventions demonstrating quick adaptation, while transdisciplinary collaboration among experts and residents could develop long-term water management strategies. Insights from these short-term actions would refine broader plans, illustrating how iterative, integrated practices can foster resilient, adaptive, and community-driven urban environments.

6. Conclusion

In the context of Türkiye, it is essential to draw on the insights gained from both tactical urbanism practices and inter/transdisciplinary approaches to counterbalance the impacts and limitations of top-down planning initiatives. Urban planners can play a transformative role in this process by raising awareness among local authorities and citizens, thereby shaping the trajectory and outcomes of urban interventions. Building urban resilience requires diverse, multifaceted pathways that embrace innovation and collaboration. Tactical urbanism represents a flexible, grassroots-driven strategy that facilitates rapid and localised responses to urban challenges, while transdisciplinary approaches provide a more systematic, long-term framework for addressing the complex and interrelated problems cities face. By recognising the respective strengths and constraints of these two approaches, cities can integrate them to cultivate urban environments that are both resilient to

present challenges and adaptable to future uncertainties.

Democratic participation extends beyond the simple involvement of citizens or local authorities; it requires the establishment of an integrated and coherent system capable of realizing a city's collective aspirations. The "right to the city" is grounded in egalitarian principles, rejecting hierarchical structures that privilege certain groups over others. Instead, it evolves through a dynamic redistribution of power and shared responsibility. Crucially, both transdisciplinary approaches and tactical urbanism must orient themselves toward the creation of regenerative cities—urban systems that merge long-term ecological renewal with short-term resilience. Such cities cultivate ecosystems that sustain themselves, foster circularity, and support the well-being of all forms of life, not only humans. Achieving this vision requires equitable and inclusive planning and design processes grounded in community-centered prosperity. However, a critical debate arises regarding the extent to which tactical urbanism and transdisciplinary approaches can effectively operate in tandem. In some contexts, these strategies may be appropriated by local governments as symbolic gestures that only partially fulfil the "right to the city." In this regard, the transdisciplinary approach may hold deeper transformative potential—emerging as an inherently grounded and long-term pathway toward realizing a genuine and enduring "right to the city."

Abstract
When broadly defined, urban form is a key dimension of planning, directly tied to the challenges of 21st-century urbanization. In France, municipalities and metropolitan areas use the Local Urban Plan (PLU) as a powerful tool to move beyond outdated functionalist approaches. For these plans to engage meaningfully with urban form, however, their baseline assessments must identify the strengths and weaknesses of built forms and their multiple connections to related issues. Yet the French Urban Planning Code remains vague on both the content and methodology of such assessments, resulting in varied and often inconsistent practices. A comparative textual analysis, supported by an analytical grid applied to diagnostics from Lille, Bordeaux, and Lyon, shows that urban form is generally reduced to physical features of the built environment. However, it belongs to a broader systemic perspective, which is unevenly recognized across the documents. The absence of standardized protocols, spatial analyses, and detailed cartography reflects the lack of a shared framework—ultimately limiting these cities' ability to produce robust, spatially informed strategies.

Keywords: Urban form in planning; Baseline Assessments; Human practice in public space; Urban morphology theories; France

1.Urban Form, Public Space, and the Limits of Baseline Knowledge in French Planning

In a changing global context, 21st-century cities face both new and enduring challenges — in France, as elsewhere in the world. The impacts of climate change and socioeconomic tensions at all scales demand more resource-conscious urban development models centered on human needs. At the same time, the complexity of urban systems challenges planning practices, pointing to inevitable interconnections between geographic scales and policy domains. The United Nations' New Urban Agenda (UN-Habitat, 2017) calls for a fundamental reorientation of planning goals and approaches. After decades of functionalist urbanism, urban form is increasingly recognized as a key driver of cost efficiency, ecological performance, and social sustainability. Its spatial dimensions — from the human scale to the integration of metropolitan infrastructures — are now seen as essential to achieving inclusive, integrated, and environmentally responsible urbanisation. Together with buildings and building codes, the New Urban Agenda identifies urban public space as a key element of the form of the human-centred sustainable city. It is explicitly recognized in the new urban paradigm and is the focus of eight specific planning commitments.

How can the solemn commitments of the New Urban Agenda be translated into operational practice? National planning cultures, along with differing priorities across urban contexts, inevitably shape how this question is answered in practice. A central issue lies in the specific forms of knowledge that are mobilized in the conception of plans and policies.

Since the foundational work of Patrick Geddes (1915), planning has relied on preliminary assessments (civic surveys, in his terms) to build a shared understanding of the urban condition. In France, since 2000, the core document of local planning has been the Local Urban Plan (Plan Local d'Urbanisme – PLU)[1], which articulates a municipality's overall spatial development strategy. It must be grounded in a baseline assessment (diagnostic territorial), often informed by the expertise of public urban planning agencies. Unlike the highly functionalist Land Use Plan (Plan d'Occupation des Sols – POS)[2] it replaced, the PLU is intended to address a broader set of local

1 Due to resource constraints, Local Urban Plans (PLU) were initially implemented in cities within major urban areas. It was only later that Intercommunal Local Urban Plans (PLUi) were extended to rural territories. By 2019, 49% of French municipalities were covered by a PLU, representing 89% of the national population (CEREMA, 2020).

2 Adopted under the Land Use Planning Act (Loi d'Orientation Foncière, LOF) in 1967, the Land Use Plans (Plans d'Occupation des Sols, POS) remained in effect until 2000, when the Solidarity and Urban Renewal Act (Loi Solidarité et Renouvellement

challenges: limiting the consumption of natural and agricultural land, ensuring access to quality housing, fostering economic activity, improving mobility, adapting to climate change, enhancing public space, and more. The integration of Development and Planning Guidelines (Orientations d'Aménagement et de Programmation – OAP)[3] within PLUs reflects the ambition of local authorities to adopt more qualitative, spatially sensitive planning tools, often engaging with urban design.

In France, as in many other countries, the baseline assessments that informed functionalist plans like the POS were primarily focused on managing the demands of urban growth. Their main goal was to evaluate population trends, future needs for public services, land for housing and employment, and infrastructure development. Quantitative standards were introduced for the provision of green space, public facilities, parking, and of course Floor Area Ratio (FAR), typically without regard for the spatial configuration of the urban fabric. These assessments rarely engaged with issues of urban form — except in designated heritage districts. The Malraux Law (1962) introduced Conservation and Enhancement Plans (Plans de Sauvegarde et de Mise en Valeur – PSMV) for historic centers, where assessments necessarily addressed urban form to justify preservation (Merlin and Choay, 2015). This contributed to a lasting association between urban form and heritage, often focused on visible stylistic and architectural features.

Since the 1960s, an extensive body of academic literature has explored how urban form shapes spatial structure, human behavior, and the social and symbolic dimensions of urban life. The early work of urban morphologists such as Muratori (1960) and Conzen (1960) focused on historical cities, but later scholars extended the scope to contemporary urban contexts (Lynch, 1960; Jacobs, 1961; Alexander, 1965; Rossi, 1966; Newman, 1972; Hillier and Hanson, 1984; Hillier, 1996; Salingaros, 2005). Over time, this literature has come to advocate for human-centered urban environments (Alexander 1979; Lynch, 1981; Gehl, 2011). Recent meta-analyses (Carmona 2018) synthesize empirical findings to highlight how urban form directly influences the usage value of space and the nature of everyday urban practices. Nevertheless, urban form remains marginal in many baseline assessments of French urban plans. To understand why, it is necessary to trace the intellectual and institutional trajectory of form-based thinking within the French planning context.

The emergence of urban morphology as an interdisciplinary field in France was explicitly intended to raise awareness of urban form among planners and designers (Vernez-Moudon, 1997). Despite the academic importance of the French school, best known as "école de Versailles" (Panerai et al., 1997; Panerai et al., 2004), urban morphology was the subject of strong critique from leading voices in the planning establishment (Merlin, 1984). These critiques shaped both academic legitimacy and practical influence, particularly during the 1980s and 1990s (Fusco, 2023). It was only at the end of the 1990s and beginning of the 2000s, within the new agenda of sustainable urban development, that urban form re-emerged in official discourse. The French Ministry of Ecology — also responsible for planning — and various research bodies began to reframe urban form through related themes: densification (Wiel, 1999), walkability and public space use (CEREMA, 2021), and landscape or townscape quality (MEDDE, 2015).

However, the French Urban Code remains relatively ambiguous regarding the integration of urban form in baseline assessments. While the assessment must anchor the plan in demographic and economic trends, it is also required to address landscape — including its forms and perceptions — as well as infrastructure and mobility systems. Densification potential must be assessed "while taking into account urban forms." In contrast, public space, although now central to the objectives of many PLUs, is not explicitly listed as a required theme in the baseline assessment. PLUs must include by law objectives related to the improvement of public space, the promotion of social cohesion, and the spatial coherence of streets, squares, sidewalks, vegetation, and other elements — indicating a growing association between public space and urban form. Yet, at the diagnostic stage, these concerns remain optional or inferred rather than obligatory.

Urbain, SRU) replaced them by PLU, also establishing a minimum quota of social housing in each municipality (Merlin and Choay, 2015).

3 Flexible components of Local Urban Plans (PLU), Orientation and Planning Guidelines (OAP) translate planning objectives into operational and qualitative terms. They may focus on a specific area, a particular theme, or both (CEREMA, 2023).

Within this contradictory framework, a few pioneering local authorities began to address urban form — most often through the lens of public space strategies or densification policies. Lyon took an early lead in both areas: since the 1990s, it has combined urban renewal with the requalification of public space as a structuring tool (Cosnier, 2001). It was followed by ambitious regeneration in Lille and the transformation of Bordeaux into a walkable, design-oriented metropolis, where the quality of public space became a central component of urban marketing. In each case, planning agencies produced studies, charters, and frameworks — often non-regulatory, and not always integrated into PLUs — that nonetheless helped shape local debate.

It is therefore legitimate to ask: to what extent have these form-conscious strategies influenced the baseline assessments of the PLUs in these three cities? This is the central question of the present paper, which also examines how different dimensions of urban form thinking are represented and interrelated within official planning documents.

The remainder of this paper is structured as follows. Section 2 defines the concept of urban form as it will be used in this study, identifying the key components that will guide our analysis of baseline assessments. Section 3 presents our methodology for analyzing planning documents from Lyon, Lille, and Bordeaux. Section 4 reports the results of this analysis. Section 5 offers a comparative synthesis and critical discussion of the findings. Finally, Section 6 concludes the paper and outlines directions for future research and policy development.

2. Framing Urban Form for Planning Analysis

Urban form has long been a subject of debate in urban planning. Several studies have offered critical insights and proposed alternative approaches. Four main perspectives have proven particularly fruitful: the need to go beyond reducing urban form to the urban fabric alone; the view of street networks as dynamic systems, not just mobility infrastructures; the concept of landscape as a way to connect natural and built environments; and the focus on uses—especially public space uses—as key to understanding and designing cities.

In France, Lévy (2005) was among those who most clearly challenged the narrow definition of form in urban morphology. Here, it is often limited to the relations between buildings, parcels, and street grids at fine scales, or to major urban layouts. According to Lévy, these represent only two dimensions—fabrics and structural layouts—whereas urban form is inherently multifaceted and polysemic. Earlier (Lévy 1999), he also criticized the tendency to focus on historic city centers, overlooking vast areas shaped by more recent urbanization.

Configurational approaches to street networks (Space Syntax, Hillier 1996) allow for computational analysis of entire metropolitan areas. But their value goes beyond digital modeling. They offer a new analytical lens—focused on the topological properties of networks in relation to mobility, social interaction, and spatial control. Contrary to Lévy (2005), Fusco (2018) considers the configuration of street networks as an additional dimension of urban form. Space Syntax reverses the usual perspective: it prioritizes the spatial void of public space over the built environment. Yet this focus is not new. Camillo Sitte (1889), an early figure in urban morphology, already placed public space at the heart of his thinking. The novelty of configurational methods is the multi-scale analysis of the complex network of public space in the city.

The landscape approach also deserves attention. Spatial analysis lends itself well to reading both urban (cityscape) and natural/rural (townscape) forms through the lens of landscape. Early urban morphologists drew inspiration from rural geography and its analysis of landscape units—highlighting the intellectual overlap between fields. This overlap is even more evident today, as diffuse urbanization, green and blue networks, and urban agriculture form complex continuums between urban, peri-urban, and rural forms. Capturing this complexity is essential.

A final shift has come from the humanistic turn mentioned earlier. Since the work of Jacobs (1961), Alexander (1977), and Gehl (1971), urban form can no longer be reduced to geometry. What matters is spatial affordance

(Gibson 1979)—how form enables or constrains action, whether in motion or at rest. This refocuses attention on public spaces that are accessible and usable by many, and on the affordances of different mobilities—walking, cycling, or driving. More broadly, it raises the issue of human scale and conviviality, in Illich's sense (1973): urban forms that support autonomous, creative use of space without heavy reliance on technology.

Indeed, Lévy has also outlined other dimensions of urban form: visual and material landscapes (corresponding to the already mentioned landscape approach), the spatial distribution of populations and functions (social morphology), and bioclimatic form—how the physical arrangement shapes environmental phenomena.

All these dimensions of urban form intersect with key planning concerns: housing, socio-spatial inequalities, health, economic development, tourism, retail, energy, risk management, pollution, and more. But this expanded view also brings a risk: turning urban form into a catch-all category, compensating for its earlier reduction to fabric alone. How, then, should urban form be understood?

A good starting point is to examine how urban form is addressed in the baseline assessments of French local urban plans (PLU). Given the diversity of existing approaches, looking at the operational practices of local governments can help reveal both limitations and opportunities, and suggest ways forward.

In this light, and building on the perspectives above, we propose four entry points to analyze how PLU assessments frame urban form:

- **Urban fabrics**, including building typologies—whether analyzed through their historical layers, heritage value, or functional aspects (housing, densification, etc.);
- **Public spaces**, with attention to their qualities, usages and degrees of conviviality;
- **Natural spaces**, as components not only of natural landscapes, but also of urban ones, structured by the ecological connections that link them together;
- **Mobility networks**, including transport infrastructure such as stations, terminals, and parking, which strongly influence both urban fabric and landscape.

Because of their clear intent to develop a more complex understanding of the city—its forms, functions, and uses—the metropolitan areas of Bordeaux, Lille, and Lyon have been chosen for focused analysis. In France, these cities are seen as pioneers in efforts to observe and reshape the city through the lens of public space. The baseline assessments in their local urban plans (PLU) are examined in the following sections, first individually, then comparatively, to identify shared insights and common directions.

3.Analyzing How Urban Form Is Framed in the Baseline Assessments of Local Urban Plans

Our analysis of the baseline assessments (diagnostics) from the local urban plans (PLU) of Bordeaux (2016), Lille (2024), and Lyon (2019) followed a two-phase approach. The first phase consists of a textual analysis of the occurrences of the keywords "urban form(s)" and "morphology(ies)," to understand how these terms are used in the documents (3.1). The second phase involves a deeper reading of the texts to examine how urban form is addressed, even when it is not explicitly named (3.2). For this second phase, we used a conceptual graph as a heuristic tool, structured according to a predefined evaluation grid. This method was chosen for its ability to represent complex interrelations between concepts and their uses (3.3).

3.1.Phase 1: Keyword Occurrence Analysis

The terms "urban form(s)" and "morphology(ies)"—whether singular or plural—appear in all three baseline assessments. For "morphology(ies)," we only considered occurrences related to urban morphology, excluding unrelated uses (e.g. river morphology or household composition).

The table below shows the number and frequency of keyword occurrences in the three documents. Overall, while the absolute number of "urban form(s)" references varies—partly due to differences in document length—the

frequency is similar for Lille and Lyon, but nearly cut in half for Bordeaux. As for "morphology(ies)," it is almost absent from the Lille and Bordeaux assessments, while present in Lyon's.

Table 1 : Occurrences and frequencies of selected keywords in PLU baseline assessments.

	Lille	Bordeaux	Lyon	Total
Page Count	**214**	**190**	**660**	**1 064**
Occurrences				
Urban Form: Forme(s) urbaine(s)	14	7	48	69
Urban Morphology: Morphologie(s)	1	0	20	21
Frequencies (= occurrences / page count * 100)				
Urban Form: Forme(s) urbaine(s)	6,5	3,7	7,3	6,5
Urban Morphology: Morphologie(s)	0,5	0	3,6	2,3

For each occurrence, we identified how the term was defined and what issue or policy domain it was connected to. For example: is "urban form" mentioned in support of densification strategies to limit sprawl and soil sealing? Or is urban morphology discussed in relation to urban greening and climate adaptation? These recurring themes are explored further in section 3.2.

The low frequency—or near absence—of terms directly linked to urban form in some cases confirmed the need for a second phase of analysis.

3.2.Phase 2: Item Analysis Using a Conceptual Grid

To deepen our understanding of how urban form is handled in the three assessments, we developed an analytical grid to extract, describe, and interpret elements referring to urban form and morphology—even when the terms themselves are not used.

The grid is structured around three guiding questions that helped extract and interpret concepts:

1. Content: what is being addressed? What does each assessment actually say about urban form? Are the elements presented in isolation, or are links made between them? While not all assessments address urban form directly, the analysis of fabrics, public spaces, natural areas, and mobility networks contributes to capturing urban morphology in its physical and qualitative dimensions, as previously stated.

Following this logic, Alexander et al. (1977) approached urban form as a set of interrelated elements, giving rise to a "pattern language." Inspired by this, we extracted items related to the core components of urban form—typically discussed as fabrics, public spaces, natural areas, and mobility networks. The goal was to detect the "language" each city might have developed.

We thus followed the anthropological distinction (De Sardan, 1998), between emic and etic perspectives: terms and logical categories used by the surveyed human group vs those used by the researcher. We treated all extracted elements as equally important, preserving the terminology used in the original texts (emic perspective). The researcher's only role was to assign each item to one of the four pre-identified domains.

To go beyond a simple list, we mapped the items and their connections—causal links, composition, association, reciprocal implication, etc.—into concept graphs. Each document produced four such graphs, one per domain. By analyzing the links within and across graphs, we could reconstruct how each assessment implicitly or explicitly

addresses urban form. Items appearing in multiple graphs were duplicated and linked to show identity.

2. Evaluation: are the elements assessed? Does the baseline assessment lead to an explicit evaluation of the various elements it describes? And how does it characterize them? An assessment cannot be limited to a neutral description, a snapshot of existing conditions, or an inventory of features. Beyond mere observation, an evaluation is expected—at a minimum through plain-language judgments, and ideally through a reproducible protocol that can guide public decision-making as part of the PLU development process.

This kind of protocol-based evaluation typically involves either a qualitative or quantitative scale. It may establish a threshold to distinguish what is considered "good" versus "less good," or define minimum or maximum standards that help assess how far the current state of the space deviates from an ideal or target condition. Evaluation, in this sense, depends on the reference framework adopted, which is itself chosen to focus and structure the diagnostic process.

For each element extracted from the baseline assessments, we therefore recorded whether it was subject to an explicit evaluation and whether this evaluation was framed in positive or negative terms. In doing so, we aimed to understand not just what is observed, but also how it is valued—what is considered desirable or problematic within the documents.

3. Spatialisation: are the elements mapped? Are the elements spatially located, and if so, how are they represented cartographically? Spatialization—especially through maps—is a powerful tool in planning, particularly during diagnostic phases (Debarbieux and Lardon, 2003; Lascoumes, 2007). It enables a transition from isolated evaluations to a spatial overview that reveals patterns, which can be recognized as strengths of weaknesses.

Urban form is inherently spatial and scale-dependent. Smaller-scale forms combine to create larger ones. For instance, mapping the walkability of public space at a fine scale can show whether pedestrian-friendly corridors create a coherent network across the city (Mezoued, 2020).

To assess spatialization, we noted whether items were mapped, whether the spatial granularity was coarse or fine, and whether maps used full choropleth coverage or focused on specific zones.

These three criteria—content, evaluation, and spatialization—form the analytical grid through which we read and interpreted the three baseline assessments. To make the results of this analysis more legible and comparable, we translated the grid into a visual format, using a standardized legend (Figure 1) to guide the construction of the graphs. This graphical coding system allowed us to represent, in a consistent way, how each element was addressed in the documents across the different dimensions of analysis.

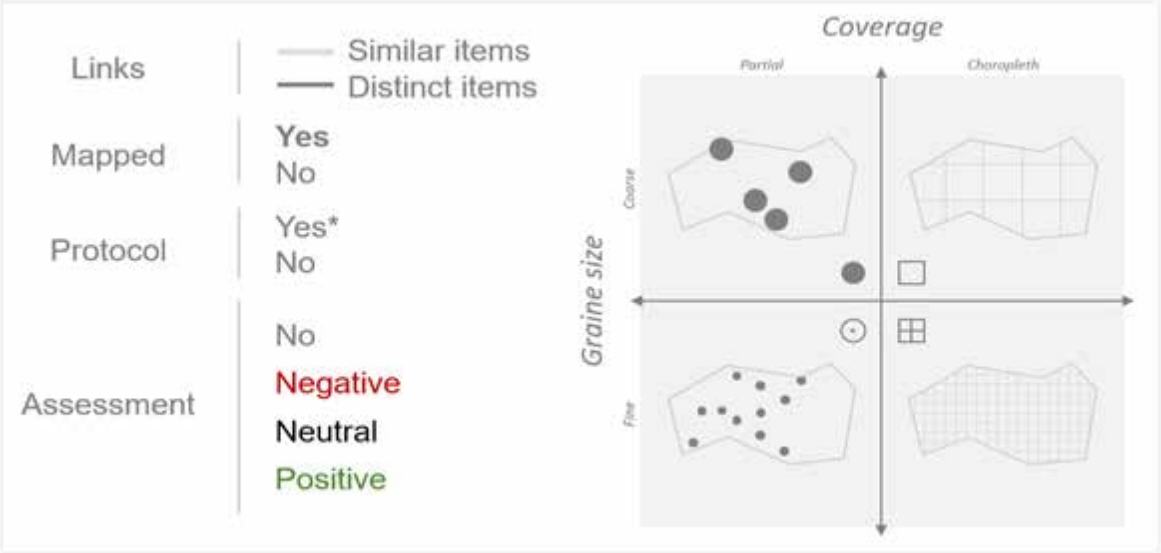

Figure 1 : Constitutive elements in the legend of graphs

This graphical language was used to produce the concept graphs presented and discussed in Section 4. The graphic representation is a heuristic visual method: graphs serve both as visual summaries of dense textual material and as tools for analysis. In short, drawing the concepts helped us understand them. These graphs aim to make visible—however imperfectly—how urban form is perceived and addressed in each document.

3.3.Concept Graphs: Strengths and Limits

It's important to clarify what the graphs represent. They do not depict the actual urban systems of the cities, nor do they reflect the full knowledge of local authorities. Instead, they show how the assessments express their understanding of urban form—filtered through our own reading.

For example, while there is a clear link between parking and public space usage, if that link isn't made explicit in the document, it's not shown in the graph. That doesn't mean authors are unaware of it—only that it wasn't articulated.

These results reflect only what is in the texts. A richer understanding would require complementary methods such as interview-based discourse analysis—a promising direction for future research. Very recently, (semi-)automated methods have been developed in this direction, such as those by Salazar-Miranda and Talen (2025) or Arlati and Nagel (2025). However, these methods do not offer a nuanced analysis of grammatical relationships between words or of evaluative and mapping modalities as we do here

Another limitation lies in the nature of the graph itself. It's built incrementally, item by item, and the overall picture may not match how the authors see the subject. In reality, different sections of the assessments are often written by separate teams (in-house or outsourced), coordinated by project managers and steering committees. The graph is thus a reconstructed vision of fragmented statements. It may not reflect a shared consensus among all contributors. It is a partial and situated representation of how a city presents and positions itself on the topic at a given moment.

A final challenge arises from the distinction between items and labels—that is, between the underlying concept (which is general and abstract) and the specific terms used to refer to it. For instance, labels such as "motorway system," "highways," or "major automobile corridors" all refer to the same broader concept: large-scale mo-

bility corridors. Beyond the practical issue of choosing which label to use when adding an item to the concept graph—should it be the most frequent, the most intuitive, or the most precise?—this raises the deeper problem of conceptual ambiguity. That is, how clearly defined is each concept being represented? And how do we deal with the grey areas between similar terms? This is a common difficulty in terminological or ontological approaches (Roche and Papadopoulou, 2020): how do we strike the right balance between grouping together different expressions that refer to the same thing, and avoiding the mistake of merging two distinct concepts just because they sound similar or are used interchangeably?

To manage these issues, we applied a few guiding principles. First, we started from a list of concepts drawn from the academic literature, but remained open to including more specific terms found in the actual planning documents. Second, we kept the original labels (in French) used in the documents, as noted earlier. Third, in constructing the graphs, we prioritized the most commonly used label in each document, to remain consistent with an emic approach—one that reflects the internal logic and language of each local case. This also allowed us to highlight semantic differences between the ways different cities refer to similar concepts, and to make these variations visible in the resulting graphs.

We deliberately chose not to build a full formal ontology, despite the many advantages such a method offers (Keita et al., 2008). In our case, that approach would have flattened the diversity and complexity of the documents we analyzed. Like a palimpsest, these texts carry meaning not only through what they say clearly, but also through their ambiguities, contradictions, and contextual nuances. A formal ontology would risk stripping away those layers and undermining the richness of the source material.

4.Understanding Urban Form in the Metropolitan Areas of Lille, Bordeaux, and Lyon

Following the corpus analysis protocol described above, this section aims to examine the content of the Local Urban Plan (PLU) for each of the selected metropolitan areas, before outlining comparative insights in the next section. Initial observations based on the analysis of textual occurrences are followed by broader and more in-depth reflections drawn from the infographic representation approach using graphs.

4.1.The Lille Case: A Systemic Vision Structured around Core Items, with human uses as the Guideline

In the baseline assessments section of Lille's Local Urban Plan , the term "urban form(s)" (forme(s) urbaines) is primarily mentioned within the typology of urban fabrics developed by Lille's urban planning agency (ADULM, 2017a). This work was carried out in preparation for evaluating the optimization potential of these same fabrics (ADULM, 2017b), in compliance with legislation requiring PLUs to analyze the potential for densification and transformation of all built-up areas, taking into account both urban and architectural forms[4]. A connection is also made with the 2021 Climate and Resilience Act, which sets the Zero Net Artificialization aim (ZAN) by 2050[5]. In this context, the typology proposed by the Metropolitan Authority of Lille (MEL) has the merit of presenting a wide range of urban fabrics at a fine level of granularity—namely the parcel—across the entire administrative territory of the metropolis. However, some aspects are debatable: only a functional approach is used to define fabric types (primarily based on building use), and the classification does not take into account the relationship between buildings and public or open spaces, nor with their broader environment. The concept graph allows to go beyond the limited view of urban form conveyed by these textual occurrences.

Overall, the graph extracted from the text is structured around a few main "core items"—that is, words that hold the most connections with other items—such as metropolis (métropole), major roadways (axes routiers majeurs), parking (stationnement), waterways (voies d'eau), public space (espace public), hemicycle (hémicycle), and fabrics (tissus). The four domains we identified as essential for understanding urban form in a PLU baseline assessments are all represented, though disparities in treatment are evident. There is a lower density of items in the domain of public spaces, and conversely, a higher density in the domain of urban fabrics. These core items are most often

4 Article L151-4 (2022) of the French Urban Code (2025), which frames the content of a Local Urban Plan (PLU).

5 This law prohibits the artificialisation of new agricultural, natural, or forested areas by 2050, requiring municipalities to turn to other urbanisation processes such as densification, renovation, or rehabilitation (Vie publique, 2023).

evaluated and more rarely mapped. They link to a wide range of peripheral items, mostly shown in grey—meaning they are neither evaluated nor mapped.

Moreover, the numerous cross-domain references and relationships reflect a systemic vision of the Lille metropolis. For instance, the hydrographic network (réseau hydrographique), located at the bottom right of the graph, highlights the relationship between built and natural elements through the development of riverside walkways (promenades). Another example is suburban expansion, in the top left of the green cluster dedicated to landscape, which connects with the domains of public spaces and urban fabrics.

In terms of evaluation, lengthy descriptions often accompany the items, sometimes leading to textual assessments. These evaluations are relatively evenly split between positive and negative observations, with some intermediate cases as well. Few evaluations follow a standardized protocol; they typically consist of simple ratios to the population size, followed by comparisons with other French metropolitan areas as part of a benchmarking approach. For example, the total length of the cycling network is compared with that of other major cities. Similarly, parking provision is ranked in comparison with other large French urban areas. This reflects the broader strategy of metropolitan competitiveness observed in France, where each metropolitan authority seeks to highlight its strengths and uniqueness to support its attractiveness.

Finally, some key elements are treated in a particular way.The document provides an in-depth analysis of two main elements. First, the typology of urban fabrics, which accounts for most of the fine-grain maps in the diagnostic, even though these do not undergo a systematic or protocol-based evaluation. Despite the density of items and relationships in this domain, the star-shaped structure of the graph shows few links between the different types. This suggests an image of the city as a juxtaposition of fabric types, rather than an integrated assembly of subtypes forming a complete urban fabric. Second, the notion of centralities (centralités) is also subject to in-depth analysis, again conducted by the Lille urban planning agency. Entirely addressed in a dedicated chapter of the diagnostic, this approach is functionalist: various levels of concentration of functions are identified as centralities based on the availability of amenities and services within a 500-meter grid. The centralities item, located in section of the graph dedicated to public spaces, also demonstrates Lille's ability to conduct inter-domain analyses: it links the domain of public spaces with those of mobility and landscape.

To conclude, two final points should be highlighted, as they cut across the four domains and, more broadly, the entire diagnostic.

The issue of human uses appears throughout the document, across the sections—particularly in relation to public spaces, centralities, and networks. Although not fully developed, this approach has the potential to recognize usage as an essential element of any urban baseline assessments, whether focused on urban form or not.

Lastly, and it's an important point for us, at the neighborhood or city scale, the Lille diagnostic acknowledges the importance of the street as a key component of urban form. Seen as a building block of public space and a support for human uses, particularly "mobility, commerce and dining, socialization and exchanges between neighbors..." (p. 201, PLU). The street acts as a link between the domains of urban fabric, public space, transport, and amenities, though it is worth noting the strong emphasis placed on mobility and transport.

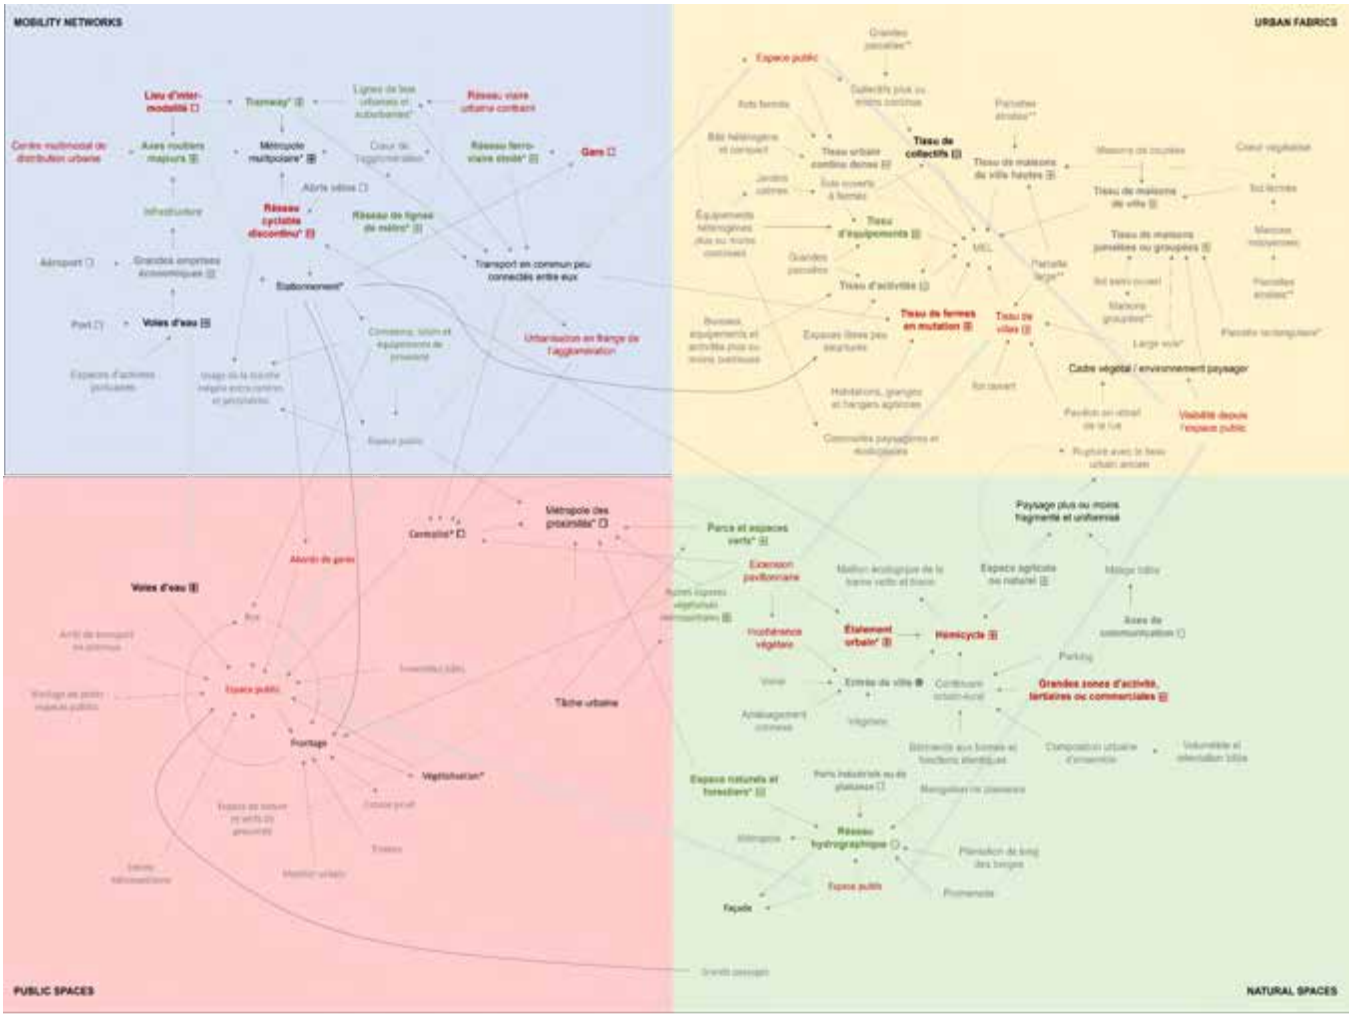

Figure 2: graph of Lille

4.2.The Bordeaux Case: A Diagnostic Rich in Challenges, but Lacking Spatialization and Systematization

In the diagnostic of the PLU for the Bordeaux metropolitan area, analysis of the occurrences of the term "urban form(s)" (forme urbaine) reveals that, as in Lille, the concept is primarily linked to the domain of urban fabric. However, when considering the broader context of its use, some nuances emerge, as these occurrences are associated with a variety of challenges (enjeux). Indeed, these fabric types are mainly discussed in relation to their density, organization, or broader environment: "fairly dense urban form" (p. 61), "urban form with scattered buildings" (p. 77), "low-compactness urban forms" (p. 35), or "surrounding urban forms" (p. 91). Urban fabrics are not viewed in isolation, but rather in relation to their surroundings—particularly for reasons of landscape and heritage coherence. There is also the question of densifying these fabrics in the context of "urban recycling and renewal," to use the terms of the diagnostic. Finally, unbuilt, impermeable, and green spaces—whether public or private—are included in the analysis of the urban fabric as supports for various uses, contributing to a high-quality living environment and human health. They are recognized for their potential to support "soft mobility, sports, relaxation, education, social interaction..." (p. 35).

However, no systematic analysis of the urban fabric or public spaces appears in the PLU of the Bordeaux metropolitan area, despite two notable studies produced by its urban planning agency.

The first is a document from 2008, related to the former PLU, which presents a zonal typology of the metropolitan space. This is a morpho-functional typology broken down into four main categories (heritage fabrics, collective

housing fabrics, suburban fabrics, and economic activity and facility zones) and 21 types. It identifies potential metropolitan centralities and assesses the quality of the living environment, in which public spaces link built forms with major landscapes. Combined with other variables, this typology was later used to create a mapped evaluation of urban heat island risk levels (a'urba and Alec, 2019).

The second is a collection of maps of public spaces in the Bordeaux metropolitan area, produced by the urban planning agency in 2015. Urban forms are analyzed through various lenses (bioclimatic, social, urban fabric), with public spaces as the keyline: alignment of building fronts with the street, relationship between facilities/functions and public spaces, form of transportation networks, integration of waterways and urban parks into the green and blue infrastructure, etc. With a 500-meter grid, this abundance of maps covers the entire metropolitan territory, is the result of a structured methodology, and occasionally includes cross-evaluations.

Although these notable works are nowhere to be found in the current PLU Baseline assessments of the Bordeaux metropolitan area, the concept map produced nonetheless reveals a relatively systemic vision of the metropolis in its understanding of the territory, with a high density of connections between items across different domains—mainly between those related to transport, urban fabric, and urban landscapes. However, there are significant disparities between the domains. While mobility and natural spaces are the focus of entire chapters, the domain of public spaces seems largely neglected. The domain of urban fabric suffers from the absence of a typo-morphological analysis comparable to Lille or Lyon. Unlike Lille, the core items are less obvious; although some, like rail and road infrastructure (infrastructures ferroviaires et routières), street mesh (maillage viaire), public space (espace public), and hydrographic network (réseau hydrographique), do stand out. Another possible interpretation is that this reflects a broader and more systemic approach that assigns equal value to all the components of urban spaces.

Evaluations are generally scarce. The few existing protocols are similar to those found in Lille—simple and comparative. The limited evaluations that are provided are expressed in textual form, but they are relatively balanced between negative, intermediate, and positive assessments. Maps are also less frequent, and most are either produced at a coarse granularity or cover only part of the metropolitan area.

To conclude, three more targeted reflections emerge from the analysis of the Bordeaux diagnostic.

Despite the interesting approach mentioned earlier regarding the connection between urban fabrics and planning challenges, the observations remain fundamentally focused on the city of Bordeaux itself, omitting the rest of the metropolitan area. Moreover, the document provides figures with limited spatial context, indicating only a specific municipality or vaguely referring to the west or east of the river, which hinders a more rigorous analysis of urban fabrics and a systematic reflection on their potential for densification.

Secondly, the PLU acknowledges both the environmental and social qualities of the green and blue infrastructure. On the one hand, it presents a wealth of descriptive information on biodiversity and the state of ecosystems within the administrative perimeter of the metropolis with items such as wetlands (zones humides), landscape entities (entités paysagères), ecosystems (écosystèmes), and ecological heritage (patrimoine écologique). On the other hand, it recognizes the human uses of this green and blue meshes (trame verte et bleue), such as green and local loops (boucles vertes et locales).

Finally, a specific reflection is dedicated to public facilities (educational, healthcare, sports, cultural, tourism, and leisure). The authors recognize their role in metropolitan attractiveness, but once again the spatial dimension is underdeveloped. The evaluation is carried out solely through comparisons with other metropolitan areas, and by calculating the equipment ratio.

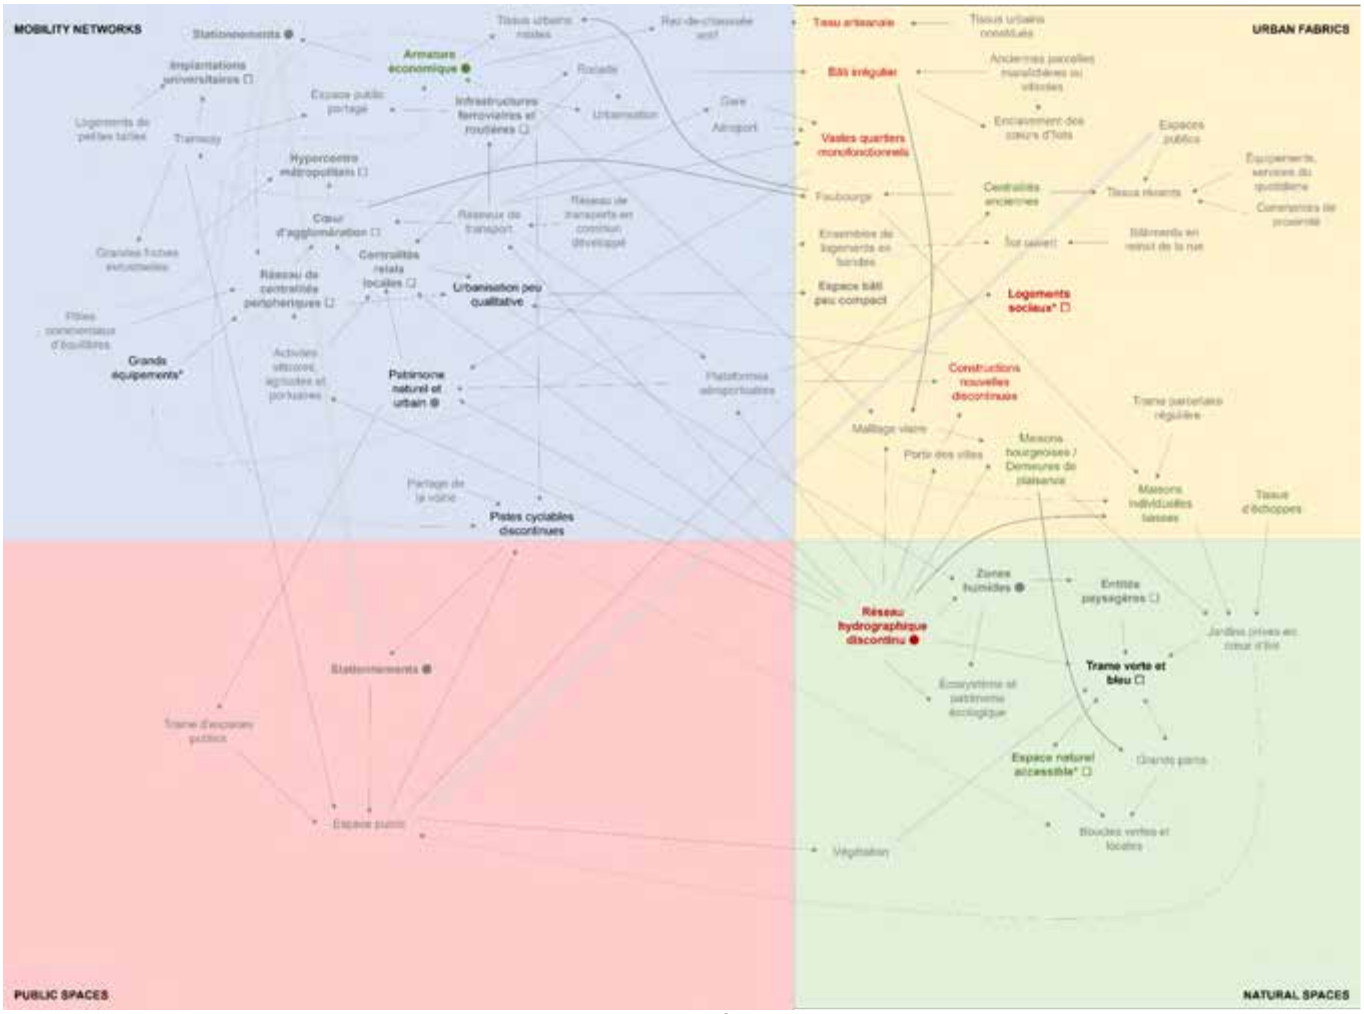

Figure 3: graph of Bordeaux

4.3.The Lyon Case: An Apparent Siloed Vision saved by the Underlying Role of Public Spaces

In the diagnostic of the Lyon metropolitan area's PLU, the terms "urban form(s)" and "morphology(ies)" refer once again primarily to the typology of urban fabrics (27 mentions)[6], or to the architectural characteristics of buildings (23), and to a lesser extent, to the spatial organization at the neighborhood scale (7). Produced by the Lyon urban planning agency, this typology of urban fabrics—first introduced in the 2005 PLU—covers the entire administrative territory of the metropolitan area with a granularity between the block and the neighborhood. Its morpho-functional approach provides a relatively comprehensive reading of urban fabrics, including highly vegetated, natural, or agricultural areas. Moreover, the proposed typology takes into account the relationship between built and unbuilt spaces, as well as a criterion of spatial homogeneity. However, no detailed information is provided on the methodology used to combine all variables and produce the resulting typology.

The treatment of urban fabrics is primarily based on the architectural characteristics of the buildings that compose them (17 mentions). Occasionally, their analysis is linked to issues of heritage (8), landscape (4), and densification (5) or housing typologies (collective, individual, and suburban) (4). Quality of life (3), centralities (2), and urban functions (2) are also addressed. Other topics are mentioned only once, such as the consistency and integration of buildings with their environment, greening, the fight against urban sprawl, and the articulation between built forms and public spaces.

6 It's the document that contains the highest number of occurrences of the targeted expressions (Table 1). Consequently, in the case of Lyon, it becomes relevant to report the number of occurrences—something that was not done for the cases of Lille and Bordeaux.

The Lyon metropolitan area presents a segmented image of the diagnostic, which is reinforced by the structure of the document itself: it first addresses natural spaces, then transport, and finally urban fabrics and landscapes—these forming the first three chapters of the document. Public space does not have a dedicated chapter, yet it plays an important role, as the concept map demonstrates.

Although the map is dense in items and relationships, interrelations between domains are rare and of highly uneven nature and density. Only a few cross-domain relationships are observed—for instance, the item shared public space (espace public partagé), which links the transport domain with public spaces, or urban nature network to be developed (réseau de nature en ville à constituer) , which connects the landscape domain to many items from the urban fabric domain –although these latter are not subsequently linked to other items. However, this relative independence among the different domains is mitigated by the role of public space, which subtly links them in the background.

Finally, beyond inter-domain relations, other core items structure the overall concept map—similar to the case of Lille: infrastructure mesh (maillage d'infrastructures), polycentric metropolitan areas (métropole polycentrique), public space (espace public), different types of urban fabrics, and the green and blue meshes (trame verte et bleue). These items are frequently evaluated and mapped, generally forming clusters of related items around them.

In the case of Lyon, no formal protocol is followed by evaluation of the different items. With a majority of intermediate cases, these evaluations are sometimes positive, more rarely negative. The authors aim less to deliver evaluations and more to identify challenges, which results in a more neutral stance throughout the baseline assessments. These issues are revealed through lengthy descriptions, with varying degrees of quantification and quality—particularly concerning urban forms.

As for mapping treatment, urban fabrics and natural areas are mainly represented through choropleth maps at a fine grain size. The domain of public spaces lacks any map, and the items related to it are systematically interrelated with items from other domains. In the case of transportation, maps vary in both coverage and grain size. Among the specific considerations regarding the approach employed by the Lyon metropolitan area, the treatment of urban fabrics, public spaces, and uses deserves particular attention.

The domain of urban fabrics is structured as a constellation, similar to the case of Lille. Numerous connections exist between the various components of the fabric types, such as historical axes (axes historiques), plots (parcelle), vegetation (végétation), or public spaces (espaces publics), leading to this in-between state. Presented as a morpho-landscape typology, it places significant emphasis on the role of vegetation in defining urban fabrics, and—albeit to a lesser extent—on public space, notably through the item of the street (rue). As shown in the graph, the street is recognized as an organizer of the building on the plot, creating visual links with the built and natural heritage.

The domain of public spaces is a triple-star constellation. Its numerous links to other domains reveal this concept as the backdrop of the entire baseline assessments. Public space is considered both as a component of urban fabrics linked to items such as: plots (parcelles), blocks (îlots), streets (rues), inner-block gardens (jardin en coeur d'îlot), frontages, etc., as a primarily shared space (illustrated through items such as sidewalks (trottoirs), pedestrian crossings (traversées piétonnes), parking (stationnement), public transport (transports en commun), car (voiture), soft mobility (mobilité douce), etc., and also as a space encompassing natural areas (as demonstrated by connections to items like green and blue meshes (trame verte et bleue), vegetation potential (potentiel de végétation), and built and natural landscape heritage (patrimoine bâti et naturel), for instances.

Finally, the topic of uses takes a much more prominent role than in Lille's baseline assessments, and even more so when compared to Bordeaux's. However, their treatment remains relatively vague and indirect in relation to

urban forms, becoming apparent primarily when parks and natural spaces are discussed.

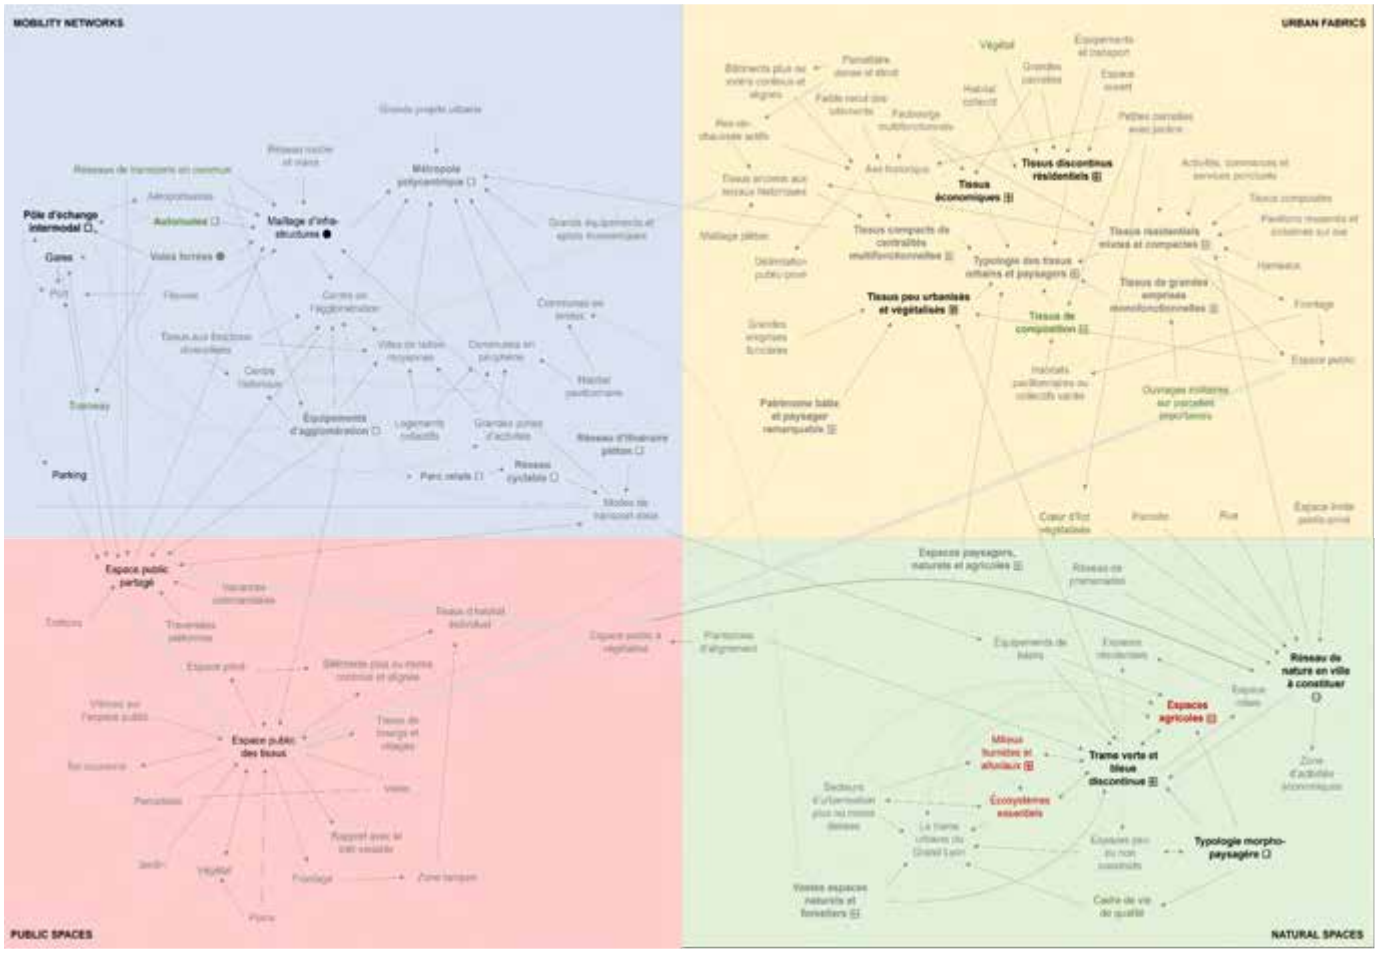

Figure 4: graph of Lyon

5.Urban Form in PLU Baseline assessments: A Relatively Systemic Vision, with Limited Protocols and Mapping under a Constraining Context

The analysis of PLU baseline assessments from the three selected metropolitan areas highlights specific observations for each case. Lille shows an approach to urban form through a few key concepts. Bordeaux demonstrates a wide reflection on urban space and its issues, but this momentum is hindered by insufficient methods for evaluation and spatialization. Finally, Lyon reveals a more siloed approach to diagnostics, but one that has the merit of recognizing public space as a foundational element of urban form, linking the various components. Beyond the specificities of each metropolitan area, broader reflections can be drawn about how urban forms are understood in France in PLU baseline assessments—insights that can also inform approaches developed in other French cities.

In general, when PLU authors refer to urban forms and morphologies, it is mainly to describe types of the urban fabric, buildings, or housing types. This reflects a broader trend in France to reduce urban form to the materiality of the built environment—an approach that overlooks key contributions already established by Italian typomorphology since the 1970s, which emphasized the broader context of urban form, including urban history and everyday uses. It also ignores the more recent developments brought by configurational approaches such as Space Syntax.

However, the creation of graphs—extending beyond what is conventionally referred to as "urban form"—broadens the definition to include a wider set of spatial registers, which are present in the baseline assessments and are variously linked to the narrowly defined issues of built-up forms. It is thus interesting to note that the analyzed metropolitan areas demonstrate both the intent and the capacity to grasp urban spatiality through a variety of elements beyond the built form. Yet this promising openness is not consistently supported by a rigorous and systematic methodology.

A transversal reading of the three graphs also reveals a similar treatment of the four domains selected for analysis. Three of the four—mobility networks, urban fabric, and natural spaces—proved to be well aligned with the contents of the diagnostics. Public spaces, however, suffer from the absence of a dedicated analytical section, even though they are consistently addressed across the other three domains, even linking them. Public space can serve as the guiding thread, as in the case of Lille, or as a background theme connected to the issue of uses and feeding into the characterization of urban form, as seen in Lyon.

Among the background elements present in the baseline assessments, human uses also emerge, though they are treated in a more superficial way. They are more often associated with transport and natural spaces, while their connection to the urban fabric—and more broadly to urban form—is only vaguely addressed. No diagnostic attempts to spatialize these uses, unlike many anthropological or sociological studies that examine how frequently and in what ways residents use public space (Gehl and Svarre, 2013). Even urban planning agencies have started addressing such issues: studies on children's presence in public space (a'urba, 2021), or on gendered and socio-economically differentiated mobility (urbalyon, 2021), have recently appeared.

Finally, the three graphs follow more or less general structures—star, constellation, lattice. They also rely on a variety of "core items" that are surrounded by numerous peripheral items, reflecting how the diagnostics are conducted. The texts unfold linearly, presenting the elements considered important by the authors: urban fabric, green and blue networks, transport systems, and so on. However, each diagnostic also features rich cross-domain connections, revealing a degree of systemic vision that these metropolitan areas nonetheless have of their territories.

Evaluation is generally rare and lacks standardized protocols. Scientific methodology traditionally involves building a reproducible protocol, applying it with appropriate adjustments to produce results, interpreting those results, and then offering an assessment. Here, however, the diagnostics bypass this effort, providing a series of qualitative evaluations in natural language without formal procedures. There are a few exceptions: the rare existing protocols rely on counts, quantified inventories, or simple calculations (e.g., equipment ratios, volume), enabling comparisons with other metropolitan areas.

One would also expect these protocols to be followed by proper evaluations, but there seems to be a disconnect between the two stages. Instead of evaluation, the notion of challenges (enjeux) is often preferred—intellectually richer but less demanding in terms of method and vague in spatial terms. Without being qualified and spatialized, challenges remain vague in terms of assessment,and spatial delimitations, strengths, or areas for improvement are neither clearly recognized nor encouraged.

As for cartography, it remains rare, thematically and compositionally variable in style. Three domains favor mapping: transport, urban fabric, and natural spaces—especially green and blue networks. These maps are usually choropleth. When not, they tend to highlight only major instances of a given item or focus on a limited area within the broader metropolitan perimeter. As mentioned previously, these maps are almost always descriptive or indicative, rather than evaluative. The distinction lies in the fact that it is possible to map existing elements (e.g., road layouts or hydrographic networks) without illustrating the quality of those spaces.
In the French professional literature, a few examples of such evaluative cartography do exist: maps of wide sidewalks with or without vegetation in the Lille metropolitan area (ADULM, 2017c), or maps showing areas with

sufficient or insufficient public space density in Bordeaux (a'urba, 2015). These maps are valuable because they help precisely locate and assess areas requiring intervention, or conversely, areas to preserve or enhance. However, these cartographic outputs produced by urban planning agencies are not found in the PLU baseline assessments, raising broader questions about the relationship between metropolitan authorities and their planning agencies in the development of Local Urban Plans.

In conclusion, one final point is essential to situate the considerations we present here regarding the quality of PLU baseline assessments. Our analysis is based on an initial assumption: we argue that a diagnostic should mobilize multidimensional content with a systemic vision, follow structured protocol evaluations, and spatialize analysis results using fine-grained choropleth mapping. However, questions arise concerning the predefined objectives set by the authors of these baseline assessments at the time of their drafting. The criteria and objectives we propose here are not necessarily those of the authors: while PLU baseline assessments are a regulatory requirement in urban planning, the methodology used in their preparation and the outcomes they are expected to achieve remain unclear. Moreover, it is important to recall that PLUs are short-term planning documents, subject to electoral calendars and political pressures. They are heavy documents, produced in institutional and political contexts that can be unstable or conflictual. In addition, the skills, time, and resources available for their development can vary widely, which may partly explain the scarcity of evaluation protocols and maps. Therefore, our considerations should be understood more as suggestions—an invitation for planning authorities to broaden their perspective on urban form, beyond the built environment—and as reflections that could, at a later stage[7], lead to an alternative method for approaching urban form in a more systematic way.

6.Conclusions

In general, the analysis of baseline assessments documents reveals that French metropolitan areas share a common vision: cities of high quality, accessible to pedestrians and public transport users, with efficient and safe mobility, pleasant public and natural spaces, and a good diversity and density of services, amenities, and local functions. However, this shared ideal does not lead to a unified reference model applicable to all cities. While similarities exist, each territory develops its own approach to conducting territorial diagnostics. This allows for an appreciation of local specificities, but also makes it difficult to establish a collectively recognized framework and methodology for understanding and analyzing urban spaces.

In this context, the understanding of urban form in France remains largely confined to a typo-morphological approach, based on the architectural and functional qualities of the built environment. While this perspective is valuable for identifying and distinguishing the urban fabrics that make up different territories—and for ensuring protective attention to built heritage—it overlooks a more complex vision and a rigorous methodology capable of integrating the various elements that constitute and animate urban form.

The ambition of the research project underlying this article is precisely to propose urban form—as long as it is approached in a systemic and protocol-based way—as a coherent and rich method for producing meaningful and comparable territorial baseline assessments at the national scale. The development of a reference urban model goes beyond existing legislative objectives, such as the Zero Net Artificialisation (ZNA) target (Climate and Resilience Act, 2021), or mandatory quotas of social housing (SRU Law, 2000). While we acknowledge that these objectives are closely related to urban form and have implications for other contemporary urban planning issues, these are often addressed independently within diagnostics.

Our hypothesis is that urban form, if properly conceptualized, constitutes a strategic dimension through which the material, social, and politico-economic dynamics of urban spaces can be more effectively understood, spatialized, evaluated, and finally acted on. Moreover, developing an urban model that integrates a vision of the desired forms of the city—and their connection with the various objectives of urban planning—should also enable

7 This contribution forms part of the early stage of Grégoire Picard's doctoral research, the article's first author, whose ultimate objective is to propose a new method for understanding urban form within the beeline assessments sections of Local Urban Plans (PLU) in France.

the production of more evaluative baseline assessments. Not merely descriptive overviews, but differentiated spatial assessments across the metropolitan area, identifying what aligns most or least with the intended goals.

Abstract
The increasing convergence of technology and media interactivity continues to shape novel urban landscapes and social connections, catalysing the emergence of place in media and the phenomenon of "Wang Hong urbanism". This research investigates urban aesthetic appeal in the digital era through analysis of photographs posted on the social media platform Douban under #CityWalk, utilising a deep learning scene recognition model with Class Activation Mapping. The visual content analysis established three primary categories: natural landscapes, built structures, and human presence. This classification framework illuminates how distinct aesthetic elements are emphasised in user-generated urban representations. The findings demonstrate how pedestrians reconstruct their perceptions of walkable urban spaces through social media engagement, whilst providing insights into contemporary urban tourism within the context of Wang Hong's urbanism.

Keywords: Citywalk, wanghong urbanism, social media, urban design

1. Introduction

In recent decades, urban China has witnessed a significant shift in leisure patterns, marked by increased free time and disposable income among city dwellers. Despite these changes, the range of daily leisure activities has remained relatively constant (Newman et al., 2014). Within this context, walking has emerged as a universally appealing leisure pursuit, transcending age barriers and offering an accessible, cost-effective, and flexible form of physical activity. This rise in urban walking not only reflects changing lifestyle preferences but also represents a unique form of engagement with the city itself. As previous research notes, walking serves as a powerful medium through which individuals interact with and interpret urban heritage, embodying qualities that are at once grounded in place, performative in nature, and potentially transformative in impact (Middleton, 2018).

Jan Gehl (1987) highlighted that optional and social activities, particularly non-purposive recreational pursuits, are more sensitive to the built environment than necessary activities, offering rich opportunities for shaping urban spaces. This insight has gained renewed relevance in the post-pandemic era. Since the World Health Organization declared the end of the pandemic in May 2023, there has been a noticeable shift in people's preferences towards "high-quality" travel and leisure experiences, often beyond conventional tourist destinations (Lehtinen and Vihanninjoki, 2020). In the wake of this global tourism resurgence, localities worldwide are striving to position themselves as objects of the tourist gaze (Zheng et al., 2024). This trend marks a significant shift in urban identity: cities are no longer content to be merely centres of production or symbols of power, but increasingly seek to reinvent themselves as sites of entertainment and leisure (Zhang et al., 2023). Consequently, urban environments now serve a dual purpose - as aesthetic objects and as crucial venues for recreational activities (Li et al., 2024)there is currently limited attention given to related research. Based on this, the study focuses on Jinshan Park in Fuzhou City, Fujian Province, China, to investigate the relationship between landscape features and the coexistence of landscape aesthetics and recreation values of urban parks. The research employed field observations and questionnaire surveys to assess the landscape aesthetic and recreational values of urban parks and explore their coexistence. Additionally, semantic segmentation and other methods were introduced to quantify landscape features. Linear regression analysis was then applied to further examine the impact of landscape features on the landscape aesthetic and recreational values in urban parks, as well as their coexistence. The results revealed: (1. This dual role of urban spaces underscores the importance of balancing aesthetics and functionality. A space that prioritizes only utilitarian functions while neglecting aesthetic considerations would likely be perceived as uninteresting (Li et al., 2024)there is currently limited attention given to related research. Based

on this, the study focuses on Jinshan Park in Fuzhou City, Fujian Province, China, to investigate the relationship between landscape features and the coexistence of landscape aesthetics and recreation values of urban parks. The research employed field observations and questionnaire surveys to assess the landscape aesthetic and recreational values of urban parks and explore their coexistence. Additionally, semantic segmentation and other methods were introduced to quantify landscape features. Linear regression analysis was then applied to further examine the impact of landscape features on the landscape aesthetic and recreational values in urban parks, as well as their coexistence. The results revealed: (1. Therefore, maximizing the synergistic interplay between the aesthetic and recreational values of urban spaces has emerged as a critical focus for urban research and design. This approach not only enhances the appeal of cities for tourists but also improves the quality of life for residents, creating environments that are both visually pleasing and functionally enriching.

On the other hand, there has been a growing emphasis on the quality of leisure activities among the public (Wu, 2023). "City Walk," an emerging travel mode, has gained particular popularity among younger generations due to its focus on "nearbyness"(Xiang, 2021) and authentic experiences. In the digital age dominated by social media, the advent of geomedia has transformed the traditional urban walking experience, creating a dynamic interplay between physical cityscapes and digital representations that allows individuals to engage with urban spaces in unprecedented ways, blending personal narratives with collective urban exploration (McQuire, 2017).

Previous research has identified several factors influencing leisure walking, including built environment features, leisure facility provision, walkability, and land use diversity (Bayar and Yılmaz, 2023; Jian et al., 2020; Wang and Yang, 2019). Walkability encompasses environmental features, outcomes fostered by walkable environments, and serves as a proxy for better urban design (Forsyth, 2015). While extensive research exists on walking tours in tourism and urban morphology from a top-down perspective (Giddy and Hoogendoorn, 2018; Wan, 2023)this exploratory study examined the stimuli that triggered tourists to take a casual walk in an urban tourism setting, whether and how these stimuli interacted, and how the stimuli evoked the tourists' emotions, experiences, and responses. Macao (China, there's a lack of understanding of city walkers' preferences in everyday urban settings. The interaction between urban landscapes, particularly socio-cultural landscapes and built environment elements, and this emerging leisure activity of city walking remains unknown.

In light of this, this study aims to capture and collage the multidimensional experiences of walkers from the landscape of visual accumulation (spectacle), revealing how they encounter, interpret, and present the urban environment. We seek to understand the relationship between landscape elements and aesthetic values during their recreational city walk behaviours in urban settings. This study will provide new perspectives for urban planners, policymakers, and marketers to better understand and promote vibrant interactions with urban daily life.

2. Literature Review

2.1 Wang-hong Urbanism: A Geomedia Perspective

In 18th century Europe, painting was the primary medium for landscape dissemination, giving rise to the picturesque aesthetic. Subsequently, the advent of photography, development of mass media, and widespread transportation contributed to the flourishing of mass tourism and popularization of photo-op spots in scenic areas (Adams, 2009). Since the early 21st century, advancements in geographic information technology have strengthened the connection between media and physical space, promoting research and development in media geography. The widespread adoption of digital technologies, particularly social media platforms that facilitate the sharing of text and images, has transformed how individuals document and share their daily experiences, creating a vast collection of digital data that serves as a powerful medium for communication. Against this background of geomedia (McQuire, 2017), the contemporary urban experience is characterized by a simultaneous engagement with both physical environments and digital media, offering new perspectives on the multifaceted nature of everyday life (Zook and Graham, 2007). Contrary to initial concerns, research suggests that the advent of digital communication technologies has not replaced local community connections but rather enhanced them, fostering a stronger sense of belonging among users (Boy and Uitermark, 2017). The urban landscape is now shaped by a complex interplay between tangible and virtual social dynamics, with physical attributes influenc-

ing digital behaviours, while digital trends reciprocally impact the material world in a continuous cycle of mutual influence (Zook and Graham, 2007).

This study conceptualises "Wang-hong Urbanism" as an urbanization phenomenon rooted in the intricate interrelationships between physical, digital, and social spaces (Jian et al., 2022, Figure 1). The rise of social media has created a pervasive communication infrastructure that enables instant local and global connections (Adams, 2009). Within this framework, users actively participate in shaping urban narratives by creating and sharing diverse representations of specific places across multiple platforms. This process of digital place-making blends the virtual and physical aspects of urban life, leading to a reimagining of city spaces. The digital footprints left by users through shared photos, stories, and interpretations collectively influence how places are perceived and experienced (Bronsvoort and Uitermark, 2021). This interplay between media and urban spaces creates what can be described as "media in place" and "place in media". "Media in place" refers to how digital platforms intersect with physical urban environments, while "place in media" encompasses the digital representations and narratives that shape perceptions of urban spaces. This digital layer of urban experience has begun to shape physical development, with new spaces being designed to cater to social media aesthetics and "Instagrammable" (Boy and Uitermark, 2017). The constant flow of digital content about urban spaces feeds back into the physical realm, influencing urban planning and design decisions. Wang-hong Urbanism thus represents a cyclical process where digital representations inspire physical changes, which in turn generate new digital content. This phenomenon is reshaping urban landscapes, potentially altering the way cities are developed, experienced, and understood. As this trend continues, it raises important questions about authenticity, inclusivity, and the future direction of urban development in an increasingly digitally-mediated world.

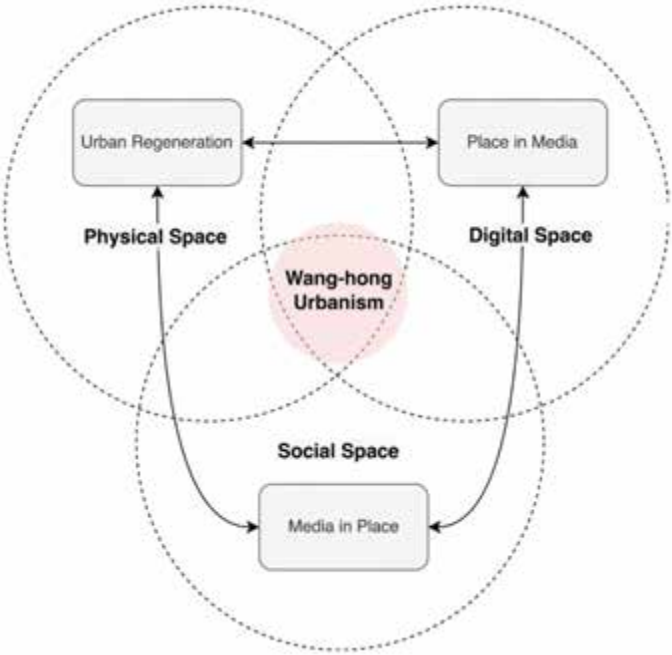

Figure 1. Conceptual framework to understand Wang-hong Urbanism
Source: (Jian et al., 2022)

2.2 City Walk in China: Explore the Nearby

In the context of Chinese urban life, city walking has emerged as a significant cultural phenomenon, embodying the concept of exploring the nearby as a scope of seeing the world (Xiang, 2021). In Chinese social media, City Walk is associated with spontaneity, leisure, and exploring non-mainstream attractions (Wu, 2023). This trend is closely linked to the "micro-vacation" model popularised during the pandemic. The 2023 Tourism Research Report lists city walking as a highly favoured emerging travel mode, with 82% of respondents willing to try it. Social media platforms have seen hundreds of thousands of "#citywalk" tagged posts. This practice, popularised through social media platforms and amplified by pandemic-induced travel restrictions, represents a shift in how urban residents engage with their immediate environments.

This study views City Walk as a daily leisure activity rather than solely a tourism practice. Unlike "commando-style travel," walking is the goal itself, not just a means to reach a destination. This approach to urban exploration encourages people to discover beauty and meaning in the quotidian aspects of urban landscapes. It serves multiple functions: it re-enchants ordinary cityscapes, prompts the re-discovery of familiar neighbourhoods, and deepens the perception and appreciation of local culture (Borucka, 2019).

The rise of city walking in China reflects a growing desire among urban dwellers to authentically interact with their surroundings in the context of attention economy and digital era (Giddy and Hoogendoorn, 2018), countering the homogenising effects of wang-hong urbanism (Jian et al., 2022). By engaging in this embodied leisure activity, participants not only alleviate stress and anxiety but also develop a more nuanced understanding of urban spaces and issues. This practice transforms urban landscapes into sites of everyday aesthetic discovery, where the physical act of walking intersects with digital documentation and sharing. Consequently, city walk in China has become a powerful tool for (re)connecting with urban spatial landscapes, fostering local identity, and cultivating a sense of belonging. It represents a microcosm of global exploration within the confines of one's local environment, offering a rich, multifaceted experience that challenges standardised representations of urban life while promoting a more sustainable and mindful approach to urban living and tourism (Wan, 2023)

City Walk has transformed urban landscapes into sites of everyday aesthetic practice, with participants documenting and sharing their experiences through photos (Cao, 2023). This intersection of physical exploration and digital documentation offers a unique window into urban residents' aesthetic preferences. Despite the proliferation of City Walk imagery, there remains a critical gap in our understanding of what specific urban elements attract walkers' attention and how they choose to frame and present their city, particularly in the context of China's diverse and rapidly changing urban landscapes. By analysing these shared images, researchers can gain valuable insights into how individuals perceive, interact with, and value different elements of their urban environment. This visual data provides a nuanced understanding of the evolving relationship between urban residents and their landscapes, revealing both overlooked beauty in everyday scenes and changing patterns of urban appreciation. Such analysis contributes to our understanding of urban aesthetics and holds potential implications for urban planning and design.

3. Methodology

In the realm of urban studies and tourism research, social media data analysis has emerged as a pivotal method for uncovering socio-cultural characteristics and collective digital imaginaries or urban spaces (Kelley, 2013). This approach harnesses the pervasive nature of geographic media and real-time feedback, thereby transcending the constraints of traditional data collection methods in terms of scale and timeliness (reference). Our study employs web scraping techniques to extract user-generated content from the "CityWalk|Urban Street Wandering Project" topic on the Douban website (www.douban.com), a popular Chinese social networking platform focused on user reviews and discussions of various media. This methodological choice aligns with our objective to explore the "place in media" constructed by users, offering insights into contemporary urban experiences (Figure 1). The data collection process, concluded in February 2024, yielded 10,185 valid images. To ensure the integrity and accuracy of our analysis, we implemented rigorous data preprocessing procedures, including data cleaning and error correction. Notably, the absence of geographic tags in Douban posts precluded the inclusion of spe-

cific location information. Moreover, to maintain ethical standards and protect user privacy, we systematically removed all user IDs and identifiable personal information during data processing. We then employed Class Activation Mapping (CAM), an advanced technique for interpreting Convolutional Neural Network (CNN) predictions, to analyse this visual dataset. CAM enables the identification of discriminative image regions crucial for prediction outcomes (Deena Divya Nayomi et al., 2023). In our study, this method allows us to pinpoint the primary elements within urban landscape photos that capture user attention and inform their descriptions of cities on social media platforms.

3.1 Method – Class Activation Mapping

Our study employs the PlacesCNN model, introduced by Zhou et al. in 2017, which offers a multifaceted approach to image analysis by simultaneously predicting scene categories, attributes, and generating Class Activation Maps (CAMs) (Zhou et al., 2018). This model's architecture is based on a ResNet-18 backbone, augmented with two separate fully-connected layers for scene category and attribute prediction, respectively. The core idea behind generating CAMs is to leverage the final convolutional feature maps and the classification layer weights to compute an importance score for each feature map with respect to a particular class. These important scores are then summed and upsampled to obtain the CAM for the input image. The mathematical formulation is as follows:

$$C_c(x,y) = \sum_k w_c^k f_k(x,y)$$

Where C_c *(x, y)* denotes the CAM for class *c*, w_c^k is the weight corresponding to the *k*-th feature map in the classifier for class *c*, and f_k *(x, y)* is the value of the k-th feature map at location *(x, y)*.

3.1.1 Scene Classification Framework

This study uses a scene classification model trained with the Places365 dataset to perform scene recognition on self-collected image samples. To facilitate a more systematic analysis of the model's outputs, we propose a hierarchical classification framework that consolidates the 365 fine-grained scene categories identified by the model into 10 high-level semantic categories. This approach provides a more structured and interpretable analysis framework, enabling us to elucidate the relationship between image content and scene types from a macro perspective. Our proposed high-level categories are as follows:

- Natural environment

This category includes scenes that are identified as natural landscapes that have not been modified by humans. It covers a variety of landforms such as mountains, beaches, forests, deserts, glaciers, etc. These environments usually represent areas with less human activity and reflect the original state of the earth.

- Artificial outdoor environment

This category covers scenes that are identified as outdoor spaces that have been artificially designed and built. Including urban streets, parks, squares, courtyards, etc. These environments reflect how humans shape and organise external spaces to meet social needs.

- Indoor public spaces

This category includes scenes that are identified as indoor places for public use. For example, airport terminals, train stations, shopping malls, libraries, etc. These spaces usually have social, transportation or commercial functions and are an important part of the operation of modern society.

- Private/residential spaces

This category covers scenes identified as private spaces for personal or family life. Including various residential interior spaces, such as bedrooms, living rooms, kitchens, etc. These environments reflect personal lifestyles and home culture.

- Transportation-related places

This category includes scenes identified as places related to various modes of transportation. Such as parking lots, gas stations, airport runways, train platforms, etc. These places support and promote the mobility of mod-

ern society.
- Commercial/service places
This category covers scenes identified as various commercial and service facilities. Including shops, restaurants, bars, beauty salons, etc. These places reflect the characteristics of consumer culture and service economy.
- Cultural/educational places
This category includes scenes identified as places related to cultural dissemination and education. Such as schools, museums, art galleries, libraries, theatres, etc. These places play an important role in knowledge dissemination and cultural protection.
- Sports/entertainment places
This category covers scenes identified as various sports and entertainment facilities. Including stadiums, gyms, amusement parks, cinemas, etc. These places reflect the leisure and entertainment needs of modern society.
- Industrial/production places
This category includes scenes that are identified as places related to industrial production and resource development. Such as factories, mines, farms, construction sites, etc. These environments reflect economic activities and production processes.
- Special/other places
This category covers scenes that are identified as special places that are not easily classified into other categories. Including religious places, medical facilities, military bases, etc. These places often have unique functions or social significance.

The framework demonstrates the complexity of urban environments, breaking down each main category into numerous specific locations (e.g., alley, skyscraper, subway station). This granular approach enables us to explore the distribution of different environmental types within our collected image samples and investigate potential correlations between image content and scene categories.

3.1.2 Implementation Details

Based on the proposed framework, the implementation of the PlacesCNN model and CAM generation in our study follows a systematic approach using PyTorch:

i) Model initialization: Load the model weights pre-trained on the Places365 dataset (Deena Divya Nayomi et al., 2023).
ii) Feature extraction: Define a hook function to obtain the final convolutional feature maps from the model.
iii) Image processing: Perform a forward pass on the input urban landscape image.
iv) CAM computation: Compute the CAM using the feature maps and classifier weights from the fully-connected layer corresponding to the scene category prediction.
v) Visualisation: Visualise and save the CAM as an image overlay on the original input.

4. Results and Discussions

The results show a clear predominance of outdoor scenes, accounting for 7,638 images (75.0% of the dataset), while indoor environments are represented in 2,547 images (25.0%). Examples of the analysis results can be found in Figures 2, 3, and 4. This distribution suggests that urban wanderers on the platform have a strong preference for documenting external urban spaces, which aligns with the nature of city walks and urban exploration. To provide a more nuanced understanding of the urban landscapes captured, we further analysed the subcategories within these broad classifications.

Figure 2. Example of analysis results: alley
Figure Source: "CityWalk/Urban Street Wandering Project" topic on the Douban website (www.douban.com)

Figure 3. Example of analysis results: promenade
Figure Source: "CityWalk/Urban Street Wandering Project" topic on the Douban website (www.douban.com)

Figure 4. Example of analysis results: sky
Figure Source: "CityWalk / Urban Street Wandering Project" topic on the Douban website (www.douban.com)

4.1 Predominant Photographed Categories

Table 1 presents a comprehensive overview of the categories of urban elements captured in city walk photography. The data reveals that urban explorers sharing photos on social media during city walks demonstrate a clear preference for human-made structures and unique urban locations.

Table 1. Top 10 Photographed Urban Categories

Category	3 Example elements and counts	Count	Percentage	Rank
Artificial Outdoor Environment	Street (265) Parking garage/outdoor (218) Crosswalk (214)	2014	19.77%	1
Special/Other Places	Cell (167) Medina (116) Loading dock (114)	1441	14.15%	2
Transportation-related Places	Historic transportation hub (285) Highway (138) Canal/urban (120)	1253	12.30%	3
Cultural/Educational Places	Pagoda (174) Temple/asia (104) Synagogue/outdoor (91)	1145	11.24%	4
Commercial/Service Places	Beauty salon (182) Gas station (212) Fastfood restaurant (90)	1140	11.19%	5
Natural Environment	Sky (310) Forest/broadleaf (81) Lagoon (76)	1001	9.83%	6

Industrial/Production Places	Industrial area (135) Skyscraper (129) Hangar/outdoor (68)	891	8.75%	7
Indoor Public Spaces	Booth/indoor (110) Elevator shaft (67) Subway station/platform (54)	525	5.15%	8
Sports/Entertainment Places	Water park (82) Ice skating rink/outdoor (46) Amusement park (39)	491	4.82%	9
Private/Residential Spaces	Residential neighborhood (154) Beach house (64) Tree house (61)	284	2.79%	10

To elaborate, Artificial Outdoor Environment dominates the photographs, accounting for 19.77% of all images. This category includes common urban features such as streets, parking garages, and crosswalks. Special/Other Places rank second (14.15%), followed closely by Transportation-related Places (12.30%). This suggests that city walkers are particularly drawn to unique or unusual urban spaces, as well as the infrastructure that facilitates movement within the city. It's noteworthy that functional areas like Transportation-related Places and Industrial/Production Places feature more prominently than purely recreational areas such as Sports/Entertainment Places. This suggests that city walkers are particularly drawn to the infrastructure and daily operations of the city, rather than its leisure facilities. Cultural/Educational Places and Commercial/Service Places occupy the middle ranks, each accounting for about 11% of the photographs. This near-equal representation indicates a balanced interest in both the cultural aspects of a city and its commercial offerings, reflecting the diverse attractions of urban environments.

Interestingly, there's a marked inclination towards capturing built environments over natural ones. While Artificial Outdoor Environments top the list, Natural Environments rank sixth, comprising only 9.83% of the photos. This suggests that city walkers are more captivated by urban architecture and infrastructure than by parks or green spaces within the city. The data also highlights a significant preference for public spaces over private ones. Categories representing various public areas dominate the top of the list, while Private/Residential Spaces rank last at just 2.79%. This trend underscores the public nature of city walks and the focus on shared urban experiences.

4.2 Top 10 Recurring Visual Elements

Table 2 provides a more granular look at the specific urban elements most frequently captured in city walk photography. From natural environments to cultural spaces and encompassing both large-scale elements (like sky and streets) and localised features (such as alleys and beauty salons), the top 10 list demonstrates that urban explorers are drawn to a wide spectrum of urban characteristics. This diversity suggests an appreciation for both macro and micro aspects of city landscapes, extending beyond traditional tourist attractions. The list covers various urban functions including transportation, commerce, culture, and public spaces, providing a holistic representation of the urban fabric. Such a comprehensive engagement with different facets of the built environment offers valuable insights into how people perceive and interact with cities, highlighting the complex nature of urban appeal and the importance of considering diverse elements in urban planning and design.

Table 2. Top 10 Recurring Urban Elements

Class name	Category	count	Percentage	Rank
sky	Natural Environment	310	3.04%	1
historic transportation hub	Transportation-related Places	285	2.80%	2
street	Artificial Outdoor Environment	265	2.60%	3
parking garage/outdoor	Artificial Outdoor Environment	218	2.14%	4
crosswalk	Artificial Outdoor Environment	214	2.10%	5
gas station	Industrial/Production Places	212	2.08%	6
promenade	Artificial Outdoor Environment	200	1.96%	7
alley	Artificial Outdoor Environment	199	1.95%	8
beauty salon	Commercial/Service Places	182	1.79%	9
pagoda	Cultural/Educational Places	174	1.71%	10

Six out of the top ten elements (sky, street, parking garage/outdoor, crosswalk, promenade, and alley) are associated with outdoor environments, underscoring the importance of open-air spaces in the urban exploration experience. Interestingly, while Artificial Outdoor Environment dominates in the broader category analysis, the single most photographed element is the sky, a Natural Environment feature, with 310 occurrences, ranks as the most photographed element. Even in the heart of cities, people are drawn to open spaces and the visual relief provided by the expanse above the urban landscape. It's important to note that even the highest-ranked element (sky) only accounts for 3.04% of the total, indicating a high degree of variety in the dataset beyond these top elements.

On the other hand, the prominence of everyday urban elements in the dataset reveals the fundamental role of urban network infrastructure in shaping a city's character and the urban exploration experience. "Street," ranking third with 265 occurrences, alongside "crosswalk" (ranked 5th, 214 occurrences), "promenade" (ranked 6th), and "alley" (ranked 8th), each with approximately 200 occurrences, emphasises that city walkers find significant interest in the everyday urban spaces. These elements, serving as the arteries of urban life, capture the essence of city movement and design beyond monumental or extraordinary sites. For instance, promenades, normally designed for leisurely walks and social interaction, represent the more aesthetic and planned aspects of urban design. In contrast, alleys often embody the more intimate, less curated sides of urban environments. The near-equal representation of these contrasting elements in the dataset suggests a balanced interest among urban explorers in both the polished and grittier facets of city life.

The appearance of "parking garages/ outdoor" (ranked 4th), "gas station" (ranked 6th) and "beauty salon" (ranked 9th) in the list indicates that functional and service-oriented spaces also capture the attention of urban explorers, possibly due to their role in daily urban life or their aesthetic qualities. These functional spaces often feature distinctive architectural styles, signage, and lighting that contribute to the visual landscape of a city. Gas stations, for instance, may attract attention due to their often bold, modernist designs or retro aesthetics, while beauty salons might showcase vibrant storefronts or unique interior designs visible from the street. Parking garages, especially multi-story structures, offer unique vantage points of the city. They may attract urban explorers for their potential to provide elevated views of the urban landscape, adding a vertical dimension to the exploration experience. On the flip side, Parking garages and gas stations serve as transition points between modes of transportation, representing liminal spaces in the urban fabric. The frequent appearance of these spaces in the dataset may also simply reflect their ubiquity in urban environments, making them common subjects for urban photographers.

The inclusion of "pagoda" in the top 10, as a representative of Cultural/Educational Places, highlights urban explorers' interest in historical and cultural landmarks. These structures serve as both functional elements and

symbolic representations of a city's heritage and global connections. Their popularity among photographers reflects an appreciation for the blend of architectural grandeur and historical significance in urban landscapes. This focus also suggests a broader fascination with how cities evolve, inviting observers to contemplate the intersection of ancient traditions and modern urban life within the cityscape.

5. Conclusions

The analysis of City Walk imagery provides valuable insights into the everyday aesthetic preferences of urban residents, revealing a nuanced appreciation for urban landscapes that often diverges from mainstream or "wang-hong" representations. This analysis reveals that city walkers engage with a diverse range of urban elements, from grand vistas to intimate street-level details, and from historical landmarks to everyday functional spaces. Our study indicates that city walkers are particularly drawn to elements that embody the authentic character of their urban environment. These include historical architecture juxtaposed with modern structures, vibrant street life scenes, hidden alleyways, and pockets of urban nature. Notably, there is a marked preference for scenes that capture the interplay of light and shadow on urban surfaces, as well as moments of serendipity in daily urban life. Moreover, there is a clear appreciation for spaces that facilitate community engagement, such as public squares, parks, and street corners that serve as informal gathering spots. These insights underscore the importance of preserving and enhancing the diverse tapestry of urban environments, rather than pursuing homogenised urban aesthetics.

From an urban design perspective, these findings have significant implications. They suggest a need for urban planning strategies that prioritise the preservation of local character, the integration of historical elements with contemporary design, and the creation of spaces that encourage spontaneous social interactions, so as to facilitate walkability. Urban designers should consider incorporating elements that enhance the sensory experience of walking, such as varied textures, engaging streetscapes, and green corridors. Furthermore, the popularity of images capturing transitional spaces and thresholds between different urban zones highlights the importance of thoughtful design in areas of urban connectivity. By aligning urban design with the aesthetic preferences revealed through City Walk practices, cities can create more engaging, livable environments that resonate with residents' everyday experiences and foster a stronger sense of place and community.

Abstract
Extreme weather events are frequent in the context of climate change, which brings severe challenges to cities. Therefore, it is urgent to explore more adaptive planning methods to achieve climate resilience. Correspondingly, this paper conducts spatiotemporal perception research on typhoon disasters in Shanghai based on social media data. The results show that there are 3 types of disaster themes. Meanwhile, there presents different spatiotemporal characteristics among public concern index, negative sentiment intensity and positive sentiment intensity. Based on above situation, this paper proposes corresponding planning response strategies, and the purpose of this paper is to explore social media data in responding to climate change challenges and provide reference for resilient urban planning.

Keywords: climate change, resilient city, social media, spatiotemporal perception, typhoon disasters

1. Introduction

Due to the intensification of global climate change, various extreme climate disasters have occurred frequently, which poses a huge threat to urban safety. Typhoon is one of the most frequent and widespread natural disasters in the world, and the harm of hurricane and typhoon is becoming more prominent with the intensification of climate change. From the perspective of global cities, many cities in the world (such as New York, New Orleans, Tokyo, and Singapore) have experienced the impact of hurricane and typhoon disasters which caused a large number of casualties and property losses. China is one of the countries affected by typhoon disasters, and most of Chinese cities affected by typhoon disasters are located in the southeastern coastal area with highly concentrated industries and high-density population. Meanwhile, cities in the China's eastern coastal areas have accommodated more and more people with the advancement of urbanization, which means the impact of typhoon disasters will become increasingly serious. Therefore, it is urgent to enhance the climate resilience through urban spatial planning to cope with typhoon disasters.

In 2016, United Nations Conference on Housing and Sustainable Urban Development (Habitat III) advocated the construction of inclusive, safe, sustainable and resilient cities to meet the challenge of climate change. In recent years, city resilience improvement and resilient city development have received increasing attention and recognition with the advancement of Chinese new urbanization strategy and high-quality urban development strategy. For example, Shanghai has proposed the urban development goal of "responding to global climate change, enhancing the city's ability to resist natural disasters, and building a more sustainable and resilient ecological city". However, typhoons can bring secondary disasters such as strong winds and rainstorms which are characterized by high disaster intensity, rapid changes, and high uncertainty. Traditional urban disaster prevention planning methods (such as improving defense standards and formulating prevention planning) cannot respond to rapidly changing disaster situations in a timely manner. It is urgent for city planners to explore more adaptive planning methods to cope with the challenges brought about by climate change. In this context, urban planning should use dynamic models to improve the spatiotemporal governance paradigm and technical system except traditional static spatial strategies (Cai et al., 2018).

With the promotion and popularization of mobile Internet technology, disaster-stricken people can post real time disaster information on social media platforms at first time, such as disaster time, rescue request messages, and disaster locations. Social media data has become an emerging source of disaster situation information. Compared with traditional media reports, social media data has the advantages of large data volume, strong timeliness and wide spatial coverage (Allaire, 2016, Li et al., 2024). Based on identifying, extracting and analyzing

relevant disaster information from social media data, urban planners and policymakers can better perceive disasters and dynamically optimize spatial elements according to changes in disaster characteristics to ensure the governance effectiveness of urban planning and achieve climate resilience.

This paper selects Shanghai as the research area and analyzes the spatiotemporal perception characteristics of typhoon disasters by the real time disaster information published on social media during the disaster. It explores the application path of big data technology and social media data in responding to climate change challenges in order to provide reference for exploring new technical methods for resilient urban planning.

2. Literature review

Disaster perception is the process of hazardous environment cognition and risk avoidance (Kieu and Senanayake, 2023). Due to global climate change, extreme weather intensifies the uncertainty and complexity of disaster risk, which leads to the weakened significance of accurate prediction, control and prevention for disaster reduction (Linkov et al., 2013). Correspondingly, it is more important for disaster response to obtain disaster information and conduct disaster perception. However, it is not enough to cope with complex and changeable disaster disturbances based on traditional methods of data acquisition and analysis. Firstly, comprehensive spatiotemporal data on disasters cannot be obtained through disaster information of traditional news media. Secondly, although statistical survey can provide direct disaster information, this method is costly and often accompanied by safety risks (Guo et al., 2025). Thirdly, it is also technically difficult for real-time emergency response to analyze remote sensing images (Shastry et al., 2023), because remote sensing cannot take into account both time and spatial resolution (Hou et al., 2024). In recent years, social media has increasingly become the main medium for information dissemination natural disasters (Chu et al., 2024). The widespread use of social media has promoted the rapid dissemination of real-time information during disasters (Liang and Ramirez-Marquez, 2024), which can integrate a large amount of spatiotemporal disaster information in a short time, and Therefore social media can make up for the method defects of traditional disaster information acquisition such as high cost and poor timeliness (Hou et al., 2024).

Social media can enhance situational perception during the disaster (Li et al., 2023a). Many scholars have paid attention to the role of urban public in disaster response, and try to conduct perception analysis through disaster information published on social media. At present, the application dimensions of social media in disaster mainly include temporal dimension, spatial dimension, text dimension and network dimension (Li et al., 2023a), and the analysis methods include sentiment analysis, text themes analysis, spatial correlation analysis and social network analysis. In the time dimension, social media data can be applied to analyze the changing characteristics of public sentiment and disaster themes. For example, Zhang et al. analyzed the public sentiment changes during typhoon disasters based on social media data, and find that typhoon disasters lead to a corresponding increase of negative sentiment (Zhang et al., 2024). Han and Wang identified 6 types of flood-related themes and 9 types of public sentiment reactions with text analysis on Sina microblog, and found that different types of themes and sentiment reactions closely corresponded to different development stages of flood disaster (Han and Wang, 2019). In the spatial dimension, social media data can be applied to analyze the distribution pattern of disaster vulnerability. For example, Forati and Ghose analyzed the spatial distribution characteristics of social media data during Hurricane Irma based on Twitter data and found the uneven characteristics of community vulnerability (Forati and Ghose, 2022). Zou et al. analyzed the geographical location of rescue requests on Twitter during Hurricane Harvey and found that communities with more rescue requests had more vulnerable environments and socioeconomic conditions (Zou et al., 2023). In the text dimension, social media data can be applied for sentiment recognition and disaster theme classification. For example, Karimiziarani et al. conducted sentiment recognition and topic classification of Twitter text with natural language processing (NLP) methods, and reveal the characteristics of social media responding to hurricanes (Karimiziarani et al., 2023). In the network dimension, social media data can be applied to analyze the relationship among Individual actors in social networks in order to identify important disaster information. For example, Lu and Brelsford applied Twitter data and the Infomap method to analyze the dynamic evolution of social networks during Japanese earthquake and tsunami in 2011, which reveals the change pattern of social interaction mechanisms under extreme events (Lu and Brelsford, 2014).

From an objective point of view, there are also certain challenges in applying social media data to disaster perception. In terms of data sources, disadvantaged groups may lack access to social media, resulting in "digital divide" problem (Xiao et al., 2015). Meanwhile, there may be low engagement in social media use in these area which suffer from severe disasters (Crawford and Finn, 2015). In terms of data processing, social media data may also present problems with the spread of misinformation (Erokhin and Komendantova, 2024). Therefore, it is still a major challenge to extract disaster information from massive social media messages (Hou et al., 2024). Fortunately, the analysis accuracy of social media can be improved through the improvement of analysis methods and the combination of multi-source data and it means that social media data can cope with the application challenges. At the same time, residents in different environments may suffer from differentiated disaster risks (Kaźmierczak and Cavan, 2011, Carvalho et al., 2022, Smiley et al., 2022, Nielsen et al., 2023). Therefore, as a type of real-time big data, social media data is essential for the efficiency improvement of disaster response in the case of disaster uncertainty challenge.

In general, the application of social media has profoundly changed the way of social communication and interaction. Correspondingly, social media has become an important element of "social perception", and it has become a research focus to conduct disaster perception based on social media data (Liu et al., 2015, Fang et al., 2019). In China, because of frequent and diverse disasters, social media is equally significant for the level improvement of urban disaster perception and the capability enhancement of disaster response. However, due to the complexity of Chinese semantics and the differences in social media type, it is under development to apply social media data to disaster perception in China (Jin et al., 2021). Therefore, there is still great application potential in the research on social media data such as city cases, disaster types, and research methods (Xie and Shao, 2024).

3. Research method

3.1. Study area

As the center of Chinese economic and technological innovation, Shanghai is a well-known megacity with a high population density and frequent economic activities. However, Shanghai is extremely vulnerable to typhoon disasters because of subtropical monsoon climate. According to statistics, Shanghai has suffered from typhoon disasters almost every year, which have had an impact on infrastructure damage, urban transportation, and social economy (Table 1). It means that typhoon disasters have become a challenge of resilient city development in Shanghai. Therefore, this paper selected Shanghai as the research object, the spatial scope covers the entire administrative region of Shanghai.

Table 1. Typhoon disasters statistics in Shanghai from 2010 to 2024

Year	Number of typhoon	Typhoon name and typhoon number
2010	0	/
2011	1	Typhoon Muifa (1109)
2012	1	Typhoon Haikui (1211)
2013	1	Typhoon Fitow (1323)
2014	2	Typhoon Fung-wong (1416), Typhoon Vongfong (1419)
2015	3	Typhoon Chan-hom (1509), Typhoon Goni (1515), Typhoon Dujuan (1521)
2016	1	Typhoon Meranti (1614)
2017	1	Typhoon Talim (1718)

2018	6	Typhoon Ampil (1810), Typhoon Jongdari (1812), Typhoon Yagi (1814), Typhoon Rumbia (1818), Typhoon Maria (1808), Typhoon Kong-rey (1825)
2019	4	Typhoon Lekima (1909), Typhoon Mitag (1918), Typhoon Lingling (1913), Typhoon Tapah (1917)
2020	3	Typhoon Hagupit (2004), Typhoon Bavi (2008), Typhoon Maysak (2009)
2021	2	Typhoon In-Fa (2106), Typhoon Chanthu (2114)
2022	1	Typhoon Muifa (2212)
2023	0	/
2024	2	Typhoon Bebinca (2413), Typhoon Pulasan (2414)

Data sources: The data is collected from China Meteorological Disaster Yearbook, and China Climate Bulletin.

3.2. Analysis scenarios and data sources

3.2.1. Analysis scenarios

From September 14, 2024 to September 22, 2024, Typhoon Bebejia and Typhoon Prasang landed in Pudong New Area and Fengxian District of Shanghai respectively, and passed directly through the urban area. Typhoon Bebejia and Typhoon Prasang caused serious disasters in Shanghai such as rainstorm and waterlogging. Specifically, the central wind speed of Typhoon Bebiga reached level 14 (the range of wind speed is 41.5m/s - 46.1m/s) when it landed, making it the strongest typhoon to land in Shanghai since 1949. Typhoon Plasang brought a 500-year rainstorm to Shanghai especially Fengxian district and Pudong New Area. Furthermore, it was the first time that Shanghai was hit by two typhoon disasters in a week. Therefore, this paper selects Typhoon Bebejia and Typhoon Prasang as research scenarios, and conducts the spatiotemporal perception of typhoon disasters with the real time disaster information published on Sina microblog during the disaster (Figure 1).

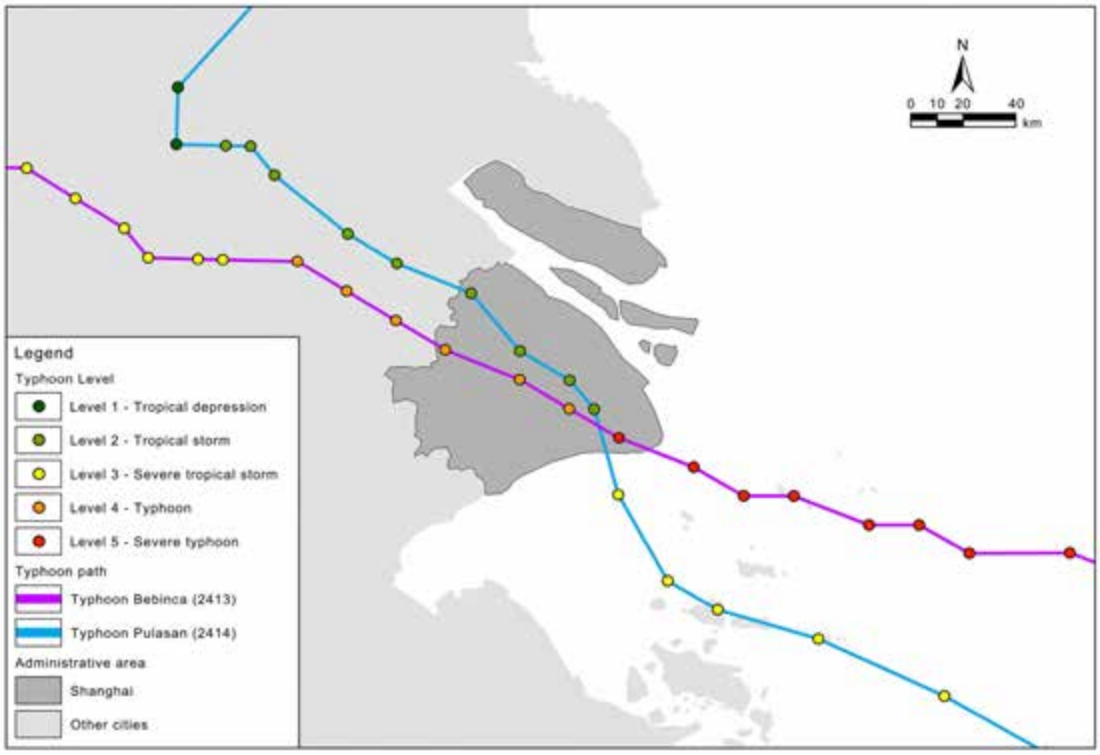

Figure 1. The paths of Typhoon Bebejia and Typhoon Prasang

3.2.2. Data sources

Sina microblog is a very popular social media in China which is equivalent to Twitter (Li et al., 2023b). Therefore, this paper collects typhoon disasters information from Sina microblog messages. Firstly, this paper collects Sina microblog messages in Shanghai area with a time range from September 14, 2024 to September 22, 2024. According to statistics, 27521 pieces of Sina microblog message are collected, which includes comment text, time and spatial location. Secondly, these Sina microblog messages are filtered based on keywords related to typhoon disasters (such as typhoon, Bebejia, Prasang, rainstorm, strong wind, waterlogging, water outage, and power outage). Thirdly, 2734 pieces of relevant messages are sorted out.

3.3. Research design

3.3.1. Text features analysis

Text features analysis includes disaster themes determination and text sentiment evaluation according to the disaster information published on the Sina microblog.

In terms of disaster themes determination, this paper classifies the disaster themes that the public is concerned about based on the LDA (Latent Dirichlet Allocation) topic model. LDA is a commonly used topic model in natural language processing, which can identify different themes from a text collection. At the same time, this study determines the optimal number of disaster theme through the perplexity test and pyLDAvis (python library for Latent Dirichlet Allocation visualization). The perplexity test formula is:

$$\text{perplexity}(D)=\exp\left\{-\frac{\sum_{m=1}^{M}\log P(W_m)}{\sum_{m=1}^{M}N_m}\right\} \qquad (a1)$$

In the formula a1, D represents the text dataset, M represents the number of text items in the text dataset, N_m represents the number of words in the text item m, W_m represents the word sequence of the text item m, P(W_m) represents the appearance probability of each word in the text set.

In terms of text sentiment evaluation, this paper firstly applies the HowNet sentiment dictionary to identify and score the sentiment of Sina microblog text. Next this paper calculates the scores of positive or negative microblog texts respectively, and the range of sentiment score is limited to [0, 5] to avoid extreme values.

3.3.2. Analysis of disaster perception in the time Dimension

This research step mainly analyzes the change characteristics of Public Concern Index of Time Dimension (PCITD), Negative Sentiment Intensity of Time Dimension (NSITD) and Positive Sentiment Intensity of Time Dimension (PSITD) during the typhoon disasters. PCITD indicates the public attention to the event. Meanwhile, NSITD and PSITD reflect the overall change of the public sentiment towards the event.

(1) The formula of PCITD is:

$$PCITD=\frac{NT_{related}}{NT_{total}} \quad (b1)$$

In the formula b1, $\mathrm{NT}_{\mathrm{related}}$ represents the number of Sina microblog messages related to typhoon disasters within the t time interval, $\mathrm{NT}_{\mathrm{total}}$ represents the total amount of Sina microblog messages within the t time interval, which can also be called background information.

(2) The formula of NSITD is:

$$NSITD=\frac{\sum_1^t(ntmes_i)}{nn_t} \quad (b2)$$

In the formula b2, represents the sentiment score of each negative Sina microblog message within the t time interval, nn_{t} represents the total number of negative Sina microblog messages within the t time interval.

(3) The formula of PSITD is:

$$PSITD=\frac{\sum_1^t(ptmes_i)}{np_t} \quad (b3)$$

In the formula b3, represents the sentiment score of each positive Sina microblog message within the t time interval, np_{t} represents the total number of positive Sina microblog messages within the t time interval.

3.3.3. Analysis of disaster perception in the spatial Dimension

Firstly, this research step mainly analyzes the characteristics of Public Concern Index of Spatial Dimension (PCISD), Negative Sentiment Intensity of Spatial Dimensions (NSISD), and Positive Sentiment Intensity of Spatial Dimensions (PSISD) based on ArcGIS in order to quantify the public perception level of typhoon disasters and the spatial distribution characteristics of the typhoon disasters impact on the public. Secondly, this paper performs spatial autocorrelation analysis and hotspot analysis on PCISD, NSISD, and PSISD.

Importantly, there will be few data in many grids due to the division of the 1km*1km grid which will result in small sample problems (Wang et al., 2020). Therefore, this paper applies a 2km*2km grid for spatial statistics.

(1) The formula of PCISD is:

$$PCISD=\frac{NS_{related}}{NS_{total}} \quad (c1)$$

In the formula c1, $\mathrm{NS}_{\mathrm{related}}$ represents the number of Sina microblog messages related to typhoon disasters in the grid, $\mathrm{NS}_{\mathrm{total}}$ represents the total amount of Sina microblog messages in the grid.

(2) The formula of NSISD is:

$$NSISD=\frac{\sum(nsmes_i)}{nn_s} \quad (c2)$$

In the formula c2, represents the sentiment score of each negative Sina microblog message in the grid, nn_{s} represents the total number of negative Sina microblog messages in the grid.

(3) The formula of PSISD is:

$$PSISD=\frac{\sum(psmes_i)}{np_s} \quad (c3)$$

In the formula c3, represents the sentiment score of each positive Sina microblog message in the grid, np_{s} represents the total number of positive Sina microblog messages in the grid.

4. Results

4.1. Text features

4.1.1. Disaster themes determination

This paper applies the perplexity test and pyLDAvis to determines the optimal number of disaster themes. In terms of the perplexity test, the optimal number of themes corresponds to the low perplexity. In terms of the overlap analysis among themes, each circle represents a theme, and the area of the circle is positively correlated with the frequency of the topic. The distance between different circles represents the independence between different topics, and the distance between circles is positively correlated with the independence between subjects. When the circle does not overlap, it means that the optimal number of disaster themes is determined. Combining the perplexity test and the overlap analysis among themes, this paper finally determined three disaster themes (Figure 2).

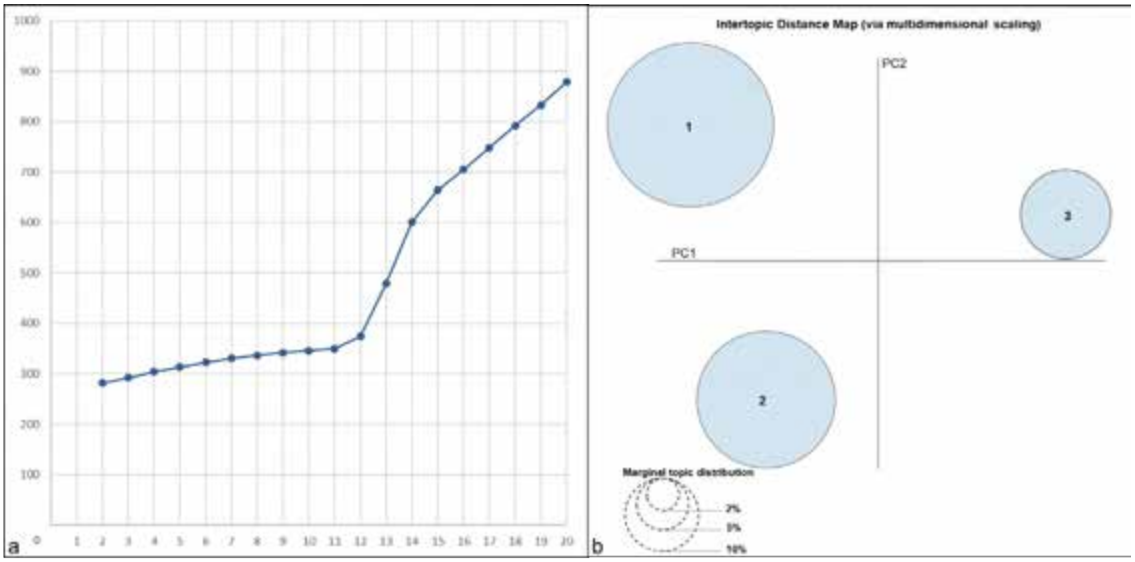

Figure 2. The perplexity test (a) and pyLDAvis (b)

At the same time, this paper screens the keywords within each disaster theme and filters out a total of 30 keywords by eliminating duplicates, unclear meanings and other invalid words. This paper finds that the keywords of each theme have different focuses. Among them, the keywords of theme 1 focus on the interference of typhoons in daily activities, especially the daily travel activities of urban residents. The keywords of theme 2 focus on the disaster-stricken places and people, especially Fudan University, ports and urban streets. The keywords of theme 3 focus on the status of public places after the disaster, such as campuses, hotels, squares, Shanghai Bund, subway stations and other public places (Table 2).

Table 2. Statistics of disaster themes determination

Number	Keywords	Disaster theme focus
Theme 1	Typhoon landfall (24.10%), garden (12.17%), impact (10.98%), life (10.04%), strong typhoon (9.35%), terminal building (8.55%), flight (7.10%), Pudong New Area (6.47%), outings (5.91%), community (5.33%)	Interference on daily activities
Theme 2	Fudan University (14.90%), rainstorm (13.84%), ferry (10.60%), Shanghai Port (10.43%), building (8.58%), wind and rain (8.58%), river bay (8.54%), road (8.35%), Suzhou River (8.32%), students (7.85%)	Affected locations and populations
Theme 3	After the disaster (16.15%), campus (14.61%), hotel (11.33%), square (10.89%), Bund (10.56%), notes (8.31%), power outage (8.24%), weather (7.67%), Baoshan district(6.39%), subway station (5.85%)	Post-disaster public places

Note: The value behind the keyword represents the discussion proportion of keyword in the disaster theme.

Combined with the actual situation of Shanghai, the characteristics of typhoon disasters can be summarized according to the disaster theme. Firstly, the typhoon disasters caused secondary disasters such as strong wind, rainstorm and waterlogging. These secondary disasters led to flight delays, subway suspension and public traffic interruption which had a great impact on travel activity of residents. Secondly, typhoon caused damage to houses and public service facilities. Therefore, affected places and people have become one of the focuses in the disaster. Finally, Typhoon Bebinca and Typhoon Pulasan landed in Shanghai consecutively within a week, which had a certain impact on the progress of post-disaster recovery, especially the restoration of the public places.

4.1.2. Text sentiment evaluation

According to the sentiment identification and sentiment score, there are 559 texts of negative sentiment (accounting for 20.45%), 1016 texts of positive sentiment (accounting for 37.16%), and 1159 texts of neutral sentiment (accounting for 42.39%). From the perspective of sentiment intensity, the average score of negative sentiment is -1.53, and the average score of positive sentiment is 1.71 (Table 3). From the perspective of the frequency distribution of the sentiment scores, there shows the characteristics of normal distribution among negative sentiment, positive sentiment and neutral sentiment (Figure 3). These statistics show that the sentiment intensity of positive sentiment is slightly higher than that of negative sentiment, which means the overall mood of urban residents was relatively optimistic during this typhoon.

Table 3. Statistics of text sentiment evaluation

Type	Quantity	Percentage	Average score
Sina microblog messages expressing negative sentiment	559	20.45%	-1.53
Sina microblog messages expressing positive sentiment	1016	37.16%	1.71
Sina microblog messages expressing neutral sentiment	1159	42.39%	0
Total	2734	100%	/

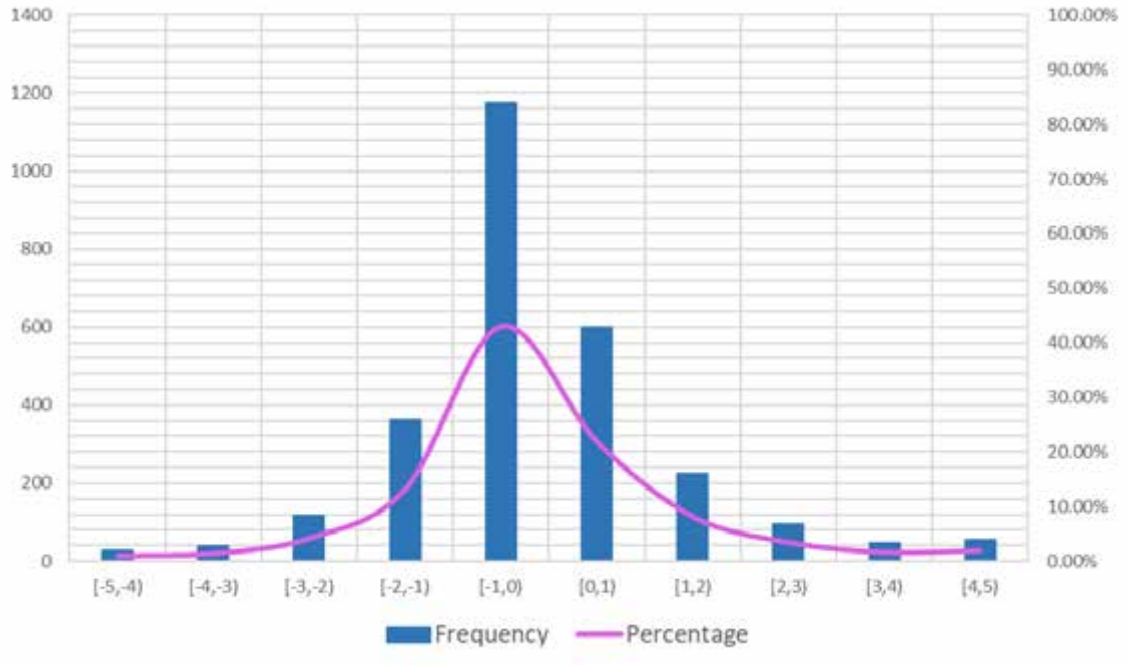

Figure 3. Frequency distribution of sentiment scores

4.2. Disaster perception in the time dimension

The entire period of typhoon disasters is from September 14, 2024 to September 22, 2024 which includes pre-disaster prevention stage, emergency response stage and post-disaster recovery stage (Table 4). The public perception and sentiment intensity also show obvious fluctuations and changes due to the impact of the typhoons.

Table 4. The impact of Typhoon Bebinca and Typhoon Pulasan on Shanghai

Time	Event	Disaster stage
September 14, 2024	Shanghai Central Meteorological Observatory issues typhoon warning for Typhoon Bebinca.	Pre-disaster preparation stage for Typhoon Bebinca
September 15, 2024	Shanghai Meteorological Bureau launches highest level typhoon emergency response.	
September 16, 2024	Typhoon Bebinca landed in Shanghai Pudong New Area.	Emergency response stage for Typhoon Bebinca
September 17, 2024	Typhoon Bebinca moved away from Shanghai, and Shanghai entered the post-disaster recovery stage.	Post-disaster recovery stage for Typhoon Bebinca
September 18, 2024	Shanghai Central Meteorological Observatory issues typhoon warning for Typhoon Pulasan.	Pre-disaster preparation stage for Typhoon Pulasan
September 19, 2024	Typhoon Bebinca landed in Fengxian District, Shanghai.	Emergency response stage for Typhoon Pulasan
September 20, 2024	Rainstorm occurs in Shanghai	

September 21, 2024	Typhoon Pulasan moved away from Shanghai, and Shanghai entered the post-disaster recovery stage again.	Post-disaster recovery stage for Typhoon Pulasan
September 21, 2024 - September 22, 2024	Post-disaster recovery work is basically completed.	

Source: The information is collected from news reports related to Typhoon Bebinca and Typhoon Pulasan

4.2.1. Change characteristics of PCITD

PCITD presents obvious double peak characteristics. The first peak occurs from 0:00 to 12:00 on September 16, 2024 (Emergency response stage for Typhoon Bebinca) and the second peak occurred from 0:00 to 12:00 on September 20, 2024 (Post-disaster recovery stage for Typhoon Pulasan). It shows that PCITD always reaches the peak when the typhoon landed in Shanghai, and the peak level of PCITD during the occurrence of Typhoon Bebinca was higher than that during the occurrence of Typhoon Pulasan (Figure 4).

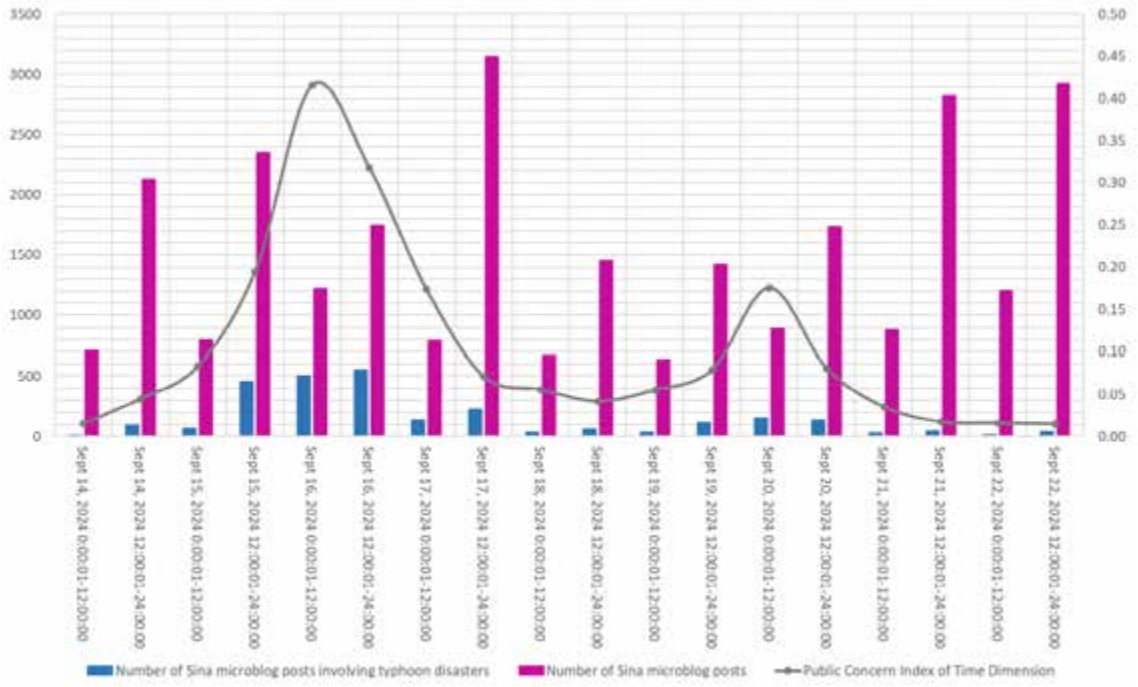

Figure 4. Change of PCITD

4.2.2. Change characteristics of NSITD and PSITD

NSITD and PSITD also presents double peak characteristics. The first peak occurred from 0:00 to 12:00 on September 18, 2024 (Post-disaster recovery stage for Typhoon Bebinca) and the peak of NSITD is higher than the peak of PSITD. The second peak occurred from 0:00 to 12:00 on September 22, 2024 (Post-disaster recovery stage for Typhoon Pulasan) and the peak of PSITD in this stage is higher than the peak of NSITD. At the same time, there is a significant difference between the NSITD and PSITD. The two peak levels of NSITD are basically the same, while the two peak levels of PSITD are quite different. The second peak level of PSITD is higher than the first peak level of PSITD (Figure 5).

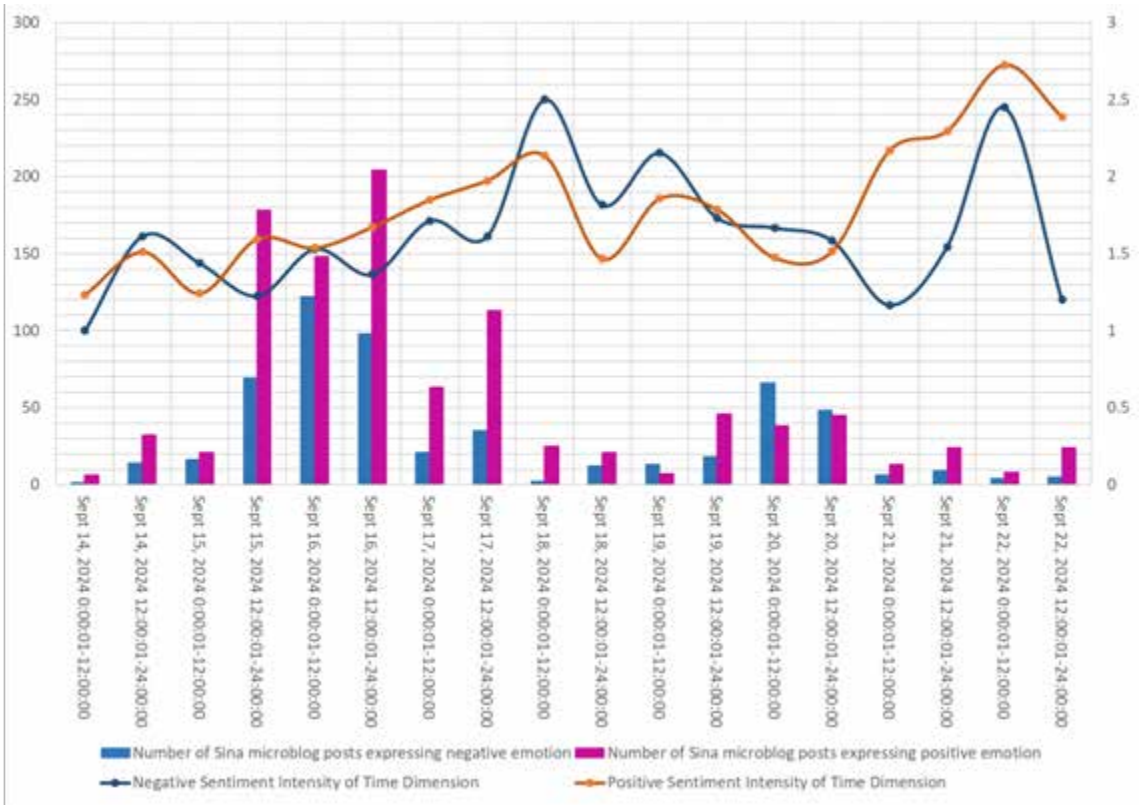

Figure 5. Change of NSITD and PSITD

4.2.3. Comparative analysis of PCITD, NSITD and PSITD

Although PCITD, NSITD and PSITD have two peaks, they have different characteristics. Firstly, the peak of NSITD and PSITD lags behind the peak of PCITD. The peak of PCITD occurs in the emergency response stage, while the peak of NSITD and PSITD occurs in the post-disaster recovery stage. Secondly, the time curve of PCITD is relatively smooth with obvious upward and downward trends, while the time curves of NSITD and PSITD show the fluctuating characteristics. In view of this disaster period, Typhoon Bebinca is stronger than Typhoon Pulasan, and Typhoon Bebinca causes greater damage to the city than Typhoon Pulasan. Therefore, PCITD during the Typhoon Bebinca is higher than that during the Typhoon Pulasan, which also causes the NSITD to be significantly higher than PSITD during the Typhoon Bebinca. At the same time, the continuous disaster impact also caused NSITD to reach two peaks. Fortunately, PSITD rises faster during the Typhoon Pulasan, which also shows the high efficiency of post-disaster recovery work in Shanghai.

4.3. Disaster perception in the spatial dimension

4.3.1. Distribution characteristics of PCISD

The areas with high value of PCISD are mainly distributed around the Shanghai Suburban Ring Road, especially in the southern coastal areas. While, the value of PCISD is relatively low in the areas within the Outer Ring Road (Figure 6).

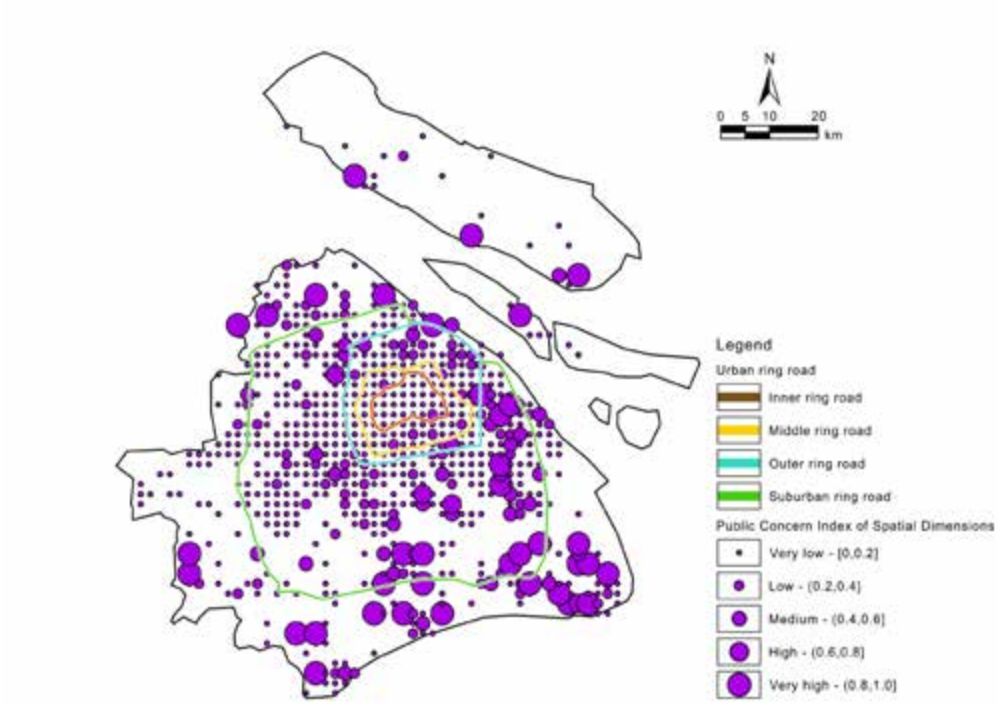

Figure 6. Spatial distribution of PCISD

According to spatial autocorrelation analysis, it shows that the spatial distribution of PCISD has obvious spatial clustering characteristics. For example, the hotspots are distributed in the coastal areas near the south of suburban ring road which are close to the typhoon landing sites and subject to typhoon disasters. While, the cold spots are distributed in the inland areas which are relatively less affected by typhoon disasters (Figure 7).

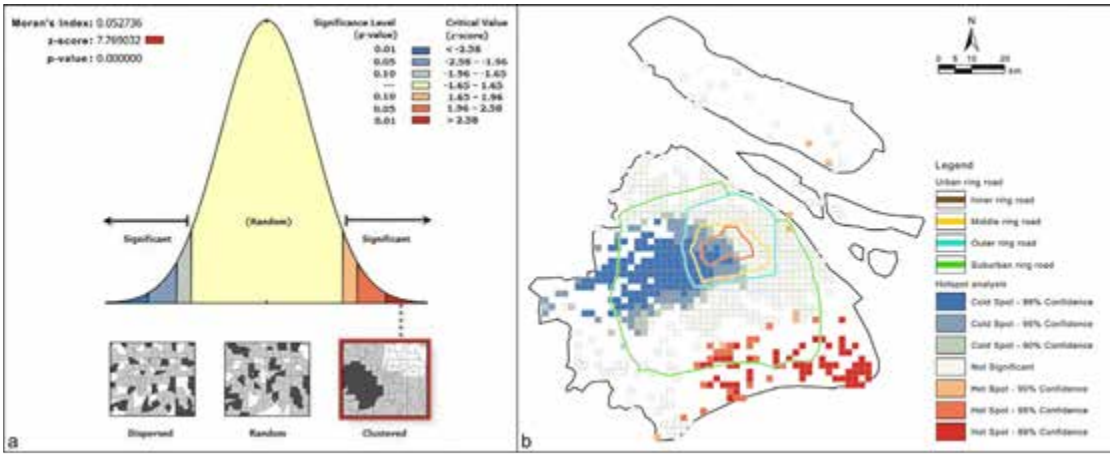

Figure 7. Spatial autocorrelation analysis of PCISD (a) and hot spot analysis of PCISD (b)

4.3.2. Distribution characteristics of NSISD and PSISD

In terms of NSISD, the areas with high value of NSISD are generally located within the outer ring road, while the areas outside the outer ring road present low high value of NSISD, with a small number of high value points of NSISD (Figure 8). In terms of PSISD, the spatial distribution of high value of PSISD is dispersed, the areas with high

value of PSISD includes the area within the outer ring road, the area between the outer ring road and suburban ring road, the area near the southern coast (Figure 9).

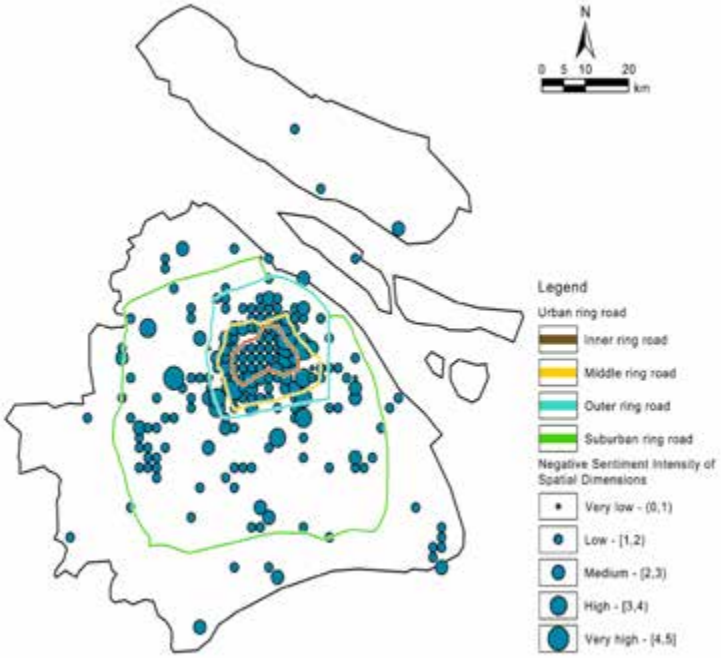

Figure 8. Spatial distribution of NSISD

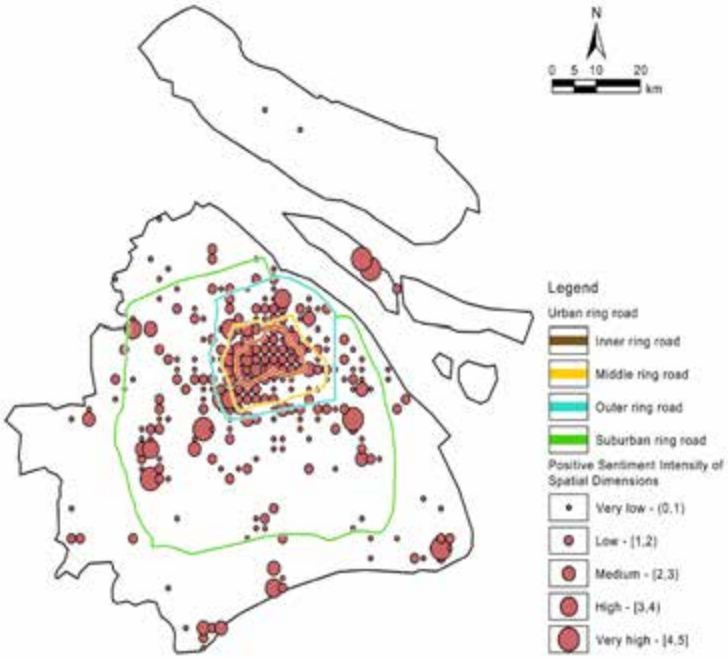

Figure 9. Spatial distribution of PSISD

According to spatial autocorrelation analysis, NSISD and PSISD present different spatial clustering characteristics. In terms of NSISD, NSISD exhibits obvious spatial clustering characteristics. Meanwhile, hotspots of NSISD concentrated within the middle ring road and cold spots of NSISD located in the western area of the suburban ring road (Figure 10). In terms of PSISD, PSISD exhibits random distribution characteristics (Figure 11). Furthermore, there are densely populated population and public service facilities within the middle ring road, which are highly vulnerable to typhoon disasters. Therefore, negative sentiment easily gathers in these areas and becomes hotspots.

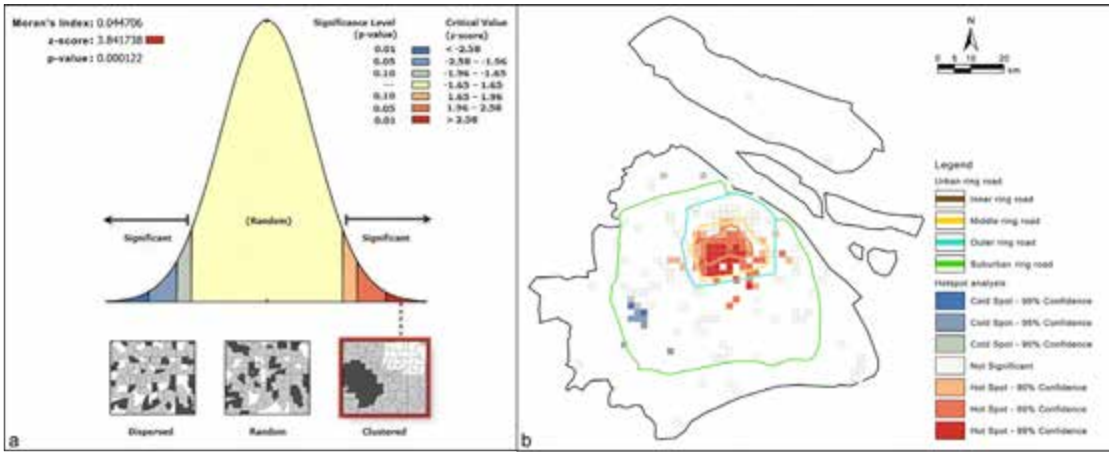

Figure 10. Spatial autocorrelation analysis of NSISD (a) and hot spot analysis of NSISD (b)

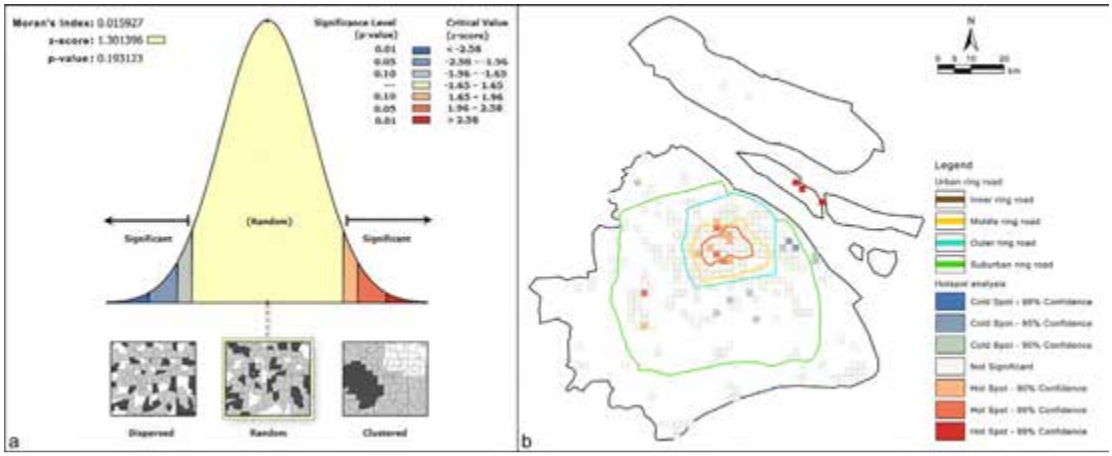

Figure 11. Spatial autocorrelation analysis of PSISD (a) and hot spot analysis of PSISD (b)

4.3.3. Comparative analysis of PCISD and NSISD

By comparing the hotspots of PCISD and NSISD, there is spatial differentiation between PCISD and NSISD. The area with high attention (high value of PCISD) distributes in the southern coast where the negative sentiment is not obvious (low value of NSISD). However, the area with low attention (low value of PCISD) distributes within the middle ring road where negative sentiment concentrated (high value of NSISD). Because low density of population and facility distributes in the southern coast with the greatest typhoon disasters impact, negative sentiment are not concentrated. Meanwhile, high density of population and facility distribute in the area within the middle ring road, but typhoon disasters have different impacts on people in different neighborhoods, which may cause public attention to be dispersed. This phenomenon shows that extreme weather events have greater uncertainty and cause different impacts on different parts of the city.

5. Discussion and conclusion

5.1. Discussion

Based on social media data, this paper conducts spatiotemporal perception analysis on typhoon disasters in Shanghai. Firstly, during the typhoon disasters, residents mainly focused on three themes, including daily travel activities, disaster-stricken locations and people, and post-disaster public places. It means that the focus of typhoon disasters prevention should include urban transportation, highly vulnerable neighborhoods and people, and public spaces. Secondly, the peak of PCITD occurs during the emergency response stage, while the peak of PSITD and NSITD occurs during post-disaster recovery stage. It means that PCITD can reflect the changing trend of the disaster impact, and disaster recovery effects can be evaluated based on NSITD and PSITD. Thirdly, PCISD can reflect the spatial distribution of disasters impact, and NSISD can reflect the spatial distribution of disaster-stricken conditions.

Typhoon disaster is the main type of natural disasters that affect the resilience level of cities in the China's eastern coastal areas. With the intensification of climate change, it is urgent to strengthen the ability of typhoon disaster prevention and improve the effectiveness of planning response. According to the above analysis, this paper proposes the following planning strategies.

(1) Construction of disaster intelligent perception platform for planning support system
Social media data provides a data source matching the dynamic change of disaster events, which can establish the disaster intelligent perception platform to achieve intelligent monitoring of typhoons. On the one hand, social media data can be applied to determine the impact and changing trend of the typhoon disasters based on the analysis of the disaster themes, the change of public perception, and the evolution of sentiment intensity. On the other hand, the disaster intelligent perception platform should integrate multiple data resources such as social media data, mobile signaling data and remote sensing data in order to identify disaster hotspots, delineate risk zones, and determine the location of disaster-stricken people.

(2) Layout optimization of emergency facilities based on disaster perception
In the pre-disaster preparation stage, urban planners can timely strengthen the refunction of emergency facilities and plan emergency evacuation routes based on hotspots of public concern on the social media. In the emergency response stage, urban planners can identify the location of disaster-stricken areas and provide decision-making support for the allocation of emergency relief resources through the text features analysis of social media. In the post-disaster recovery stage, urban planners can determine the spatial distribution characteristics of disaster damage, allocate relief supplies and set up emergency rescue sites and emergency hospitals based on the analysis of disaster themes and public sentiment intensity.

(3) Integration social media analysis tools into resilient urban planning
In order to cope with the uncertain challenges of disasters, resilient urban planning needs to incorporate dynamic analysis models to enhance adaptability. In terms of spatial dimension, social media data can be applied to conduct spatial distribution analysis of disaster hotspots and sentiment intensity. Meanwhile, these analysis results can be incorporated into disaster risk maps to support shelters selection and evacuation routes organization. In terms of temporal dimension, social media data can be applied to conduct the analysis of disaster themes and sentiment intensity, which can help determine the risk level of typhoon disasters and the key disaster response tasks at different stages.

5.2. Conclusion

As one of the most significant stakeholders in urban governance system, citizens are important force in resilient city construction. In the process of disaster response, it is crucial to analyze the disaster impact on citizens for the formulation of disaster response strategies and the improvement of urban emergency response capabilities. This paper shows that disaster perception through social media data can help reveal the characteristics of typhoon disasters impact on urban residents, which can provide reference for disaster management departments and explore new technical methods for resilient city planning.

With the development of social media and the advancement of messages dissemination, social media data contains multiple data formats such as sound, pictures, and videos in addition to text data, which contain a large amount of disaster information. This paper focuses on text data. In the future, we will further explore the potential of social media data in disaster perception, and conduct comprehensive analysis in combination with multiple data formats to improve the accuracy of disaster perception.

Intelligent Urban Design: Self-organized Block Form Generation Using Reinforcement Learning - An Empirical Study from Nanjing, China

Yuyue HUANG
Affiliation: School Of Architecture, Southeast University, Nanjing, China
Email: huangyy0628@163.com

Abstract
With the rapid rise of AI technologies, intelligent design has enhanced urban planning through algorithm-driven diversity, flexibility, and efficiency. This study proposes a reinforcement learning-based method for the self-organized generation of block forms, enabling adaptive spatial layout optimisation. Using Nanjing, China, as a case study, geometric calculations extract topological relationships to build a prototype database. A reinforcement learning model is then applied, incorporating design constraints like development intensity, building density, height, and green space ratio. Generative design experiments on three Nanjing blocks demonstrate how feedback allows dynamic adjustments, achieving economic, ecological, and social benefits. Unlike traditional rule-based approaches, this model learns through autonomous interaction with the environment and can better adapt to environmental characteristics, offering a novel framework and practical support for intelligent urban design.

Keywords: Block form; self-organized generation; reinforcement learning; intelligent optimisation; urban design

1. Introduction

With the acceleration of global urbanisation, urban design systems are facing the continuous impact of multiple dynamic constraints, such as population mobility and demand for mixed land use [1]. Traditional static planning methods (e.g., zoning planning or morphological guidelines) gradually reveal fundamental flaws in dealing with these real-time changes: First, the construction of the rule base is highly dependent on the experience of experts, and it is difficult to cover the special requirements of different cultural backgrounds and geographic conditions; Second, when faced with the multi-objective optimisation problem, the fixed weight allocation mechanism will easily lead to the solution falling into the local optimum, and often produces a single morphologically homogeneous solutions. This dilemma has given rise to the urgent demand for adaptive generative design methods, to dynamically adjust the spatial form through a real-time feedback mechanism instead of fixed rules [2,3].

Current intelligent design methods are mainly presented as two types of technological paths: multi-objective optimisation based on evolutionary algorithms and generative adversarial networks based on deep learning [4,5]. The former can generate Pareto frontier solution sets, but in practice, it is found that a single iteration is too time-consuming and the morphological diversity is limited; the latter can quickly generate visually reasonable solutions, but there are response delays and the decision-making process lacks transparency [6]. In essence, the existing methods have not yet broken through two key technical bottlenecks: (1) How to maintain the coherence of spatial topological relationships (e.g., the connectivity of the street network); (2) How to achieve real-time integration of dynamic constraints (e.g., dynamic adjustments of construction indicators). These shortcomings seriously restrict the practical application value of self-organised generation of neighbourhood morphology [7].

Reinforcement Learning (RL) provides new possibilities to solve the above problems. Its 'trial-and-error-feedback-optimisation' mechanism is intrinsically compatible with the process of self-organization of urban space: by simulating environmental interactions (e.g., crowd activity scenarios), intelligences can autonomously explore morphological evolution paths that satisfy multiple constraints [8]. The breakthrough research of Zheng et al. (2023) [9] indicates that RL can significantly enhance the working efficiency of human planners in architectural layout optimisation and efficiently generate design schemes of different styles. This lays a theoretical foundation for constructing an adaptive design system at the plot scale. Based on this, this study proposes a reinforcement learning framework that integrates spatial topological relations and dynamic constraints. Its technical implementation includes three core links: Firstly, the spatial topological characteristics of typical blocks in Nanjing are extracted through geometric operations to construct a design prototype database; Secondly, the constraint conditions such as development intensity and building density are quantified as reward functions; Ultimately, generative design was implemented in three districts in Nanjing, and the dynamic optimisation of form was

achieved through the real-time feedback of the revenue function.

Compared with the traditional rule-driven methods, the innovation of this study is reflected in: (1) Mapping the theory of spatial self-organization systematically into the state-action space of reinforcement learning for the first time, which makes the morphogenesis process both environmentally adaptive and topologically stable; (2) Developing an interpretable reward mechanism, which achieves the comprehensive optimisation of economic, ecological and social benefits in the Nanjing case; (3) Constructing a design assistance link to support planner interaction, and the response time of the system was controlled within 30 minutes. The empirical results show that the method can not only meet the current design constraints, but also respond to future demand changes through continuous learning, providing a new technical paradigm for intelligent urban design.

2. Methods

2.1 Technical framework

The Dynamic Coupled Reinforcement Learning (DCRL) framework proposed in this study realizes the intelligent generation and optimisation of building layout schemes through the collaborative operation of four core modules (Fig. 1).

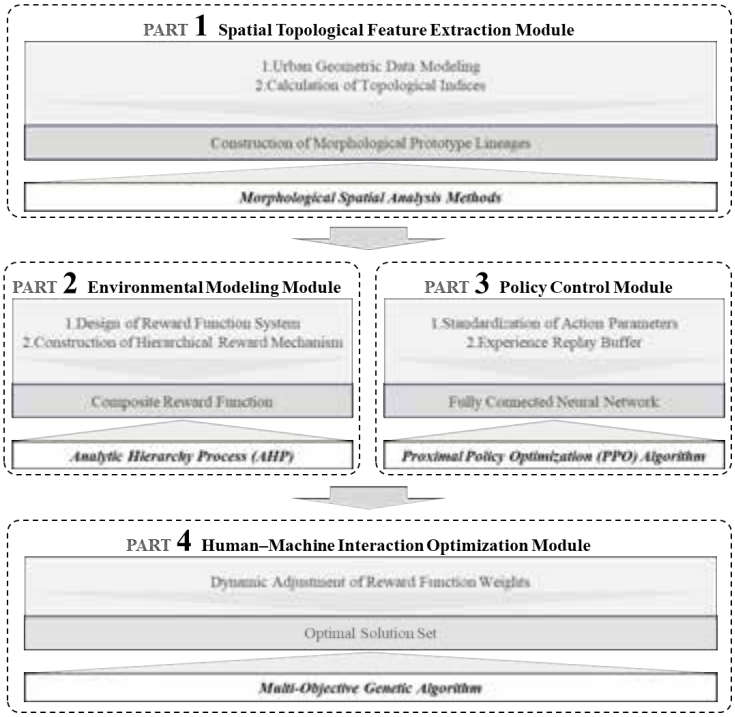

Fig.1. Technical framework

Firstly, the spatial topological feature extraction module conducts three-dimensional modeling of the geometric data of urban blocks, integrates spatial elements such as plot boundaries, street and lane networks, and the contours of existing buildings, and extracts topological indicators such as the curvature of streets and lanes, the fractal dimension of plots, and the proportion of building base area through computational geometric algorithms. Then, the Morphological Spatial Analysis (MSA) method is used for clustering to form a benchmark library containing multiple basic morphological prototypes [10], covering typical patterns such as “grid-type blocks - low-density development” and “radial road networks - mixed functions”, providing multi-dimensional morphological evolution benchmarks for reinforcement learning.

Secondly, the environmental modeling module converts the control elements of urban design into a calculable

reward function system, builds a hierarchical reward mechanism for legal indicators such as floor area ratio and green space ratio, penalizes the indicators deviating from the target interval through the exponential attenuation function, and finally forms a comprehensive reward function through hierarchical weighting, where the weight coefficients are determined by the initial values of the AHP analytic hierarchy process.

Thirdly, the strategy control module adopts the improved Proximal Policy Optimisation (PPO) algorithm [11] to construct the state input layer containing multi-dimensional spatial features and multi-dimensional constraint indicators. Feature fusion is achieved through the fully connected neural network, and the output layer generates standardized action parameters using the Tanh function. Design a double-loop training mechanism: The inner loop synchronously updates the policy network and the value network, and reduces the variance through dominance estimation; For external environmental storage, the strategy transfer is carried out with the optimal 5% scheme of each generation to avoid local optima. In the specific implementation, a 10,000-capacity experience replay buffer is set up, the mini-batch update model is adopted, and the learning rate decays according to the cosine annealing strategy.

Finally, the human-computer interaction optimisation module builds a two-way interaction system. Designers can dynamically adjust the weight of the reward function (such as increasing the green space ratio weight to 0.4). The scheme optimisation module uses the multi-objective genetic algorithm for Pareto frontier optimisation. The iteration termination mechanism is set so that the comprehensive score change rate of the optimal scheme for 10 consecutive generations is less than 1.5% or triggered by manual intervention. Finally, output the solution set of the preferred scheme.

2.2 Case selection and feature extraction

The study selected three typical blocks in Nanjing as the experimental objects: The Gulou Historical Block (1.2 km²) retains the "fishbone-shaped" street and alley layout of the Republic of China era, contains three cultural relics protection units, and has a floor area ratio of 1.2-1.8, representing the protective development of the historical urban area; The CBD of Hexi Area (1.5 km²) features a modern grid-type road network with a plot ratio of 2.5 to 3.5, reflecting high-intensity business development. The Zhujianglu Area (0.8 km²) integrates multiple functions through a radial road network, with a plot ratio of 1.8 to 2.8, reflecting the mixed functional scenarios in urban renewal (Fig. 2).

Fig.2. Three experimental areas

The feature extraction process is divided into two stages: Firstly, the ArcGIS platform is used to conduct geometric analysis of the basic spatial data of the study area, quantitatively extracting topological parameters such as street and alley connectivity, plot division patterns, and plot construction intensity. Secondly, K-means clustering analysis was conducted on the topological characteristics of buildings and plots in the main urban area of Nanjing, and they were classified into different prototype categories to construct a design prototype database. This database not only provides the initial state set for reinforcement learning, but also can generate composite topological structures through parameter combinations, effectively enhancing the diversity basis of form generation.

2.3 Reinforcement learning model construction

The state space design integrates three layers of feature vectors: static features, dynamic constraints, and spatial performance. The static layer includes the One-hot coding of the plot prototype and location features (standardized coordinate values, unique hot coding of road grades, and land use mixing degree index). The dynamic layer covers deviations of legal indicators, simulated values of environmental performance, and social indicators (such as walkability; The performance evaluation layer determines the weights of secondary indicators through the entropy weight method and linearly weights to generate the comprehensive score as the measurement of state value.

The action space defines four types of explainable form adjustment operations: ① Building volume reorganization (base area ±20%, height ±50%, step lengths 5% and 10% respectively), which needs to meet the requirements of fire fighting surfaces and aviation height limits; ② Interface offset (street-back line ±4m, step length 1m, continuous interface ±15%), it is necessary to ensure the width of the sidewalk and the continuity of the interface. ③ Public space replacement (minimum 100 square meters unit, conversion between green space and hard ground) must comply with the lower limit of the green space ratio and the proportion limit of public space in the plot. ④ Development intensity adjustment (FAR±0.2 for adjacent plots, not exceeding 20% of the original index), it is necessary to ensure that the indicators of each plot are compliant and the total construction volume change is ≤5%. Before each action is executed, a multi-constraint verification module that includes 3D spatial conflict detection, planning regulation inspection, and engineering feasibility assessment is adopted to ensure the implemtability of the plan.

3. Results

3.1 Spatial Topological Relationship Graph

The 180 plots of the three typical blocks in Nanjing were geometrically analyzed through the ArcGIS platform, and four types of spatial parameters including Road network, Land function, Development intensity and Building density were extracted. Through K-means clustering, a total of 54 spatial combination prototypes were formed (Fig. 3).

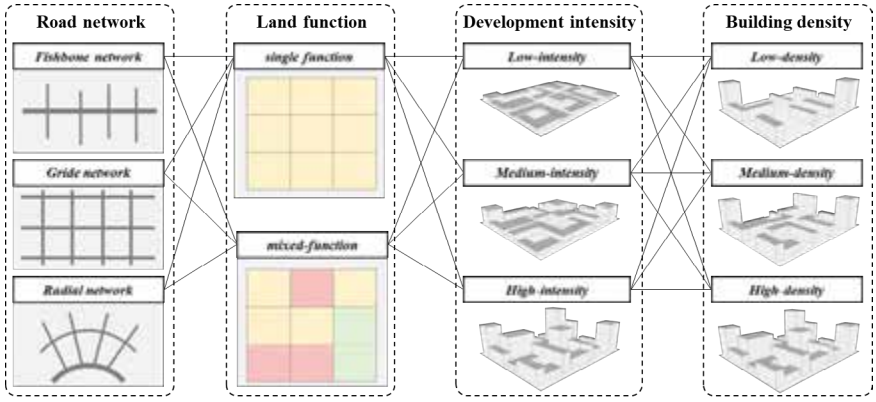

Fig.3. Space prototype combination mode

Among them, the Gulou Area is mainly based on the prototype of "fishbone-shaped streets and alleys + small-scale plots (average 3,000 square meters) + high building density (35%-45%)", and the integration degree of the streets and alleys (spatial syntax α=0.5) reaches 0.82, reflecting the high accessibility of the historical space. The Hexi Area is mainly based on the prototype of "grid-type road network + medium and high-intensity development (FAR=2.5±0.3) + low building density (20%-30%)", and the plot compactness index (0.75±0.05) reflects the regularized form of the modern business district. The Zhujianglu Area presents the characteristics of "radial streets and alleys + mixed functional layout + medium development intensity (FAR=2.2±0.3)", and the variation coefficient of the plot shape coefficient reaches 0.38, reflecting the morphological diversity brought by functional mixing. The prototype database contains various types of geometric parameter thresholds (such as the building aspect ratio 1:1.2-1:1.5) and planning constraints (such as the building height of the plot ≤150m), providing a multi-input space for the initial state vector for reinforcement learning.

3.2 Generation of the design plan for the Gulou Area

In response to the protection and renewal requirements of the Drum Tower Historical Block, the agent generated 32 effective solutions through 150 generations of iterations, and the Pareto optimal solution scheme was obtained through NSGA-II screening (Fig. 4). The optimal plan, while maintaining the integrity of the historical street and alley framework (92%), increases the green space ratio from 18% to 25%, and at the same time reduces the number of households with substandard sunlight exposure in cultural relics protection units from 12 in the initial plan to 0. The specific optimisation strategies include: ① Through the "building volume reorganization" action, reduce the base area of the three plots by 10%-15% to release the space for the construction of pocket parks at street corners; ② Utilize the "interface offset" operation to adjust the receded lines of the buildings along the street (with an average retracement of 2.5 meters), and widen the pedestrian passage to 4.5 meters without disrupting the continuity of the historical interface (maintaining a line alignment rate of 85%). ③ By adjusting the development intensity across plots (reducing the FAR from 1.8 to 1.6), the saved construction volume is transferred to non-protected plots to balance the protection requirements and development benefits. Compared with the traditional rule-driven method, the sunshine compliance rate of the DCRL scheme is increased by 23%, and it avoids the conflict between the green space ratio and building density caused by manually setting weights (the traditional scheme sacrifices an average of 5% of the green space ratio to meet the density requirements).

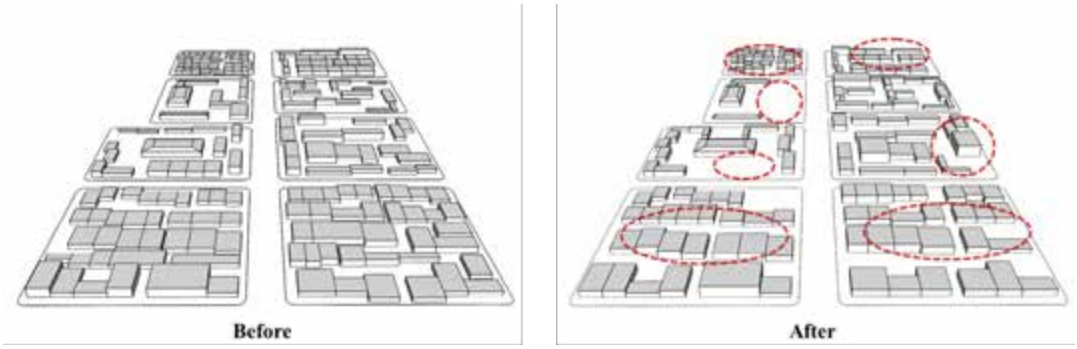

Fig.4. The design optimization plan of the Gulou Area

3.3 Generation of the design plan for the Hexi Area

In the high-intensity development scenario of the Hexi Area, the agent generated 56 compliant schemes after 200 generations of training. The optimal scheme achieved a comprehensive balance of a plot ratio of 3.0 and a building density of 25% (Fig. 5). The key optimisation paths include: ① Converting idle and inefficient land into green space in the center of the plot through "public space replacement", increasing the green space ratio of the block from 18% to 22%; ② Increase the floor area ratio to meet the demands of high-intensity development by raising the FAR of commercial plots from 1.5 to 4.0-7.0; ③ Add landmark buildings. Add landmark high-rise buildings to the plots close to the main roads to enhance the visual experience of the economic core area and economic corridors.

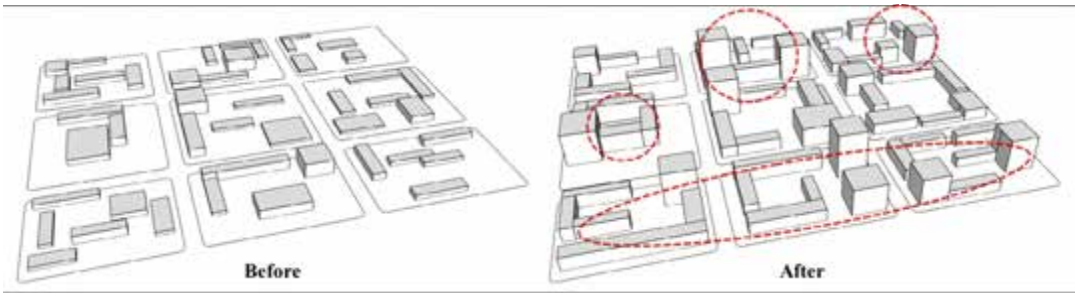

Fig.5. The design optimization plan of the Hexi Area

3.4 Generation of the design plan for the Zhujianglu Area

In response to the complex constraints of the Zhujianglu Area, the agent generated 45 effective schemes. The optimal scheme achieved a functional ratio of commercial building area accounting for 35%, residential building area accounting for 50%, and office building area accounting for 15% (Fig. 6). At the same time, the coverage rate of bus stops within a 500-meter walk reaches 100% (Figure 5). The core optimisation methods include: ① Through the "interface offset" operation, continuous arcade interfaces (200m in length) are set up in commercial plots to enhance the commercial atmosphere of the street, while meeting the requirement that the width of the sidewalk is ≥3m; ② Utilize "building volume reorganization" to adjust the building height of the residential plot (increase by 15%), expand the residential area without exceeding the height limit (50m), and maintain the uniformity of the street interface simultaneously through the control of the line connection rate (75%). ③ Through cross-plot development intensity adjustment (FAR±0.2), the excess 0.3 FAR of residential plots was transferred to commercial plots to achieve functional optimisation without changing the total construction volume. Compared with the traditional scheme, the scheme generated by DCRL has significant improvements in social indicators such as the functional mixing degree (the mixing degree index calculated by the entropy method is 0.89) and the efficiency of the walking network (the average shortest path is reduced by 120m).

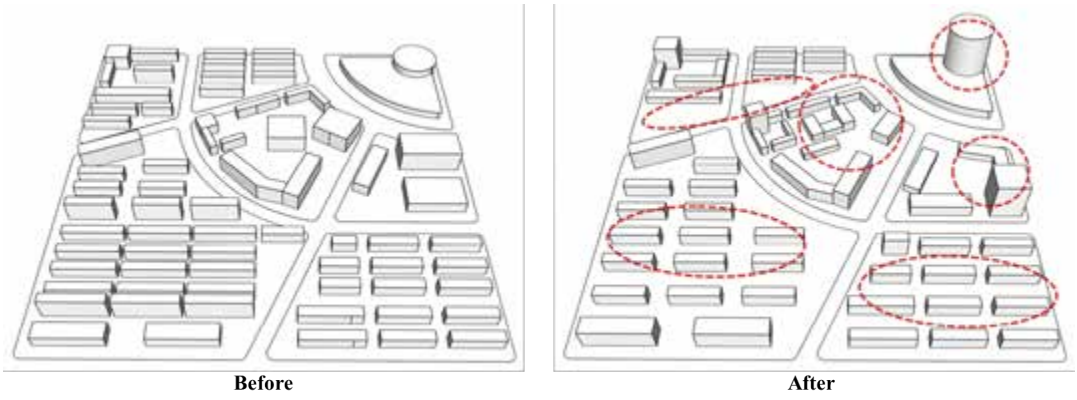

Fig.6. The design optimization plan of the Zhujianglu Area

Experimental data show that the optimal schemes of the three types of blocks all meet all the legal constraints (floor area ratio deviation ≤±0.1, green space ratio ≥ the legal lower limit), and on average increase by 18%-25% in environmental and social indicators compared with the initial schemes. The average training time was shortened by 15% compared with expectations, verifying the improvement effect of the elite solution set transfer strategy on computational efficiency. Visual analysis shows that the retention degrees of the morphological prototypes of each block generation scheme all exceed 70%, proving that DCRL has achieved innovative optimisation while maintaining the stability of spatial topology.

4. Discussion

4.1 Method Innovation

The core difference between the DCRL proposed in this study and the traditional generative design method lies in the construction of an intelligent decision-making mechanism of "dynamic feedback - continuous optimisation", breaking through the limitation of the traditional method that relies on "static rule base + heuristic search". Traditional generative design mostly generates schemes based on preset form rules (such as building regression lines, floor area ratio zoning, etc.), and its optimisation process is essentially parameter traversal under fixed constraints, making it difficult to respond in real time to complex environmental changes and multi-objective conflicts (such as the dynamic balance between economic benefits and ecological benefits). The DCRL converts urban design constraints into quantifiable dynamic reward signals through the environmental modeling module. Combined with the PPO algorithm of the policy optimisation module, it enables the agent to independently learn the optimal layout strategy in the interaction with the virtual environment, achieving a paradigm shift from "rule-driven" to "data-rule dual-driven". For example, when dealing with the contradiction between floor area ratio and green space ratio, traditional methods require manual setting of priority weights. However, DCRL, through the adaptive adjustment of the reward function, can dynamically search for the optimal solution that takes both into account in the Pareto front solution space, avoiding the local optimal problem caused by static rules.

The design of the reward mechanism plays a key coordinating role in multi-objective optimisation. The comprehensive reward function constructed in the research integrates the legal control indicators, environmental performance and social effects. Through hierarchical weighting (determining the initial weight by AHP) and dynamic adjustment (the human-computer interaction module supports real-time weight modification), the systematic quantification of multiple design goals is achieved. Compared with the linear weighting method commonly used in traditional multi-objective optimisation (with fixed weights and difficulty in reflecting the nonlinear relationship between objectives), the reward mechanism of DCRL has stronger dynamic adaptability: On the one hand, the implicit design requirements are transformed into calculable optimisation objectives through continuous reward signals (such as real-time simulation values of sunlight accessibility and pedestrian network convenience); On the other hand, combined with the generation and visualization of Pareto frontier solutions (the NSGA-II algorithm supports multi-scheme trade-offs), it provides designers with clear solutions to target conflicts, enabling the balance process of "economic benefits - ecological benefits - social benefits" to shift from empirical judgment to data-driven. This method of encoding urban design knowledge into computable reward signals provides a universal framework for the intelligent generation of complex built environments.

4.2 Practical Significance

The DCRL framework has shown significant application potential in the scenario of urban stock renewal. Stock renewal faces challenges such as complex spatial ownership, numerous constraints of existing facilities, and diverse demands of stakeholders. Traditional design methods are difficult to efficiently handle the dynamic coupling problem of multi-dimensional constraints. Take the Nanjing Gulou Historical Block as an example. Its spatial prototype of "fishbone-shaped streets and alleys + high-density plots" has strict protection requirements for building volume and interface continuity, and at the same time needs to meet the demands of modern traffic organization and public service improvement. The prototype database constructed by the spatial topological feature extraction module of DCRL can accurately identify existing morphological genes (such as small-scale plot boundaries and historical interface alignment rates), and combine the reward mechanism to quantitatively balance the protection elements (sunlight spacing of cultural relics protection units) and the renewal demands (new green space ratio). Generate a layout plan that not only meets the requirements of historical style protection but also enhances spatial performance. This workflow of "prototype recognition - constraint translation - intelligent optimisation" is particularly suitable for the refined design of complex existing Spaces such as old urban areas and industrial heritage areas, providing technical support for urban renewal to shift from "incremental expansion" to "existing quality improvement".

In terms of interface compatibility with the urban planning management system, DCRL has achieved seamless

integration of intelligent design achievements with the existing planning control system through standardized data interaction mechanisms and constraint translation methods. Firstly, the spatial topological feature extraction module adopts the CityGML standard to construct a three-dimensional spatial information model, and forms data intercommunication with the ArcGIS platform commonly used in the planning management system to ensure the consistency of basic parameters such as plot division and construction intensity. Secondly, the environmental modeling module directly converts legal indicators such as floor area ratio and building density into the core variables of the reward function, enabling the schemes generated by the agent to naturally comply with the planning control requirements (such as the development intensity deviation controlled within ± 0.2FAR), reducing the frequent compliance verification costs in the generation of traditional schemes. Finally, the human-computer interaction module enables designers to adjust the constraint weights in real time (such as adjusting the priority of the green space ratio according to the control plan), enabling the optimisation process to respond synchronously to changes in planning management policies and forming a closed-loop workflow of "intelligent generation - manual guidance - policy adaptation". This compatibility lays the foundation for the deep integration of the planning approval system and intelligent design tools, promoting the transformation of urban design from "experience-based decision-making" to "data-driven intelligent decision-making".

4.3 Limitations and Future Prospects

Although the DCRL framework shows advantages in method innovation and practical application, its performance is still limited by the quality of training data and computational efficiency. Firstly, the construction of the spatial prototype library relies on the typical morphological features obtained by K-means clustering. When facing small sample scenarios (such as special functional blocks and extreme terrain conditions), the limited training data may lead to insufficient prototype coverage, thereby affecting the diversity and adaptability of the generation schemes. For example, if a certain block has a unique form of "valley landform + irregular road network", and there is a lack of similar samples in the prototype library, the agent may not be able to effectively identify the key constraints, resulting in spatial performance deficiencies in the scheme. Future research can introduce transfer learning techniques. By using the pre-trained basic prototype model combined with a small amount of data in the target area for fine-tuning, the generalization ability of the model in small sample scenarios can be enhanced. Meanwhile, explore self-supervised learning methods to automatically discover potential morphological patterns and dynamically expand the coverage of the prototype library.

Secondly, the balance between the real-time computing efficiency and the design cycle of the reinforcement learning model urgently needs to be optimized. The PPO algorithm adopted in the current strategy optimisation module takes a long time in a single iteration when dealing with the high-dimensional state space and the continuous action space (a single case requires approximately 4 to 6 hours to complete 200 generations of training), and it is difficult to meet the requirements of rapid scheme comparison and selection in actual projects. Although the research has improved the training efficiency through the experience replay buffer and the elite solution set transfer mechanism, in the design of large-scale urban districts, the consumption of computing resources still increases exponentially. In the future, breakthroughs can be made in two aspects: algorithm optimisation and hardware acceleration. On the one hand, develop lightweight neural network architectures (such as the combination of deep reinforcement learning and graph neural networks) to reduce the computational complexity of state processing. On the other hand, the distributed computing platform is utilized to process the optimisation tasks of multiple plots in parallel. Combined with GPU acceleration technology, the time of a single iteration is shortened, promoting the framework to be implemented from the experimental environment to engineering application scenarios. Furthermore, exploring the two-tier architecture of "offline training - online rapid generation", pre-training the universal layout strategy model, and conducting rapid fine-tuning only for site-specific constraints in specific projects can further balance computational efficiency and design flexibility.

Unravelling the Complexity of Urban Functional Organization Based on Explainable GeoAI

Xinzhuo Zhao
Affiliation: Southeast University, China
Email: zhao.xinzhuo@foxmail.com

Abstract:
Urban expansion and population diversity have created increasingly complex functional organizations, challenging traditional land use strategies and highlighting the need for advanced analytical approaches. This study leverages explainable GeoAI, specifically a Multi-level Receptive Field Graph Convolutional Network, to decipher underlying patterns in urban functional organization across different spatial scales. The explainable AI framework enables interpretable analysis of spatial-functional interactions among urban functions across varying distance thresholds. Comparing five metropolitan five representative cities, the model achieves 92% accuracy while providing transparent insights into scale-specific spatial interactions. Results reveal distinctive distance-dependent patterns: Chinese cities exhibit stronger long-range dependencies, Western cities show balanced multi-scale interactions, while Paris demonstrates short-range relationships. This explainable GeoAI approach advances both methodological transparency and cross-cultural understanding of urban functional complexity.

Keywords: Explainable AI, Graph Neural Networks, Urban Functional Organization, Multi-scale Spatial Analysis, Cross-cultural Urban Planning

1. Introduction

Urban land use planning represents one of the most critical components of sustainable urban development in contemporary cities. The strategic allocation of spatial resources not only shapes the physical landscape of urban environments but also profoundly influences socioeconomic dynamics, environmental sustainability, and residents' quality of life. As cities continue to expand both horizontally and vertically, the importance of efficient and adaptive land use strategies has never been more pronounced.

The complexity of urban land use systems has escalated dramatically in recent decades. This increasing complexity is characterized by intricate interdependencies between diverse urban functions, multi-scale spatial interactions, and emergent behavioural patterns that often defy traditional analytical approaches. Urban areas no longer adhere to simplistic mono-functional zoning paradigms but instead exhibit polycentric, mixed-use configurations driven by changing social preferences, technological advancements, and economic imperatives. Understanding these multi-level spatial interactions requires analytical approaches that can simultaneously capture local neighbourhood dynamics, intermediate district-level relationships, and metropolitan-scale structural patterns, a challenge that traditional analytical methods struggle to address comprehensively.

Under this complexity, incompatible land use allocations can lead to inefficient transportation networks, socioeconomic segregation, environmental degradation, and diminished urban resilience. Conversely, thoughtfully designed urban functional arrangements can foster social cohesion, economic productivity, environmental sustainability, and human wellbeing. The far-reaching impacts of these decisions necessitate sophisticated analytical approaches that can capture the multidimensional complexity of urban functional organizations across different spatial scales while remaining interpretable for planning practitioners who must translate analytical insights into actionable policy recommendations.

Modern urban systems are characterised by hierarchical spatial organization patterns that operate across multiple scales simultaneously. Drawing from central place theory (Christaller, 1933) and more recent polycentricity frameworks (Kloosterman and Musterd, 2001), urban functions naturally organise themselves into nested hierarchies where different activities serve catchment areas of varying sizes. Daily convenience services typically operate within pedestrian catchments (300-500m), while specialised services and employment centres serve larger regional catchments (5-10km). However, the spatial configuration of these hierarchical patterns varies significantly across different cultural and institutional contexts. Theoretical frameworks from geographic economics suggest that spatial interaction patterns reflect underlying preferences for mobility, social organization, and service delivery models deeply embedded in cultural practices (Fujita et al., 1999). European cities, shaped by

millennia of pedestrian-oriented development, tend to emphasize short-range spatial interactions and neighbourhood self-sufficiency. In contrast, cities developed during the automobile era, or those with different transportation philosophies, may exhibit fundamentally different spatial organization principles where longer-range interactions dominate functional relationships. Thus, under the complex multi-scale urban structure, it is the key step to make the proper urban decision of land use from understanding the relationship between inner emerging pattern within multi-level functional layers.

This research posits that the interactions among diverse urban functions, particularly their spatial arrangements along network-constrained pathways at multiple distance thresholds, hold the key to understanding emergent urban phenomena and cultural variations in urban organization. By examining how functional relationships operate differently at pedestrian (0-500m), cycling (500m-1km), and transit/automotive (1-2km) scales, we can decode the underlying organizational principles that distinguish different urban planning paradigms. By leveraging recent advances in explainable graph neural networks and multi-level spatial analysis, we develop a framework that not only predicts urban functional patterns but also illuminates the scale-specific causal mechanisms underlying these patterns across different global cities, providing both scientific rigor and practical relevance for cross-cultural urban planning applications.

2. Related Work

The application of neural networks in urban studies has gained significant momentum in recent years, offering powerful tools to model complex urban systems. Convolutional Neural Networks (CNNs) have been widely employed to extract spatial features from urban imagery and remotely sensed data, enabling automated land use classification (Zhang et al., 2019) and urban growth prediction (Boeing., 2017). Recurrent Neural Networks (RNNs) have proven effective in capturing temporal dynamics of urban phenomena, including traffic flow prediction (Veličković et al., 2018) and human mobility patterns (Yuan et al., 2012). While these approaches have demonstrated impressive predictive performance, they often function as "black boxes," providing limited insights into the underlying mechanisms driving urban spatial patterns.

The urban planning discipline emphasizes evidence-based decision-making, where understanding causal relationships is as important as predictive accuracy. This requirement has spurred interest in explainable AI techniques within urban research. Doshi-Velez and Kim (2017) emphasized that explainability in AI systems is crucial for domains where decisions have significant societal impacts. In urban studies, Arrieta et al. (2020) employed attention mechanisms to highlight influential features in transportation mode choice models. Despite these advances, explainable AI in urban planning remains nascent, with significant challenges in translating model insights into actionable planning recommendations. The planning profession's need for transparent and interpretable models stems from several factors, due to its career nature of public service and decision. First, it should provide reliable as well as legal and ethical requirements for justifying planning decisions. Second, the multidisciplinary nature of planning has to necessitate communication across different expert domains. Finally, its result is highly relate to daily life, which requires to build public trust in each process. As noted by Batty (2018), while AI may enhance the efficiency of planning analyses, the discipline's emphasis on participatory processes and value-based judgments requires models that can effectively communicate their reasoning processes to diverse stakeholders.

Spatially explicit neural networks have emerged as a promising approach for incorporating geographical context into predictive models. Yao et al. (2017) developed a spatial autoencoder for neighborhood-level land use classification that preserved spatial relationships between urban features. Similarly, Gao et al. (2017) employed spatial attention mechanisms to capture location-specific influences in housing price prediction models. These approaches recognise that urban phenomena are inherently spatial, with observations exhibiting dependencies based on proximity and connectivity.

However, most spatially explicit models rely on Euclidean distance metrics that fail to capture the network-constrained nature of urban interactions. Urban activities typically follow street networks rather than straight-line paths, making topological distance more relevant than Euclidean distance for many analyses. This limitation has

been partially addressed by recent graph-based approaches that model cities as networks, as seen in Zhong et al. (2014)'s application of Graph Convolutional Networks (GCNs) to analyze urban functional mix patterns. Nevertheless, these graph-based models often lack interpretability, limiting their utility for planning practice despite their strong predictive performance.

The integration of explainability into graph-based models for land use analysis represents an emerging frontier. Early work by Ying et al. (2019) utilised GNN Explainer techniques to identify influential nodes in urban mobility networks. Ying et al. (2019) proposed a self-attention GCN for land use classification that provided attention weights as a measure of feature importance. Despite these advances, existing approaches typically offer post-hoc explanations rather than incorporating explainability directly into model architecture.

A particularly critical gap in current research is the lack of methods that align neural network operations with established urban planning theories. The AI applications in planning should not merely provide statistical predictions but should be designed to complement and extend existing theoretical frameworks. This study addresses this gap by developing a GNN architecture that explicitly incorporates urban behavioral theories through spatially constrained receptive fields and multi-level aggregation mechanisms that correspond to different scales of urban interaction.

3. Methodology

We represent the urban environment as a graph G = (V, E), where vertices V correspond to street intersections or points of interest, and edges E represent street segments connecting these locations. Each vertex is associated with a feature vector xi that encodes local urban characteristics, including land use types, building attributes, and socioeconomic indicators. This graph-based representation captures the network-constrained nature of urban interactions, recognizing that urban activities and flows primarily follow street networks rather than Euclidean paths.

Traditional GCN approaches often suffer from over-smoothing when propagating information across multiple hops, potentially obscuring the distinctive characteristics of local neighborhoods. Additionally, they typically employ fixed-distance aggregation that fails to account for varying scales of urban interactions. Different urban functions operate at different spatial scales—daily convenience services typically serve smaller catchment areas compared to specialised commercial or recreational facilities.

To address these limitations, we propose a Multi-level Receptive Field Graph Convolutional Network (MRF-GCN) that controls information propagation based on urban behavior theories. Specifically, we define multiple receptive fields for each node, corresponding to different travel distance thresholds that align with common urban mobility patterns (e.g., 5-minute walking distance, 15-minute cycling distance, 30-minute driving distance). Formally, for each vertex vi, we define a set of receptive fields {Ri1, Ri2, ..., Rik}, where each Rik represents the subgraph containing vertices reachable from vi within the travel time threshold from k-1th to kth. The graph convolution operation at level k is then defined as:

$$H_i^k = \sigma\left(D^{k^{-\frac{1}{2}}} A^k D^{k^{-\frac{1}{2}}} X^k W^k\right)$$

Where H_i^k represents the hidden representation at receptive field level k, A^k is the adjacency matrix restricted to connections within the k-th travel time threshold, D^k is the degree matrix corresponding to A^k, X^k is the feature matrix restricted to nodes within the k-th travel time threshold subgraph, W^k is a learnable weight matrix, and σ is a non-linear activation function.

These level-specific representations are then combined through an attention mechanism that learns the relative importance of different spatial scales for predicting urban functional patterns:

$$H_i = \sum_{k=1}^{K} \alpha_{ik} H_i^k$$

Where α_{ik} are attention coefficients determined by:

$$\alpha_{ik} = \frac{\exp(q^T \tanh(W_a H_i^k + b_a))}{\sum_{k'=1}^{K} \exp(q^T \tanh(W_a H_i^{k'} + b_a))}$$

Here, q, W_a, and b_a are learnable parameters. This formulation allows the model to adaptively weight the importance of different spatial scales based on the specific prediction task.

Our MRF-GCN architecture offers three levels of explainability that directly align with urban planning theory and practice:

• Behavioral-Technical Unification: The graph convolution operation mathematically formalises the urban planning concept that neighborhood characteristics emerge from the aggregation of nearby functions and activities. By structuring the aggregation process along the street network, our model captures how urban functions interact through actual travel paths rather than direct Euclidean distance, providing a more realistic representation of urban behavior.
• Scale-Specific Functional Interactions: The multi-level receptive fields allow us to identify which urban functions interact strongly at different spatial scales. For instance, the model might reveal that residential satisfaction is more strongly influenced by proximity to daily necessities at the 5-minute walking scale, while employment opportunities at the 30-minute driving scale have greater impact on housing prices. These insights directly inform planning decisions about functional mix and distribution.
• Attention-Based Importance Attribution: The attention mechanism provides quantitative measures of which spatial scales and functional combinations most strongly influence particular urban outcomes. By analysing attention weights , planners can identify the critical spatial thresholds for different urban phenomena, potentially revealing threshold effects in urban service provision.

This explainability framework transcends mere technical transparency, offering insights that are directly interpretable within established urban planning paradigms. Rather than providing post-hoc explanations of model predictions, our approach integrates explainability into the model architecture itself, ensuring that the model's internal representations align with meaningful urban concepts.

4. Results

1.1 Data Collection and Preprocessing

Our study utilises comprehensive urban data collected from five major metropolitan areas with varying urban morphologies, development histories, and cultural contexts: Shanghai, Beijing, New York, London, and Paris. These cities were strategically selected to represent diverse urban development paradigms and cultural backgrounds. Shanghai and Beijing, both Chinese megacities, share similar political and economic systems but exhibit distinct functional organizational characteristics, providing a test case for detecting subtle intra-cultural variations. New York and London represent Western global cities with comparable international connectivity and economic structures. Paris serves as a distinctive European model, smaller in scale compared to the other four cities and with unique historical urban development patterns.

For each city, we extracted the complete road network from OpenStreetMap and integrated Points of Interest

(POI) data encompassing 12 primary functional categories (residential, commercial, educational, healthcare, recreational, transportation, industrial, governmental, religious, cultural, financial, and mixed-use) and their subcategories. We also incorporated socioeconomic indicators from census data and human mobility patterns from anonymised smartphone trajectories. The final dataset comprises over 1.5 million POIs across the five cities, geocoded and associated with their nearest network nodes to construct a graph representation where nodes represent urban intersections and edges represent road segments.

Unlike conventional land use classification tasks, we designed our experiments to test whether our model can identify distinctive urban functional patterns that characterize different cities based solely on their spatial-functional organization. Specifically, we extracted subgraph samples representing local urban areas of approximately 4km × 4km each, ensuring sufficient spatial coverage to capture meaningful functional interactions while maintaining computational feasibility. The prediction task requires the model to identify which of the five cities each subgraph originated from, based solely on its functional arrangement patterns and network structure.

The inherent similarities and differences among these sample cities are crucial for validating our model's explanatory capabilities. The functional organizational similarities between Shanghai and Beijing increase identification difficulty, testing the model's ability to detect subtle variations within similar cultural contexts. Conversely, Paris's relative difference in scale and global connectivity compared to the other four cities provides a contrasting sample that helps validate the model's sensitivity to distinctive urban organizational patterns.

1.2 Model Performance

Our MRF-GCN demonstrates robust performance in distinguishing urban functional organization patterns across the five metropolitan areas. The model achieved an overall accuracy of 92%, with F1 scores ranging from 0.75 to 1.0 across different cities, as shown in table 1:

Table 1: Model Performance

City	Accuracy	F1 Score
Beijing	0.60	0.75
London	1.00	0.91
New York	1.00	1.00
Paris	1.00	0.91
Shanghai	1.00	1.00
Overall	**0.92**	**0.91**

The performance variations across cities reveal important insights into urban functional organization complexity. Beijing exhibits the lowest individual accuracy (60%), reflecting the challenge of distinguishing it from Shanghai due to their shared cultural and institutional context. However, the model's ability to achieve 92% overall accuracy while successfully differentiating between culturally similar cities demonstrates the effectiveness of our multi-scale spatial analysis approach. The perfect accuracy achieved for New York, Paris, and Shanghai indicates that these cities possess distinctive spatial-functional signatures that are readily identifiable through our multi-level receptive field approach. London's high accuracy (100%) but slightly lower F1 score (0.91) suggests some classification uncertainty, likely reflecting London's complex hybrid characteristics that blend elements of both European and global city patterns. The overall F1 score of 0.91 indicates balanced precision and recall across all cities, confirming that our model avoids overfitting to specific urban patterns while maintaining sensitivity to cross-cultural variations in functional organization.

The performance variations across cities reveal important insights into urban functional organization complexity that extend beyond simple classification accuracy. Beijing's comparatively lower individual accuracy (60%)

is particularly revealing when examined alongside Shanghai's perfect classification rate (100%). This performance differential suggests that while both cities share broad cultural and institutional frameworks, Beijing exhibits more heterogeneous spatial organization patterns that occasionally overlap with characteristics found in other global cities.

The perfect accuracy achieved for New York, Paris, and Shanghai indicates that these cities possess highly distinctive spatial-functional signatures that create clear decision boundaries in our model's feature space. For New York, this distinctiveness manifests in consistent grid-based organization combined with high functional density across all scales. Shanghai's distinctiveness emerges from systematic long-range functional relationships combined with planned community structures that create recognizable spatial signatures. Paris demonstrates uniquely consistent short-range functional clustering that differentiates it clearly from all other urban contexts. London's classification performance (100% accuracy, 0.91 F1 score) reveals an interesting pattern where the model exhibits high confidence in positive classifications but shows some uncertainty in boundary cases. Further analysis indicates that London's complexity lies in its hybrid characteristics—combining European pedestrian-scale organization in historic areas with global city-scale commercial districts, creating spatial patterns that occasionally approach other cities' signatures without fully overlapping.

1.3 Multi-Scale Spatial Interaction Analysis

The most significant contribution of our research lies in the interpretable analysis of spatial-functional interactions across different distance thresholds. We extracted attention weights from our model to reveal how different cities prioritize spatial interactions at varying scales: short-range (0-500m), medium-range (500m-1km), and long-range (1-2km) spatial dependencies, as shown in figure 1. The attention weight analysis reveals three statistically distinct patterns of urban functional organization, each representing fundamentally different approaches to spatial resource allocation and accessibility:

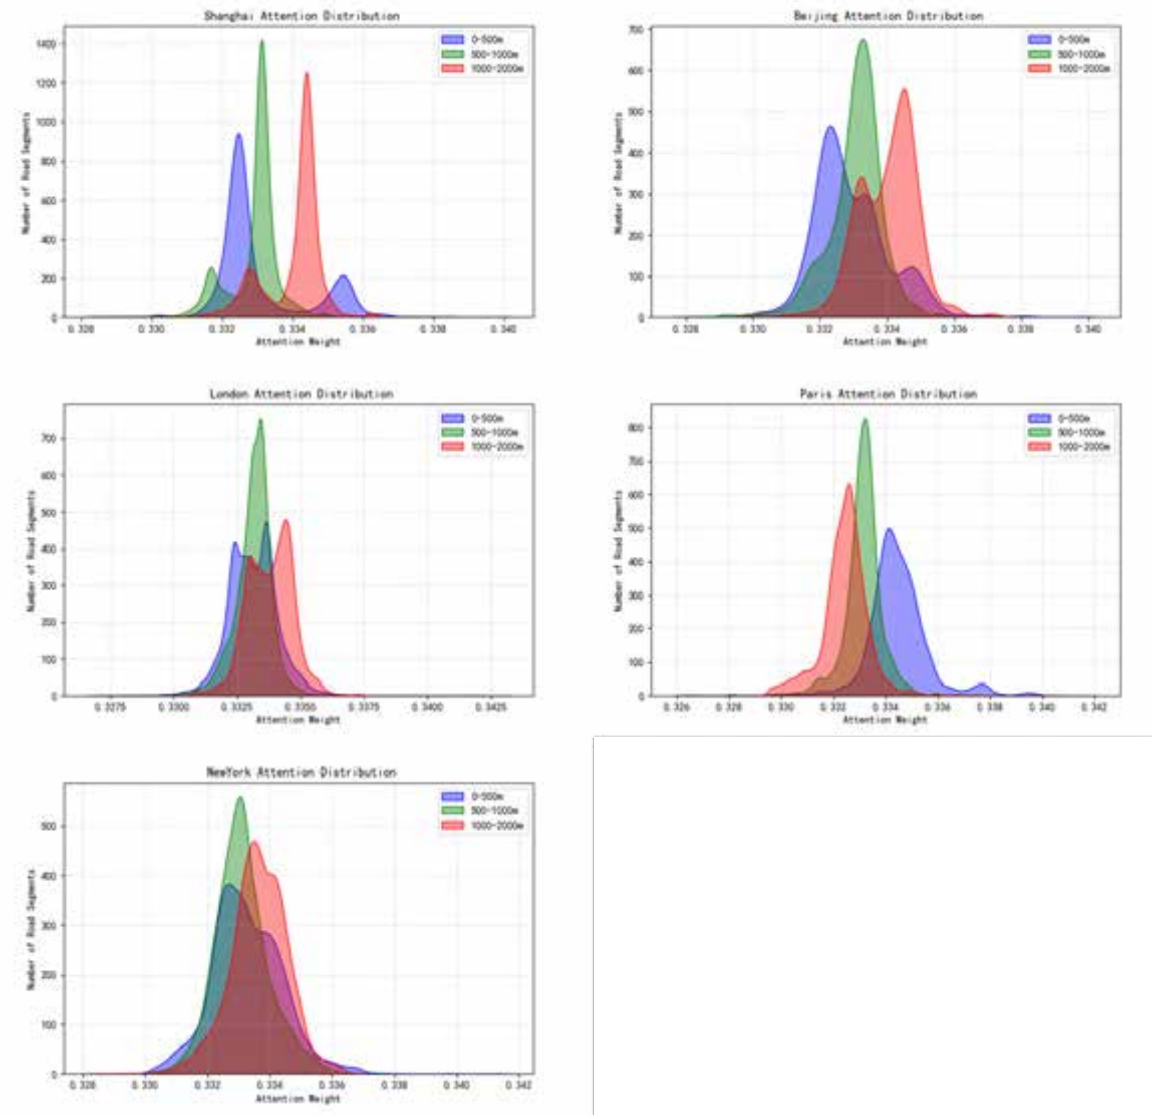

Figure 1: Attention Weight Distributions Across Multi-Scale Spatial Interaction Thresholds in Five Metropolitan Areas. This figure presents the attention weight distributions extracted from the Multi-level Receptive Field Graph Convolutional Network (MRF-GCN) across five representative metropolitan areas: Shanghai, Beijing, London, Paris, and New York. The distributions reveal distinct patterns of urban functional organization at three spatial interaction scales, represented by different colours: Blue (0-500m): Short-range pedestrian catchment areas, Green (500m-1km): Medium-range cycling accessibility zones, Red (1km-2km): Long-range transit/automotive accessibility areas

The attention weight analysis reveals three distinct patterns of urban functional organization:

Chinese Cities Pattern (Beijing and Shanghai): Both cities exhibit pronounced peaks in long-range spatial dependencies (1-2km). This pattern indicates that functional organization in Chinese cities relies heavily on long-distance spatial relationships, likely reflecting the impact of large-scale residential compounds, centralised service provision, and relatively low-cost transportation systems that enable residents to access services across larger geographical areas.

Western Global Cities Pattern (London and New York): These cities demonstrate relatively balanced attention across all three spatial scales. This balanced pattern suggests that Western global cities maintain functional organization coherence at multiple scales simultaneously, reflecting mixed-use development patterns, diverse transportation options, and polycentric urban structures.

European Regional Pattern (Paris): Paris exhibits a distinctive emphasis on short-range spatial interactions, with maximum attention weight for the 0-500m range, second for medium-range, and minimal for long-range dependencies. This pattern reflects Paris's compact urban form, pedestrian-oriented neighborhoods, and strong emphasis on local amenity provision within walking distance.

1.4 Cultural and Planning Implications

The spatial interaction patterns revealed by our model have significant implications for understanding cultural differences in urban functional organization:

Chinese Urban Planning Philosophy: The emphasis on long-range spatial dependencies in Beijing and Shanghai reflects China's planning approach of creating large-scale residential compounds with centralised service provision, but this pattern also reveals cultural acceptance of mobility-based urban living strategies. Detailed mobility analysis shows that Chinese urban residents demonstrate higher tolerance for travel distances and greater reliance on public transportation for daily activities. The lower importance assigned to short-range interactions indicates higher functional homogeneity within immediate neighbourhoods, reflecting planned community development that prioritizes large-scale efficiency over neighbourhood-scale diversity.

Western Polycentricity: The balanced attention patterns in London and New York reflect the polycentric nature of Western global cities, where urban functions are organised to serve residents at multiple spatial scales. This pattern aligns with market-driven development principles that create redundancy across scales—neighbourhood services provide convenience, district services offer choice and specialization, and regional services deliver metropolitan-scale amenities. Economic analysis suggests this multi-scale redundancy increases urban resilience but also reflects higher land values that support multiple service layers.

European Pedestrian Culture: Paris's short-range spatial emphasis aligns with European urban design principles, emphasizing walkability and neighbourhood self-sufficiency. The 500m walking radius emerges as the critical scale for understanding Paris's urban functional organization, supporting the concept of the "15-minute city" that has gained prominence in European urban planning discourse. However, this pattern also reflects historical urban development patterns where neighbourhood-scale infrastructure developed before automotive transportation, creating a path-dependent spatial organization that persists despite technological change.

5. Discussion

Our research demonstrates that explainable GeoAI can successfully unravel the complexity of urban functional organization while revealing systematic cultural differences that have important implications for both urban theory and planning practice. The methodological contributions of our Multi-level Receptive Field Graph Convolutional Network extend beyond technical innovation to address fundamental challenges in making urban AI interpretable for planning practitioners.

The development of our explainability framework represents a crucial advancement in bridging the gap between computational urban analysis and planning theory. Unlike previous approaches that provide technical explanations primarily meaningful to data scientists, our distance-threshold explainability framework translates complex neural network operations into concepts directly relevant to urban planning. This achievement is particularly significant given the planning profession's emphasis on evidence-based decision-making and the growing regulatory requirements for AI transparency in public decision-making contexts.

The cross-cultural insights revealed through our comparative analysis challenge conventional assumptions

about optimal urban organization. The identification of three distinct spatial interaction patterns—Chinese long-range dependency, Western balanced multi-scale organization, and European pedestrian-oriented emphasis—provides empirical evidence that successful urban organization takes multiple forms rather than converging on universal optimal patterns. This finding has profound implications for international planning practice and development cooperation, suggesting that planning strategies cannot be directly transferred between different cultural contexts without careful adaptation to local spatial organization principles.

The finding that Chinese cities rely more heavily on long-range spatial dependencies particularly challenges Western planning orthodoxies that prioritize neighborhood-scale self-sufficiency. Rather than indicating planning deficiencies, this pattern reflects successful adaptation to different cultural preferences, transportation systems, and institutional contexts. The superior performance of Chinese cities in our classification task indicates that their spatial organization patterns are highly systematic and coherent, suggesting effective planning coordination at metropolitan scales.

Similarly, Paris's emphasis on short-range interactions validates European urban design principles while demonstrating the continued relevance of pedestrian-scale planning in contemporary urban contexts. The statistical significance of these differences across functional categories indicates that these are not superficial variations but reflect deep structural differences in how different cultures organise urban space and daily life.

These insights have immediate practical applications for planning education and professional development. Planning professionals working in international contexts can use these insights to better understand local spatial organization patterns and adapt their approaches accordingly. The quantitative identification of critical spatial thresholds can inform service provision planning, helping planners understand which amenities need to be provided at neighborhood scales versus regional scales in different cultural contexts.

6. Conclusions

This study successfully demonstrates that explainable GeoAI can decode the complexity of urban functional organization while providing interpretable insights that bridge computational analysis and planning practice. Our Multi-level Receptive Field Graph Convolutional Network achieves high accuracy in distinguishing urban functional patterns across diverse global cities while revealing systematic differences in spatial organization that reflect fundamental cultural, institutional, and developmental variations.

The identification of three distinct spatial interaction patterns provides empirical validation for cultural theories of urban development while challenging universal approaches to urban planning. Chinese cities' emphasis on long-range spatial dependencies, Western global cities' balanced multi-scale organization, and European cities' pedestrian-oriented short-range focus represent coherent and successful alternative approaches to urban organization rather than stages in a linear development progression.

Our explainable framework addresses growing regulatory requirements for AI transparency while providing practical value for planning decision-making. By integrating explainability directly into model architecture rather than relying on post-hoc analysis, we ensure that computational insights remain interpretable within established planning frameworks. This approach positions explainable GeoAI as an essential tool for contemporary urban planning practice that enhances rather than replaces professional judgment.

Looking forward, our framework provides a foundation for expanding comparative urban research to include cities from different developmental stages, sizes, and cultural contexts. The successful integration of graph neural networks with urban planning theory demonstrates the potential for AI to extend human understanding of urban systems while maintaining interpretability for practical application. As cities worldwide continue to grow and evolve in response to technological change, climate challenges, and shifting social preferences, understanding the complexity of urban functional organization becomes increasingly critical for sustainable urban development.

Importantly, our model focuses exclusively on identifying characteristic distance-dependent interaction patterns rather than making normative evaluations of urban quality. This analytical neutrality preserves the framework's utility for diverse planning contexts while maintaining objective comparative analysis capabilities. For applications requiring evaluative assessments of urban performance, the framework could be integrated with appropriate outcome indicators, maintaining its flexibility for diverse analytical purposes.

Future research should explore the temporal dimensions of these spatial organization patterns, investigating how cultural differences in spatial organization respond to technological change, policy interventions, and evolving social preferences. The framework developed here provides both the methodological foundation and empirical baseline for understanding how different urban systems adapt to contemporary challenges while maintaining their distinctive organizational characteristics.

Abstract
This study examines the impact of urban regeneration projects carried out in Istanbul within the scope of Law No. 6306 on green infrastructure. The change in green infrastructure between 2014 and 2024 in three distinct regeneration sites was analysed using remote sensing, spatial texture analysis and machine learning techniques. NDVI, NDBI, and first-order statistical metrics derived from Landsat 8 satellite imagery are integrated into the change detection analysis using random forest classification. The findings show significant losses in green infrastructure, especially in areas where vertical densification is at the forefront. The results support that the level of integration of disaster-focused urban regeneration policies with climate adaptation and sustainability goals in the Istanbul case is limited, pointing to the need for more holistic planning approaches.

Keywords: urban regeneration; green infrastructure; NDVI; random forest; change detection

1. Introduction

Urban regeneration projects as transformative operations that strengthen and restructure the built environment under the risk of natural disasters have become one of the prior urban policies. These disaster-responsive projects aim to support resilience, contribute to sustainability, and increase the quality of life by optimizing the green infrastructure (Tzoulas et al., 2007; Wolch, Byrne and Newell, 2014). Green infrastructure is identified as a network of natural and semi-natural areas, including both green and blue spaces and it is part of the strategic planning approach for land conservation and optimized land use (Benedict and McMahon, 2006). It encompasses not only conserved natural areas, ecological corridors, urban drainages, and wetlands but also semi-natural, functional open spaces such as parks, farmlands, recreational sites, and greenways (Schilling and Logan, 2008; Fletcher et al., 2015). Also, as one of the main components of the urban ecosystem, green infrastructure supports adaptation to climate change (Oke, 1989; Spronken-Smith and Oke, 1999; Norton et al., 2015; Ramyar, Ackerman and Johnston, 2021). It helps mitigate the urban heat island effect, improve water and air quality, and manage stormwater, which are crucial for reducing the impacts of climate change and enhancing urban resilience (Nowak, Crane and Stevens, 2006; Meerow and Newell, 2017; Matasov et al., 2020; Senosiain, 2020; Halecki, Stachura and Fudała, 2025). Also, designing green infrastructure enhances city biodiversity by providing habitats for various species, contributing to ecological stability (Mathey et al., 2015; Pitman, Daniels and Ely, 2015). Apart from its advantages for the environment, green infrastructure is supposed to support public health, social cohesion, equity, and accessibility (Pauleit et al., 2019; Lu et al., 2023; Ogwu et al., 2025). Thus, green-driven urban renewal initiatives have evolved into useful instruments for resilience-oriented climate change adaptation policy (Gill et al., 2007; Semeraro, Aretano and Pomes, 2017). Supported by policy frameworks encouraging the use of green infrastructure, successful urban regeneration projects need the integration of resilience and sustainability ideas into urban agendas (Ignatieva and Mofrad, 2023; Zhang et al., 2025).

In Turkey, urban regeneration implementations are based on state law 6306 on the Regeneration of Areas at Disaster Risk. The main objective of the law is to constitute healthy and safe urban settlements (T. C. Resmi Gazete, 2012). Hence, the regeneration projects are recognised as opportunities for increasing sustainability in urban areas and developing climate-adaptive cities (Köylüoğlu, 2015; Yalazi et al., 2017; Korkmaz and Balaban, 2020; Yenidünya and Limoncu, 2024). By simulating possible risks such as flooding, the integration of the blue-green infrastructure systems in urban regeneration projects is highlighted as a strategy to adapt to climate change effect and improve urban resilience (Gündel and Kalaycı Önaç, 2025).

As a metropolitan city with vulnerable building stocks, Istanbul faces great seismic risk. Therefore, within the aim of law 6306, urban regeneration projects are operated as comprehensive planning tools in the city. According to the Istanbul Planning Agency's report (2023), after the law entered into effect, 70 urban areas have been declared

as risky in Istanbul. Those risky areas correspond to about 2000-hectare urban settlements and 84,000 buildings at least. Policies for climate change mitigation and disaster mitigation-led urban regeneration have the potential to be conducted together. However, the actions for developing green infrastructure through regeneration projects are lower than expected (Kocabas, Gibson and Diren, 2015). Despite efforts to incorporate sustainability, the regeneration projects in Istanbul imply many speculative implementations, such as green gentrification, where green spaces become exclusive and inaccessible to the public (Yazar et al., 2020).

Contrary to the expectation of contributing to the quality of life by increasing the amount of green space in the city, preliminary findings show that urban regeneration projects implemented in areas declared risky have a diminishing effect on green spaces (Cengiz, Atmiş and Görmüş, 2019; Yağçı, 2025). Mostly, those projects result in higher density, and green spaces per cap remain inadequate. Limited empirical research focuses on how urban regeneration projects have influenced the green infrastructure in Istanbul over a long time. Addressing this issue, the study aims to investigate how urban regeneration projects based on law numbered 6306 impact the changes in urban green infrastructure. Under the green infrastructure umbrella, the study particularly focuses on urban green fabric as a projection of green infrastructure into the urban settlements, including all vegetation that can be observed in two dimensions by remote sensing, such as parks, urban forests, woodlands, grasslands, narrow green strips, street trees, green roofs, and green unfunctional spaces between buildings.

2. Material and Methods

In this study, a holistic method based on remote sensing and machine learning was designed to analyse the temporal change of urban green fabric in risky areas subjected to regeneration under law no 6306. Within the scope of the research, urban regeneration areas with sufficient data (n=21) were clustered, and three representatives from each cluster were selected as study areas. NDVI, NDBI, and first-order texture statistics were derived using Landsat 8 satellite multispectral images from 2014 and 2024 and clipped into those selected areas. These layers were composites into a multispectral raster mosaic for each year and random forest algorithm was used for the classification. As a final step, spatial transformations in green fabric were revealed through categorical change analysis over two years (Figure 1).

This methodological approach provides to evaluate the effects of urban regeneration practices on green fabric with objective data. It seeks to obtain accurate results through advanced spatial analysis that can direct policies for sustainable urban regeneration. In contrast to traditional planning methods, the use of machine learning techniques in this study enabled more optimised spatiotemporal analysis to address the complexity of urban space (Hoang and Tran, 2021; Jia, Cui and Liu, 2022; Rahaman et al., 2025).

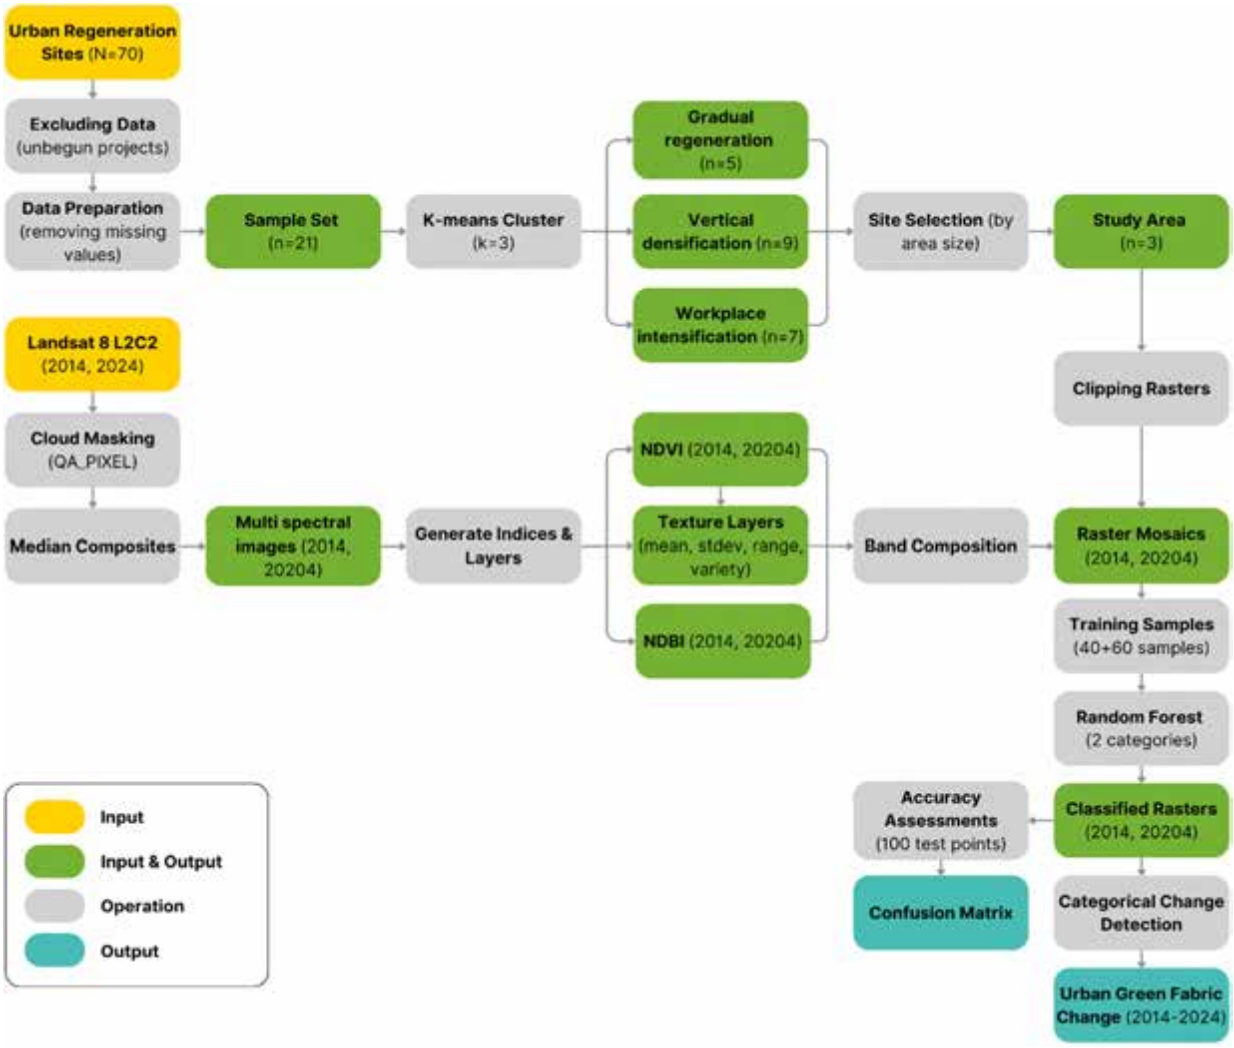

Figure 1. Workflow of the study.

2.1. Sample Selection and Study Area

Istanbul, one of the most highly populated and valued cities in Turkey, is in great seismic risk. By law 6306, 70 urban risk areas have been declared as urban regeneration sites in the city by the government (T. C. Resmi Gazete, 2012; Istanbul Planning Agency - IPA, 2023). This study focused on 25 projects which implementation has already begun of 70 declared urban regeneration sites, and 4 regeneration projects with missing data were excluded from the evaluation. Thus, 21 urban regeneration sites with sufficient data were accepted as the sample set (Table A. 1). To analyse the change in urban green fabric between 2014 - 2024 in different type of urban regeneration sites, k-means cluster analysis was applied with the logarithmic change rate of the following criteria below.

- Population capacity: the change in population capacity in the project area calculated before and after implementation
- Number of buildings: change in the number of buildings in the project area before and after implementation
- Number of workplace units: the change in the number of workplace units in the project area before and after implementation
- Gross construction area: the change of the total construction area in the project area before and after implementation

• Building renewals: the number of new buildings built for every building demolished during the implementation phase

Based on the Elbow score, regeneration sites have been clustered into three groups: (1) Gradual regeneration, (2) Vertical densification, and (2) Workplace intensification (Table 1).

Gradual regeneration represents areas with relatively low intervention levels, with values below the average in log-ratio-based indicators. Negative ratios in the number of buildings (-0.64) and gross construction area (-0.28) indicate that regeneration has been conducted gradually. The decrease in the number of workplaces (-0.37) indicates that the regeneration process in these areas is progressing with a priority on housing and away from functional diversity. In addition, the building renewal rate is also quite low (-1.96), which may indicate that the regeneration is more in the "processing" stage (Yazar et al., 2020).

On the other hand, vertical densification stands out with radical reconstruction and urban fabric densification practices. The construction area change rate (+2.47) indicates that parcels are combined to produce larger buildings. While the number of buildings is decreasing (-1.56), the increase in population capacity (+0.64) and the number of workplaces (+0.21) is a distinct indicator of vertical growth and mixed-use developments. The low rate of building renewal (-2.41) shows that the regeneration model in these areas is not "renewal" but entirely redevelopment-based. This cluster covers areas mostly high-investment, densely populated, and open to speculative development, which are symbolic examples of urban regeneration discussions in Istanbul (Turk, Tarakci and Gürsoy, 2020).

Workplace intensification defines the areas where the regeneration process is shaped towards gaining trade and services function. The workplace unit change rate is quite high (+4.03). This situation shows that existing housing or empty buildings are transformed into new function or mixed structures are built with commercial layers. Population growth (+0.98) and an increase in construction areas (+1.22) support this regeneration. Although the building renewal rate is relatively low (-1.36), it points to a scenario where functional transformation is preferred instead of dense construction.

Following cluster analysis, the urban regeneration site with the largest area size from each cluster was selected as a representative so that the classification analysis (random forest) could be applied in the study and yield reliable results (Figure 2). Features of designated study areas, cluster centre distances, and area sizes are given in Table 2 and Table 3.

• Site – 1: Karabekir, Fevziçakmak project site is located on the east side of Gaziosmanpaşa district (41°5′7″ N - 41°5′46″ N, 31°54′17″ E - 31°54′58″ E). The regeneration has started in 2017; it is still in the early stages of demolition and reconstruction (Figure A. 1). Based on the capacity population before the regeneration project, the total construction area per capita was 41 m2, and it is expected that the construction area per capita will decrease by 12% and become 36.21 m2 after the project. This regeneration site is one of the highly representative samples of the gradual regeneration cluster.

• Site – 2: Fikirtepe project site is located at centre of Kadıköy district near to D100 highway (41°0′17″ N - 41°0′18″ N, 32°2′36″ E - 32°4′15″ E). The project's start date was 2012 (Figure A. 1). While the total construction area per capita based on the capacity population was 22.33 m² before the regeneration project, this value is expected to increase by 473% and reach 128 m² after the project based on the planned capacity population. This situation indicates a remarkable increase in the building density. The project strongly represents a vertical densification cluster.

• Site – 3: Çınar, İnönü, Sancaktepe, Yavuzselim, Merkez project site is located in the south-east of Bağcılar district (41°2′56″ N - 41°3′11″ N, 31°51′7″ E - 31°51′33″ E). The beginning date of the implementations was 2013 (Figure A. 1). While the total construction area based on the capacity population before the project was 65.09 m2, the

construction area per capita is expected to decrease by 32% and become 44.21 m2 based on the planned capacity population after the project. The regeneration site is a moderate-represented member of the commercial intensification cluster; however, it is the only project site with a considerable area size for the classification.

Table 1: Attributes of urban regeneration zones.

Average Change Rates					
Clusters	Population capacity	Buildings	Workplace units	Construction area	Renewals
Gradual regeneration	0.14	-0.64	-0.37	-0.28	-1.96
Vertical densification	0.64	-1.56	0.21	2.47	-2.27
Workplace intensification	0.98	-0.93	4.03	1.22	-1.36

Figure 2. Study Areas in 2024: (a) Site – 1; (b) Site – 2; (c) Site – 3.

Table 2. Features of the selected study areas.

Indicators	Rates of Change Between Periods		
	Site - 1	Site - 2	Site - 3
Population capacity	0.295	0.556	0.685
Number of buildings	-0.082	-1.568	-0.185
Number of workplace units	-0.256	-0.063	6.895
Gross construction area	0.170	2.302	0.298
Building renewals	-1.686	-3.112	-2.114

Table 3. Cluster representation of the selected study areas.

Regeneration Site	Cluster No	Cluster Centre Distance	Area Size (Ha)
Karabekir, Fevziçakmak - Gaziosmanpaşa	1	0.788	59.03
Fikirtepe - Kadıköy	2	0.901	98.73
Çınar, İnönü, Sancaktepe, Yavuzselim, Merkez - Bağcılar	3	3.204	22.07

2.2. Satellite Images and Data Processing

Landsat 8 surface reflectance images (Collection 2, Level-2) were used for 2014 and 2024 to classify urban green fabric in regeneration sites. Based on the project start date of selected regeneration sites, the oldest year, one year after Landsat 8 was launched, has been selected as the reference year. The image data was obtained from the Google Earth Engine platform. Cloud-free composite images were generated by applying a pixel-based median compositing technique after cloud masking with the QA_PIXEL band. After filtering out low-quality pixels, annual median composites were generated by taking the median reflectance values from all valid images within each two years. All images were clipped to the Istanbul metropolitan area and exported at 30-meter resolution in EPSG:4326 projection (41.0082° N, 28.9784° E).

NDVI was used as the basis to analyse urban green fabric in Istanbul regeneration sites. For more accurate classification, NDVI was supported with NDBI and texture layers. The pre-classification process (clipping, band composition, etc.) and advanced analysis were conducted in ArcGIS Pro 3.1.

NDVI Calculation

NDVI is a well-accepted index to quantify vegetation in urban areas by comparing reflectance values in the red and near-infrared (NIR) spectral bands (Weng, Lu and Schubring, 2004; Yuan and Bauer, 2007; Feyisa, Dons and Meilby, 2014). It helps to identify vegetation density, vegetation health, and developed areas. The NDVI value ranges from -1 to 1; an upper value than 0.2 refers to vegetation cover. The index is also useful in spatiotemporal analysis and monitoring the vegetation change over time (Jeevalakshmi, Reddy and Manikiam, 2016; Luo et al., 2021). Here, NDVI was generated from Landsat 8 multispectral image data for 2014 and 2024. The calculation is as follows:

$$NDVI = \frac{\rho_{nir} - \rho_{red}}{\rho_{nir} + \rho_{red}} \quad (1)$$

Where p_{nir} and p_{red} represent the red reflected radiant flux (Band 4, 0.64 - 0.67 µm) and near-infrared radiant flux (Band 5, 0.85 - 0.88 µm) respectively. However, granular surfaces in urban areas with high heterogeneity may have similar NDVI values. NDBI and texture layers were also used to avoid this misleading and to facilitate the discrimination of low vegetation areas such as parks, gardens, and grasslands from built-up areas (Haralick, Dinstein and Shanmugam, 1973; He et al., 2010).

NDBI Calculation

The primary use of NDBI is to map and monitor urban built-up areas. It also combines with NDVI to distinguish vegetation from built-up areas. It ranges from -1 to 1, and similarly to NDVI, positive values indicate built-up areas (Zha, Gao and Ni, 2003; Bhatti and Tripathi, 2014). NDBI addresses the challenge of distinguishing urban areas from bare ground and providing more accuracy in identifying urban green fabric. Hence, its combination with NDVI especially assists in separating barren land from urban areas (He et al., 2010). NDBI is computed as below:

$$NDBI = \frac{\rho_{swir} - \rho_{nir}}{\rho_{swir} + \rho_{nir}} \quad (2)$$

Where p_{swir} and p_{nir} represent the short-wave infrared - 1 reflected radiant flux (Band 6, 1.57 - 1.65 µm) and near-infrared radiant flux (Band 5, 0.85 - 0.88 µm) respectively.

Texture Analysis

Texture analysis in image processing is effectively used to classify vegetation in urban areas. As one of the texture extraction methods, the grey-level co-occurrence matrix (GLCM) captures the spatial relationship between pixel pairs in an image, reflecting the texture by considering the direction, distance, and magnitude of changes in grayscale values (Haralick, Dinstein and Shanmugam, 1973; Gao et al., 2015; Yan, Shaker and El-Ashmawy, 2015). The method has been used to extract texture features from high-resolution satellite images to classify various types of urban vegetation, such as parks, street trees, grasslands, and scrub vegetation (Liu and Yang, 2013). Combining GLCM with spectral indices significantly improves the classification accuracy of green fabric in urban areas (Wu et al., 2019). Alternative to GLCM, some research measures texture using histograms based on the sum and difference of pairs of pixels (Unser, 1995; Sarker and Nichol, 2011). Other researches argue that geostatistical texture metrics provide more accuracy in classification (Rodriguez-Galiano, Chica-Olmo, et al., 2012).

Although texture measures such as GLCM and geostatistical-based metrics can improve classification accuracy, they require increased computational demands and higher data dimensionality (Pacifici, Chini and Emery, 2009; Ghimire, Rogan and Miller, 2010; Sarker and Nichol, 2011). In this study, first-order statistical descriptors (mean, standard deviation, range, and variety) were used instead. They offer an efficient alternative with adequate discriminatory power for medium-resolution imagery.

Here, first-order statistical metrics were derived from the NDVI raster using the Focal Statistics tool in ArcGIS Pro. These metrics included mean, standard deviation, variance, and range – each calculated over a 7×7 moving window (Franklin et al., 2000; Kayitakire, Hamel and Defourny, 2006): (i) Mean represents the local green density where x_i is for each pixel value and N for total number of pixels; (ii) Standard deviation reflects surface heterogeneity and variation where µ is for mean, x_i for each pixel value and N for total number of pixels; (iii) Range was used to identify environmental transition areas, indicating structural contrast where x_i stands for each pixel value; and (iv) Variety counts how many different pixel values are in the neighbourhood window. It measures diversity like "entropy" in GLCM but in terms of class diversity, not randomness (Table 4).

Table 4. Texture layers calculation.

Texture ayers of NDVI	Raster Calculation	GLCM Calculation
Meanv	$\frac{1}{N}\sum_{i=1}^{N} x_i$	-
Standard deviation	$\sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i-\mu)^2}$	-
Range (contrast)	$max(x_i) - min(x_i)$	$\sum_{i,j}(i-j)^2 . P(i,j)$
Variety (entropy)	$UniqueClasses(x_i)$	$-\sum P(i,j).\log_2 P(i,j)$

2.3. Green Fabric Classification and Accuracy Assessments

This study performed a random forest classifier to distinguish between urban green fabric and built-up areas in urban regeneration sites. This technique offers high accuracy rates in different image data (Rodriguez-Galiano, Ghimire, et al., 2012; Talukdar et al., 2020) and gives balanced performance in both homogeneous and heterogeneous land cover classes (Shi and Yang, 2017). Studies have shown that random forest-based classification is suited for reducing the data dimensionality of complex urban land cover types while reserving discrimination of different classes (Gan et al., 2016; Isaac, Easwarakumar and Isaac, 2017). It is also robust to reductions in training data size and noise (Rodriguez-Galiano, Ghimire, et al., 2012) and the risk of overfitting by averaging the predictions of multiple decision trees (Gislason, Benediktsson and Sveinsson, 2006).

As detailed in Section 2.2, NDVI, NDBI, and texture layers generated from NDVI were computed separately and composed into a multispectral image for each year. Due to the radiometric inconsistencies observed in parts of the 2014 Landsat 8 image, particularly in non-urban northern-east regions, the classification process was restricted to the regeneration project boundaries. This spatial constraint minimizes the uncertainty introduced by low observation density and ensures that the classification model is trained and applied to radiometrically stable regions.

Two main classes were determined to run random forest classifications: urban green fabric and built-up area. The training data were manually selected from the composited multispectral images. For both classes, sample polygons were determined by considering clearly separated areas, and pixel samples were taken from these regions for two images. The samples were collected individually for both years. The class distribution of the training samples was determined in parallel with the existing spatial ratios in the study area; 40% of samples were used for the urban green fabric class, and 60% of them were used for the built-up area class.

Classification results for 2014 and 2024 show that the model is adequately accurate (Table 5 and Table 6). In 2014, the overall accuracy was 84%, and the kappa statistic was 0.68; in 2024, these values were 85% and 0.70%, respectively. For both years, the built-up area class performed very strongly regarding user accuracy (94% and 98%), demonstrating the model's ability to correctly identify built-up areas. The urban green fabric class performed relatively low in user accuracy (74% and 72%) despite high producer accuracy values (92.5% and 97%). The relatively low user accuracy in the urban green fabric class indicates that some class assignments may be inaccurate when classifying small and fragmented urban areas using satellite imagery with a spatial resolution of 30 meters. This is related to the lack of clear spectral separation of green areas that have been transformed or are simply intersected with buildings, making them hard to identify. However, given the overall accuracy of the model (84-85%) and the kappa statistics (0.68-0.70), this limitation does not undermine the overall reliability of the classification results. It reveals that the outputs obtained are acceptable (Figure 3).

Table 5. Accuracy assessment of green fabric classification for 2014.

	Built-up Area	Green Fabric	Total Count	User's Accuracy
Built-up Area	47	3	50	0.94
Green Fabric	13	37	50	0.74
Total Count	60	40	100	0
Producer's Accuracy	0.78	0.925	0	0.84
Kappa Statistics: 0.68				

Table 6. Accuracy assessment of green fabric classification for 2024.

	Built-up Area	Green Fabric	Total Count	User's Accuracy
Built-up Area	49	1	50	0.98
Green Fabric	14	36	50	0.72
Total Count	63	37	100	0
Producer's Accuracy	0.77	0.97	0	0.85
Kappa Statistics: 0.70				

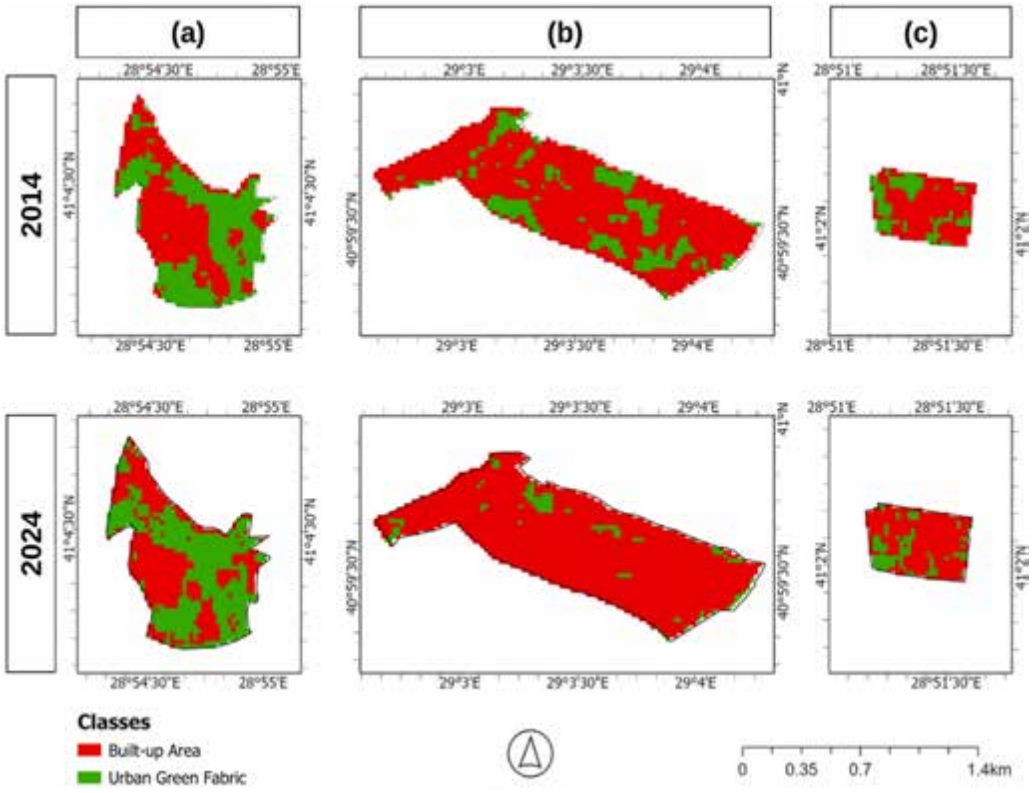

Figure 3. Urban green fabric classification in 2014 and 2024: (a) Site – 1; (b) Site – 2; (c) Site – 3.

3. Urban Green Fabric Change in Regeneration Sites

To analyse the change of green fabric in selected regeneration sites between 2014 and 2024, categorical change detection was processed with defined classes of urban green fabric and built-up areas. In order to suppress pixel-level random noise in the classification results and to ensure spatial consistency in the change map, a 3×3

smoothing neighbourhood window was used, and the median was preferred as the statistical filling method. This configuration reduces the effect of random pixel fluctuations in fragmented and small-scale urban green areas, allowing for more reliable and coherent change detection (Chen, Stow and Gong, 2004; Ghimire, Rogan and Miller, 2010).

The findings show that remarkable spatial changes were observed in the three representative urban regeneration sites between 2014 and 2024 (Figure 4). In Site – 1, which represents a gradual regeneration cluster, there is a 9.18% increase in green fabric, accompanied by a 9.43% loss of building development (Table 7). Since regeneration interventions are still in process and reconstruction not being completed substantially, the increase in green fabric cannot be interpreted as final result unlike in the other two regeneration sites (Figure A. 1). The green fabric per capita decreased from 21.47 m2 to 17.45 m2 by the planned population capacity (Table 7 and Table 8). Based on the current population in 2023, the amount of green fabric per capita is 58.56 m2. This current high ratio supports the inference about ongoing reconstruction process.

Site – 2, as a strong member of the vertical densification cluster, reveals an intensified urban regeneration process, exhibiting an increase of 18.42% in buildings with a very high green fabric loss of 74.15% (Table 7). During the regeneration process, this area has come under intense building pressure and exhibited a negative picture regarding environmental sustainability and life quality. According to planned population capacity, green fabric per cap has dramatically decreased from 4.61 m2 to 0.68 m2. Also, the current green fabric per cap is 3.07 m2 (Table 7 and Table 8). These rates are significantly below the World Health Organization's (WHO) minimum rate – 9 m2 (World Health Organization - WHO, 2012).

As a member of the workplace intensification cluster, in Site – 3, the building rate increased by 11.7%. In comparison, the green fabric decreased by 28.79%, indicating that the green fabric was largely transformed into built-up areas (Table 7). Here, it should be considered that Site – 3, which has been selected due to its optimal area size, has relatively low cluster representation; so, similar rates may not be seen in other areas where functional transformation has occurred. During the regeneration, green fabric per capita has decreased from 18.85 m2 to 6.76 m2. As seen in Table 7 and Table 8, the current rate is more negative than the planned one; green fabric per capita is 4.94 m2 by the population in 2023. Considering the functional transformation of the project, it is expected that some of the current population will be replaced. However, according to WHO's minimum limit, planned green fabric per capita is still lower than the rate before the regeneration (World Health Organization - WHO, 2012; Russo and Cirella, 2018).

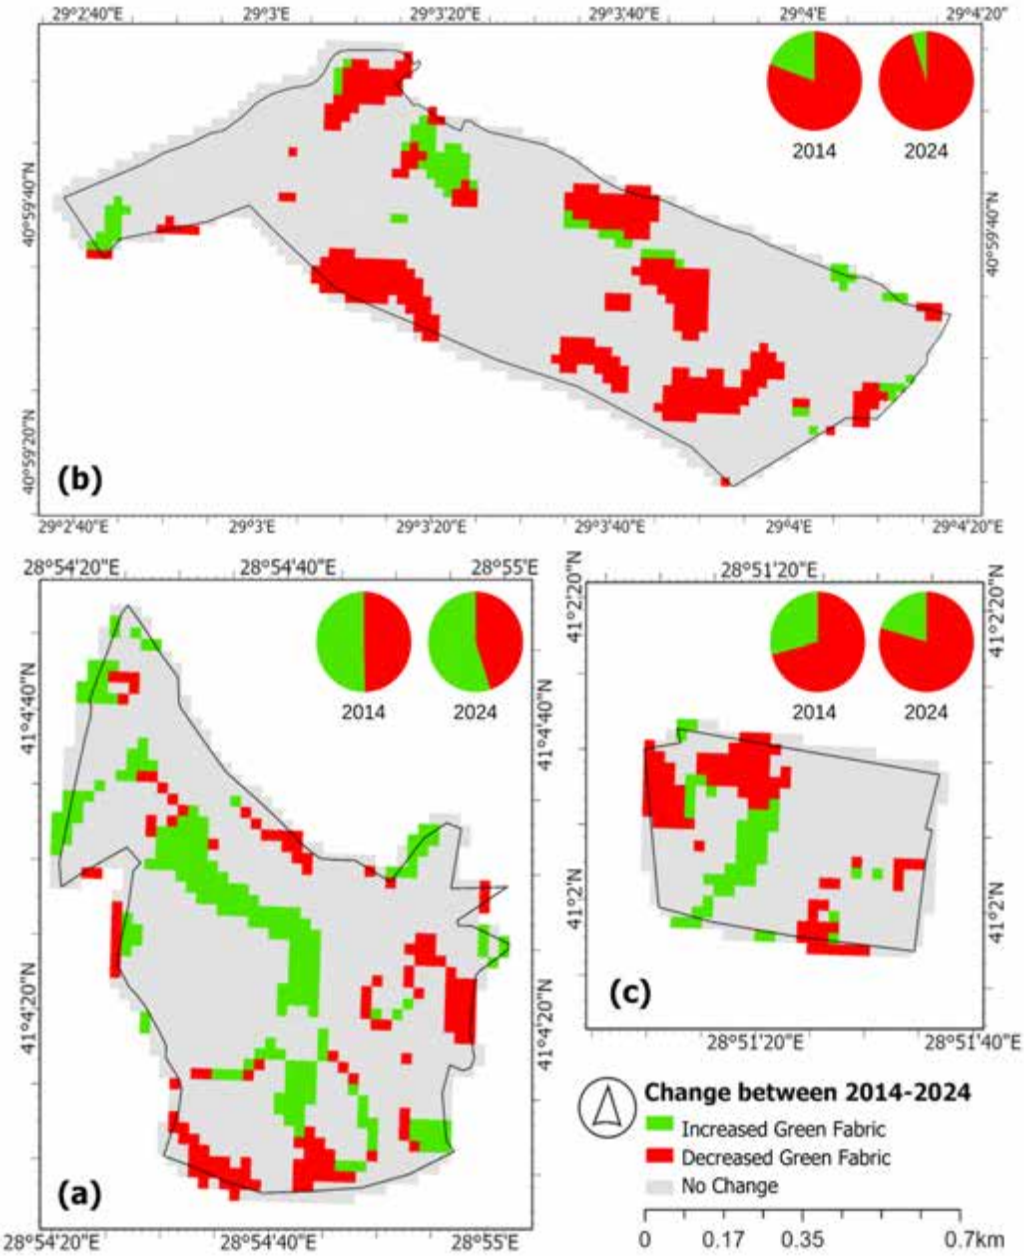

Figure 4. Urban green fabric changes in selected regeneration sites between 2014- 2024: (a) Site – 1; (b) Site – 2; (c) Site – 3.

Table 7. Change in urban green fabric between 2014-2024.

	Area Size						Change Rate (%)		
Project Site	2014			2024					
	Built-up (ha)	Green Fabric (ha)	Green Fabric per cap (m2)	Built-up (ha)	Green Fabric (ha)	Green Fabric per cap (m2)	Built-up	Green Fabric	Green Fabric per cap

4. Conclusion

This paper investigates the spatial change in urban green fabric between 2014 and 2024 using three representative areas in Istanbul subjected to urban regeneration policies under law no. 6306. Combining NDVI, NDBI, and texture-based statistics with random forest classification reveals the different effects of various regeneration strategies on green areas in the analysis. Notably, the vertical densification cluster experienced a drastic decline of 74.15% in green fabric, highlighting the conflict between intensive redevelopment and environmental sustainability. The workplace intensification site also experienced a significant transition from green to built-up zones (28.79%). In contrast, the gradual regeneration cluster showed a moderate increase in green areas. However, this increase in green fabric detected based on NDVI should not be interpreted as a final conclusion comparable to the other two regeneration sites since construction activities are largely incomplete in Site-1 (in Gaziosmanpaşa). The decrease in planned green fabric per capita in post-regeneration of Site -1, as shown in Table 7, supports this caution. In all areas, the amount of green fabric per capita (based on the planned capacity population) after regeneration remained below the pre-regeneration era. Additionally, current rates in Site – 2 (in Kadıköy) and Site – 3 (in Bağcılar) are lower than the minimum value recommended by the WHO.

Although law no. 6306 aims for healthy and safe urban settlements, the findings show that it remains insufficient in terms of protecting or increasing green fabric during the implementation phase. The spatial decrease in urban green fabric in different regeneration clusters emphasize the decisive role of planning strategies on ecological and climate-adaptive outcomes. However, it should be noted that the negative change in the urban green fabric detected through remote sensing and advanced spatial analysis cannot be evaluated only in two-dimensional spatial criteria that are reduced to urban settlement. Urban green fabric functions as a part of a regional green infrastructure that includes urban elements (parks, street trees, gardens, etc.) as well as forests, agricultural areas, riparian zones, and wide-open spaces outside the city. Although these urban periphery natural elements are located outside urban settlement areas, they directly affect the quality of urban life by providing critical ecosystem services such as improving air quality, providing biodiversity corridors, climate regulation, and groundwater recharge. Therefore, changes in the urban green fabric should also be evaluated in the context of the continuity and integrity of the holistic green infrastructure network, not limited to urban borders. Accordingly, there is a need for multi-dimensional planning approaches that integrate disaster-focused response objectives with cli-

mate adaptation and urban ecology. Green infrastructure should be considered a holistic planning component in regeneration areas and a fundamental precondition for building sustainable and resilient cities.

Although this study proposes a powerful method based on remote sensing and machine learning, it has some limitations. First, to improve classification accuracy, the regeneration project with the largest area from each cluster was selected as a representative. However, this choice may have weakened how well some clusters are represented. Second, the 30-meter spatial resolution of Landsat 8 imagery may be insufficient to detect small-scale green areas like narrow strips, street trees, or green roofs. Although NDVI, NDBI, and texture statistics were used to improve classification accuracy, spectral similarities between low-density vegetation and built-up areas may still cause confusion. Additionally, first-order statistics (mean, std, range, variance) were used instead of second-order metrics like GLCM to describe spatial texture, which reduced computational cost but also limited detailed discrimination. Third and finally, the analysis only covers the years 2014 to 2024, so it cannot fully reflect all temporal changes, regeneration stages, or land use transitions during the ongoing projects. This may lead to temporary vacant areas or unbuilt parcels between new buildings being misleadingly perceived as green fabric on NDVI. Future studies can address these limitations by using higher-resolution data, time series analysis, and field observations.

Abstract
This study analyzes over one million geo-tagged Sina Weibo posts (2019–2024) to evaluate emotional patterns and influencing factors on internet-famous streets in Nanjing Old City. First, high-traffic streets and their functional zones are identified using ArcGIS-based spatial analysis. Second, advanced large language models (LLMs) are used to detect residents' and tourists' emotions through a four-dimensional structure: primary and secondary emotions, intensity, and polarity. These emotional labels are mapped to street-level sentiment profiles. Spatial clustering and semantic analysis reveal distinct emotional dynamics driven by spzeatial semantics and functional typologies.

Keywords: large language model; internet-famous streets; social media sentiment; urban emotion map; Nanjing old city

1 Introduction

With the rapid development of information and communication technologies, society has quietly entered the era of big data. The widespread use of GPS, mobile devices, and the internet has brought new opportunities for urban spatial perception research. Since 2012, disciplines such as urban geography, planning, and sociology have increasingly embraced big data, with location-based social media becoming a prominent data source. Check-ins are considered conscious behaviors—users tend to post only when they spend significant time in a location worth recording, reflecting their emotional and psychological states (Yadollahi, A., 2017).

Against this backdrop, geo-tagged data from social media enables researchers to capture spatial emotional interactions and geographic tendencies. It has been widely applied in urban zoning, spatial evaluation, vitality analysis, and spatiotemporal behavior studies. Sina Weibo, as one of China's most popular social media platforms, offers broad national coverage and robust user-generated data for such analyses.

Meanwhile, networked communication has reshaped social and spatial experiences. The rise of online interaction has increasingly influenced physical urban space—cloud experiences often replace physical ones, and media representation tends to precede actual function. As a result, media-oriented "internet-famous streets" have proliferated (Niu, X. and Lin, S., 2022). Streets, as key urban spaces for communication and culture, now serve as dynamic platforms for emotional expression and interaction among users.

However, traditional sentiment analysis methods based on rule-based or shallow classifiers struggle with unstructured, ambiguous, or sarcastic content common in social media texts (Nandwani, P. and Verma, R., 2021). With the advent of large language models (LLMs), such as ChatGPT, sentiment analysis has entered a new phase. Trained on vast corpora, LLMs can understand context, capture nuanced emotions, and infer user attitudes and motivations (Lü J., 2022.), significantly enhancing the accuracy and interpretability of emotional computing.

In the field of emotion research, scholars have developed relatively mature theoretical frameworks across various dimensions. Emotion dimension theories propose that emotions can be understood through multiple attributes,

with two- and three-dimensional models being the most widely used. Russell introduced the two-dimensional model, suggesting that emotions can be interpreted along two axes: valence (positive to negative) and arousal (high to low intensity) (Russell, J.A., 1980.). Valence reflects pleasantness, while arousal captures emotional intensity or excitement. Later, Mehrabian and Russell (1994) proposed the PAD model (Mehrabian, A., 1980.), a three-dimensional theory consisting of Pleasure, Arousal, and Dominance. In this model: Pleasure (P) represents the positive or negative quality of the emotion; Arousal (A) indicates the level of emotional activation or excitement; Dominance (D) reflects the degree of control or influence the individual feels within a given environment. In terms of classification, psychological theories typically distinguish between basic and complex emotions. However, definitions of basic emotions vary significantly among researchers due to differing perspectives from linguistics, behavioral science, and other fields. Figure 1 below outlines several mainstream classification systems and their respective emotional categories.

Researcher	Categories	Specific Emotions
Darwin	6 types	Joy, Sadness, Anger, Fear, Disgust, Surprise
Arnold	11 types	Sadness, Anger, Terror, Disgust, Anticipation, Hope, Frustration, Disappointment, Expectation, Resentment, Love
Izard	10 types	Joy, Sadness, Anger, Fear, Disgust, Surprise, Interest, Shame, Guilt, Contempt
Ekman	6 types	Joy, Sadness, Anger, Fear, Disgust, Surprise
Johnson	5 types	Joy, Sadness, Anger, Fear, Disgust
Lazarus	10 types	Joy, Sadness, Anger, Fear, Disgust, Jealousy, Pride, Shame, Love, Comfort

Figure 1: Basic Emotion Classifications (Image source: redrawn based on Reference 6)

In the domain of spatial emotion research, scholars began exploring the relationship between space and emotion as early as the mid-20th century, proposing concepts such as “place perception” and “place attachment” to examine how spatial environments influence human emotions. Initial studies emerged in philosophy, sociology, and psychology before expanding into specific investigations on how spatial elements trigger emotional responses and the types of emotions involved. These studies often adopt macro, meso, or micro-scale perspectives to depict the spatiotemporal distribution of emotions and explore their associations with physical spatial elements.

At the macro scale, research focuses on citywide emotional distributions and their correlations with urban form and built environment. This stream typically employs big data analysis, especially from geo-tagged social media. Bertrand mapped emotional tendencies across New York City using Twitter data, finding that parks concentrated positive emotions, whereas facilities like transport hubs, cemeteries, hospitals, and prisons correlated with negative sentiment (Bertrand, K., Bialik, M. and Virdee, K., 2015.). Shanshan Chen et al. analyzed Twitter data from 26 parks in Berlin to examine how cultural demands and green space supply interact to affect public emotions (Chen, S., Liu, L., Chen, C. and Haase, D., 2022.). Sakshi Khare et al used Bhopal, a rapidly growing Indian metropolis, as a case study to explore the link between urban built environment and subjective well-being (Khare, S. and Chatterjee, A., 2023.).

At the meso and micro scales, studies often focus on streets, parks, squares, and neighborhoods, using data sources such as surveys, interviews, or physiological signals. Li et al. examined the emotional coupling between people and urban spaces to evaluate spatial environments and provide recommendations for improving urban design (Li, X., Hijazi, I., Koenig, R., et al., 2016.). Hijazi et al. combined Twitter sentiment data with spatial features to analyze how certain spaces or spatial sequences trigger emotional arousal (Hijazi, I.H., Koenig, R., Schneider, S., et al., 2016.). Similarly, Koenig et al. used one week of Twitter data from Osaka to show how pedestrian emotions shift with spatial sequences (Koenig, R., Schneider, S., Hamzi, I., et al., 2014.).

In the context of large language models (LLMs) and sentiment analysis, scholars have argued that "emotions have never been aliened in AI." LLMs have demonstrated promising potential in understanding social emotions. Traditional sentiment analysis methods—including dictionary-based approaches, machine learning, and deep learning—have been widely used. While dictionary-based methods match words with emotion tags, and machine/deep learning models can identify emotional types within specific contexts, they often struggle with complex emotional structures, mixed emotions, sarcasm, and contextual nuances. As a result, they risk misclassifying emotions in nuanced or ambiguous content (Maynard, D.G. and Greenwood, M.A., 2014.).

Recent advances in large language models (LLMs) have demonstrated exceptional performance in understanding human language. Fu highlighted the effectiveness of LLMs in analyzing public sentiment, emphasizing their ability to significantly reduce the time and cost associated with processing emotional corpora. Unlike traditional methods ((Fu, X., Sanchez, T.W., Li, C. and Reu Junqueira, J., 2024.), LLMs approximate human-like comprehension of complex emotional expressions. Li Yin applied ChatGPT to analyze multi-category and multi-level sentiments in COVID-19-related tweets across New York State, identifying nuanced emotional patterns such as relief, hope, and anxiety. The study achieved refined sentiment classification and thematic associations, revealing regional differences in emotional attitudes (Yin, L., Han, M. and Nie, X., 2024.). Gao M conducted sentiment analysis on geo-tagged social media data from 32 urban blue spaces in London using LLMs, introducing three indices—the Happiness Probability Index (HPI), Happiness Intensity Index (HII), and Happiness Equilibrium Index (HEI)—to quantify the impact of blue spaces on public well-being (Gao, M. and Fang, C., 2025.).

Building on existing sentiment analysis frameworks, this study utilises LLMs to analyze the spatiotemporal patterns of public emotion on internet-famous streets in Nanjing's old city. First, using preprocessed social media data and ArcGIS-based spatial analysis, high-traffic and high-engagement internet-famous streets are identified. Second, the functional tags of Weibo check-in locations are manually sorted, and classified into standardised categories: education, public services, parks and squares, transportation, commerce, residential, cultural and sports services, and others. Based on this, the dominant functional type of each street is determined. Finally, by applying a GPT-based LLM, the study extracts complex emotional structures from the dataset and conducts a street-level spatiotemporal analysis of emotion patterns in relation to spatial features and function types.

This research focuses on the following core questions:
(1) How can internet-famous streets be identified through virtual media, and how can their online popularity boundaries and physical boundaries be accurately delineated?
(2) How can the functional types of internet-famous streets be classified based on social media perspectives?
(3) How can LLMs be used to mine multi-level sentiment structures from Weibo texts, and what are the relationships between emotional spatial patterns and functional types on these streets?

2 Data and Methods

2.1 Data Source

Using "Nanjing" as the keyword, original Weibo posts containing check-in information for Nanjing from July 31, 2019 to July 31, 2024 were collected via a Python-based web scraping framework. After removing invalid entries—such as abnormal check-in records, advertisements, and blank posts—and cropping the dataset to the boundaries of Nanjing's central urban area, a total of 1,004,755 valid records were obtained.
Each valid entry contains the following fields: user nickname, province, check-in location name, check-in location

type, geographic coordinates (latitude and longitude), post time, and Weibo text. The check-in location type is a label provided by the Weibo API, which tends to be fragmented and thus required manual cleaning and classification.

This study focuses on internet-famous streets rather than the entire city or old town of Nanjing. Therefore, the text dataset is constructed at the street scale. Buffer zones were generated using a length of 150 meters—corresponding to pedestrian-scale street segments—around identified street linear features. All Weibo posts falling within these buffers were included in the final dataset of internet-famous streets, resulting in a total of 68,215 valid records.

nickname	province	Location name	Location type	latitude	longitude	post time	Weibo text
A roadside little flower kid	Other	Taiyanggong Square	Square	118.8089	32.06694	2024/7/31	To the one I may be separated from—salute giving up. ps: my crying voice is too ugly.
I want you to become a persimmon cake	Jiangsu	Baolong Times Plaza	Shopping mall	118.6333	32.05627	2024/7/31	The most relaxing moment after work every day. July comes to an end.
Big Bastard Pig	Jiangsu	Nanjing University of Aeronautics and Astronautics	University	118.8152	32.03713	2024/7/31	After the plum rain season comes the dog days—seamlessly connected.

Figure 2: Weibo Dataset Structure (Figure source: self-compiled)

2.2 Kernel Density Spatial Analysis

The principle of kernel density analysis is that each analyzed point is covered by a smooth surface, where the surface value is highest at the point's location and gradually decreases with distance until it reaches zero at the defined search radius. A larger search radius yields a smoother and more generalised raster surface, while a smaller radius results in steeper, more detailed raster outputs.

In this study, kernel density analysis is employed to identify the spatial clustering boundaries of point-based datasets, thereby delineating the virtual heat boundaries of hotspot check-in streets.

2.3 Multi-Level Sentiment Analysis Framework Based on Large Language Models

This study utilises OpenAI's pretrained generative transformer model (GPT) as the primary tool for multi-category and multi-level sentiment analysis. The model excels in text comprehension and generation, offering human-like interpretation of social media content and outperforming traditional natural language processing methods in semantic depth and accuracy. OpenAI's model has demonstrated excellent performance in multiple benchmark evaluations and is particularly effective for processing unstructured, noisy, and linguistically diverse data such as tweets. Compared to open-source large language models that often require complex GPU deployment, OpenAI's API offers greater accessibility and ease of use, enhancing both the efficiency and stability of this research.

Prior to emotion classification, we used the LLM to objectively extract the emotional tone of each tweet without preset category labels or emotional constraints. By analyzing the natural emotional expressions in a large corpus of raw texts, and based on commonly recognised emotion types in Chinese contexts, we identified frequent emotional categories within social media discourse. The model ultimately classified the following sentiment types:

- Positive emotions: anticipation, happiness, affection
- Negative emotions: sadness, disgust, anger
- Neutral emotions: neutrality

The model was instructed to identify both a primary sentiment and a secondary sentiment for each post. If a secondary sentiment could not be detected, it was left blank, but a primary sentiment was always required. Through prior prompt tuning, we also enabled the model to output both the sentiment intensity and polarity for each sentence.

2.4 Research Framework

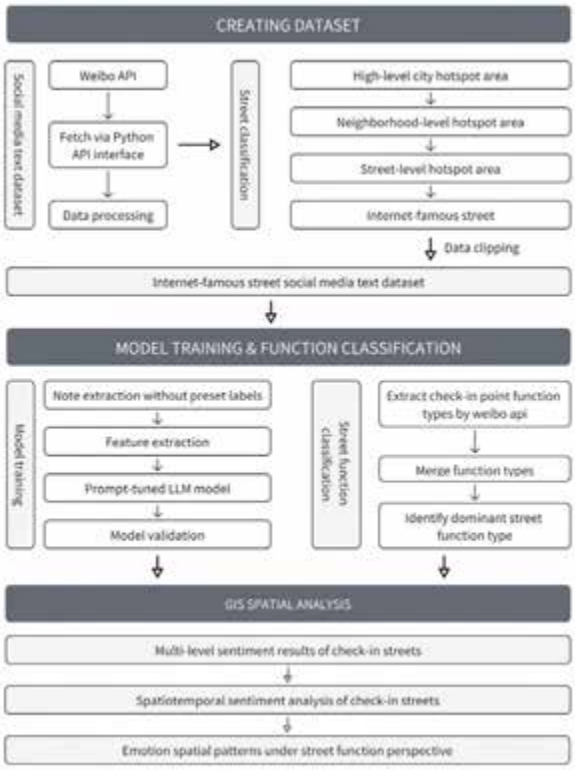

Figure 3: Research Framework (Figure source: self-compiled)

From Figure 3, this study establishes a Weibo text-based framework for identifying and classifying the functions of "internet-famous streets," encompassing three main stages: data collection, model training, and GIS spatial analysis. Data are collected via the Weibo API, functional types are determined using a large language model, and spatiotemporal patterns of internet-famous streets are ultimately visualised from a functional perspective through spatial analysis.

3 Case Study

3.1 Introduction to Nanjing

Nanjing is the capital of Jiangsu Province, a major central city in eastern China, and a megacity within the Yangtze River Delta region. As a historically and culturally renowned city, Nanjing boasts a profound cultural heritage and is historically known as the "Ancient Capital of Six Dynasties" and the "Metropolitan Capital of Ten Dynasties." In addition, the city is celebrated for its natural and urban landscape— "embracing the river and lakes, coiled like a dragon and crouching like a tiger"—and for its spatial structure characterised by "mountains and water interwoven, nested and layered." Immersed in such rich cultural and natural surroundings, Nanjing was named "China's Most Livable City" for the fourteenth time by 2023. This reflects the high level of happiness and satisfaction reported by its residents. The city's cultural and tourism vitality is also notable: during the 2025 May Day holiday alone, Nanjing received more than 12 million tourists. The shared access to high-quality urban space and cultural experiences among residents and visitors further reinforces a sense of belonging and emotional connection to the city.

The Old City of Nanjing, as shown in Figure 4 located in the heart of the urban core, serves as both the origin and continuation of the city's historical and cultural legacy. Its spatial form is framed by the Ming Dynasty's city wall, forming a structure of "outer city enclosure with an inner-city core." The Old City is not only a concentrated area of historic architecture but also a quintessential representation of traditional urban life. With a dense street network and human-scale dimensions, it offers strong walkability and a localised experience. This area integrates multiple functions including cultural tourism, commercial activity, and community life—preserving traditional atmospheres while blending with modern urban elements. Driven by the dynamics of social media, distinctive streets in the Old City—such as Laomendong, Gongyuan Street, and the Qinhuai River waterfront—have gradually evolved into popular "internet-famous" check-in spots, becoming key nodes for emotional expression, cultural identity construction, and urban image dissemination.

Figure 4: The old city of Nanjing (Figure source: self-compiled)

3.2 Hotspot Check-in Streets

3.2.1 Identification of Internet-Famous Check-in Streets

In studies focusing on the identification of internet-famous streets or blocks based on social media data, Zhang Wenquan proposed a method to delineate internet-famous districts. He identified high-popularity roads and blocks and then integrated real traffic networks with social media heat data, outlining check-in districts using a "connect-line-to-polygon" approach (Zhang, W., 2023.). Meanwhile, Yu Yidong et al. divided internet-famous spaces at the city, regional, and block levels into polygonal areas, and further identified the most representative check-in spaces at the block level. Both approaches provide valuable references: Zhang's framework effectively captures road-level connectivity but lacks a broader macro perspective, while Yu's model covers macro to meso-levels but does not extend down to the street scale(Yu, Y., Wang, J., Jiang, X., et al., 2024.).

This study builds on both methodologies and establishes a multi-level identification framework that progresses from city-level hotspot delineation,
district-level hotspots, block-level hotspots, final identification of internet-famous check-in streets, as is shown by Figure 5.

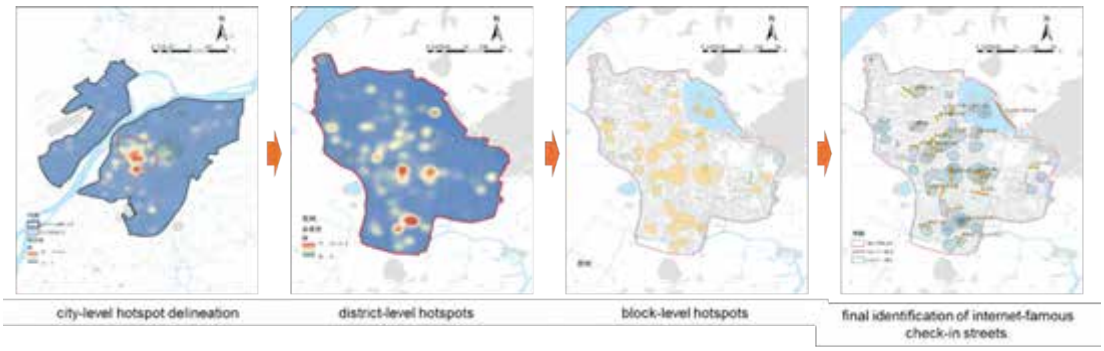

Figure 5: Multi-Level Identification Framework for Internet-Famous Streets (Figure source: self-compiled)

The scope of this study is defined through four hierarchical steps: (1) delineation of city-level hotspot zones, (2) district-level hotspots, (3) block-level hotspots, and (4) the final identification of internet-famous check-in streets.

First, the full dataset of 464,494 check-in Weibo posts with location information from Nanjing's main urban area is filtered by levels. Kernel density analysis of the main urban area reveals that internet-famous check-in zones are highly concentrated in the old city, with smaller clusters in Jiangning and Qixia districts. Due to their lower intensity and scale, the second-level scope is refined to focus on the old city, which contains 285,966 check-in posts.

Kernel density and raster binarization analyses are conducted within the old city to delineate block-level hotspots. Among the many hotspot areas, Xinjiekou, Daxinggong, and the Fuzimiao area show the most intense clustering.

Finally, based on block-level hotspot zones, check-in streets are identified. The top 20 streets and blocks in the old city are selected based on term frequency, along with the top 200 most popular check-in locations. The study integrates these block-level hotspot boundaries with the physical street boundaries to define the spatial extent of check-in streets, excluding overly long streets like Beijing East Road and Zhujiang Road that fall entirely outside hotspot areas. For blocks labeled as area-based check-in types, streets that connect the highest number of check-in points are selected as proxies—e.g., "Zhongshan South Road (Xinjiekou section)" is used to represent the Xinjiekou area.

Moreover, if a road clearly connects multiple check-in spots within a hotspot zone and displays a linear relationship, it is considered a check-in street—for example, Ke Xiang (Kexiang) and Taogu Xincun Road (Taogu New Village Road), which link numerous check-in points. Based on this classification approach, the final set of

internet-famous streets within the study area is determined, as is shown in Figure 6 and Figure 7.

Street Name (English)	Check-in Frequency
Zhongshan South Road (Xinjiekou Section)	13,592
Yangtze River Road	6,293
Fuzimiao Pedestrian Street	5,622
Zhujiang Road	5,513
Zhongshan North Road	4,120
Zhongyang Road (Xinjiekou Section)	3,399
Jimingsi Road	3,089
Kexiang Street	3,029
Shanghai Road	2,801
Shiziqiao Pedestrian Street	2,638
East Ring Road of Xuanwu Lake	2,443
Gutong Alley (Laomendong Area)	2,281
Sanshan Street	2,215
Mochou Road	1,958
Yihe Road	1,486
Changfu Street	1,347
Sanpailou Street	1,228
Jiqingmen Road	1,208
Houzaimen Street	1,011
Shanyin Road	1,005
Taogu Xincun Road	932
Fengfu Road	620
Jinyin Street	442

Figure 6: The list of the famous check-in streets (Figure source: self-compiled)

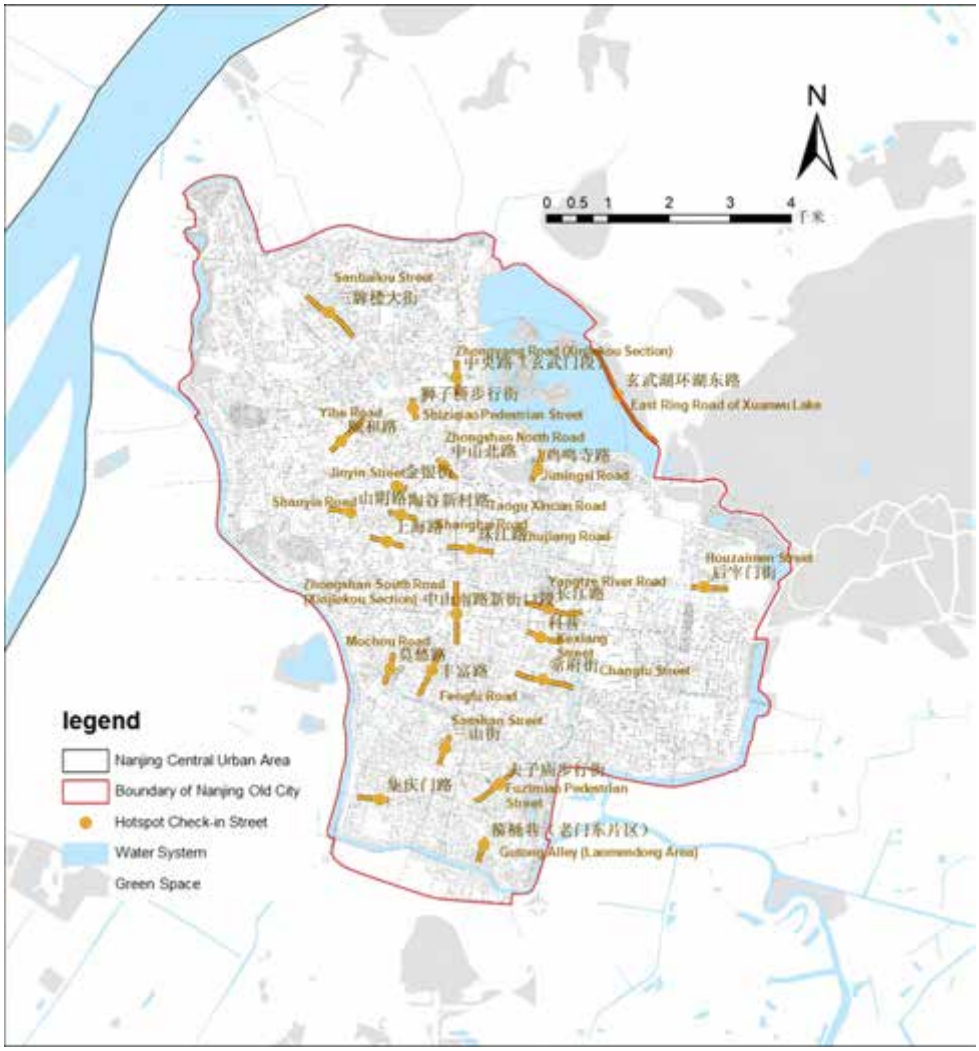

Figure 6: The list of the famous check-in streets (Figure source: self-compiled)

3.2.2 Identification of Check-in Location Functions

The Weibo API provides functional labels for check-in locations; however, these classifications are relatively broad, covering 154 categories such as five-star hotels, dining facilities, road infrastructure, metro station shops, cafés, bars, and more. To streamline the analysis, all location types were manually reclassified into eight major functional categories: education, public services, parks and squares, transportation, commerce, residential, cultural and sports services, and others, as is shown in Figure 7 and 8.

Category	Classification Criteria
Education	Includes educational institutions providing various levels of education, such as universities, secondary schools, and kindergartens.
Public Services	Covers facilities related to government, healthcare, and administration, focusing on public service and welfare functions.
Parks and Squares	Refers to open urban spaces with ecological, landscape, leisure, and social functions, including urban parks, pocket parks, and green plazas.
Transportation	Includes transportation infrastructure such as bus stops, metro stations, and railway stations.
Commerce	Encompasses spaces with commercial functions such as retail, dining, business offices, and entertainment or leisure venues.
Residential	Consists of residential-dominant units including commercial housing complexes, affordable housing, and dormitory areas.
Cultural and sports services	Facilities aimed at culture, education, leisure, or physical activities, such as libraries, stadiums, exhibition halls, and cultural centers.
Others	Special or mixed-use spaces that cannot be classified under the categories above.

Figure 7: Functional Types of Check-in Locations (Summarised Based on Weibo API Check-in Labels)

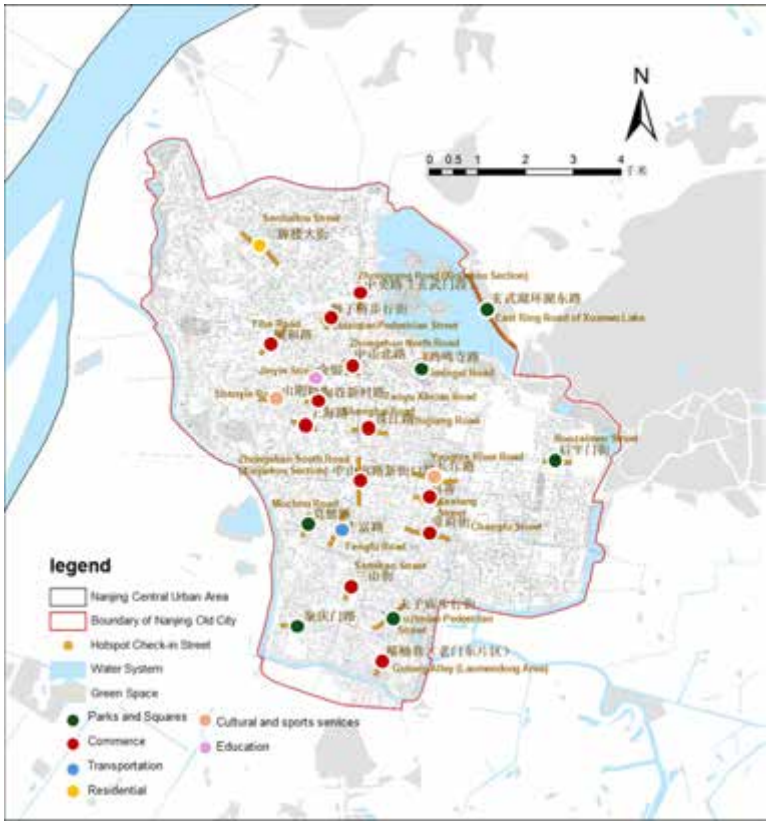

Figure 8: Dominant Functional Type of Internet-Famous Check-in Streets (Figure source: self-compiled)

3.3 Spatiotemporal Analysis of Emotional Patterns in Hotspot Check-in Streets

3.3.1 Overall Emotional Pattern Recognition of Internet-Famous Check-in Streets

Figure 9 illustrates the multi-category and multi-level emotional structure of the internet-famous check-in streets in Nanjing's Old City. Overall, public emotions are predominantly positive, with "happiness" and "affection" forming a strong co-occurrence relationship. Together, they constitute the core positive emotional backbone of the street spaces in the Old City. This emotional structure reflects not only a high level of public approval of the spatial environment but also highlights the streets' appeal as high-quality public spaces that integrate leisure, consumption, and culture, resonating strongly with positive emotions.

Within the positive emotion spectrum, "happiness" tends to convey immediate sensory experiences—such as pleasant scenes or a comfortable atmosphere—while "affection" emphasises long-term spatial preference and emotional attachment. This dual nature suggests that the Old City's streets provide both immediate experiential value and deeper emotional significance.

In contrast, "anticipation," as a secondary positive emotion, flows between several primary emotional nodes, playing a transitional and bridging role. It is positively linked with both "joy" and "affection," but also connects with "neutral" and even "sad" emotions, indicating that when expressing anticipation, users may reveal hopes for future spatial experiences, intertwined with dissatisfaction or desires for improvement in the present environment.

Negative emotions appear more fragmented and complex. Although the overall proportion of negative sources such as "sadness," "disgust," and "anger" is relatively low, their emotional pathways are highly scattered. For example, "sadness" connects not only to "disgust" and "anger" but also to positive emotions like "affection" and "anticipation." This suggests that negative emotions are not merely rejections of space but often represent critical feedback embedded within active urban experiences—such as perceptions of street congestion, over-commercialization, or disorder—interwoven with aspirations for improvement and positive transformation.

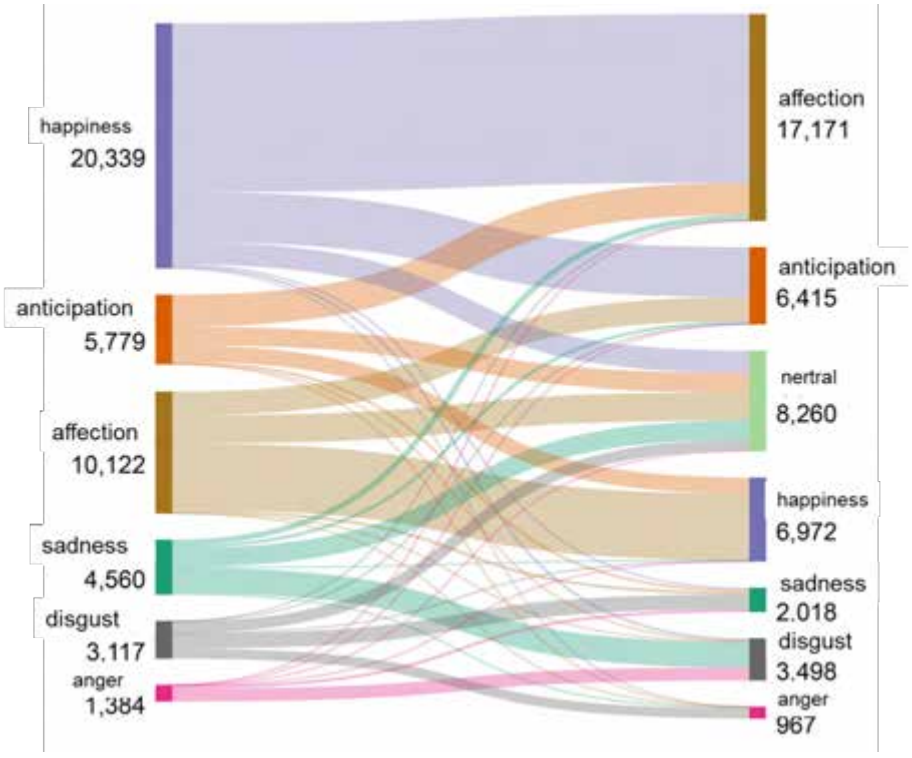

Figure 9: Dominant Functional Type of Internet-Famous Check-in Streets (Figure source: self-compiled)

3.3.2 Overview of Emotional Patterns in Internet-Famous Check-in Streets

Overall, the internet-famous check-in streets in Nanjing's Old City exhibit a predominantly positive emotional pattern, with a generally uplifting spatial atmosphere. Figure 10 illustrates that in most streets, positive emotions account for over 70%, with "happiness" and "affection" consistently serving as dominant sentiments. This pattern indicates a strong foundation of emotional perception among the public—these streets not only fulfill functional needs but also create environments imbued with a sense of pleasure and belonging.

From a finer spatial perspective, the emotion of "affection" highlights spatial identity and cultural attachment. Streets such as Mochou Road, Taogu Xincun Road, and Gutong Alley (Laomendong Area) show a significantly higher proportion of "affection" than other streets. This suggests that these locations carry strong cultural symbolism in the public consciousness and enjoy greater emotional recognition in terms of spatial image, historical memory, and sense of belonging.

A few streets, such as Shanyin Road, Houzaimen Street, and Kexiang Street, show relatively higher proportions of negative emotions like "sadness" and "disgust," potentially reflecting localised issues in functional facilities, environmental ambiance, or congestion experiences.

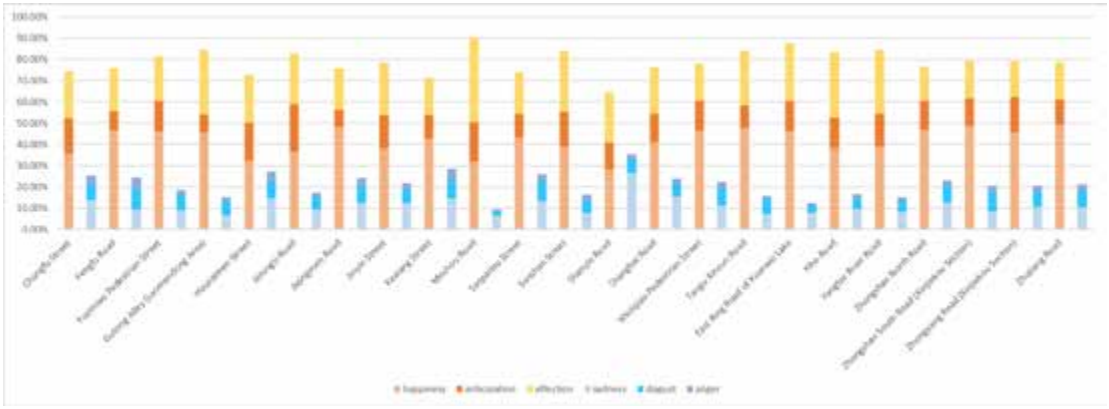

Figure 10: Primary Emotion Categories of Different Check-in Streets (Figure source: self-compiled)

As is shown by Figure 11, streets with different functional types exhibit significant structural differences in emotional expression. Streets characterised by commercial, park and square, transportation, and cultural-sports service functions show a highly consistent pattern of dominant positive emotions. Among these, the emotion "joy" holds an overwhelmingly dominant position across all functional types—particularly in transportation and park/square streets, where it accounts for over 40%, reflecting the public's immediate sense of pleasure and positive experience in such spaces.

In contrast, streets serving educational and public service functions show more pronounced expressions of negative emotions. Specifically, "sadness," "disgust," and "anger" are relatively more prevalent on streets surrounding university areas. This may be linked to issues such as traffic congestion, commercial sprawl, inadequate infrastructure, or restrictive management policies in these zones. Public service streets also display a strong emotional polarization. Although residential streets are similarly dominated by "happiness", they also show relatively high proportions of "disgust" and "sadness," which may be closely related to challenges in old urban residential areas, such as high housing density, lack of supporting public amenities, and spatial aging.

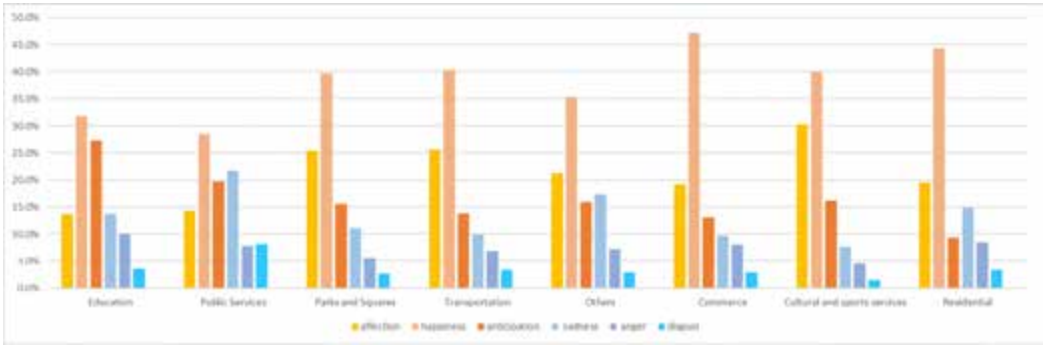

Figure 11: Emotional Patterns from the Perspective of Check-in Location Functions (Figure source: self-compiled)

3.3.3 Spatiotemporal Analysis of Emotional Patterns in Internet-Famous Check-in Streets

(1) Temporal Patterns of Emotions in Internet-Famous Check-in Streets

Figure 12 illustrates the monthly emotional trends of internet-famous check-in streets in Nanjing's Old City from 2019 to 2024. In terms of check-in volume, the overall frequency remained relatively stable between 2019 and 2022, fluctuating between 500 and 1,000 per month, with seasonal peaks typically occurring during summer holidays and national festivals. Since 2023, the check-in volume has seen a steady rise, with significant growth from early 2024 onward. Monthly check-ins have exceeded 3,000, marking a 3–4 fold increase compared to earlier years.

Emotional intensity (blue line) has remained between 0.65 and 0.7, with minimal fluctuation, indicating a strong and consistent level of emotional expression. The absolute value of emotional polarity (green line) has stabilised between 0.55 and 0.6, suggesting that emotional responses are steady and sustained. Emotional polarity (red line) consistently remains positive, fluctuating between 0.3 and 0.4, reflecting a persistently favorable emotional evaluation of the area by the public.

During the COVID-19 outbreak in early 2020, check-in volumes temporarily declined, but emotional indicators remained stable. From 2023 onward, check-in activity rebounded rapidly, with a noticeable surge in early 2024. Overall, despite the sharp increase in activity, emotional indicators remained positive, indicating that the internet-famous streets in Nanjing's Old City have achieved a robust post-pandemic recovery while maintaining a high-quality public space experience amid growing traffic.

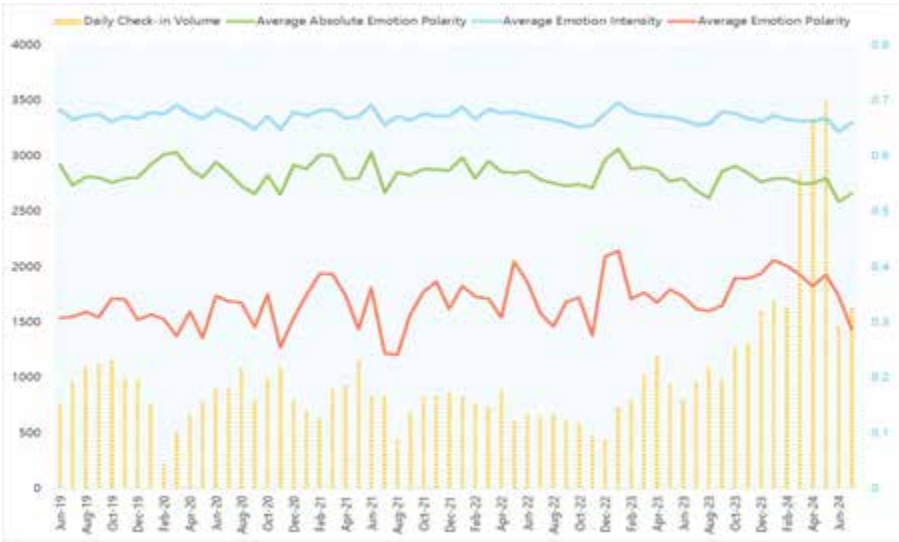

Figure 12: Monthly Analysis of Check-in Frequency, Emotion Polarity, and Emotion Intensity in Internet-Famous Streets (Figure source: self-compiled)

According to Figure 13, based on weekly-scale statistics, the emotional and check-in behaviors on Nanjing Old Town's internet-famous streets exhibit clear cyclical patterns. Firstly, check-in volumes show a typical "weekend effect," with significantly higher activity on Saturdays and Sundays compared to weekdays, reflecting the streets' primary roles in leisure, entertainment, and socializing. Interestingly, check-in volumes on Mondays are slightly higher than other weekdays, possibly due to the "Monday syndrome," as people tend to share their weekend outings and social experiences. During the workweek (Monday to Friday), check-in volumes remain relatively stable, suggesting that these areas attract consistent foot traffic even on weekdays.

In terms of emotional indicators—emotion intensity, polarity, and absolute polarity—there is little variation across the week, with all metrics maintaining a steady level. Even during peak weekend traffic, emotional values do not show notable fluctuations, indicating that these streets possess strong capacity and resilience in spatial management. They consistently deliver a satisfying urban experience across different time periods. Overall, Nanjing Old Town's internet-famous streets demonstrate a high degree of temporal stability in both spatial appeal and emotional perception.

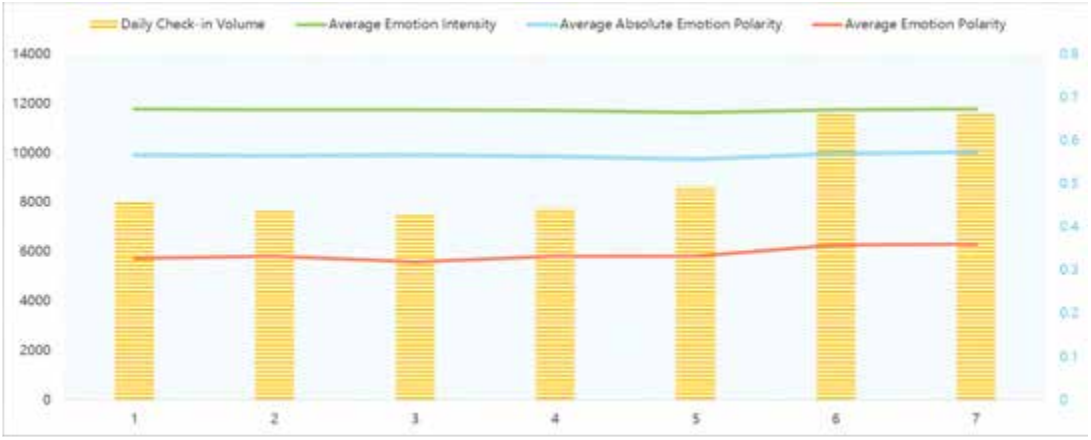

Figure 13: Emotional Patterns from the Perspective of Check-in Location Functions (Figure source: self-compiled)

Based on statistics by the dominant function of streets and on a monthly scale, two key insights emerge:

From the temporal perspective, emotional indicators fluctuated significantly and check-in volumes remained low during 2019–2020, reflecting the impact of the pandemic on urban vitality across all functional areas. In 2021–2022, emotional metrics began to stabilise and check-in volumes gradually recovered, indicating a transitional recovery phase. By 2023–2024, check-ins rose markedly, and emotional indicators remained steady, signaling a positive development trend.

From the functional perspective, commercial streets exhibited the highest level of activity and check-ins, showing sensitivity to holidays and seasonal changes. Due to the large data volume, the emotional indicators were relatively smooth. Parks and squares followed with high activity levels and strong seasonality, performing well particularly in spring and autumn, with stable emotional indicators. Streets with cultural and sports services had moderate activity and generally positive user experiences. In contrast, streets with traffic, residential, or university functions saw relatively low check-in volumes and more noticeable emotional fluctuations, especially under extreme values. Notably, university streets showed negative emotional polarity in the first half of 2020.

Figure 14: Emotional Analysis of Streets with Different Functions from a Monthly Perspective (Figure source: self-compiled)

(2) Spatial Emotional Patterns of Internet-Famous Streets
As shown in Figure 15, the emotional spatial pattern of internet-famous streets in Nanjing's Old Town demonstrates a dual characteristic of "highly clustered positive emotions + locally scattered negative emotions."

Areas dominated by positive emotions are highly concentrated. Red and orange grids representing high emotional polarity are widely distributed in commercial and park/square-type streets. Notable examples include Xinjiekou, Zhongshan South Road, Jiqingmen Road, and Gutong Alley (Laomendong area), where positive emotional polarity is particularly strong and grid coverage density is high. This indicates that such streets not only possess strong commercial appeal but also consistently evoke positive emotional experiences among users. Although streets like Fuzimiao Pedestrian Street and Houzaimen Street show some fragmented expressions of negative emotions, their overall sentiment remains predominantly positive.

Negative emotions are more scattered and localised. University-related streets (e.g., Jinyin Street) exhibit relatively higher proportions of negative sentiment. Transportation-oriented streets (e.g., Fengfu Road) also show high levels of negative emotions, potentially due to factors such as noise pollution, traffic congestion, and accessibility stress. Residential streets (e.g., Sanpailou Street) maintain a certain level of positive emotion but are also interspersed with negative sentiment. Cultural and sports service streets (e.g., Shanyin Road and Changjiang Road) reveal similarly elevated levels of negative emotions, which may be linked to inadequate public facilities, aging infrastructure, or limited capacity for hosting activities—suggesting these spaces may lack adaptability for high-frequency public use.

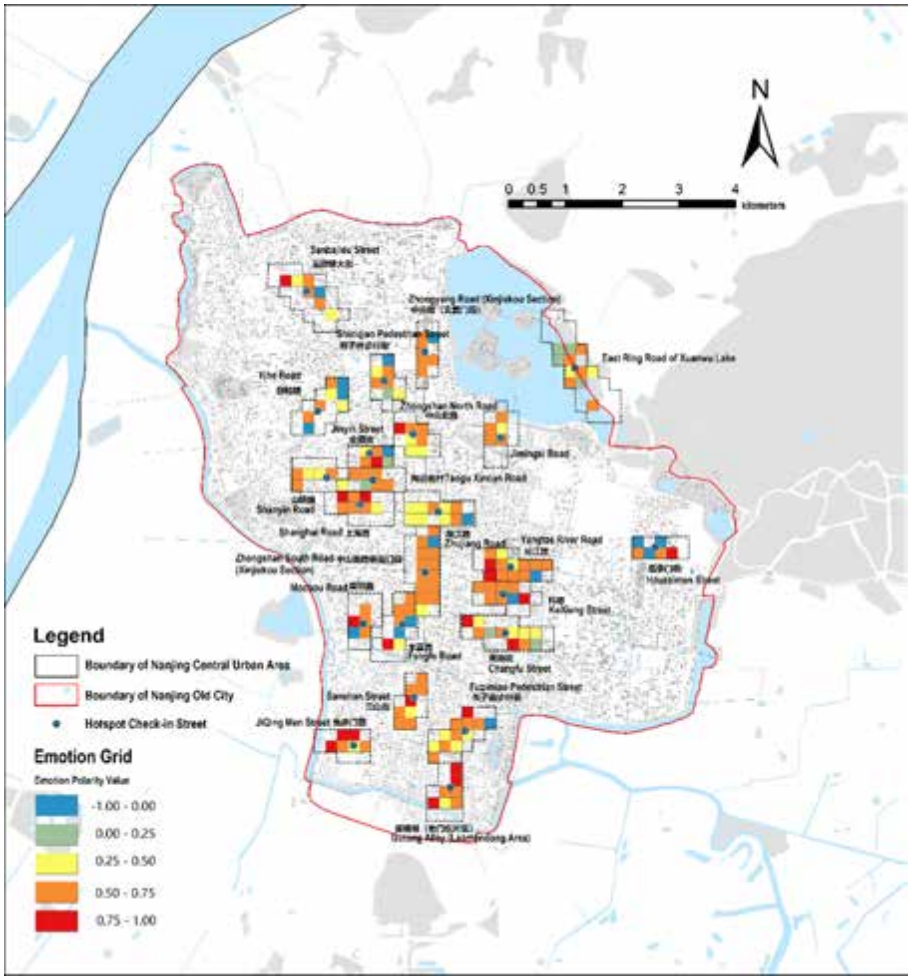

Figure 15: Spatial Visualization Analysis of Emotion Polarity in Internet-Famous Streets (Figure source: self-compiled)

3.4 Emotional Pattern Analysis of Hotspot Check-in Streets from a Functional Perspective

As is shown from Figure 16, from the commercial function perspective, commercial check-in points are the most prominent among Nanjing's hotspot streets. Streets such as Zhongshan South Road (Xinjiekou section), Gutong Alley, Kexiang, and Changfu Street display multiple red and orange grids, representing areas with the strongest positive emotional polarity. Overall, the high proportion of orange grids reflects a well-developed commercial environment and a strong consumer atmosphere in these areas.

From the public service function perspective, the emotional distribution of internet-famous streets in Nanjing's Old City shows a more prominent tendency toward negative sentiment. A higher proportion of blue grids is observed, indicating a pattern of low-value clustering with mixed positive and negative emotions. Negative emotions are dominant, and spatial consistency is relatively weak. Low emotional polarity zones are mainly concentrated along streets such as Shanyin Road, Changjiang Road, Zhongshan North Road, and Huanhu East Road of Xuanwu Lake, suggesting certain negative perceptions regarding the spatial environment, functional amenities, or user experience of public service facilities.

From the perspective of cultural and sports services, the emotional spatial distribution of hotspot check-in streets shows a more dispersed pattern of positive sentiment. Overall, red and orange grids are spread across

multiple streets, forming a generally positive emotional landscape. High-value zones are mainly concentrated along Gutong Alley, Taogu Xincun Road, and Kexiang. In contrast, grids representing negative emotions (blue or green) are relatively few and scattered, primarily appearing in limited areas such as Zhongshan North Road and the Xuanwumen section of Zhongyang Road. Although the distribution of positive emotions in cultural and sports service spaces lacks strong spatial continuity, most check-in locations maintain a high level of positive emotional expression, indicating strong positive spatial perception.

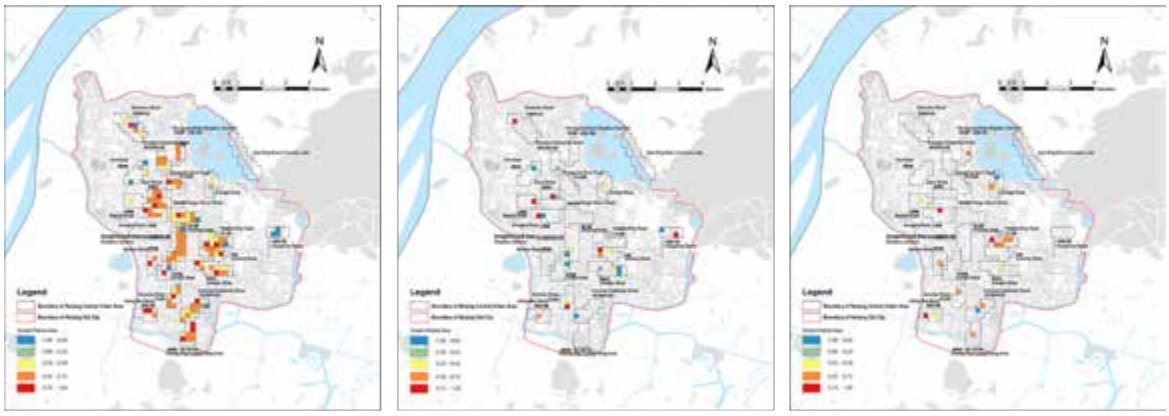

Figure 16: Spatial Visualization Analysis of Emotion Polarity in Internet-Famous Streets from Commercial, Public Service, Cultural and Sports Service Function (Figure source: self-compiled)

From the perspective of university-related functions, the emotional spatial distribution of internet-famous check-in streets in Nanjing's Old City is relatively limited. Overall, check-in points associated with universities are few and sparsely distributed. The primary low-emotion grids (blue and light blue) are concentrated in areas surrounding Jinyin Street and the Xuanwumen section of Zhongyang Road, indicating more prominent expressions of negative emotions.

From the perspective of parks and squares, both tourists and residents in Nanjing show high levels of satisfaction with such spaces. Red and orange grids are densely concentrated in areas such as the surroundings of Xuanwu Lake, Laomendong, and Mochou Lake, suggesting that these park and square spaces receive strong positive emotional feedback in public check-ins. In contrast, more negative comments are found around Yihe Road and Kexiang, which may be linked to crowd congestion, insufficient maintenance, lack of facilities, or conflicts with nearby developments.

From the perspective of transportation functions, the emotional spatial distribution of internet-famous streets in Nanjing's Old City is generally dominated by positive sentiment, with fewer negative expressions. Most transportation-related check-in points fall within orange and yellow grids, indicating a reasonably planned transportation layout and a relatively pleasant travel experience. However, localised high negative emotion zones are concentrated around Yihe Road and Kexiang, reflecting potential inconveniences or congestion issues in traffic conditions or accessibility in these areas, as is shown in Figure 17.

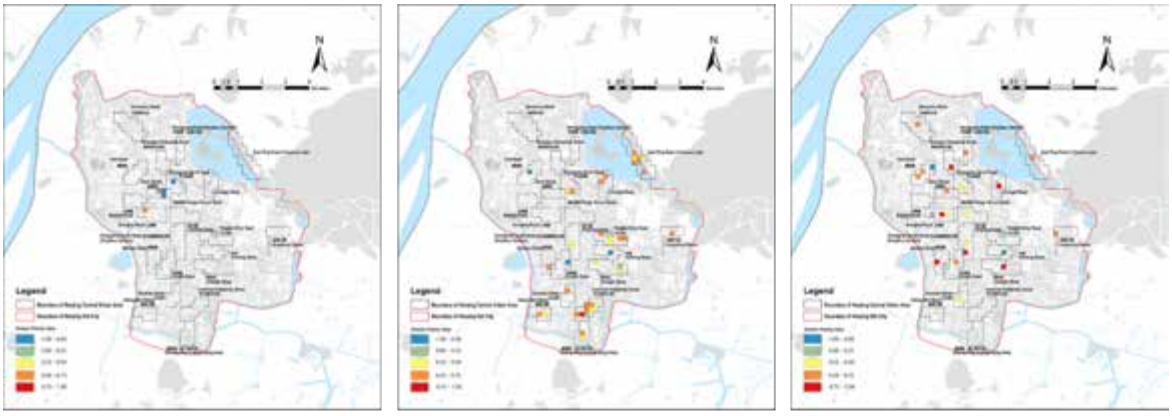

Figure 17: Spatial Visualization Analysis of Emotion Polarity in Internet-Famous Streets from Education, Parks and Squares and Transportation Function (Figure source: self-compiled)

4 Discussion and Conclusion

4.1 Discussion

This study provides an in-depth analysis of the emotional spatial patterns of internet-famous check-in streets in Nanjing's Old City. The findings show that public sentiment is predominantly positive, with "joy" and "affection" being particularly prominent. This emotional structure reflects a high level of public approval toward the street environment and indicates that these spaces offer both immediate experiential value and long-term emotional attachment. For example, Xinjiekou, as a core commercial area, shows exceptionally high levels of positive emotion, highlighting strong public resonance with its vibrant commercial atmosphere.

A detailed analysis of emotional patterns further reveals that while negative emotions account for a smaller portion overall, they exhibit fragmentation and complexity. Emotions such as "sadness" often interact with positive ones like "anticipation" and "affection," indicating that critical feedback from the public is often accompanied by expectations for spatial improvement. For instance, although Kexiang Street demonstrates generally positive emotions, there are noticeable localised expressions of negativity, likely due to crowding and inadequate facilities.

From a spatiotemporal perspective, the emotional activity on internet-famous streets in the Old City shows clear cyclical characteristics, with higher emotional engagement during weekends and holidays, suggesting that these areas serve primarily recreational, social, and cultural functions. Monthly and yearly trends further demonstrate the streets' emotional resilience and recovery—especially after the impacts of the COVID-19 pandemic—with a notable revival in vitality from 2023 onward, and stable sentiment levels, reflecting the rapid recovery capacity of urban public spaces after disruptive events.

This study offers two key methodological innovations: First, it incorporates large language models (LLMs) for emotion analysis, significantly enhancing the accuracy and efficiency of detecting emotional patterns in complex social media texts. Second, while most previous research has focused on citywide emotional mapping, this study adopts a street-level perspective, uncovering fine-grained interactions between public sentiment and spatial function types at the micro-scale. This shift in scale not only enriches the field of emotional geography but also offers precise decision-making support for urban planning and spatial optimization.

Future research could further extend the application of emotion analysis technologies, exploring the interaction between emotional patterns and spatial optimization strategies, thereby advancing urban governance toward greater refinement and human-centered development.

4.2 Conclusion

From a functional perspective, the internet-famous check-in streets in Nanjing's Old City exhibit clear spatial emotional distribution characteristics. Commercial streets—such as Xinjiekou, Zhongshan South Road (Xinjiekou section), Shiziqiao Pedestrian Street, Gutong Alley, Taogu Xincun Road, and Mochou Road—are dominated by positive emotional clustering, forming the core zones of highest emotional polarity. Streets associated with parks and squares—such as Fuzimiao Pedestrian Street, Houzaimen Street, and the East Ring Road of Xuanwu Lake—also feature mainly positive emotions, though some areas display scattered negative sentiment.

Cultural and sports service streets—such as Shanyin Road and Changjiang Road—exhibit a bipolar pattern, with both positive and negative emotions relatively balanced. University-oriented streets—such as Jinyin Street and the Xuanwumen section of Zhongyang Road—show a more pronounced distribution of negative emotions. Transportation-oriented streets—such as Fengfu Road—present a stronger concentration of negative emotions. Residential streets—such as Sanpailou Street—display a mix of both positive and negative emotions.

Overall, commercial and park/square streets emerge as primary hubs of positive sentiment, whereas streets associated with universities, transportation, and some residential or cultural service functions exhibit relatively more negative sentiment. The emotional spatial pattern shows a clear functional differentiation driven by street type.

Abstract
China's urbanization has spurred the growth of urban villages, with Shenzhen's Gangxia exemplifying intersections of social complexity, policy shifts, and digital innovation. This study designs a gamified digital platform engaging migrant workers, landlords, and officials in participatory urban planning. Quantitative coding of structured interviews revealed core interaction patterns and preference clusters, informing platform architecture integrating real-time feedback loops and tiered rewards. Key findings: 1) Adaptive UI/UX layers address technological literacy gaps; 2) Dynamic scoring algorithms reconcile power asymmetries; 3) Behavioral data granularity determines platform efficacy. This data-driven approach demonstrates context-sensitive digital tools for informal settlements, proposing a replicable framework for technology-mediated planning that bridges socioeconomic divides while enhancing governance. The research advances practical applications of gamification and AI analytics in sustainable urban renewal.

Keywords: Urban Villages, Gamification, Digital Participatory Design, Digital Platform - Urban Renewal

1. Introduction

Since the economic reforms of 1978, China has experienced transformative socio-economic growth, with substantial increases in investment, consumption, and overall living standards that have reshaped the urban landscape and driven significant rural-to-urban migration (Hao et al., 2011). In this context, urban villages—known as "villages in the city" (Chengzhongcun)—have emerged as distinctive informal settlements within Chinese urban centers. Originally traditional rural villages, they have become gradually surrounded by expanding urban zones, evolving into unique communities that coexist within the larger urban fabric (Wang et al., 2009). In first-tier cities such as Shenzhen, the status quo of urban villages has created a series of challenges, including poor housing conditions, low land utilization and poor infrastructure. Meanwhile, Different social groups within urban villages have varying resources, including capital, skills, land rights, and social rights, leading to conflicts of interest (He et al., 2010). These villages play a critical role in providing affordable housing and fostering informal economies, yet they face significant challenges such as poor infrastructure, weak governance, and limited public participation in urban renewal processes (Lin et al., 2014). Traditional top-down urban planning approaches often exclude local residents from decision-making, resulting in conflicts and inefficiencies in redevelopment projects (Wu, 2016).

Digital participatory design (DPD) has emerged as a promising solution to address these challenges by integrating digital tools into participatory urban planning (Foth et al., 2009). Community digital interaction platforms, such as mini-programs, offer accessible interfaces that enable residents to express their preferences, provide feedback, and engage with urban renewal initiatives. However, the willingness and ability of urban village residents to adopt such tools remain uncertain, particularly given their unique socio-economic conditions and varying levels of digital literacy.

While digital participation has been extensively studied in urban governance (Stern et al., 2020), its application in informal urban areas like urban villages requires further exploration. Residents of urban villages often face barriers such as limited digital skills, low trust in government initiatives, and distinct socio-economic constraints, all of which may influence their acceptance of digital participation platforms. Therefore, understanding their technology acceptance and developing a tailored digital participation framework is essential for enhancing their involvement in urban planning. This research proposes a gamified digital platform tailored to the unique context of Gangxia Village to address the challenges of participatory urban renewal. Grounded in quantitative coding of structured interviews with key stakeholder groups—including migrant workers, landlords, and municipal officials—the study systematically identifies interaction patterns, participation barriers, and preference clusters.

These insights directly inform the platform's architecture, including adaptive user interfaces, real-time feedback mechanisms, and a tiered reward system designed to incentivize engagement and mitigate power asymmetries.

The findings underscore two core insights: first, localized, data-driven interface design is essential to accommodate varying levels of technological literacy and cultural diversity; second, gamification fosters not only participation but also cross-group empathy, reframing urban planning as a collaborative rather than transactional process. By demonstrating how context-sensitive digital tools can support inclusive planning in informal settlements, this research offers a replicable framework for developing technology-mediated participation platforms, contributing practical strategies for more equitable and sustainable urban governance.

2. Literature Review

2.1 Spatial Marginality in Urban Villages

The establishment of the Shenzhen Special Economic Zone initiated a fragmented land acquisition process, wherein the nascent government selectively appropriated agricultural land for critical public infrastructure—including the civic center—while largely excluding existing village settlements from urban road networks and municipal services (Wang et al., 2009). This piecemeal spatial governance, compounded by fiscal constraints that hindered comprehensive employment provision, accelerated the dissolution of agrarian landscapes. As urbanization intensified post-1990s, residual rural enclaves evolved into "urban villages," their transformation propelled by market-driven responses to rural migrants' demand for affordable housing (Zhang, 2005). These urban villages now epitomize a paradoxical spatiality: While functioning as self-contained nodes through dense commercial ecosystems (Laclau & Mouffe, 1985; Abrahamson, 2005), they simultaneously exhibit infrastructural collapse—manifested in chronic sewage overflow and waste accumulation (Liu et al., 2010). This duality reflects deeper contradictions in urban rights allocation. Traditional communal spaces like ancestral halls coexist uneasily with gated sports facilities and pay-to-access venues (Chung, 2010; Hsing, 2010), materializing the erosion of spatial justice into a structural impediment to sustainable community development. Spatial segregation further crystallizes identity politics. The hukou system institutionalizes rural migrants as "floating populations" (Fan, 2002; Wu, 2004), a bureaucratic label that persists despite their demonstrated aspirations for permanent settlement and civic engagement (Wu, 2012). Excluded from participatory planning processes, migrants inhabit a liminal state of "physical presence but political absence" (Kochan, 2009), a condition amplified by local residents' monopolization of social capital. Consequently, urban villages become both symbolic markers of failed integration in mainstream discourse (Siu, 2007) and concrete arenas for class antagonism.

By 2021, Shenzhen hosted over 1,000 urban villages exhibiting divergent evolutionary trajectories. Some retain low-rise vernacular architectures encircled by remnant farmland, while others metamorphose into high-density mid-rise clusters embedded within modern urban grids. This morphological diversity encapsulates the contested interplay between institutional elasticity and capitalist spatial logic.

2.2 Evolution and Digitalization of Public Participation

Citizen participation refers to the process by which citizens actively engage in political and economic processes through the redistribution of power, enabling previously marginalized poor citizens to be intentionally included in shaping the future. Public participation is crucial in urban planning and decision-making, allowing community members to take part in policy formulation, spatial planning, and project development. With the rapid pace of urbanization and the increasing complexity of social demands, the significance of public participation has grown substantially. However, Arnstein's (1969) "Ladder of Citizen Participation" model highlights the issue of tokenistic participation in traditional civic engagement, where actual power devolution remains limited.

In the context of urban renewal, low-income community residents often lack long-term planning capabilities, are unfamiliar with abstract matters, distrust urban institutions, and experience a low sense of efficacy in organized actions, making them less likely to engage proactively in urban governance. The concept of "planning with residents" assumes that communities have the willingness and capacity to collaborate in pursuing the common good. However, when urban renewal entails large-scale demolition, mandatory housing standard upgrades, or

requires residents to bear renovation costs themselves, this willingness is often absent. Additionally, due to differences in organizational capacity across social classes, middle-class groups are more likely to be included in "collaborative planning," while low-income groups tend to be excluded, becoming passive recipients of urban renewal processes (Wilson, 1963). These issues are particularly pronounced in informal urban areas such as urban villages, where many residents are migrants with limited access to information and resources. The urban-rural divide further exacerbates their exclusion, highlighting the need to explore new mechanisms to enhance participation and inclusivity.

To address these challenges, Digital Participatory Design (DPD) has emerged as a potential solution, leveraging information technology and digital platforms to facilitate community engagement in urban planning and governance (Smith, 2009). Digital platforms offer an accessible and interactive means for residents to participate in decision-making, providing real-time feedback and opportunities for involvement (Lee & Kim, 2019). This is particularly important in urban villages, where the lack of physical public spaces for participation limits engagement. However, the implementation of DPD also raises concerns, including the digital divide, technological adaptability, and platform usability (Muller, 2017). Many urban village residents, especially older generations and those with limited digital literacy, may struggle to use these technologies effectively. Furthermore, debates persist over whether digital platforms genuinely enhance democratic decision-making or merely serve as symbolic participation tools (Carver et al., 2008). To maximize the effectiveness of DPD, platform design must align with community needs, minimize accessibility barriers, and foster meaningful interactions among residents.

By integrating discussions on public participation challenges, digital participatory design, and technology adoption theories, this analysis underscores the importance of bridging both digital and social divides in urban village governance. Ensuring that digital participation platforms are both accessible and effective can play a transformative role in enhancing civic engagement, promoting social inclusion, and improving urban planning outcomes in informal settlements.

3. Research Methodology

3.1 Case study Area Background information - Gangxia, Shenzhen

China's open-door policy, initiated in 1979, led to the establishment of Shenzhen as an innovative and experimental metropolis. Situated in the Pearl River Delta of South China, Shenzhen has since evolved into one of the country's most dynamic cities, characterized by extraordinary economic growth and rapid population expansion, largely driven by its market-oriented economy (Ng, 2003). Originally a small border town with a population of approximately 310,000, Shenzhen's strategic proximity to Hong Kong made it an ideal candidate for developing an export-driven economy. In 1980, Shenzhen was designated as China's first Special Economic Zone (SEZ), marking a pivotal shift towards a market economy aimed at attracting foreign investment, advanced technology, and modern management expertise. Over the decades, Shenzhen has transformed into a sprawling metropolis with a population of 14 million (Zacharias & Tang, 2010), significantly surpassing the official count of 8.8 million recorded in 2008 (Yearbook, 2020). The Shenzhen SEZ encompasses 410 square kilometers across the districts of Luohu, Futian, Yantian, and Nanshan, while the adjacent districts of Baoan and Longgang, covering 714 km^2 and 845 km^2 respectively, extend to its north.

When the Shenzhen Special Economic Zone was established, the government acquired land for development from nearby villages in a gradual and piecemeal manner. While ancient villages were preserved, new agricultural land was repurposed for planning the civic center and other significant public structures. Village dwellings were often excluded from road and infrastructure projects, creating a unique urban-rural dichotomy. The nascent administration faced challenges in providing employment opportunities for all local village residents due to its limited size and financial constraints. As urbanization accelerated and more agricultural land was converted for urban use, these ancient villages gradually evolved into "urban villages" (Wang et al., 2009). These urban villages emerged as a direct consequence of urban expansion, but their transformation into migrant enclaves was a commercial response to the growing demand for affordable housing among rural migrants (Zhang, 2005). Under China's hukou system (Fan, 2002; Wu, 2004), rural migrants, often referred to as the "floating population" (Good-

kind & West, 2002), are considered transient residents in urban areas. Consequently, the influx of these migrants has fueled the growth of urban villages. By 2021, Shenzhen was home to over 1,000 urban villages, evenly distributed across the city (Du, 2020). Over the past four decades of rapid urbanization, these urban villages have undergone significant transformations, albeit at varying speeds and times depending on their locations. They have transitioned from "low-rise traditional building forms surrounded by large tracts of farmland" to "high-density mid-rise building forms surrounded by modern urban blocks."

This study focuses on the urban villages in Shenzhen: Gangxia Village(Table 1).

Table 1. The information of Gangxia

Category	Content
Village Name	Gangxia Village
Location	Located in central Futian, Shenzhen
Area	Approximately 151,600 m²
Population	Around 100,000 people
Initial Redevelopment Proposal	Proposed by the municipal government in 1998 (Hin & Xin, 2011)
Project Launch	Initiated by the Futian Urban Renewal Office (FURO) in 2002 (Hin & Xin, 2011)
Start of Demolition	April 2009, after redevelopment agreements were reached (Hin & Xin, 2011)
Impact of 1992 Urbanization Reforms	- Transition from rural to urban governance - Villagers granted urban household registration - Village committees converted into neighborhood committees - Production teams restructured as joint-stock companies - Legalized leasing led to dense rental housing and commercial construction (O'Donnell, 2021)
Designation as Urban Renewal Unit (URU)	Officially designated in 2009 as part of early urban renewal efforts (Hin & Xin, 2011)
Shift in Renewal Strategy	In response to resident concerns, a more integrated rehabilitation approach was adopted in 2016, focusing on infrastructure upgrades while preserving community identity (Hin & Xin, 2011)
Community Function	Provided affordable housing and diverse commercial services such as family-run shops, restaurants, and small businesses (O'Donnell, 2021)
Economic and Geographic Role	Due to its proximity to high-end urban infrastructure, Gangxia served as an accessible space for workers and businesses priced out of other parts of Shenzhen (O'Donnell, 2021)
Social Structure	- Original residents: property owners relying on rental income - Migrant workers: attracted by low rents, working in low-income sectors- Shop owners: operating small-scale businesses - Renters: short- or long-term tenants (He et al., 2010)
Social Relations and Power Dynamics	- Economically interdependent groups - Original residents hold the most decision-making power, especially in redevelopment matters - Migrants and shop owners are vulnerable to displacement and lack formal representation (He et al., 2010)
Challenges in Redevelopment	- Issues of safety, sanitation, and unregulated development - Tensions due to unequal influence in redevelopment decisions - Balancing renewal with community preservation (Hin & Xin, 2011; He et al., 2010)

3.2 Interview Design

The study provides insights into the willingness, needs and barriers of different stakeholders to use digital participation platforms in urban regeneration, and therefore semi-structured interviews were conducted in Gangxia Village, Shenzhen, with three key groups: migrant tenants (n=15), local landlords (n=15), and government officials (n=10), for a total of 40 interviewees. In order to guarantee representativeness while accounting for the viability of research resources, the sample size was determined using Creswell's (2013) guidelines for qualitative research in case studies. Purposive and snowball sampling techniques were used to recruit participants in order to guarantee diversity in terms of age, gender, occupation, and degree of digital literacy. Interviews were conducted mainly face-to-face, with some interviewees being interviewed by telephone or video, and each interview lasted approximately 30 minutes, and was recorded with the written or verbal informed consent of the interviewees and with strict protection of their privacy.

A number of central themes guided the interview outline, such as respondents' perceptions of the usefulness and usability of digital platforms, their experiences participating in communities at the moment, potential obstacles (such as the digital divide, a lack of trust, and power asymmetry), and their expectations for future digital participation tools. The questions were customised according to the respondents' identities to better reflect their specific roles and concerns: migrant tenants' questions focused on the living environment, the use of digital devices, and motivation to participate; landlords focused on policy attitudes and acceptability of the platform; and government officials focused on the difficulties of policy implementation, cross-sectoral collaboration, and the role of technological tools in governance. The design of the questions follows a logical sequence from individual experience to attitude expression, and from problem recognition to policy recommendations.

The interview data were transcribed and processed using thematic analysis, with open coding to extract core information units, and then axial coding to summarise key themes such as 'digital trust', 'data accessibility', 'motivation to participate', 'perception of fairness', and so on. The main themes such as 'digital trust', 'accessibility', 'participation fatigue' and 'perception of fairness' were then summarised through axial coding. The qualitative interview findings from the study were not only used to understand user perspectives, but also directly guided the design of the subsequent digital platform system. For example, the multi-role interface, gamified feedback mechanism, and low-threshold interactive features in the platform were all tailored based on the interview findings. Thus, the interview design not only serves as an information-gathering tool, but also lays the empirical foundation for the socio-technical system architecture of this study.

4. System design

4.1 Functional & Non-Functional Requirements Analysis

To ensure the effectiveness and inclusivity of the gamified digital platform proposed for participatory urban renewal in Gangxia Village, a detailed requirement analysis was conducted. This analysis distinguishes between functional and non-functional requirements to structure the system architecture in a way that responds to the socio-technical complexities identified in prior sections.

Drawing upon the structured interviews with migrant workers, landlords, and local officials, as well as a contextual understanding of the digital divide, power asymmetries, and participatory inertia in informal settlements, the platform must not only provide basic participation functionalities but also address user diversity, trust-building, feedback responsiveness, and long-term behavioral engagement. Therefore, the requirements are rooted in both empirical insights and participatory design principles, ensuring the platform serves as a meaningful vehicle for deliberative engagement and not a mere symbolic interface.

Functionally, the platform must support multi-role user interaction, reward-based engagement, and real-time feedback loops, as these features have been identified as central to enhancing motivation, mitigating decision-making asymmetries, and reinforcing transparency. Non-functional requirements such as accessibility, scalability, adaptability, and usability are equally critical, particularly in contexts characterized by low digital literacy, infrastructural limitations, and cultural heterogeneity.

The following table summarizes the identified requirements:

Table 2. Functional & Non-Functional Requirements

Requirement Type	ID	Description	Justification
Functional Requirements	F1	Multi-role account system: Supports differentiated user roles (migrants, landlords, officials)	Reflects socio-political heterogeneity and supports role-specific interaction paths.
	F2	Gamified feedback mechanism: Real-time scoring, reward tiers, and progress tracking	Enhances user motivation, reduces participation fatigue, and addresses power asymmetry by creating transparent recognition mechanisms.
	F3	Issue reporting and suggestion module: Allows submission of community concerns and renovation suggestions	Enables bottom-up expression of needs, aligned with participatory design objectives.
	F4	Real-time feedback from authorities: Government can respond to suggestions and report renovation progress	Builds trust and accountability through bidirectional communication.
	F5	Community voting and prioritization feature	Facilitates deliberative democracy and helps identify consensus-driven priorities.
	F6	Mobile-friendly interface with intuitive navigation	Addresses digital literacy gaps prevalent in urban village populations.
Non-Functional Requirements	N1	Accessibility across devices and OS platforms	Maximizes reach and ensures usability for users with different technical resources.
	N2	Scalability to other urban villages	Ensures long-term replicability and cross-context adaptation.
	N3	Data privacy and consent safeguards	Addresses concerns over surveillance and fosters digital trust among vulnerable populations.
	N4	High usability and low learning curve	Critical for older residents and digitally marginalized groups; reduces entry barriers.
	N5	Cultural localization: Multilingual options and culturally resonant visual design	Enhances inclusivity and emotional engagement by tailoring the interface to diverse user demographics.
	N6	Offline data caching and low-bandwidth compatibility	Enables reliable use in low-connectivity environments, which is essential in underdeveloped or congested urban infrastructures.

4.2 System Working Flow

The designed system workflow captures the full process of participatory engagement facilitated by a gamified digital platform in the context of Gangxia Urban Village. The system is intentionally structured to accommodate a diverse user base—including migrant workers, landlords, and residents—and to promote their sustained involvement in urban renewal processes through meaningful feedback loops and incentive mechanisms.

The workflow begins when users identify a potential urban issue within their local environment. Utilizing a mobile device or terminal, they request location information via integrated GPS services or mapping APIs (e.g., Google Maps or open-source platforms). Once the digital map of the target area is retrieved, users are prompted to pinpoint the location of the problem.

If the issue can be effectively geolocated, the system activates a problem description interface, where users may provide textual input, visual evidence, and perceived urgency levels. This input is then analyzed by the backend system using a hybrid model combining rule-based filters and AI-driven semantic clustering to determine the problem's significance and validity.

A novel feature of this platform is its gamified reward system. When the system confirms that the submitted issue is valid and relevant to ongoing urban renewal efforts, the social group responsible for reporting it (e.g., a specific user or user type) receives quantifiable rewards—typically in the form of digital points or merits. These rewards not only contribute to a leaderboard system but are also symbolically visualized in the digital twin environment, where the user's virtual avatar and contribution record are permanently stored. This mechanism fosters long-term engagement, enhances user identity within the community, and transforms digital participation into an emotionally and socially rewarding experience.

In parallel, the issue is routed to government stakeholders through a secure firewall-protected channel, where it is reviewed and incorporated into the digital twin simulation of the target area. IoT sensor data, where available, is utilized to validate and cross-reference the reported issue, further enhancing system accuracy.

Finally, feedback is delivered back to the original user through the platform, including status, timeline for resolution, or requests for additional information. The feedback loop reinforces accountability and provides a clear indication that citizen input translates into visible action. The entire process is visualized in Figure 1, highlighting multi-directional information flows and the integration of reward-driven participation within a socio-technical system for equitable urban governance.

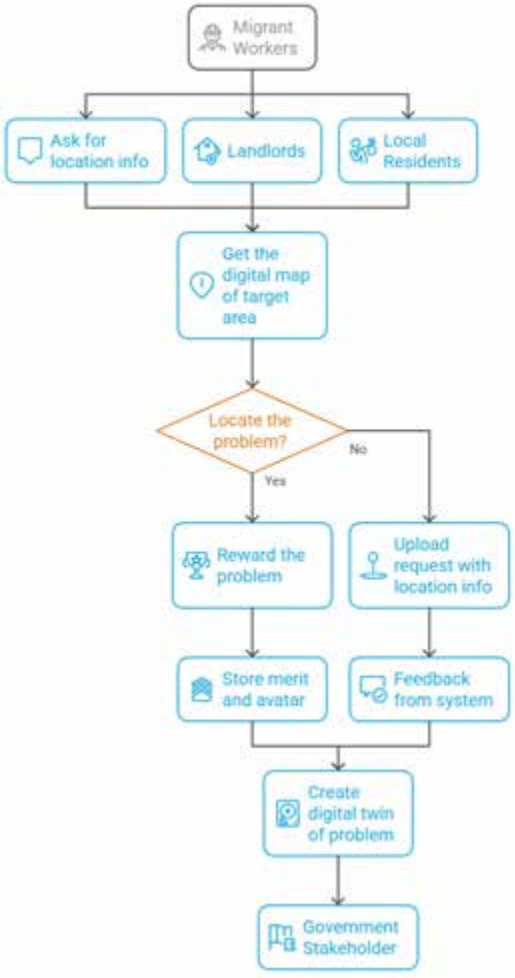

Figure 1. Working Flow of Gamified Urban Issue Reporting System

5. Discussion

This study explores the feasibility of implementing a gamified digital participation platform and its impacts in the urban village of Gangxia, Shenzhen by combining insights from three stakeholder interviews with system design requirements. The findings reveal the complex interplay between digital inclusiveness, power asymmetry, and willingness to participate in informal area renewal contexts.

5.1 Acceptance and expectations vary between stakeholder groups

Semi-structured interviews revealed different expectations and concerns between the three stakeholder groups. Mobile tenants, while expressing dissatisfaction with living conditions, showed cautious optimism about digital platforms, especially when defining them as simple, reward-based systems. Their main concerns include technological unfamiliarity, privacy protection, and scepticism about government responsiveness - issues echoed in the wider literature on digital marginality (Muller, 2017; Stern et al., 2020). In contrast, landlords emphasise property rights protection and are concerned that digital engagement may be detrimental to their financial interests. However, some landlords expressed interest in digital tools for tracking policy updates and accessing curated landlord-only content. Government officials recognise the potential of digital platforms to streamline feedback collection and increase transparency, but also express concerns about disinformation, opinion overload, and the administrative capacity of digital engagement.

These different perspectives reinforce the need for differentiated design logic and adaptive interfaces, and validate the platform's multi-actor architecture and customisable user experience features. The use of gamification - particularly point-based rewards and visual presentation of contributions - was found to be a cross-group motivator, especially when designed to recognise opinions without undermining authority or triggering economic anxiety.

5.2 Digital divide and power asymmetry

The interviews demonstrated that digital participation in urban villages is not just a matter of tool availability, but is deeply affected by structural inequalities, the digital divide and asymmetries of institutional power. Mobile tenants often lack digital literacy and political voice, resulting in 'physical presence and political absence' (Kochan 2009). At the same time, landlords and officials have easier access to digital and institutional capital. These dynamics are in line with Arnstein's (1969) critique of symbolic participation, which tends to be more symbolic than substantive. The platform is designed with a low-threshold interface, localised language support, offline data caching, and tiered participation features that identify different user capabilities. In addition, gamification mechanisms not only act as incentives, but also provide partial balance to otherwise excluded voices by providing visibility and recognition. However, gamification alone cannot address deeper systemic inequalities, suggesting the need for parallel offline empowerment and institutional reform.

6. Conclusion

This study explores the potential of a gamified digital engagement platform to enhance stakeholder participation in the urban regeneration process of urban villages in Gangxia, Shenzhen. By incorporating semi-structured interviews with stakeholder groups (migrant workers, local landlords, and government officials) into the platform design process, the study designed a contextual system to address technical, social, and institutional barriers common to informal regional settings.

The findings emphasise the capacities, motivations and concerns of different stakeholders. Migrant workers expressed a willingness to participate when the platform was easy to access, trustworthy and practically achievable. For landlords seeking mechanisms that both protect property rights and keep them informed, government officials also acknowledged that such platforms can help improve governance efficiency, despite concerns about inaccurate information and the complexity of data processing. These diverse needs have directly shaped the functionality of the platforms, including multi-role account architectures, gamified feedback systems and adaptive user interfaces.

The research confirms that digital participation is not just a technological intervention, but a socio-political process. The digital divide, unequal access to institutional power and participation fatigue remain structural challenges that cannot be solved by interface design alone e.g. UI, UX. Thus by embedding transparency, recognition and feedback mechanisms, digital platforms can create inclusive digital opportunities while potentially reforming traditional pathways of community governance.

The contribution of this study lies in its empirical foundation, participatory methodology and the application of digital design thinking to complex urban governance issues. This study advances the discussion on digital participatory design (DPD) by demonstrating how gamification can be a strategic tool under the construction of fine contexts that not only enhances participation, but also balances different stakeholders in urban spaces.

Appendix A

Stakeholders	English Question
Migrant Workers	How long have you lived in Gangxia? Are you satisfied with your current living environment? What aspects would you like to improve?
	Have you ever participated in community affairs? If not, why?
	Do you use mobile phones or apps like WeChat? Do you find them easy to use?
	If a platform allowed you to share suggestions on community improvement, would you use it? Why or why not?
	Would you be concerned about privacy or your opinions being ignored on a digital platform?
	Would earning points or rewards motivate you to participate more actively?
	How do you think the government should listen to the voices of people like you?

Stakeholders	English Question
Local Landlords	What's your view on the current urban renewal policy? Have you participated in related discussions?
	Would you use a digital platform to track progress or express your opinions?
	Do you worry that information on the platform might affect your rental income or property rights?
	Do you think different groups are treated fairly during urban renewal?
	What are the most important issues that need coordination between landlords and tenants?
Government Officials	How does the government currently collect public opinions? Are there challenges in the feedback process?
	Are you concerned about public backlash or irrational comments on the platform? How can these be managed?
	In what ways do you think digital platforms can enhance policy transparency?
	What key features should an ideal digital participation platform include?

Using Social Media Big Data and ChatGPT for Identifying Counter-urbanisation Hot Spots in China

Jian Chen, Guy Garrod & Menelaos Gkartzios

Abstract
While urban areas remain home to most of the global population, the countryside is increasingly becoming a preferred place of residence, even in some developing nations such as China. Potential benefits and challenges for rural development posed by this counter-urbanisation trend make it essential to monitor its extend and progression. However, in China, statistical data on this phenomenon remains scarce due to the restrictions on rural property ownership by outsiders, who mostly rent properties from individual rural residents, leaving no formal record. This research uses the data from the Chinese social media platform, XiaoHongShu (or RedNote, a platform similar to Instagram), where specific users share their experience renting houses in rural areas or moving back to home villages. A web crawler was developed to collect all these 'big data', which was subsequently cleaned and processed by ChatGPT AI model. To ensure credibility, partial human validation was also applied to AI-generated results. Despite certain limitations, the findings provide original insights into the counterurbanisation trend in China, highlighting its widespread occurrence and identifying several hot spot areas. This study demonstrates that combining social media big data with AI processing offers an effective and timely way to identify human migration flows between urban and rural areas, enabling valuable reference for policymakers and the real estate sector.

Keywords: Big data; ChatGPT; Counterurbanisation; Rural; China

1 Introduction

The countryside has become the preferred place of residence for an increasing number of people, although the majority of the world's population still generally dwell in urban areas. Whereas this phenomenon of rural inflows, termed as counterurbanisation (Berry, 1976), was initially perceived as a form of 'population redistribution' or rural 'population renaissance' (Fielding, 1982) in the early stages during the 1970s and 1980s, emerging research has presented that counterurbanisation carries diverse economic, social and environmental potentials to support local development in both developed and developing countries.

However, in developing countries like China, the lack of relevant statistical migration dataset makes it difficult to monitor and access the extend and progress of counterurbanisation trend, although a growing number of case studies with a focus of rural tourism and rural entrepreneurship has add up nuanced knowledge to enlarge the global counterurbanisation story. This research explored the possibility to use massive social media data source and efficient AI-based data processing methods to generate an overview of the counterurbanisation progress in China.

This paper begins by introducing relevant concept and theories of counterurbanisation, followed by a synthesis of Chinese scholars' perspectives, including dominant understanding, ongoing debate, and methodological approaches. It then examined the challenges associated with using social media data source and AI-based methods in existing literature. Subsequently, this paper outlines the ethic considerations, data source and its limitation, and technical aspects of research methodology, covering data acquisition, data cleaning, AI-based data processing, case mapping, and thematical analysis. The results are presented in two parts: geographic distribution maps of identified counterurbanisation cases and narrative insights into general counterurbanisation patterns and specific cases. Finally, the discussion addresses new findings and their alignment with existing literature, as well as the advantages and limitations of the methodology applied in this study.

2 Literature review

2.1 Counterurbanisation

2.1.1 What is counter-urbanisation?

In the 1970s, attention was drawn to anomalous – at least for the then data – population growth in non-metropolitan America as a result of downward migration by Beale (1975) and this phenomenon was subsequently studied and popularised by Berry (1976) who coined it as 'counterurbanisation'. Robert and Randolph (1983) indicate that counterurbanisation has a clear division between extended suburbanisation and is comprised of both population growth in the hinterland of 'a metropolitan area's "daily urban system"' and movement beyond that system.

The literature has created various taxonomies of different counterurbanisation types based on the location of counterurbanisation and the different motives associated with it. For example, Mitchell (2004) proposed three sub-forms of counterurbanisation: ex-urbanisation (the commuter); anti-urbanisation (those who want to escape from cities); and displaced-urbanisation (households forced to move due to 'new employment, lower costs of living and/or available housing'). Today counterurbanisation is also commonly discussed in the global south and emerging economy contexts (Gkartzios and Halfacree, 2023). The breadth and richness of counterurbanisation research have extended to involve a diverse group of rural newcomers and returnees, to cover various rural areas, and to generate different context-specific experiences of migration worldwide (ibid., 2023).

2.1.2 Rural Incomers

The inflow of rural populations resulting from internal or international movement is commonly observed to follow two directions: primarily downward within urban hierarchies (from urban to rural areas) and, to a lesser extent, lateral migration between different rural areas (Stockdale, 2016).

However, there is no very clear distinction in the types or characteristics of newcomers between accessible and remote rural areas based on the literature review in Table 1, although this may vary geographically and in terms of quantity.

Table 1 Types and characteristics of newcomers in both accessible and remote rural areas

Factors	Accessible rural areas	Remote rural areas
Employment	well-educated (Herslund, 2012) /professional (Burchardt, 2012) /creative class (Herslund, 2012) /artists (Yang and Xu, 2022) /remote working (LiuBai and Ravenscroft, 2023) /entrepreneur (Bosworth, 2010) /retired people (Gallent, 2014)	well-educated (Löffler and Steinicke, 2006) / ~~professional/ creative class/ artists/remote working~~ /entrepreneur/seasonal proprietors (Shannon and Mitchell, 2020) /retired people (Winkler, 2013)
Income	Wealthy/affluent (Burchardt, 2012) / high-and-middle income (YuWang and Li, 2024)	Wealthy/affluent (Löffler and Steinicke, 2006) /~~high-and-middle income~~
Age	young families with children (Herslund, 2012) /retired people (Gallent, 2014)	young families with children (Zollet and Qu, 2024) /retired people (Winkler, 2013)
Motives	returnees (ChenZhang and Wang, 2022) /second-home owner (Gallent, 2014) /tourist (ChenZhang and Wang, 2022)	Returnees (Ji, 2024) /second-home owner (Winkler, 2013) /tourist (Winkler, 2013)/

2.1.3 Factors and Motivations

Generally, rural inflows are driven by two causes of interactions: individuals' will to move to rural areas (personal factors), and the facilitation or permission to do so (macro factors). Despite a little dated, these two causes can also be interpreted as 'desirable' and 'feasible' factors by Beale (1975), or 'motivational' and 'environmental' aspects by Champion (1998). Migration behaviours is typically a combination of macro factors and personal motivations, though the balance between these varies from case to case. The distinction is intended for descriptive purpose only, as these factors often overlap and cannot be clearly separated.

Gkartzios (2013) concluded that 'early research centred around a dualism between economic (or job-led) and quality of life (or people-led) considerations of the migrants involved'. But currently, counterurbanisation has globally become a much more story-based narrative of different experiences and representatives (ibid., 2013).

2.1.3.1 Macro factors

In terms of liveability, the advantages of urban life have been diminished by massing populations (Beale, 1975) and recent or ongoing challenges including covid-19 pandemic and climate crisis (ScottGkartzios and Halfacree, 2024), Whilst the countryside has undergone modernisation and can offer access to more natural and green spaces, safer neighbourhood. And the enhanced mobility and its enabling development, in other words, 'easy transportation and communication' (Beale, 1975) or 'freedom to move' (Berry, 1976), 'wider spread of services and the changing distribution of employment' (Champion, 1998) or 'ruralisation of employment' (Frost and Spence, 1984), further facilitate rural in-migration. Besides, general societal changes, such as increased overall affluence and aging populations (Beale, 1975), have led to the accumulation of individual rural inflows as a demographic trend later accepted as counterurbanisation.

2.1.3.2 Personal motivations

Rural newcomers can have very diverse and personal motives for moving in, which are usually grouped under headings such as employment, housing, neighbourhood, proximity to families/partners/friends or services, preference for living pace or the environment (Halfacree, 1994, Champion, 1998). Each category encompasses considerable variability among individuals and locations.

2.1.4 Implications

In the early stages during the 1970s and 1980s, counterurbanisation was initially only perceived as a form of 'population redistribution' (Robert and Randolph, 1983) or rural 'population renaissance' (Fielding, 1982).

Emerging research has presented that counterurbanisation carries diverse economic, social and environmental potentials to support rural development and local communities. Rural incomers may bring or bridge new investments, create jobs, demonstrate business running and disseminate new commercial concepts. They help maintain the village as a human settlement and 'provide new hope' for locals (LiuBai and Ravenscroft, 2023), '"bridge" social capital' – exchange of skills, knowledge and resources – to the 'closed' or 'more limited' rural network 'to solve collective problems and improve or maintain the wellbeing of that community' (Gallent, 2014). Besides, newcomers tend to introduce organic agriculture or businesses, engage in green volunteer work, and advocate for environmentally friendly construction practices (LiuBai and Ravenscroft, 2023).

However, positive contributions associated with counterurbanisation can remain limited and many issues also have arisen in the literature. Economically, it varies in specific business types and places whether these in-migrant proprietors will create extra or attractive jobs for rural locals and contribute to the 'local' market rather than outside market (Pristed Nielsen, 2022, LiuBai and Ravenscroft, 2023). Incomers may even take away the job opportunities (Yan et al., 2023) or business customers (LiuBai and Ravenscroft, 2023) from locals because of the inequality of marketing knowledge and networks. Socially, the countryside can be reconfigured as alternative settlements, taking into account the fact that amenity and lifestyle inflows are the mainstream of counterurbanisation, which has reportedly led to the loss of some residential services (Clout, 1986, Stabler, 1987, Herslund, 2012), housing affordability and social exclusion issues, and gentrification and displacement problems (Phillips et al., 2021).

2.2 Counterurbanisation in China

2.2.1 The progress of counterurbanisation in China and related debate

Two decades after the introduction of counterurbanisation in the English literature, Chinese researchers like Zhang (1987) started to introduce relevant theory and international cases from developed economies into China concerning the US, the UK, some western European countries and Japan. Drawing on aggregate demographic data Kong and Liu (2011) reported that counterurbanisation happens after the urbanisation rate reaching 70%, while in China it was 51% in 2011 and increased to 70% by 2021.

However, there has been debate about what kinds of rural incomers can be identified as counterurbanisers, or whether China has been experiencing a counterurbanisation process. Some Chinese scholars such as Cai and Zhou (2014) regarded working-class rural returnees who constituted the dominant rural inflows during periods of economic crisis as counterurbanisers. But, Liu and Li (2017) argued that these crisis rural returnees in China

cannot be treated as counterurbaniser but stakeholders who are just 'unable' to urbanise rather than those who are 'unwilling' to migrate to cities (Xue and Zhang, 2017). Similarly, Wu (2020) also found that Chinese governments historically promoted young people moving to rural areas during periods of economic depression and high urban unemployment rate. And this promotion always failed to meet government expectations, as evident by the subsequent return of these rural incomers to urban areas.

Duan (2015) highlights that urban out-migration was closer to sub-urbanisation rather than counter-urbanisation. These rural inflows and outflows in China were just a dynamic process of migration distinct from the counterurbanisation in western countries, which occurs in the premise of relative balance between urban and rural infrastructure and public service provision (ibid., 2015). But most Chinese rural areas were significantly underdeveloped then.

Beyond western counterurbanisation paradigms, Chen (2020) emphasises the profound cultural foundation in China that historically motivated Chinese educated gentry moving to rural areas whether for retirement or pastoral seclusion. This Chinese traditional cultural foundation can be associated with the new term, 'imagined rurality', that Yang and Xu (2022) employ to frame Chinese gentrification phenomena or British 'rural idyll'. Also, it parallels the western notion of anti-urbanisation involving those who want to escape from cities (Mitchell, 2004).

Besides, Li (2017) offers a nuanced interpretation, acknowledging that while the migration patterns in China have not yet to exhibit full-scale counterurbanisation, related phenomena are emerging in diverse forms—including an increasing number of rural amenity consumers and diverse rural returnees, such as rural tourists, outside retirees, tenants from cities, and returning entrepreneurs—across multiple regions.

The challenge in measuring counterurbanisation in China lies not in mapping western models directly but in exploring its unique and emerging forms through a bottom-up approach. This involves examining everyday practices, imaginations and representations in relation to rural in-migration.

2.2.2 General methods to investigate counterurbanisation in China

Regardless of the debate around the understanding of counterurbanisation by Chinese scholars, the methods they adopted mainly include case studies and qualitative interviews, or statistical analysis, quantitative questionnaire sampling, and Roxy model indexing.

Specifically, case studies and qualitative interview methods tend to focus on analysing individual motivations for rural incomers, their local life and social network development, and implications of counterurbanisation. Typical cases in literature include middle-class inflows in Dali, Yunnan Province, China (Zhang, 2018), entrepreneur in-migrations (tourism entrepreneurs in Yiwu (Wang, 2022) and Hangzhou (Zhou, 2024), Zhejiang Province, China, agricultural entrepreneurs in Yaoan, Yunnan Province, China (Wei, 2022)), seasonal second-home flows traveling more than 600 kms between Lichuan and Wuhan, Hubei Province, China (Xu and Xu, 2023).

Quantitative methods based on secondary data generally are applied to monitor the extend of counterurbanisation trend in certain geographical regions with discussions around its causes. For example, Wang (2024) sampled 312 villages in Guangdong Province, China, and sent questionnaires to local village councils or town governments investigating whether there were rural incomers. Fan (2022) used agricultural census data to analyse the population changes in 3, 772 villages in Beijing, China. Several researchers applied statistical data to structure Roxy index model which is close to the deconcentration of population in cities (Tang and Xiao, 2017) to identify the 'counterurbanisation situation' in Beijing, Tianjin, Shanghai cities (Tang and Xiao, 2017), urban agglomerations alongside Yangtze River Basin (Zhang and Mei, 2020), or Yangtze River Delta (Chen, 2023).

2.3 Quantitative and qualitative research using AI-based methods

Researchers often face challenges when analysing collected data—whether quantitative or qualitative—via specialised software R, Stata, SPSS, Python or NVivo. These tools frequently demand expertise that extend beyond

'an individual's established skillsets and technical knowledge' (PrandnerWetzelhütter and Hese, 2025). Particularly, qualitative content analysis is 'notoriously time and labor intensive because of the work to detect, assess, and code a large amount of data' (Bijker et al., 2024), compared to usually well-structured quantitative data.

Scholars have been exploring how to use machine assisted methods, or more precisely Artificial Intelligence (AI), to reduce data analysis burden and accelerate the process. These methods evolve from machine learning, pre-trained/fine-tuned models, to large language models. However, it can raise two main questions (Morgan, 2023): a) whether AI methods can produce similar results without the demanding process by human; and b) whether the simplicity of using AI methods and time savings worth the effort. Generally, AI methods are more adapted in qualitative research and more deeply involved in qualitative data analysis. According to the search results in Scopus database with keywords 'AI + qualitative/quantitative research' on 28 April 2025, qualitative group outweigh quantitative set by 4292 versus 3432. And AI methods often are only applied to help with scripts, get help for visualisation in quantitative research (PrandnerWetzelhütter and Hese, 2025).

Large language models developed in the past few years, such as ChatGPT, are proved to be acceptably effective, efficient, and simple to apply in a variety of settings. It is argued that ChatGPT can 'create code, category and theme, cite directly from within the text, interpret data sets, and analyse the meaning at the core of the data sets' (ŞenŞen and Şahin, 2023), and 'performed better in developing an inductive coding scheme that emerged from the data than adapting an existing framework into an unconstrained coding scheme or coding directly into a structured matrix' (Bijker et al., 2024). Specifically, many social science researchers use ChatGPT chatbots to interactively code interviews, focus groups, social media posts and the like, either big or small data, which is 'quite easy to use and required very little effort' (Morgan, 2023). For example, Bijker et al. (2024) used the ChatGPT chatbots in ten different dialogues to analyse the same 537 forum posts data, and generate ten versions of responses. When comparing with the results from three human, the precision of ChatGPT results were evident to range from 66% to 88%, which is 'fairly reliable' (ibid., 2024).

However, using AI methods does not mean there is no need for any human work. Bijker et al. (2024) stated that AI generated results also require various postprocessing steps to clean the data and check whether responses are in line with the instructions. Regardless of how many argue for the reliability of AI methods, human validation remains essential—not only to build trust for the researchers themselves but also to ensure credibility for readers and broader audiences.

3 Methodology

3.1 Ethical considerations

The ethic concerns for using social media data and AI methods were considered (London School of Economics and Political Science, 2025) during the whole process of data collection, processing and reporting.

The data collected from the social media platform, XiaoHongShu (, includes posters' user name (all pseudonyms), profile URL, postdate and post IP (provinces – the first-level administrative division in China, if available), posts' title, content and hashtags, comments replied by the poster. The general location of their house (such as village name or city district), tenancy conditions, personal emotions, marriage status, employment status may be involved. This information may be considered as sensitive or private but technically, it is open data which originally is published to all the users on XiaoHongShu platform, and the original intention of these posters is to share this information to present a whole story to all the other users.

Following the anti-crawler restriction of XiaoHongShu platform, a two steps web crawler was developed based on python using Google Chrome to automatically explore the XiaoHongShu platform and save targeted data properly simulating human behaviours.

Subsequently, these data were cleaned and processed in Python using OpenAI API[1], which accesses the ChatGPT AI model. According to the OpenAI Data Usage Policy (OpenAI, 2023), data submitted through the API will not be used for training purposes but retained for 30 days to monitor potential abuse and misuse. Regarding concerns about bias, inaccuracy and misinformation, in the research, ChatGPT AI model was applied solely to extract targeted information, primarily through direct quotations in the original language (Chinese). And the accuracy of any directly quoted information in this paper were double checked.

Data reported in this paper will not be identifiable for original posters and the quotations either direct or indirect are also all anonymised or paraphrased to avoid this issue. Additionally, we took care to translate the quoted text from Chinese to English but we accept that some details and nuances may have been lost (LiuBai and Ravenscroft, 2023). Besides, location data-without any other identifiable information about the poster-will be converted into geographic coordinates using Gaode Map (a Chinese navigation service provider) API and visualised on national base map of China using ArcGIS Pro only to show the rough distribution of these rural incomers.

3.2 Data collection

3.2.1 Data source and limitations

The data for this present paper comes from one of the main Chinese social media platforms, XiaoHongShu (http://xiaohongshu.com) that translates to 'the small red notes'. Its function is similar to Instagram where 320 million[2] of the 1.4 billion Chinese share their daily lives. Many rural second home tenants and rural returnees make posts sharing their rural relocation experiences. Although the number of these posters is relatively small compared to the Chinese population and can only represent certain groups especially young generation, this data source still supplements the absence of official statistical data related to counterurbanisation in China and provide an insightful lens to explore the spread of this migration phenomenon. These bottom-up representations are intrinsically connected with Chinese culture and as such provide a fascinating dimension towards understanding China's counterurbanisation. As Halfacree (2008) argues, the 'more culturally imaginative dimensions of counterurbanisation also come through in the way the phenomenon is represented in popular telling of the counterurbanisation story' (p489-490).

In addition to being limited to specific user group, each social media post collected from XiaoHongShu platform may not contain all the targeted information. Consequently, the total number of valid cases varies across different thematic analysis.

3.2.2 Raw data collection: a web crawler

Following the anti-crawler restriction of XiaoHongShu website, a two steps web crawling strategy was developed based on python using Google Chrome to automatically explore the website properly simulating human behaviours and on 24 December 2024, recorded 668 counterurbanisation related posts covering 644 different posters. At step one, the web crawler searches by two sets of keywords in Chinese, which can be translated into 'rent in countryside/rural areas/villages' and 'return to countryside/rural areas/villages from cities'. Given the complexity of the term rural outside anglophone uses (GkartziosToishi and Woods, 2020), we have used five original Chinese keywords in total trying to include all related data considering the multi expressions of 'countryside' in Chinese. The four keywords, in group 'Rent in countryside/rural areas/villages', were searched in the order as shown in Table 2 and duplicated posts were excluded during web crawling. Post URL, title, poster username and poster profile URL were recorded. At step two, the web crawler browses recorded poster profile to open the targeted post recording its contents, hash tagged topics, comments replied by the author, postdate and post IP (if available), which is saved in spreadsheets like Table 3.

1 An API (Application Programming Interface) allows applications or code to send request to another service and receive data or results in return. In the case of web APIs, URL addresses typically serve as endpoints that specify where the requests should be directed. In this research, API services were used to automate batches of data processing tasks.

3.3 Data Process

3.3.1 Data clean and key information extraction: ChatGPT

3.3.1.1 Information extraction piloting

Five sets of information are established to be coded into 'Post Information', 'Poster Information', 'House Information (include house location)', 'Tenant or Returnee-Specific Information', 'Letting or Renting-Specific Information'.

10 posts covering various posts were picked to pilot the information extraction results by human and batch ChatGPT 40-mini-2024-07-18 model, showing an 87% average accuracy with no key information missing only some small mistakes (e.g. identify a 'landlord' as 'returnee') and different information grouping (e.g. save 'village description' in 'complaints').

3.3.1.2 ChatGPT prompts and batch

A clear prompt is expected to go with these posts to tell ChatGPT what task it is, steps to follow, and which information to extract and extraction requirements.

First it is suggested to ask ChatGPT to adopt a persona, such as

'You are an information extraction assistant. Follow the steps below to extract targeted information with delimiters '*' from social media posts provided. And structure the output as JSON[3] format.'

3 JSON (JavaScript Object Notation) is a lightweight, text-based format for storing and exchanging data. Results in JSON format are saved as Excel spreadsheets later through Python.

Second, considering the original language of the social media data is Chinese, it is better to require ChatGPT to use original language:

'Requirements for extraction: if there is targeted info, use original text from the post as detailed as possible and do not translate it into English.'

Third, after checking the relevance to counterurbanisation topic, ask ChatGPT to extract targeted info one by one using human language, such as:

House Information:
- House Location: Where is the house located?
- Refurbishment: (Options: refurbished, needed refurbishment, no need)
- .....

Once the prompt is established, it is very easy to use the codes provided on OpenAI platform to submit batch information extraction requests. Calling ChatGPT-4o-mini to batch the tasks in non-peak hours costs around one day for all returns and less than $0.01 for one request covering approximately at most 100 thousand words inputs and 25 thousand words outputs.

Table 4 ChatGPT batch input examples (anonymised, rephrased and translated by ChatGPT)

Post content go with the prompt	Post comments go with the prompt
Chinese Original ID: 26 title:*，租到600元山上的房子 post by* on 2024-09-10 in 广东 with content: 今年四月，我因公司裁员而离职，带着赔偿金开始了一段随心所欲的旅行，走访了多个城市。随着时间推移，我对大城市的喧嚣愈发感到厌倦。九月，我来到了这个被绿色环绕的小县城，租下了一间每月仅600元的山景房。每天清晨，拉开窗帘便能看到青翠的山峦，阳光洒满整个房间。房子前面是热闹的街道，后面则是宁静的乡村，真正实现了"出门在市井，归家入山林"的生活。日出日落之间，山色光影不断变化，我沉浸在风声、雨景、朝霞与晚霞之中。散步成了我最享受的日常。在这里，我的思绪慢了下来，曾在大城市中积累的焦虑逐渐被抚平。连续熬夜五个月的我，终于开始按时入睡。皮肤也肉眼可见地变得细腻白皙，痘痘消失了。从小我就有一个隐居的梦想。还记得高中时第一次读到"离群索居"这个词，内心便怦然心动。那时我特别喜欢李白的山水诗、王维的田园诗，常常在笔记本上抄写和背诵。我原以为要等到四五十岁退休后，才能实现山水田园的生活。没想到在30岁这一年，我就提前实现了这个梦想。真的感到非常幸福，也非常幸运。 #隐居 #山居生活 #躺平 #低成本 #失业 #裸辞 #租房 **Translation** ID: 26 title:30-year-old girl unemployed, moved into a 600 yuan mountain view room post by * on 2024-09-10 in Guangdong with content: After being dismissed by the company in April this year, took the compensation to open the roaming, to play a few cities. More and more tired of the big city, September came to this small county full of green, living in the 600 yuan mountain view room. Every morning when I woke up and pulled open the curtains is the green mountains, sunshine sprinkled all over the house. In front of the house is a lively street, behind the house is the countryside, really out of the downtown, home hermitage. Every day, you can see the green mountains from sunrise to sunset, in different light and shadow of each moment. Listening to the wind, watching the rain, watching the sunrise and chasing the sunset. Walking has become the most enjoyable thing in my daily life. Thinking just slowed down, and some of the anxious nerves from the big city were soothed. After 5 months of staying up late, I finally went to bed on time. My skin went from pore size to fine, yellowish black to fair, and acne disappeared as far as the eye could see. My childhood dream of seclusion was realized. I remember reading the word "seclusion" in high school, and my heart thumped like a deer in the headlights. At that time, I loved Li Bai's landscape poems and Wang Wei's idyllic poems, and I copied one after another in my notebook, and I memorized one after another. I thought I would have to retire in my forties or fifties before I could realize my idyllic landscape. I didn't expect to suddenly realize my dream of seclusion just in the year I turned 30. Really happy and lucky~ #seclusion #mountain life #lying flat #low cost #unemployment #naked resignation #rental housing	Chinese Original (incomplete) [('others: 对于隐居来说房租太贵，你这是短暂疗伤可以'， 'author: *农村等地更便宜，但我更看重交通便利和山景，这里最合适'), ('others: 白天睡觉会吵吗作息颠倒的夜猫子的疑问'， 'author: 有时外面施工，会有点吵'), ('others: 这是多大平米的房子？单人套房吗？有独立厨房卫浴吗？'， 'author: 三室三卫一厅，客厅有厨房区'), ('others: 这是*进入一点'， 'author: 是的，你很熟悉啊'), ('others: 感觉还不错，生活方便吗，购物买菜呢？这种山里要注意蚊虫吧'， 'author: 骑电瓶车十分钟买菜，外卖能送，附近也有饭店'), ('others: 大*风景就是美丽'， 'author: 如画中游'), ('others: 600一个月？'， 'author: 是的，是和朋友合租的一间房'), ('others: 这个价格是合租吗？','author: 是的')] **Translation** [('others: rent is too expensive for a hermitage, you're a short-term healing can', 'author: rent is cheaper in many places, such as the silver beach in *, 2,000 yuan can be rented for a year, or two or three thousand a year inside the countryside, but for me to be easily accessible, and to go out to the nature, and also need a mountain view, the house would be more than suitable'), (' others: daytime sleep will be noisy? work and rest reversal of the night owl's questions', 'author: sometimes there is construction outside, will be noisy'), ('others: this is how big square meters of the house? 3.3.2 Data clean and selection

After processed by ChatGPT-4o-mini-2024-07-18 model, the 668 outputs still required cleaning for further analysis (Table 6), leaving 426 posts from 394 unique posters. The cleaning work based on the ChatGPT-generated outputs and manual filtering. Specific cleaning includes excluding posts not in China, posts not relevant to counterurbanisation, and updating other miscellaneous information such as location and poster types. The effort of updating unspecified or unclear house location aims to safeguard the credibility of further cases mapping in ArcGIS pro. Besides, 222 entries of rural incomers were extracted out, including 66 cases of rural returnees and 142 rural tenants. Posts from one same poster are merged using an Excel formula[4].

Table 6 Data cleaning and selection

Criteria	Method	Processed /posts	Remain /posts (668)
Not in China	Human (post IP) ChatGPT (content)	16 (excluded)	652
Not relevant	ChatGPT Human (occassionaly)	189 (excluded) 35 (excluded)	463 428
House location	Unspecified house location (e.g. '村子(a village)', '县城 (a county)', '老家 (hometown)' Unclear house location (e.g. only has town or village name)	175 (update)	428

3.4 Data Analysis

3.4.1 Mapping

To identify the counterurbanisation hot spots in China, Geocoding and ArcGIS Pro are applied to map the location of recorded rural incomers. Geocoding is the process of converting addresses or place names into geographic coordinates. Locations of rural incomers—such as accurate village names, or rough city/county/province names and nearby tourism attractions—were processed in Python[5] using GaoDe Map (or Amap, one of the main Chinese

4 Formula example: =TEXTJOIN(", ", TRUE, IF(A2:A100=A2, B2:B100, ""))

5 The script was published in https://gitee.com/sidchen0122/coordinates-convertor

navigation service providers) API. For imprecise locations, GaoDe Map will use the geographical coordinates of their administrative governments-usually located in the city centre-as replacement. For example, if the rough location is Shanghai, returned geographical coordinates will be the Shanghai City Government. Subsequently, all these coordinates were loaded into ArcGIS Pro to create XY points on the base map of the whole China. Since there were too many points overlapped in one same location, Kernel Density analysis[6] was conducted to provide a clearer view of the concentration of rural incomers (exclude very rough province level house locations).

3.4.2 Thematic analysis

Thematic analysis aims to construct a general narrative of counterurbanisation in China, focusing on the associated population groups, their characteristics, motivations and levels of post-move satisfaction. For each theme, Excel's filtering and statistic tools like PivotChart were used to extract and summarise relevant information. However, due to occasional inaccuracies in ChatGPT-generated outputs, researchers were required to manually correct certain text coding and revisit original social media posts.

4 Analysis results

4.1 Overview of counterurbanisation hot spots and general distribution

As shown in Figure 1, Figure 2, and Table 7, identified counterurbanisation migration in China has presented to be relatively widespread covering general South and East China, with a high concentration in the Yangtze River Delta region (Shanghai, Zhejiang, Jiangsu), Beijing, Chengdu (Sichuan) and Dali (Yunnan), and less concentrated around Guangzhou (Guangdong), Chongqing, and Changsha (Hunan). Apart from these metropolitan areas, there were also many counterurbanisation cases in Shandong Province and Guangxi Province (Table 1).

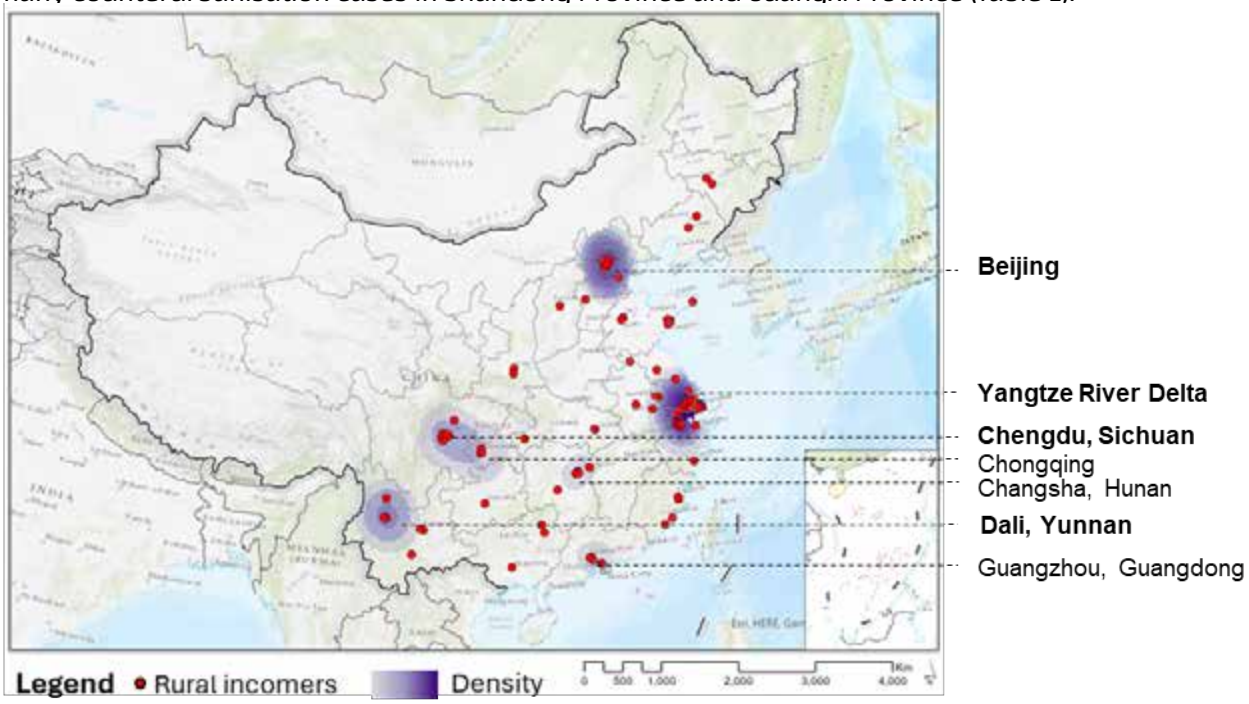

Figure 1 Distribution and Density of Rural Incomers
(Topographic basemap provided by ArcGIS Pro; boundary data obtained from China standard map service: http://bzdt.ch.mnr.gov.cn/)

6 '*Calculates a magnitude-per-unit area from point or polyline features using a kernel function to fit a smoothly tapered surface to each point or polyline.*' (https://pro.arcgis.com/en/pro-app/latest/tool-reference/spatial-analyst/kernel-density.htm)

4.1.1 Identified counterurbanisation hot spots

Zooming in onto these hot spots, it is found that most counterurbanisation cases are in metropolitan areas (examples in Figure 3) with good transportation connections and natural resources enabling both urban and rural amenity consumption. This is a typical scenario for counterurbanisation—living within a 'daily urban system' (Robert and Randolph, 1983).

Figure 3 Counterurbanisation cases in selected hot spot areas
(Topographic basemap provided by ArcGIS Pro)

To be more precise (Figure 4), the distance from the village populated by rural incomers to nearby city centre usually are within 50 km requiring 1-1.5 hrs driving or bus, calculated through GaoDe Map navigation API based on 54 valid cases with precise village level location.

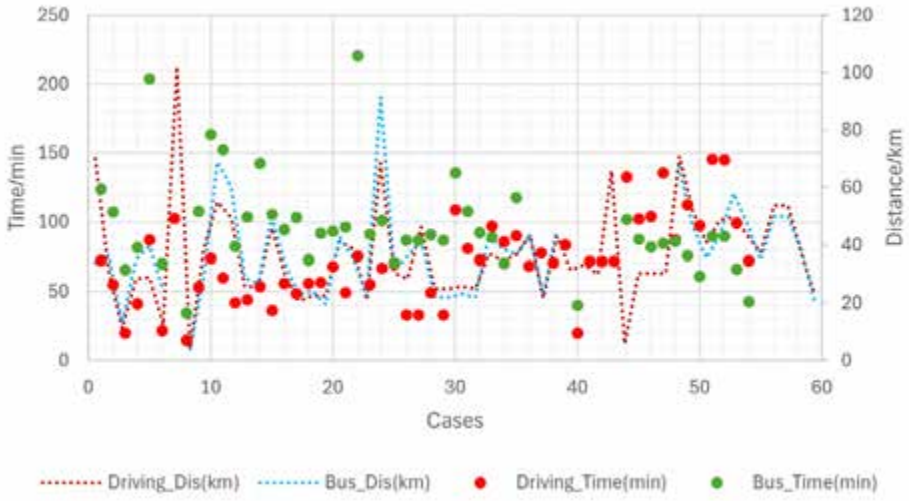

Figure 4 Navigation distance and time from recorded villages to city centre by car and bus
(Calculated using Gaode Map navigation API)

Most of these hot spots (Figure 1) have been documented in the literature (see, for example, section 2.3) with comparative fewer mentions of cases in Changsha City, Chongqing City, Shandong Province and Guangxi Province. Besides, existing literature mostly focuses on tourism-oriented villages, tourism or agriculture entrepreneurship incomers, gentrification phenomenon, or population deconcentration in metropolitan areas.

However, beyond these counterurbanisation narratives, there remain a number of cases within identified hot spots where stakeholders have relocated to the general countryside primarily for residential purpose. To provide a concrete illustration of identified residential counterurbanisation, three cases were selected from top hot spot areas (Table 8).

For Shanghai case (case ID:[7]: 41), the tenant rented a two-floor rural house living with children. There is a metro station in 10 minutes away by car and the tenant need around another 1.5 hrs commuting to work on metro. It was considered convenient to live in the village due to the accessibility of essential facilities and the availability of home delivery services. This individual expressed that 'the aspiration to live in Shanghai—as an outsider—is fulfilled by moving to the beautiful "socialist new countryside", where I have a yard, vegetable fields, and a small forest nearby'.

For Beijing case (case ID: 538), the tenant had lived in a small rural house with two bedrooms for two years and commuted to work by a 40-minute drive. This individual was very satisfied with the comfortable and convenient life there. One wonderful moment was 'enjoying sunshine at the yard, getting a cup of coffee, feeling the bleeze, listening to the birdcall or music, and petting the dog'.

For Chengdu case (case ID: 190), the tenant rented a whole rural house (about 1,000 m^2) in west Chengdu for 20 years when this individual will be 50 years old. The individual spent ¥280,000 on all refurbishment work. Adding up the average refurbishment expense to original rental, the monthly rent was ¥2500, which was five times cheaper than ¥1,2000 for a similar size property in the nearest cheapest urban district[8]. And the house was just rented for private living rather than commercial purposes.

The selected Shandong case (case ID: 216) is in the provincial capital city of Shandong, Jinan City. It is a little bit similar to Shanghai case in terms of location, although Jinan is far less developed, with a per capita GDP of around ¥55,000 in 2024—four times lower than Shanghai's ¥217,000. The tenant rented a rural house in the northeast of Jinan. There is a railway station and metro station (connecting to the airport) nearby. The rent was cheap, and the house included a yard and a vegetable field with clean and green neighbourhood and welcoming villagers. This individual said, 'I deeply regret not renting (a similar rural house) earlier'.

7 Case IDs are anonymised reference to individual social media posts in the dataset.

8 It is ¥12 per square metre per month in Shou'an County, Wenjiang District, Chengdu. Data from website: https://cd.bendibao.com/fangchan/2025418/196937.shtm

Case	Location	Village
Qingpu, Shanghai case		
Haidian, Beijing Case		
Wenjiang, Chengdu case		imprecise location
Jinan, Shandong case 216		

4.1.2 Widespread occurrence in East and South China

This research highlight the widespread occurrence of counterurbanisation in general East and South China. Both existing literature and identified hot spot areas in the previous section predominantly concerned with the most developed (Shanghai and Beijing) or well-known regions (Dali) in China. However, even based on the limited data source (Figure 1, Figure 2), evidence suggests that counterubanisation cases also occur in less developed areas in general South and East China (1-2 cases for each province as shown in Table 7). These cases, however, are also located near the provincial capital cities—typically most developed district in their respective regions—reflecting both the general improvement of societal wealth and emerging signs of the counterurbanisation tendance.

Once again, several residential counteruabnisation cases are illustrated below (Table 9) to enrich existing counter-

urbanisation story in China with newly observed scenarios.
For Changsha case (case ID: 225) in south-central China, the tenant decided to rent a rural mountain house for 20 years after coming across it when driving by. It is located 20 km away from the centre of Changsha city, approximately half an hour driving away. The refurbishment work was estimated at ¥200, 000 and monthly rental was ¥300. This individual said, 'at my youth, I felt exhausted and anxious about building a life. my dream was simple: have a house with a garden. Now, in middle age, I gathered courage to reconnect to the nature and to rest peacefully in that garden'.

For Liaoning case (case ID: 116) in the northeast of China, the tenant paid only ¥50 for a rural house with two bedrooms and vegetable fields in both the front and back yard. This individual spent summer there with families and moved back to urban home during winter because of the coldness. The biggest motivation for having a rural second home was to 'growing vegetables' and experience rural life.

For Xi'an Case (case ID: 199) in central China, the tenant rented a huge rural house in the south to Xi'an City, with 4 bedrooms and a large garden. It is 40min driving distance away from nearby city centre and 10min on motorcycle to nearest county centre. The commuting time to the city is similar—or even shorter—due to lighter traffic. This individual lived with families and parents, and was motivated by the concern about virus in cities, aiming to prevent the child from falling ill too often. This individual's one-and-a-half-year-old child and parents were very happy to live in a home with bigger space for daily activities. Besides, the house is very close to many nearby orchards and mountain valleys. The tenant felt very satisfied to live there, 'I find myself liking this place more with every passing day'.

Table 9 Selected residential counterurbanisation cases in South and East China (Imagery basemap provided by ArcGIS Pro)

Case	Location	Village
South-central China: Lianhua County, Changsha case		
Northeast China: Fushun, Liaoning case		imprecise location

Central China: Xi'an case		imprecise location

4.2 General counterurbanisation stories in China

Based on recorded social media posts, two main groups of rural incomers were identified: rural returnees (66 records), who moved back to home villages, and rural tenants (142 records), who rented houses in rural areas—although most rural tenants also originally came from the countryside. This distinction was made in consideration of differing challenges each group faces when integrating into village life, particularly in terms of land ownership and social bonding. However, these two groups were found to share many similarities regarding personal characteristics, migration motivations, post-move satisfactions—an unsurprising outcome, given that both involves transition from urban life to rural life. Nevertheless, quantitative comparisons were constrained due to the limited data source.

4.2.1 Personal characteristics

Recorded rural incomers consist of a variety of groups, including the employed, unemployed and retired (Table 10). Individuals who commute to work outside the village typically travel by electric motorcycles for 10 to 30 minutes, while a few drive cars for journey over 40 minutes. Self-employed tenants usually work from home or within the village, for example running business such as homestay or engaging in artistic work.

Table 10 Employment status of rural incomers

Poster type	Employed	Work Online	Self-employed	Unemployed	Retired	blank	Grand Total
Tenant	40	1	7	4	2	88	142
Returnee	10	0	5	2	2	47	66
Grand total	50	1	12	6	4	135	208

4.2.2 Migration motivations

There is no significant difference in migration motivations between rural returnees and rural tenants. Although it is generally easier for returnees moving back—since they already own a rural house and farmlands and are members of local communities—relocating to rural areas fundamentally reflects the shift of preferences from urban to rural life. Specifically, for example, the difference can be that rural returnees may have rural parents to visit or live with, whereas rural tenant may choose to rent a rural house because their parent who originally come from countryside struggle to adapt to urban life. Generally, their key motivations—often individually mixed—can be grouped under eight headings, acknowledging potential overlapping among them.

'Escaping' from cities and shift to (imagined) 'rural life'. Many rural incomers indicated that they were seeking refuge from the noisy, congestion and health risks of urban environment. Their relocation patterns varied; some moved temporarily, such as for a weekend, to get recovered from tiring work or life in cities; others relocate seasonally to enjoy more milder climate; and some opted for almost permanent settlement, exemplified by long-term tenancy agreements up to 20 years. From their perspectives, rural life is quiet, slow-paced, relaxing, simple, free ('ultimate freedom' for certain individuals), natural, and environmentally healthy with clean and well-oxygenated air. Incomers could more focus on their own life, even do pastoral seclusion, or start a 'new life after retirement'. A lot of incomers found it easier to have high quality sleep and fostered better work and rest routine

after moving to the countryside.
