The power of local community network is primarily derived from the direct rights and interests of the local community members from grassroots level. Real-estate property-related rights and rights as neighbourhood member/ "the public" can be two major categories of the actors in this network. Real-estate property rights, based on the Constitution (National People's Congress of the PRC., 2018, art. 13) and the Civil Code (National People's Congress of the PRC, 2020, Article 114, 117& 207), are among the fundamental de jure power bases worldwide. (Li, 2025) In the context of HUD regeneration, there can exist multiple forms of real-estate property related rights (Liu et al., 2014; Li, Song and Lv, 2020), some times even distributed in a highly "fragmented" manner (Shi, 2022, pp. 159–184) resulting from multiple reasons including the path-dependent of Danwei (working unit) collectivism, the housing policy switches, and the influx of migrants since the late 20th century. There are multiple types of housing rights in the Chinese residential and commercial-residential HUDs, including private ownership, public housing ("Zhiguan" public housing, Danwei-owned public housing, military Danwei-owned public housing, etc) [2], tenants in private owned houses, informal temporary. (Wu, 2007; Li, 2025) Beyond real-estate property rights, local communities can also possess power as neighbourhood members or "the public" when comes to non-private affairs such as Hutong alley renovation and courtyard renovation for community outreach, though the legal basis of this right can be vague and controversial.[3]

Local residents can have various preferences when it comes to detail. While generally speaking, when the basic living conditions in HUDs are still limited, the locals are likely to prioritize the issues directly related to their real estate property and housing conditions over shared courtyards over the improvement of shared courtyards or "public" spaces and services, such as streetscape enhancements. (Shi, 2022, p. 256; Li, 2025) They tend to seek direct and visible benefits and address "practical issues" like expanding their housing space, upgrading basic living facilities such as kitchen and restroom facilities, and improving insulation and drainage. (Li, 2019, p. 50)

1 As an example, addressing HUD population pressure may be reduced to merely reducing the total population in the quarter, without taking into consideration the micro-scale population imbalances or the further rehabilitation of vacated housing.

2 Public housing is a product of the planned economy time in the last century. The de-jure owner of these properties is the local Housing Management Bureau (Zhiguan public housing)or property-owned Danwei (multiple types of danwei housing) and the household can "rent" the houses at a low cost and the lease can function as a "de-facto infinite contract" (Ni, Zhang and Huang, 2017, p. 66) that can be passed to their off-springs. The households of the allotted public housing can not merely be considered as "tenants" and their scope of property-related interests is not clearly-defined in the switch away from the planned economy since the late 20th century.

3 Agreements have not been reached whether the local residents should be considered as "stakeholders" or merely "the public" in this kind of issues. (Zhao, 2015)

They may also make "private intrusion into public space" (Amin, 2008, p. 23; Li, 2021, p. 400), wait for governmental support as "free riders"(Li, 2018, p. 72), and appear to offer "flexible and tactful" arguments (Wei, 2024, p. 156) based on their own interests.[4]

The structure of the local community network is comparatively loosely-organized and holds limited power. In urban conservation contexts, three main types of organizations at grassroots level are commonly observed, namely Neighbourhood Committees (NCs, "ΔΔΔ"), Owner's Committees (OCs), and community-based Civil Social Organizations (CSOs). Among them, NCs are always the most fundamental and widespread setting throughout urban China, featuring a dual nature. (Li, 2025) On one hand, they serve as "self-governance" bodies intended to support local residents in "managing their own affairs, educating themselves, and serving own needs." (Standing Committee of the National People's Congress (NPC), 2018) On the other hand, they function as grassroots extension of the party-state bureaucracy, especially when implementing tasks delegated by local governments and their agencies. In practice, some NC members may adopt a behaviour logic of "selective policy implementation" (Yang and Yu, 2012, p. 107) among the administrative sub-contracts and diverse local interests.[5]

In addition to these formal organizations, there can also exist informal and implicit institutions in the local communities. For example, there can be small-scale endogenous structures in some HUD courtyards (with multiple families and households) through kinship, prestige, tenancy relationships, and long-term gaming, etc., and there might be a endogenous "leader" or "facilitator" within this structure. (Li, 2025) When it comes to HUD renovation, the courtyard "leaders" in these endogenous structures can serve as important roles during multi-actor negotiations. (Feng et al., 2020, p. 47)

3.4.Economic Network

The power of the economic network lies in the possession, control, or authorized use of diverse forms of resources in the circuits of production, exchange, distribution, etc. (Li, 2025) In the Chinese context, the institutional structure of economic networks is characterized by intricate interactions between state control and capital appreciation especially through market operations. Instead of "the functioning of the government will have to follow market principles," (Zheng and Huang, 2018, p. 23), the market in China is always "subordinate to the state" and operates "within the boundaries set by the latter." (Zheng and Huang, 2018, p. 58) and the state can control over key scarce production factors, such as land and natural resources. In HUD renovation, the key production factors, the ownership and use rights of urban construction lands, often playing a dominant role in the practical circuits of economic activity.

As for HUD renovation and redevelopment, the key actors in the economic network always feature a combination of state management and market operation. These entities typically function both as participants in the marketplace and as "operators" extending the influence of local states. Among the most representative organizational forms are Chengtou platforms (urban investment platforms) and venture companies jointly established by developers and local state actors. (Li, 2025) Chengtou platforms are state-owned enterprises "specialized in urban development and investment." (Feng, Wu and Zhang, 2022, p. 1260) They are always responsible for specific governmental-led projects related to financing, infrastructure construction, urban development, and public sector management. Most, if not all, Chengtou platforms depend significantly on governmental resource injection, operate in alignment with local state objectives, instead of simply prioritizing short-term profit as purely market-driven players. However, the state affiliation cannot exempt them from the rules of financial and production markets. (Li, 2025) Even with local state backing up, Chengtou platforms have to pay attention to their debt risks and cash flow circuits. Therefore, a number of key actors in the economic networks, exemplified by the Chengtou Platform and the venture companies, can feature a dual character of state governance and market functioning.

4 As for an example, residents in cramped living spaces may argue the encroached areas as public when seeking governmental funding for yard renovation, yet assert ownership of the additions when requesting compensation for demolition. (Li, 2021, p. 401)

5 As an example, Li-Alin, a university scholar, and her team once worked on a Beijing Hutong courtyard improvement in Dashilar. (Li, 2018) At first, the local NC actively supported Li and her team since the NC members wanted to make Li's renovation as part of their administrative achievements in performance assessment. When they found that the local state would not cover all the expenses and the courtyard residents have to pay around 80% of the renovation cost, they considered it a "thankless task" and might create conflicts with the courtyard residents. So they stopped their support for Li's renovation project. The switch in the attitude of the local NC indicates their selective priorities in the course of time.

In addition to real-estate property operation entities, HUD renovations may also involve other marketplace-related actors, including actors and companies engaged in creative industries and tourism development as well as local-based business associations and chambers of commerce (Wu, 2014).Similar as the Chengtou platforms, not all of these actors prioritize on the top of the list the monetary profits under a capitalized market, which can be further discussed in more specific cases or scenarios.

3.5.Expertise network

The power of the expertise network comes from the recognition and authority of expertise, the reliable judgement based on professional knowledge, rules, theories, and standards. (Li, 2025) Actors within this network, such as university scholars and industry experts, often share foundations in philosophical orientations, methodological approaches, education backgrounds, or normative principles in their specialized fields and these consensuses can be reflected in academic research, professional practices, and collaborative projects. (Li, 2025) The expertise network may be described as a community with "a certain degree of autonomy" (Chen, 2018, pp. 144–151) grounded in shared professional consensus, typically camped at academic or professional institutions, exemplified by planning institutes, colleges, and universities. Ideally speaking, the actors in the expertise network adhere to their professional standards and ethical norms, though in practice their decisions are often shaped by competing concerns and contextual constraints that need be further examined in specific scenarios.

HUD renovation projects call for the engagement of expertise network actors, particularly those in urban studies, planning, architecture, landscape design, and heritage conservation. Currently in China, they are most likely to take on roles as technical supporters and consultants -- exemplified by the urban planners and conservationists drafting HUD planning plans and proposals for the local states – or as procedure reviewers, such as the Expert Committee, assessing and evaluating the conservation plans. However, in most of the cases, the experts as technical supporters are not collaborators for decision-making and it is local party-state that have the actual power to make the final decisions. (Wei, 2024, p. 147)

In addition to technical supporters and procedure reviewers, actors in the expertise networks have increasing chances to be involved in a growing scope of grassroots-level HUD renovation. For example, urban planners and university scholars in Beijing now have the opportunity to act as "responsible planners," serving as versatile roles covering "planning issue researcher, planning and design document reviewer, neighbourhood/ community renewal guide, cooperation facilitator and coordinator, public participation organizer" (Tang and Zhang, 2023, p. 140) in various community-building and environmental improvement practices.

3.6.Other Actors

There are also other actors in the renovation that embody the characteristics of multiple power networks depending on the case. NGOs, for example, may play an active role particularly in incremental HUD renovation projects rooted in local communities. NGO members may come from the expertise network, offering skills in design, environmental management, and community engagement, while others may be part of the local community network, such as long-term residents or Neighbourhood Committee workers involved in daily governance and grassroots coordination.

4.Discussion

4.1Reflections on the Chinese HUD power network

Drawing on the bounded rationality hypothesis and actor-centred institutionalism, the study proposes a theoretical framework to depict and analyse the actors' power, institutional structure, mindsets and behaviour pattern. It may not capture the full complexity of every individual actor, but it can contribute to understanding HUD renovation mechanism from an actor institutional perspective as well as creating explanations for renovation processes and results. Through the identification and analysis of major actor networks in China, the research generates insights into both the contextual features and practical pathways of HUD renovation efforts.

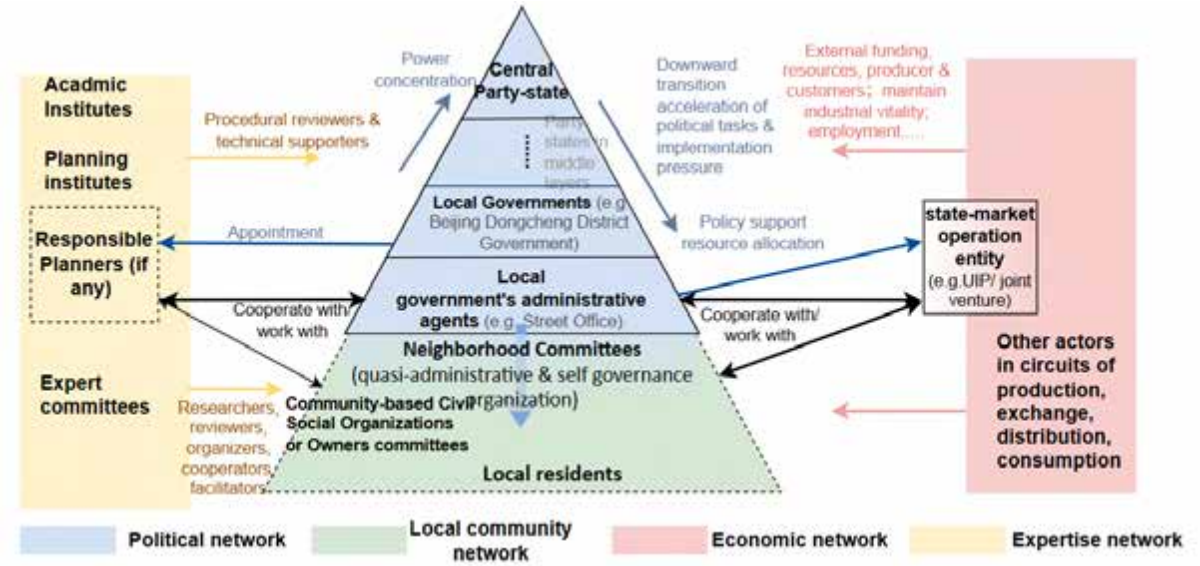

Figure 2 Diagram of the four network interaction in a typical Chinese HUD renovation/regeneration cases

First, party-state institutions in China possess substantial power and resources, enabling them to more readily initiate or promote HUD renewal projects and act as a leading role in major decision-making processes. A number of key actors in other networks, exemplified by the Neighbourhood Committee members (local community network) and Chengtou Platform (economic networks), and even some professional groups (expertise network), often feature dual nature and take into party-state interests into account. Thus it highlights the importance of closely examining the behavioural logics of the party-state institutions. Therefore, promoting inclusive, multi-actor engagement must go hand-in-hand with efforts to strengthen internal motivation within state institutions, for example, by establishing more balanced and context-sensitive performance evaluation criteria within the governmental system. In addition, given the risk of functional fragmentation among different governmental sectors, fostering inter-departmental collaboration may be a key challenge in HUD renovation, particularly in addressing interdisciplinary concerns and achieving holistic improvement.

Further explorations are required on an increasingly inclusive participatory approach, where local communities and professionals play increasingly significant roles in the decision-making process. As we can see, though the other three networks have been largely impacted by the power of the party-state, they still have separate primary thrusts and power sources other than political power and a number of local residents, experts, and business operator have their own mindsets, interests, and insistence beyond or against the pursuit of local governmental political goals and personnel evaluation, and many of they did or do challenged the local party-state decisions through multiple channels based on their rationale or principles. (He, 2016, pp. 88, 133–135, 158–159; Zhang *et al.*, 2019; Wei, 2024) For example, it can be encouraging to see a growing trend of professionals in urban planning, architectural design, and heritage conservation engaging in long-term, locally rooted studies. Rather than serving solely as technical consultants to local authorities, they are more likely to create a deeper and more comprehensive understanding of the sites and the local communities and contribute to more resilient, empathetic, and place-sensitive renovation strategies by immersing themselves in the site and developing interpersonal relationships with local residents.

4.2.Reflections on the power network analyse framework

The research creates the four-power network framework and applies it to the context of Chinese HUD regeneration contexts. The framework proves effective in analysing and illustrating the power source and institution-shaped motivation and behaviour patterns of various actors involved. However, its application in the Chinese context reveals that the framework serves more as a preliminary tool for analysing actor participation. While diverse actor networks can be identified, they are often not fully independent in practice. Its application to the Chinese HUD contexts indicates that the framework is just a starting point of the actor participation analysis. Though diverse actor networks can be identified, they are not that independent in real cases. In the Chinese contexts, it is

clear to see that the power of the party-state can always be more determined and dominant than others in the Chinese contexts and actors in other networks can feature dual characters shaped by the pervasive influence of the party-state apparatus. Therefore, further case-specific studies are still required to look into the interactions and negotiations among different networks.

5.Conclusion

The study draws on the bounded rational hypothesis and Mann's power network framework and proposes a descriptive and analytical methodology for examining actor institutions within the context of Chinese HUD renovation. By constructing a panoramic overview of key actors' power bases, organizational structures, and motivations and mindsets, the study identifies several institutional challenges regarding the Chinese HUD renovation, especially the imbalanced power distribution. Although the methodology is applied specifically to the Chinese urban renewal context, it holds potential for broader implementation by categorizing and analysing various types of power networks and their distinctive features in other cases. One of the key strengths of this approach lies in its capacity to interpret actor-related urban dynamics from an integrated and holistic perspective. By examining the institutional mechanisms underlying individual actions, it helps to reveal the structural drivers behind actor decision-making, thereby offering meaningful implications for future institutional design.

Typologies and Dynamics of Urban Growth Projects in Ethiopia: A Discursive Analysis

Han GAO
Southeast University
gaohanseu@outlook.com

Abstract
This paper analyses the typological evolution and discursive construction of urban growth projects (UGPs) during the EPRDF and Prosperity Party (PP) periods in Ethiopia. Using typological analysis and critical discourse analysis (CDA), the study identifies three types of UGPs, namely housing and infrastructure, urban renewal, and industrial parks, and reveals their continuity at the material level despite their different development patterns. Despite the Prosperity Party's critique of the EPRDF model, both use UGPs as a legitimising tool for governance. The study highlights that UGPs consolidate authoritarian governance pathways, shift discursive logics from state-led industrialisation to market-oriented global competition, and document grassroots tensions between national narratives and local realities.

Keywords: Ethiopia; Discourse; Urban Growth Projects

1 Introduction

Ethiopia is one of the fastest growing economies and urbanising countries in sub-Saharan Africa. The rapid expansion of existing urban areas and the significant increase in the number of new cities highlight the remarkable trend of urban growth in Ethiopia. Up to 2015, Ethiopia's GDP growth rate exceeded 10%, and although the growth rate has slowed in recent years, it remains above 5% per annumΔWorld Bank, 2025Δ Urbanisation has also progressed at a remarkable pace alongside economic growth, with an urbanisation rate of 23% by 2022, indicating a period of rapid urbanisation. According to the Blue Ribbon Panel Report, the urbanisation rate is projected to reach 37.5% by 2050 (Ethiopia2050). According to Ethiopia's Ten-Year Development Plan, the country has approximately 4,000 urban areas, while the 2007 National Population and Housing Census recorded over 2,000 urban areas. The significant difference between these figures not only reflects adjustments in statistical methodologies, but also highlights the rapid urban development that Ethiopia has experienced over the past decade. In the context of rapid urbanisation, the Ethiopian government has long promoted urbanisation and modernisation at the national level through a series of large-scale Urban Growth Projects (UGPs). These projects are not only spatial development initiatives, but also crucial tools for national governance, economic restructuring and the construction of political legitimacy.

I tracked three major types of urban development projects implemented in Ethiopia after the collapse of the Derg regime in 1992, with a particular focus on comparing project dynamics during the EPRDF and Prosperity Party eras. We found that the Prosperity Party emerged as a challenge to the EPRDF's failed attempts at democratisation and ethnic issue management, promoting political and economic policies that were fundamentally different from, and even in conflict with, the EPRDF's vanguard capitalism. It has widely criticised the material legacy of the EPRDF era, pointing out that numerous large-scale development projects (such as the urban light rail, industrial parks and the Addis Ababa-Djibouti railway) have faced controversy and challenges in implementation, reflecting the UGP's 'fragility' and 'insecurity' at the material level. However, the two parties share continuity in the types of large-scale projects they choose to develop and similarities in the material forms they adopt. Nevertheless, the symbolic functions of these projects in national narratives, the construction of ethnic identities and the maintenance of regime legitimacy remain powerful. To explain this contradiction between ideological denial and practical consistency, we further introduce the method of Critical Discourse Analysis (CDA), following a research path of 'textual analysis-interpretation-explanation', to explore the discursive practices of the UGP in different discursive contexts, as well as their continuity and discontinuity in the ideological dimension. Focusing on the linguistic construction practices of Ethiopian discourse, this study attempts to explain the representation of the discourse of large-scale urban projects from the perspective of critical discourse analysis, demonstrating its role within the framework of national ideological formation and governance logic.

This study first outlines the "toolkit" for promoting the growth of urban spaces in the Global South. Second, we describe the typology of urban growth in Ethiopia through its urban policy documents and urbanisation policies, and compare the similarities and transformations in their trajectories between the EPRDF period and the PP period. In the fifth part, we analyse representative discourse cases to examine their constitutive functions, especially in relation to the macro-political environment, and the interpretive role of macro-discourse in the projects.

2. A toolkit for spatial growth in sub-Saharan African cities

Under the dual influence of globalisation and neo-liberal development, cities in sub-Saharan Africa are widely adopting different urban development projects. Through radical 'character-shaping' approaches, they are reconfiguring territorial resources, transforming social structures and pre-emptively establishing urban economic systems(Ansar et al., 2017; Flyvbjerg, 2014) to help emerging cities - especially megacities in sub-Saharan Africa - move towards the vision of becoming "global cities"(Hirschman, 2014). These tools are diverse, including radical mega-urban renewal projects, new city concepts such as smart cities and eco-cities, and location-based industrial policies represented by industrial parks (IPs) and special economic zones (SEZs). The spatial growth instruments of cities in sub-Saharan Africa can be divided into two categories based on their interaction with the local economic system and urban structure: inward-oriented and outward-oriented.

The core of outward-looking spatial policy tools lies in the creation of 'hyper-localised' spatial hubs to effectively connect cities in the Global South to the global network. These tools often break through existing spatial patterns and functional divisions of urban systems, constructing new engines of growth that are relatively parallel to the local economic system but serve global capital flows and supply chain integration. Among these, place-based policy instruments, represented by industrial parks (IPs) and special economic zones (SEZs), are widely seen as the key link between industrialisation and urbanisation(Kihiko, 2018; Shen et al., 2023; Weldesilassie et al., 2017a). In sub-Saharan Africa, industrialisation is widely recognised as an effective way of improving factor productivity, promoting labour transfer and optimising resource allocation. Faced with the twin pressures of urban sprawl and rapid population growth in the context of globalisation, SEZs and IPs have therefore been given high priority by governments as important strategies for promoting urban growth.

In addition to IPs and SEZs, new cities have also emerged as an important spatial form in recent years. Compared with traditional industrial parks, new cities are more flexible in terms of spatial location and functional positioning, usually located on the outskirts of cities, with diverse structures and composite functions. These new cities are not only key components of the country's overall political and economic strategy, but also take on the task of promoting the development of specific industrial sectors (such as information technology, ecological and environmental protection, and smart city construction)(Côté-Roy and Moser, 2022). It is worth noting that new city projects are often led by private capital or multinational corporations, targeting the middle-class consumer market(Keeton, 2019), with the core objective of attracting foreign direct investment (FDI) and stimulating economic growth(Watson, 2014). In contrast to SEZs and IPs, which prioritise the integration of industry and urban development, new cities place greater emphasis on spatial image, livability and the incorporation of global governance concepts, serving as 'showcase spaces' that link local and global contexts.

Inward-looking UGP aims to address structural deficiencies in existing urban systems by activating the productivity of local elements through spatial interventions, typically implemented within urban boundaries. This category includes mega urban renewal projects and green space projects within cities, such as light rail infrastructure projects. MURP serves as a tool for large-scale restoration and redevelopment of urban spaces, reshaping the topography of existing large cities as part of efforts to strengthen the economic competitiveness of megacities in the context of global competition(Swyngedouw et al., 2002). Due to widespread structural problems in sub-Saharan African cities, such as weak infrastructure and inadequate governance frameworks(Kamana et al., 2024) African cities in a quest for modernity and prosperity have been urgently playing catch up to deal with the increasing demand for adequate urban systems and infrastructure. At the turn of the 21st century, many spatial planning models, technological trends, environmental challenges, and socio-economic realities are influencing African cities' dynamics largely causing confusion and a lack of consistent planning policies. To efficiently guide a coherent and coordinated vision, frame an integrated long-term spatial logic, and give a precise direction for sustainable urban development, this paper aims to develop a localized and contextualised analysis of urban planning challenges and development strategies shaping African cities. The study provides a broad perspective

looking at the potentiality of spatial planning practices to envision and transform urban life by prospecting integrated urban planning and development strategies to face increasing urban challenges in Africa. Through Systematic Literature Review (SLR, urban renewal in these cities is based on rapid urbanisation and slum expansion, and aims to comprehensively and radically reshape the existing spatial structures of several African cities(Grant, 2015). Drawing on examples from South Africa and Ethiopia, MURPs can also be part of broader modernisation reforms that follow the neoliberal logic of urban development(Lindell, 2019), accompanied by global mobility and gentrification(Hayes and Zaban, 2020). National governments drive regional development through large-scale investment, using the externalities of urbanisation to stimulate other sectors of the economy(Zhang et al., 2023). These cities undergoing large-scale reconstruction are typically the capitals of African countries, which use MURPs to reshape the urban landscape and spatial layout, thereby demonstrating the power of the national government(AFRICA, 2018).

3. Methodology

This study aims to analyse the typological evolution of UGPs in Ethiopia through different historical periods and the logic underlying their discursive construction. Given the complexity of urban development policies in the dual dimensions of 'materiality-symbolism' and 'practice-narrative'(Smith, 2016), single spatial or institutional analytical approaches are insufficient to fully explain how UGPs are continuously conceived, legitimised and adapted as tools of development governance. Therefore, this study adopts a research approach that combines typological analysis and critical discourse analysis (CDA) to reveal the spatial practice mechanisms and discursive legitimation logic of UGPs within the political-economic structure.

3.1 Theoretical Methods

First, this paper uses typological analysis to identify the main characteristics of urban growth projects in Ethiopia across different time periods in terms of policy orientation, spatial form and governance models, and identifies four types of UGPs represented by mega-infrastructure projects, urban renewal, industrial parks/special economic zones. This classification not only facilitates spatial comparison, but also reflects the interactive logic between UGP and national development strategies, and forms the basis for structural analysis.

In order to understand the operational mechanisms of UGP projects not only as "material entities" but also as "symbolic representations", this study also introduces CDA as a core explanatory tool. Based on a constructivist theoretical stance, which posits that social reality is not an objective, independently existing entity, but a social process of constant construction, negotiation and reproduction through language and discourse in specific contexts(Fairclough, 2013; Van Dijk, 2015), discourse exists in a dialectical relationship with the social world(Mendes et al., 2024). The core assumption of discourse analysis is that "discourse not only reflects policy but also constitutes policy itself", with policy practices and discourse structures being mutually embedded and co-constructing reality(Hansen, 2013). CDA focuses on the role of discourse in structural elements such as power relations, ideology, institutional arrangements and social identity(Van Dijk, 2015). The theoretical tradition of CDA includes two main strands: the Marxist-oriented macro-historical discourse analysis, which focuses on the relationship between power structures and ideology; and the post-structuralist-oriented micro-discourse practice analysis, which focuses on the detailed interpretation of discourse practices in specific contexts(Sonn and Park, 2023). This study draws on the macro-level analytical approach of the Marxist tradition(Lees, 2004) and focuses on how discourse shapes the meaning and practice of urban growth projects in the intertwined power structure of state, capital and society. It situates linguistic practice within institutional settings and historical processes, revealing the dynamic relationship between events and discourse in UGP, as well as the diachronic changes of UGP in different institutional settings.

This paper introduces Fairclough's (1992) three-dimensional analytical framework(Lees, 2004), namely text analysis, discourse practice analysis and social practice analysis. Text analysis focuses on the use of vocabulary, grammatical structures, rhetorical devices and narrative strategies. The discourse practice level examines the production context of policy texts in relation to their interactive relationships with other texts, speeches and discussions. The social practice dimension discusses the ideology and power effects carried by discourse in specific social contexts, revealing how discourse shapes institutional arrangements and spatial practices.

3.2 Data and Method

This paper collects policy documents, project planning texts, speeches by leaders, memoranda of cooperation, mainstream media reports, and official promotional materials at multiple scales and levels, such as official development planning texts, development project texts, and influential media materials such as Addis Fortune, Addis Standard, and ENA. These texts constitute the 'official expression' sources for the discourse construction of the UGPs and provide the primary corpus for discourse analysis.

In addition, the research draws on fieldwork conducted in Ethiopia in 2024 and online and offline tracking of Ethiopian developments since 2016 to obtain interview material from a range of stakeholders, including government officials, Chinese company managers, local officials, project residents, academics, and media professionals. In addition to formal interviews, the research team conducted ongoing field observations and informal interactions during visits to the Eastern Industrial Park, Bole Lemi Park, and Corridor Plan sites during the UGP, and recorded informal conversations to further supplement the micro-level understanding of discourse practices.

4. Continuity of Ethiopian UGPs

Since the EPRDF (Ethiopian People's Revolutionary Democratic Front) came to power, Ethiopia has promoted three types of urban growth projects: first, housing and infrastructure projects, which are at the core of the EPRDF's strategy and are used to promote regional economic integration and national spatial integration; second, urban renewal projects, which were systematically implemented during the PP (Prosperity Party) period; and third, location-based industrial park development projects, which promote the coordinated development of industrialisation and urbanisation.

4.1 Mega-infrastructure

Large-scale infrastructure projects are key tools in the EPRDF's urban growth strategy, particularly in addressing the population pressure, urban poverty and developmental imbalances caused by rapid urbanisation. The EPRDF government emphasises strengthening regional connectivity and national unity through state-led infrastructure projects. Under the Growth and Transformation Plan (GTP), such projects not only serve to reshape the spatial structure of the country, but also symbolise the construction of a modern state.

In terms of transport infrastructure, the Addis Ababa Light Rail Transit (AALRT) and the Addis Ababa-Djibouti Railway are representative projects. The AALRT, which began construction in 2011 and was completed in 2015, is Africa's first electrified urban light rail system. It was built by the China Railway Group and the China International Engineering Consulting Corporation, financed primarily by low-interest loans from the China Exim Bank, and reflects the urban planning concept of Transit-Oriented Development (TOD). The 752km Addis Ababa-Djibouti Railway began construction in 2011, began trial operations in 2016 and was officially opened in 2018. It is East Africa's first modern electrified railway, built to Chinese standards by China Railway Group and China Civil Engineering Construction Corporation. It serves as a model for integrating the Belt and Road Initiative into Ethiopia's national development strategy.

While the policy logic and implementation pathways for infrastructure development underwent adjustments during the PP era, they continued to adhere to the basic characteristics of state-led, foreign investment-driven and engineering-integrated development established during the EPRDF era. Building on traditional road, rail and hydropower infrastructure development, the Abiy Ahmed government has continued to prioritise renewable energy projects, including wind farms such as Ashegoda, Adama I & II and Aysha. These projects not only meet the energy needs of industrial zones, but also support rural electrification and the Green Legacy initiative. Infrastructure projects during this period also showed more diversified characteristics, such as the experimentation with public-private partnership (PPP) models, the introduction of private capital, and the promotion of local government involvement in early project planning to improve implementation efficiency. At the same time, some projects attempted to localise the industrial chain, such as wind power projects that introduced local equipment manufacturing and tower production enterprises to explore ways for industrial synergy and development.

4.2 Urban renewal projects

During the EPRDF era, urban renewal was in its initial exploratory phase, focusing mainly on the spatial renovation of a small number of public nodes in urban core areas and the construction of civic amenities such as squares, parks and memorials. These projects showed clear characteristics of national image building and the strengthening of capital city functions. Overall, however, they remained fragmented and engineering-driven, lacking a systematic spatial intervention logic.

The Integrated Housing Development Programme (IHDP), launched in 2004, was the first institutionalised large-scale urban plan of this period, aiming to achieve multiple objectives such as spatial governance, social stability and urban image reconstruction through the construction of housing and the provision of infrastructure to address informal settlements. In Addis Ababa, the programme built nearly 500,000 low-income housing units over 20 years, primarily in the city's peripheries and secondary centres such as Bole-Summit, Yeka-Abado and Bole Arabsa, and extending to regions such as Legetafo-Legedadi in the Oromia region. This formed a model of urban expansion based on "residential orientation", which encouraged inter-district commuting and labour mobility.

During the PP era, urban renewal increasingly prioritised improving the city's image and global competitiveness, promoting a number of commercial, high-end and iconic urban projects, including the ADWA Museum and Unity Park, which are national symbolic engineering projects. Real estate and business development projects such as the 'Future City Economic Zone' (Lemi Future City) led by China Communications Investment Group, the La Gare Complex, Gelan Gura Village and Windows of Africa have also become key drivers of land restructuring and urban form transformation.

Launched in 2022, the Corridor Development Plan (CDP) has been hailed as 'the first development-centred public urban project since 2020' and represents the PP government's most ambitious urban spatial strategy. The CDP focuses on regional centres and major urban nodes, with road upgrades at the forefront, and integrates infrastructure network upgrades (including drainage, electricity and internet), slum rehabilitation, public service facility construction, tourism revitalisation and land development, reflecting the multiple objectives of African cities under the modernisation paradigm, environmental utopianism and the 'park city' ideal.

The most representative component of the CDP is the Addis Ababa Corridor Development Plan (AACDP), which was launched by the Addis Ababa City Administration in December 2022 and covers all of the city's sub-cities. The corridors in the plan range in length from 3.1 kilometres to 40.4 kilometres, with functions ranging from transport connectivity to urban renewal, such as the Anbesa Garage-Jakros-Goro section and the Kasanchis-Meskel Square-Arat Kilo axis. Each corridor links residential, commercial, industrial and entertainment zones, promoting multi-dimensional urban regeneration.

In addition, the plan includes two waterfront development projects: the Qebena River Corridor and the Entoto-Peacock River Corridor. These projects redefine the future development direction of the city by restructuring spatial interfaces. According to a relevant official from the Addis Ababa Planning Bureau (who was involved in the 2017-2027 Structural Plan and the design of the AACDP), although the AACDP, as an independent project, has a certain degree of 'planning exceptionality', its spatial structure still inherits to a large extent the urban structural design established during the EPRDF period, continuing the TOD concept and the high-density mixed-use development strategy of Zone 2.

4.3 Place-Based Industrial and Urbanisation Projects

IP projects represent the high degree of integration of the 'spatial expansion-industrial transformation' logic in Ethiopia's urban growth strategy. Since the establishment of the Eastern Industrial Park (EIP) through Sino-Ethiopian cooperation in mid-2007, Ethiopia has begun to formulate a spatial strategy for industrialisation based on the "enclave" model - the establishment of industrial parks in specific areas to attract the relocation of production and boost employment, exports and economic growth.

The EPRDF government sees SEZs and IPs as key instruments of its industrial policy, combining urban planning(Tesfaye, 2021), infrastructure development and investment promotion measures to establish functional parks in key cities(Tang, 2019).

The Ethiopian Industrial Zone Development Corporation (EIZDC), established in early 2010, serves as the national implementing agency for park development and was reorganised in 2014 as the Industrial Park Development Corporation (IPDC) to centrally coordinate the development and investment promotion of state-owned parks(Rodríguez-Pose et al., 2022; Zhang et al., 2018).

Since the establishment of institutions and legal frameworks for industrial park development, Ethiopia began to systematically plan and construct industrial parks. Currently, Ethiopia has 13 state-owned industrial parks, including the Bole Lemi Industrial Park, the Bahir Dar Industrial Park and the Hawassa Ecological Industrial Park, as well as 6 private industrial parks, 4 agro-processing parks and 2 public-private partnership special economic zones(Gao and Wang, 2025). However, criticism of Ethiopia's industrial park strategy has outweighed praise, with media, academic literature and official government reports widely pointing to its limited role in promoting industrial transformation, creating urban linkages and driving external infrastructure development(Weldesilassie et al., 2017b). The New Property Party and Prime Minister Abiy have adopted an ambiguous stance towards the legacy of the EPRDF, such as its intellectual property policy, while federal government officials at all levels have expressed a preference for economic zones in both public statements and private conversations(Wang and Zhang, 2024). In April 2024, the Ethiopian Parliament approved the Notification No. 1322/2024 (Economic Zone Declaration) to regulate Special Economic Zones (SEZs) [v]. In September 2024, the management teams of the country's industrial parks were required to transition to economic zones within a short timeframe, and the EIC established a new project office to oversee this process. At the same time, the EIC announced the upgrading of 10 out of 13 IPs under the IPDC to SEZs, including industrial parks such as Adama, Bahir Dar, Bole Lemi and Jimma. All private (mostly Chinese-invested) industrial parks were excluded from this process. An interview with an EIC consultant supported this view: "*Private parks (investors) can choose whether to upgrade to an SEZ, provided the procedures are followed. We are not currently taking any proactive measures to urge them (to upgrade)*". Taking the AWSEZ as an example, the construction of the ATSEZ, including the land preparation activities carried out by the city government before making the land available to CCCC, is part of the Capital Corridor Development Plan since 2023, marking the first integration of economic zones into the city's strategic framework. The ongoing Addis Ababa Corridor Development Project connects other areas of the capital with the ATSEZ in the Gotera region, positioning it beyond a traditional industrial park to become what the mayor has described as a "new city within the city" repositioning Addis Ababa's global urban competitiveness, commercialising land and becoming a major international shopping destination.

5 Discussion: The Discourse of Urban Growth Projects in the Dynamic Structure of National Governance

UGPs are not only tools for economic development and spatial restructuring, but also important arenas for the operation of state power and the production of ideology. Different types of UGPs are always embedded in the national development strategies and political governance logics of specific historical stages during their implementation, and their discourse forms and institutional settings exhibit complex dynamics. This chapter uses CDA to explore how the discursive dimensions of UGPs reflect, construct and shape national governance structures, and to analyse their manifestations in legitimacy construction, ideological production and discursive negotiation.

5.1 The Continuity of Power Discourse: The Multiform Expression of Authoritarianism

Although Ethiopia has undergone changes in its political structure and ruling ideology during the transition from the EPRDF to the PP, and the urban political discourse has been adapted and updated accordingly, the logic of power and the pathways of governance exhibit a high degree of continuity. This continuity is manifested in the state's continued dominant control over urban growth projects, their high degree of embedding in the spatial discourse, and the continued use of urban development as a tool for reshaping national identity and constructing legitimacy.

Three categories of urban growth projects - including IHDP, symbolic urban node projects (such as Unity Park and the ADWA Museum), and CDP - differ in their specific implementation content, policy objectives, and mobilising language. However, they all serve a common governance purpose: to reinforce the dominance of the state in the urban space, to shape the national development discourse, and to demonstrate national capacity in the context of globalisation. They concretise national development goals at the spatial level, mobilise collective emotional identity at the social level, and reaffirm the legitimacy of the regime at the political level.

The symbolic significance of these projects is particularly striking. In the IHDP, large-scale public housing not only attempts to solve the problem of urban slums, but also reflects the state's definition and norms of 'modern life'. Cultural landmark projects such as the ADWA Museum and Unity Park spatialise national historical narratives and the ideology of ethnic unity, reinforcing identification with national identity; the Corridor Plan, with its grand narrative of 'connecting to the future', projects a modern image externally while legitimising governance internally, serving as a multifaceted tool for urban governance and national construction. Media, government propaganda and policy texts often use discourses such as 'global gateway', 'model for African urban revival' and 'new spaces for the future' to legitimise development visions and integrate them into urban spatial practices.

More importantly, these projects translate national visions into tangible spatial entities that shape 'visible development'. In a context of relatively limited fiscal resources and administrative capacity, the visibility of development becomes a crucial mechanism for the exercise of power. By prioritising resources for a few symbolic projects, the government creates a visual landscape that conveys the state's control over the future, exerting a powerful perceptual influence on both the public and external observers. This approach perpetuates the spatial governance logic of authoritarian regimes, where 'symbolism trumps substance' - even if the actual services and welfare outcomes of projects are limited, their discursive efficacy can be manifested far beyond the projects themselves, providing a visualised legitimation for the state-led development logic.

In this process, discourse is not just a packaging language for policies, but an integral part of governance. Although the 'national imagination' behind urban growth projects takes different forms at different stages, it is highly normative and exclusive in nature, defining what constitutes the 'ideal space', the 'ideal citizen' and the 'ideal development'. This is the multifaceted expression of authoritarian governance discourse: it achieves political control through physical space and regulates social expectations and collective memory through cultural narratives. Urban space thus becomes a vehicle for ideology, and projects themselves are imbued with symbolic and emotional significance that transcends their functional purpose.

Urban growth projects are therefore not only economic and technical development practices, but also key tools of state governance discourse and symbolic politics. They embed symbolic structures of regime legitimacy in urban space and serve as important strategies for maintaining the ruling order 'in the name of development', revealing the deep-seated interaction between the continuity of urban policies and the symbolic logic of governance under Ethiopia's authoritarian governance.

5.2 From "developmental" to "development" The shift in development discourse

Ethiopia's development discourse has undergone significant changes under different regimes. From the 'developmental state' discourse of the EPRDF era to the 'development' discourse centred on governance performance and market orientation under the PP party, the nature and discourse logic of the UGP has also undergone a transformation.

During the EPRDF era, the development discourse was characterised by state-led initiatives, planning priorities and structural transformation, emphasising the promotion of 'industrial catch-up' and 'spatial balance' through state-led large-scale infrastructure and industrial policies. For example, Arkebe Oqubay, a key figure in Meles Zenawi's senior official team, frequently cited China's reform and opening up and the East Asian miracle as development experiences, and proposed the strategic goals of 'structural transformation' and 'industrial catch-up', closely linking the country's industrialisation efforts with China's assistance[i][ii]. The discourse of this period had a strong institutional learning orientation, describing development as a collective national goal whose legitimacy was derived from the state's right to shape the 'future'. This development logic emphasises state-led development, the prioritisation of large-scale projects and the institutional design of a developmental state. The development trajectory is based on structural economic conditions, a political party with a vanguard ideology of centralised policy and a capitalist market. Rents are seen as a strategic resource to expand the regime's economic base, redistribute wealth to integrate different social strata into the EPRDF, and promote sectoral and regional integration[iii]. These projects are directly linked to the EPRDF's state development discourse and its ideology-driven, organisation-based political system.

Since Abiy Ahmed came to power, the development discourse has placed greater emphasis on governance performance and market logic, in line with the state's radical privatisation of state-owned assets. The promotion of urban renewal projects often uses terms such as 'livability', 'connectivity' and 'transformation', representing a shift in the development narrative from statism to urban entrepreneurship. This shift in discourse structure reflects not only the evolution of development concepts, but also the shift in the state's approach to legitimacy - from "development promise legitimacy" to "governance performance legitimacy".

In addition, the development discourse expresses the competitive aspirations of the global city, selectively defining the actors of development rather than the socialist ideology of equity and integrated development emphasised during the developmentalist period. These projects became the PP's standard discourse for implementing neoliberal reforms, which gradually evolved into an entrepreneurial discursive framework centred on the 'image of the global city', 'investability' and 'efficiency of spatial governance'. Corporate discursive frameworks. Promotional materials and government statements use terms such as 'vibrant', 'liveable', 'competitive', 'transformation' in an attempt to transform urban space into a showcase for attracting capital.
"(AACDP) is the first development-focused public project since 2020, when completed, will deliver significant long-term benefits to relevant stakeholders. "

5.3 Counter-narratives and bargaining practices in the discursive space

Although the content of the discourse has been constantly adjusted under different regime changes, its logic of power and path of implementation show a high degree of continuity. The discursive forms of the three types of urban growth projects, although different, serve to consolidate national spatial dominance and the development discourse.

Urban growth projects are highly symbolic in the political space of Essex. They are not only tools for development, but are also used to carry the national imagination, demonstrate political achievement and guide identity. For example, the ADWA Museum has been described as a "spiritual symbol of national unity' and the Corridor Project as 'Addis Ababa's gateway to the world city".

By projecting and legitimising visions, the government creates a tangible visibility of development and reinforces its discourse with spatial objects. This symbolic politics plays a key role in the production of regime legitimacy, especially in the context of the state's relatively limited financial and administrative capacity, and the UGP is imbued with political and emotional significance beyond its function.Each of these discourses, although very different in form, has a normative role and is an integral part of the discourse of authoritarian government, with utility usually manifesting itself outside the project as a vehicle for the ideology of a given period.

Dominant discourses are not ironclad and are not always fully accepted or internalised. In specific local practices, the implementation of UGPs is often accompanied by a complex process of re-semanticisation, generating multiple negotiations and tensions around planning visions, spatial legitimacy and distributive justice. In the process of sinking, the national discourse faces both the reproduction of legitimacy and the challenge of resistance and counter-narratives.In the field research, some of the residents interviewed interpreted the 'modernisation' project as a process of 'displacement and exclusion', questioning its inclusiveness and local benefits. For example, a trader who has lived around Unity Park for almost a decade said of the park's construction: 'It's not our park, it's for tourists to take pictures of. For her, spatial regeneration does not mean a redistribution of public resources, but rather 'invisible exclusion' under the guise of 'visible development'. This micro-discursive practice reveals the tension between the dominant discourse of the state and the lived experience of the locality, as well as the multiple meanings of 'development' as a discourse of governance. Not only ordinary residents, but also local technical officials often play the role of negotiators and 'translators' in the implementation of projects. Not only do they have to carry out the spatial transformation tasks assigned by the central government, but they also have to respond to local realities of land disputes, relocation and resettlement, social stability, and other issues. As a result, some urban planners have confessed in interviews that in designing UGP projects they have to 'find a compromise between the national vision and local affordability', an act of mediation that reflects the 'gaping operating space' of planning in an authoritarian environment.

In addition, outside the mainstream discourse, some independent media and international observers in Ethiopia have gradually developed a counter-critical approach to the UGP discourse. Local media such as Addis Standard and Addis Fortune have repeatedly pointed out the lack of contractual transparency in large-scale infrastructure projects built by Chinese companies (e.g. the Addis Ababa-Djibouti railway, the 'beautification of Shegele' project and the Oriental Industrial Park), Addis Ababa-Djibouti railway, the 'Beautification of Shegele' project and the Oriental Industrial Park) have been criticised for their non-transparent contracts, unsustainable finances and limited local employment and technology transfer. These criticisms not only challenge the national narrative of 'development success'[ii], but also reflect the fact that there is a lack of transparency and financial sustainability behind the scenes of development projects. They also reflect the asymmetrical power relations inherent in development projects.

Although these critical voices are often subject to political regulation, censorship restrictions and even exclusion from official planning texts, they form the 'echo of marginal discourse' in the ecology of urban discourse and continue to influence public discussions and policy adjustments. These counter-narratives have not completely undermined the dominant discourse of the state, but they have forced it to make compromises and adjustments in practice, reflecting the 'limited space for negotiation' in an authoritarian environment. Ultimately, the UGP project is not a 'linear' process of development, but a field in which multiple forces, discourses and practices are intertwined. The generation of meaning is not predetermined at the outset, but is negotiated, contested and reconstructed in dynamic power relations. It is within these local tensions and negotiations that the true politics of the UGP project are revealed.

Email: betterliubin@zju.edu.cn

Abstract
China's urban development is shifting from expansion to quality enhancement, with urban renewal emerging as a key policy priority. The Zhegong New Village case in Hangzhou presents an innovative resident-funded renewal model that addresses limitations of traditional approaches. Through a "Rules-Roles-Procedures" analytical framework, this study identifies three critical success dimensions: (1) supportive policy environment and favorable economic conditions; (2) collaborative governance featuring government's service transformation and enhanced resident participation; and (3) transparent procedural mechanisms including early engagement and professional evaluations. This model not only reduces fiscal burdens but also redefines responsibility allocation mechanisms, demonstrating significant improvements in both efficiency and social sustainability. The findings provide valuable insights for developing context-sensitive urban renewal models that balance economic viability with community empowerment, offering a replicable framework for China's ongoing urban quality improvement initiatives.

Keywords: Old Urban Residential Communities Resident-Funded Renewal Multi-Agent Collaboration Rules-Roles-Procedures Zhegong New Village

1. Introduction

China's urbanization rate is approaching the inflection point of 70%(Gu *et al.*, 2017), with urbanization entering its second half. Urban development is shifting from "high-speed growth" to "high-quality development"(Cao *et al.*, 2014; Guan *et al.*, 2018), making urban renewal the primary agenda for city development at this stage(Cao *et al.*, 2024; Shen *et al.*, 2024). According to China's Seventh National Population Census data, the country's urban housing stock reaches 33.3 billion square meters, with buildings constructed before 1990 accounting for 8.7% (approximately 2.9 billion square meters) and those built before 2000 representing 27.5% (about 8.1 billion square meters). China faces increasingly heavy pressure to renew aging communities(Liu *et al.*, 2024).

However, amid the downturn in the real estate market pressures, traditional development-oriented demolition-and-reconstruction renewal models and government-led old neighborhood renovations confront severe challenges(Xie *et al.*, 2024). The traditional renewal model, driven by sharing differential land rent through real estate demolition and resettlement, has seen its feasibility significantly decline due to high land replacement costs, making it difficult to meet current urban development needs and urgently requiring innovation and reform. In 2020, the General Office of the State Council issued the "Guiding Opinions on Comprehensively Advancing Urban Old Community Renewal Work," demanding the establishment of a "reasonable cost-sharing mechanism for renovation funds among government, residents, and social forces," rationally implementing residents' funding responsibilities, and actively promoting resident-funded renovations according to the principle of "who benefits, who pays."

In recent years, cities such as Beijing, Hangzhou, and Guangzhou have begun exploring renewal practices led by social forces, where residents actively participate in in-situ reconstruction(Wang *et al.*, 2022). These efforts provide new ideas for resolving urban renewal dilemmas and offer new pathways for improving living environment quality, stimulating effective consumption, and promoting high-quality urban development. Autonomous renewal is not merely simple in-situ reconstruction; its requirements for property rights integration, planning management, fiscal finance, and social governance reforms essentially constitute a comprehensive restructuring of China's spatial governance system and represent important content in the modernization of national governance capacity. Among these initiatives, Hangzhou's Zhegong New Village autonomous renewal project has achieved phased success. It has not only realized resident self-funding, conserving government financial resources, and redefined the division of responsibilities between government and residents in housing improvement and maintenance, but also significantly reduced renovation costs and substantially enhanced renovation efficiency and quality through supply-demand matching.

This paper uses the Zhegong New Village case as a window, combined with multi-agent collaboration theory, to propose a "rules-roles-procedures" analytical framework, attempting to decode the practical pathway and internal mechanisms of autonomous renewal in Hangzhou's old neighborhoods.

2. Literature Review and Analytical Framework

2.1 Paradigm Shift in Stock Land Renewal and Special Challenges of Community Renewal

China's urban community renewal is undergoing a profound paradigm shift. During the early reform and opening-up period under the land finance-driven incremental development model, community renewal primarily manifested as government-led physical space reconstruction and developer-driven commercial projects, exhibiting distinct economic-oriented characteristics(Sun *et al.*, 2025). With the implementation of the new urbanization strategy and the advent of the stock development era(Zhang *et al.*, 2024), renewal philosophies have gradually evolved from "spatial reproduction" to "social reorganization," extending from "physical environment improvement" to "community governance innovation". This transition demonstrates three salient features: a value orientation shifting from efficiency-first to balancing equity and efficiency, operational methods transitioning from large-scale demolition to incremental micro-renewal, and participation structures transforming from government-market duality to pluralistic co-governance. Particularly after the 14th Five-Year Plan proposed urban renewal actions, policy directions have increasingly emphasized historic preservation, equitable public services, and community resilience enhancement, fostering a people-centered, quality-oriented development paradigm(Chen *et al.*, 2016; Chen *et al.*, 2019; Zhao *et al.*, 2024).

The urban renewal process involves complex interactions among government, market, and societal actors(Liu and Zhang, 2024). Governments exert foundational influence through policy formulation and fiscal investment, yet exhibit distinct functional differentiation across administrative levels: central government focuses on institutional design, local governments on policy implementation, while grassroots units handle conflict mediation. Market entities, driven by investment returns, dominate commercial projects but frequently abstain from public-good initiatives with long payback periods. Social stakeholders-including residents and NGO-influence decisions through participatory mechanisms, though their effectiveness is constrained by organizational capacity(Zhuang *et al.*, 2019). These tripartite actors engage in dynamic game theory interactions: governments prioritize policy goals, markets seek profit maximization, and communities emphasize livelihood improvements. Innovative models like Chengdu's Caojialiang self-governance and Shanghai's public-private partnerships demonstrate successful equilibrium-seeking under institutional constraints.

Residential stock renewal faces unique implementation challenges requiring tailored mechanisms. Compared to commercial projects, residential renewals exhibit: 1) complex property rights structures with fragmented ownership, 2) economic infeasibility due to "negative rent gaps," and 3) divergent resident demands regarding facility upgrades(Zheng *et al.*, 2020). Consequently, residential renewal mechanisms rely on blended government-resident financing, grassroots party-building coordination, and synchronous maintenance systems. Current nationwide old neighborhood renovations demonstrate "government-led, community-participated, market-supplemented" characteristics, utilizing special subsidies and shared-cost mechanisms. Persistent challenges including funding sustainability and governance deficits necessitate breakthroughs in property rights systems and financial instrument innovation.

2.2 Public Participation Theory and Research Dilemmas in the Chinese Context

Sherry Arnstein's Ladder of Citizen Participation (1969) establishes an eight-rung typology from "non-participation" to "citizen control," systematically articulating hierarchical levels of public engagement and substantive influence(Varwell, 2022). This framework categorizes participation into three tiers: "non-participation" (manipulation and therapy) as tokenistic power-dominated pseudo-participation; "tokenism" (informing, consultation, placation) representing formalized limited involvement; and "citizen power" (partnership, delegated power, citizen control) signifying genuine decision-making authority(Lane, 2005). The theory reveals participation's essence as power redistribution, providing analytical tools for assessing participation quality across political systems. Subsequent theoretical developments evolved along three trajectories: 1) Hierarchical refinement, exemplified by Connelly's 12-level "participation continuum" emphasizing digital-enabled "virtual participation"; 2) Quantitative metrics, notably the World Bank's "Participation Intensity Index" employing 21 indicators across five dimensions for cross-national comparison; 3) Critical reconstruction, where scholars like David Harvey critique the theory's insufficient attention to capital's distortion of participatory processes,

advocating integration with "spatial justice" theory(Innes and Booher, 2004). Notably, global urban renewal practices since the 21st century demonstrate that "citizen control" remains rare in large-scale projects, with gradational government-led participation predominating.

China's urban public participation typically originates at the community level, emerging from governance issues concerning communal affairs. It is initiated by appeals to individual, collective, and localized public interests, mobilized by influential stakeholders, and expands from neighborhood committees to grassroots governmental agencies – thereby broadening channels for orderly political participation in grassroots governance. Community participation constitutes a governance behavior wherein resident groups and local authorities employ deliberative interaction, interest articulation, and public service provision under institutional, regulatory, and cultural frameworks to safeguard civic rights and communal interests in public affairs.

Arnstein's theory encounters three adaptive challenges in China's localization context: First, China's "strong government–weak society" tradition diverges from Western civil society foundations, creating disjuncture between formal participation and substantive impact during model transplantation. Second, community renewal complexities necessitate transcending linear participation models – evidenced by Beijing's "Jinsong Model" proving effective participation requires a government-market-resident "triangular governance structure." Research reveals China's community participation exhibits "embedded development": multi-stakeholder co-governance under Party leadership (e.g., Shanghai's "Red Property Management"); closed-loop procedures encompassing "demand collection-joint deliberation–implementation oversight-impact evaluation" (Chengdu's Caojia Alley model); and legal frameworks anchored in the Urban Residents Committee Organic Law. Third, while Carol Pateman's participatory democracy theory prioritizes individual rights, Chinese communities emphasize collective interest balancing. Consequently, "co-decision" concepts transform into "deliberative consensus" models during localization, exemplified by Guangzhou's Yongqing Lane renewal adopting "neighborhood covenants" to reconcile private rights and public welfare. Successful localization cases exhibit three characteristics: public-interest orientation at the value level, incremental renewal strategies operationally, and institutionalized participation channels at the governance level.

2.3 Analytical Framework: Institutional Foundations for Public Participation in Urban Renewal

Multidimensional practices in urban renewal reveal that the localization dilemmas of public participation and governance efficacy fundamentally stem from structural deficiencies in institutional foundations. The adaptation of Western participation theories in China exposes a core contradiction: when power allocation models encounter the traditional "strong government-weak society" governance structure, purely technical transplantation fails to achieve substantive empowerment; when capital logic intervenes in community renewal, value conflicts emerge between market entities' profit-seeking motives and the inclusivity of public welfare; when multiple stakeholders enter deliberative arenas, communication barriers arise between professionalized discourse systems and residents' quotidian demands. These structural contradictions manifest acutely in residential renewal projects-Chengdu's Caojia Alley redevelopment stalled through 107 failed negotiations due to fragmented property rights, while Guangzhou's Yongqing Lane commercial development ignited disputes over local cultural preservation, both reflecting trust crises rooted in institutional supply gaps(Ye *et al.*, 2021).

Essentially, the validity of public participation depends not merely on participation ladder gradations but crucially on institutionalized capacities enabling multi-stakeholder collaboration, requiring three safeguards: normative establishment of legal frameworks defining rights and responsibilities to avoid "tokenistic participation" traps; cultivation of professionalized stable actor networks to balance diverse interests; and operational design of predictable procedural mechanisms to reduce deliberation costs.

Therefore, transcending the conventional "government-market-society" tripartite analytical paradigm becomes imperative to focus on systemic institutional construction. This paper proposes a "Rules-Roles-Procedures" framework where rules encompass urban renewal legislation, technical standards, and certification systems; roles denote key institutional actors operating predictably through reputation and expertise, including renewal implementers, expert decision-making systems, and independent social intermediaries; and procedures refer to regularized action plans such as standardized renewal protocols, robust participation/supervision mechanisms, and full-cycle information disclosure.

Collectively these constitute stabilized standardized shared expectations: roles and procedures directly form explicit expectations while rules indirectly shape expectations through institutionalizing roles and procedures. Together they establish the institutional bedrock for trust-building in urban renewal.

3. Study Area Context and Key Challenges

3.1 Background of Hangzhou's Urban Renewal

Hangzhou's urban renewal process exhibits distinct phased evolutionary characteristics. In the early 21st century, the city pioneered old-town renewal projects focused on improving living environments, primarily addressing aging infrastructure and public service shortages. With accelerated urbanization after 2008, efforts shifted to urban village redevelopment through spatial restructuring to enhance urban aesthetics and functionality. From 2015 onward, systematic renewal emerged, with comprehensive neighborhood revitalization as the cornerstone, promoting equitable public services and intensive land use. Entering the 2020s, Hangzhou transitioned to holistic renewal, balancing high-quality economic development with quality-oriented urban enhancement. By 2023, cumulative implementation of 2,498 renewal projects with 48.9 billion yuan in investment had created a dual-pattern emphasizing both scale and demonstration effects.

In governance innovation, Hangzhou progressively established a pluralistic collaborative modern governance system. In terms of actors, it evolved from government-dominated approaches to "government-market-society" co-governance-exemplified by Gongshu District's "community planner" system introducing professional expertise, and Shangcheng District's "resident council" mechanism ensuring public(Innes and Booher, 2004) participation. Methodologically, practices shifted from crude "demolition-reconstruction" approaches to refined quality improvement of existing assets, as seen in Xihu District's "micro-renewal" techniques preserving historic neighborhood character. Strategically, renewal models transitioned from real estate-driven development to sustainable operations, with Qiantang District piloting "renovation+operation" integrated models to balance social and economic benefits. The 2023 Implementation Opinions on Comprehensive Urban Renewal institutionalized tasks like dilapidated housing renewal and neighborhood rehabilitation, marking a new standardized phase.

3.2 Zhegong New Village: Profile and Renewal Challenges

3.2.1 Basic Profile

Zhegong New Village, situated in Gongshu District of Hangzhou, was established in 1983 as faculty housing for Zhejiang University of Technology (ZJUT), representing a typical aging residential community. The complex comprises 13 residential buildings constructed before 2000, with unit sizes ranging from 38 m² to 93 m². The property rights consist of a mix of public housing and privatized public housing, primarily occupied by university faculty and their families. In 2014, four buildings (including Building 67) were professionally assessed as Class C dangerous structures, indicating compromised load-bearing capacity and safety risks. Since 2012, residents had repeatedly negotiated renewal with district authorities. In 2015, the former Xiacheng District government proposed a complete reconstruction plan for all 13 buildings, but it was suspended due to failure to achieve the required 90% resident consensus. Subsequently, resident representatives persistently advocated for renewal through legislative proposals and petitions. After 11 years of efforts, the organic renewal project formally commenced in April 2023 under an innovative "resident-initiated application and demand with government service provision" model. The project achieved key milestones including resident agreements finalized in June 2023, project approval in August, feasibility study endorsement in September, preliminary design completion and resident relocation in October, and construction permit acquisition with demolition commencement in November – setting the "Zhegong Speed" benchmark for Hangzhou's urban renewal. Total investment reached approximately 532 million yuan, with residents contributing about 470 million yuan (88.5%), supplemented by government special funds for old community renewal, elevator installation, and future community development. As Hangzhou's inaugural resident-led renewal pilot, it established a "resident-funded, government-subsidized" renewal paradigm.

3.2.2 Key Challenges

As a typical university-affiliated community, Zhegong New Village exhibits three demographic features: high aging rate (71% aged 60+), high homogeneity (68% retired faculty), and high property rights complexity (public/privatized/commercial housing mix).

First, multi-dimensional conflicts hampered consensus-building. According to official records, significant financial disparities divided the 538 households: owners of 38 m² units faced 360,000 yuan expansion fees under Hangzhou's 2021 pricing standards, while larger-unit owners paid only base reconstruction costs. Community surveys revealed 43% of elderly residents could not afford expansion fees, resulting in polarized support. During June 2023 signing, 132 households (24.5%) objected – 89 being small-unit owners. Furthermore, 35% public housing tenants needed upfront payments of 50,000–80,000 yuan for ownership conversion per municipal regulations, with 62% unable to shoulder dual expenses.

Second, institutional barriers arose from complex property rights. The coexistence of unconverted public housing (35%), privatized public housing (60%), and commercial housing (5%) created complications. Twenty-eight public units had unresolvable historical ownership issues per real estate registry records. Area expansion policies triggered disputes: while provincial guidelines allowed purchasing ≤20 m² at 18,000 yuan/m², 41% residents deemed this higher than the neighborhood's 12,000 yuan/m² market average. Ownership allocation of new underground parking spaces (231 added to original 82) also caused conflicts, with ground-floor residents claiming priority rights.

Third, financial sustainability concerns persisted due to an inverted pyramid funding structure. Residents bore 88.5% (471 million yuan) of total costs. Owners of 38 m² units faced combined fees of 739,000 yuan – equivalent to 9.7 times their average annual income. Twenty-seven low-income households could afford no payments, with compensation only permitting 16 m² housing purchases in remote suburbs. The requirement for an initial 60% payment severely strained cash flows for over half of residents relying on housing fund withdrawals.

4. Analysis and Discussion

4.1 Changes in the Environment

4.1.1 Changes in Political-Economic Environment

The advancement of self-renewal in Hangzhou's old residential communities first stems from macro policy guidance and shifts in local fiscal models. Since 2020, national policies such as the Guidelines on Comprehensively Promoting Urban Renewal in Old Residential Districts have explicitly required establishing a sustainable renewal mechanism of "government guidance, market operation, and public participation." As a common prosperity demonstration zone, Zhejiang Province pioneered a fiscal fund "phase-out" mechanism, with provincial urban renewal special funds decreasing by 37% in 2023 compared to 2021, forcing local governments to innovate financing models. Hangzhou achieved breakthroughs through three key measures: first, establishing a "shared renovation cost" mechanism, exemplified by the Zhegong New Village project where residents bore 60% of construction costs, government subsidies covered 30%, and enterprises conceded 10%; second, innovating the "renewal unit" land policy, allowing increased floor area ratio post-renovation to generate value-added benefits for cost balancing; third, issuing China's first "special urban renewal bond," with Shangcheng District raising ¥1.26 billion through this channel in 2024. This transformation effectively avoided government debt risks from traditional shantytown redevelopment, reducing Hangzhou's government debt ratio by 4.2 percentage points in 2024 compared to 2021.

4.1.2 Socio-Cultural Environment Changes

Increased resident agency consciousness and improved community governance systems formed the social foundation. A 2023 survey by Hangzhou's Housing and Urban-Rural Development Bureau revealed that 68% of residents in core urban old communities held bachelor's degrees or higher, with average household financial assets reaching ¥2.87 million, driving strong demand for asset-value preservation. In the Zhegong New Village case, a resident-initiated renewal committee achieved a 98.4% signing rate after 11 months of consultations with all 252 households—setting a record for Hangzhou's renewal projects. This high compliance resulted from three mechanisms: First, the "sunshine disclosure" system requiring three rounds of community hearings for renovation plans; second, the "tiered reward" policy granting 5%–15% area incentives to early-signing households; third, the "objection negotiation" platform implementing individualized solutions (e.g., "property-right exchange + rental subsidies") for seven disadvantaged households. Notably, integrating community renewal with "Future Community" initiatives completed 56 standard installations (e.g., elevators, smart security systems) by 2024, directly enhancing resident satisfaction.

4.1.3 Transformation of Urban Renewal Concept

A paradigm shift from "development-oriented" to "operation-oriented" reshaped value assessment frameworks(Ouyang *et al.*, 2025). Hangzhou's 2022 Urban Renewal Action Plan established the "Three No's Principles": no large-scale demolition, no destruction of historical features, and no floor-area ratio increases for resource overdraft. Three implementation pathways emerged: For brick-concrete structures built before the 1980s (23% of total inventory), adopting "structural reinforcement + functional implantation," such as converting textile factory dormitories in Gongshu District into cultural-creative spaces; for frame-structure buildings constructed in the 1990s (61%), implementing "comprehensive refurbishment + facility upgrades," exemplified by photovoltaic roofs and rainwater recycling systems in Cuiyuan area; only Grade-D dangerous buildings (16%) underwent reconstruction. Crucially, Hangzhou established a "whole-life-cycle" revenue assessment model incorporating 20 years of operational income into scheme evaluations, shifting social capital from "quick profits" to "long-term operation."

4.1.4 Innovations in Planning Policy Support

Systematic institutional breakthroughs provided implementation safeguards. Hangzhou created a "1+4+N" policy framework: "1" refers to the 2023 Hangzhou Urban Renewal Regulations, legally affirming self-renewal legitimacy; "4" comprises specialized documents on planning management, land policy, funding mechanisms, and technical standards; "N" denotes district-level implementation rules. Operational innovations included: First, a "dual-track" approval process reducing processing time from 96 to 15 days for sub-3,000 projects via a filing system; second, a "renewal land price" system valuing land at original-use prices (40–60% below auction prices); third, an "architect responsibility system" requiring design institutes to oversee 10-year operations. These innovations shortened average project cycles from 3.2 to 1.8 years, with 2024 new project launches increasing 217% year-on-year.

4.2 Transformation of Participant Roles and Division of Labor

4.2.1 Government Entity: Paradigm Transformation from Administrative Dominance to Collaborative Service

The Hangzhou municipal government achieved a systematic shift from unitary management to diversified services in urban renewal, with core changes manifested in three dimensions: in organizational structure, establishing a three-tier governance system of "leading group decision-making - task force coordination - local government implementation," integrating approval authorities of 12 departments to create a "one-stop urban renewal" comprehensive window, reducing project approval time from an average of 96 days to 15 days; in institutional innovation, promulgating the Hangzhou Urban Renewal Regulations and 11 supporting rules, establishing the legal validity of "self-renewal agreements" to provide institutional guarantees for projects like Zhegong New Village; in funding mechanisms, forming a diversified financing model of "fiscal guidance + market participation + resident sharing," with the proportion of direct municipal fiscal investment decreasing from 62% to 38% in 2024 while simultaneously increasing social capital participation to 41%. This transformation shifted the government role from "omnipotent manager" to "rule-maker" and "service provider," achieving 100% nearby relocation for elderly residents through special fund support in Zhegong New Village while establishing transitional rent compensation mechanisms to protect other residents' rights.

4.2.2 Resident Entity: Identity Evolution from Policy Object to Governance Subject

Resident groups achieved role upgrading through triple mechanisms: legally, the Hangzhou Urban Renewal Regulations granted property owners plan joint-review rights and renovation supervision rights, enabling Zhegong New Village residents to possess substantive veto power over key indicators like FAR adjustments, with the exercise rate of this right decreasing from 17% in 2019 to 3% in 2024; implementationally, establishing a "sunshine disclosure + tiered incentives" system requiring all renovation plans to undergo three rounds of community hearings while granting 5%-15% area rewards to early-signing residents; in rights protection, constructing a dual-track protection system for "property owners - tenants," covering 1,327 tenant households through rent differential compensation and transitional relocation measures, with cumulative provision of 12,000 units of guaranteed rental housing by 2024. This shift transformed residents from passive recipients into governance subjects with decision-making, supervision, and benefit-distribution rights, as demonstrated in Zhegong New Village where residents determined 7 unit-type plans and 468 parking space allocation standards through self-renewal agreements.

4.2.3 Market Entity: Business Logic Restructuring from Short-Term Development to Long-Term Operation
Developers and operators underwent profound business model transformations: in operational mechanisms, adopting 15-20 year franchise rights models, such as Binfen Community operators allocating 30% of Δ0.8/m²/ month property fees specifically for public facility maintenance to form sustainable capital cycles; in design innovation, implementing "community planner" residency systems where 74% of projects adopted participatory design methods, with Zhegong New Village requiring 7.3 rounds of plan modifications to finalize 7 unit-type ratios; performance evaluation shows every 10% increase in market entity participation reduces post-project complaint rates by 6.2 percentage points. This transformation propelled market entities from traditional "development-sales" models to "investment-operation" models, evidenced by Zhegong New Village's design institute achieving 65-117 unit gradient configurations through customized plans while reserving public service spaces for elderly care and fitness.

4.3 Clear Rules
4.3.1 Equity Dimension Analysis
Zhegong New Village embodied the integration of procedural justice and substantive fairness in its housing replacement rule design. The core replacement formula "old unit's internal area ÷ new unit's usable area ratio" ensured precise property area conversion; the benchmark unit price of ¥1,350/ referenced Hangzhou's 2019–2021 average renovation cost for old communities, validated by third-party auditors as market-reasonable. A minimum 53 guarantee standard covered all households originally below 48, with fiscal subsidies bridging 23% of the cost gap. The 20 expansion policy adopted a "graded pricing" mechanism, where the ¥34,520/ assessed price deviated within 8% from surrounding commodity housing prices and allowed installment payments to ease resident burdens. This "basic guarantee + market-oriented" dual-track design prevented post-renovation living standard downgrades while providing a legal pathway for improvement needs.

4.3.2 Independence Dimension Verification
The project established a "tripartite checks-and-balances" decision-making supervision system: the Resident Self-Renewal Committee drafted proposals, the subdistrict office acted as a neutral procedural supervisor, and the District Urban Development Group solely served as the construction agent. Key stages implemented "double-blind review," such as anonymous submissions of unit layout designs by seven design institutes, with resident representatives voting without knowing designers' identities. Third-party evaluations showed a 79% resident opinion adoption rate across 213 consultation meetings, with no forced voting or selective listening. Notably, 13 building representatives were elected through competitive voting, with candidates signing Conflict of Interest Commitment Letters requiring disclosure if relatives contracted project work.

4.3.3 Transparency Implementation Pathway
Information disclosure adopted an "online + offline + mobile" full-channel model. Fund management followed a "dual-account" system: ¥470 million in resident-raised funds underwent bank-supervised account custody, with every expenditure requiring tripartite co-signatures from the Resident Self-Renewal Committee, subdistrict office, and auditors. Key milestones like construction drawing reviews invited on-site supervision by 5% of resident representatives with signed confirmations. A "objection-recheck-arbitration" three-tier mechanism resolved disputes, with all 17 area determination conflicts settled through third-party remeasurement.

4.3.4 Representativeness Safeguard Mechanism
A "one representative per building" system ensured all 13 buildings' differentiated needs entered decision-making. Representatives were selected via "open nomination + rotational duty," with one-third rotated quarterly to prevent power consolidation. Critical decisions set a "dual 95%" threshold: resolutions required 95% attendance and 95% approval, with 13 actual votes averaging 98.6% approval. For elderly residents, a "voice broadcast + proxy participation by children" system enabled full-process engagement for 32 solitary seniors. Post-project evaluation showed ≤7% satisfaction gaps in scheme fairness across income groups.

4.4 Standardized Procedures
The project established physical consultation points equipped with self-service kiosks in community rotundas according to Gongshu Release's November 2023 report while Hangzhou Housing Bureau released 32 policy interpretations through the "Gongshu Urban Renewal" official account; The two-stage lottery system for unit selection implemented the first-round supervision by Hangzhou Notary Office per Gongshu Housing Bureau's

January 2024 Selection Announcement with the second round executing published unit-type price tables as confirmed by Zhejiang Online in March 2024; Zhejiang University of Technology's April 2024 disclosure indicated 12 architectural experts participated in quality supervision while Hangzhou Construction Quality Safety Supervision Station records showed 63 rectification notices issued; Hangzhou Development and Reform Commission's December 2023 approval document set resident contributions at ¥1,350-1,580/Δ and Transparent Real Estate Network's January 2025 data demonstrated a 58% post-renovation secondary housing price increase.

5. Conclusions

5.1 Main Findings

This empirical study of Zhegong New Village reveals the unique mechanism of public co-production in China's urban renewal. The research identifies a distinctive "top-down meets bottom-up" model under China's centralized governance and underdeveloped civil society, differing from Western grassroots activism and traditional administrative-led approaches. The project established innovative implementation principles ("resident-led, government-guided, construction department-propelled, subdistrict-executed, construction entity-accountable") and a shared funding mechanism combining resident contributions with government subsidies. The success stems from unique participant traits: as a university faculty community, residents' high education levels, stable pensions, and strong community attachment formed essential social capital. These enabled technical empowerment, democratic consultation, and efficient fundraising. Three governance breakthroughs emerged: government transitioning from omnipotent regulator to rule-maker; resident participation evolving from token consultation to substantive co-decision; implementation shifting from campaign-style to standardized procedures. This reflects both institutional supply since 2013's governance modernization and rising civic awareness. Limitations include replication barriers: social capital prerequisites; institutional adaptation costs (policy breakthroughs); technical capacity demands While demonstrating humanistic values, mature mechanisms require further development in evaluation standards decision tools, and dispute arbitration.

5.2 Implications The project demonstrates a viable path for community-led renewal within China's governance system, establishing a "government-market-society" synergy. Key insights include institutional clarification of "resident-led/government-guided" frameworks through 12 supporting policies, suggesting future improvements in land development rights trading and dynamic property valuation standards; procedural innovation via the "two-stage lottery + blockchain" model proving transparent decision-making benefits from full documentation disclosure and third-party arbitration; and a replicable triple empowerment system granting residents legal decision-making rights, technical advisory support, and professional training. The "five-party responsibility list" achieved precise state-society interface, providing developing nations a "controlled autonomy" reference. Challenges like heterogeneous needs necessitate dynamic interest mediation through property swaps and tiered subsidies. Deeper institutional innovation requires land value recapture mechanisms via property tax standards and public facility feedback policies to sustain community benefits. This "policy pilot-local adaptation-diffusion" gradualist approach aligns with China's governance logic while contributing global solutions.

Abstract
In the current era of intersecting global crises, crisis discourse has evolved to encompass holistic and inclusive frameworks. Terms such as "planetary crisis," "Anthropocene crisis," "Capitalocene crisis," "polycrisis," "meta-crisis," "cumulative crisis," and "technological crisis" reflect the multidimensional nature of these challenges. These crises manifest across multiple scales and generate profound social, political, economic, and spatial transformations. This study takes the 2008 global crisis as a paradigmatic moment and examines the social movements in Turkey that have catalyzed radical spatial and political change. It investigates how actors operating at different scales have responded to spatial interventions, the dynamics of cross-scalar interactions, the spatial gains achieved through these struggles, and how these gains have reshaped the meaning and character of space.

Keywords: Governance, scale, Cross-Scale transactions, commons

1.Beyond Scales

Brenner describes the crises that capitalism entered after the 1970s as "creatively destructive" and endorses Lefebvre's concept of explosion. He emphasizes that restructuring at all spatial scales is implemented through processes of "destruction and creation" (Brenner, 2003). These practices are referred to as "restructuring," but these processes are unstable and polarizing. Neoliberalism's fundamental restructuring slogan is carried out through the creation of space, capital, and hegemonic spaces. This is done through ideas such as "localization, glocalization, decentralization, expansion of spatial networks, new regionalizations, and learning regions," as well as through practices involving these ideas. Such terms and practices, including those that place socio-spatial restructuring processes at the geographical level within a hegemonic perspective, have been identified (MacLeod & Goodwin, 1999; Swyngedouw, 2004).

In urban space debates, the scale of the city reflects the material organization of capitalist processes. Urban scale, shaped by diversification under capitalism, gains meaning not in isolation but through its relationship with broader geographical scales (Giordano, 2003). Today, rural areas are increasingly framed as resources serving urban functions. The urban-centric face of capitalism masks extractive operations—mines, landfills, and fields—now restructured as rural production zones (Cash et al., 2006).

. Modern capitalism operates across multiple scales—local, regional, national, and global. These scales are not fixed; rather, they are shaped by contested political and economic relations. The social movements that emerged in the 1970s were, in essence, movements that challenged these scales, opened the way to produce alternatives for restructuring, and introduced a new dimension to the debate on scaling (Brenner, 2019). The issue of scale has been a subject of discussion in various disciplines of critical urban studies since the 1990s, with a focus on socio-spatial relations. Castells (1977) conceptualizes the city as a "collective consumption space," while Baudrillard (2017) defines it as a "showcase for consumption objects," a stage for simulation and hyperreality. Despite their divergent theoretical approaches, scholars who conceptualize cities as sites of consumption posit that urban space constitutes more than merely a physical structure; rather, it is a social arena in which economic, cultural, and social relations are shaped. Consequently, it is imperative to conceptualize space as the aggregate of social relations and processes, necessitating the adoption of a socio-political perspective in this regard. Discussions regarding scales are generally defined as "local, regional, national, global," and this definition expresses the spatiality of capitalist production relations and these relations. These spatialities establish connections between

1 This study was prepared based on the initial findings of the doctoral thesis titled "Urban Space and Commoning Practices: Examples From Turkey And Spain," which was prepared at Akdeniz University, Faculty of Architecture, Department of Urban and Regional Planning, under the supervision of Prof. Dr. Hilal Erkuş. This paper contains early-stage findings from doctoral research and is intended solely for presentation purposes at [AESOP Congress, 2025, Istanbul]. It will not be published elsewhere in this format.

disparate geographical regions due to the heterogeneity of production activities, thereby exacerbating existing inequalities across geographical areas (Termeer et al., 2010; Gibson et al., 2000). Consequently, the differentiation and inequalities between production and consumption spaces both differentiate and expand scales (Smith, 2017). As the situation progresses, diverse forms of engagement emerge at both the national and local levels. Conducting analyses based on specific geographical scales results in the rejection of dynamic processes involved in these forms of engagement. The rejection of these forms of interaction has been demonstrated to contribute to the escalation of conflicts at various levels. For instance, national policies restricting local policies, and place-specific dynamic factors have the potential to intensify existing conflicts. Because of this relationship, spaces become a shared arena for these conflicts (McCann, 2016).

Crises and conflicts that are caused directly by human activity at different spatial scales have global impacts. Neil Brenner and Christian Schmid (2014) identify " planetary urbanization" as the primary cause of these issues and propose the implementation of multi-scale governance models as a solution to address these spatial crises and conflicts. The most significant roadmap for creating this alternative is predicated on the spatial and political gains achieved through social struggles. The challenges encountered in shared spaces have been shown to offer a novel spatial perspective and a new ontology of politicization in the creation of this roadmap and the development of a new alternative (De Angelis, 2017). In this novel ontology, relationality, processes, and inquiries concerning human-nature relations are rendered accessible through a "multiple perspective" (Caffentzis & Federici, 2014). The concept of "commons," which emphasizes inter-scale and even inter-level interaction and reciprocity, offers an important conceptual framework and highlights the "use value" in all spatialities (Akbulut, 2018).

2.Commons and Scales

The concept of the commons entered academic discourse with Hardin's (1968) "The Tragedy of the Commons," which argued that shared resources such as forests, oceans, and pastures are inherently prone to overuse unless privatized or nationalized. Ostrom (2002) challenged this view, demonstrating that local communities often develop effective, context-specific governance models and that problems typically arise from external interventions. She framed commons as spaces where collective rights and decision-making emerge, constituting a sphere beyond conventional public–private binaries (Angelis & Harvie, 2017). As such, commons became a conceptual response to complex environmental challenges involving multi-level governance (Bakker, 2007). The underlying cause of this conflict stems from the efforts of various actors, such as institutions, community interests, political identities, and different civil society organizations, to participate in these processes (Brenner, 2019). A subset of these initiatives prioritizes safeguarding the space and the human and living communities that collectively constitute the environment. A secondary set of initiatives underscores the utilization value of the space to maximize its economic return.

Critical approaches extend beyond Ostrom's bounded definition, drawing on Lefebvre's (2015) concepts of "transforming life by transforming the city" and the "right to the city"—an assertion of society's collective authorship of space (Caffentzis & Federici, 2014; Angelis & Harvie, 2017; Stavrides, 2019). Within this literature, the commons is understood not merely as a resource or an economic alternative, but as a political project enabling social reconstruction and cross-scalar interaction. Within this literature, the commons is understood not merely as a resource or an economic alternative, but as a political project enabling social reconstruction and cross-scalar interaction.

The idea of commonality shows how a group works together. It also shows the important parts of a group's life and living space. The whole group can take part in decisions about these things (Bianchi, 2019: 80). In social theory, space is generally viewed as the ground for action and is treated as fixed and static. At this stage, time is regarded as an independent variable, while space is defined as a dependent variable. In social theory, Lefebvre redefines this meaning by approaching space as a process and revealing the dialectic between the social and the spatial. Lefebvre (2014) defined the spatial triad, referring to absolute space, sacred space, historical space, abstract space, contradictory space, and differential space. He studied these types of space through periodization, addressing changes in modes of production over time.

The historical process is defined as a combination of building blocks, not as the end of one period and the beginning of another.Common space is defined as an "alternative" social space that intersects with these processes and emerges in response to spatial practices during moments of crisis (Dardot & Laval, 2018).

Theorists of spatial scale argue that scale encompasses more than spatial or temporal metrics; it also refers to jurisdictional, institutional, and epistemic dimensions in today's interconnected world (Cash et al., 2006; Termeer et al., 2010; Young, 2002). Social movements defending the commons operate across multiple scales, revealing that scale is not merely a geographical construct, but a political terrain shaped by governance dynamics and actor relations (Swyngedouw, 2004; Brenner, 2004)

Defending the commons typically begins at the local level, grounded in local knowledge (De Angelis, 2012). Yet such localized organization often links with national and global networks as struggles intensify and institutional pressure grows, forming a multi-level political transaction space (Cash & Moser, 2000). The widely cited principle of the commons—"belonging to no one and yet belonging to everyone"—captures the motivation behind these cross-level interactions (Caffentzis & Federici, 2014). This networked, upward scaling fosters socio-political spaces rooted in community rather than capital, enabling the reclamation of space and the transfer of public goods and commons governance to local actors (Berkes, 2002). In this governance model, or practice of commoning, central and local governments are expected to operate independently of market forces, with decisions shaped by active local participation. However, upward involvement remains essential to preserve the heterarchical and self-managed nature of the commons, and to ensure lasting institutional outcomes (Brenner, 2019; García-López et al., 2021; Cash et al., 2006; Harrison, 2006).

3.Fields and Methods of the Study

The study examined social movements (rural and urban) carried out in Türkiye on different scales in 2008 and thereafter, as well as the actors of different scales with whom these movements established relationships during the process of achieving their gains. To establish the study's scope, a media scan was conducted from 2008 to 2023 using the keywords "protest, struggle, urban movement, and environmental action." This scan also encompassed related terms such as "resistance, action, and activism," drawn from the digital archives of newspapers offering diverse perspectives, including liberal, right-wing, and left-wing viewpoints. Consequently, these scans have led to the identification of movements that have been met with public acclaim and have achieved success. The following examples illustrate these findings: A multitude of social movements have emerged in opposition to various development projects, including those involving the construction processes in Validebağ Grove, the planned mining activities in Kazdağları, the Çeşme Tourism Project, the Gerze Thermal Power Plant, the Düzce Hope Houses Cooperative, the Alpu Coal Thermal Power Plant, and the cooperative movement initiated by the BÜKOOP Consumer Cooperative concerning the spatiality of food.

A total of 125 interviews were conducted with local people, experts (planners, lawyers, academics, architects, doctors, engineers), NGOs (local, national, regional, and global), and local governments through semi-structured interview forms. These interviews were conducted directly at the sites between April 24, 2024, and May 28, 2024. The qualitative data were analyzed manually. Interview transcripts were read repeatedly to understand the narratives. Recurring patterns, frames, and configurations were identified. These themes were then categorized around key conceptual axes such as interaction across scales, commoning practices, governance dynamics, and spatial gains. The comparison across seven cases allowed for tracing similarities and divergences in coalitions, resistance, and scalar politics. An interpretive model guided the analysis to uncover the embedded meanings, spatial strategies, and power dynamics articulated by actors.

4.Findings and Discussion

4.1.Social Movements Against Development in Validebağ Grove

Validebağ Grove is one of the last remaining green spaces in Istanbul's dense urban landscape. It is a first-degree natural protected site that hosts numerous historical structures (Akyıldız, 2019). However, it has been targeted for development under various projects, including religious complexes, parking areas, housing, and a "nation's garden." For the past 26 years, the local residents, professional chambers, environmental organizations, activists, academics, and experts from various disciplines have opposed these spatial interventions, demanding the preservation of the grove's natural and cultural heritage. Throughout this lengthy struggle, collective practices have emerged, including prolonged vigils, events, forums, open-air classes, and spontaneous conversations at

petition stands, which have contributed to the commoning of the grove. Local actors integrated the protection of the grove and the capacity to swiftly respond to threats into their daily routines. After many years of legal proceedings, the public struggle ultimately prevailed. The Validebağ Grove movement is a significant example of defending the use value of a common space and reconstituting space as a socially produced entity. The ongoing struggle against various interventions has fostered an upward scaling of the commons through interactions among neighborhood, judicial, and global-level actors.

4.2.Boğaziçi University Members' Consumer Cooperative (BÜKOOP) — Istanbul

The Boğaziçi University Members' Consumer Cooperative (BÜKOOP) is an initiative that emphasizes the spatial nature of food, asserting that the local and spatial aspects of food production and consumption generate a commoning relationship. As a consumer cooperative, BÜKOOP organizes collective production and distribution based on principles of "clean, fair, and local food," serving as an important example of shared food and knowledge practices (Saydam ve Kadirbeyoğlu, 2019) Opposing the commodification of food by the capitalist system, BÜKOOP regards food as "common knowledge, common production, and common consumption." For the cooperative, the physical structure known as "BARAKA" had functioned as a common space where knowledge, production, and consumption practices were enacted. However, in 2022, the BARAKA was dismantled by an anti-democratic university administration, forcing the cooperative to relocate. Nevertheless, members viewed the new space as a platform for continuing commoning practices, where food and knowledge are re-produced daily. What began as a practice within the university has gradually developed relationships with producers and institutions at other scales, demonstrating an upward scaling interaction rooted in solidarity across levels.

4.3.Düzce Tenant Homeless Earthquake Victims Solidarity Housing Cooperative - Düzce

In the aftermath of the Düzce earthquake that occurred on November 12, 1999, housing assistance was exclusively allocated to property owners, thereby neglecting to provide support to tenants affected by the seismic event. In response to this inequality and the resulting housing crisis, tenant survivors formed a housing cooperative and initiated a rights-based struggle for housing (Yucak, 2004: 375). The local community constituted the primary actor in this movement, with subsequent participation from various NGOs, academics, and international networks. Following an extended period of legal proceedings, the plaintiffs successfully obtained the rights to allocate land for residential development. The design of the housing units was conducted collaboratively, with all cooperative members participating in the process. The project was constructed through participatory and co-design principles, and its implementation resulted in the creation of physical dwellings as well as the formation of a community-wide practice of commoning. The cooperative's organizational structure was entirely dependent on civil initiative and legal efforts, initially at the local level but eventually evolving into a model of upward scaling. The movement has established a multi-level governance model through both legal and organic ties with actors at different levels.

4.4.Social Movements Against the Gerze Thermal Power Plant – Sinop

A thermal power plant project that was proposed in 2009 in the Gerze district of Sinop aimed to cut down 16,000 trees in a region containing natural protected areas, forests, and agricultural land. The opposition to the project was initiated by the Gerze Municipality and the Yaykıl village leadership, and subsequently received support from villagers, ecological organizations, professional chambers, and NGOs and activists operating at local, national, and international levels(Kaymaz, 2017 ; Aldemir, 2016) Consequently, the project was terminated because of this determined and far-reaching social and legal struggle. A modest resistance outpost, erected on the site of struggle, was transformed into a symbol of collective memory. Subsequently, it was converted into a "resistance museum," thereby becoming a space for shared heritage. The Gerze example elucidates a commoning practice in which the use value of space was defended against market logic that emphasizes exchange value. This upward scaling movement offers a compelling illustration of cross-scalar interaction.

4.5.Social Movements Against the Alpu Coal-Fired Power Plant – Eskişehir

In 2017, the Ministry of Energy and Natural Resources unveiled plans for an underground coal mine project in Alpu Plain, a region distinguished by its exceptional agricultural productivity and situated within Eskişehir. The initiative was endorsed by substantial modifications to the urban planning framework. Local people, farmers, local authorities, NGOs, professional chambers, the Eskişehir City Council, and activists united in opposition to the coal plant, arguing that land is the foundation of life and that this polluting project should be canceled.

After public mobilization and legal proceedings, the project was officially terminated, thereby ensuring the preservation of the agricultural nature of the land(Temiz Hava Hakkı Platformu, 2018). The scientific reports, prepared collaboratively by experts from various fields, along with the detailed public information efforts, created a "knowledge commons" that enabled the space to gain collective value. The Alpu case exemplifies a top-down neoliberal scaling process initiated by the state. However, it also demonstrates a counter-intervention that was carried out through cross-scale collaboration among actors. This movement underscores the potential of commoning in counteracting neoliberal agendas that prioritize exchange value, thereby emphasizing the significance of use value in economic activities.

4.6.Kazdağları: Social Movements Against the Gold Mining Project – Çanakkale, Balıkesir

In 2010, environmental initiated protests gold mining operations near Kirazlı in the Kazdağları region, where approximately 350,000 trees were scheduled to be harvested for cyanide-based extraction. These demonstrations evolved to encompass local people and a diverse array of other stakeholders. The project posed grave ecological threats due to the area's biodiversity and vital water resources (MAD, 2020). Beginning in 2010, the implementation of continuous watch camps, festivals, workshops, and open-air discussions contributed to the preservation of the area, while concurrently facilitating its reconstruction as a collective living space. Legal victories in 2019 led to the project's complete cessation. The Kazdağları case demonstrates that scaling is not confined to upward scaling; it also occurs horizontally and diagonally. It underscores the importance of local knowledge in commoning and demonstrates a multi-scalar defense of the commons supported by international interaction.

4.7.Social Movements Against the Çeşme Tourism Project – İzmir

The Ministry of Culture and Tourism has proposed the "Çeşme Tourism Project," which encompasses approximately 16,000 hectares. This project encompasses natural protected zones, agricultural and pasture lands, and olive groves (TMMOB İzmir, 2020).. This case exemplifies a downward neoliberal scaling process. Local people, professional chambers, national and local NGOs, environmental groups, bar associations, and various experts opposed the project, arguing that it would harm nature, cultural heritage, and the public interest. Concurrent with the ongoing legal and social resistance, archaeological discoveries were made in the area, and a portion of the region was designated as an archaeological site. The area's reclassification as a "cultural and ecological commons" can be attributed to heightened public awareness and collective mobilization. The Çeşme case demonstrates the significance of upward, multi-scalar actor networks in resisting neoliberal downward scaling of state processes and exemplifies their capacity to redefine space.

5.Conclusion

In the social movements examined in this study, it is predominantly local-scale actors who initiate mobilization, while the support of national-scale actors proves crucial throughout the process. At the local level, residents, local NGOs, and local governments (municipalities and neighborhood heads) are typically seen as initiators of social struggles. At the national level, professional chambers and national NGOs play a prominent supportive role. In cases where support from local governments is strong—such as in Gerze and Alpu—success was achieved more quickly. These spaces of success demonstrate an upward rescaling process, while the presence of global actors during and after the process also signals a multi-level rescaling dynamic that includes both upward and downward interactions. The connections established with global actors provide valuable insights into the expanded scope of governance scales and the cross-scalar nature of interactions.

The struggles in rural areas and the involvement of urban actors further validate cross-scalar interactions, revealing that these actors' expectations for urban life align with the principles of sustainable nature and participatory governance. When considering the views of actors in the spaces where success was achieved, it becomes clear that cross-scalar interaction has significantly increased, necessitating multilayered and multilevel forms of governance. The success of these movements is contingent upon their ability to establish networks and reconfigure spaces through the implementation of multi-scalar governance strategies.

Our findings from the field reveal that space is not merely perceived as something to be preserved, but rather as a commons practice that is collectively re-produced and within which social relations are restructured. An alternative mode of organization has emerged, characterized by commoning practices. This framework is characterized by collective organization of decision-making processes, the production and sharing of knowledge, and the subjectification of space as a commons. The scaling processes observed in the cases examined

demonstrate not only upward scaling but also the development of alternative multi-level governance practices, indicating the expansive influence of scale (Young, 2002).

The limitation of local policies by national ones provides a clear indication that cross-scalar dynamics are being disregarded. The lack of attention to place-based (local) knowledge at the national and international levels remains a significant issue (Brenner, 2019). The primary motivation for diverse levels of organizational support for these movements lies in the ability to communicate local knowledge through scientific means to national and international media.

In terms of the legal framework in Türkiye, although there are certain protection mechanisms in place, it is evident that legal authority has been undermined in many areas. The main reasons for this include arbitrariness in the application of law, the politicization of judicial processes, inadequate institutional capacity, and the prevalence of decision-making mechanisms that facilitate market operations at the expense of participatory principles (Bakker, 2007). In contrast, the scale interactions and scalar fluidity created by these social struggles are supported by legal capacity aligned with local actors, expert knowledge and professions that scientifically demonstrate the interconnection between nature and public health, media visibility, international solidarity networks, and the persistent engagement of the public in organized resistance.

Pursuing total volume or efficiency? A study on the coupling pattern of rural population and space: A case study from Huangyan District, Zhejiang Province, China

Zhuyang LIU, Guiqing YANG*

Email: 2330323@tongji.edu.cn

Abstract
Under globalization, rural areas worldwide are experiencing population decline and built-space decay. Traditional rural development theories posit a positive correlation between residential population size and built-space efficiency. Following this theoretical assumption, China's eastern coastal villages should follow the trajectory of rural decline observed in developed nations. However, a paradoxical phenomenon of "quantity reduction with quality enhancement" has emerged in some eastern villages, which cannot be adequately explained by conventional "aggregate quantity coupling" models linking population and built space. This study proposes an "efficiency coupling" theoretical framework, demonstrating that rural systems can maintain vitality through spatial efficiency compensation when quantity balance falters. We identify three underlying mechanisms driving this transition and validate the efficiency coupling model through multi-scale case studies in Huangyan District and Shatian Village, Zhejiang Province. The analysis particularly examines Shatian Village's efficiency coupling mechanisms through two critical dimensions: companionship-based planning and multi-stakeholder co-creation. These findings offer new insights for villages grappling with population loss and spatial decay during urbanization processes.

Keywords: Quantity; Efficiency; Coupling Modes; Rural Residential Population; Built-up Space

Introduction

Under globalization, rural areas worldwide are grappling with dual challenges of residential population loss and built-environment decay[1]. UN-Habitat (2022) data indicates that over half of rural regions have experienced functional degradation since the 21st century, manifested through rising housing vacancy rates, declining utilization of public spaces, and fractured social networks[2]. Scholars such as Gobillon, L. (2003) have further elucidated the mechanisms linking population outflow to rural decline: when residential population density falls below the critical threshold required to sustain built environments, economies of scale in infrastructure vanish, marginal costs of public services surge, and spatial quality enters a downward spiral[3]. This evolutionary trajectory aligns with theories of "shrinking villages" in Europe and North America[4-6], as well as empirical studies on Japan's "marginal settlements" (genkai shūraku) and "hyper-depopulated villages" (kasoka sonraku)[7]. Against this backdrop, addressing the "hollowed village" dilemma and achieving dynamic equilibrium between population and built space has emerged as a pivotal issue for rural development.

Traditional rural development theories posit a positive correlation between residential population size and utilization efficiency of built-up spaces (Woods, 2011)[8]. Under this theoretical framework, coastal villages in eastern China would ostensibly follow the trajectory of "rural demise" observed in developed nations, as evidenced by statistical trends showing continuous reduction in natural village numbers and unidirectional outflow of registered residents[9]. However, intensive field observations reveal counterintuitive spatial practices: in economically vibrant regions such as the Yangtze River Delta and Pearl River Delta, certain villages demonstrate distinctive adaptive renewal capabilities in their built environments despite experiencing negative population growth. Field investigations by Zhu et al. (2022) further corroborate this phenomenon, showing that 43% of sampled villages in the Yangtze River Delta maintained or enhanced built-space utilization efficiency amidst persistent population outflow[10]. This paradoxical phenomenon of "quantitative contraction and qualitative enhancement" challenges conventional population-space equilibrium models, suggesting the emergence of novel systemic balancing mechanisms.

The theory of spatial production provides a critical lens for deconstructing this paradox. Lefebvre's (1984) triadic spatial dialectic posits that when the material function of physical space becomes decoupled from residential population size, dynamic equilibrium within the system can be achieved through the reconstruction of spatial representations[11]. Empirical cases from eastern Chinese villages demonstrate that traditional farmhouses, through functional conversion into cultural-creative spaces, not only preserve their material structures but also reconfigure the social value of built environments (Zhang et al., 2025)[12].

This process of "spatial re-territorialization" (Brenner, 1999) fosters novel coupling mechanisms[13]: despite persistent outflows of permanent residents, the adaptive recalibration of built-space functions alongside periodic influxes of mobile populations sustains or even enhances spatial utilization efficiency (Yunqi Guo, 2024) [14].

Building upon conventional "aggregate coupling" frameworks, this study proposes an "efficiency coupling" theoretical paradigm: rural systems can sustain robust functionality when built-space efficiency compensates for quantitative imbalances. This transformation is fundamentally driven by three mechanisms: First, adaptive retrofitting of rural built environments through the integration of agricultural production spaces with emerging industries such as cultural consumption and e-commerce; Second, innovative preservation and creative reinterpretation of historical-cultural resources, enabling traditional villages to undergo metamorphosis and revitalization; Third, urban creative cohorts, empowered by digital media and social networks, emerging as novel users and critical stakeholders in rural built-space utilization, actively engaging in community co-governance. These mechanisms collectively facilitate "efficiency re-coupling"—achieving enhanced output per unit area through spatial intensification, even as residential population density declines.

This theoretical framework demonstrates three distinctive innovations compared to existing paradigms: First, diverging from Western-centric concepts of rural gentrification (Smith, 2002) [15-16]or amenity migration (Gosnell & Abrams, 2011)[17], the Chinese model reveals unique advantages in government-market collaborative governance. Village collectives, through coordinated land consolidation leasing and joint development with market entities (Zhou, L., 2024)[18], construct hybrid governance structures that transcend institutional path dependence. Practically, the proposed efficiency-coupling framework advances beyond traditional quantitative equilibrium analyses by establishing an efficiency-oriented evaluation system for rural built environments, offering an Eastern perspective to "smart shrinkage" theory (Hollander, 2018)[19]. Methodologically, the study innovatively integrates census data to track demographic shifts, POI data to decode rural functional transitions, and multi-temporal remote sensing imagery (2000–2022) for land-use change detection, thereby developing novel tools for quantifying population-space adaptation. Ultimately, these findings align with China's new-type urbanization and dual-circulation development strategies, while providing actionable insights for resolving the paradox of "population decline versus spatial underutilization" in rural revitalization.

1. Literature Review and Theoretical Framework

1.1 Aggregate Coupling Model

Existing research on the coupling between residential population and built-up spaces predominantly focuses on absolute coupling, which posits that within a defined geographical unit, the total residential population and the scale of built-up spaces must adhere to a "rigid matching" principle. This hypothesis underscores an absolute correspondence between population and spatial capacity, asserting that the number of residents in a specific area must strictly align with the available spatial scale to achieve efficient resource utilization and rational spatial allocation. Deviations beyond established threshold intervals are theorized to trigger systemic risks, including resource mismatches, infrastructure vacancy, and economic decline (see Figure 1).

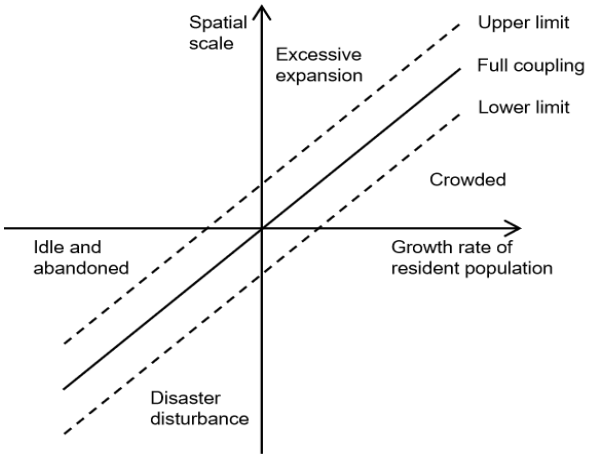

Figure 1 Traditional Resident Population–Built Space Coupling Model

To quantify such imbalances, scholars have introduced the Residential Population-Land Urbanization Index (a), defined as:

$$a = D_R / L_R$$

where a represents the coupling coefficient between residential population urbanization (D_R, annualized change rate of population urbanization level) and land urbanization (L_R, annualized change rate of spatial expansion). An a value of 1 indicates synchronized progression of population and land urbanization; a > 1 signifies spatial overexpansion relative to population growth, while a < 1 reflects population agglomeration outpacing spatial supply. Empirical evidence from international studies suggests that regions with sustained a values exceeding 1.2 consistently surpass the 15% critical threshold for vacant land ratios.

1.2 Efficiency Coupling Model

The absolute coupling model between residential population and built-up spaces establishes linear correlations to provide a quantitative diagnostic framework for urban shrinkage and rural hollowing. However, this paradigm reduces complex human-environment interactions to static correspondences, overlooking dynamic feedback mechanisms between systems and underestimating the built environment's capacity for resilient adaptation under population decline. Consequently, it struggles to explain empirical phenomena in rural China, where sustained population outflows coexist with "contraction without decline" or even "reverse revitalization" outcomes.

Building on traditional "aggregate coupling" principles, this study proposes a theoretical framework for the Residential Population-Built Space Efficiency Coupling Model. The framework posits that spatial efficiency can compensate for quantitative imbalances through resilient adaptation strategies—such as functional repurposing of spaces and adaptive reuse of structures—to maintain or enhance spatial performance despite population loss, thereby sustaining systemic viability in rural areas.

This transformation is fundamentally driven by three mechanisms: First, adaptive retrofitting of rural built environments is propelled by industrial shifts, such as converting agricultural production spaces into cultural consumption hubs or e-commerce facilities. Second, innovative preservation and creative reinterpretation of historical and cultural resources enable traditional villages to revitalize through heritage-led regeneration. Third, under the influence of digital media and social networks, urban innovators (e.g., digital entrepreneurs, cultural creators) emerge as new users and key stakeholders in co-managing rural built spaces.

The efficiency coupling paradigm challenges traditional developmentalist approaches by prioritizing functional transformation and spatial innovation over population retention. Theoretically, it repositions built spaces as dynamic productive assets rather than passive containers. Practically, it offers innovative pathways for rural revitalization that transcend simplistic narratives of reversing population outflows.

2. Research Methodology and Case Selection

2.1 Study Area Overview

This study selects Huangyan District in Zhejiang Province as a representative case, given its significance in reflecting urban-rural transition dynamics in China's developed coastal counties. Statistical data reveal that from 2020 to 2022, the rural population in Huangyan District decreased from 261,745 to 255,150—a reduction of 6,595 residents[20]. However, through spatial functional restructuring and capital infusion, the district had established 30 provincial-level beautiful villages by the end of 2022[21]. This paradoxical phenomenon of "population outflow alongside spatial upgrading" underscores the complexity of rural system restructuring under China's new urbanization paradigm, where demographic decline does not inevitably lead to spatial decay but may instead enhance the coupling efficiency between residential populations and built environments.

For a micro-scale analysis of the "high-efficiency coupling" model between residential populations and built spaces under new media-driven community co-management, this study further selects Shatian Village in Yutou Township as a nested case. Located in the southeastern part of Yutou Township, Huangyan District, Taizhou City, Zhejiang Province, Shatian Village experienced a period of decline after the relocation of the Yutou Township government in the late 1990s. However, leveraging the national Qianwan Project (Thousand Village Demonstration

Project), the village underwent organic renewal under the guidance of Professor Yang Guiqing's team from Tongji University's School of Urban Planning and Architecture. Through adaptive spatial transformations, it introduced diversified economic activities such as conference training, tourism, and rural e-commerce, ultimately becoming a provincial-level demonstration village for beautiful habitation.

2.2 Data Sources and Processing

This study employs a multi-source heterogeneous data fusion analysis approach, integrating three primary datasets: population distribution, spatial elements, and land use. Population census data were sourced from the Huangyan District Population Census Yearbook (2010) and Huangyan District Population Census Yearbook (2020), with permanent population statistics aggregated at the administrative village level and supplementary data compiled at the township level.

POI (Point of Interest) data, a core geospatial dataset in digital mapping, represent specific geographic entities such as restaurants, shopping centers, schools, hospitals, and tourist attractions. Each POI is geocoded as a point feature with attributes including name, category, address, and contact information. The POI data used in this study were extracted from Amap (AutoNavi Map) for the years 2015, 2017, 2019, 2021, 2023, and 2025.

Land use data were derived from the SinoLC1 database developed by Wuhan University, featuring 1-meter resolution and 73.61% classification accuracy. The dataset categorizes land cover into 11 types: Tree cover, Shrubland, Grassland, Cropland, Building, Traffic route, Barren and sparse vegetation, Snow and ice, Water, Wetland, and Moss and lichen. The "Building" category, representing built-up spaces, serves as the focal land use class for this research.

3. Empirical Analysis: A Case Study of Huangyan District, Taizhou City, Zhejiang Province

3.1 Regional-Level Analysis

3.1.1 Residential Population Dynamics

This study systematically examines the spatiotemporal evolution of population distribution in Huangyan District using census data and floating population surveys. The findings reveal differentiated development trajectories in the western mountainous and hilly areas: Beiyang and Ningxi Towns have emerged as secondary population agglomeration centers, leveraging their roles as central towns to establish local growth poles. In contrast, townships such as Yutou and Shangzheng, constrained by topographic limitations, exhibit persistently low population densities.

Temporal analysis (2010–2020) demonstrates pronounced spatial heterogeneity in population mobility. Western mountainous townships generally faced population decline, with Shangzheng Township recording the region's highest negative annual population growth rate. Conversely, Beiyang and Maoshe Townships experienced modest population rebounds, with Maoshe Township showing particularly notable growth trends.

Figure 2c 2010–2020 Permanent Resident Population Change

Figure 2d 2010–2020 Permanent Resident Population Growth Rate
Figure 2 Resident Population Statistics in Huangyan District

3.1.2 Characteristics of Built-Up Space Distribution

This study investigates the evolutionary trajectory of built-up areas in Huangyan District, eastern Zhejiang Province, through three temporal cross-sections (2000, 2010, and 2020), revealing phased characteristics and spatial differentiation patterns in urban-rural restructuring. The analysis demonstrates a persistent expansion of built-up spaces in the study area. Between 2000 and 2010, the central urban built-up areas expanded markedly outward, while township-level built-up spaces largely retained their original spatial configurations, with only localized low-intensity infill development.

Post-2010, spatial expansion exhibited a gradient diffusion effect. The central urban areas continued their outward growth, while key western towns entered a phase of rapid built-up area expansion, forming contiguous development zones. Mid-sized townships displayed edge-permeation growth, with built-up spaces extending outward along existing settlement boundaries to create compact spatial forms. Notably, in ecologically sensitive zones, built-up areas in certain townships showed limited scale increases but adopted discrete patch-like distribution patterns, reflecting spatial adaptation strategies for rural construction under ecological constraints.

3.1.3 Coupling Characteristics of Residential Population and Built-Up Space

An analysis of the coupling relationship between residential population size and built-up area changes in Huangyan District from 2010 to 2020 reveals significant differentiation in coupling patterns across townships: Yutou and Maoshe Townships exhibited basic coupling, with slight synchronized growth in both population and built-up areas at comparable rates. In contrast, Shangzheng, Ningxi, and Tuotuo Townships displayed anomalous inverse revitalization patterns, contradicting field observations of spatial stagnation phenomena such as hollowing-out traditional villages and idle rural homesteads. The study hypothesizes that administrative seat towns may attract rural populations through spatial reproduction strategies—such as concentrated educational and medical resources or industrial park development—while ordinary villages continue to face persistent population outflows. To unravel this paradox, further investigation into the micro-scale dynamics of population and built-up space changes at the village level is required.

3.2 Village-Level Analysis

3.2.1 Development Overview of Shatang Village

Shatang Village in Huangyan District was historically a declining settlement plagued by population exodus. Located in the western mountainous and hilly terrain, the village faced dual constraints of inadequate transportation accessibility and diminished regional economic influence due to its complex topography and peripheral location. Although the historic Taiwei Temple complex embodies local cultural and spiritual heritage, its lack of designation as a protected cultural site hindered the conversion of its cultural capital into tourism appeal. As a traditional agrarian village, its spatial organization initially aligned with small-scale farming practices. However, accelerated regional urbanization triggered sustained outmigration of working-age residents, resulting in a hollowed-out demographic structure dominated by elderly populations, which further eroded community vitality. Public space systems deteriorated into disorder due to insufficient maintenance, with alleyway textures eroded by encroaching vegetation and functional streets devolving into waste accumulation zones.

Since 2013, the Tongji University Huangyan Rural Planning team initiated the formulation and implementation of the Beautiful Village Plan for Shatang Village. During built environment optimization, planners adopted acupuncture-style interventions to repurpose vacant farmhouses into multifunctional community service facilities, preserving villagers' spatial habits while integrating tourism functions. This spatial reproduction strategy effectively revitalized existing architectural resources, enhancing built space utilization efficiency. As environmental quality improved, the village gradually integrated into the regional tourism network, leveraging its strategic position as a key node in the Rou River Scenic Area to attract emerging industries such as educational tourism and cultural innovation.

3.2.2 Coupling Characteristics of Residential Population and Built Environment in Shatang Village

As of the end of 2023, Shatang Village comprises 300 households with a registered population of 1,074. Between 2019 and 2023, the village's registered population exhibited a gradual decline. According to the Seventh National Population Census, individuals aged 21 or younger account for 22% of the total population, while those aged 60 or older represent 11%.

In 2023, the village's operational income reached ¥1.52 million, with collective income amounting to ¥786,100. The per capita annual income of villagers in 2022 was ¥20,000. The village currently hosts eight enterprises specializing in plastic products, cardboard packaging, daily goods, agritourism, and agricultural products, alongside 24 convenience stores and 11 restaurants. A development model led by the Rural Revitalization Academy, managed by professional teams, and operated with collective village equity has been established, generating over ¥200,000 in annual revenue and driving sales of local agricultural products exceeding ¥15 million.

Shatang Village has cultivated a robust cultural tourism industry. Anchored by the Rou River Scenic Area (4A-rated), the village now includes one hotel (Zhenshan Hotel Rou River Branch), two boutique guesthouses (Mountain Letters·Grain Lodge and Xiaoqi Homestay), one bar, two bookstores (Sanjing Book House and Rural Study), one restaurant (Family Restaurant), two cafés (Wangchuan Coffee and Dounai Coffee), and seven retail outlets (two convenience stores, three steamed bun shops, one△△△[traditional rice cake shop], and one rice wine shop). In 2023, the village received over 1.1 million tourists (Figure 3).

Figure 3 Spatial Distribution of Projects in Shatang Village

An analysis of residential population dynamics and built environment utilization efficiency reveals that over the past decade, despite the persistent decline in permanent residents due to urbanization, the functional efficiency of built spaces has paradoxically increased. This inverse evolution of population-space efficiency challenges traditional coupling models, which posit a linear correlation between population size and spatial utilization—where population shrinkage should theoretically reduce efficiency. Field investigations, however, demonstrate that through functional repurposing and spatial reproduction of vacant rural dwellings, traditional residences have been transformed into hybrid-use spaces, including cultural exhibition halls, maker workshops, and homestay clusters. These interventions have significantly enhanced the frequency of use and service capacity per unit of built space. Consequently, this "inverse revitalization" scenario aligns more closely with the residential population-built space efficiency coupling model proposed in this study.

3.2.3 Analysis of Efficiency Coupling Mechanisms in Shatang Village

β1βCompanion-Style Planning

Since 2013, the Tongji University Huangyan Rural Planning team has formulated and implemented the Beautiful Village Plan for Shatang Village. By systematically assessing the distribution patterns and structural conditions of underutilized public facilities, the plan strategically integrates future village development with the adaptive reuse of existing infrastructure, anticipating new functional demands under evolving urban-rural dynamics.

Over a decade of implementation, the village has acquired new socioeconomic roles while preserving its original spatial texture and architectural heritage. Eight vacant public facilities in the Old Street Block—all constructed during the People's Commune era (1960s–1980s)—have been revitalized and repurposed (Figure 4). For instance, a disused grain storage station was transformed into a homestay, a derelict veterinary station became a tourist service center, and an abandoned township administrative building was converted into a boutique hotel. This approach balances preservation and adaptation, retaining the village's historical memory while revitalizing its physical fabric. Such interventions not only safeguard cultural continuity but also create spatial prerequisites for attracting new demographics and economic activities.

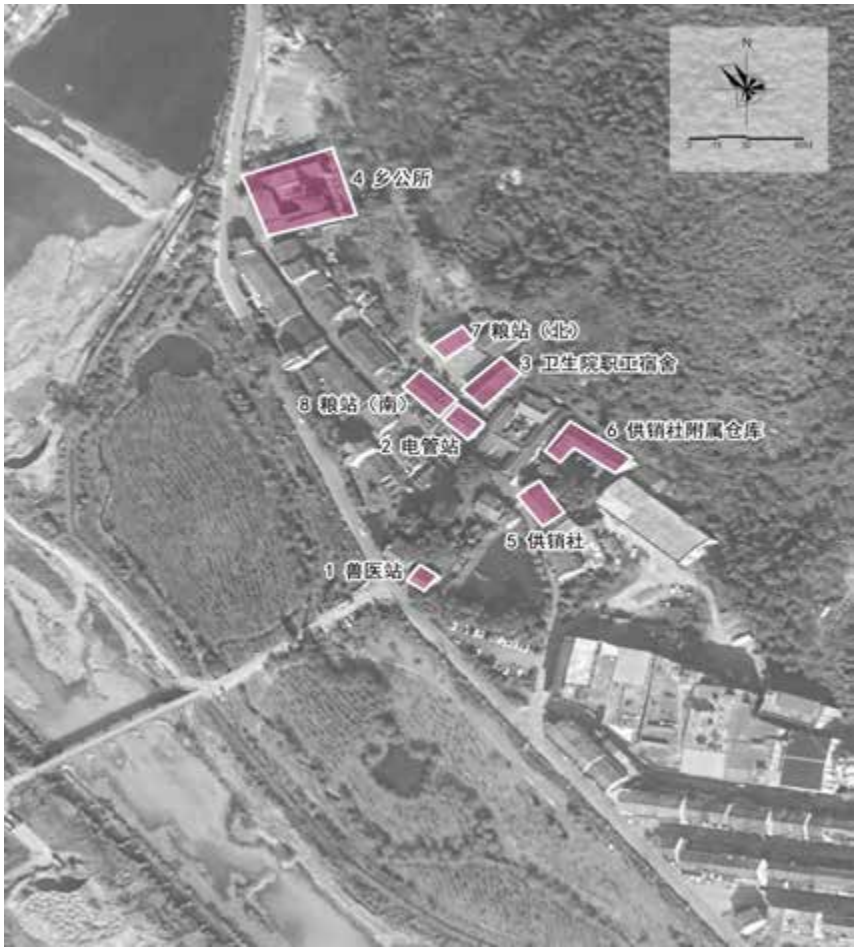

Figure 4 Adaptive Reuse of Existing Assets in Shatang Village

β2β Multi-Actor Collaborative Placemaking

During the initial phase of revitalizing Shatang Old Street, the absence of both tourists and commercial tenants posed a significant challenge. Following deliberations between village cadres and resident representatives, a bold policy was enacted: three years of rent-free occupancy for businesses operating on the Old Street. This incentive attracted local enterprises such as A'ling Steamed Buns and Xiaoya Rice Cake shops, alongside external businesses including Dounai Coffee, Grain Lodge Homestay, and Yuguang Bar.

Their establishment filled critical gaps in the street's commercial ecosystem, while the steady influx of visitors generated robust revenue streams, transforming these venues into social media hotspots.

Notably, Dounai Coffee—an unremarkable rural residence in early 2024—was revitalized in April through collaborative efforts by the Huangyan District Youth League Committee, Huangyan Young Entrepreneurs Association, and the Wenyi Society team. Leveraging platforms like Xiaohongshu and Weibo, the café achieved over one million online impressions (Figure 5), drawing nearly 1,000 young visitors. Its innovative operational model has injected vitality into rural revitalization, with daily coffee sales exceeding 100 cups during peak holidays (e.g., Labor Day, National Day). Collaborations with local heritage brands like Da Huang Steamed Buns have created hybrid "coffee + local culture" consumption experiences. Concurrently, the Yutou Has Light | Youth in the Village sustainable rural art festival (Figures 7, 8) has attracted over 100 young artists nationwide, fostering the Rural Art Creation Officer residency program.

Huang Kunpeng, founder of Da Huang Steamed Buns, transitioned from the competitive e-commerce sector in 2024 to explore opportunities in his hometown. Starting with no prior experience, he apprenticed under local artisans to master traditional bun-making techniques. Struggling initially with distribution, he pivoted to social media marketing, posting short videos on Xiaohongshu to amplify brand visibility (Figure 6). His account now boasts 19,000 followers and 98,000 likes, driving a surge in orders. To meet demand, Huang recruited over 10 villagers, structuring operations into three specialized divisions—digital marketing, sales, and production—to optimize efficiency under a novel business model.

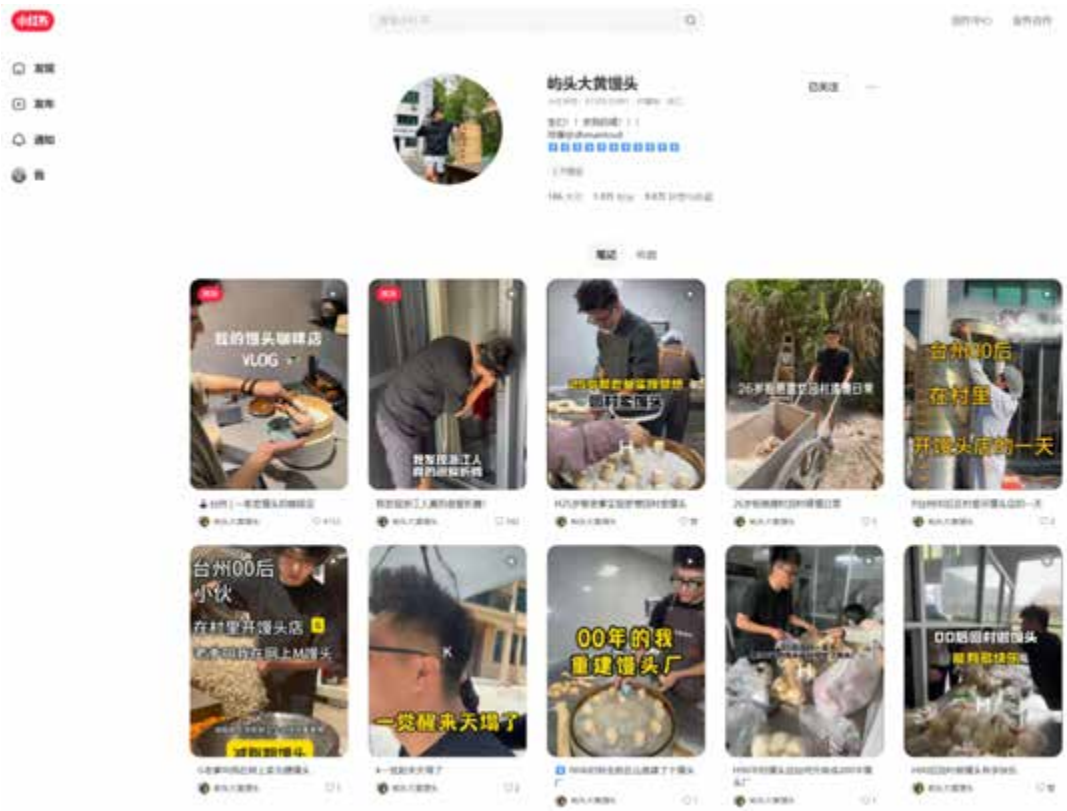

Figure 6 Page Display of Da Huang Steamed Buns' Xiaohongshu Account

Figure 7 Recruitment for the 2024 Inaugural Youth in the Village Sustainable Art Festival

Figure 8 Recruitment for the 2025 Shatang Village Youth Art Season

Further analysis delves into the tripartite actors influencing the "resident population–built space efficiency coupling" in Shatang Village—original inhabitants, returning migrants, and new migrants—and their evolving complementary synergies.

Original inhabitants, as core nodes of the rural social network, not only serve as inheritors of traditional lifestyles but also effectively express governance agency through participation in collective decision-making mechanisms. Their place-based knowledge ensures cultural compatibility in spatial transformations, exemplified by their role as cultural gatekeepers in architectural style preservation and public space layout. Returning migrants, leveraging cross-regional social capital and modern management concepts, act as bridges for bidirectional urban-rural resource flows. By introducing external market resources through entrepreneurial ventures in homestays and cultural industries, this group generates demonstration effects. Their dual identity mitigates conflicts between external capital and local culture. New migrants, as carriers of heterogeneous innovation, drive functional upgrades in traditional spaces by introducing urban consumption cultures and new economic formats. Their professional expertise in artistic interventions and brand marketing significantly enhances the market recognition of rural spaces, injecting innovation momentum into community development through their external characteristics.

The interaction mechanisms among these multiple actors exhibit distinct spatiotemporal evolutionary characteristics. During the initial stage of spatial reproduction, policy-guided resource aggregation formed a primary commercial ecosystem. As social networks between actors deepened, this evolved into a value co-creation model anchored in cultural identity. Specific synergies include: the complementary relationship between original inhabitants' spatial usage rights and new migrants' operational management; returning migrants' social capital reducing transaction costs; and the continuous influx of consumer groups reinforcing positive feedback mechanisms in spatial reproduction. Notably, the role boundaries among the three actors in spatial practices demonstrate a dynamic blurring trend. This deepening intersubjectivity facilitates a transformation from the traditional "host-guest dichotomy" to a symbiotic network.

Research on Demand-Side Oriented Spatial Governance in Innovation Districts: A Case Study of Hangzhou West Sci-Tech- Innovation Corridor

Lu Chenyan, Huang Yi[1*]

*Email:huangyi@tongji.edu.cn

Abstract
To address global competition and economic transition, the development of innovation districts necessitates an urgent shift from a supply-side to a demand-side orientation. This shift implies that the "bottom-up" practical demands should be given due attention. This paper identifies entrepreneurs and employees, the key practitioners in the spatial production of innovation districts, as the parameters for effective demand. Using the Hangzhou West Science & Technology Innovation Corridor as a case study, this paper conducts in-depth fieldwork, surveys, and interviews. By thoroughly analyzing and understanding their characteristics, spatial needs, and the inadequacies of current regional supplies, the study proposes strategies for sustainable planning and governance of innovation districts based on these findings.

Keywords: Innovation District; Entrepreneurs; Employees; Spatial Governance

1. The development needs of the innovation districts shifting to the "demand side"

Since the reform and opening-up policy in1978, China's rapid industrialization and urbanization have fueled the construction of industrial zones. Local governments have adopted a cycle of large-scale new city (district) planning, land development, industrial and real estate investment, land financing, and new development projects, leading to the formation of various industrial zones, development zones, science and technology parks, and new cities. In response to the uncertainties in the global economic system since the 21st century and the transform demands between old and new economic drivers domestically, China's existing industrial zones or new districts have begun to transition from a "large-scale infrastructure + real estate" model to a "technological innovation + digital economy" model. Driven by policy incentives, a multitude of innovation districts have emerged, shaping diverse innovation spatial forms such as technology corridors, future science and technology cities, Characteristic Towns, maker spaces, and smart valleys. These innovative spatial forms not only provide a vast stage for industrial innovation but also inject new vitality into economic transformation and upgrading.

However, despite the remarkable achievements in the construction of innovation zones, the supply-oriented land development model still faces multiple challenges, including mismatch between the supply and demand of spatial products [1], inefficient resource allocation [2], imbalance between industrial and urban relations as well as jobs-residence relations [3], inadequate bearing capacity of public facilities, and spatial segregation [4]-[7]. Against this backdrop, the development of innovation zones urgently needs to shift from the supply side to the demand side to better accommodate the demands of the new economy. Specifically, this shift implies the need for effective demand benchmarking and planning guidance, that is, focusing on the genuine user demands within innovation districts and adjusting spatial supply and governance to meet the requirements of technological innovation and industrial transformation. Therefore, this paper takes entrepreneurs and employees in innovation districts as the practitioners of spatial production and regards them as parameters for effective demand. By exploring their characteristics and spatial demands, this paper explores spatial governance strategies for innovation districts, which holds certain contemporary significance and academic value for the planning and research of innovation districts.

2. Innovation District Spatial Governance Approach: People-Oriented and Demand-Driven

The concept of "the production of space" was first proposed by French sociologist Henri Lefebvre in 1974 [8]. He interpreted space as the fundamental organizational form of all human social production and practical activities, encompassing three dimensions: "spatial practice," "representations of space," and "spaces of representation." Space is "(social) space as a (social) product," and "each epoch produces its own space" [8]. Since then, scholars such as Manuel Castells, David Harvey, and Edward Soja have linked space to society, history, and social actors from the perspectives of the network society, space of flows, spatial capital, and spatial justice. They regard humans as the practical subjects of space and interpret the dynamic mechanisms of spatial development in urban or rural areas through the "dialectics" of space [9]-[12].

Led by Lefebvre, the theory of spatial production breaks through the "container" perspective of space. The manifestation of space is not merely seen as an objective entity but as a system of spatial production and relational reconstruction by social actors. Spatial entities continuously develop and change through purposeful human practices, thereby forming conceptualized abstract spaces. Society operates through space, and the boundaries of groups, along with their social power relations, are embedded and embodied in specific spatial structures [13]. In other words, space interacts with behavior, and each acting subject interprets and expresses their understanding and utilization of space through their practical activities in space, thereby constructing a unique and meaningful space.

From the perspective of spatial production, the spatial practice in innovation districts is a process of actors' (i.e., governments, entrepreneurs, and employees) practices and the reconfiguration of their relationships within regional spaces. As the spatial suppler in innovation districts, the government proactively recalibrates land use configurations, spatial provisions, and managerial support frameworks through integrated planning, development, and construction initiatives. This macro-level intervention crystallizes the "representations of space"—manifesting as the government's strategic vision for innovation district development.

Concurrently, entrepreneurs and employees on meso-micro level, functioning as demand-side spatial users, construct the "spaces of representation" through innumerable location-choosing and career-seeking activities with industrial development trends and personalized needs. These real demands behind these spatial representations serve as the direction for the adjustment of innovation districts. The dialectical interaction between supply-side interventions and demand-side responses constitutes the core mechanism of spatial practice within innovation districts (See Figure 1).

In light of this, this study investigates the genuine spatial demands from entrepreneurs and employees within innovation districts, and basing on the existing space supply background, it proposes a holistic methodology for spatial development adjustment. Taking the Hangzhou West City Sci-Tech Innovation Corridor as a case study, through a mixed methods investigation of corridor-based practitioners—including enterprise' organizational growth aspirations and employees' occupational and personal requirements—the study establishes a demand-based framework for spatial supply and governance in innovation districts. This framework informs spatial strategies to align physical environments with the dynamic needs of innovation ecosystems, ensuring sustainable and inclusive development of innovation districts.

2.1 Individual characteristics and types subdivision of practitioners

Entrepreneurs and employees, serving as the key practitioners driving spatial production of innovation districts, continuously mold the region's spaces of representation through their actions. This spatial environment is profoundly imbued with the distinct characteristics of these practitioners, encompassing their personal experiences, value, production methodologies and lifestyles. These elements seamlessly integrate into the regional cultural, exerting a far-reaching influence on the cultural ethos of the local entrepreneurial ecosystem. They further shape entrepreneurial activities by establishing acceptable entrepreneurial practices and norms [14]. At the level of physical space, the industry choices of entrepreneurs and their establishment (or " selecting location ") directly impact the composition of the regional industrial landscape. Similarly, the occupational preferences and mobility patterns of employees are intricately intertwined with the region's spatial structure.

Consequently, this study from the perspectives of people-oriented and demand-driven, initiates its inquiry by examining the individual characteristics and categorizations of the region's practitionersΔby focusing on the interconnections between the practitioners and the spatial production, sociocultural dynamics, economic growth trajectories, and value orientations of innovation district. It offers insights for a profound understanding of the spatial production within innovation districts.

2.2 Entrepreneurship and Spatial Representation Characteristics

Innovation districts function as a spatial carrier for government-led industrial innovation and clustering, reflecting the government's vision regarding industrial spatial layout. The ultimate realization of this planning vision hinges on the enterprises established by entrepreneurs, meaning that the location choices made by enterprises directly shape the actual configuration of industrial space within the innovation district. The process

of enterprise location selection adheres to the "principle of maximum satisfaction" [15], being influenced by numerous factors such as the personal preferences of decision-makers (entrepreneurs), costs, market dynamics, labor availability, the socio-political environment, and the natural environment. It is a "bottom-up" process, and companies with different levels of development have different needs. Drawing on previous entrepreneurial research [16] [17], this paper classifies entrepreneurial enterprises into four categories: start-ups (established within 42 months), growth-stage enterprises (established between 42 months and 8 years), mature enterprises (established for over 8 years), and declining enterprises (determined based on the firm's specific circumstances) (as shown in Table 1). From the dimensions of entrepreneurial needs, motivations, modes of innovation, spatial preferences, organizational inclinations, and practical requirements, this study conducts an in-depth exploration of the spatial demands and representative features of industrial development within the innovation districts.

Table 1 Classification of Entrepreneurial Enterprise Cycles (Source: Drawn by the Authors)

Stage	Definition	Classification Criteria	Main Characteristics
Start-up Enterprises	The stage where enterprises newly enter the market seeking survival	Within 42 months of establishment	Facing issues such as resource scarcity, market instability, information asymmetry, etc., known as "new entry defects," with a high mortality rate
growth-stage Enterprises	The rapid development stage of enterprises	42 months to 8 years after establishment	Enterprises gradually stabilize in the market, their products begin to be accepted by customers, and their organization and scale grow, integrating into the industrial ecosystem
Mature Enterprises	The stage where enterprises expand to have a certain degree of market discourse power	Over 8 years after establishment	Having market influence, stable operations, sound industrial mechanisms, and typically occupying key links in the industrial ecosystem
Declining Enterprises	The period when enterprises enter a stage of decline or weakness in development	Judged based on the enterprise's own situation	Due to market saturation, product substitution, or management rigidity, they often maintain the status quo and need to restructure industrial relations to prevent decline

2.3 Employment and Spatial Representation Characteristics

Employees are not only crucial participants in the regional industrial economy but also significant shapers of the regional spatial landscape. While the regional industrial structure selects employees, it is simultaneously influenced by their occupational choices and mobility. This interactive dynamic further impacts the development of regional production and living facilities, as well as other functional aspects such as commerce, leisure, and residential areas. From the perspective of employment development, this study explores the demands and representation characteristics of industrial spaces, various supporting facilities, and spatial configurations within innovation districts by examining the considerations of employees in terms of career choice, location selection factors, spatial preferences, and resource inclinations.

Based on the exploration of the individual characteristics of the practitioners (entrepreneurs and employees) in regional representation spaces and the factors behind their spatial location choices, this study discusses spatial governance strategies for innovation districts. Taking the Hangzhou West Science and Technology Innovation Corridor (referred to as the Grand Corridor) as an example, questionnaires were distributed and over 60 open-ended interviews were conducted with practitioners of the innovation district. The questionnaires were disseminated via WeChat, and individuals outside the Grand Corridor were excluded based on IP addresses. A total of 158 questionnaires from entrepreneurs and 171 from employs were collected, totaling 329 valid questionnaires.

The questionnaire respondents comprehensively covered the main industries in the Grand Corridor, and the industry distribution closely aligned with the regional industrial pattern, demonstrating good reliability (Figure 2). Based on this data, the paper proceeds with its analysis.

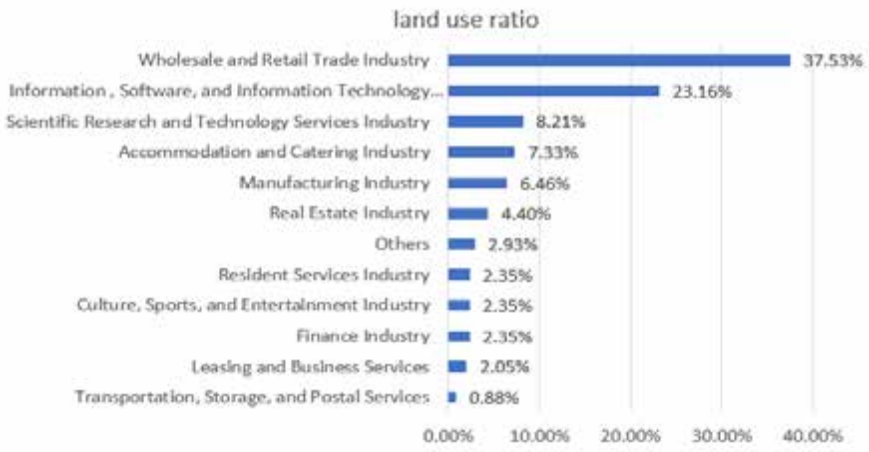

Figure 2: Industry Distribution of 329 Enterprises (Source: Questionnaire Survey)

3 "People-Oriented" Spatial Representation Characteristics in Innovation Districts: A Case Study of the Hangzhou West Science and Technology Innovation Corridor

The Hangzhou West Science and Technology Innovation Corridor (referred to as the Grand Corridor) originated from the West Science and Technology Industry Cluster Zone which is established in 2009.It was the only cluster zone focusing on science and technology innovation among Zhejiang Province's 15 industrial cluster zones. At the end of 2015, it was officially renamed as the Grand Corridor, as a key development zone by Zhejiang Province and Hangzhou City for promoting economic transformation and upgrading .Situated in the western part of Hangzhou City, Zhejiang Province, the Grand Corridor spans from Zijingang Campus of Zhejiang University in the east, to Zhejiang Agriculture and Forestry University in the west, encompassing numerous universities and research institutions. According to the "The 14th Five-Year Plan for the Development of Hangzhou Chengxi Science and Technology Innovation Corridor (2021)" planning , the Grand Corridor covers a total area of 416 square kilometers (Figure 3).

As outlined in "The 14th Five-Year Plan for the Development of Hangzhou Chengxi Sci-Tech Innovation Corridor (2021)", the Grand Corridor's planning vision (presentations of space) aims to establish a globally leading digital science and technology innovation center, a leading area for high-quality development, a pioneer area for urban modernization, and a demonstration area for integrated intelligent governance. It seeks to initially construct an innovation source that embraces the world, leads the future, serves the nation, and propels the entire province (Figure 4).

Figure 3. Location Map of the Hangzhou West Science and Technology Innovation Corridor

Figure 4: Schematic Diagram of the Corridor's Development Layout (Source: The 14th Five-Year Plan for the Development of Hangzhou Chengxi Sci-Tech Innovation Corridor)

3.1 Characteristics of the Practitioners in the Grand Corridor

Survey findings reveal distinct characteristics of the practitioners of the Grand Corridor. Entrepreneurs are predominantly male (62.66%), with individuals aged 26-35 constituting the main entrepreneurial force (50.63%). Furthermore, a significant majority of entrepreneurs possess at least a bachelor's degree (80.38%) and extensive work experience with 61.4% having more than 5 years of work experience . Among employees, females account for a slightly higher proportion 54.97% than males, with the "18-25" and "26-35" age groups making up 75.44%. The educational background is predominantly bachelor's degree or above, with a relatively balanced distribution of work experience years, reflecting the stable mobility of employees in the region. Both entrepreneurs and employees predominantly originate locally, supplemented by inflows from outside the region. This indicates that entrepreneurs in the Grand Corridor generallexhibit individual traits of localization, youthfulness, high educational attainment, and substantial work experience, while employees demonstrate localization, youthfulness, high educational attainment, and stable mobility (Figures 5-12 and Tables 2-3).

Table 2: Survey on the Channels Through Which Entrepreneurs in the Region Came to Hangzhou

Channels of Coming to Hangzhou	Number	Proportion
Local Background (Studying or Having Family Locally)	81	51.27%

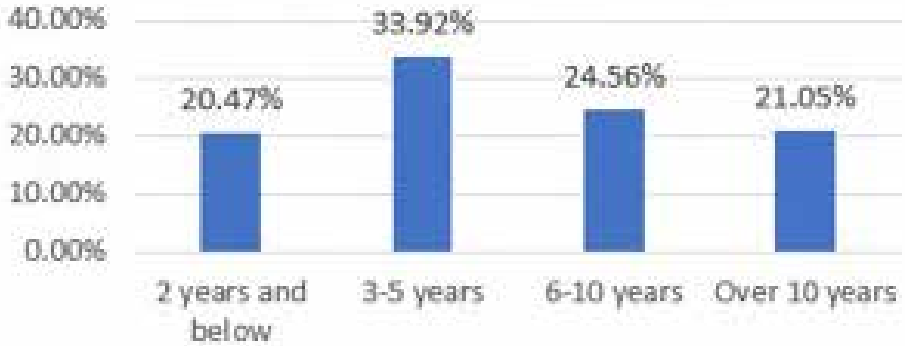
F10: Age Distribution of Employees

F11: Educational Background Composition of Employees

F12: Work Experience Duration of Employees in the Region (Source: Questionnaire surveys)



The Grand Corridor boasts a high proportion of "proactive" entrepreneurs (81.1%), in contrast to a mere 18.9% of passive entrepreneurs (Figure 13). Not only do entrepreneurs acknowledge the entrepreneurial opportunities available in Hangzhou, but a substantial portion of employees also harbor aspirations for entrepreneurship. Among interviewed entrepreneurs (Table 3), over 60% report having "many acquaintances who are entrepreneurs." Similarly, among interviewed employees (Table 5), nearly half perceive "many individuals around them as

entrepreneurs," with only 39.18% preferring stable employment, whereas 26.9% express a willingness to "attempt entrepreneurship if given the opportunity." Almost one out of four employees could be a potential entrepreneur. The local populace has a strong sense of initiative in entrepreneurship, and the region is imbued with a robust entrepreneurial action attribute.

This phenomenon may be attributed to the region's long-standing tradition of valuing commerce, which can be traced back to the Spring and Autumn Period in the history, exemplified by the era of "Business Saint" Fan Li. Over time, the practice of valuing both culture and commerce has cultivated a cultural tradition that "values commerce and technology" and "considers industry and commerce as foundational," alongside a behavioral pattern characterized by "pragmatism" and "daring to innovate."

Consequently, the local populace has developed a distinct preference for risk, with more prominent business opportunity capture capabilities and risk tolerance, thereby fueling widespread entrepreneurial and innovative endeavors within the region.

3.2 Entrepreneurship and Its Spatial Representation

This study delves into the industrial space of innovation districts that is selected and constructed by the entrepreneurial cohort, through the perception of entrepreneurs. From the perspective of entrepreneurial motivation, "identifying good business opportunities" stands out as the primary driving force for entrepreneurs in the Grand Corridor, followed by "increasing wealth," "achieving self-worth," and "pursuing freedom." The proportion of those who start businesses due to "being unable to continue with their current jobs" is the lowest (Figure 14). This indicates that entrepreneurs in the region are relatively proactive in their ventures, with most being motivated by business opportunities and a keen sense of market trends, thus belong to proactive entrepreneurship.

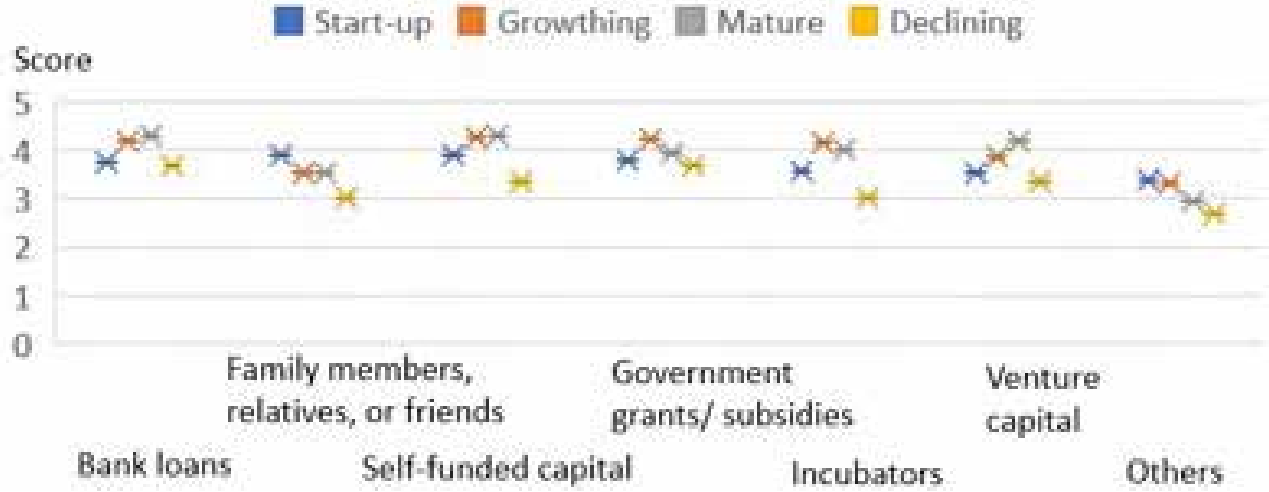
Growthing	5.66%	45.28%	35.85%	11.32%	1.89%
Mature	0	4.35%	14.49%	37.68%	43.48%
Declining	0	16.70%	16.70%	50.00%	16.70%

F18: Scoring of Funding Sources for Enterprises at Different Stages (Rating Scale: 1-5)



In terms of innovation, while establishing new brands, the region entrepreneurs place equal emphasis on multiple innovation models (Figure 15). Innovation is significantly influenced by the product market. The largest proportion of research and development (R&D) activities are driven by "customer requirements" and "dealer market reports," followed by internally generated ideas. Self-directed R&D is the main approach, with a certain demand for external collaborative innovation (Figures 16 and 17).

From the perspectives of resource demands and spatial choices, entrepreneurs exhibit distinct needs at different stages of their ventures, generally leveraging existing social connections or resource networks. During the start-up phase, most enterprises have fewer than 10 employees, affording a relatively small scale (Table 6). Beyond self-funded capital, "family members,", "friends and relatives,", and "colleagues" emerge as the primary and most immediate sources of financial support for startups, predominantly sourced through the entrepreneurs' personal resource pools and network ties (Figure 18). Consequently, startups prioritize "preferential policies and financial support" as the most crucial factor, followed by "low costs for pilot-scale production and processing" and "low office rental costs." This prioritization is linked to the exploratory and uncertain nature of products during the startup phase, which necessitates continuous capital infusion (Figur19).

In terms of location selection (Figure 20), the "favorable atmosphere for innovation and entrepreneurship" in the Grand Corridor is a significant influencing factor for startups choosing to establish themselves there, with a satisfaction rating of 4.17. This is closely followed by "attractive preferential policies and incentives" (4.12), "proximity to relevant industrial clusters" (4.11), and "convenient transportation and facilities" (4.09). Other factors, such as "a beautiful urban environment", "abundant human resources", and "proximity to customers or suppliers", also play a role. Evidently, when considering the cost expenditures and opportunities associated with setting up a business, entrepreneurs often opt for regions with a vibrant entrepreneurial atmosphere and access to preferential policies. They also take into account costs related to transportation and facilities, preferring areas with convenient transportation and well-developed public infrastructure.

Hence, when it comes to specific spatial selections (Figure 21), startups exhibit a preference for "small but excellent" spaces. The option of "characteristic courtyard spaces" garners the highest preference rate among startups (44.38%), closely followed by "shared workstations with complete facilities" (41.25%) and "technology parks that match their professional fields" (41.25%). These choices underscore the startups' quest for comprehensive entrepreneurial support facilities while keeping costs low. However, field research has revealed that "small yet exquisite" spaces favored by startups, such as Dream Town, often come with high entry barriers and insufficient supply. As a result, more startups can only be located in surrounding villages and towns, collective land, old factories, and other areas with low rent and close to intellectual density and convenient transportation. In choosing their locations, startups prioritize convenience within the framework of economic affordability.

The resource requirements of enterprises in the growth stage significantly differ from those of startups (Figure 19). The growth-stage enterprises prioritize "entrepreneurial services such as product promotion and patent applications," reflecting their urgent need to meet market production capacity demands. Subsequently, they emphasize "venture capital" and "preferential policies and financial support"," as capital remains a pivotal factor determining their ability to expand production and explore new markets. The office and pilot-scale production costs, which were once major considerations, are no longer primary focuses for these enterprises. From the perspective of funding sources (Figure 18), "incubators" are an important channel for growth-stage enterprises to obtain capital, which is closely related to the one-stop incubation services mainly provided by incubators in the Grand corridor. Incubators represent the primary avenue through which growth-stage enterprises can readily access funds and other resources. The following incubators, such as "government subsidies"," "self-financed capital"," and "bank loans" are also significant funding sources. "Family, relatives, or friends" have become less important as entrepreneurs expand their external channels and are no longer the main funding channels they rely on.

In terms of location selection (Figure 20), "favorable entrepreneurial policies" (84.44%) emerged as the most crucial factor for growth-stage enterprises when choosing to settle in the Grand Corridor. This was followed by factors such as "having a relevant industrial chain foundation" (82.89%), "abundance of relevant talents" (81.61%), "strong reputation and a favorable atmosphere for innovation and entrepreneurship" (81.19%), and "convenient technical support/R&D cooperation" (81.14%). Next in importance were "sufficient land for enterprise expansion

and development" (79.02%) and "local background" (76.89%). It is evident that the growth-stage enterprises place greater emphasis on obtaining preferential funds, market access, and talent acquisition, which are essential for establishing a foothold in the market. Regarding specific spatial choices (Figure 21), the growth-stage enterprises prioritize spaces that offer growth and development potential in the future. As a result, comprehensive and high-quality science and technology parks are the preferred choice for these enterprises, followed by "modern large-floor-space premises" (39.62%) and "independent buildings" (38.68%).

Compared to other enterprises, mature enterprises pay more attention to industry prospects and new business opportunities (Figure 19). They rank "industry technology and information" and "entrepreneurial services such as product promotion and patent applications" as their top priorities, indicating their development needs to explore new growth points and maintain a leading position. In terms of accessing entrepreneurial funds (Figure 18), apart from profits generated from enterprise sales, "bank loans" and "venture capital" are important channels for them to obtain funds, followed by "incubators" and "government subsidies"." As enterprises grow, "self-funded capital" and "funds from family, relatives, or friends" become less significant. Mature enterprises have successfully established a resource network based on themselves, demonstrating strong anti-risk capabilities and smooth access to market-oriented investment and financing channels.

In terms of location selection (Figure 20), mature enterprises prioritize "abundant human resources" (4.22) and "sufficient development space/land" (4.19). This is followed by factors such as "proximity to customers or suppliers" (4.15), "attractive policy incentives and rewards" (4.12), and "having a local background" (4.08). Other factors include "a beautiful urban environment"," "a favorable atmosphere for innovation and entrepreneurship"," "convenient transportation and facilities"," and "proximity to industrial clusters"." It can be seen that considering their development scale and the ease of talent acquisition, entrepreneurs of mature enterprises tend to choose regions with relatively abundant human resources and surplus land. They also pay more attention to the overall technological foundation and knowledge level of the region. The mature enterprises surveyed in this study generally possess independent buildings or parks, indicating a certain degree of independence in their spatial location choices. Many enterprises have expressed a vision for later relocation and expansion, but they are cautious about new locations, preferring to move within the same region rather than deviating from existing human or resource channels. Their location selections are more proactive and prudent. Regarding specific spatial choices (Figure 21), mature enterprises prefer independent land use, favoring "independent buildings" (51.68%) and "modern large-floor-space premises" (49.13%). This is related to the expansion of their organizational structure and employee scale. To alleviate the sense of oppression brought about by their scale, mature enterprises place greater emphasis on the leisure and stress-relieving aspects of their internal office areas, paying more attention to the spiritual relief needs of public spacesuch as natural spaces.

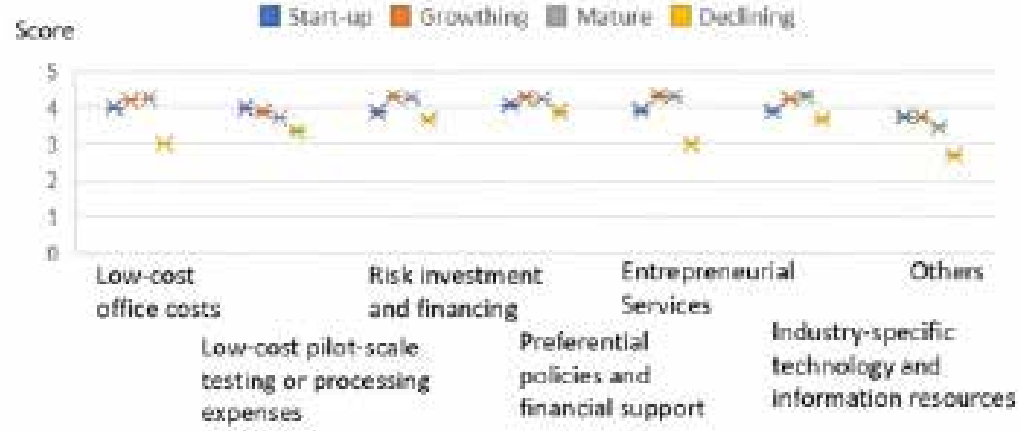
Decline enterprises are relatively limited in number, and thus their analysis primarily relies on interview data. Most of the decline-stage enterprises surveyed were established before the naming of the "Grand Corridor". These enterprises are predominantly from traditional manufacturing sectors such as electronics, electrical appliances, textiles, or and building materials. Due to the factors such as technological substitution, market renewal, and upgrades, they have progressively lost their competitive edge in the industry and are now at risk of being phased out. They harbor aspirations to develop new business ventures but are simultaneously apprehensive about the associated risks, leading to a lack of innovation drive.

Maintaining the status quo yields low profits and inadequate cash inflows. "Bank loans" and "government subsidies" are their main channels for obtaining external financial support, and their demand for innovation is significantly lower than that of enterprises in the other three stages. Consequently, in the evaluation of resource preferences, declining enterprises place the highest value on preferential policies and financial support. They also require external resources like industry-specific technological information and venture capital to facilitate industrial transformation or enhancement. However, their overall resource preference ratings are not high, suggesting limited internal initiative.

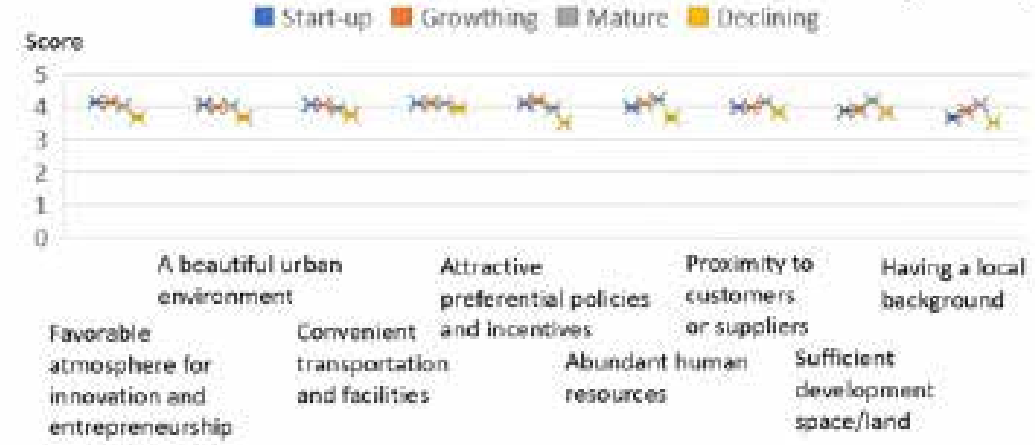
In terms of location selection, urban improvements and economic development have enhanced the appeal of their locations, resulting in an appreciation of enterprise land values.

Nevertheless, most enterprises opt to increase the output value and corporate earnings of their existing lands by leasing or selling them, reflecting insufficient innovation momentum. They express hopes for policy-driven relocation or replacement processes but exhibit low proactivity in independently choosing new locations.

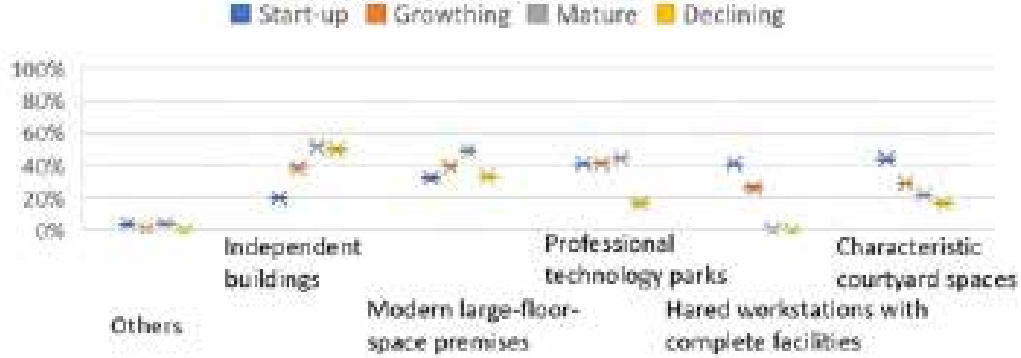
F19: Evaluation of Resource Needs for Enterprises at Different Stages (Rating Scale: 1-5)



F20: Evaluation of Location Selection Needs for Enterprises at Different Development Stages



F21: Analysis of Specific Spatial Choices for Enterprises at Different Development Stages (Source: All from Questionnaire Survey)



3.3 Employment and Its Spatial Representation

By examining the perceptions and job-selections of employees, we can understand the characteristics of the industrial spaces preferred by employees, as well as the representation of other functional spaces involved in their production and daily lives. From the perspective of job-selection motivations (Figure 22), respondents in the questionnaire ranked “salary” and “self-actualization” as their top two priorities, followed by “alignment with corporate culture”, “personal interest”, “promotion opportunities”, and “commuting distance”.” Next came

"alignment with one's major" and "work environment". Employees in the Grand Corridor do not regard salary as their sole pursuit; instead, they place greater emphasis on realizing their own value and matching their individual spirits with enterprise. This reflects a high-level spiritual need among employees in the Grand Corridor to transcend salary pursuits and value the alignment between their own worth and that of the enterprise.

This spiritual pursuit is similarly manifested in considerations for job location selection. In open-ended interviews, the majority of employees deemed the Grand Corridor as their ideal employment area. Exploring the reasons behind this (Figure 23), "beautiful urban environment" emerged as the top factor, followed by "promising development prospects of the industry", "a large number of like-minded individuals"," and "high government efficiency"." Next were "well-developed public facilities", "convenient transportation", "strong foundation for cooperation and innovation"," and "preferential policies and incentives". Finally came "cost of living or work"." This reflects a characteristic among employees where they prioritize personal growth over cost considerations in employment, placing greater importance on regional environment, job prospects, and opportunities for their own development.

Specifically, these characteristics vary among employees of different age groups. Firstly, the motivations driving job location selection differ among age groups (Figure 25). The "18-25" age group places significantly higher emphasis on "convenient transportation", "well-developed public facilities", and "relatively low living or working costs" compared to other age groups. This can be attributed to their new entry into the job market, limited resource accumulation, and concerns about convenience and economic pressures. The "26-35" age group exhibits relatively balanced ratings across various factors, indicating a comprehensive and meticulous consideration of all aspects. The "36-45" age group places the utmost importance on "salary". Employees in this age bracket often serve as the primary financial providers for their families and hope to reflect their professional value and sense of accomplishment through higher salaries. The "46-55" age group prioritizes "the development prospects of the industry they belong to". Employees in this age range are typically in the later stages of their careers and place greater importance on industry stability and long-term development trends.

Secondly, the pursuit of innovative spirit also varies among age groups. The "36-45" age group has the highest proportion (31.58%) of employees who "feel that they have the opportunity to try entrepreneurship", followed by the "26-35" age group (28.24%). The "18-25" age group has the lowest proportion (22.73%) of those willing to attempt entrepreneurship. These differences result in distinct demands for the employment environment among different groups of employees.

Thirdly, the demands for regional spatial amenities also differ across age groups. Based on the survey of job environment satisfaction, employees within the Grand Corridor are generally quite satisfied with the existing employment environment. Those expressing "relatively satisfied" or "very satisfied" attitudes account for 66% of the total respondents, while only 5% hold "dissatisfied" or "very dissatisfied" views (Figure 24). Specifically, the "18-25" age group exhibits lower satisfaction levels with the surrounding transportation and public facilities, particularly noting a lack of diverse recreational and entertainment amenities. Employees in the "26-35" age group believe that the most pressing areas for improvement in their current industrial parks are external supporting facilities, followed by external transportation conditions and the availability of public transportation. Within the park, they express relatively high satisfaction with the spatial organization and indoor environmental quality of the enterprises they work for. They perceive the need for improvement primarily in "internal supporting facilities", particularly advocating for an increased supply of high-quality spaces and amenities for communication and leisure activities.

Both the "36-45" age group and those aged "46 and above" highly appreciate the cultural atmosphere and beautiful natural environment of the Grand Corridor. Nevertheless, they note a relative dearth of high-quality supporting facilities such as education, healthcare, and recreational amenities. In particular, the scarcity of high-quality educational facilities struggles to meet the expanding needs of families. This is also reflected in the interviews, where the majority of employees mention that the most urgent areas for improvement in the Grand Corridor are public facilities related to transportation, commerce, leisure, daily living, as well as communication spaces.

In terms of office space and facility usage within specific park, many employees have a high level of satisfaction with the internal and external environment, building appearance, building functions, and building space of the park or office building where they are currently employed (Figure 26). "Open-plan offices" and "flat organizational structures" are widely recognized and accepted forms of office organization among employees, who believe that these arrangements can effectively enhance office efficiency and facilitate collaborative efforts.

Public spaces focus on stress relief and relaxation, but the supply varies depending on the conditions of the enterprise (Figures 27 and 28). Start-up enterprises and declining enterprises prioritize basic needs in the use of public spaces, making the "dining area" the most popular space among startup personnel (30.63%). Growth-stage enterprises exhibit needs similar to those of start-ups, but there is a notable increase in the preference for natural spaces that aid in stress relief and tea-break areas for relaxation. In contrast, employees in mature enterprises show the strongest preference for "outdoor natural spaces" (31.88%), followed by "fitness and exercise areas" (23.19%), "dining areas" (20.29%), and "tea-break areas" (13.04%). This indicates a growing emphasis on the mental and emotional well-being aspects of public space utilization, a trend that gains prominence as enterprises expand in scale and enhance their capabilities.

F22: Survey on Entrepreneurial Motivations of Entrepreneurs in the Region

Options	Score (Likert 5)
Work environment	3.89
Alignment with one's major	3.95
Promotion opportunities	4.01
Commuting distance	4.01
Personal interest	4.04
Alignment with corporate culture	4.06
Self-actualization	4.12

4 Suggestions for "People-Oriented" Spatial Governance Strategies in Innovation Districts

Based on the characteristics of the practitioners and the spatial representations of entrepreneurs and employed individuals within the Grand Corridor, this paper proposes "people-oriented" spatial governance strategies for innovation districts.

4.1Overall-Level: Strengthening Regional Characteristics and Industrial Resources to Construct a "People-Centered" Spatial Governance Framework for Innovation Districts

On one hand, anchored in the region's long-standing cultural tradition of "merchant-oriented" values and the population's inherent trait of "risk-taking spirit," we aim to establish the regional image of the "entrepreneurial and innovative haven "in the Grand Corridor, , thereby mentally unifying the spatial governance approach of the innovation district.

Through urban marketing strategies such as elite guidance, policy incentives, and case shaping, we can encourage or emphasize the region's innovativeness and inclusiveness, attracting innovators to settle down and fostering the emergence of entrepreneurs and employees.

On the other hand, we spatialize the perception of the image. Beginning with the spatial requirements of entrepreneurs and employees, we construct a "people-oriented" spatial governance framework for the innovation district. Firstly, we build a cultural concept of "humanistic pragmatism" and "risk-taking spirit", "and efficient inclusive policy mechanism. Secondly, starting the dimensions of cultural image implantation, public space creation, industrial space revitalization, and supporting facilities provision, and utilizing the ecological foundation and rich historical context of the region's "Three Lakes and Two Belts", the Grand Corridor will be transformed into a "wetland lake chain, innovative street, and shared living room" innovation district (Figure 6). By connecting six "lake chain living rooms"," thirty town living rooms, and hundreds of neighborhood living rooms with forty-nine "interesting innovation streets," a multi-level spatial landscape pattern of the innovation district is formed, which seamlessly blends industries with landscapes, and where production and social interaction are vibrant and dynamic. Through multi-level planning and collaborative governance, we achieve the governance goal of diversified development of industrial innovation space at all levels in the region.

4.2 Meso-level: Adhering to Entrepreneurial Demands and Organizational Patterns to Promote a Governance Approach for the Diversified Development of Enterprises

The spatial characteristics of entrepreneurship indicate that entrepreneurs in the Grand Corridor demonstrate a high degree of initiative. In the initial stages of entrepreneurial endeavors and resource acquisition, they predominantly rely on their personal networks. As enterprises grow, there is a gradual shift towards networks constructed by the enterprises themselves. Consequently, it is imperative to implement differentiated policy provisions and spatial supply strategies tailored to the diverse needs of enterprises at various developmental stages in institutional design.

For start-up enterprises, increased financial grants and resource-matching initiatives should be provided. Specialized venture capital funds or guiding funds targeting startups should be established, and social capital should be actively encouraged to participate in the incubation service ecosystem for startups. This will facilitate the establishment of collaborative mechanisms between startups and other enterprises, industry associations, scientific research institutions, etc.

For grow-stage enterprises, market-oriented expansion is the linchpin. This can be achieved by strengthening intellectual property protection, establishing robust channels for industry-university-research collaboration, streamlining administrative procedures, and enhancing resource integration and operational efficiency. These measures will continuously broaden the avenues for socialized innovation , thereby meeting the growth needs of enterprises.

For mature enterprises, the focus should be on enhancing their industry-leading capabilities and promo the construction and expansion of their industrial ecosystems. This can be achieved by encouraging continuous innovation and the cultivation of new industries through research funding subsidies and innovation platform collaborations. Support for talent acquisition should be provided through talent recruitment programs, vocational education initiatives, and the development of supporting infrastructure. Additionally, facilitating upstream and downstream cooperation and innovation within the industrial chain through information-sharing platforms and industry alliances will be crucial.

For declining enterprises, facilitating industrial transformation, optimization, or orderly exit can be achieved through the introduction or collaboration with new industries, the establishment of an orderly exit mechanism (such as transformation subsidies, M&A collaborations), employee resettlement and education, as well as the reuse of inefficient spaces.

4.3 Micro-level: Design Strategies Prioritizing Human-centric Needs to Foster a Diverse, Integrated, and Inclusive Innovative Spatial Environment

Given the characteristics of the regional practitioners, which are youthfulness and high educational attainment, there are distinct differences in their demands for facilities and venues related to work, life, entertainment, and leisure compared to those in typical urban areas. Therefore, the spatial supply in the Grand Corridor should center on the needs of practitioners, through urban design methods, solutions should be proposed to meet the humanistic needs of various groups, and a diverse, composite, and characteristic shared spatial environment should be jointly constructed in the region.

Firstly, various functions should be organized with public spaces as the core, creating a high-quality open public space system that serves as an "entrepreneurial and innovative haven "in the Grand Corridor. Taking advantage of the region's favorable ecological environment, the construction of public spaces should emphasize the integration of ecological advantages with entrepreneurial landscapes, shaping urban memories and a sense of place that combines innovative culture with ecological culture, thereby fostering more possibilities for entrepreneurial and innovative activities.

Secondly, in terms of land utilization, a human-oriented approach should be adopted to augment the flexibility of land use. The composite utilization of industrial land should be actively encouraged, fostering spatial integration and innovation. New spatial units that integrate multiple elements, such as entrepreneurial campuses, innovative parks, maker communities, creative scenic areas, and intelligent manufacturing industrial zones, should be constructed in accordance with local circumstances, forming environmental carriers conducive to communication and innovation. In the layout of living areas, boundaries between production and daily life should be boldly broken, encouraging the composite development of small-scale, non-polluting industries with other functions to create living spaces with community-based industrial functions.

Thirdly, in terms of facility support, it is imperative to prioritize the equitable distribution and accessibility of diverse facilities across the industrial spaces within the region. Life service facilities should be provided to cater to the differentiated needs of multi-level talents in the innovative industries. This includes not only facilities for the general public but also tailored for practitioners. Attention should also be given to the psychological, emotional experiences, and value identification of various groups. While ensuring convenient and economical facilities for employees, cultural, artistic, commercial, and leisure functions should be integrated to enhance the region's cultural, recreational, and service capacities for multi-tiered talents. Spatially, it's important to monitor and adapt to demand changes over time, such as upgrading educational and healthcare facilities to meet the evolving needs of a younger workforce.

Additionally, for micro-architectural spaces, greater importance should be attached to the design of communication and learning areas, with a focus on integrating natural elements. Functions such as ecology, leisure, and entertainment should be embedded to soften the work environment and infuse innovation spaces with a human touch. Utilize natural elements such as water bodies and green plants to create leisure spaces, establish public dining, entertainment, and fitness centers, and promote the formation of informal learning and communication. Exploring the integration of office landscapes, ecological landscapes, commercial landscapes and tourist landscapes, foster a sustainable and vibrant ecosystem that promotes economic, social, and cultural coprosperity. This also serves as a response at the planning level to the needs of practitioners.

5 Conclusion

This paper, adopting a human-oriented and demand-side-oriented perspective, delves into the spatial needs of the key actors in innovation districts—entrepreneurs and employees. This analysis facilitates the formulation of more precise and effective strategies for constructing innovation spaces, thereby promoting higher-quality development of innovation districts.

The research findings, exemplified by the case of the Hangzhou West Science and Technology Innovation Corridor, indicate that: • Demographic Traits: Entrepreneurs exhibit localized, youthful, highly educated, and experienced individual traits, daring to actively start their own businesses; employees are localized, youthful, highly educated, and have stable mobility, pursuing self-worth. These traits are associated with the region's "mercantile" cultural characteristics. • Spatial needs: Enterprises at different stages present different resource needs and spatial

choices. Startups prioritize low costs and convenience, growing enterprises focus on the potential for specialized development, mature enterprises emphasize access to human resources and future expansion possibilities, while declining enterprises look forward to the reuse of inefficient spaces; employees prioritize personal growth over employment cost considerations, and employees of different age groups have varying motivations for job location choices and needs for spatial amenities, leading to different spatial location choices. Δ Local supply: Existing planning focuses on the supply of industrial spatial resources in the region, with insufficient attention to startups and declining enterprises; the supporting industrial spaces in the region still follow traditional layouts, neglecting the special needs of high-quality talents in innovation districts.

Redefinition of Urban-Rural Boundaries Under Centralized Governance: Urban Ecological Movements in the Case of a Coastal Town, Ayvalık, Turkey

Bilgesu Sever
Bilkent University, Faculty of Art, Design and Architecture, Department of Architecture, Ankara, Türkiye
bilgesu.sever@bilkent.edu.tr

Abstract
This paper investigates the socio-ecological impacts of Turkey's 2012 Metropolitan Law (No. 6360) by analyzing how it redefined urban–rural boundaries through the case of Ayvalık. The law expanded metropolitan jurisdictions to include rural areas, intensifying top-down governance and triggering land use transformations. Drawing on urban political ecology and planetary urbanisation, the study explores how environmental movements in Ayvalık resist these changes and advocate for participatory governance. Through ethnographic research and spatial analysis, it reveals the tensions between centralized state planning and local socio-ecological dynamics. The findings highlight Ayvalık as a metropolitan hinterland shaped by contested governance, contributing to debates on planning amid planetary crisis and the need for more inclusive, ecologically tailored governance frameworks.

Keywords: Urban-rural boundaries; Centralized governance model; Urban ecological movements; Metropolitan Law; Ayvalık

Introduction

More than half a century ago, Henri Lefebvre had a strong assessment with the following hypothesis: "Society has been completely urbanized" (Lefebvre, 2003, p. 1). A notion of 'urban society' has been put forward as a result of an urbanisation process. He had a considerably sharp argument towards the disruption in 'well known' distinctions between the city and the rural through pointing out the emergence of the urban society. Since the emergence of Lefebvre's thesis, the notion of urban served as the encompassing phenomenon beyond the 'limits' of the city towards the rural areas, where the borders between them sought to disappear. His ideas have pioneered new theoretical frameworks and provided the understanding of the necessity to discuss changing urbanisation processes. Based on this, the crucial threshold of total urbanisation has exposed as being surpassed, indicating the practical realization of a "planetarization of the urban" (Lefebvre, 2014, p. 569).

The assertion that the urbanisation process, in serving as a paradigm, has come to delineate the entire globe, was expanded by Neil Brenner and Christian Schmid (2014), acquiring contemporary relevance through the concept of "planetary urbanisation". This development has also infused new vitality into critical urbanisation theories and led the way to critically reconceptualize the relation between the urban–non-urban, city–rural, and centre–periphery. In the context of these dialectics, the emerging urban era is started to be discussed as characterized by planetary social and environmental interactions, establishing novel constraints on the utilization and alteration of the global built environment, presenting the potential for significant disparities and conflicts, while simultaneously offering new opportunities for democratic engagement and self-appropriation, reclaim of space across all scales. From a political ecological perspective, urbanisation involves a profound transformation of both physical and social environments. David Harvey (1996) points to the ecological dimensions of urbanisation as contingent upon the reproduction of specific socio-spatial relations. Similarly, Cronon (1992) emphasizes that these processes continually produce new urban natures—hybrid socio-natural formations that reflect shifting modes of production and resistance. Under capitalist urbanisation, nature is not only physically absorbed into the urban fabric but also symbolically redefined, serving as both a site of exploitation and a terrain of contestation. Urban natures are thus constantly reshaped through the dynamic interplay of political economy, social struggle, and spatial transformation.

Urban Political Ecology (UPE) has emerged as a critical framework capable of addressing these complexities. While Angelo and Wachsmuth (2014) were dealing with the unexplored aspects and, correspondently, potentials of UPE by telling the story of it in relation to current urbanisation dynamics and theories, they asserted that, there is a need for a return by adhering to UPE's previously adopted understandings—the desire to reinterpret urbanisation through Lefebvrian roots of provocative thinking. In line with this, the urbanisation process must then be understood as the "production of specific and quite heterogeneous spatio-temporal forms embedded within different kinds of social action" (Angelo et al., 2014, p. 381). The idea of reinterpreting urbanisation as a 'socionatural' process is argued to provide means to critically reframe urban environmental issues within a broader context embracing economic, social, and historical dimensions. Thus, a political ecology of urbanisation

is made possible to be discussed through focusing on the process of "densely connected but unevenly differentiated urban fabric" (Angelo et al., 2014, p. 11). In this context, UPE has the potential to explore the planetary, ecological, political understanding of contemporary urbanisation when it is addressed in a diverse range of scales, encompassing 'city' and 'non-city' sites (Arboleda, 2016). However, the promise of a truly transdisciplinary UPE research agenda capable of capturing the implications of planetary urbanisation remains only partially fulfilled. I aim to address this by analysing a coastal town amidst intensifying urban-environmental tensions, where socio-spatial struggles unfold not only within conventional urban boundaries but also across peripheral and ruralized territories shaped by extractive and speculative pressures.

Urbanisation, is increasingly understood not as confined to the city but as a planetary process that restructures socio-natural relations across both urban and rural territories. In Turkey, this understanding has been institutionalized through a long-standing nationalist-conservative governance agenda that prioritizes urban expansion, leading to the growth of metropolitan areas to encompass their rural hinterlands. A key turning point in this trajectory was the enactment of Law No. 6360 in 2012—popularly known as the "Metropolitan Law" (Bütünşehir Yasası)—which extended the jurisdiction of metropolitan municipalities to entire provincial territories, thereby dissolving the legal distinction between urban and rural areas (Mengi et al., 2024). The law redefined the administrative structure by absorbing villages and small towns into metropolitan districts, transforming them into urban neighbourhoods and effectively marginalizing rural governance and identity (Batuman, 2017). This paper, in this context, examines the socio-ecological implications of these transformations in the case of Ayvalık, a coastal town in western Türkiye renowned for its ecological and cultural heritage.

Within this context, Ayvalık is conceptualized as a "metropolitan hinterland"—a space absorbed into the urban regime yet politically and geographically peripheral. Here, nature becomes simultaneously instrumentalized and symbolically contested, revealing the contradictions of neoliberal urbanisation. The study argues that the restructuring of governance and space under the Metropolitan Law has intensified socio-environmental inequalities and catalysed new forms of grassroots resistance. These dynamics are explored through the lens of urban political ecology, which provides a critical framework for analysing how capitalist urbanisation reshapes both environments and the social movements that emerge in response.

Although urban social movements have been widely studied, ecological resistance in administratively urbanized but geographically peripheral contexts remains underexplored. This paper posits that the ecological movements in Ayvalık represent an emergent form of urban ecological resistance—a localized response to the restructuring of nature as part of urban space. By confronting the contradictions of planetary urbanisation, these movements offer a situated critique of centralized planning and a reimagining of the urban-rural interface. Accordingly, the central research question guiding this study is: What kinds of environmental movements evolve in response to the changing conceptualization and perception of 'nature' under the conditions of planetary urbanisation intensified by a governance reform such as the Metropolitan Law?

The analysis is based on qualitative social science research conducted in Ayvalık over a period of 2 years (2023-2025) complemented by policy document analysis and a review of academic and gray literatures. This involved 6 in-depth interviews with the actors of resistance (activists and locals who comprise the resistance), academicians, and architects working specifically on Ayvalık and the ongoing spatial change. In doing so, it contributes to critical planning and urban theory by illuminating how peripheral geographies expose the uneven, multi-scalar nature of urbanisation and the political possibilities that arise from it. By foregrounding the role of legal instruments in reshaping territorial governance, the study demonstrates how planetary urbanisation reconfigure both material environments and forms of political agency. Through the case of Ayvalık, the paper reveals the entangled geographies of urban and rural transformation and the grassroots resistances that contest and redefine these boundaries under centralized governance.

Tracing The Urban-Rural Boundary Through Ayvalik's Socio- Ecological Transformations

The coastal town of Ayvalık is located in the Aegean region of Balıkesir Province, in northwestern Turkey. It is bordered by Gömeç to the north, Dikili to the south, and Bergama to the southeast (Figure 1). Characterized by its undulating topography, Ayvalık is an archipelago consisting of more than twenty islands and islets, the most prominent being Cunda Island—also known as Alibey. Due to its positioning within an archipelago, Ayvalık lies on a small inland sea, protected by Cunda within a sheltered bay. The broader geographical context includes

the Madra Mountains to the east and the Aegean Sea to the west, with the city itself expanding between coastal areas and hills rising 100–200 meters inland. Over time, the urban fabric has extended toward these hills and further northward. Its location on the western edge of this inland sea, formed between Central Anatolia and the island of Lesvos (Midilli), has long shaped Ayvalık's identity as a key node in olive oil production since the 19th century.

Figure 1. The location of Ayvalık. Source: Google Earth.

Ayvalık is designated both as an 'urban conservation area' due to its historic port and traditional settlement patterns, and as a 'natural conservation area' to preserve its olive groves and protected landscapes. A range of legal frameworks concerning cultural heritage, forestry, and agriculture regulates and safeguards the region. The olive groves, central to Ayvalık's heritage, are protected under specific agricultural policies, and conservation designations cover areas such as Cunda Island, parts of the Hakkı Bey Peninsula, and 20 of the 22 surrounding islands. Portions of this landscape have also been incorporated into a national park to ensure long-term ecological preservation. In recognition of its cultural and industrial significance, the Ayvalık Industrial Landscape was added to the UNESCO World Heritage Tentative List in 2017 (Tentative List Ref. No. 6243). The town's well-preserved industrial buildings, along with its port, traditional settlement, and olive groves—covering 13,200 hectares—offer a comprehensive portrayal of the industrialization process (UNESCO World Heritage, 2017). By the 1980s, with the growing prominence of the tourism sector, Ayvalık began to be recognized as a desirable tourist destination due to its coastal features and natural beauty.

The earliest documented references to Ayvalık date to the 16th century, while local oral traditions trace its founding to around 1580 by members of the Greek community (Şahin Güçhan, 2008). Despite a lack of continuous documentation, it is known that Ayvalık was granted autonomy by imperial edict around 1789, marking a period of rapid urban growth and a predominantly Greek population (Sağlam, 2022). During the 19th century,

within the Ottoman Empire, Ayvalık became a key port town on the western Anatolian coast, owing to its thriving olive oil and soap production and trade networks (Akin Akbüber, 2015).

By this time, Ayvalık was home to over a hundred olive oil presses and more than thirty soap factories. It supplied a substantial portion of Istanbul's olive oil and soap needs, with exports extending to regions such as Thrace, Macedonia, and even Russia (Yaman-Kocadağlı, 2011). This economic boom, especially during the late 18th and early 19th centuries, significantly increased the town's population and wealth. Infrastructure developments, alongside the olive oil industry's profitability, transformed Ayvalık from a modest coastal settlement into a significant "commercial harbor city" within just a century (Akin Akbüber, 2015, 2020; Uçar, 2015; Sağlam, 2022). Despite the enduring spatial imprints of its port-based industrial identity, Ayvalık's urban fabric and social composition have been continually reshaped by social and ecological upheavals. From the earliest records to the 2000s, major shifts in population, social structure, and spatial organization can be attributed to Ayvalık's coastal geography and ecological vulnerability. However, the nature and impact of these ruptures have evolved considerably in recent decades (Figure 2).

In the 18th century, the population was predominantly Turkish. However, by the 19th century, the influx of Greek migrants dramatically shifted the demographic composition (Balcı Akova, 2011; Yaman-Kocadağlı, 2011). Nationalist sentiments following the French Revolution contributed to uprisings among the Greek population, and the first major rupture in Ayvalık's socio-environmental history was the 1821 Greek Revolution. While this period was devastating, historical accounts emphasize Ayvalık's resilience and subsequent recovery (Sağlam, 2022). Later crises included a destructive earthquake in 1866 and, nearly fifty years later, the turmoil and abandonment caused by the Turkish War of Independence (1919–1923).

The 1923 population exchange between Turkey and Greece marked a fundamental transformation, permanently displacing the original Greek inhabitants and replacing them with Turkish populations from Lesvos, Crete, and Thrace (Anastassiadou, 2012, as cited in Sağlam, 2022). This exchange drastically altered the city's social, spatial, and economic structures (Balcı Akova, 2011; Yaman-Kocadağlı, 2011). According to the 1927 national census, Ayvalık's population had dropped from 31,894 in 1914 to 16,873, reflecting the effects of war and forced migration. Two additional earthquakes in the 1940s marked the final major crises in the town's pre-contemporary history.

Periodic uprisings and interethnic tensions in this once multi-religious, multilingual, and multiethnic town disrupted both its economy and built environment. The aftermath of the population exchange triggered a period of stagnation, as the newly settled communities faced challenges adapting to the existing social and economic structures. However, by the 1960s, Ayvalık entered a new phase of development. While agriculture and agro-industrial activities remained important, tourism began to play a growing role in the town's economy. Investments in accommodation facilities, beaches, and coastal infrastructure increased tourism revenues (Yorulmaz, 1997, p. 127). After 1963, the Turkish government provided financial support for coastal tourism development, and in 1969, Ayvalık was designated a priority area for tourism investment (Cantimur, 2011). This sector expanded significantly after the 1980s, becoming central to Ayvalık's urban and economic trajectory (Yaman-Kocadağlı, 2011).

The increasing influence of tourism created an urgent need for a structured development plan in the second half of the 20th century. A 1/1000-scale development plan was prepared in 1972, but its implementation was limited. Proposed developments on Cunda and Lale Islands were not realized due to low construction demand (UNESCO World Heritage, 2017). A major initiative from this plan—the relocation of olive oil factories outside the city—was implemented in the 1980s. During this time, Ayvalık and parts of Cunda were designated as Natural and Historic Conservation Areas in 1976, followed by temporary development regulations in 1978. Until 1982, the plan was revised and partially applied outside the conservation zones (Şahin Güçhan, 1986, pp. 28–35; UNESCO World Heritage, 2017).

The Protection of Cultural and Natural Properties Law (Law No. 2863), enacted in 1983, brought Ayvalık under the jurisdiction of the newly formed Bursa Regional Conservation Council. In the late 1980s, the boundaries and regulations of the conservation zones were revised. Regional development plans were approved in 1990 for non-conservation areas, and in 1994, an urban heritage conservation plan was adopted and remains in use (Şahin Güçhan, 1986, pp. 28–35).

Between 1976 and the mid-1990s, new developments were permitted only outside urban conservation zones, leading to the construction of low-density summer houses and tourism facilities. The relocation of polluting industries helped mitigate some environmental issues, but also left many industrial buildings unused. However, since the 2000s, there has been renewed interest in preserving these structures through local initiatives involving businesses, the municipality, and civil society organizations. These efforts contributed to a more organized heritage conservation strategy in Ayvalık (Cantimur, 2011; UNESCO World Heritage, 2017).

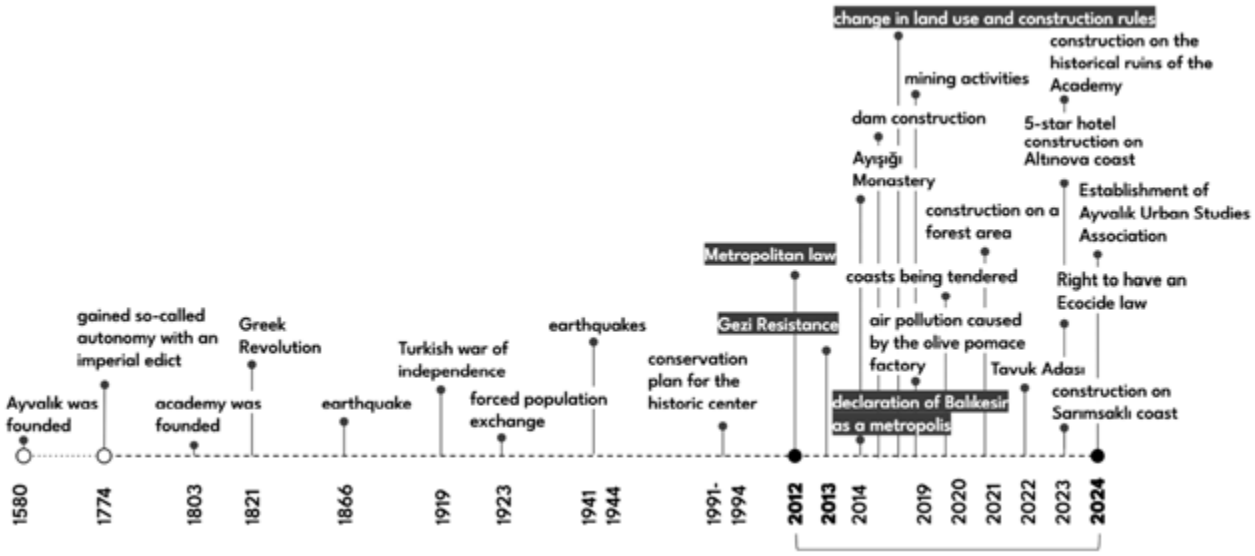

Figure 2. The brief history of Ayvalık. Produced by the author.

The social and ecological crises in Ayvalık—referred to here as "ruptures"—involve abrupt transformations in population dynamics (Balcı Akova, 2011), spatial organization (Sağlam, 2022), and urban governance. David Harvey (2011, 2012), in his analysis of urban revolutions, identifies such crises as intrinsic outcomes of capitalist accumulation, noting that urban environments are both sites of accumulation and of resistance. In Ayvalık, these crises have intensified since 2012 with the growing influence of neoliberal urbanism and tourism-driven development, accompanied by the privatization of public goods and services and a consequent decline in quality (Harvey, 2012; Friedmann, 2014). In this context, nature has increasingly been commodified, repurposed as a vehicle for capital accumulation (Smith, 2007), yet these processes have also provoked significant resistance.

Metropolitanization: Planetary Urbanisation Arrives In Ayvalik

Back in 2002, 65% of Turkey's population was noted as urban, with more than half residing within the boundaries of sixteen metropolitan municipalities. Early in its term, the AKP government moved to expand these metropolitan boundaries through legislation in 2004. By 2012, as a result of a series of reforms, 76% of the population lived in areas designated as metropolitan, which encompassed 55% of the nation's land (Arıkboğa, 2013; Zengin, 2014). At the latter end, the last regulation in 2012 redefined the metropolitan structure and villages were integrated into metropolitan districts by expanding municipal governance into peripheral areas. This does not only entail the expansion of municipal administration to the peripheries, it also changes the definition of urban with the increasing influence of the periphery in urban politics (Batuman, 2017, p. 110).

Balıkesir was among the provinces affected by these governance and policy changes. With the enactment of Law No. 6360, titled "The Establishment of Metropolitan Municipalities in Fourteen Provinces, the Formation of Twenty-Seven Districts, and Amendments to Certain Legislative Decrees," which was adopted on November 12, 2012, and published in the Official Gazette on December 6, 2012, Balıkesir Metropolitan Municipality was established, and its jurisdiction was defined as the entire provincial territory (Resmî Gazete, 2012). According to the Turkish Statistical Institute (TÜİK), as of 2014, Balıkesir no longer has a statistically defined rural population due to its designation as a metropolitan municipality. In 2012, however, 61.32% of the population resided in provincial and district centres while 38.68% lived in towns and villages (Balıkesir Büyükşehir Belediyesi, 2024).

In addition to Balıkesir, in the provinces of Aydın, Denizli, Hatay, Malatya, Manisa, Kahramanmaraş, Mardin, Muğla, Ordu, Tekirdağ, Trabzon, Şanlıurfa, and Van, metropolitan municipalities were established under the same name, with their jurisdiction defined by the provincial administrative boundaries (Resmî Gazete, 2012). Consequently, the existing provincial municipalities in these areas were restructured as metropolitan municipalities. With the legislative amendment, the number of metropolitan municipalities in Turkey has reached 30.

The regulation became effective in 2014 with the local administration general elections held on March 30. Since that time, Balıkesir has been governed as a Metropolitan Municipality. In the days following the elections, public statements began appearing in the media, emphasizing plans to transform Balıkesir into an "attraction center." It was announced that numerous new projects would be introduced to achieve this goal. These projects ranged from infrastructure developments, such as wastewater treatment facilities to reduce marine and environmental pollution, and the construction of overpasses and highways, to large-scale investments aimed at making both the city center and its districts key attraction points. These included tourism centers, ports, a regional hospital, an airport, shopping malls, and new residential developments. The Balıkesir-Çanakkale Planning Region 1/100,000 Scale Environmental Plan also provided a higher-level framework supporting these large-scale projects and investments. Additionally, the invitation and brochure for the 7th Emerging Cities Summit, held on May 6–7, 2015, described Balıkesir as the "shining star of the Marmara region," highlighting its central location at the intersection of major highways and positioning it as a prime destination for investors (Özerk, 2017). During presentations at the summit, Balıkesir's strategic location—close to major highways and metropolitan areas—was emphasized to attract investment for planned projects. Meanwhile, numerous so-called "visionary projects," promoted under the goal of making Balıkesir a "brand city," began to receive extensive coverage in both print and digital media (Özerk, 2017).

The delineated concentration of production, population, and infrastructure within the metropolitan area serves as a driving force for capital accumulation and transformation of locations, regions, and landscapes across various spatial scales (Soja, 2000; Krätke, 2014; Scott et al., 2015). As previously discussed and presented in earlier sections, contemporary forms of urbanisation are already disrupting and redefining the traditional boundaries of cities, including those of major metropolitan areas, as they alter existing regional arrangements and increasingly blur the distinction between urban and non-urban areas (Brenner, 2013; Brenner et al., 2014). The metropolitan law on the other hand has adopted a disruptive approach, accelerating and evolving the process and drawing its own boundaries. In this sense, legal and regulatory changes have been politically instrumentalized within the context of urban spatial reproductions to find new ways of capital accumulation.

Ayvalık was deeply affected by the changes in metropolitan structure. In 2012, Balıkesir was declared a metropolitan city, and Ayvalık's local administration saw changes in its authority. Similar to what has been argued with the thesis of planetary urbanisation, the Metropolitan law can be considered to crystallize the explosion and expansion of the urban, leading to the autonomy of small and medium-sized cities, transforming them into the 'virtual colonies of the metropolis' (Schmid, 2014, p. 69). In this sense, Ayvalık became liable to be conceptualized as a 'virtual colony' of its neighbouring metropolitan cities, namely Izmir and Istanbul, considering the established trade network settled primarily on olive.

Upon examining the urbanisation process following the change in administration in Ayvalık, urban projects tendered or proposed by the Balıkesir Metropolitan Municipality have been brought forward. Following this decision, what is frequently emphasized is the revival of numerous proposals, which were previously planned but reportedly suppressed in the past due to strong opposition from the local municipality. In addition, one of the most significant challenges currently facing the local community is the lack of sufficient attention and support from the metropolitan municipality towards local issues. The ongoing socio-ecological issues of Ayvalık are being marginalized by the metropolitan municipality, eliciting apprehensions regarding the prevailing perception of an unattended local voice.

Following Balıkesir's declaration as a metropolitan city in 2014, Ayvalık experienced negligible advantages. The top-down management style of the metropolitan municipality was unable to adequately address the local needs. (A representative of ATP)

With the changes in jurisdiction, the Water and Sewerage Treatment Plants were transferred to the metropolitan municipality. In the past, we saw that these treatment plants were not being operated before the election. We organized many protests and made significant efforts to get the treatment plants running, but we couldn't achieve any results. The Metropolitan Municipality Law has also become something that exacerbates such problems and disruptions from an ecological perspective. I believe it was entirely created out of political concerns (TİP Balıkesir Provincial Administration Ecology Officer)

Giving the decision-making power to higher levels of governance undermines the autonomy and effectiveness of district municipalities. This shift in power diminishes the decision-making capacity and active participation of local governments, which are best suited to manage and respond to the immediate needs of their communities, such as waste collection and maintaining clean streets. Governance should be grounded in the local context, where the management of daily life is most effective, and where resources, personnel, and decisions can directly address the specific needs of the area. Centralizing authority not only disrupts the functionality of local governance but also weakens the direct connection between the government and the community it serves.

Delegating governance to a higher level inherently means bypassing the local will. It restricts decision-making capacity, reduces agency, and diminishes participation. In essence, it strips the locality of its governing power. A district municipality operates at the smallest scale—handling tasks such as waste collection, street maintenance, and addressing community needs. Governance must be approached from within the flow of everyday life; it cannot be effectively managed from a different scale. Managing the district requires establishing a framework that aligns with its budget, personnel, and tangible presence in daily life. (Group member of AKVG)

The shift in the governance model shows the indicators of metropolitanization and how planetary urbanisation have arrived in Ayvalık through different modes of reshaping urban space and nature. Whether through appropriation or degradation, and whether under protection or without, nature remains central to capitalist strategies, which seek to integrate it into the circuits of capital accumulation, often without regard for the resulting socio-ecological consequences (Cortes-Vazquez et al., 2019). In this sense, employing a historically and geographically grounded approach to the study of urban nature production allows for a critical understanding of the unequal power relations shaping these processes, which also guides the potential transformation of these power relations (Swyngedouw, 2006). In the case of Ayvalık, the changes in authority and legislation embark on the socio-ecological exploitations, which have also manifested themselves through several cases within the contemporary capitalist form of urbanisation patterns embedded in the urban realm.

Despite Ayvalık having confronted various instances of social and environmental disruption in the past, including earthquakes, the Greek Revolution, and the population exchange between Greece and Turkey, it has never experienced such heightened socio-ecological degradation as it currently faces in the present neoliberal era. The AKP government has demonstrated a distinctly exploitative approach toward nature (Çoban, 2019). Since 2002, the government has worked hand in hand with capital, depleting both human and non-human aspects of nature to sustain and expand a capitalist accumulation regime. However, the environmental destruction caused by the AKP government is not a new phenomenon in Turkey. This phenomenon is not limited to the advanced economies of the West but is even more pronounced in emerging centres of capitalist expansion, such as China, Turkey, and India. The restructuring of urban and natural environments plays a pivotal role in the accumulation and circulation of capital in the contemporary era (Karakayali et al., 2014). As history has shown, wherever capitalism exists, environmental degradation inevitably follows (Çoban, 2019). Nevertheless, Ayvalık endeavours to resist and firmly preserve its pre-established urban and ecological identity which is characterized by designated urban and natural conservation areas, alongside first-degree protected islands and nature parks. Despite efforts to preserve Ayvalık's established urban and ecological identity, current urbanisation trends are largely shaped by ongoing changes in governance, planning, and legislation. The dissolution of district municipalities, modifications to urban plans, and shifting regulations have created conditions that enable capitalist-driven environmental exploitation, exerting a dominant influence over the region's development.

Recent developments, especially over the past five years, serve as indicators of the impact of neoliberal urbanisation in Ayvalık; every part of the city bears the results of various exploitations (TİP Balıkesir Provincial Administration Ecology Officer)

The urbanisation of Ayvalık has not only altered its material and administrative configuration but also transformed its socio-political landscape. As urban expansion reaches peripheral territories, existing environmental conflicts have intensified, while new socio-spatial tensions have emerged. These developments reflect broader patterns of socio-environmental inequality and undemocratic spatial change, hallmarks of the neoliberal urban condition (Cortes-Vazquez et al., 2019). In this context, resistance movements have acquired an urban ecological character—rooted in the localized defence of nature yet shaped by planetary processes of urban transformation. These movements challenge rent-seeking urban development and centralized governance while articulating alternative visions of ecological stewardship, spatial justice, and democratic agency. Additionally, as cities increasingly become arenas for financial speculation, urban spaces have emerged as primary sites of contestation, where struggles focus on preserving and shaping the fundamental conditions of human life—including public spaces, neighborhoods, and natural landscapes (Karakayali & Yaka, 2014). In this context, within the framework of consciousness towards the democratic 'rights'—the right to the city and nature, as the activists have frequently stated— the accumulation of socio-ecological challenges in Ayvalık has originated urban ecological movements. Furthermore, resistance in these areas acquire a potentially radical and transformative nature, as it directly challenges the urban and environmental transformations that have become central to capital circulation in the neoliberal era (Karakayali & Yaka, 2014).

Urban Ecological Movements In Ayvalik

The interaction between urban spaces and natural environments has become increasingly complex, particularly in contemporary capitalist relations. In cities like Ayvalık, where commercial activities and tourism largely depend on natural resources and a capital-oriented approach to urbanisation is prevalent, the city, and nature are simultaneously contradictory and mutually reinforcing. The expansion of the urban, in this sense, can also be associated with the exploitation of natural resources, significantly altering the relationship between cities and the environment. It is driven by economic imperatives, where both nature and urban are reconstructed by the forces of capital. This process of reconstruction was argued to be defined as urban interference towards nature, in which the transformation of nature into urbanized environments reflects broader trends in neoliberal development. In this section of the study, I will exemplify nature that has been intensely subjected to urban interventions driven by dominant urban and environmental policies.

A considerable number of areas in Ayvalık, particularly those located in the coastal region, have been experiencing a process of spatial and ecological degradation as a result of urban interventions, which are primarily driven by profit-oriented projects. These environmental issues have become focal points of resistance for volunteers, residents, and civil initiatives, leading to the recreation of both urban space and nature, as well as the adoption of new social practices. In this context, spaces shaped by the intersection of environmental degradation and collective opposition begin to constitute what can be described as oppositional landscapes—geographies marked by contestation, grassroots activism, and alternative imaginaries of urban-nature relations.

While these oppositions have been spatially grounded in Ayvalık, their roots lie in a broader trajectory of ecological activism across Turkey. In particular, in the Black Sea, Marmara, and Aegean regions, numerous local and civil initiatives are actively organized in opposition to the planned energy investments. These mobilizations have been so effective that they have led to a stay of execution (Kadirbeyoglu, 2005; Gönenç, 2022). In this context, the concept of 'counter-hegemonic flows' (as conceptualized by E. Turan & AydΔn, 2023) has experienced a resurgence as local ecological struggles have expanded opposition to renewable energy in Turkey. Although environmentalism provided the most effective critique of neoliberal urbanisation in Turkey, its influence declined significantly after the 2011 elections, as evidenced by the failure of environmental activists to get most hydroelectric power plant (HPP) projects cancelled (Batuman, 2017). However, the Gezi Park protests in 2013 marked a critical turning point, revitalizing environmental activism and broader urban struggles. As a defining moment, Gezi not only lend impetus for collective mobilization against neoliberal urbanisation but also introduced a new vision of urban social movements in Turkey, bringing environmental concerns to the urban agenda (Karakayali et al., 2014) by fostering new political imaginaries that connected and reinforced various grassroots and political mobilizations that had preceded it (Erensü et al., 2017). While some studies have pointed to the absence of a cohesive environmental movement and limited political representation, along with the financial constraints hindering rural communities from engaging in sustained activism (Duru, 2013; Paker, 2013), the past fifteen years have nonetheless seen significant civil society efforts and government-led initiatives opposing large-scale investments at both local and national levels. The impact of the Gezi protests extended well beyond its time, with the so-called 'Gezi spirit'

continuing to inspire opposition movements and shape Turkey's cultural landscape and political discourse (Erensü et al., 2017, p. 2). Consequently, the urbanized conditions of Ayvalık have come to delineate new forms of resistance shaped around the accumulation of urban crises and the extension or spread of the urban resistance agenda, gained during and after the Gezi Park protests.

In the wake of the 2014 local elections, a substantial part of the coastal area in Sarımsaklı Beach was leased to the Metropolitan Municipality with the intention, as expressed by the municipality, of capitalizing on and incorporating it into the market to promote Ayvalık as a global brand and boost tourism (Durgun, 2023). The initial proposal according to this intention was unveiled in 2015, however, postponed due to strong oppositions from the community of Ayvalık. Nevertheless, as of 2021, Sarımsaklı coast has been reclassified from a 'public beach' to a 'sustainable protection and controlled utilization area', rendering the existing plan ineffective. Based on this, the construction on the beach has started following the proposed design. The natural environment was attempted to be instrumentalized as an accumulation strategy. It is defined as an urbanized intervention that has led the way for the further construction of Sarımsaklı and the marketing of Ayvalık under the name of tourism. As discussed earlier, alterations in the conservation status of areas in Ayvalık, influenced by top-down decisions, are dominant factors shaping the condition of 'natural' spaces within the current neoliberal urbanisation dynamics.

This change in Sarımsaklı coast has paved the way for construction under the label of 'Recreation Area,' marking the final step of a long-planned project. Despite claims by authorities that the ongoing construction on Sarımsaklı beach is situated in a degraded sandy area, this assertion does not align with the actual circumstances. Since the enactment of the Metropolitan law, district governance has been marginalized in addressing this dimension of the socio-environmental crisis. In addition to this, despite repeated claims by Balıkesir Metropolitan Municipality that the process was conducted with public participation through field research in 2022, the project has encountered significant opposition from both the local populace and resistance groups; the criticisms mainly pointing out the deviations from coastal law, planning and urbanisation principles, and public interest.

The social practices that have emerged in response to ongoing spatial and environmental interferences in Ayvalık manifest in the form of petition campaigns, press statements, and organizing demonstrations; the sites hosting these movements show the differentiated modes of urbanisation by looking at the emerging social practices. The resistances that we would like to specifically mention in this section are the 'Beach Towel Revolt' that took place in Sarımsaklı beach and the coastal resistances mobilized with the frame of "We are all on the coast," reclaiming the coastal areas by demanding the right to the city and nature.

The most recent protest in Ayvalık concerns the privatization of the coasts and demanding the implication of existing coastal laws; it has spatialized in various points locally and nationally encompassing the other coastal towns, i.e. Bodrum, Datça, Çeşme, Fethiye, Burgazada, Daylan, etc. The struggle has evolved into an urban ecological movement because of the reason for it and the connections established among the national sites of resistance. The interconnectedness of sites of protest emphasizes the powerful potential of environmental issues to resonate with one another, making it easier to achieve collective unity in the resistance. In this regard, while Sarımsaklı Beach stands as a protest site that overlaps directly with the object of contention, other instances in Ayvalık illustrate how spatial strategies of resistance can also unfold in more symbolically charged or centrally located public spaces.

Figure 3. Excavator traces on sand, Sarımsaklı. Photographs are taken by the author in January 2024.

The ongoing construction on Sarımsaklı Beach (Figure 3) and the restriction of public access have manifested in a form of protest rarely encountered in an 'urban' context, as part of broader urban and environmental activism by the local people and resistance groups. In response to the call by the Ayvalık Initiative for the Protection of Cultural and Natural Heritage (Ayvalık Kültür ve Tabiat Varlıklarını Koruma Girişimi – AKVG) and Ayvalık Nature Platform (Ayvalık Tabiat Platformu – ATP) under the 'Beaches Belong to the People' movement, residents of Ayvalık mobilized in streets, squares, and beaches symbolically using 'beach towels' to claim the right to the city and reappropriate the contested urban space through bodily engagement. Soon after the actions and press statements of activists from the ATP, environmental volunteers, and the AKVG began to be organized at Sarımsaklı Beach, the area was transformed from a site of daily life into a space for activism. These individuals, institutions, and initiatives, characterized by their opposition, played a crucial role in the spatial transformation of the beach by organizing activities that intertwined with the ordinary flow of daily life at the beach—events that would otherwise be considered unusual and extraordinary at any other beach.

Through their practices, Sarımsaklı Beach has been transformed and differentiated, becoming a place where political activism has become an ordinary part of everyday life. This illustrates how the daily routine in a space where urban and non-urban intersect is momentarily disrupted by the dynamics of differential urbanisation, transforming the beach into both a site of protest and a site of resistance (Dinçer, 2016). Therefore, while Sarımsaklı Beach is ecologically significant due to its endemic plant diversity and holds importance as a popular tourism and holiday destination, it can be said that the activism on the beach has further emphasized its distinctiveness distinguishing it from other beaches.

Figure 4. A photograph taken during an urban ecological movement happening in Sarımsaklı. Source: Archives of Ayvalık Nature Platform

What sets Sarımsaklı Beach apart is the intertwining of daily life with political activities in a space where the effects of environmental destruction and neoliberal urban and environmental policies are most clearly observed. Notably, the Beach Towel Revolt transformed the most common activity on the beach—sunbathing—into an expression of protest, making protest a natural part of life at the beach (Figure 4). This convergence and integration mean that the beach is seen as more than just a site for demonstrations; it allows the potential for individuals from the flow of everyday life at the beach to participate in the resistance. Thus, resistance becomes a practice that can be experienced within daily life, even at the beach, allowing anyone to become an actor in collective activism. Here, the ease and perceived 'safety' of participating in resistance efforts with an environmental aspect, compared to other types, undoubtedly has a significant impact.

I find the ecological struggle to be somewhat successful because it is one of the forms of activism that people find most comfortable and easy to participate in. They start out with a love for nature and animals, and it doesn't necessarily require a serious political consciousness at first. That political awareness develops throughout the process. (TİP Balıkesir Provincial Administration Ecology Officer)

These actions occur as practices that do not interrupt the ongoing daily life at the beach, but rather integrate into it. Political activities and sunbathing, along with swimming, occur in the same space, becoming intertwined. Yet, the protest was not limited to a certain site; with resonance on social media among locals of Ayvalık, it also evolved into action to protect public areas under the Coastal Law. These protests highlighted the socio-ecological exploitation occurring in an area previously designated as a 'Public Open Beach,' now reclassified as a 'Recreation Area.' Hence, the ongoing socio-environmental exploitation and urban ecological movements in the Sarımsaklı coast exemplify the urbanized interventions during the period of neoliberal urbanisation.

Concluding Remarks

This paper has examined the socio-ecological implications of Law No. 6360 through the lens of Ayvalık, highlighting how centralized governance mechanisms reshape the urban–rural interface under the conditions of planetary urbanisation. By extending the jurisdiction of metropolitan municipalities, the law not only redefined legal and administrative boundaries but also restructured material environments and social relations across previously rural territories. According to the analyses it is observed that in Ayvalık, these transformations have intensified land commodification, environmental degradation, and socio-spatial inequalities—revealing the deep entanglement of ecological and political crises within the contemporary urban condition.

Framing Ayvalık as a metropolitan hinterland has allowed us to trace the uneven geographies of state-led urbanisation, where peripheral spaces are subsumed into the urban regime while remaining politically marginalized. Yet, these same geographies have become sites of contestation, where grassroots actors engage in ecological resistance not merely to preserve landscapes, but to reclaim decision-making power, assert local autonomy, and articulate alternative spatial imaginaries. These movements expose the contradictions of capitalist urbanisation and challenge the symbolic and functional erasure of the rural under centralized rule.

By foregrounding the relational production of space and nature, this study contributes to a growing body of work within urban political ecology that seeks to re-theorize urbanisation as a socio-natural process. It suggests that attention to peripheral, administratively urbanized territories can reveal important insights into the workings of state power, the material politics of planning, and the emergence of new forms of environmental activism. In doing so, it calls for planning and governance frameworks that are ecologically informed, territorially sensitive, and democratically accountable—capable of recognizing the situated knowledge and lived experiences of those who inhabit urbanizing landscapes.

Construction of Regional Multi-dimensional Proximity Network from the Perspective of Collaborative Agglomeration — Analysis of Geographical Proximity Networks in Contiguous Rural Spaces

Guyue Sun, Hong Jiang
Affiliation: Southeast University
Email: geniesun0110@163.com

Abstract
This study applies collaborative agglomeration theory to investigate how geographical proximity influences rural spatial networks across 678 villages in Xinghua, China. We analyze three key dimensions of geographical proximity network: morphological distribution patterns, geographical scale relationships, and cultural superposition characteristics. Based on this, it was found that the river network and historical wei-field development jointly shaped the settlement pattern of clustering in the east and dispersion in the northwest. And the region forms a "core-edge" network structure with the urban area and Dainan Town as the core, and the northwest water network area as the edge. Water-aligned cultural resources show dual-core clustering with collaborative potential. Study provides spatial optimisation basis for rural contiguous development, and further integration of industrial and social proximity will be constructed in the future.

Key Words: Geographical proximity network; Rural space; Morphology agglomeration; Gravity model; Regional multi-dimensional proximity

1. Introduction

In the context of global urbanisation and sustainable development, the concept of "Collaborative Governance" proposed in the 2016 United Nations New Urban Agenda breaks through the limitations of traditional administrative boundaries and advocates cross regional collaboration to address global challenges such as climate change. This concept has gained widespread consensus not only in the study of various factors such as environment and transportation in cities (Fan et al., 2022, Wang and Zhao, 2021, Jinsoo and Suh, 2012), but also in the analysis of urban networks(Luo et al., 2025) and industrial associations between urban clusters, revealing the promoting effect of collaborative agglomeration on regional innovation (Ma et al., 2021, Huggins and Prokop, 2017, Shearmur, 2012). Similarly, rural spaces are also showing a significant trend of collaborative development(He et al., 2019, Luo et al., 2020), gradually transitioning from dispersed layout to networked agglomeration through resource integration and functional complementarity. This new paradigm of coordinated urban-rural development provides important theoretical support and practical paths for regional spatial reconstruction.

The formation and development of contiguous rural spaces are the result of multiple factors working together. This study draws on the concept of multi-dimensional proximity (Tobler, 1970, Ma et al., 2021, Zhou et al., 2024) in economic geography, which is divided into geographic proximity, social proximity and cognitive proximity. The study applied them to rural spatial analysis to reveal how these factors synergistically shape the spatial organisation of rural spaces. From a spatial perspective, geographical proximity shapes the similarity of regional background characteristics through natural geographical conditions and historical accumulation. From the perspective of development, social proximity is manifested as the convergence of industrial technology paths and development directions. From a cognitive perspective, the values of villagers and development vision constitute the impetus for promoting collaborative development. Through complex interactions of the three dimensions, they jointly affect the agglomeration form and collaborative development path of rural spaces. This study takes the geographical proximity of rural spaces as the starting point, and provides a theoretical basis for revealing the underlying factors of regional coordinated development by analyzing their spatial distribution characteristics and network correlation mechanisms.

In terms of the geographical agglomeration of contiguous rural spaces, academic and practical study on rural areas mainly focuses on three aspects: spatial distribution patterns, historical dynamics, contiguous protection methods, and patterns. 1) Study on the spatial distribution patterns of villages. Most studies evaluate the spatial layout of rural spaces at the meso and micro scales through modeling methods such as gravity models and rank scale rules(Liu et al., 2024, Sun et al., 2025), and use this as a basis to divide rural clusters and optimise resource allocation. 2) Study on the formation and evolution mechanism of rural geographic space from the perspective of historical evolution. By proposing a hierarchical model of the "human-earth-network" relationship in cyberspace (Guo et al., 2021), the relationship between different elements combined and overlaid in space to

form different spatial forms can be determined. Then, the correlation analysis and classification of the division of concentrated contiguous areas were carried out, emphasizing the layering of history. 3) Exploration of traditional village contiguous protection methods and models. This aspect emphasises the formation of a comprehensive control system covering the entire process from the perspective of operational management and control (Pan et al., 2024). The three major stages are sorting out the resource base before application, formulate protection and utilisation guidelines during planning, and regularly monitor the results after implementation, which are interrelated. Most current study examines key villages through multi-factor analysis while neglecting studies on ordinary village patterns. Additionally, these studies consistently overlook historical and cultural dimensions in their assessment of village influencing factors.

In the process of conducting study on rural spaces, the geographical background characteristics serve as the basic carrier of spatial similarity and functional connections, providing a background explanatory framework for identifying the agglomeration characteristic of rural space. After incorporating historical and cultural factors, they profoundly influence the spatial organisation mode and development path of rural space together. This study constructs a geographical proximity network analysis model from the perspective of collaborative agglomeration. Through quantitative analysis of geographical scale, history and other data, it not only intuitively displays the spatial distribution pattern of villages, but also reveals the potential multi-dimensional proximity relationship network between settlements. Thus, it can break through the static description limitations of traditional rural spatial study. By combining this with subsequent social and cognitive proximity analysis, study could deepen from spatial proximity to functional proximity. Thereby we can identify key hubs and weak links in regional collaborative development more accurately.

2. Study region and background

Xinghua is a county-level city under the jurisdiction of Jiangsu Province and managed by Taizhou in China. It is located in the central part of Jiangsu Province, between the Yangtze River and the Huai River. The total area of the city is 2393 square kilometers, with 26 townships and 3 streets under its jurisdiction, and a total of 678 incorporated villages. Xinghua is a typical Lixiahe Plain, centered around a plain depression based on beach tidal flats. The overall style is unique and has the potential for collaborative agglomeration and development. And it has currently achieved full coverage of development-oriented village planning, shouldering the important task of national-level rural revitalisation work such as the Construction of Characteristic Rural Demonstration Areas. This study combines the case of Xinghua to illustrate the practical characteristics of rural space, providing ideas and practical guidance for the delineation of regional collaborative agglomeration units.

The landform of the same origin is gradually differentiating, with distinctive features

Geomorphic bases with similar regional ranges will gradually generate regional differentiation due to the dual effects of human intervention and natural evolution. For example, Xinghua is located in the hinterland of the Lixia River. Since ancient times, the hydrographic net has been dense and the lakes and marshes have been intertwined. Although the terrain is similar, it has gradually differentiated due to the evolution of the hydrographic net and human activities during history, forming unique landscape patterns such as raised fields, wei-fields, and lakes and marshes (Yuan, 2025). In the early days, our ancestors lived by water, built embankments and fields, and piled up soil which formed raised fields to adapt to the water environment, laying the foundation for the basic agricultural form (Shi et al., 2022, Yuan and Wang, 2019). With the development of water transportation and the rise of docks along the river, commercial and handicraft industries have gathered, and the settlement pattern has evolved accordingly(Hu, 2024). Areas with dense river networks form streets and markets due to the prosperity of commerce and trade. On the edge of the lake, fishing villages have emerged due to aquaculture. Areas with less dense river networks are still dominated by traditional agriculture.

Settlements are difficult to cluster due to their scattered and disordered distribution

The traditional small-scale agricultural production methods and scattered rural industries have jointly led to the inefficient spatial structure of villages. It manifests as limited residential area size and scattered factor allocation, making it difficult to form agglomeration effects. Despite the continuous efforts of the country's rural development policies in recent years, the problems of low space utilisation efficiency and fragmented layout have not been fundamentally alleviated. For example, Xinghua rural areas also have problems of scattered scale and spatial fragmentation. Due to the scattered raised fields formed during the development of wei-fields in the Ming Dynasty, farmers settled nearby, forming a “one wei-field, one village” pattern. Some villages are distributed

in a bead-like pattern along tributaries such as the Bangyan River and the Luting River. The average size of these villages is much smaller than that of incorporated villages in Jiangsu Province, China, where the average village typically has about 350 households. Due to the overall lack of central agglomeration areas, coupled with the trend of hollowing out and idle homestead land, there are serious problems of scattered scale and spatial fragmentation.

The phenomenon of insufficient resource utilisation and uneven development of villages and towns is prominent

The insufficient utilisation of characteristic resources, policy differences, and varying development drivers can lead to the formation of a multi-level differentiated development pattern in the region (Wang et al., 2024). For example, the development of rural areas in Xinghua presents obvious characteristics of differentiated driving forces, forming an unbalanced spatial pattern. The cultural and tourism driven areas, represented by Shagou Town and Qianduo Town, rely on historical and cultural resources and raised field landscape to drive the development of tourism supporting industries in surrounding villages. But due to their limited radiation range, villages 5 kilometers away have not been affected and are still dominated by traditional industries. Therefore, the development of villages is insufficient and uneven.

3. Construction of geographic proximity network and empirical study of Xinghua

The geographical proximity network is mainly divided into three components, namely morphological distribution characteristics, geographical scale characteristics, and cultural superposition characteristics. Study uses morphological distribution characteristics as the geographical background attributes of this region to determine its resource endowment and spatial agglomeration properties. During the study process, regional differences were followed. On this basis, specific network analysis is carried out through the geographical scale characteristics of the region, representing the multi-dimensional connectivity of village and town clusters, emphasizing the connectivity of network scale. Finally, an abstract network analysis is conducted based on the cultural attributes of villages and towns to determine the relationship between different geographical backgrounds and cultural elements, focusing on the collaborative development of culture.

Morphological distribution characteristics

Construction of morphological characteristics method system

In order to determine whether villages and towns have similar resources and characteristics in morphology, the study is divided into two dimensions based on terrain, land use, resource endowment, and other characteristics. Firstly, eight types are extracted from the patch and class agglomeration characteristics to study their morphological distribution agglomeration patterns. Then, from the perspective of the overall pattern, the above types will be assigned contract values to distinguish the degree of difference between each indicator. Thus, the aggregation, cohesion, and fragmentation characteristics of the geographical distribution of villages and towns were determined. The overall regional morphological features were summarised.

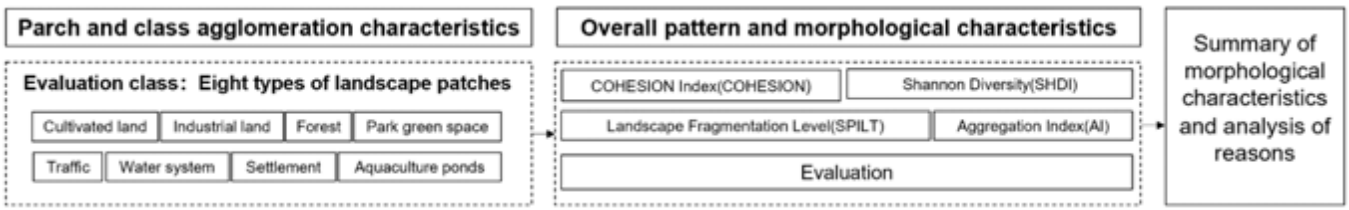

Fig.1 Technical route for evaluating morphological distribution characteristics

The study evaluated the region using the landscape pattern index tool in Fragstats, and the moving window algorithm was employed for image generation and processing. The moving window algorithm opens an analysis window centered around each pixel, calculates the selected level of indicators, and returns the calculation results to the centre of the window. By repeating this process for each pixel, the final result is the generation of a new grid surface that represents a gradient of the local landscape structure. This can reflect the detailed features of the landscape pattern and the differences in internal space.

Tab.1 Patch and class agglomeration characteristics and overall pattern and morphological characteristics indicators

Index	Formula	Formula description	Index explanation
Shannon Diversity (SHDI)	$SHDI = -\sum_{i=1}^{m}(P_i \times \ln P_i)$	Measurement index based on information theory, reflecting landscape heterogeneity.	In a landscape system, the richer the land use and the higher the degree of fragmentation, the greater the content of uncertain information, and the higher the calculated SHDI value.
Aggregation Index (AI)	$AI = \left[\frac{g_{ii}}{max - g_{ii}}\right](100)$	Used to describe the degree of aggregation of different patches or regions in a landscape, as well as the connectivity between patches of each landscape type.	A higher degree of aggregation indicates that patches of the same type are clustered together, while a lower degree of aggregation indicates that they are more dispersed and can be used to evaluate the agglomeration patterns of patches of the same type in the landscape.
Cohesion Index (COHESION)	$CO = \left[1 - \frac{\sum_{j=1}^{m} p_{ij}}{\sum_{j=1}^{m} p_{ij}\sqrt{a_{ij}}}\right]\left[1 - \frac{1}{\sqrt{A}}\right]^{-1} \times 100$ p_{ij} represents the circumference of the num. j patch in the num. i type landscape, A is the total area of the landscape	Used to describe the degree of aggregation of spatial structures within patches in a landscape, the index reflects the spatial connectivity or aggregation within patches of the same type.	A higher COHESION value indicates that different types of plaques are more concentrated or densely distributed together, forming a more compact spatial structure.
Landscape Fragmentation Level (SPILT)	$S = \frac{N_i}{A_i}$ N_i is the number of patches in landscape i, A_i is the total area of landscape i	The degree of fragmentation or fragmentation of a landscape refers to the degree of separation between different patches in the landscape.	When the landscape is divided into multiple smaller segments, the degree of fragmentation is higher; When the landscape maintains large continuous patches, the degree of fragmentation is lower.

3.1.1. Measurement of morphological characteristics

In the analysis of patch and class agglomeration characteristic, this study quantified the agglomeration patterns of eight types of landscape patches in Xinghua, including cultivated land, aquaculture pond, water system, forests, transportation, settlement, green space, and industrial land, based on aggregation index.

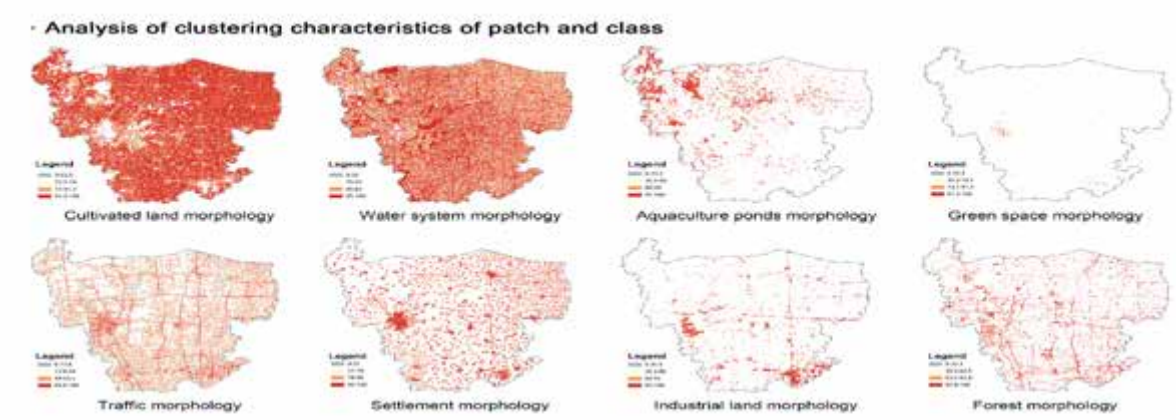

Fig.2 patch and class agglomeration characteristics

The results indicate that cultivated land shows significant agglomeration in the northeast and southwest regions, while the agglomeration degree is weaker in the central, western, and northwest regions. The complementary spatial feature is the high concentration of aquaculture ponds and water systems in the northwest. The aquaculture ponds are uniformly clustered in small areas in the north, and are less distributed in the south. The water system forms an overall uniform agglomeration pattern in the eastern and southern parts, but is more scattered in the central and northwestern parts, with scattered large blocks distributed irregularly.

In terms of settlement agglomeration characteristics, Xinghua presents three significant agglomeration cores. Firstly, there is a radiating agglomeration area centered around the central urban area of Xinghua in the central and western regions. Secondly, there is an industrial led agglomeration area centered around Dainan Town in the southeast, consisting of multiple secondary agglomeration points. Finally, there is a small-scale agglomeration area centered around Anfeng Town in the northwest. The distribution of other settlements is relatively scattered and has not formed a clear centripetal structure. The transportation network is highly consistent with the agglomeration pattern of settlements, with the main agglomeration areas distributed in the central and western regions, southwest, southeast, and northeast. The eastern transportation nodes are evenly distributed, while the northwest is significantly sparse.

This spatial differentiation is closely related to the regional geomorphological features. As can be seen from Figure 3, the overall geomorphology of Xinghua can be divided into swamp, western raised field, southern wei-field, central small wei-field and east big wei-field five parts.

Wei-fields are widely distributed throughout the region, indicating that Xinghua has a low-lying terrain and has long relied on artificial reclamation to transform swamps into farmland. The wei-field system has universality in this region. So in the analysis of the clustering characteristics of cultivated land, we found that there is not much difference in the clustering level of the entire region. On the basis of this regular distribution in the water network system, the transportation system is evenly distributed in the northeast and south, with big wei-fields concentrated in the northeast and small wei-fields distributed uniformly in the south. And artificial embankments for flood control and irrigation have been built in the northeast, combined with natural water systems, to develop into contiguous and orderly big wei-fields.

There are a large number of swamp areas in the central and northwestern parts. Corresponding to the clustering characteristics of aquaculture ponds, it was found that the current swamp areas are a composite form of wetlands, lakes, wei-fields, and aquaculture ponds. It can be seen that this area has not only been transformed into wei-fields for traditional agricultural planting, but also diversified development through raised fields and aquaculture ponds, such as aquaculture and wetland tourism development. Swamp and wetland resources are utilised at multiple levels in this way.

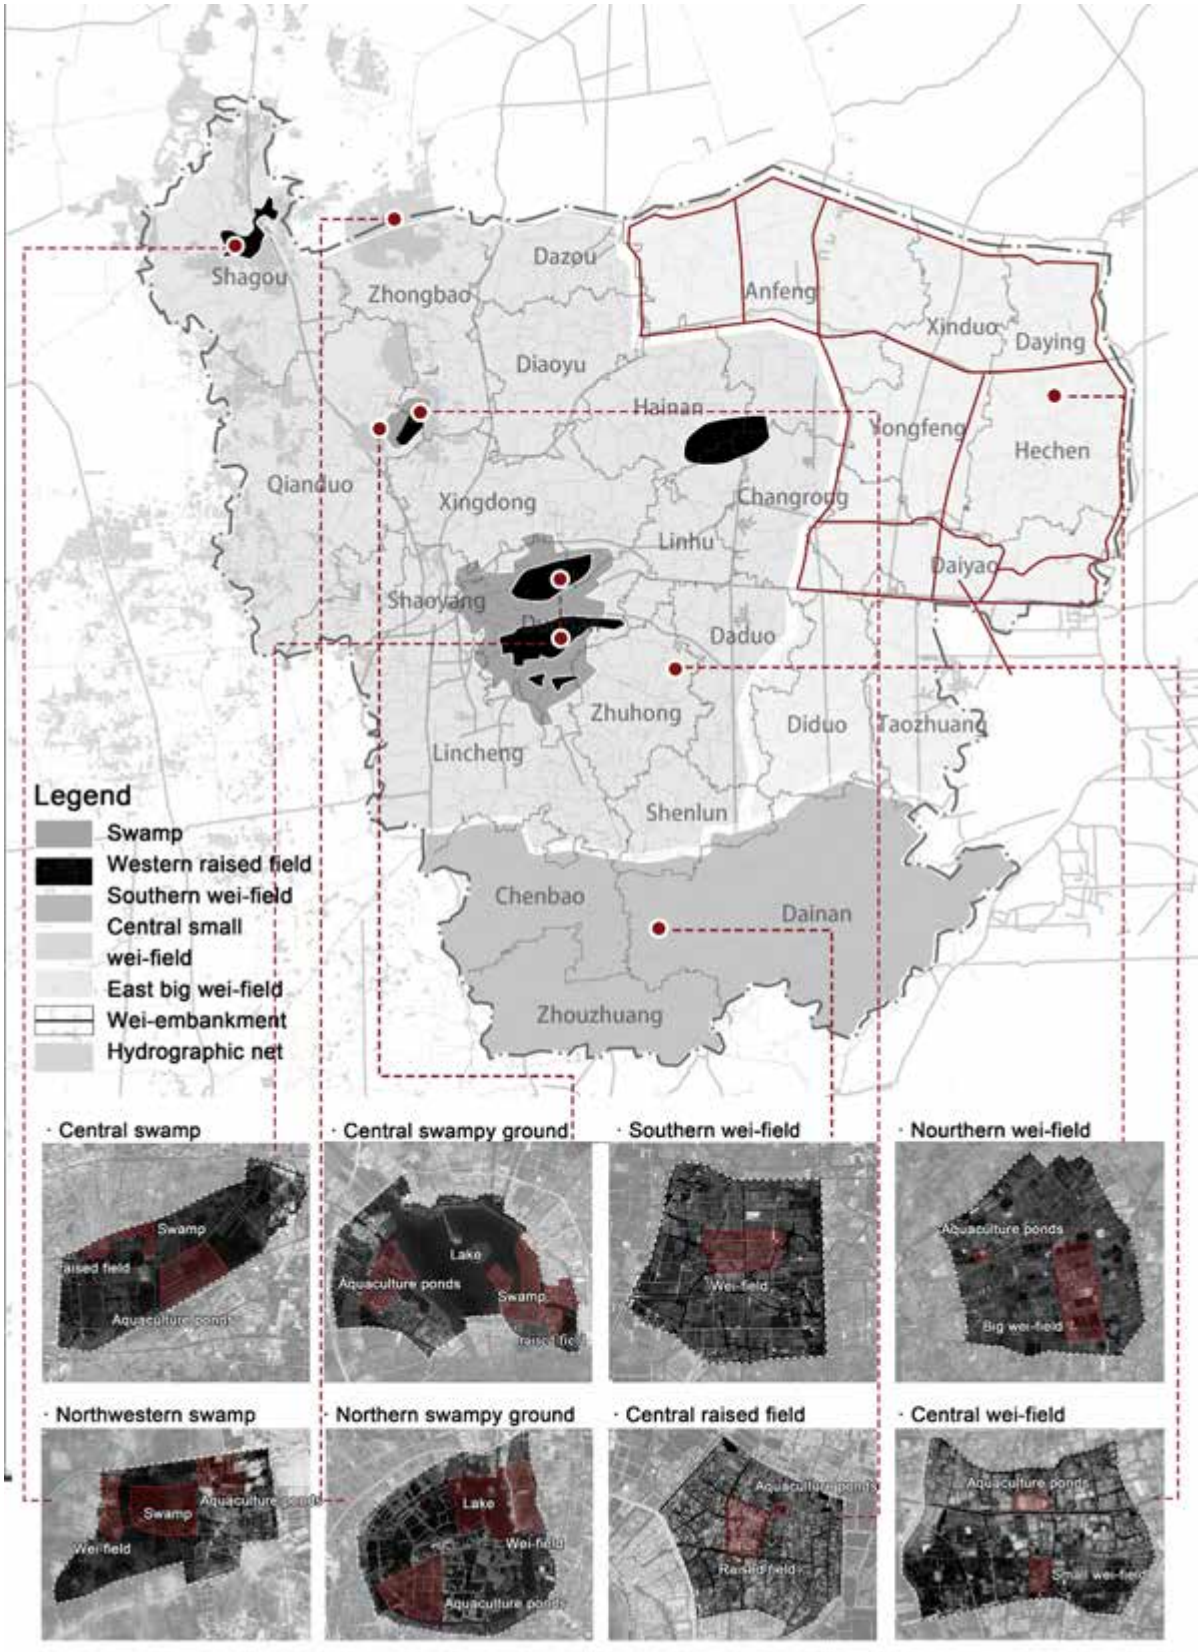

Fig.3 Regional geomorphic features: Explanation for agglomeration characteristic of patch and class

In the analysis of the overall pattern and morphological characteristics, this study selected four landscape pattern indicators, namely aggregation index (AI), cohesion index (COHESION), Shannon diversity index (SHDI), and landscape fragmentation level (SPILT), to systematically quantify the spatial structure of Xinghua. These indicators reveal the characteristics of regional landscape patterns from four dimensions: patch aggregation degree, spatial connectivity, type diversity, and landscape segmentation degree.

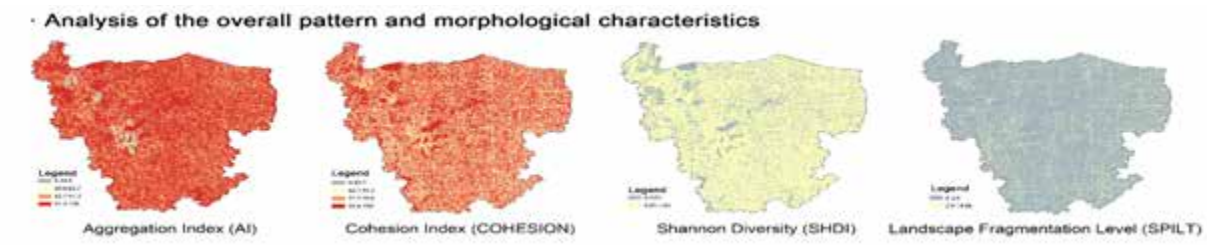

Fig.4 Overall pattern and morphological characteristics

The aggregation index shows that the overall aggregation degree of Xinghua is relatively high, indicating that the same type of land use patches in the region tend to be concentrated. Specifically, the eastern and southern regions exhibit obvious clustering characteristics of the same type of patches, which is mainly related to the local large-scale agricultural production layout. There are three significant areas of low polymerisation degree in the central and northwestern regions, indicating that the distribution of patches of the same type in these areas is relatively scattered. It should be influenced by the natural terrain such as swamps and the historical development model of raised fields and scattered wei-fields formed as a result.

The cohesion index shows that the overall spatial connectivity of the region is strong, with the index generally>82.7, but there is significant spatial differentiation. It is worth noting that the central and northwestern regions exhibit abnormally high values, reflecting that although these areas have a lower degree of aggregation. But different types of patches have formed a dense and interwoven compact spatial structure, which is related to the traditional raised field agricultural system in the area. In contrast, the cohesion index distribution in the eastern and southern regions is uniform and the values are moderate, indicating that the patch combinations in these areas are relatively loose. Their spatial connectivity needs to be improved.

The Shannon diversity analysis results show that the overall SHDI value is relatively low, indicating that the overall land use types in the region are relatively single, which is consistent with the landscape characteristics of Xinghua dominated by agriculture. However, the northwest region exhibits significantly higher diversity values, indicating the coexistence of multiple land use types and the formation of a more complex landscape mosaic fusion area. This high diversity is firstly due to the transitional geographical location of the region, and secondly due to the diverse land use patterns such as raised landscape planting, aquaculture, and wei-field agricultural planting. The landscape heterogeneity and uncertainty it brings need to be taken seriously in subsequent planning.

The results of landscape fragmentation show that the overall landscape integrity of the region is strong, and the degree of fragmentation is relatively low. Further analysis shows that this integrity is mainly due to the developed water system network in the region. These water systems not only divide the landscape, but also serve as a link between different landscape units. It is worth noting that although the overall fragmentation is low, a certain degree of landscape segmentation can still be observed in local areas, such as around towns, which should be the result of human disturbance caused by land reclamation and construction activities.

3.2 Geographical scale characteristics

3.2.1 Construction of geographic scale network based on gravity model

In response to the problems of scattered scale and spatial fragmentation, we introduce and improve “network methods” such as gravity models and social network analysis based on the various scale characteristics and transportation accessibility of villages and towns. By doing so, we can characterise the connectivity of rural communities from multiple dimensions, identify high-level nodes, and determine the “centre” and “edge” of the

region. And the study emphasises network connectivity, with the aim of identifying rural areas that are spatially dispersed and have integrated elements under low-density conditions.

The gravity model can measure the interaction between two spatial entities and is widely used in the study of regional spatial structures. Based on the spatial scale characteristics of rural areas, the following improvements are made to the traditional gravity model to measure the network correlation strength of geographical scale between villages and towns. The study replaces the "comprehensive quality parameter" with the "comprehensive geographic scale of villages and towns" as the core parameter for measuring the attractiveness and radiation effect of villages and towns. Traditional gravity models typically use single indicators such as total population and GDP to represent mass parameters. However, rural areas are different from cities in that their population size is small and the differences are not significant. In addition, Xinghua has always had a landscape with dense river networks and intertwined lakes. Therefore, the study comprehensively considers the size of villages and towns, water systems, cultivated land, and population, and incorporates them into the gravity model.

$$R_{ij} = K_{ij}\frac{M_i M_j}{D_{ij}^2}$$

$$K_{ij} = \frac{g_i}{g_i + g_j} = \frac{G_i/p_i}{G_i/p_i + G_j/p_j}$$

R_{ij} is the strength of the connection between village node i and village node j. M_i and M_j respectively represent the comprehensive calculation results of the indicator items of a certain village node, which is the gravity value of the village. D_{ij} represents the distance between node i and village node j. K_{ij} is the correction coefficient. G_i and G_j represent the area of the town or street where the village is located. p_i and p_j represent the population of the township or street where a village is located. The correction coefficient is used to adjust the size of villages and towns based on township data.

Tab.2 Index of comprehensive geographic scale

Element	Index	Unit	Data sources	Weight
Area Scale	Total area of administrative village	km^2	Survey data of land-use	0.190769
	Proportion of land area for village construction	%	Survey data of land-use	0.28968
Scale of water system	The total length of the water system flowing through the village area	km	*List of Backbone Rivers in Jiangsu Province Revised in 2018* OpenStreetMap	0.117638
	Proportion of water area within the village area	%	OpenStreetMap	0.052713
Scale of cultivated land	Proportion of cultivated land area in villages	%	Survey data of land-use	0.141012
Population scale	Population of administrative villages	/	Jiangsu Government Service Network https://www.jszwfw.gov.cn/*Layout planning of towns and villages in Xinghua Revised in 2022*	0.208188
Area Scale	The area of the town or street where the village is located	Km^2	Survey data of land-use	/
Population scale	The seventh population census of the township or street where the village is located	/	*Statistical Review of Xinghua*	

3 .2.2 Data standardisation processing and weighting

The study used Min-Max normalisation method to normalise data such as village area and river length. And the entropy weight method and analytic hierarchy process are used to calculate the weights of each indicator separately and comprehensively consider them to obtain the weight of each indicator, thereby calculating the gravity value of the village node. According to the gravity model formula mentioned above, the strength of the connections between two villages can be calculated. When processing data, the distribution of network related data will exhibit a heavy daily distribution characteristic, and the core structure will be obscured by a large amount of data with excessively small connection values. The study used heavy tail extraction method to extract network associations that are greater than the average, and ignored the association values between two villages that are less than the average as being too small. The gravity model constructed in this study is an undirected matrix between two villages, and the pairwise connections between each village are visualised on the ArcGIS platform. Study categorises the size of connection values using the natural breakpoint method and constructs a network association pattern for the geographic scale of villages and towns.

3.2.3 Measurement of the network correlation pattern of geographical scale

Preliminary assessment of the centrality based on the comprehensive scale of village and town geography to determine the level of each village and town, clarify the unit centre and the geographical network correlation pattern between each village and town. Firstly, the centrality of each village and town is determined based on their comprehensive geographic scale, and the villages and towns are divided into three levels. From the perspective of node attributes (Fig.5), strong gravity villages and towns are mainly concentrated in the central urban area of Xinghua, Dainan Town in the southeast, and Anfeng Town in the northeast, forming a multi-core structure. The villages and towns with moderate gravity are distributed in a circular pattern around the core nodes. The weak gravity village points are scattered in the northwest and the edge of the village, forming the end nodes of the network system. This “core edge” spatial differentiation pattern reflects the uneven agglomeration of regional geographic scale factors. From Fig. 6, it can be seen that the centrality of geographical scale and network correlation strength within the region are consistent with the distribution of transportation networks. The comprehensive geographical scale of villages and towns in the central and eastern regions with developed transportation routes is relatively strong. It shows an opposite trend to the distribution of water networks to some extent, with areas with denser water networks having relatively weaker overall geographic scale of villages and towns.

There is a significant “core-edge” differentiation pattern in the strength of geographical scale network associations within the region. The high-intensity correlation is concentrated in two core areas: the central and western regions centered around the Xinghua central urban area, and the southeastern Dainan Town area. The correlation strength between these two core areas is the highest, forming the main axis of the regional network. Medium intensity checkpoints are mainly distributed around the core area, connecting secondary nodes such as Anfeng Town and Zhouzhuang Town. But the regularity of their correlation is not obvious. Low intensity associations are sporadically distributed in the densely populated water network areas in the northwest and the agricultural areas in the east, exhibiting short distance and low-density connectivity characteristics. However, the hierarchical nature of the overall network correlation strength and the secondary centres of aggregation are not obvious.

The geographical factors that contribute to the formation mechanism are influenced by topography and hydrology. High intensity association areas are mainly distributed in the central and southern small wei-field areas with good water system connectivity but moderate water network density, while low-intensity association areas are concentrated in the northwest lake and depression areas. The complex water system significantly reduces regional connectivity. And it is related to the distribution characteristics of settlements. The first level associated nodes are located in areas with large settlement scales and dense distributions, which conforms to the core agglomeration law of the central place theory. The small and scattered settlement scale in the edge area leads to a decrease in network connection strength. At the same time, it is also affected by the accessibility of transportation, and the high-strength interconnected corridor is spatially consistent with major transportation channels such as provincial highway and Yanjing River. However, the northwest region is affected by water system segmentation, and the land transportation network is sparse, which directly restricts the frequency of node interaction. From the perspective of historical development path, the central urban area, Dainan Town, and Anfeng Town, as traditional regional centres, have long accumulated infrastructure and public service

advantages, making them natural hotspots of network attraction. The peripheral areas are limited by natural geographical conditions and transportation location, and their development is relatively lagging behind.

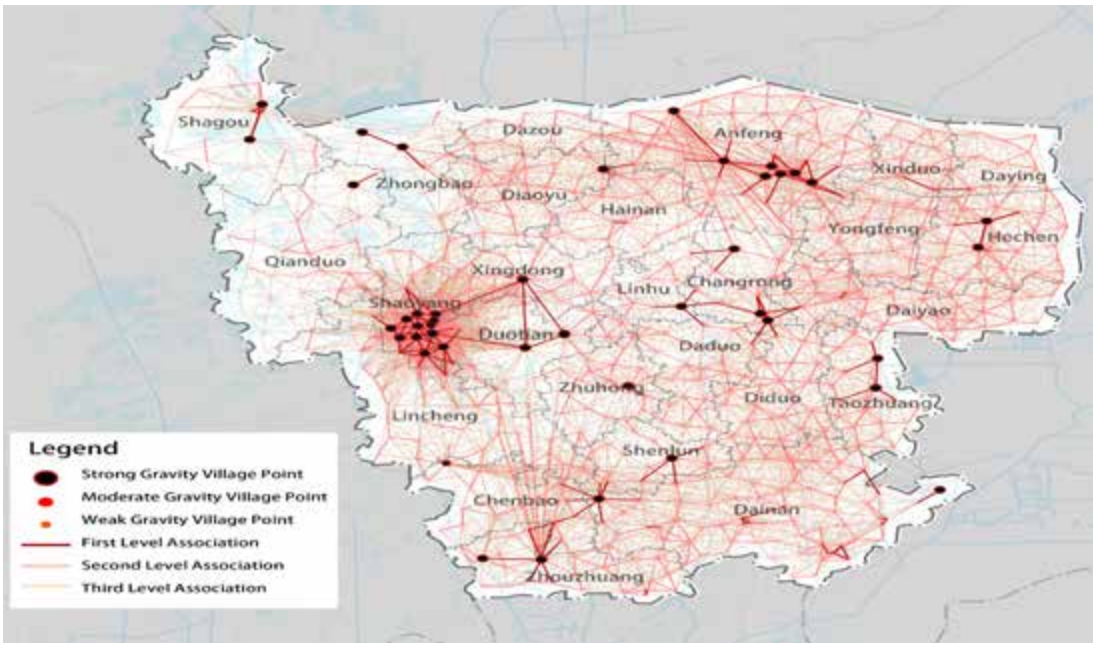

Fig.5 Geographical scale network correlation gravity model for villages and towns

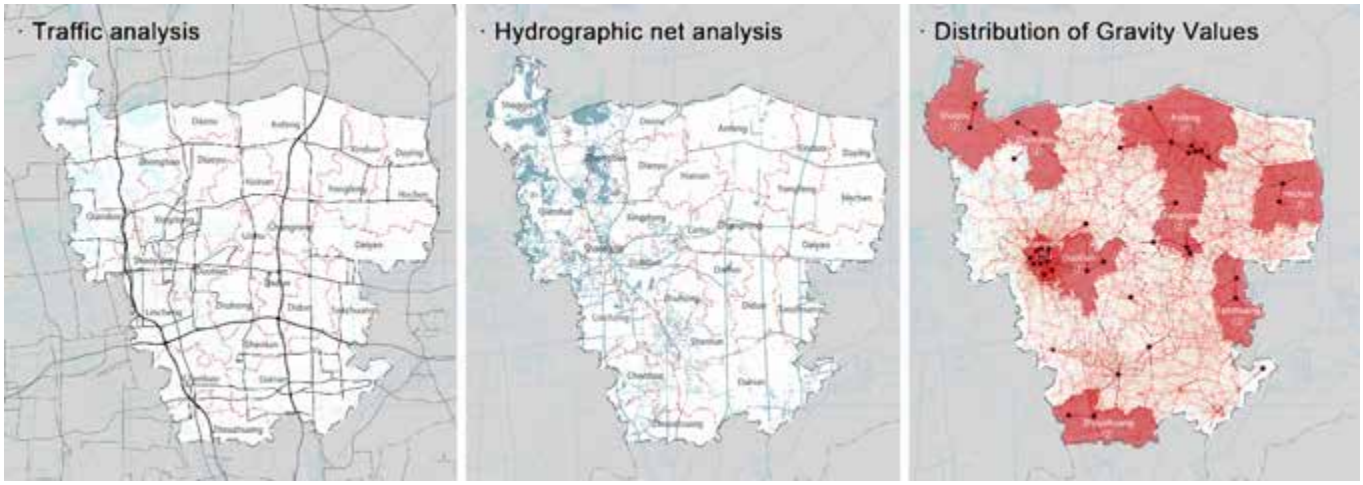

Fig.6 Geographic feature analysis of gravity model

3.3 Cultural superposition characteristics

3.3.1 Distribution characteristics of geographical name categories

The classification of place names and distribution of settlements in Xinghua area exhibit significant geomorphic adaptability and explicit features of historical elements. The settlement types can be divided into four categories: water dominated, agricultural, commercial, and military. The distribution pattern of these settlements is closely related to the unique swamp and wei-field landform and historical and cultural factors in the area.

Tab.3 Geographical name classification explanation

Type of place name		Main Words	Settlement type	Description
Natural geographical name	River system	ditch	Water dominated settlement	Flowing water channel
		sea		The waters near the connection between the mainland and the ocean
		jiang		The general term for large rivers
		river		Natural or artificial large waterways
		port		A river bay that can be anchored
		marsh		Shallow water lake, a depression with accumulated water and grass
		bay		Bend of river
		sand		Arable land by the water's side
		bridge		A bridge, a building erected on water or in the air for passage
		dam		Buildings used to reinforce embankments in hydraulic engineering
	Agriculture	duo	Agricultural settlement	A raised high field formed by excavating a network of deep trenches or accumulating soil along a lake or river network
		pasture		Fields in suburb
		wei		Rice paddies surrounded by earthen embankments
		mount		The towering part formed by the ground, the soil slope
		forest		Clusters of trees
		yard		Vegetable garden, orchard
Humanistic place name	Business	yao	Commercial settlement	Places for firing bricks, tiles, and ceramic vessels, coal kilns
		zao (stove)		Salt boiling household
		chang		Flat open space, threshing ground
	Military	fort	Military type settlement	Small fort, a market town or shop with a city wall
		ton		A few smaller households are established, with surnames added in front of them
		manor		The post station belongs to the official and garrison fields, as well as some official villages
		guan		Temporary stationed barracks
		town		The walls surrounding the city are used for defense
		barrack		Living and camping around the soil

The distribution of settlements and the types of place names in Xinghua area deeply reflect the dual influence of natural landforms and historical culture. Water dominated settlements are widely distributed in areas with dense river networks, and settlements named after words such as "port" and "bay" highlight the adaptive use of water environment by local residents. Agricultural settlements are marked by characters such as "duo" and are concentrated in artificially transformed wei-field and stack areas, reflecting the wisdom of wetland agriculture development. The distribution of military settlements such as "fort" and "ton" in the northern region is not only related to flood control needs, but also closely related to the history of Zhang Shicheng's uprising in this area at the end of the Yuan Dynasty. Some defensive settlements may be remnants of military activities at that time. Commercial settlements such as "yao" and "zao" are scattered, reflecting the layout of salt and handicraft industries relying on water transportation. This settlement distribution pattern vividly demonstrates the human land relationship jointly shaped by natural wetland environment and historical and cultural elements.

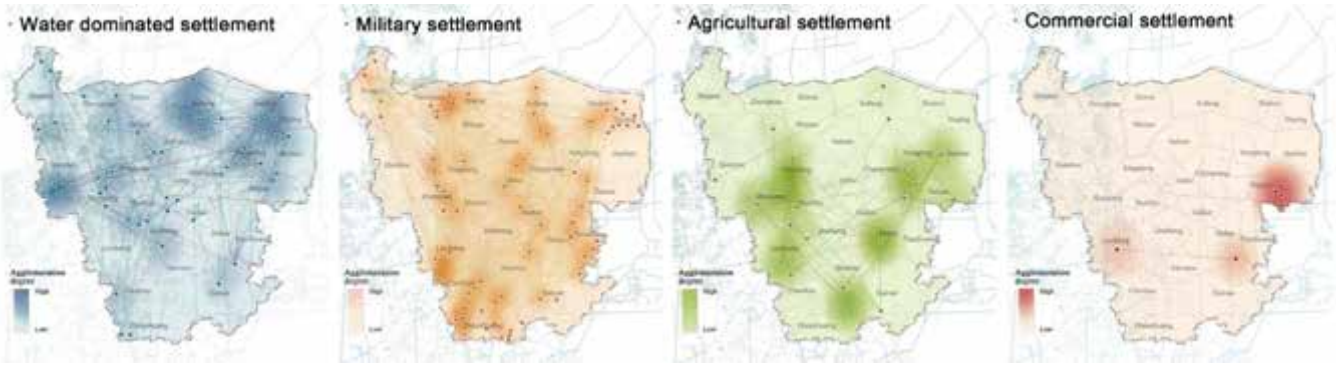

Fig.7 Geographical name analysis results

3.3.2 Analysis of the distribution of historical and cultural values

Tab.4 Historical and cultural elements

Heritage type	Category	Quantity	
Cultural relics	Archaeological Sites	5	337
	Traditional architectural group	9	
	List of Historical Buildings	197	
	artifacts of the revolution	14	
	Traditional street and alley spaces	19	
	All levels of cultural heritage preservation units	93	
Intangible cultural heritage	Traditional skills, folk customs, traditional music, traditional dance, traditional drama, folk literature, traditional medicine	124	

By sorting out the carriers of historical and cultural values in Xinghua, they are divided into two parts: Cultural relics and intangible cultural heritage. The distribution of historical and cultural values is analyzed using kernel density and gravity models. The results show that the historical and cultural resources in Xinghua area have formed a distribution pattern centered on the urban area and radiating along the main water systems. The high-density areas are mainly concentrated in two areas: one is the core cultural circle centered on Xinghua Ancient City, which includes a large number of Ming and Qing Dynasty ancient buildings and celebrity residences. The second is

the sub-centre cultural circle around Shagou Ancient Town, characterised by modern commercial buildings and revolutionary sites. These two high-density areas are interconnected through a water transportation network, forming the main axis of regional culture. And there is a significant cultural radiation effect within the region. The national level cultural heritage sites in the central region, such as the Jiangzhuang Site and Xinghua Duotian, as well as provincial-level cultural heritage sites, constitute the main attraction source and have a significant attraction effect on the surrounding cultural resources.

From the perspective of time and space, the formation of this distribution pattern has a profound historical and geographical background. The sites from the Neolithic Age to the Spring and Autumn Period and Warring States Period are mostly distributed around lakes with higher terrain, reflecting the survival strategy of early humans who chose to live higher. During the Ming and Qing dynasties, with the development of wei-field agriculture and the prosperity of imperial examination culture, a gentry cultural circle centered on ancient cities and spread along water systems was formed. It is manifested as densely distributed literati residences and clan ancestral halls. Since modern times, commercial activities and revolutionary movements have left unique cultural imprints in ancient towns such as Shagou, making the region a typical representative of multicultural integration.

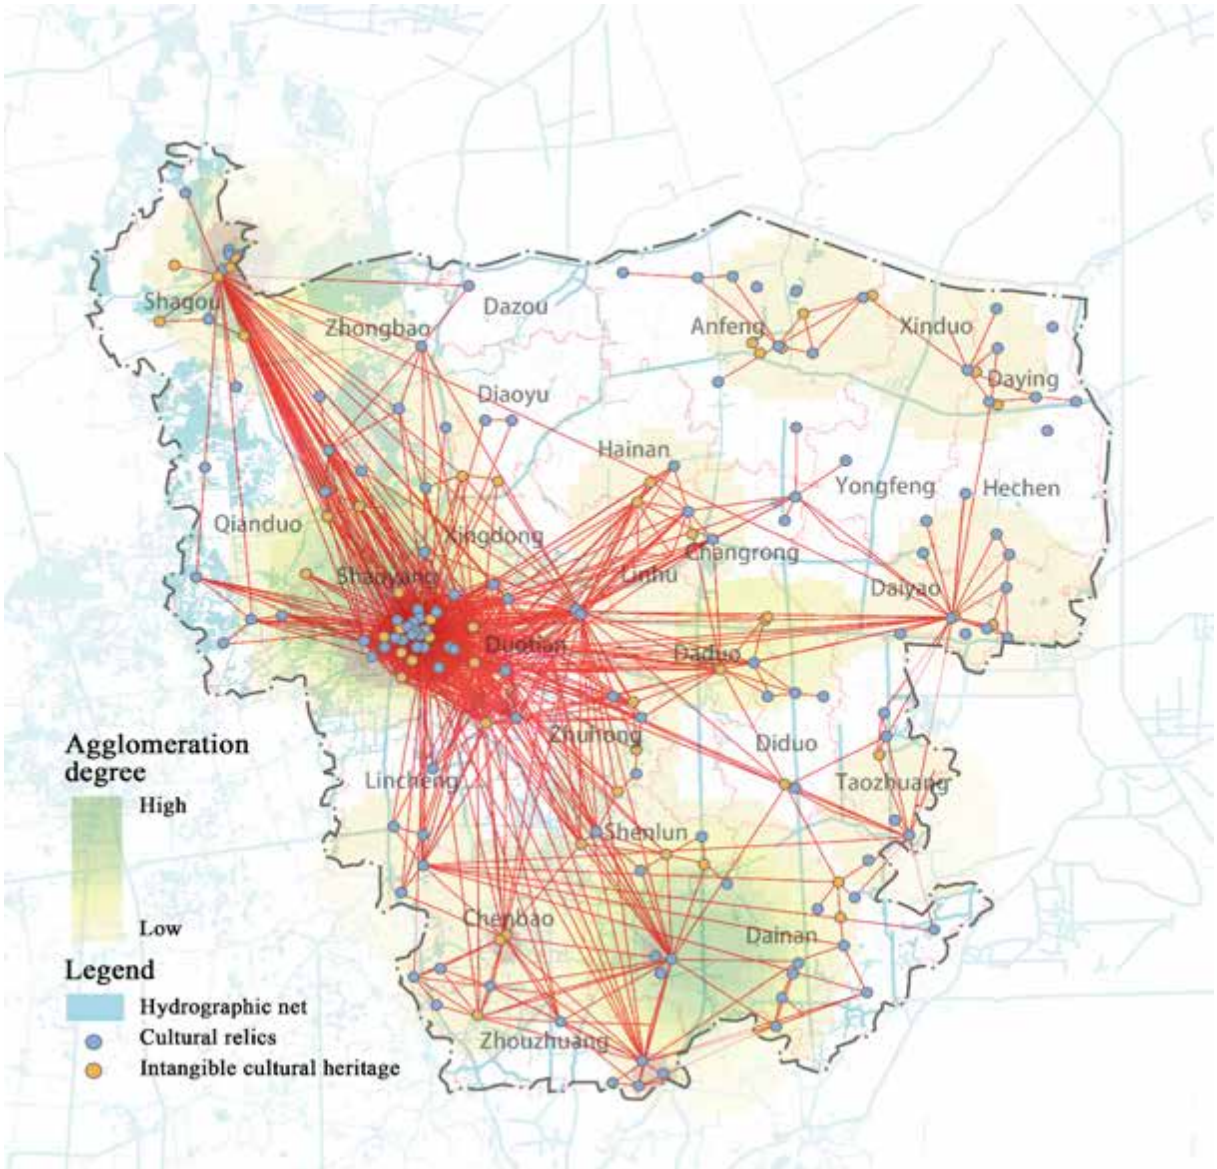

Fig.8 Analysis of gravity model and agglomeration degree based on historical and cultural values

Overall, the spatial distribution of cultural resources is highly consistent with the regional water system network and the geographical scale network of villages and towns measured in the previous section. Bridges, docks and other water transportation facilities are distributed along the river, forming a key link connecting various cultural nodes. Special cultivation methods such as raised field and wei-field are also transformation methods that people adopt based on hydrological conditions. This cultural landscape pattern, with water as its veins, vividly demonstrates the characteristics of the relationship between people and land in Xinghua as a water town area. At the same time, the cultural layering effects of different historical periods have resulted in significant spatiotemporal overlapping features of regional cultural landscapes, providing important samples for understanding the historical and cultural evolution of the Lixiahe region.

4. Conclusion and discussion

This study is based on the perspective of collaborative agglomeration and systematically investigates the multi-dimensional proximity relationships of rural contiguous spaces in Xinghua by constructing a geographical proximity network analysis model. The study reveals the profound impact of geographic background characteristics, scale network correlations, and cultural superposition effects on the spatial organisation of rural settlements, providing new theoretical basis and practical inspiration for regional coordinated development.

4.1 Geographical morphological characteristics shape the spatial differentiation of settlements

The morphological distribution characteristics of rural settlements in Xinghua reflect the synergistic effect of geographical background conditions and cultural development activities. As a typical area in the hinterland of Lixia he, the natural geographical features of dense river networks form the basic framework of settlement distribution, while the artificial wei-field system formed in historical periods further strengthens this spatial pattern. Specifically, the eastern big wei-field area has benefited from the systematic construction of embankments, forming a concentrated and orderly cluster of settlements. The northwest lake and swamp area maintains a relatively scattered distribution of settlements due to the preservation of natural wetlands. This spatial differentiation is manifested in the landscape pattern as follows: the eastern and southern agricultural dominated areas have higher patch aggregation and lower landscape diversity, reflecting the characteristics of large-scale agricultural production. The northwest region, on the other hand, exhibits high landscape heterogeneity due to the coexistence of various utilisation methods such as raised field agriculture and aquaculture. Moreover, the core agglomeration area of the settlement is highly aligned with the main transportation corridors in space, which confirms the crucial role of transportation conditions in the development of the settlement. At the same time, the traditional development of “one wei-field, one village” formed since the Ming Dynasty, and the resulting small-scale characteristics of settlements, still influence the distribution pattern of regional settlements today. These findings not only reveal the decisive influence of natural geographical conditions on the spatial organisation of settlements, but also demonstrate the lasting shaping effect of historical development paths on contemporary settlement patterns, providing important basis for understanding the spatial evolution mechanism of rural settlements.

4.2 The correlation of geographic scale networks presents the fundamental correlation characteristics of centrality

This study constructs a gravity model based on geographic scale indicators, including basic elements such as area, water system, cultivated land, and population, aiming to strip away complex factors and focus on the fundamental impact of geographic background on village associations. We found that the village and town network present a spatial agglomeration pattern centered on the central urban area of Xinghua and Dainan Town, while the water network intensive area in the northwest forms an associated vulnerable area due to natural barriers. This “core-edge” structure reflects the basic distribution law of geographical scale elements: strongly correlated nodes are mostly concentrated in areas with superior transportation conditions and complete geomorphic units, and the correlation strength decays significantly with distance. However, this single dimensional analysis also exposes limitations: Firstly, the network structure presents a flattened feature, which can only identify explicit associations in spatial proximity and lacks explanatory power for cross regional functional connections. Secondly, some villages with collaborative potential, such as those with rich cultural resources but smaller scale, have not been highlighted. This indicates that although geographic scale networks can effectively characterise the spatial basis of village associations, in order to comprehensively reveal the mechanism of collaborative development, it is still necessary to incorporate dimensions such as cultural proximity and industrial complementarity for comprehensive analysis.

4.3 Cultural superposition effect strengthens regional synergy potential

The analysis of place names and the distribution of historical and cultural resources reveal the spatiotemporal layering of natural and cultural elements. Water dominated settlements are distributed along the river network, agricultural settlements are concentrated in wei-field areas, and military settlements are related to historical defense needs. The cultural resources present a distribution pattern with Xinghua Ancient Town and Shagou Ancient Town as the dual cores, and radiate to the surrounding areas through the water system network. Moreover, cultural layers from different historical periods exhibit significant overlapping effects in space. For example, Neolithic sites are mostly distributed around lakes with higher terrain, while literati residences from the Ming and Qing dynasties are distributed in a strip along the main water system. The deep interweaving of cultural landscapes and geographical environments not only strengthens regional cultural identity, but also provides a spatial framework based on historical context for cross village functional collaboration.

The study breaks through the limitations of traditional administrative boundaries and reveals the spatial differentiation pattern and network connectivity characteristics of rural settlements in Xinghua from the perspective of geographical proximity. It lays the foundation for the subsequent integration of multidimensional proximity research such as organisational proximity and social proximity. The geographical background characteristics shape the initial distribution pattern of settlements, while the cultural overlay effect further enriches the potential for regional coordinated development. Moreover, there is a significant spatial autocorrelation between the types of landforms and the distribution of cultural heritage, revealing the layered effect of the coupling between nature and culture. To promote regional coordinated development, it is necessary to innovatively utilise the cultural aspects of villages based on similar geographical resources. Cultural coding strategies can be used to transform agricultural place names such as “duo” and “wei” into ecological agricultural brand logos, such as Qianduo Town achieving tourism revenue growth through the “duo tian (raised field)” IP. Utilise existing resources to activate historical networks. For example, by utilizing the Ming and Qing water transportation corridors to connect scattered cultural nodes, a cross-town cultural industry chain can be formed in the Dainan Shagou area, driving the participation of surrounding villages in collaborative operations. This transforms the hierarchical effect of historical and cultural heritage into an endogenous driving force for the development of rural characteristics. This can not only solve the problem of mismatch between spatial planning and administrative boundaries, but also organically integrate cultural heritage into development planning through quantitative historical and cultural analysis, achieving the coexistence and prosperity of natural ecology and humanistic values.

Are you a Stakeholder or Streekholder? Formal and informal planning in the Flemish-Dutch Delta

Alankrita Sarkar
Delft University of Technology and Deltametropolis Association
Email: a.sarkar-4@tudelft.nl

Abstract
Grenspark Groot Saeftinghe (Borderpark of Saeftinghe), a transboundary region along the Scheldt estuary in the Flemish-Dutch Delta, faces overlapping ecological, climate, and socio-political pressures. As part of the INTERREG project, this region brings together formal stakeholders, and local citizen groups known as "*streekholders*" (Grenspark Groot Saeftinghe, 2025). This paper investigates how formal stakeholders and *streekholders*, co-shape spatial planning decisions in this contested landscape. Drawing on qualitative methods, including stakeholder mapping, literature review and discourse analysis, the study analyses partnerships across formal, informal, and research-based planning domains. It reveals how tensions between environmental, economic, and cultural values are negotiated through multi-actor collaborations. By comparing dynamics at both regional and delta scale, the paper illustrates how the planning arrangements can enhance adaptive governance and demonstrate pathways towards resilient and transnational development.

Keywords: Transnational territory; Stakeholder dynamics; Spatial planning; Flemish-Dutch Delta.

1. Introduction

Spatial planning in transboundary regions increasingly requires governance approaches that transcend national jurisdictions, administrative silos, and sectoral boundaries (Slinger, 2023; Merk & Notteboom, 2013). This paper proposes to examine spatial planning and governance across two interrelated scales. At the macro-regional level, it considers the Vlaams Nederlandse Delta as a complex, coordinated but fragmented visions (OECD, 2013; CBK Zeeland, 2020) where ecological vulnerabilities and socio-economic transitions converge with intricate institutional arrangements (Deelstra et al., 2020). At the local level, it focuses on Grenspark Groot Saeftinghe, a tidal landscape at the border of Flanders and Zeeland, where water management, ecological restoration, and cultural heritage practices demonstrate embedded modes of "living with water" (Grenspark Groot Saeftinghe, 2024; Interreg Vlaanderen–Nederland, 2023). This dual-scale lens provides insight for an interesting case to understand how formal governance frameworks interact with more informal and culturally embedded planning practices in cross-border contexts (Slinger, 2023; Van der Valk & Van Dijk, 2009). The urgency of climate adaptation adds another layer of complexity, requiring coordinated action across different sectors and administrative systems.

A key inquiry is how governmental institutions, civil society groups, research consortia, and local collectives are integrated into decision-making processes. By identifying the interscalar dynamics between formal stakeholders and informal "*streekholders*" Grenspark Groot Saeftinghe, 2025), this paper contributes to the discourse on adaptive and inclusive governance under conditions of climate transition and ecological uncertainty (Mundell, 2018; (van Bets et al., 2020).

The research is developed alongside the New European Bauhaus project *Bauhaus of the Sea Sails*[1], which facilitates co-design activities with regional actors. Data are drawn from storytelling sessions, participatory workshops, and interviews conducted as part of this broader PhD research. This article presents the first phase of an ongoing research project, aimed at analysing the current institutional and governance configurations of the selected case study. In the coming years, the research will be expanded to examine historical path dependencies and explore future-oriented planning scenarios.

2. Setting the transnational context

Water has a major role in maintaining peace and political stability across borders (Transboundary water cooperation, European Commission2). This research focuses on two significant scales for spatial analysis: the Border Park of Saeftinghe and the Flemish Dutch Delta. In the Border Park of Saeftinghe, water emerges as a pivotal force driving collaboration among stakeholders. Conversely, at the larger scale, Flemish Dutch Scheldt Delta, the foundation is water for shaping both the physical and socio-economic fabric of the region. However, due to the presence of the two largest ports, Rotterdam and Antwerp-Bruges, water presents challenges marked by conflicts and competition, reflecting the complexities of industrial and urban landscapes intertwined with maritime activities. Each of these scales reveals distinct dynamics concerning the relationship between water, land, and human activities. As a result, spatial planning in such a transnational delta calls for a multi-scalar governance approach that bridges institutional divides and connects strategic visioning with operational capacity.

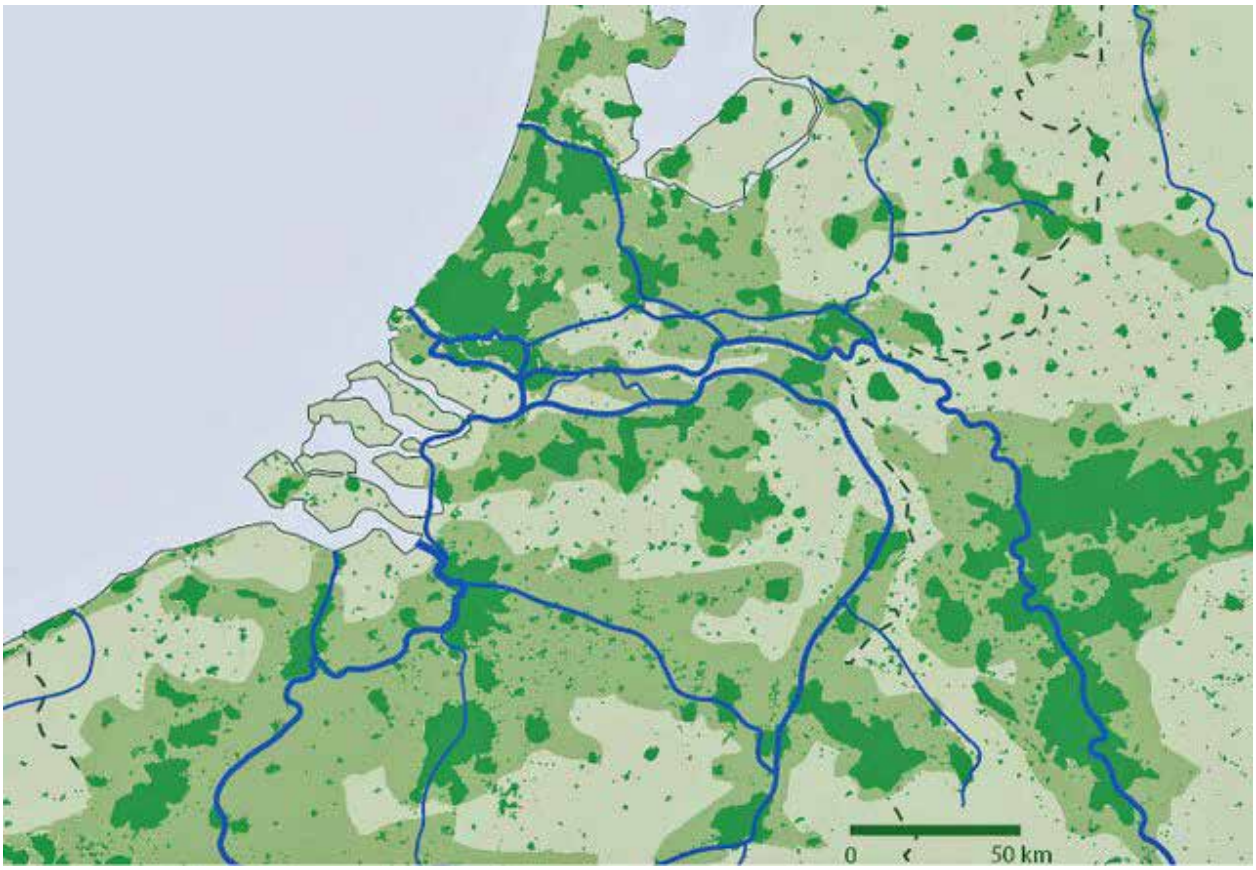

Fig 1: The Dutch Belgian Rhine Meuse Scheldt Delta Deltanet-2014

2.1 Grenspark Groot Saeftinghe (GGS) (Region and community)

At the very local scale of Scheldt estuary, spanning the border between the Netherlands and Belgium, is the Drowned Land of Saeftinghe (*Verdronken land van Saeftinghe*). Along with the drowned land, one of the largest contiguous salt marshes and mudflat ecosystems in Europe, covering 3,500 hectares is the area of Grenspark Groot Saeftinghe, including 18000 hectares and roughly 27,000 population (2020). It connects with adjacent reclaimed polders such as the Hedwige, Prosper, and Doel polders, forming a border zone shaped by hydrological dynamics, port development, and agrarian landscapes (Grenspark Groot Saeftinghe, 2024). This spatial configuration brings together ecological sensitivity and strategic economic infrastructure, as the park borders the Port of Antwerp and the Doel nuclear power plant (The Brussels Times, 2022).

2 https://international-partnerships.ec.europa.eu/policies/climate-environment-and-energy/transboundary-water-cooperation_en

Fig 2: Gebiedsagenda Grensark Groot Saeftinghe, 2019

In recent decades, the Saeftinghe region has been shaped by a series of overlapping dynamics that bring competing spatial agendas into conflict. The expansion of the Port of Antwerp has frequently intersected with ecological protection and local community interests, particularly in the contested future of the village of Doel, which was designated for demolition in the 1960s to accommodate industrial expansion but was officially returned to its residents in 2022 following prolonged civic opposition (The Brussels Times, 2022). Simultaneously, the decision to depolder the Hedwige and Prosper polders was formalised through the 2005 Dutch-Flemish Scheldt Treaty and later upheld by the Dutch Council of State in 2012. This triggered intense political controversy in the Netherlands, where farmers and local representatives opposed the intentional flooding of agricultural land for estuarine habitat restoration (Van Buuren & Warner, 2014). The measure was framed as nature compensation for deepening the Western Scheldt shipping channel, which was necessary to maintain the competitiveness of the Port of Antwerp. These events illustrate a spatial environment where water safety, environmental policy, and economic development collide, producing a complex and politically charged planning landscape.

In response to these intersecting dynamics and competing spatial agendas, Grenspark Groot Saeftinghe was formally established through a cross-border EU INTERREG project launched in 2016. This initiative was supported by the EU's Interreg Vlaanderen-Nederland programme and co-funded by regional governments and environmental agencies (Interreg Vlaanderen-Nederland, 2025; (Nationale Landschappen en Nationale Parken, 2019)). The project sought to integrate ecological restoration with economic and cultural development, creating a cross-sectoral planning agenda for this vital border region. Key formal stakeholders involved in the GGS include the Province of Zeeland and the Province of East Flanders, nature conservation bodies, as well as various municipal administrations and port authority. These actors operate within a collaborative framework that has been further institutionalised by the European Grouping for Territorial Cooperation (EGTC) Linieland van Waas en Hulst, established in 2011 to promote structured governance between border municipalities (EGTS Linieland, 2024).

In addition to institutional actors, the GGS initiative places significant emphasis on civic participation through the concept of "streekholders." These are local citizens, farmers, and entrepreneurs who are actively involved in the planning and development of the park. They contribute to working groups, thematic sessions, and decision-making processes, offering locally grounded perspectives on nature-based solutions and cultural heritage (Grenspark Groot Saeftinghe, 2024). Their involvement reflects a broader shift toward participatory spatial governance at the landscape scale.

2.2 Flemish-Dutch Delta (Territory and governance)

The Flemish Dutch Delta (Vlaams Nederlandse Delta) is a transboundary estuarine region located in the southwestern part of the Netherlands and northern Belgium. It spans six provinces: Zeeland, South Holland, and North Brabant in the Netherlands, and East Flanders, West Flanders, and Antwerp in Belgium. The delta has a population of approximately 1.5 million people and is shaped by the interaction of the Rhine, Meuse, and Scheldt river systems (Vanelslander et al., 2011). Spatial developments in this delta are shaped by decisions taken at multiple levels of government. At the national level, spatial and environmental strategies are influenced by the Dutch Ministry of Infrastructure and Water Management and the Flemish Department of Environment and Spatial Development. At the provincial level, spatial policy and land-use regulation fall under the authority of the respective provincial governments, who act as key stakeholders in planning processes and cross-border cooperation (Vanelslander et al., 2011). These government institutions also contribute to joint spatial visions and regional development strategies.

Fig 3: Administrative boundaries of Vlaams Nederlandse Delta (https://www.vndelta.eu/)

The confluence of river delta and the coastal front of North Sea creates a dynamic hydrological system of tidal wetlands, estuarine ecologies, complex freshwater–saltwater gradients and reclaimed landscapes. Due to the ecological pressures such as salinisation and sea-level rise, a range of environmental stakeholders are active in the region (Schelde Delta Geopark, 2024), including Rijkswaterstaat (Netherlands) and the Flemish Environment Agency, and nature conservation organisations such as Natuurpunt and Staatsbosbeheer. These actors are involved in water management, flood risk mitigation, and the ecological restoration of tidal zones (Schelde Delta Geopark, 2024). These agencies are not merely supportive actors; they constitute the backbone of ecological stewardship and climate adaptation in the region.

The territory occupies a central position and plays a significant role in European and global trade. The broader Seine to Scheldt zone accounts for around 17 percent of the European Union's gross domestic product and manages 60 percent of its maritime trade (Advisory & Oost-Vlaanderen, 2013). The two principal maritime

stakeholders are the Port of Rotterdam Authority and the Port of Antwerp-Bruges. Both institutions have far-reaching influence on regional infrastructure, industrial zoning, and hinterland connectivity. Their role in shaping spatial development is reinforced by their partnership in spatial-economic initiatives such as the North Sea Port District (including Ghent-Terneuzen- Vlissingen). These economic stakeholders are integral to port expansion, land reclamation, and affecting the delta regarding climate adaptation.

3. Research question and methodology

This study is fundamentally guided by the central research question: "How do formal and informal governance frameworks/partnerships interact in transnational spatial planning, and what role do stakeholder and "*streekholder*" dynamics play in shaping sustainable development in the Flemish-Dutch Delta?" This overarching inquiry is further explored through two key lines of investigation: identifying the various types of partnerships and collaborations at play and gaining a deeper understanding of the "*streekholders*" concept, particularly how local citizens are actively influencing and shifting established narratives in spatial planning.

To answer this, the study adopts a multi-scalar qualitative research. The analysis focuses on two interlinked spatial levels: (1) the Vlaams Nederlandse Delta as a macro-regional, transboundary planning context shaped by intergovernmental coordination; and (2) Grenspark Groot Saeftinghe as a localised case of civic participation situated along the Dutch-Flemish border. This dual-scale lens allows for an exploration of how formal planning institutions (e.g., governments, port authorities, interregional commissions) interface with informal actors (e.g., citizens, farmers, civil society groups), particularly in contexts where ecological urgency and socio-economic transformation converge.

Empirical data were collected through a combination of qualitative methods. These include extensive document analysis of strategic planning documents, INTERREG project reports, and online communication platforms maintained by GGS. Stakeholder mapping is employed to systematically identify and categorise the diverse actors involved in the region's governance and planning. Participatory observation in storytelling workshops and co-design sessions carried out as part of the *Bauhaus of the Sea Sails* project. Semi-structured interviews are conducted with key formal stakeholders from public authorities and port entities, as well as representatives from civil society groups. A reflective component is highlighted in this method and is critical for interrogation of the literature, highlighting discrepancies and convergences between documented policies and on-ground practices. A comprehensive literature review situates the study within broader academic and policy discourses on interscalar governance and transnational collaboration. This approach enabled triangulation across multiple sources and actor perspectives, offering grounded insights into the existing governance arrangements and frictions. The methodology is designed to bridge theoretical frameworks with practical insights, providing a nuanced understanding of the interplay between formal planning structures and informal "*streekholders*."

The structure of this paper reflects the layered nature of the inquiry. Following the introduction, context-setting of the two spatial scales, the problem statement, section 5-6 presents the partnership analysis in transnational spatial planning, distinguishing between formal, informal, and research-based configurations, examining actor roles, scalar negotiations, and tensions between environmental, economic, and cultural objectives. Section 7-8 concludes by identifying opportunities for adaptive and inclusive governance, emphasising the potential of transboundary planning to respond to climate, ecological, and social challenges when both stakeholders and streekholders are meaningfully involved.

4. Problem statement – escalating conflicts and environmental pressures

The governance of the Flemish-Dutch Delta is characterised by a "wicked problem" where economic, environmental, and societal conflicts are not isolated but deeply interconnected and intensified by the overarching impacts of climate change. This intricate web of interdependence means that addressing one issue often creates unintended negative consequences in another, making the interplay between nature, industry, and society a continuous process of negotiation. While the region is functionally interdependent, it remains institutionally fragmented across national borders, challenging the development of cohesive and resilient spatial planning.

The Flemish-Dutch Delta, despite its historical resilience and economic importance, is currently grappling with intensifying environmental pressures that fundamentally threaten its long-term sustainability. Formal cooperation has emerged between institutional actors through the Vlaams Nederlandse Delta platform, which facilitates

coordination between provinces and includes national ministries, planning departments, and intergovernmental entities such as the Benelux Union and are engaged in policy alignment and development of shared planning agendas (Vanelslander et al., 2011). On the local scale, Grenspark Groot Saeftinghe, a landscape of intersecting future opportunities, climate-related vulnerabilities, and ongoing tensions between conflicting interests, where efforts toward environmental resilience are continually challenged by socio-economic transformation. GGS illustrates how formal and informal governance frameworks must interact in complex border landscapes, where spatial planning must mediate between environmental resilience and socio-economic transformation.

Social acceptance is eroded by this policy patchwork. The inherent tension between nature, port, and society is not merely a policy challenge but a fundamental conflict deeply embedded in the delta's identity. This conflict is demonstrably intensifying with the climate crisis and the lack of efficient decision-making frameworks. Local residents perceive ecological restoration as an imposed sacrifice for metropolitan shipping interests; port communities fear economic stagnation if draft limitations are introduced; and farmers view nitrate caps as threats to cultural identity. Without a governance framework capable of coupling economic, ecological and cultural values across scales, each incremental intervention re-ignites hidden conflicts.The contested future of the village of Doel is a stark example, having been designated for demolition in the 1960s for industrial expansion, only to be officially returned to its residents in 2022 following prolonged civic opposition (The Brussels Times, 2022).

Economic growth or dredging or PFAS, what are port activities - On both scales, port-driven growth is the principal engine of prosperity yet simultaneously the main driver of cumulative environmental degradation, dredging, land reclamation and heavy logistics emit pollutants (PCBs, PFAS, trace metals) and accelerate habitat loss (Baeyens et al., 2005). While deepening the Western Scheldt shipping channel secures Rotterdam and Antwerp-Bruges in global trade networks, it also triggers compensatory depoldering of agricultural polders such as Hedwige-Prosper, provoking intense local resistance and exposing a persistent gap between national competitiveness narratives and everyday rural livelihoods (Van Buuren & Warner 2014).

Pollution illustrates this systemic misalignment. High livestock densities load the delta with nitrate and phosphate, fuelling eutrophication and biodiversity decline (Van Meerbeek et al. 2015). Intensive agriculture in the region contributes significantly to nutrient pollution, leading to high concentrations of nitrogen and phosphorus in surface and groundwater (Greenhood, 2025). Simultaneously, sediment-bound POPs and heavy metals from historical industrial discharges exceed ecological thresholds in the Scheldt estuary, making routine seafood consumption unsafe (Van Ael et al., 2012). Emerging PFAS contamination now compounds these legacies, highlighting weak preventive regulation and fragmented monitoring regimes. Addressing any one pollutant in isolation risks displacement effects: dredged contaminated sediments are relocated, nutrients are exported downstream, and carbon-intensive port retrofits shift emissions offshore.

Water is the binding medium of these tensions. Centuries of "Dutch Approach" hydraulic engineering have produced a technically safe but rigid landscape whose dykes and sluices struggle to accommodate twenty-first-century sea-level rise, salt-water intrusion and episodic droughts (Meijer, 2016; Interreg 2 Seas[3]). In Saeftinghe the tidal gradient between salt marshes and reclaimed polders increasingly undermines farming viability, while across the wider delta peat dykes desiccate, freshwater shortages intensify, and salinisation erodes both ecological integrity and agroeconomic resilience (Vermeulen 2025). Climate change thus multiplies the trade-offs already inherent in the port–nature–society triangle.

Living with water and sea-level rise. Sea-level rise and climate change impacts pose an existential threat to the Flemish-Dutch Delta. Global mean sea level is projected to rise significantly by 2100 and potentially by 2 to 5 meters by 2300, necessitating urgent and comprehensive adaptation strategies (Interreg 2 Seas). While the Drowned Land of Saeftinghe showcases dynamic estuarine processes, the surrounding reclaimed polders highlight the constant challenge of living with water in intensely used land. This includes the direct impacts of tidal dynamics, the complex interplay of fresh and saltwater (salinisation in coastal areas), and the vulnerabilities of agricultural lands being less suitable for traditional crops to changing water levels. These intensive uses of the delta landscape, coupled with the impacts of climate change, collectively threaten the integrity of natural ecosystems, the viability of agricultural areas, and the overall resilience of urban environments (Vermeulen, 2025).

3 https://www.interreg2seas.eu/

5. Mapping the actor landscape

The actors involved in the governance and planning of the Flemish-Dutch Delta, particularly within the Grenspark Groot Saeftinghe framework, are 11 partner organisations from the Netherlands and Flemish side of the border. They are typically governmental bodies at various levels, including the Province of Zeeland and East Flanders, De Vlaamse Waterweg, Municipality of Beveren and Hulst, which operate within established legal and administrative frameworks. Environmental organisations like Stichting Het Zeeuwse Landschap, Maatschappij Linkerscheldeoever, Agentschap voor Natuur & Bos and Natuurpunt Waasland also fall into this formal category, advocating for nature conservation and ecological restoration and includes influential Port of Antwerp-Bruges, whose economic interests are central to the region's development. It also includes EU funded organisation EGTC (European Grouping of Territorial Cooperation) Linieland van Waas en Hulst, which in itself is a group of eight Flemish and Dutch authorities joining forces around various themes

In contrast, Informal "*Streekholders*" represent a grassroots layer of engagement. This group encompasses local citizen groups, residents, farmers, businesses, tourism guides, youth, and enthusiastic volunteers. They are distinguished by their deep connection to and commitment to the future of their immediate region, or "streek". Volunteers, such as the "hosts and hostesses" in GGS, provide invaluable local knowledge and lead excursions, further integrating community perspectives into the region's activities. Table 1 provides a comprehensive overview of these key organisations and groups, illustrating their respective roles within the Grenspark Groot Saeftinghe project.

Table 1: Key actors in Grenspark Groot Saeftinghe

Actor Type	Organisation	Critical review
Lead Partner (2023–2026)	EGTS Linieland Van Waas en Hulst	Key facilitator of cross-border cooperation; its legal structure enables formalised collaboration, yet it may struggle with visibility at the community level.
Co-lead Partner	Province Zeeland (NL)	Strong institutional actor with strategic oversight; however, it may be constrained by national priorities or limited regional flexibility.
Governmental Authority	Gemeente Beveren (VL)	Crucial for implementing local strategies but may face political pressure from port expansion, land-use tensions and lack of finance.
Governmental Authority	Gemeente Hulst (NL)	Provides local governance input; may have limited resources compared to larger partners.
Governmental Authority	Province Oost-Vlaanderen (VL)	Important for aligning regional planning, though its coordination with other provinces, across the border and national authorities may be complex.
Port Authority	Port of Antwerp-Bruges (VL)	Economically dominant actor, positively influencing economy and negatively influencing land and water; pressurised for sustainable transformation.
Nature Conservation	Stichting Het Zeeuwse Landschap (NL)	Anchors ecological concerns in governance; its involvement in crowdfunding reflects creative approaches to citizen engagement.
Nature Conservation	Natuurpunt Antwerpen Noord vzw (VL)	Key player in preserving biodiversity; complements state-led efforts but lack political leverage.
Governmental Authority	Vlaamse overheid (Flemish Government) (VL)	Provides overarching governance support and coherence across sectors; but perceived as distant from local needs.
Governmental Authority	Vlaamse Landmaatschappij (VLM) (VL)	Key in land management and farming-related strategies; bridges rural stakeholder interests with ecological targets.
Governmental Authority	De Vlaamse Waterweg (VL)	Critical for flood safety and water infrastructure; however, technical focus underrepresent socio-cultural factors.
Tourism Body	Toerisme Oost-Vlaanderen (VL)	Promotes regional identity and sustainable tourism; yet their role in spatial planning remains secondary.
Informal Actors	"*Streekholders*"	Represent bottom-up, place-based knowledge; strengthen cultural sensitivity but lack of decision-making power.
Volunteers	Hosts and Hostesses	Act as knowledge representation; enhance public outreach, though their input is often symbolic rather than decisional.

6. Multi-scalar partnerships in transnational spatial planning

Spatial planning challenges in border regions often transcend administrative boundaries, requiring strategies that integrate efforts across various levels of governance, from local to global (Laine, 2016). Metropolitan regions have emerged as dominant economic units globally, with their growth governed by complex networks of organisations that extend beyond single geographic bounds and involve multiple levels of government (Healey, 2007). This necessitates multi-scalar interactions, often forming large institutional networks. Effective spatial planning in such dynamic and complex environments requires collective action and collaboration across various actors and scales (Marin et al., 2023). The integration of diverse perspectives and resources, from local communities to international bodies, is crucial for developing sustainable and equitable solutions that address interconnected challenges like climate change, pollution, and socio-economic disparities (Adger, 2003). This section elaborates on the necessity of such partnerships and defines key typologies: formal planning partnerships, informal planning partnerships, and research-based (or research by design) partnerships.

6.1 Formal planning partnerships

Formal planning partnerships are collaborative arrangements involving established governmental bodies, intergovernmental organisations, and legally recognised entities. These are partnerships which are structured within defined institutional frameworks, typically formalised through treaties, agreements, or statutory mandates (Perkmann, 2003). They have clear mandates, hierarchical or coordinated decision-making processes, and are often designed to operate on and across national, regional, and local administrative levels in order to achieve shared policy objectives (Popescu, 2008).

Such partnerships play a crucial role in fostering cross-border cooperation, particularly in spatial and territorial development. For example, the European Outline Convention on Transfrontier Co-operation between Territorial Communities or Authorities (Madrid Convention) offers a legal basis for establishing cooperative frameworks between municipalities or regional governments across borders (Council of Europe, 1980). These institutional arrangements can take the form of Euroregions[4], cross-border metropolitan platforms, or European Groupings for Territorial Cooperation (EGTCs), and are often designed to support sustainable regional development initiatives (Sustainable Planning, 2018).

Table 2: Analysis of formal planning partnerships

Initiative	Description	Key Actors	Reflection
Flemish-Dutch Long-Term Vision for the Scheldt Estuary (LTV) (Slinger, 2023)	A foundational bilateral policy adopted in 2001 to create a healthy and multifunctional estuarine water system, balancing safety, accessibility, and nature. Established specific cross-border organizations for daily management.	Netherlands (Government, Parliament), Flanders (Government, Parliament), Technical Scheldt Commission (TSC), Joint Nautical Authority (GNA)	The LTV stands as a monumental achievement in cross-border governance, providing a foundational, enduring bilateral framework for integrated estuarine management. Its strength lies in explicitly balancing competing objectives (safety, accessibility, nature) and establishing dedicated cross-border organisations (TSC, GNA). However, its "long-term" nature can sometimes struggle with adapting to rapid, unforeseen challenges (like extreme climate events or new pollution concerns), and achieving the delicate balance in practice often leads to ongoing political and social tensions, as demonstrated by depoldering controversies.
INTERREG Projects (e.g., Grenspark Groot Saeftinghe)	European Union funding instrument promoting cross-border cooperation. The GGS project (2016-2021 and 2023-2026 phases) brings together numerous partners to balance ecological, economic, and social interests in a transnational nature park.	11 institutional partners (government organisations)[5]	INTERREG projects are vital catalysts for fostering transnational cooperation by providing dedicated funding and a structured framework for diverse partners. Their strength is the direct promotion of cross-border integration and the ability to address specific regional challenges through collaborative action. However, their project-based, time-limited nature can create challenges for long-term sustainability and institutionalisation of outcomes once funding cycles end. Moreover, coordinating such a broad range of formal actors across different national legal and administrative systems remains inherently complex.

4 Euroregions: http://www.espaces-transfrontaliers.org/en/resources/territories/euroregions/

5 11 partners - EGTS Linieland Van Waas en Hulst (Lead Partner), Provincie Zeeland (Co-lead), Gemeente Beveren (Waas), Gemeente Hulst, Provincie Oost-Vlaanderen, Stichting Het Zeeuwse Landschap, Port of Antwerp-Bruges, Agentschap voor Natuur en Bos, Natuurpunt Antwerpen Noord vzw, De Vlaamse Waterweg

Dutch Delta Program / Multilayered Safety (MLS)	A national program in the Netherlands aimed at flood risk management, shifting from traditional prevention to a more adaptive, polycentric governance approach emphasising resilience and adaptivity.	Dutch Delta Program, various levels of Dutch government, civil engineers, planners, spatial designers	This program represents a progressive shift in national flood risk management, moving beyond solely "hard" engineering to embrace adaptive, polycentric governance and resilience. Its strength is its systemic approach to climate adaptation, integrating spatial planning with water safety. A potential critique is that while it advocates polycentricity, its implementation can still be largely driven by national priorities and expert-led frameworks, sometimes struggling with genuine local-level integration and the inherent socio-cultural resistance to transformative land-use changes.
International Scheldt Commission (ISC)[6]	An international body involving France, Belgium (Walloon Region, Brussels-Capital Region, Flanders), and the Netherlands, focused on integrated water management for the entire Scheldt river basin.	Governments of France, Belgium (Walloon Region, Brussels-Capital Region, Flanders), Netherlands	The ISC is fundamental for comprehensive, basin-wide water management across multiple nation-states. Its strength lies in providing a high-level, formal platform for international dialogue and coordination on shared water resources and pollution control. However, as an intergovernmental body, its effectiveness can be limited by the lowest common denominator of agreement among sovereign states, potentially slowing down decisive action or limiting the scope of truly integrated, binding policy implementation across the entire basin.
Territorial Water Management Strategies (Belgian Pilot Action) [7]	A Belgian initiative under the Territorial Agenda, focusing on cross-border cooperation to address risks of flooding, drought, and water shortages, involving regional governments and European partners.	Brussels-Capital Region, Flemish Region, Walloon Region, European partners (e.g., European metropolis of Lille)	This initiative highlights a commendable effort within the Belgian context to address water risks through cross-border cooperation at a regional level, linking to broader European agendas. Its strength is the direct focus on specific risks (flooding, drought) and involving regional governments. The challenge often lies in scaling up pilot actions, ensuring consistent implementation across different regional administrations, and securing sustained political will and funding beyond the initial pilot phase.
Vlaams-Nederlandse Scheldecommissie[8] (VNSC) and Schelderaad	Promotes collaboration between Flanders and the Netherlands on Scheldt Estuary policy and management, including monitoring and research. The Schelderaad is an advisory platform to the VNSC.	Vlaams-Nederlandse Scheldecommissie (VNSC), Schelderaad, scientists, policymakers, water authorities	The VNSC is a critical operational arm of the LTV, ensuring ongoing collaboration between Flanders and the Netherlands on the Scheldt Estuary. Its strength lies in providing a dedicated, structured platform for policy coordination, monitoring, and research. The inclusion of the Schelderaad as an advisory platform is positive, but a critical perspective would examine whether this advisory role genuinely translates into significant influence on policy and decision-making, particularly when faced with strong economic or political imperatives.
Interreg Flanders-Netherlands	A specific INTERREG program funding cross-border projects like Grenspark Groot Saeftinghe, focusing on smart, green, and inclusive growth.	European Union (ERDF), EGTS Linieland van Waas en Hulst, Provincie Zeeland, other project partners	As a specific INTERREG program, its value lies in providing targeted EU funding and a clear framework for cross-border projects within this specific region. It directly supports smart, green, and inclusive growth, fostering practical cooperation. Similar to other INTERREG initiatives, its project-based funding can lead to a focus on discrete project successes rather than deeply embedded, continuous institutional change, and long-term financial sustainability for the outcomes of these projects remains a concern.
EGTS Linieland van Waas en Hulst	Lead partner for the current phase of the Grenspark Groot Saeftinghe INTERREG project, responsible for territorial cooperation.	EGTS Linieland van Waas en Hulst	As a European Grouping for Territorial Cooperation, EGTS Linieland provides a crucial legal and institutional framework for cross-border collaboration between local and regional authorities. Its strength is formalising and structuring territorial cooperation, enabling more effective joint planning and project management (e.g., as lead partner for GGS). A potential weakness lies in its administrative overhead and the need for continuous political commitment from constituent municipalities to fully leverage its potential and move beyond coordination to integrated governance.
Zuidwestelijke Delta[9] (Southwest Delta)	A regional program in the Netherlands focused on water safety, freshwater supply, and spatial quality in the southwest delta region, including coastal realignment initiatives.	Dutch government, regional authorities, water boards, local communities	This regional program is essential for integrating water safety, freshwater supply, and spatial quality challenges at a sub-national level in the Netherlands. Its strength is its comprehensive, multi-faceted approach to regional delta management, including potentially controversial initiatives like coastal realignment. The challenge lies in managing the complex trade-offs between these different objectives and ensuring local community buy-in and acceptance for potentially impactful interventions, as seen in past depoldering resistance.

7 https://territorialagenda.eu/pilot-actions/territorial-water-management-strategies/
8 https://vnsc.eu/over-de-vnsc/schelderaad-en-samenwerking/
9 https://www.zwdelta.nl/

North Sea Port (North Sea Port, 2025)	A merged port authority encompassing Vlissingen, Terneuzen, and Ghent, designated as a NOVEX area, crucial for regional economy and quality of life in Zeeuws-Vlaanderen.	North Sea Port Authority, municipalities of Vlissingen, Terneuzen, Ghent, Dutch government	The merger of Vlissingen, Terneuzen, and Ghent into North Sea Port represents a powerful strategic move for economic competitiveness and efficiency, and its designation as a NOVEX area highlights its national strategic importance. Its strength is its unified approach to port development and logistics. However, its immense economic power often places it in direct tension with environmental protection and local quality of life. A critical analysis would focus on the effectiveness of its sustainability pledges, its real commitment to mitigating its environmental footprint, and how genuinely it integrates broader societal and ecological concerns into its expansion and operational strategies beyond economic imperatives.

The formal planning partnerships reveals a consistent engagement of governmental and intergovernmental bodies, such as national ministries, regional authorities, and cross-border governance platforms like the European Grouping for Territorial Cooperation (EGTC). These stakeholders typically possess formal authority and high decision-making power, grounded in legal mandates and institutional legitimacy. Their actions are often governed by structured procedures and long-term planning agendas, enabling policy continuity and spatial coherence across borders.

Long-Term Vision for the Scheldt Estuary (2001), which involves Dutch and Flemish authorities cooperating on flood protection, accessibility, and ecological restoration is an example of how formal partnerships address complex environmental and economic priorities through negotiated, treaty-based agreements(Slinger, 2023). Although top-down in nature, these partnerships may include consultative frameworks to engage municipalities or regional platforms. Their strength lies in orchestrating durable, cross-border strategies that transcend electoral cycles. However, there are lack responsiveness to emergent local dynamics and societal values, unless actively integrated with informal or participatory processes. This integration of administrative coordination with participatory governance makes formal planning partnerships a foundational component of multilevel territorial governance. In the Flemish-Dutch Delta, formal partnerships serve as institutional transnational cooperation, structuring governance in regions where ecological interdependence and logistical functions coincide.

6.2 Informal planning partnerships

Informal planning partnerships includes communities and citizens as community-led initiatives, grassroots groups, and local networks that emerge organically, often in response to local needs or perceived gaps in formal planning processes. These partnerships are flexible with ad-hoc decision-making structures, relies on social norms, trust, and reciprocity, and may operate outside formal governmental regulations, though they can interact with formal structures (Meijer, 2018).

Such initiatives are frequently driven by inhabitants who possess a deep connection to their local living environment. They play a crucial role in shaping spatial development, particularly in contexts where formal planning mechanisms may be insufficient or unresponsive to local needs. In the Netherlands, for example, community-led planning has been observed in rural regions where residents initiate projects to preserve public facilities or develop village plans, often navigating complex policy domains and sometimes conflicting with formal planning systems (Meijer, 2018).

Table 3: Analysis of informal planning partnerships

Initiative	Description	Key Actors	Reflection
Streekholders in Grenspark Groot Saeftinghe	Local citizen groups, residents, farmers, businesses, tourism guides, and youth who actively preserve the region's socio-cultural identity and provide local insights. They complement formal governance and use mechanisms like the "Grenspark Denktank."	Local residents, farmers, businesses, tourism guides, youth, enthusiastic volunteers (hosts and hostesses), Grenspark Denktank members	This initiative represents a significant and innovative step towards genuine co-creation in spatial planning, moving beyond tokenistic public consultation. Its strength lies in integrating local experiential knowledge and fostering social cohesion, potentially mitigating the top-down tensions historically seen in the Delta. However, its long-term effectiveness will depend on truly empowering "*streekholders*" beyond advisory roles, ensuring their contributions genuinely shape outcomes, and preventing potential co-option by more powerful formal actors or fragmentation of local interests.
Room for Rivers (Local Implementation)	While a formal national program, its success relies on local engagement and adaptation, linking water safety directly to spatial quality, social issues, and broader economic and ecological improvements.	Local communities, farmers, landowners, environmental groups, local authorities	As a formal program with local engagement components, "Room for Rivers" is commendable for fostering broader ecological and economic improvements alongside water safety. Its success hinges on effective local mediation between diverse stakeholders (farmers, landowners, environmental groups). A critical aspect is ensuring that local implementation truly reflects community needs and equitably distributes the benefits and burdens of land-use changes, rather than being a merely consultative layer on a predetermined, national strategy.
Crowdfunding for Bird Hides (Grenspark Groot Saeftinghe)	A specific local initiative within GGS where a nature conservation organization (Stichting Het Zeeuwse Landschap) raises funds from the public to enhance park features, demonstrating community support and informal contributions.	Stichting Het Zeeuwse Landschap, local citizens, birdwatchers, nature enthusiasts	This is an excellent example of a specific, tangible local initiative within a larger park framework that leverages citizen support and informal contributions for conservation. Its strength lies in direct community engagement and ownership of small-scale nature enhancements. However, while valuable for local impact and demonstrating commitment, such initiatives are typically limited in scope and cannot address systemic, large-scale environmental challenges or substitute for robust institutional funding and strategic planning for core conservation goals.

Doel 202010	A local action group advocating for the preservation of the village of Doel, often in response to port expansion plans, representing community resistance and heritage preservation efforts.	Local residents of Doel, activists, heritage preservationists	Doel 2020 exemplifies profound and sustained community resistance against top-down port expansion plans, successfully challenging a decades-long designation for demolition. Its critical role lies in asserting local agency and heritage preservation against powerful economic interests. While demonstrating the power of civic opposition, its reactive nature highlights the inherent tension between economic development and local identity, and the considerable social cost and protracted conflict that can arise from a lack of early and genuine participatory planning.
Participative Platform11 (Grenspark Groot Saeftinghe)	An online platform facilitating direct engagement and feedback from local citizens within the Grenspark Groot Saeftinghe initiative, allowing citizens to participate in various groups.	Local citizens, Grenspark Groot Saeftinghe team	This online platform is a tool for facilitating direct and ongoing engagement, democratising access to participation beyond physical meetings. Its strength lies in its potential to broaden reach and enhance transparency, fostering continuous feedback loops. The critical challenge will be to ensure that online engagement translates into tangible influence on decision-making, bridging the digital divide, and preventing the platform from becoming a mere 'listening' mechanism rather than a true co-design space where diverse local voices are genuinely heard and integrated into park management.

Informal planning partnerships, studied in this research, highlights the role of grassroots actors, local associations, cultural institutions, and civic coalitions. These stakeholders often emerge in response to perceived gaps in formal governance, acting autonomously or semi-autonomously to represent local values, challenging top-down decisions, or even articulating alternative futures. While their formal decision-making power is limited and may lack structural durability, their influence can be substantial in shaping public discourse and pushing institutional actors toward more inclusive or culturally sensitive agendas. A prominent example is the Doel 2020 movement, where local residents resisted port expansion and advocated for cultural preservation and heritage-based regeneration. These partnerships tend to focus on socio-cultural sectors, landscape heritage, and identity politics, often linked to spatial claims over land, water, and memory. Their temporality may be fluid and adaptive, but they demonstrate a strong sense of place-based continuity.

6.3 Research-based planning partnerships

Research-based partnerships or Research by Design partnerships involve collaborations between academic institutions, research organisations, knowledge institutes, and practitioners to generate, integrate, and disseminate spatial knowledge. These partnerships aim to inform policy, improve planning practices, and develop innovative solutions through data collection, analysis, modelling, and participatory knowledge exchange. They are crucial for understanding complex social-ecological systems and developing transformative pathways (Henrick et al., 2017). These are long-term, mutually beneficial collaborations that promote the production and use of research. They often involve co-production of knowledge, where researchers and practitioners work together to address persistent problems of practice (Coburn et al., 2013). By integrating diverse perspectives and expertise, research-based partnerships can produce more relevant and actionable insights for policy and practice (Farrell et al., 2021).

In the context of spatial planning, research-based partnerships can facilitate the development of innovative

10 http://www.doel2020.org/index.php

11 https://www.streekholders.grensparkgrootsaeftinghe.eu/default.aspx

instruments, tools and approaches, such as scenario planning, to support decision-making processes (Geertman et al., 2013). They also play a vital role in capacity building, enhancing the skills and knowledge of both researchers and practitioners (Penuel et al., 2015).

Table 4: Analysis of research-based planning partnerships

Initiative	Description	Key Actors	Reflection
Schelde Monitor12	A Flemish-Dutch knowledge and information system established in 2003 for research and monitoring in the Scheldt Estuary. It provides expertise, literature, datasets, measurements, projects, maps, and indicators to support policy and management.	Flemish-Dutch Scheldt Commission (VNSC), scientists, policymakers, water authorities	ScheldeMonitor is a foundational asset for evidence-based decision-making in the Scheldt Estuary. Its strength lies in centralising and continuously providing comprehensive, multi-disciplinary data, research, and expertise, crucial for informed policy and management. A potential critique is ensuring its accessibility and usability for diverse stakeholders (beyond just scientists and policymakers) and maintaining its independence and funding to continue providing objective data in a politically charged environment. Its long-term operation since 2003 speaks to its established value.
SPADES13 Project (EU Soil Mission)	A Horizon Europe project combining 19 partners in 10 countries, including Deltares and TU Delft. It investigates integrating soil health into spatial planning and design through 17 pilot projects in urban, peri-urban, and rural areas.	Deltares (project coordinator), TU Delft, 19 partners from 10 European countries (universities, knowledge institutes, private partners), spatial planners, policymakers	The SPADES project is a highly relevant initiative addressing the critical but often overlooked issue of soil health within spatial planning, connecting it directly to EU policy goals. Its strength is its transnational, multi-partner approach, integrating diverse knowledge institutes and applying research through practical pilot projects. The challenge lies in ensuring that the insights from these 17 pilots are effectively scaled up and translated into implementable policy changes across varied national and regional contexts, overcoming bureaucratic and practical barriers to adoption.

12 Schelde Monitor - https://www.scheldemonitor.be/nl
13 SPADES - https://www.spades4soils.eu/

"Estuaries on the MOVE" (EMOVE) EU Interreg Project (Jan et al., 2015)	An EU Interreg project aiming to turn stakeholders into "shareholders" by fostering a shared understanding of the estuary's physical and ecological functioning and collectively formulating projects. It involves scientists and policymakers.	Scientists, policymakers, various stakeholders (e.g., environmental groups, port authorities)	EMOVE's ambition to turn stakeholders into "shareholders" by fostering shared understanding of estuarine functioning is a commendable step towards deeper collaborative governance. Its strength is building common knowledge and promoting collective project formulation among diverse actors, which is crucial for complex socio-ecological systems. However, achieving genuine "shareholder" status requires more than just shared understanding; it necessitates power-sharing, which can be challenging to implement in projects with inherent power imbalances among stakeholders (e.g., between port authorities and environmental groups).
Collaborative Eco-morphological Modeling (Scheldt LTV)	A specific activity during the development of the Scheldt Long-Term Vision (1999-2001) that used modeling to facilitate communication and create a shared understanding of the estuary's intrinsic character among diverse actors.	Scientists, policymakers, various actors involved in LTV development	This specific modeling activity during the LTV development demonstrates the power of scientific tools in facilitating communication and building shared understanding among diverse stakeholders regarding complex natural systems. Its strength is in using visual and data-driven methods to bridge knowledge gaps and facilitate consensus. However, the models are only as good as their inputs and assumptions, and their complexity can sometimes alienate non-expert stakeholders if not effectively communicated, potentially limiting genuine co-production of knowledge.
"Drought in the Delta" (IABR Atelier)[14]	A design research project portraying freshwater shortages in the Dutch Delta through visualizations and design proposals, aiming to inform a change in thinking and acting towards water retention.	IABR (International Architecture Biennale Rotterdam), researchers, designers	This initiative highlights the critical role of design research and visualisation in raising awareness and fostering new perspectives on pressing environmental challenges like freshwater shortages. Its strength is its ability to communicate complex issues through accessible design proposals, inspiring a change in thinking and action. A potential limitation is that design proposals, while visionary, often require significant political will, funding, and public acceptance to move from conceptualisation to large-scale implementation.

14 https://iabr.nl/en/research/atelier-droogte-in-de-delta

Deltaplatform Living Labs15	Initiatives focused on fostering knowledge exchange and developing practical, scalable solutions for urban resilience and water management through collaborative discussions.	Deltaplatform, international experts, various urban contexts	Living Labs are excellent mechanisms for fostering real-world knowledge exchange and developing practical, scalable solutions through iterative, collaborative processes. Their strength is in their hands-on, experimental approach that directly involves end-users and promotes rapid learning cycles. The challenge for Deltaplatform's labs lies in ensuring that the solutions developed within specific urban contexts are truly scalable and adaptable to other diverse environments, and that the knowledge generated is effectively disseminated and integrated into broader policy frameworks.
Bauhaus of the Seas	An EU initiative promoting new ways of living with water, integrating design, science, and art, with pilot projects like the Delta pilot (including Grenspark Groot Saeftinghe) as living examples.	New European Bauhaus, researchers, designers, local communities, public agencies	This EU initiative, connecting design, science, and art to re-imagine living with water, is highly innovative and holistic. Its strength is its interdisciplinary approach and emphasis on practical pilot projects like the Delta pilot, offering "living examples" of new ways to interact with aquatic environments. A potential challenge is translating broad, aspirational visions into concrete, universally applicable policy measures, and ensuring that artistic and design-led approaches are genuinely integrated with scientific rigor and policy implementation.
Panorama Zeeuws-Vlaanderen16 (De Zwarte Hond)	An investigative design study exploring the coexistence of a flourishing economy with an aging society in Zeeuws-Vlaanderen, focusing on quality of life and cross-border cooperation.	De Zwarte Hond, municipalities of Sluis, Hulst, Terneuzen, Creative Industries Fund	This investigative design study is valuable for exploring the complex interplay of economic prosperity, demographic shifts (aging society), and quality of life at a regional scale, with a focus on design solutions. Its strength is its holistic perspective and emphasis on cross-border cooperation for sustainable regional development. As a design study, its impact relies on the subsequent political uptake and financial commitment to implement its proposals and ensuring that design-led insights are fully integrated with broader planning and economic development strategies.

The aim of such partnerships, as studied within this research, is to co-produce spatial knowledge and develop experimental or adaptive planning frameworks. A key feature is their sectoral breadth, ranging from climate resilience (e.g., Resilient Delta17) to socio-economic transitions and port-city interrelations (e.g., PortCityFutures18). These partnerships often include universities as knowledge anchors, combining empirical analysis with

15 https://www.deltaplatform.nl/en/living-labs
16 https://dezwartehond.nl/projecten/panorama-zeeuws-vlaanderen
17 https://convergence.nl/resilient-delta/
18 https://www.portcityfutures.nl/

normative policy recommendations. Their decision-making power is indirect but influential, operating through policy advice, scenario development, and evidence-based recommendations. Long-term thinking is embedded in their iterative and systemic approaches, often guided by principles of transition management, participatory design, or adaptive planning.

In most of the cases, there are some partners from the government organisations in for implementation and dissemination of knowledge. While the formal government organisations are not part of the project decisions, they act as mediators between sectors and scales. By aligning research with planning needs, these partnerships can influence formal agendas and bridge governance gaps, particularly in complex transboundary contexts like the Flemish-Dutch Delta.

7. Discussion - Stakeholder and "*Streekholder*" dynamics

The governance in the Flemish-Dutch Delta illustrates a complex and elaborately intertwined interactions of diverse actors, ranging from established formal institutions to community-driven groups, referred to as "*streekholders*" (Grenspark Groot Saeftinghe, 2024). The divergent priorities of these groups, the underlying vulnerabilities of the region and the cultural mindsets, inherent the dire need for structural collaboration.
There are 4 focus points areas recognised for this region; (i) Economically, formal stakeholders such as port authorities are focused on continuous economic development and enhanced accessibility for shipping. (ii) Environmentally, this objective frequently generates friction with conservation goals pursued by environmental organisations and certain governmental bodies, particularly in a sensitive ecological zone like the Scheldt estuary. (iii) At the policy and management level, living with water inherently involve balancing the water management "safety," "accessibility," and "nature" of the Scheldt estuary. (iv) At the local level for the communities, "*streekholders*" often prioritise the preservation of their socio-cultural identity, their livelihoods (e.g., agriculture), and their quality of life.

Reflecting on the actor landscape

After critically reflecting on the vast array of partnerships, reveals certain gaps and limitations. A primary missing element is a truly unified political leadership at the transnational level capable of consistently "breaking down" borders and overcoming entrenched national interests and diverse regulatory landscapes. Despite the understanding of the advantages of cross-border collaboration, the full realisation and implementation of the potential remains largely a "political problem". Informal actors, or *streekholders*, focus on maintaining socio-cultural integrity, livelihoods, and community quality of life, which can (sometimes) directly clash with regional or national objectives, or the long-term bigger picture, vividly illustrated by the protests against depoldering initiatives (Van Buuren & Warner, 2014). Existing partnerships tend to underrepresent or inadequately integrate certain voices, including youth, marginalised communities, and small-scale local entrepreneurs, leading to a governance gap wherein grassroots perspectives remain peripheral or symbolic rather than decisively influential (Meijer, 2018).

Patterns and trends in partnerships

The evolution of stakeholder partnerships in the Flemish-Dutch Delta reveals a gradual yet persistent shift toward multi-actor engagement. Since the early 2000s, initiatives such as the Grenspark Groot Saeftinghe have increasingly institutionalised informal stakeholder involvement through frameworks like EU-funded INTERREG projects (Interreg Vlaanderen–Nederland, 2025). These initiatives have fostered dialogue among formal and informal actors, significantly marked by structured entities such as EGTC Linieland van Waas en Hulst (EGTS Linieland van Waas en Hulst, 2024). Despite growing inclusivity, the decision-making influence of informal actors remains constrained, highlighting an ongoing imbalance where strategic and economic stakeholders dominate the core decision-making processes (Popescu, 2008).

Learnings from these partnerships

The lack of integration of informal and local perspectives into formal planning frameworks to enhance legitimacy, resilience, and adaptive capacity (Adger, 2003) is purely visible. The GGS initiative itself functions as a testing ground, fostering experimental and adaptive governance approaches adept at addressing complex interactions among ecological vulnerabilities, socio-cultural identities, and economic interests. It is vital to ensure that planning processes are not only effective but also socially accepted. Thus, fostering truly inclusive governance requires specific mechanisms that formalise the roles of *streekholders* in decision-making processes, facilitate continuous dialogue, and mediate conflicting interests through sustained, adaptive collaboration (Henrick et al., 2017).

8. Conclusion and recommendations

This paper demonstrates that the future of transnational spatial planning lies not only in formal structures but in the symbiotic relationship between institutional stakeholders and local *streekholders*. In the Saeftinghe case, this interplay has produced experimental and adaptive governance models that navigate ecological vulnerabilities, socio-cultural identity, and economic interests. The study reveals that when local voices are actively incorporated, as in the case of *streekholders*, planning processes gain legitimacy and resilience. This dual involvement challenges conventional stakeholder frameworks and offers a more inclusive, place-based approach to transboundary spatial governance. The insights from Saeftinghe provide a valuable precedent for regions across Europe facing similar multi-scalar complexities. Despite promising initiatives on multiple levels, formal governmental planning, informal planning grassroots initiatives and research driven partnerships, the study reveals a critical disconnect. These approaches currently operate in parallel in different scales, limiting the potential for inclusive and resilient and integrative spatial planning in the delta. Why it matters? Below are some initial recommendations for more holistic governance at regional and delta scales:

Power of shared visions – Lack of shared frameworks for integrating diverse perspectives across scales, sectors and stakeholders, hinders the co-creation of a shared vision of future proof solutions. A centralised platform that facilitates data sharing and communication between all scales and actors could promote intentional collaboration and implementation of interventions.

Formalised process of inputs – Policy frameworks in a transnational scale, which actively incentivises collaboration across governmental, research and citizen-led initiatives. Aligning institutional mandates with participatory planning is essential for legitimacy and impact. A clearly articulated process for integrating local knowledge and feedback mechanisms into decision-making would further enhance transparency, responsiveness, and long-term institutional learning.

Navigating values and tensions – GGS presents a trinity of nature, port, and agriculture as both identity and site of contestation. This conflict is also a strength. On a delta scale, the ports hold a strong hand and are responding to these escalating pressures, strategies are emerging to balance economic growth with sustainability. Ports like Rotterdam have adopted "Green Port" initiatives, investing in renewable energy sources such as wind and solar power and actively developing a hydrogen economy to reduce reliance on fossil fuels. Antwerp also demonstrates leadership in green logistics through initiatives like dual-fuel watercraft.

Nature inclusive long-term approaches – The growing advocacy for Nature-Based Solutions as an alternative to traditional "hard" infrastructure (e.g., concrete dikes) for coastal protection and climate adaptation, are being proposed for their environmental benefits, contributing to climate resilience and biodiversity enhancement. These approaches restore ecosystems while offering flexible, robust climate adaptation strategies, while simultaneously providing vital flood protection.

Rebalancing power and sustaining collaboration – The success of integrating "*streekholders*" demonstrates that local ownership and community-based approaches are vital for the long-term sustainability and social acceptance of large-scale regional development initiatives. Interventions such as coastal realignment, while designed to enhance ecosystem services, have met with negative social responses due to the perceived loss of cultural ecosystem, including agricultural polders and traditional livelihoods. By granting local communities "real agency" and ensuring their voices are genuinely heard for building trust, initiatives must address the socio-cultural implications of spatial interventions.

Embrace adaptive and integrated planning – The evolution of governance in the Flemish-Dutch Delta reveals a dynamic interplay, or paradox, between centralisation and decentralisation in adaptive planning. While the Dutch approach has shifted towards "multilayered safety," a more polycentric and inclusive model, there remains an ongoing discussion about "Decentralisation of the Spatial Planning System" versus a potential "Recentralisation of Planning" due to doubts about locational choices. This indicates that effective adaptive governance in deltas is not a simple linear progression of control, but rather a continuous re-scaling of governance functions. Multilayered governance must balance top-down strategic direction with bottom-up contextual implementation. Such dynamic fosters a "network of governance" that is better equipped to navigate spatial challenges across administrative and national borders.

Addressing legal and administrative obstacles in cross-border water management demands systemic coordination across sectors and scales. This includes integrating water, spatial, and economic strategies to address "wicked problems" holistically, recognising their interconnected nature. Regular and sustained dialogue is therefore crucial for encouraging commitment and synergy between national and local actions, ensuring that strategies are truly effective across all levels of governance. These recommendations stem from the early phase of research within the Bauhaus of the Sea Sails project and fieldwork in the Borderpark of Saeftinghe. As a research-in-progress contribution, the next steps will deepen the analysis of institutional evolution, path dependencies from the history and future trajectories for delta scenarios. This will include extending the empirical base with national, provincial, regional and municipal policy documents from the Netherlands and Belgium.

The Bioeconomy, Experimental Governance, and Spatial Planning

Palmira Ndeshihala de Almeida
University College Dublin
Palmira.dealmeida@ucdconnect.ie

Abstract
Spatial planning, deeply rooted in institutional contexts, is a key enabler of societal transitions towards sustainability. The governance structures that influence planning are shaped by institutional frameworks and regulations determining land-use and developmental decisions. While agendas like the bioeconomy offer pathways to sustainability, their implementation is often hindered by rigid governance, fragmented coordination, and slow processes stemming from divergent perspectives and institutional inertia. Sustainability-focused governance models can improve planning effectiveness. Experimental approaches such as testbeds and living labs encourage institutional learning and collaboration among stakeholders, enabling co-creation. However, they also introduce challenges related to stakeholder interests and power dynamics. This paper analyses the interplay between planning systems and sustainable transitions such as the bioeconomy, whilst exploring how experimental governance can address some these challenges.

Keywords: *the bioeconomy; spatial planning, sustainability transitions, experimental governance, living labs*

Introduction

"Deliberately steering societal change towards a desired future is an endeavor of tremendous size and complexity." (McCrory et al., 2018, p.3).

Sustainability transitions require profound shifts in socio-technical practices, behaviours, and governance to address complex challenges like climate change and inequality (Truffer et al., 2010). Contemporary research emphasises the need to navigate uncertainty, ambiguity, and non-linearity in these transitions, advocating for learning, reflexivity, and experimentation as adaptive strategies (McCrory et al., 2018).

A growing body of literature frames human settlements and natural environments as integrated socio-ecological systems (SES), characterised by dynamic, interconnected relationships across spatial and temporal scales (Martínez-Fernández et al., 2021). Spatial planning plays a crucial yet often underdeveloped role in managing these complexities, especially in emerging fields like the bioeconomy (Grossauer and Stoeglehner, 2020).

Urban experimentation has become a prominent approach, shifting from rigid planning to open, iterative exploration (Andersson et al., 2024). Urban experiments (UEs) are deliberate interventions designed to trigger sustainability transitions (Baatz et al., 2024), but their effectiveness is deeply shaped by the socio-ecological and spatial contexts in which they occur (Sauer et al., 2015). Researchers using socio-ecological systems frameworks realised that this approach didn't account for the role of technical infrastructure in urban areas (Andersson et al., 2024). This led to the development of 'social-ecological-technical systems' (SETs), which focus on interactions between ecological, social, and technological aspects (*ibid*). Current research uses this framework to analyse urban issues like risks, resilience, ecosystem services, justice, and nature-based solutions (*ibid*).

Urban experiments unfold within specific "sites" defined by unique socio-spatial configurations physical, cultural, and institutional which actively shape and are shaped by social actions (Baatz et al., 2024). These configurations influence both the outcomes of experiments and the potential for transformative change. Experiments can disrupt established routines, alter perceptions, and reshape regulatory or cultural aspects of space (Gaba and Bretagnolle, 2020; Ehnert, 2023).

Ultimately, effective sustainability transitions depend on the dynamic interplay between experimental governance, socio-ecological-techical systems, and spatial contexts. Recognising the embeddedness of agency within these configurations enables a more nuanced understanding of how transformative change can be facilitated or constrained (Gaba and Bretagnolle, 2020).

The Bioeconomy: Navigating Spatial Dynamics, Governance Challenges, and Inherent Tensions

The bioeconomy is widely recognised as a key strategy for providing essential goods, replacing non-renewable resources with renewables, and preserving natural resources (Wohlfahrt et al., 2019). It is central to current

sustainability transitions agendas, particularly within Europe (Halonen et al., 2022). The European Commission introduced the "knowledge-based bioeconomy" in 2005, emphasising the role of education, research, and collaboration in unlocking the value of biological resources across sectors (Birner, 2017; McCormick & Kautto, 2013). Since the early 2000s, the European Union (EU) has promoted bioeconomy policies at multiple levels, launching its bioeconomy strategy in 2012 and updating it in 2018 (Lühmann, 2020). This strategy aims to foster a low-carbon, sustainable growth model, focusing on food and energy security, biodiversity conservation, and effective resource management (Altoukhov et al., 2022; Ronzon et al., 2022).

Despite being touted as inherently sustainable, the bioeconomy faces criticism. Early emphasis on biotechnology led to a focus on innovation and technical fixes, often at the expense of interdisciplinary approaches and practical solutions (Priefer et al., 2017). Critics also highlight risks of commercialising nature, prioritising market interests over environmental and social well-being, and concerns about land grabbing and greenwashing (Birner, 2017). Thus, a comprehensive understanding of the bioeconomy must go beyond techno-economic perspectives, considering spatial and governance dimensions and inherent tensions (Wohlfahrt et al., 2019; Ahlqvist & Sirviö, 2019).

The bioeconomy's spatial dynamics are rooted in specific territories, relying on local biomass and value chains, and shaped by both local and global networks (Wohlfahrt et al., 2019). Its manifestations vary by scale: globally, it involves market-driven dynamics; nationally, it creates uneven development; regionally, it highlights tensions between industrial resource use and alternative land-uses (Ahlqvist & Sirviö, 2019). Strategic spatial planning is important in balancing environmental, social, and economic goals and addressing land-use conflicts (Grossauer & Stoeglehner, 2020).

While the bioeconomy offers potential for sustainable development, it is also subject to conflicts. Debates persist over whether it perpetuates capital accumulation within neo-liberal frameworks or can drive transformative change (Ahlqvist & Sirviö, 2019). Policy frameworks often favour corporate interests, risking continued resource exploitation and exceeding ecological limits (Ville, 2023). For instance, Finland's forest bioeconomy may reinforce resource extraction rather than rural revitalisation (ibid). Integrating sustainability and circularity principles is critical to avoid replicating traditional models (Holden et al., 2022). The "biosave regime," which prioritises reduced resource use based on ecological principles, has been proposed as an alternative to growth-oriented paradigms (Halonen et al., 2022). A comparative analysis of the "biosave regime" and other predominant regimes in bioeconomy development is provided in Figure 1.

	Biotech regime	Biomass regime	Biosave regime
Idea	Technical innovations resolve ecological problems with new 'less polluting' solutions	Renewing bioresources replace the 'more polluting/non-renewing' resources and thence resolve ecological problems. Requires more efficient use of the resources so the resource use does not increase	Degrowth and restricting the use of the resource to the minimum resolve socio-ecological problems. Techno-economic solutions have a minor role
Progress	Driven by markets - > R&D and investment support, and policies follows	Driven by normative policies and related R&D and investment support - > markets follow	Driven by normative policies and regulations - > markets follow
Role of institutions	Supporting of the markets	Guiding the markets and resource use	Restricting and restraining of the markets
Driving actors	Economic/market-oriented actors, e.g. companies, business organisations	Public organisations, NGOs	Public organisations, NGOs, citizens
Supporting/enabling actors	Public organisations, consumers	Companies, customers	Companies, customers

Figure 1: *Characteristics of bioeconomy regimes (Halonen et al., 2022, p.3).*

The bioeconomy faces a salient challenge of reconciling economic growth with finite biological resources and ecological boundaries (de Schutter et al.,2019). Current bioeconomy activities are often linked to environmental degradation (e.g. intensified agriculture and land conversion leading to habitat loss and disruption of local ecosystems) (*ibid*). While the bioeconomy can contribute to Sustainable Development Goals (SDGs), it can also undermine their achievement (*ibid*). A truly sustainable bioeconomy requires actively recognising the ecological foundation of all activities and the physical boundaries of social and economic systems (Pungas, 2023).

Moreover, the bioeconomy must grapple with questions of social justice and equity (Halonen et al., 2022). Ensuring an inclusive bioeconomy constitutes an active area of research. The concept of a 'just transition' is regarded as crucial for ensuring the sustainable transition to a bioeconomy that is equitable (Faulkner et al., 2024).

Therefore, while the bioeconomy presents prospective avenues for resource substitution and advancement towards sustainability, it embodies an intricate paradigm intrinsically linked to spatial considerations, governance frameworks, and the inherent discordance among economic expansion, ecological constraints, and equitable practices. The realisation of a sustainable bioeconomy mandates a comprehensive navigation of these multifaceted challenges via spatially nuanced regional integration, robust and harmonised governance mechanisms, and dedicated initiatives to confront fundamental contradictions and safeguard equity.

Theoretical Foundations

Institutional Frameworks in European Spatial Planning

Conventional spatial planning paradigms have been critiqued for their limited capacity to effectively address increasingly intricate and unpredictable challenges (Raynor et al., 2018). The complexity of these issues stems from their cross-sectoral nature, multi-scalar operation, and the involvement of diverse stakeholders with varying perspectives and values (*ibid*). Planning processes have often perpetuated existing inequalities and followed established trajectories, projecting current conditions onto future scenarios without critical evaluation (*ibid*). This reflects a broader issue of inflexibility and path dependency within socio-technical systems, which are understood as dynamically stable complexes shaped by the co-evolution of individuals, technology, and institutions (Jensen et al., 2019). These systems tend to evolve incrementally due to lock-in effects and path dependence, which impedes radical transformation (*ibid*). Furthermore, established administrative practices significantly influence the elasticity or rigidity of public administrations in response to reform initiatives (Polverari et al., 2024).

A further challenge lies in the sectoral nature of planning and governance (Hansen and Coenen, 2015). Governing sustainability transitions necessitates encompassing multiple policy areas (Polverari et al., 2024). However, planning systems often operate in silos, impeding policy integration (*ibid*). This can sometimes be linked to the different degrees of politicisation within the public sector (Kalogiannidis et al., 2024). Addressing complex interdependencies is difficult when governance functions are dispersed, especially within multi-level systems (*ibid*). While consensus-oriented approaches exist, the increasing complexity of governance implies that the ability of urban and regional authorities to control these processes may be diminishing, with some central regulatory functions transferred to national or supranational levels (Hansen and Coenen, 2015).

Importantly, transitions are inherently and deeply political (Jensen et al., 2019). They challenge existing relations of power and capital, involving trade-offs between competing visions of the future (*ibid*). Power asymmetries are central to the politics of transitions (*ibid*). Power dynamics can shape the organisation of knowledge and institutional arrangements, potentially emphasising particular aspects of urban systems while concealing others, thereby rendering some stakeholders and actions more significant than others (*ibid*). Unequal power relations can be masked by seemingly neutral concepts like 'sustainability' or 'best practices', which can be appropriated to legitimise particular agendas or practices (*ibid*). Different actors, such as policymakers, industry associations, social movements, technology manufacturers, and individual professionals, contribute to change, but their relationships, roles, and relative positions can shift as a transition unfolds (Farla et al., 2012). Incumbent actors with established networks are often expected to favour existing systems, while newcomers may push for alternatives (*ibid*). Understanding these power dynamics, the struggles between actors with competing interests, and the resources they mobilise is crucial for assessing the governing conditions under which sustainability transitions can materialise (*ibid*).

The convergence of systemic rigidity, fragmentation, and power imbalances poses substantial obstacles to achieving sustainability transformations. While urban sustainability experiments, defined as localised, intentional interventions designed to prototype alternative future scenarios are frequently undertaken, the translation of initial political support into effective governance mechanisms for systemic change remains limited (Jensen et al., 2019). These dynamics shape the persistence of established systems, the perpetuation of power inequalities, and the distribution of advantages and disadvantages. Advancing sustainability necessitates planning strategies that are more adaptable, resilient, and responsive, with a focus on inclusive stakeholder engagement and participatory processes (*ibid*). This entails a comprehensive understanding of systemic complexity and the inherent political dimensions of transformative change (Raynor et al., 2018). Future research should further investigate strategies for actors to effectively operate within existing systems and explore mechanisms for fostering collective action to catalyse sustainability transitions (Farla et al., 2012).

Introduction to Experimental Governance

The urgent need for a fundamental societal transformation toward sustainability presents major challenges for established governance and planning systems (Laakso et al., 2017). Traditional regulatory and bureaucratic frameworks often struggle to manage the complex, non-linear dynamics of sustainability transitions (ibid). These systems have also faced criticism for ambiguity and increasing commercial influence, particularly under neo-liberalisation and local financial constraints (Haderer, 2023).

Sustainability transitions research investigates how large-scale system change occurs and how actors can influence these processes (Laakso et al., 2017). A key concept is governing through experimentation defined as inclusive, practice-based, and challenge-led initiatives that promote system innovation and social learning amid uncertainty (Sengers et al., 2019). Experimentation is seen as a vital governance tool for fostering innovation and transformative change (Kivimaa et al., 2017).

Experimental governance, alongside approaches like Strategic Niche Management (SNM) and Transition Management (TM), offers alternatives to rigid, fragmented planning (Kok, 2022). Unlike hierarchical, command-and-control regulation, experimental governance supports adaptable, exploratory, and reflexive strategies that mobilise diverse actors, develop shared visions, scale innovations, and foster learning (Kivimaa et al., 2017; Kok, 2022). It emphasises stakeholder inclusion, deliberation, and co-creation, recognising that transformative change requires collaborative and multi-actor processes (Kok, 2022).

In urban and spatial planning, experimental governance is operationalised through testbeds, living labs, and innovation districts dedicated arenas for collaboration and real-world testing of solutions (Berglund-Snodgrass & Mukhtar-Landgren, 2020). These labs prioritise co-innovation and co-creation, with continuous feedback between users and innovators, enhancing participatory planning (Massuga et al., 2024; McCrory et al., 2018; Knickel et al., 2021). Intermediary actors, such as spatial planners, often facilitate stakeholder engagement and balance diverse interests (Berglund-Snodgrass & Mukhtar-Landgren, 2020; Kok, 2022).

However, integrating experimental governance within traditional systems is challenging, requiring policy changes and risking fragmented or short-term outcomes (Grönholm, 2022). There are concerns about neo-liberal co-optation, reduced accountability, and the sidelining of public authority (Haderer, 2023). Addressing these risks demands systemic changes, democratised co-production, and reconceptualised governance to align with experimental approaches (Kok, 2022; Haderer, 2023). Ultimately, successful experimental governance in spatial planning requires intentional, coordinated efforts to confront political dynamics and avoid reinforcing existing inequities (Kok, 2022).

Living Labs as a Mechanism of Experimental Governance: Conceptualisations, Open Innovation Ecosystems, and Their Role in Advancing Sustainable Regional Development

Experimental governance, characterised by "learning by doing" and adaptive objective-setting, provides a valuable framework for addressing the complexities of sustainability transitions (Van Poeck et al., 2020). It involves actively testing new forms of territorial governance and engaging diverse stakeholders to tackle multifaceted societal challenges (*ibid*). Within this context, Living Labs (LLs) have emerged as prominent mechanisms, functioning as "societal laboratories" that foster innovation and experimentation in real-world settings (Eneqvist, 2022).

LLs are closely related to "testbeds" and "real-world laboratories," representing an experimental, co-creative approach to innovation policy (Engels et al., 2019). They are defined as user-centred, open innovation ecosystems that integrate research and innovation processes in real-life communities (ibid). LLs aim to test, demonstrate, and advance new socio-technical arrangements and governance modes under real-world conditions (Lupp et al., 2021). A central feature is their emphasis on placing citizens at the heart of innovation, fostering collaborative partnerships among public, private, and community stakeholders (Engels et al., 2019; Lupp et al., 2021). These environments enable experimental and experiential learning, involving diverse users and stakeholders (Mbatha & Musango, 2022). However, not all initiatives labelled as LLs align with these core principles (ibid). LLs can also serve as sites where the meaning of sustainability is contested and negotiated (McCrory et al., 2022).

A typology of sustainability-oriented labs includes "empower and govern" labs, which are partnership-based and focus on understanding and responding to complex sustainability challenges, often at the urban level (Mbatha & Musango, 2022). These labs catalyse relational or institutional experimentation rather than solely technical or commercial innovation (McCrory et al., 2022). LLs are intrinsically linked to spatial contexts, frequently situated in cities, neighbourhoods, or regions (Lupp et al., 2021; Mbatha & Musango, 2022). They expedite co-creation and implementation across value chains, as seen in agricultural LLs (Lupp et al., 2021; Martins et al., 2025). Their key features include fostering innovation, openness, spontaneity, knowledge generation, and the development of sustainable solutions (Martins et al., 2025).

LL methodologies are iterative and phase-based, typically involving problem understanding, stakeholder engagement, solution development and testing, and outcome evaluation (Lupp et al., 2021). Evaluation often using theory-driven or developmental approaches is crucial for supporting generative experimentation and producing actionable knowledge (Dekker et al., 2021).

LLs are increasingly used to support urban planning, enabling transformative place-making and the shaping of socio-spatial identities (Eneqvist, 2022; von Wirth et al., 2018). They make experimentation tangible for landscape and nature-based solutions by functioning as both virtual and real spaces (Lupp et al., 2021). Urban LLs are experimental forms of governance designed to address urbanisation, climate change, and resilience (Mbatha & Musango, 2022), while regional LLs promote sustainable regional planning (ibid). Implementation can be challenging due to tensions with traditional planning practices, but regulatory flexibility within LLs can foster creativity and innovation (Lupp et al., 2021).

Experimental governance and LLs are increasingly seen as essential for advancing sustainability transitions, acting as real-world laboratories to test and refine solutions (von Wirth et al., 2018). Addressing sustainability challenges requires deep system-level innovation (McCrory et al., 2022). LLs enable regions to experiment with new ideas and engage with complex issues, aligning with the broader goals of sustainability transitions. They also serve as platforms for societal reflection and learning (ibid). Labs may pursue incremental or disruptive change, contributing to global sustainability transitions and supporting UN Sustainable Development Goals, such as protecting cultural and natural heritage (SDG 11.4) (Pastorelli, 2022). The regenerative development approach, which shares elements with LLs, further informs their potential to address root causes of unsustainable development and redesign humanity's relationship with the planet (ibid).

Living Labs and the Regional Advancement of the Bioeconomy

The shift towards a sustainable bioeconomy system is increasingly recognised as important, with regions playing a central role in driving this change (Szarka et al., 2023). While most strategies and policies have been formed at the national level, there is growing awareness of the need for regional bioeconomy strategies to capitalise on local strengths and priorities, because industrial activities tend to be concentrated regionally (Ayrapetyan et al., 2022).

Regional development is a multifaceted concept that extends beyond just economic growth (Medeiros, 2022). It should encompass a broader range of factors contributing to the overall well-being of a region, such as social equity, environmental sustainability, institutional strength, governance effectiveness, and spatial planning (*ibid*). Economic growth remains a component but should not be the sole focus.

Traditional regional development theories centred on economic growth fail to adequately capture the multi-dimensional nature of development and the importance of integrated, place-based approaches (*ibid*). This has led to the emergence of alternative paradigms like sustainable development, place-based development, and knowledge-based development, which adopt more holistic, location-specific perspectives (Barca, 2009).

LLs and experimental governance are being applied to study and promote the bioeconomy (Pinsky et al., 2024). Experimental governance using LLs can help shift stakeholders from conflicts based on different economic interests towards cooperative solutions (*ibid*).

However, advancing the regional bioeconomy through this approach faces challenges, including policy coordination issues, limited collective action among actors, and a lack of incentives for systematic experimentation and learning from local experiences (Pinsky et al., 2024). Key elements for unlocking the potential of experimental governance in this domain include political will, a long-term strategy based on metrics, and a system for peer review of local experiments to support policy decisions and joint learning (ibid). The experimental problem-solving approach can have a significant impact by demonstrating and replicating successful initiatives, fostering systematic learning, and promoting socio-economic opportunities alongside environmental conservation (ibid). LLs serve as a potential mechanism within the broader framework of experimental governance, providing real-world sites and methodologies for testing, learning, and co-creating solutions to complex challenges. As open innovation ecosystems, they bring together diverse actors, to develop place-based innovations. Their link to spatial contexts makes them relevant for urban and regional planning, while their focus on experimentation and multi-stakeholder involvement positions them as key enablers for sustainable transitions. Applied to the regional bioeconomy, experimental governance facilitated by LLs offers a valuable pathway towards fostering sustainable growth, collaboration, and systemic learning, despite challenges related to coordination and institutional capacity. Successful application depends on developing organisational capacity within public institutions, ensuring democratic legitimacy, and strategically embedding experimental practices. The conceptual diagram illustrates the interconnectedness of experimental governance, bioeconomy, strategic spatial planning, socio-ecological-technological systems (SETs), living labs, and urban experimentation (see Figure 2).

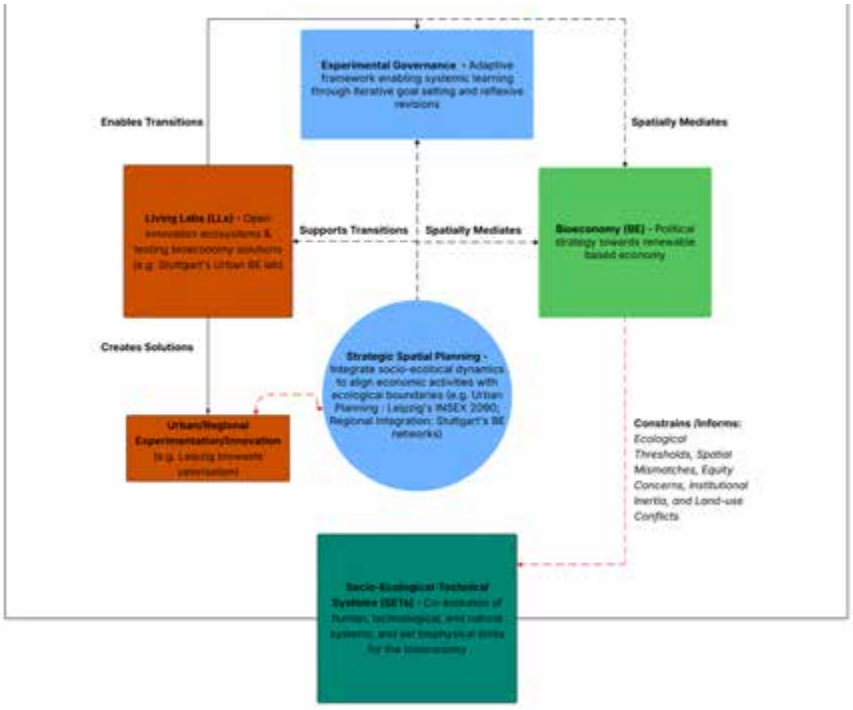

Figure 2: *Conceptual diagram showing the interconnectedness experimental governance, bioeconomy, strategic spatial planning, socio-ecological-technological systems (SETs), living labs, and urban experimentation (de Almeida, 2025)*

Methodology
This study adopts a qualitative, comparative case study design to investigate how experimental governance particularly through living labs and strategic spatial planning advances bioeconomy transitions in urban regions. The research focuses on two German cities, Stuttgart and Leipzig, selected for their contrasting yet complementary approaches to integrating innovation ecosystems and territorial coordination within Germany's national bioeconomy strategy.

Case study selection and rationale:
Stuttgart exemplifies a technical, living lab-driven model, operationalising experimental governance through the Circular Bioeconomy Strategy (ZirBioS) and the Urban Bioeconomy Lab, which integrate cascading biomass use and cross-sectoral stakeholder platforms into urban redevelopment. Leipzig, by contrast, is analysed for its policy-driven "bio-principled city" vision, embedding bioeconomy goals within the Integrated Urban Development Concept (INSEK) 2030 and piloting innovative public-private partnerships for biowaste valorisation and urban agriculture.

Data collections:
- Peer-reviewed journal articles with the broad fields of spatial planning and urban studies, urban governance, experimental governance, sustainability transition and socio-technical studies, bioeconomy and circular economy, political science and power dynamics, and environmental policy and justice.
- Policy document analysis of strategic plans (Stuttgart and Leipzig).

Analytical Framework:
A socio-ecological-technological systems (SETs) perspective is employed to assess institutional alignment, stakeholder power dynamics, spatial-material integration, and the outcomes of experimental governance. Comparative analysis highlights how multi-level governance, network structures, and spatial planning instruments mediate the effectiveness and equity of bioeconomy transitions.

Comprehensive Analysis of German Bioeconomy Transitions: Stuttgart and Leipzig Case Studies
This analysis examines experimental governance approaches to bioeconomy development in two German cities, revealing how spatial planning mediates sustainability transitions through institutional innovation and multi-stakeholder coordination. The contrasting experiences of Stuttgart and Leipzig demonstrate both the potential and limitations of experimental governance mechanisms in advancing urban bioeconomy strategies, highlighting critical factors that influence the effectiveness of spatially embedded policy integration within Germany's national bioeconomy framework.

Germany's Approach to Bioeconomy Transition: Comparative Case Studies
National Context and Urban Opportunities
The transition towards a sustainable bioeconomy represents a key strategic priority for Germany, supported by comprehensive national strategies implemented since 2010 (Wen, 2024). While rural areas have traditionally been prioritised for their biomass potential, urban regions increasingly offer significant opportunities, particularly through knowledge creation and innovation networks (Stöber et al., 2023). This analysis explores bioeconomy advancement in Stuttgart and Leipzig, two German cities that exemplify distinct approaches to experimental governance, strategic spatial planning, and institutional coordination within the broader context of national bioeconomy policy.

The involvement of diverse industries, including process and mechanical engineering, highlights the cross-sectoral nature and economic relevance of the bioeconomy beyond traditional bio-based sectors (Stöber et al., 2023). This approach demonstrates experimental governance through targeted research funding and network analysis designed to understand knowledge dynamics (ibid). However, the concentration of funding and projects among large, established actors suggests potential structural limitations, possibly hindering wider participation and network resilience across different stakeholder groups (ibid).

Stuttgart: Living Labs and Circular Bioeconomy Integration
Stuttgart's selection as a case study is anchored in its adoption of living lab methodologies to test bioeconomy solutions within urban-industrial systems. The city's Circular Bioeconomy Strategy (ZirBioS) operationalises experimental governance by prioritising cascading biomass use, carbon sink development, and cross-sectoral stakeholder platforms (Schuchardt et al., 2024). The Urban Bioeconomy Lab, a Fraunhofer Institute-led initiative, functions as a "transformation model" where municipal authorities, industries, and researchers co-design circular systems for wastewater, biowaste, and construction materials (*ibid*). This approach aligns with academic frameworks emphasising spatial experimentation as a tool for overcoming sectoral fragmentation in bioeconomy transitions (Stöber et al., 2023).

Stuttgart's strategic spatial planning further mediates these experimental initiatives through institutional coordination mechanisms. The Preparatory Land-Use Plan integrates bioeconomy objectives into urban redevelopment processes, ensuring that brownfield sites and industrial corridors are systematically repurposed for bio-based value chains (Dieckhoff et al., 2020). Academic analyses highlight how such spatial coordination enables Stuttgart to reconcile competing land-use demands while scaling pilot projects from experimental phases to broader implementation (Stöber et al., 2023). The city's governance model combines Baden-Württemberg's state bioeconomy strategy with municipal spatial planning, providing a replicable blueprint for multi-level experimentation across different administrative scales (Bioregions Facility, 2023).

Stuttgart's Network Dynamics and Institutional Challenges
Despite these innovative approaches, Stuttgart's bioeconomy innovation network exhibits concerning centralised characteristics that limit broader participation and systemic resilience (Stöber et al., 2023). The University of Hohenheim, the Fraunhofer Institute, and the University of Stuttgart have been identified as key gatekeeping institutions that control knowledge inflow and diffusion within the regional network (*ibid*). This concentration of institutional influence is mirrored in resource allocation patterns, where federal funding disproportionately benefits established research actors, allowing them to "soak up funding and relevant knowledge" while marginalising smaller stakeholders (*ibid*). Such dynamics can lead to "weak network failures," limiting collaboration and innovation among less-connected, peripheral actors and ultimately hindering the overall resilience and inclusivity of the regional innovation ecosystem (*ibid*).

Leipzig: Bio-Principled City Vision and Policy Coordination Challenges
In contrast to Stuttgart's technical focus, the Leipzig case study examines policy frameworks for transitioning towards a "bio-principled city," a comprehensive vision that integrates biological principles into urban life for enhanced sustainability and resilience (Boldt and Thrän,2023). Research indicates that Leipzig's current policy mix for this transition remains complex, uncoordinated, and lacks definitive implementation actions (*ibid*). The bioeconomy is explicitly addressed mainly at supra-national and national levels, with limited focus at state or municipal levels, despite local initiatives such as Leipzig's bioeconomy working group (*ibid*). This situation highlights significant flaws in vertical policy coordination and reveals the limited autonomy of German local governments, which remain dependent on higher policy levels and earmarked funding mechanisms (*ibid*).

Leipzig showcases elements of experimental governance through its integration of bioeconomy principles into cross-sectoral urban development frameworks. The Integrated Urban Development Concept (INSEK) 2030 embeds bioeconomy targets within a holistic vision for sustainable growth, linking circular economy initiatives such as zero-waste centres to spatial priorities including green corridors and mixed-use districts (Heinig et al., 2018). This approach reflects the New Leipzig Charter's emphasis on transformative, multi-stakeholder governance, which academic literature identifies as critical for aligning bioeconomy transitions with socio-ecological resilience objectives (Risi et al., 2020; Zeug et al., 2021).

Leipzig's Experimental Mechanisms and Governance Constraints
Leipzig's experimental governance is further evidenced by its adaptive policy mechanisms and innovative funding approaches (Kramer et al., 2024). The city's green recovery projects, funded through federal programs, test novel public-private partnerships for biowaste valorisation and urban agriculture initiatives (*ibid*).

These projects are spatially mediated through Structural Concepts that allocate land for biorefineries and community composting hubs, ensuring bioeconomy innovations align with demographic and climatic realities (Heinig et al., 2018), Academic studies note Leipzig's success in leveraging EU funding to pilot spatially targeted governance models, representing a key criterion for case study selection in sustainability transitions research (Zeug et al., 2021).

Despite these pioneering efforts in urban bioeconomy initiatives and commitment to developing "bio-principled city" concepts, Leipzig reveals significant power asymmetries at the multi-level governance scale (Boldt and Thrän, 2023). Policy-making is predominantly driven by supra-national and national actors, particularly the European Commission, constraining German local governments' financial and political capacity to implement bioeconomy transitions effectively (*ibid*). This dependency restricts their capacity for independent experimental governance and urban innovation (ibid). Furthermore, while broad stakeholder involvement is deemed essential, the lack of capacity and financial resources for comprehensive cooperation at the local level indicates that power imbalances can marginalize vital local participation (*ibid*).

Comparative Analysis of Experimental Governance Outcomes
Contrasting Governance Effectiveness
The contrasting experiences of Stuttgart and Leipzig highlight key determinants of effective experimental governance in bioeconomy-oriented spatial planning. Stuttgart's Urban Bioeconomy Lab demonstrated success through multi-level coordination, technical mediation, and spatial integration (Ministry of the Environment BW & Ministry of Rural Affairs BW, 2019). By embedding circular bioeconomy principles into land-use planning, Stuttgart enabled scalable pilot projects and resource circularity (Schuchardt et al., 2024). The Fraunhofer Institute's intermediary role fostered iterative learning and policy refinement (Federal Ministry of Education and Research, 2025). However, Stuttgart's centralised innovation network concentrated resources among dominant institutions, marginalising SMEs and grassroots actors (Stöber et al., 2023).

In contrast, Leipzig's INSEK 2030 struggled with vertical policy misalignment and limited local autonomy, impeding the translation of its bioeconomy vision into action (Boldt & Thrän, 2023; Webb et al., 2023). Fragmented coordination, rigid funding, and weak SME engagement further constrained Leipzig's circular bioeconomy initiatives (Webb et al., 2023).

Critical Success Factors for Experimental Governance
Effective experimental governance in bioeconomy transitions depends on several key conditions. Multi-level institutional alignment is fundamental: Stuttgart's success was driven by synergies between the Baden-Württemberg state bioeconomy strategy and municipal planning, which supported living labs (Webb et al., 2023). In contrast, Leipzig's fragmented policy mix revealed how misaligned agendas can undermine experimentation. Decentralised innovation networks are also crucial—while Stuttgart's centralised hubs accelerated technical solutions, they limited diversity and inclusion; Leipzig's lack of intermediaries hindered knowledge diffusion. Balancing technical efficiency with grassroots participation is essential. Spatial-material integration matters as well: Stuttgart's land-use plans anchored experiments in industrial ecosystems, enabling resource circularity (Schuchardt et al., 2024), whereas Leipzig's broad visions lacked spatial specificity, delaying implementation (Webb et al., 2023). Finally, financial and political autonomy empowers adaptive management, as seen in Stuttgart, while rigid federal funding constrained Leipzig (Ministry of the Environment BW & Ministry of Rural Affairs BW, 2019; Webb et al., 2023).

Strategic Implications and Future Directions
Both cases address strategic spatial planning dimensions that reveal important insights for bioeconomy development. Stuttgart's analysis differentiates network structures at regional and supra-regional levels, demonstrating how spatial scale influences innovation dynamics (Stöber et al., 2023). Leipzig's study strongly emphasises the urban-rural relationship, arguing that establishing the bioeconomy cannot be limited to urban areas due to biomass resource constraints (Boldt and Thrän, 2023). The city is envisioned as a nucleus driving regional structural change by revitalising urban-rural ties and fostering regional value-added networks (*ibid*). However, this approach requires improved connections to rural areas and greater involvement of SMEs, which are currently lacking (ibid).

The studies reveal key areas requiring further research and policy development. For Stuttgart, similar analyses in other urban regions are needed to validate findings and uncover regional differences (Stöber et al., 2023). For Leipzig, future work should assess how the policy mix can be improved and adapted to accelerate transitions, including mechanisms to ensure adequate funding at local levels (Boldt and Thrän, 2023). More broadly, empirical evidence is needed on the effectiveness of institutional innovations like bio-clusters on green productivity, and comparative studies across countries with different bioeconomy strategies would yield valuable insights (*ibid*).

Failure in experimental governance arises when experiments remain siloed or subordinated to incompatible higher-level agendas, as demonstrated by Leipzig's fragmented policy landscape. Future strategies should prioritise polycentric governance models that distribute agency across sectors and scales, ensuring bioeconomy transitions align with place-specific socio-ecological realities (O'Connor et al., 2023). While Stuttgart and Leipzig showcase potential avenues for bioeconomy advancement through innovation networks and integrated urban-rural systems, their experiences underscore the challenges of translating national strategies into coherent, effective local action. The current governance landscape, characterised by uncoordinated policies and limited local autonomy, reflects an experimental phase still in its 'infancy' with identifiable structural flaws. Addressing these issues through targeted policy interventions and continued research is crucial for realising the transformative potential of urban and regional bioeconomy development in Germany and across Europe more generally. See Table 1 for a comparative summary of experimental governance and bioeconomy spatial planning in Stuttgart and Leipzig, Germany.

Table 1: *Comparative Summary of Experimental Governance and Bioeconomy Spatial Planning in Stuttgart and Leipzig (de Almeida, 2025).*

Aspect	Stuttgart	Leipzig
Strategic Vision	Circular bioeconomy strategy (ZirBioS) with clear municipal and state alignment; vision operationalised through land-use planning and cascading biomass systems.	"Bio-principled city" vision embedded in INSEK 2030; remains mostly programmatic with limited concrete actions at local level.
Governance Structure	Strong multi-level coordination (municipal, state, research institutes); centralized innovation network with key gatekeepers (Fraunhofer, Hohenheim, Stuttgart University).	Fragmented policy mix; high dependence on supra-national/national directives and earmarked funds; weak local autonomy.
Experimental Approaches	Living Labs (Urban Bioeconomy Lab) as real-world testbeds for circular systems; pilots in biowaste, wastewater, construction materials.	Urban experiments in green recovery, biowaste valorisation, and urban-rural biomass networks; limited spatial and institutional integration.
Stakeholder Involvement	Broad mapping of stakeholders but practical influence concentrated among large institutions; SMEs and grassroots actors marginalised.	Policy rhetoric supports broad participation, but lack of resources, capacity, and SME engagement limits real involvement.
Spatial Planning Integration	Bioeconomy targets integrated into Preparatory Land-Use Plan; brownfield and industrial corridors repurposed for bio-based value chains.	Bioeconomy principles referenced in spatial plans, but urban-rural linkages and land allocation for biorefineries remain underdeveloped.
Key Successes	Scalable pilot projects; institutional learning; spatial mediation of bioeconomy; strong technical expertise and iterative policy refinement.	Piloting of new public-private partnerships; leveraging of EU funding for targeted innovation; recognition of urban-rural interdependencies.
Key Challenges/Failures	Centralized network limits resilience and innovation diversity; risk of "weak network failure" and knowledge gatekeeping.	Policy fragmentation, lack of vertical coordination, insufficient local autonomy, and weak translation from vision to action.
Lessons for Experimental Governance	Success linked to multi-level alignment, spatial-material integration, and financial/political autonomy; risk of exclusion if networks are too centralised.	Effective governance requires improved coordination, empowerment of local actors, and concrete mechanisms for stakeholder engagement and resource flows.

Discussion

The advancement of the bioeconomy, a key strategy for sustainability transitions, is shaped by the interplay of governance, spatial dynamics, and institutional contexts. Spatial planning plays a crucial, though often underdeveloped, role in navigating the complexities of the socio-ecological-technological systems central to the bioeconomy. Traditional planning frameworks marked by rigidity, fragmentation, and power imbalances can impede transformative change, as dominant interests may shape strategic visions and institutional inertia discourages experimental approaches.

Experimental governance, including strategies like Urban Experiments (UEs) and Living Labs (LLs), has emerged as a promising response to these challenges. These approaches advocate adaptive, reflexive, and exploratory governance that involves diverse stakeholders. LLs, in particular, act as user-centric, open innovation ecosystems embedded in real-world settings, fostering co-creation and collaborative innovation processes, often in urban or regional contexts. Such initiatives make experimentation more tangible and applicable to spatial issues.

However, the application of experimental governance faces significant obstacles. The Stuttgart case study demonstrates that bioeconomy innovation networks often revolve around prominent institutions acting as knowledge gatekeepers, with funding and projects concentrated among large, established actors potentially limiting wider stakeholder participation. The Leipzig case highlights difficulties in translating conceptual ideas into practice, revealing a fragmented and uncoordinated policy landscape and weak vertical policy coordination. This underscores the importance of urban-rural relationships but also reveals insufficient connections and SME involvement needed for effective regional transformation.

A fundamental challenge is the spatial nature of the bioeconomy, which involves production, processing, and consumption in specific locations, leading to geographical contradictions and uneven development, potentially creating resource peripheries. Spatial mismatches where governance boundaries do not align with environmental or social issues are critical, as is institutional fragmentation, which hinders the coherent implementation of experimental approaches. Addressing bioeconomy transitions effectively requires spatially integrated and regionally differentiated strategies that can navigate these complexities.

Conclusion

Steering societal transitions toward sustainability particularly through the bioeconomy is a complex challenge. While the bioeconomy promises to replace non-renewable resources and advance sustainability, its implementation is hampered by rigid governance, fragmented coordination, and institutional inertia. Power dynamics and resistance from incumbent actors further impede transformative change and experimentation. The bioeconomy's success is also shaped by spatial considerations and tensions between economic growth, ecological limits, and equity, often resulting in uneven development and spatial mismatches in governance.

Spatial planning, rooted in institutional contexts, is a crucial enabler for these transitions. When combined with a socio-ecological systems perspective, spatial planning helps map opportunities and threats, set strategic direction, and foster innovation. Experimental governance through mechanisms like testbeds and Living Labs (LLs) offers a way to address the inflexibility of traditional systems. LLs serve as real-world sites for co-creation and learning, encouraging institutional learning and collaboration, and marking a shift from top-down governance to more decentralised, participatory approaches.

However, integrating experimental governance within spatial planning is not without challenges. There is a risk of fragmentation or co-optation by powerful interests, which can perpetuate existing inequities. Overcoming these barriers requires a fundamental rethinking of systemic structures and power relations. Case studies highlight practical difficulties, such as innovation networks favouring established actors and the complexities of coordinating policy across urban and rural contexts.

Achieving a truly sustainable bioeconomy demands spatially nuanced regional integration, robust and harmonised governance mechanisms, and initiatives that address fundamental contradictions and promote equity. Multi-level governance coordinating efforts from international to local scales is essential.

Ongoing research is needed to develop strategies for collective action, spatially explicit governance instruments, and effective regional bioeconomy approaches. Ultimately, successful transitions depend not just on innovative interventions, but on their dynamic alignment with local social and ecological processes.

Rural Revitalization Beyond Administrative Boundaries: A Case Study of Villages Surrounding Taihu Lake, Chinai

Yuhang Rao
Affiliation:Tongji University
Email:2330319@tongji.edu.cn

Abstract
This study explores cross-boundary rural revitalisation in the "Six Villages around Taihu Lake," a pilot zone for urban–rural integration in Huzhou, China. Facing challenges such as fragmented governance and resource imbalance, the villages adopted a collaborative model centred on spatial planning, industrial coordination, shared infrastructure, and multi-stakeholder governance. This approach has transformed administrative divisions into functional communities, fostering industrial complementarity and inclusive governance. The model shifts focus from an "administrative region economy" to a more resilient "functional area economy," offering valuable insights for overcoming boundary constraints and promoting sustainable rural development in China and beyond.

Keywords: Rural Revitalisation; Urban-rural Linkages ; Administrative Boundaries ; Urban-rural Governance

1 Introduction

Against the backdrop of intensifying global challenges—ranging from climate change and land competition to food security crises and ecological degradation—the spatial dynamics of urban–rural interactions are being fundamentally reshaped. These compound pressures impose systemic constraints on regional sustainable development. In this context, Urban–Rural Linkages have emerged as a pivotal concept in the global sustainable development agenda, offering a pathway to address entrenched development dilemmas. The United Nations' 2030 Agenda for Sustainable Development explicitly calls for the strengthening of national and regional planning frameworks to foster social, economic, and environmental connections between urban agglomerations, peri-urban zones, and rural areas (United Nations, 2015). In alignment with this, the UN-Habitat (2019) publication *Urban-Rural Linkages: Guiding Principles outlines a value-based and operational framework* designed to support integrated territorial development through context-specific strategies.

Correspondingly, China has advanced its own agenda through policies promoting urban–rural integration and rural revitalisation, shifting from a historically dualistic spatial structure toward a stage characterised by bidirectional flows of factors and functional complementarity. However, local implementation of these national strategies continues to face significant challenges—chief among them, the constraints imposed by administrative boundaries. These boundaries hinder the efficient flow of resources, perpetuate uneven development, and dilute governance effectiveness. Overcoming such institutional fragmentation is thus critical for advancing regional coordination and integrated development.

This study focuses on the rural areas along the Taihu Lake shoreline in Huzhou, a city within the Yangtze River Delta region that was designated in 2019 as a national pilot zone for urban–rural integration. As an early experimental site for reforms in land allocation, population mobility, infrastructure connectivity, and cross-boundary rural revitalisation, Huzhou offers a valuable case for empirical analysis. This paper addresses three core research questions:

(1) What specific initiatives have facilitated rural revitalisation across administrative boundaries?
(2) Which policies and programmes have supported these efforts?
(3) What outcomes have been achieved as a result?

2 Literature Review

As a major national strategy in China, rural revitalisation aims to stimulate endogenous rural development by promoting thriving industries, liveable environments, social civility, effective governance, and increased prosperity. However, conventional rural development models—predominantly based on individual administrative units—alongside traditional administrative-region-based economies, have increasingly revealed their structural limitations. Administrative boundaries often act as invisible barriers to the free flow of resources, integrated industrial development, joint infrastructure provision, and coordinated ecological governance. These limitations have resulted in inefficient resource allocation, industrial homogeneity, insufficient innovation (Yu and Zhao, 2009),

duplication or inadequacy in public infrastructure, and fragmented responses to cross-boundary ecological challenges. Consequently, they constrain the enhancement of regional competitiveness and the achievement of sustainable development goals.

Given these challenges, traditional governance structures based on administrative divisions no longer suffice to meet the complex demands of rural revitalisation. Breaking down administrative silos and promoting cross-boundary planning, coordination, and collaboration is therefore essential for overcoming rural development bottlenecks and unlocking the systemic benefits of regional integration. It is within this context that trans-boundary planning has emerged as a vital strategy for spatial restructuring, coordinated resource allocation, and collaborative regional development. As urban–rural integration and regional cohesion accelerate, rural areas are no longer isolated or static spaces but rather nodes embedded within multi-level, multi-actor interaction networks.

Trans-boundary planning plays a crucial role in three main respects. First, it enhances resource allocation efficiency, particularly in rural areas where ecological, industrial, and infrastructural advantages are unevenly distributed. Coordinated planning across administrative boundaries enables the optimal mobilisation and integration of such diverse resources (Yang and Chen, 2024). Second, it fosters systemic governance by addressing the integrated nature of ecosystems, infrastructure networks, and cultural landscapes—many of which transcend administrative borders. Governance based on natural or functional spatial units is often more scientific and coherent than purely administrative approaches. Third, it supports collaborative industrial development by enabling innovation ecosystems, industrial chains, and service systems to operate beyond jurisdictional limits, responding more flexibly to cross-boundary demands (Zhu, Sun and Li, 2024).

Trans-boundary planning in China operates at multiple scales (Luo, Qiu and Liu, 2023). At the macro level, inter-provincial planning forms part of major national strategies—such as the Yangtze River Delta Integration, the Greater Bay Area initiative, and Beijing–Tianjin–Hebei coordinated development (Tao, 2020). These efforts require strong central leadership, high-level institutional mechanisms (e.g. joint conferences between provinces), and aim to address infrastructure, watershed governance, ecological barriers, and market integration (Chen and Zhong, 2017). Inter-municipal planning focuses on collaboration between adjacent prefecture-level cities within a province. With more concentrated coordination mechanisms, these plans address industrial synergies, integrated transport, shared public services, and peri-urban cooperation within urban agglomerations or metropolitan areas (Li, Duan and Jiang, 2025). Inter-county planning, within or between neighbouring prefecture-level cities, is more operationally feasible, tackling development imbalances at county borders, industrial connectivity, environmental protection, and coordinated social governance. It plays a key role in bridging the “last mile” of regional integration. At the micro level, inter-town and inter-village planning targets localised collaboration between adjacent rural settlements, focusing on integrated resource use, reducing redundant competition, and developing functional rural clusters such as agricultural parks or tourism zones. These efforts also support joint public services and the governance of cross-boundary environmental concerns, such as river basins and waste management, boosting collective competitiveness and strengthening grassroots collaboration.

These different levels of planning are interlinked and mutually supportive, forming a multi-scalar, layered coordination framework that spans from macro strategy to micro-level implementation. Together, they provide a robust pathway for advancing rural revitalisation beyond administrative constraints.

In recent years, trans-boundary planning has become a key topic in urban and regional studies, with expanding and deepening academic interest. One central focus has been the design of governance mechanisms, including intergovernmental collaboration, multi-stakeholder participation, and regional governance platforms. Another key area involves planning tools and methodologies, such as integrated spatial planning, functional zoning, and ecological network design—particularly prominent in environmentally sensitive and peri-urban areas.

A third concern relates to interest alignment and policy coordination, as the diversity of stakeholders and the fragmentation of administrative authority pose challenges to cost-sharing, benefit distribution, and sustainable cooperation. However, existing research has largely concentrated on urban agglomerations, metropolitan peripheries, or large-scale cross-boundary zones, with relatively limited attention paid to village- and township-level planning in rural contexts (Yang and Lu, 2023).

In practice, trans-boundary planning spans a wide range of applications. One key area is ecological governance, especially in river basin management and landscape-level restoration efforts, which inherently cross administrative borders and require coordinated action (Li et al., 2021; Talukder et al., 2020). Another is joint tourism development, where multiple villages or counties collaborate to leverage shared natural or cultural resources and build regional tourism brands—benefiting local economies and residents (Manyane, 2017). Additionally, shared infrastructure development—such as road networks, water supply systems, waste disposal, and sewage treatment—has become a practical focus area (Chavez et al., 2013), helping to reduce redundancy and resource waste. Cultural heritage preservation and intangible heritage promotion are also emerging areas, with efforts to jointly apply for heritage recognition, co-organise exhibitions, and coordinate branding and communication strategies.

In summary, trans-boundary planning is transitioning from conceptual exploration to institutionalised practice, from single-sector interventions to integrated approaches, and from isolated examples to more standardised mechanisms. It not only expands the spatial and systemic horizons of rural revitalisation but also catalyses fundamental changes in governance structures and development models. Within the broader context of spatial integration, regional coordination, and urban–rural linkages, trans-boundary planning is set to remain a crucial instrument in shaping new rural geographies and achieving high-quality revitalisation.

3 Study Area: The Six Villages around Taihu Lake in Huzhou

3.1 Geographic Location

The Six Villages around Taihu Lake are located in the northern part of Wuxing District, Huzhou City, along the southern shore of Taihu Lake. The area spans two administrative units: the High-Tech Zone and Zhili Town. It comprises six administrative villages: Huanlou, Xulou, Yanglou, Yigao, Wupu, and Miaodou, covering a total area of 17.1 square kilometres. Situated within the "urban belt along the southern shore of Taihu Lake," the Six Villages serve as a transitional zone between Huzhou's urban core and the surrounding lake region. The area lies approximately 15 kilometres from downtown Huzhou and 12 kilometres from Huzhou East High-Speed Railway Station.

To the north, the region borders Taihu Lake and the Ring Taihu Road, while the southern boundary adjoins the Shanghai–Chongqing Expressway. To the east, it connects with the Zhijiang East Expressway. The location benefits from accessibility to three international airports—Shanghai Hongqiao, Hangzhou Xiaoshan, and Nanjing Lukou—all within a two-hour drive.

3.2 Resource Endowments

The "Six Villages around Taihu Lake" are situated in the core area of the Taihu Lougang waterway system, endowed with unique and rich resources. The Lougang system is an ancient hydraulic engineering network developed by early settlers to adapt to the low-lying, water-rich environment along the Taihu lakeshore. Its hallmark lies in distinctive wetland drainage techniques, an engineered structure of transverse ponds and longitudinal channels, and a complementary set of water management infrastructures. Originating in the Xia and Shang dynasties and undergoing extensive embankment construction and channel regulation from the Spring and Autumn period to the Five Dynasties, the system gradually perfected the lakeside dykes and sluice gate waterways that regulate Taihu's water storage and discharge. This facilitated the gradual transformation of tidal flats into a complex landscape of rivers, farmlands, settlements, towns, and an integrated water management regime, establishing the Taihu Lougang and Tangpu Weitian systems and turning the Taihu basin from a sparsely populated land into a prosperous "land of fish and rice". By the Song dynasty, intensified land use and the rise of commercial agriculture along the Lougang embankments led to rapid growth in high-value industries such as sericulture and aquaculture, positioning Huzhou as a nationally important production centre for agricultural products and textiles.

The Six Villages boast an 8-kilometre lakeside scenic corridor along Taihu Lake, characterised by picturesque natural landscapes of paddy fields, egrets, and streams, evoking the poetic imagery of the Jiangnan water towns. Notably, the water quality of Taihu has significantly improved in recent years, achieving national standards for a good-quality lake throughout the year for the first time. The Lougang water system forms the ecological backbone of the area, underpinning the urban green and blue infrastructure. Numerous historical and cultural assets are closely intertwined with this water system.

This area also possesses a profound historical and cultural heritage, serving as the core zone of Taihu Lougang culture. Yigao Village preserves a wealth of ancient architecture, including the Taihu Lougang Culture Exhibition Hall, the Woodblock Printing Art Museum, and the Lake Mirror Hall, collectively known as the "Six Halls, One Institute, and One Plaza". Local cultural vitality is further expressed through traditional agricultural festivals such as the "Taihu Lougang Folk Tourism Harvest Festival", which actively promotes the Lougang cultural identity. Additionally, the Six Villages have nurtured related cultural strands including canal culture, rice cultivation culture, and silk culture, creating a distinctive cultural corridor.

To safeguard and transmit these resource endowments, Huzhou City has enacted protective regulations to institutionalise the conservation of the Taihu Lougang system. Complementary cultural events continue to foster the cultural heritage of the region. Through cluster-based rural operations, the Six Villages have established market-oriented entities that connect stakeholders' interests, attracting over 60 new industrial and business projects annually with a total investment exceeding 1.5 billion RMB.

Figure 1. Distribution Map of the Lougang Waterway System in Southern Taihu
(Source: https://m.sohu.com/a/425597230_434584)

3.3 Development Challenges

The traditional advantage industry of the Six Villages around Taihu Lake lies in aquaculture, with crab farming being a key activity. Villages such as Xulou, Huanlou, and Yanglou primarily focus on fruit and vegetable cultivation, with Xulou Village having a relatively sizeable loquat plantation; however, its development has been constrained by limited brand recognition. At the outset of their collective development efforts, the Six Villages faced multiple challenges. Firstly, there was uneven resource endowment across the villages, each encountering distinct development bottlenecks: some were constrained by land scarcity limiting project capacity, others struggled with a narrow industrial structure and short value chains, while some suffered from low visibility and insufficient local attraction. Secondly, based on their individual development situations, villages often adopted a "go-it-alone" mentality—leading early-developing villages to fear resource dilution and loss of

competitive advantage, culturally rich villages to worry about losing their core status, and weaker villages to risk industrial marginalisation, resulting in varied willingness to collaborate. Furthermore, cross-administrative coordination required overcoming the traditional fragmented 'each village for itself' approach, with the absence of unified planning and benefit-sharing mechanisms increasing the cost of cooperation. Additionally, industrial homogeneity among the villages was evident, with a lack of clear, effective differentiation in industrial roles, which risked internal competition rather than fostering synergies.

Table 1. Basic Industries and Primary Sources of Income for Villagers in the Six Villages around Taihu Lake
Source: Compiled by the author based on *the Wuxing District 'Six Villages around Taihu Lake' New Era Beautiful Countryside Model Area Planning Scheme*

Administrative Village	Primary Industries	Main Sources of Income for Villagers
Huanlong Village	Small-scale aquaculture, Taihu Lake fishing, vegetable cultivation	Income from Taihu fish market (fishing), home-based children's clothing workshops
Xulong Village	Crab aquaculture, loquat cultivation, leisure agriculture, organic vegetables	Home-based children's clothing workshops, loquat cultivation
Yanglong Village	Crab aquaculture, vegetable cultivation, guesthouses	Home-based children's clothing workshops, vegetable cultivation
Yigao Village	Historic village tourism, crab aquaculture, vegetable cultivation	Tourism services, home-based children's clothing workshops
Wupu Village	Aquaculture, fruit cultivation, vegetable cultivation	Home-based children's clothing workshops, gardening and landscaping work
Miaodou Village	Aquaculture, fruit and vegetable cultivation	Home-based children's clothing workshops, aquaculture

4 Cross-Administrative Boundary Rural Development Practices in the Taihu Lake Region

4.1 Integrated Spatial Planning: Crafting a Unified Development Blueprint

Huzhou's "Six Villages around Taihu Lake" have broken free from the spatial governance constraints typical of traditional administrative villages by employing cross-scale spatial restructuring combined with integrated multi-plan coordination. This has established a systematic framework for regional collaborative development. At its core, the approach is guided by principles of functional complementarity and factor mobility, reconfiguring dispersed village spaces into an organically connected "regional economic community." From a planning perspective, a comprehensive spatial industrial layout covering all six villages has been developed, clearly defining differentiated functional roles—such as catering services, homestay clusters, cultural tourism experiences, youth innovation incubation, agricultural production, and new industry experimentation—resulting in a spatial structure of "core nodes – functional clusters – network system." This integrated planning not only enables the holistic allocation of land, ecological, and cultural resources but also promotes infrastructure connectivity (e.g., cross-village greenways, waterway routes) and shared public services, reducing regional transaction costs and providing a physical foundation for industrial collaboration and factor flow. Fundamentally, this model transforms the "divisive effect" of administrative boundaries into a "cohesive effect" of functional complementarity through institutional innovation in spatial planning, offering a valuable practical example of spatial governance for urban-rural integration at the county level.

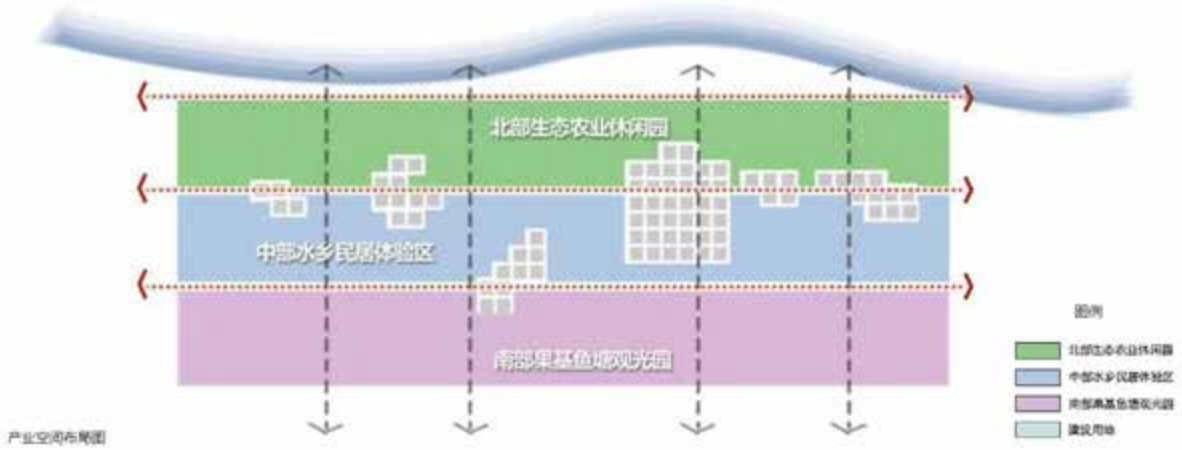

Figure 3: Industrial Layout Plan of the "Six Villages around Taihu Lake"
(Source: *Wuxing District 'Six Villages around Taihu Lake' New Era Beautiful Countryside Model Area Planning Scheme*)

4.2 Economic Development Coordination and Complementary Specialised Industries

The Six Villages around Taihu Lake have established an industrial coordination model characterised by differentiated positioning, integration of industrial chains, and cross-village flow of factors. Based on the principle of 'one village, one product' with specialised divisions of labour, a complementary industrial layout has been formed:

Huanlou Village focuses on dining (such as the 'Yili Xiang' Food Street), Yanglou Village specialises in homestays, Yigao Village develops cultural tourism (Lougong Cultural Park), Wupu Village introduces youth entrepreneurship ventures (cafés, creative spaces),

Xulou Village advances specialised agriculture (loquat cultivation), and Miaodou Village expands modern tourism (low-altitude economy, RV camping sites). Each village's industrial positioning is precisely differentiated, effectively avoiding homogeneous competition and jointly forming a complete consumption chain covering food, accommodation, tourism, creativity, agriculture, and emerging business models.

At the level of industrial integration, the six villages focus on the deep fusion of agriculture, culture, and tourism as the core development path. Speciality agricultural products (such as loquats and lake crabs) have extended from simple production to experiential consumption, creating a full value-added chain from cultivation through processing to cultural tourism experiences. Typical examples include loquat picking in Xulou Village, the cultural-tourism operation of the 'Yang Guizhen' Crab Manor, and large-scale crab farmers driving over 200 households across the six villages to participate in bundled packaging. This transforms agricultural resources into cultural-tourism attractions, achieving an average household income increase of 20,000 yuan. This integration not only enhances the added value of agricultural products but also strengthens regional industrial resilience through diverse activities such as educational tours, team-building exercises, and festivals.

Another key feature is the free flow and collaboration of industrial factors across villages. Production factors overcome administrative village barriers to achieve efficient allocation: labour is divided across villages within the crab industry chain (for example, crab farming in Xulou and joint processing involving all six villages); customers are shared across villages through unified brand marketing and integrated tourism route design (such as combined tickets for dining, homestays, and cultural experiences); and capital and social projects (such as cafés and camping sites) are established according to each village's differentiated positioning. This dynamic circulation activates resources across the entire region, forming an industrial ecosystem characterised by 'distinct village specialities and coordinated regional linkage.'

Table 2 Collaborative Economic and Industrial Model of the Six Villages around Taihu Lake(Source: Compiled by the author)

Coordination Mechanism	Specific Practices	Typical Cases	Outcomes
Differentiated Industrial Roles	'One Village, One Speciality' with precise positioning: • Huanlou (Dining), Yanglou (Homestays), Yigao (Cultural Tourism) • Wupu (Youth Entrepreneurship), Xulou (Agriculture), Miaodou (Emerging Industries)	Huanlou's 'Yili Xiang' food street accommodates 2,000 diners; Wupu cafés attract young entrepreneurs	Avoids internal competition and builds a complementary industrial chain
Industrial Chain Integration	Agricultural extension into secondary and tertiary sectors: • Agriculture (Loquat/Crab) → Processing → Cultural tourism experiences (e.g., fruit picking, educational tours, cuisine)	Crab farmers expand operations across villages, involving 200 households with an average income increase of ¥20,000; Yang Guizhen Crab Manor certified as a National 3A Tourist Attraction	Extends the value chain and increases the premium of local produce (e.g., crab farming)
Cross-Village Flow of Factors	Cross-village movement of labour, visitors, capital, and branding: • Labour: Division of labour in the crab industry chain • Visitors: Tourism routes linking all six villages • Branding: Unified regional IP operation	Joint development of the 'Six Villages around Taihu Lake' tourism brand; Village-hopping routes integrate homestays, dining, and cultural sites	Activates underutilised labour and generates income across the entire region

4.3 Joint Infrastructure Development and Regional Resource Sharing

4.3.1 Integrated Transport Infrastructure

The Six Villages around Taihu Lake have implemented a coordinated approach to transport infrastructure by integrating resources to construct a 6.9-kilometre interconnected pedestrian greenway and a 2.6-kilometre circular waterway. These routes not only facilitate daily travel for local residents but also provide convenient corridors for tourists. In addition, the scenic enhancement project of the Huxue Road, spanning 4.5 kilometres and covering Yanglou, Huanlou, and Wupu villages, included façade renovations, utility line upgrades, greening and lighting improvements, and landscape nodes. Another key initiative, the Shuichan Road upgrading project, stretches 7.5 kilometres from Huanlou to Wupu and comprises road surface improvements, roadside landscaping, and upgrades to adjacent industrial park access roads. Shared mobility facilities, such as public bicycles, have also been introduced to enhance local mobility and connectivity.

4.3.2 Shared Public Services Infrastructure

The six villages have jointly mobilised multi-level public funds totalling 628 million yuan, of which 370 million yuan has been allocated to infrastructure support. These funds have supported the upgrading of village-level infrastructure and living environments, including the development of parking facilities, parks, and cultural exhibition spaces. For instance, the former silk cocoon station in Yigao Village has been repurposed into the Taihu Lougang Culture Exhibition Hall, enhancing the village's cultural atmosphere and identity.

4.3.3 Digital Transformation and Smart Countryside Development

A digital upgrading initiative has been launched across the six villages to modernise service infrastructure. Rooted in local resource endowments, geographical features, industrial strengths, and cultural heritage, this initiative aims to build future-oriented rural settlements that are distinctive in character, well-functioning, industry-driven, environmentally appealing, digitally connected, and governed with integrated smart systems. The vision encompasses an ecologically sustainable, economically productive, and socially vibrant countryside that reflects the principles of common prosperity.

4.3.4 Ecological Restoration and Environmental Enhancement

Infrastructure development in the Six Villages has been closely aligned with ecological conservation objectives. Wuxing District has systematically promoted ecological governance across the Lougang region, including ongoing dredging of waterways and the ecological restoration of lakes and ponds. To date, 7.51 million cubic metres of silt have been cleared and seven key Lougang channels leading into the lake have been expanded. A further 16.9 kilometres of lakeside greening has been implemented, enhancing the ecological landscape. The area has also developed a 25-kilometre section of the Zhejiang Loop Trail encircling the villages. Within the cluster, 21 bus stops have been installed along two main roads, with six public e-scooter stations currently in place and 14 more planned, significantly improving accessibility and transport connectivity across the region.

4.4 Social Capital Investment and Rural Operation

The *Six Villages around Taihu Lake* (Binhu Six Villages) in Huzhou have demonstrated notable success in exploring innovative models of rural operation. At the heart of this success lies the construction of a collaborative governance and development mechanism involving multiple stakeholders. Throughout this process, both municipal and district-level governments have played a pivotal role in strategic planning and policy support.

Specifically, the Huzhou Municipal Government and Wuxing District Government jointly led the formulation of the *Special Development Plan for the Binhu Six-Village Cluster*, which defined the region's overall development orientation, designated responsible construction entities, and clarified the direction for leading industries. In parallel, a dedicated working group – the *Binhu Six Villages Green Common Prosperity Taskforce* – was established, with earmarked fiscal investment allocated to ensure the delivery of infrastructure upgrades and the implementation of key projects.

Under the guidance of government, a multi-layered participation structure has emerged. At the village level, each administrative village has actively embraced the group-based development strategy, pooling resources and coordinating planning to jointly forge the 'New Lougang of Taihu' regional brand. This has significantly strengthened inter-village cooperation and complementary development.

Village collectives have also contributed by participating in project construction and providing key resources such as land, thereby sharing in the added value generated by rural operations.

On the market side, professional rural operation firms have been introduced, while private capital has also played an increasingly proactive role. For instance, Huzhou Miqi General Aviation Services Co., Ltd. invested in and operates an aerial sightseeing project in Huanlou Village, adding diversity to the local tourism offering. From the perspective of civil society, successful rural activation initiatives—such as *Gudui Xiangchuang* in Longshan Village, Miaoxi Town—have provided valuable reference points for creative revitalisation across the Binhu Six Villages.

Professional operating firms serve as central coordinators within the Binhu model. Wuxing Xinglou Construction and Development Co., Ltd. exemplifies such a role, taking responsibility for unified infrastructure planning, project investment promotion, and long-term operational management. Their standardised project implementation has markedly enhanced the rural built environment and overall quality. More importantly, the firm has systematically integrated the six villages' resources to build the 'New Lougang of Taihu' regional brand, which has accelerated the integration and value uplift of agriculture, culture, and tourism sectors. This in turn has improved regional visibility, attracted tourist footfall, and drawn external investment. Furthermore, Wuxing Xinglou has proactively partnered with leading national cultural-tourism operators, bringing in specialised expertise to elevate operational standards.

In terms of financial sustainability, Binhu Six Villages have pioneered a diversified investment and financing model, combining state-owned capital leverage, private sector participation, financial sector backing, and village collective co-funding. This mechanism has ensured stable capital flows to support the smooth implementation of numerous integrated agriculture–culture–tourism projects.

Talent revitalisation is another critical pillar underpinning the model. Wuxing District has introduced a series of targeted policies to facilitate the return of rural talent, including platforms for young people to launch rural start-ups and the rollout of the *Youth in the Village Initiative*. These efforts have attracted 45 entrepreneurial teams and over 900 young professionals to settle and innovate in rural areas. Capitalising on the collaborative development model, the Binhu Six Villages have emerged as a 'New Era Rural Community', characterised by strong resource agglomeration, compelling investment potential, and a high degree of attractiveness to both talent and capital. A supportive entrepreneurial ecosystem and broad development prospects have, in turn, rekindled enthusiasm among young people to return to and invest in rural revitalization.

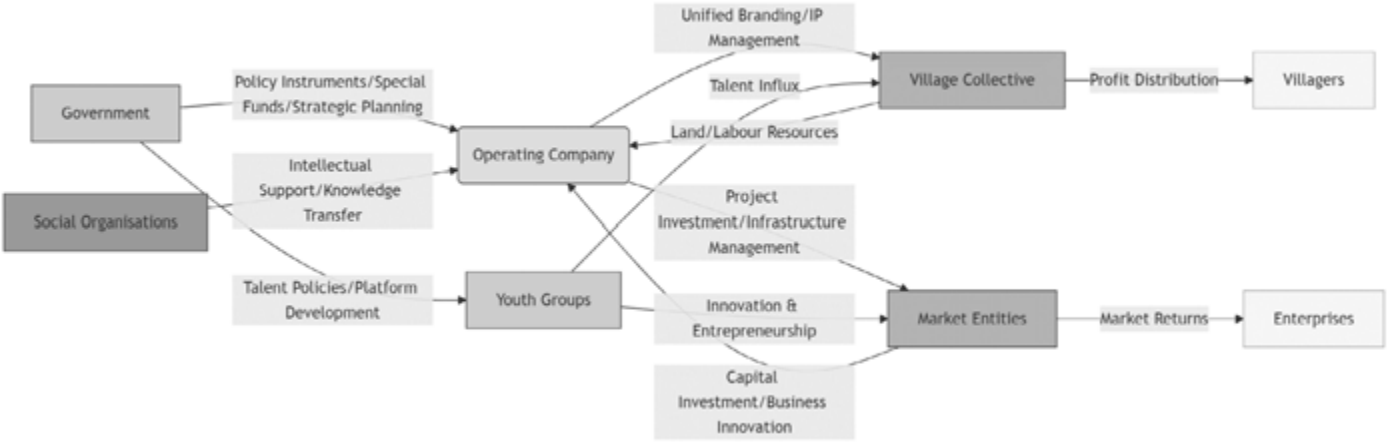

Figure 4. Operational Framework for Rural Development in *The Six Villages around Taihu Lake* (Source: Compiled by the Author)

5 Conclusions

The case of the Six Villages around Taihu Lake in Huzhou represents an innovative and pioneering approach to collaborative rural revitalisation across administrative boundaries. At its core lies an institutional breakthrough and systemic reorganisation that effectively integrates dispersed administrative villages into a functionally complementary and synergistically linked *regional economic community*.

In terms of spatial planning, the villages have adopted a unified planning framework to dismantle traditional administrative barriers. A territory-wide industrial spatial layout was developed, assigning differentiated roles to each village and establishing a networked spatial structure. This integrated approach enables the holistic coordination of land, ecological, and cultural resources. By enhancing infrastructure connectivity and enabling the joint development and sharing of public services, the initiative transforms the 'fragmentation effect' of administrative boundaries into a 'convergence effect' of functional synergy. It thus provides a new spatial governance paradigm for urban–rural integration at the county level.

From an economic perspective, the Six Villages have adopted an industrial coordination strategy centred on differentiated positioning, industrial chain integration, and cross-village factor mobility. Through clear functional specialisation, the villages avoid redundant competition and jointly build a comprehensive and diversified consumption chain. Deep integration of primary, secondary, and tertiary industries extends the value of local agricultural products from basic production to cultural and tourism experiences, thereby enabling full-chain value enhancement. The free movement of productive factors—labour, visitor flows, and capital—across village boundaries ensures efficient allocation and underpins the formation of a resilient regional industrial ecosystem characterised by 'village-level specialisation, regional-level synergy'.

Shared infrastructure serves as the physical foundation of this regional collaboration. The integration of transport systems, public services, and ecological governance enhances the support capabilities of the region. Concurrently, digital transformation and the construction of smart villages have improved overall development resilience. Environmental restoration and ecosystem enhancement efforts not only safeguard ecological security but also lay the groundwork for sustainable industrial development.

Crucially, multi-stakeholder collaborative governance ensures the sustainability of the model. The government plays a leading role in planning and policy guidance, while professional operating companies are responsible for infrastructure development, brand operation, and commercial investment. Social capital and village collectives participate through equity-based resource contributions, enabling a hybrid governance structure that combines the efforts of government, market actors, and local communities. A diversified financing mechanism—leveraging public enterprise capital, private investment, financial support, and village collective funds—has ensured a stable flow of resources to key rural development projects. Meanwhile, targeted talent revitalisation policies have reactivated rural innovation potential, successfully attracting over 900 young entrepreneurs and 45 startup teams back to the villages, thereby injecting long-term vitality into the region.

The Six Villages model demonstrates three key transitions:

- **From 'administrative islands' to a 'functional community'**: Spatial reorganisation through cross-scalar planning incorporates fragmented settlements into an integrated development framework, allowing for more efficient and coordinated allocation of resources and functions.
- **From 'homogeneous competition' to 'complementary symbiosis'**: With differentiated division of labour, integrated industrial chains, and dynamic factor flows, a robust and flexible regional economic network has been created.
- **From 'single-agent control' to 'multi-stakeholder governance'**: A cooperative governance model has emerged in which government, enterprises, collectives, and villagers share benefits and jointly assume responsibilities, ensuring inclusive and sustainable development.

This model, through the coordinated transformation of spatial structure, industrial organisation, and governance mechanisms, redefines the concept of the traditional 'administrative-region economy' as a 'functional-region economy'.

It not only enhances economic performance and improves livelihoods but also offers a replicable pathway for rural revitalisation by overcoming the limitations of administrative fragmentation through institutional innovation. Its core value lies in demonstrating that functional integration can unleash the endogenous potential of rural areas and unlock systemic dividends from regional collaboration—offering a scalable paradigm for urban–rural integration and cross-boundary revitalisation at the county level across China.

Zero Net Land Take Policy Mapping: A Multi-Level Analysis in the Context of Italy and Emilia-Romagna

Iuliia Kozlova[1], Elisa Conticelli[1], Serena Sgallari[2]
[1]Alma Mater Studiorum – Universita di Bologna:
iuliia.kozlova2@unibo.it; elisa.conticelli@unibo.it
[2]Regione Emilia-Romagna:
serena.sgallari@regione.emilia-romagna.it

Abstract
The Zero Net Land Take (ZNLT) policy seeks to reconcile urban development and land conservation by 2050. This study reviews ZNLT-related policies at the European, national, and regional levels, focusing on Emilia-Romagna region, Italy. Analysis of legal documents reveals that while strategic objectives are set at the European level, member states and regions implement ZNLT with varying approaches, reflecting their governance and planning traditions on example of Emilia-Romagna region. This study underscores the importance of a coherent multi-level governance structure to achieve ZNLT. Misalignments between national guidelines and regional or local practices create fragmentation, undermining cohesive policy action. Analyzing these gaps is crucial to advancing sustainable urban development aligned with ZNLT goals.

Key words: ZNLT, Land Consumption, Policy Mapping

Background and Rationale

Recent rapid urban expansion has led to extensive land consumption and ecological degradation. To balance growth with preservation, the EU has prioritized sustainable spatial planning, notably the Zero Net Land Take (ZNLT) objective, which seeks to match land consumed for urban development with renaturalization of previously developed areas by 2050, ensuring no net increase in urbanized land (European Commission, 2021a; 2021b). ZNLT's prominence in strategic frameworks reflects its connections to land conservation, climate adaptation, biodiversity protection, and ecosystem restoration. These strategies underscore that mitigating urban sprawl and soil sealing is vital for environmental sustainability, urban resilience, and climate adaptation.

There is a growing recognition of ZNLT policies' importance across multiple governance levels - several EU member states have adopted policies aligned with ZNLT, such as France's binding target for 2050 (République Française, 2021) and Flanders' 2040 target (Departement Omgeving, 2018), or Italian Regional Law No. 24/2017 (LR 24/2017), aiming to achieve ZNLT by 2050; however significant challenges persist, that hinder the cohesive and wide implementation of ZNLT across member states.

Local priorities, fiscal constraints and sectoral silos frequently dilute strategic intent (Idt et al., 2024; Decoville & Feltgen, 2023; Schatz et al., 2021). Fragmented competencies and limited inter-sectoral coordination further widen the gap between policy and practice (Gradinaru et al., 2023; Geneletti et al., 2017). Conceptual ambiguities allow divergent interpretations, while the absence of harmonised monitoring indicators hampers consistent tracking and accountability (Löbmann et al., 2022; Zoppi & Lai, 2014). Economic incentives for greenfield development often outweigh the long-term benefits of land neutrality, reducing local commitment to ZNLT goals (Schatz et al., 2021). Finally, stakeholder participation remains sporadic, risking the exclusion of critical perspectives needed for equitable spatial planning (Lacoere & Leinfelder, 2023; Stankovics et al., 2020). ZNLT balances fresh urban land uptake with renaturalisation or brownfield reuse so that total "consumed" land does not rise by 2050. Interpretations and implementation, however, vary widely among member states, revealing notable conceptual gaps between EU and national levels (Decoville & Feltgen, 2023; Schatz et al., 2021).

Additionally, a considerable conceptual ambiguity persists: European policies variously employ the terms No Net Land Take (NNLT) and Zero Net Land Take (ZNLT), breeding unnecessary uncertainty. NNLT, used in EU frameworks (e.g., Resource- Efficient Europe Roadmap 2011; Biodiversity Strategy 2020; Soil Strategy 2021), seems to emphasize prevention of new soil sealing, whereas the term ZNLT appears to sanction development only if it's offset by de-sealing, ecological restoration, or brownfield reuse, projecting a looser, "balance-of-accounts" stance. Besides,

as highlighted by Elisabeth Marquard (Marquard et al., 2020), there are different copes of the discussed concepts and indicators in relation to different land use/land cover categories. There is significant conceptual ambiguity in the terms to describe land conversion processes: land consumption, land take, soil sealing, artificialization, etc. The primary objective of this study is to provide a comprehensive multi- level analysis of ZNLT policy frameworks at the EU level, and their adoption, adaptation, and operationalization at national and regional scales (with Italy and Emilia-Romagna region as case studies). It seeks to identify persistent cross-level misalignments, institutional fragmentation, and operational challenges hindering ZNLT objectives local implementation. By analyzing policy adoption, the study seeks to clarify conceptual ambiguities in translating EU directives into effective land-management practices.

Methodology

This study adopts a multi- phase qualitative policy mapping to identify, analyze, and evaluate ZNLT instruments and governance frameworks at European, national, and regional scales. The study employs a mixed- methods policy- mapping framework, integrating qualitative document analysis with quantitative network- analytic metrics to interrogate the ZNLT governance architecture at supra- , national, and subnational scales.

The case studies—Italy at national level and Emilia-Romagna at regional level—were chosen for their contrasting policy landscapes: Emilia-Romagna has proactively enacted a no-net-land-take law, whereas Italy as a whole remains without a unified ZNLT framework. This divergence provides an instructive lens through which to examine the complexities of multi-level governance, highlighting both the region's innovative advances and the national–subnational coherence and enforcement challenges that arise in the absence of an overarching legal architecture.

In phase one of the study, policy documents were systematically collected that explicitly or implicitly linked to ZNLT thematic pillars. The search was built around the following topics: land take and soil sealing; urban regeneration, sustainable land management, and ecosystem restoration; and reuse of previously developed areas. Guided by a literature and policy review, the desktop search used official sources, legal databases, institutional reports, and spatial planning guidelines. The corpus of polices was enriched by involving expert consultation, database enrichment, and policy validation with sectoral representatives from Emilia-Romagna public administration,

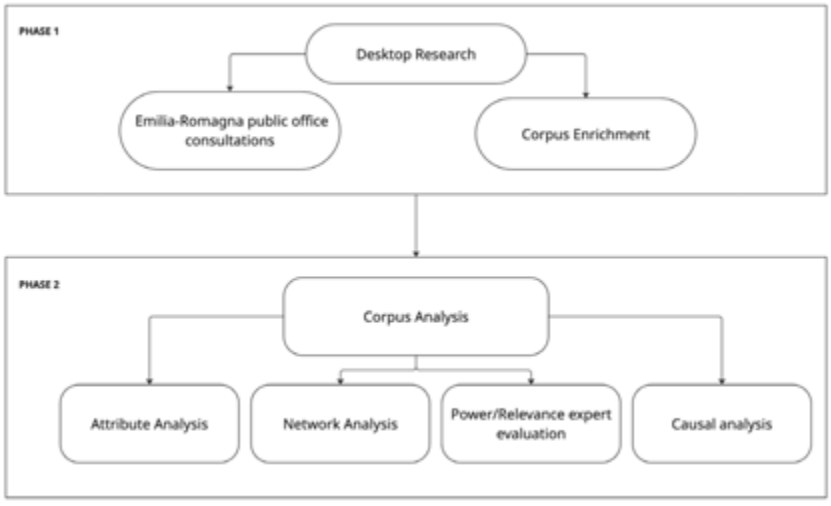

Figure 1. Methodological framework of the study, source: authors

An inclusion protocol ensured analytical rigor and relevance by requiring that documents be currently in force, and explicitly or implicitly related to at least one of the land take thematic.

The collected policies were then analyzed to assess their attributes, their linkages to other policies, their causal roles, and their relevance to local practices in Emilia-Romagna.

1. Comparative Framework and Analytical Lens

The review encompassed legally binding instruments, and non-binding strategic programmes, guidance documents, and implementation frameworks. Contextual analysis interrogated both external and internal analysis: exogenous policies attributes that affect wider governance environment and the policies' intrinsic characteristics.

To assess the governance environment, network analysis was applied to the assembled policy corpus. The principal links were grouped as following: subordinated implementation links (policies serving as subordinate components within broader frameworks), strategic execution links (policies translating high-level strategies into actionable goals without strict subordination), and operational links (policies providing financial, regulatory, or procedural mechanisms to implement other policies). Expert collaboration with Emilia-Romagna public administration further enriched and validated the findings. Based on Kristensen's (2004) framework, policy objectives were coded by entry date and DPSIR node (Drivers, Pressures, States, Impacts, Responses), revealing temporal gaps and concentrations that affect adaptive governance.

At the content analysis, policies were systematically compared across different dimensions:
1. Instrument Classification (Howlett, 2009; Belin et al., 2014): instruments were categorized as legal (binding), economic (incentives/disincentives), informational (guidance), or strategic (non-binding visions) to assess enforceability and leverage.
2. Thematic Clustering: Land Use and Soil Protection; Biodiversity and Ecosystem Restoration; Environmental Quality and Pollution Prevention; Sustainable Urban Development and Regeneration.
3. Land Conversion Scope Correspondence: Policies were grouped by targeted land conversion processes, using different terms from described in Marquard study (Marquard et al., 2020) - soil sealing, land take, land consumption, SDG 11.3.1 and also also fragmentation (division of habitats due to conversion).
Soil sealing: Permanent covering of land by impervious materials, impairing soil functions.

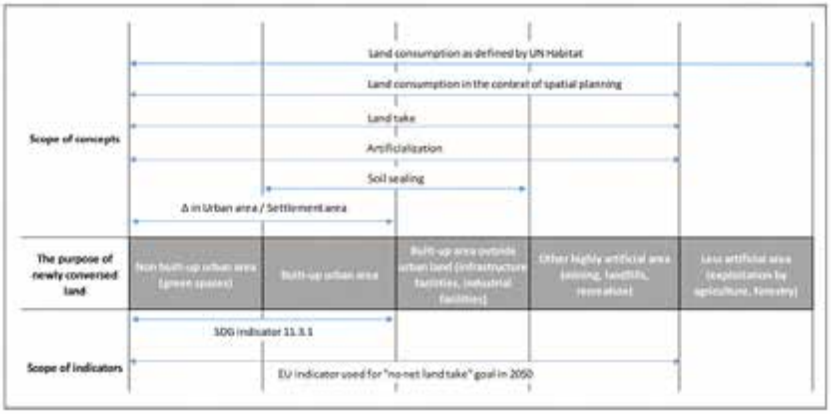

Figure 2. Scopes of the concepts and indicators in relation to different land use/land cover categories, source: Marquard et al., 2020

Each policy's relevance and contribution to reusing abandoned land was jointly scored by researchers and Emilia-Romagna experts according to their relevance to local practices on ZNLT, ensuring analytical rigor and practice-oriented evaluation.

2. Defining the ZNLT Policy Corpus at European, National, and Regional Tiers

Following a desk review, the first 44 policy documents were identified. Subsequently, policy officers from the Emilia-Romagna administration recommended three additional texts. This corpus then served as the basis for a network-mapping analysis designed to visualise inter-document linkages and thematic overlaps (SocNetV tool).

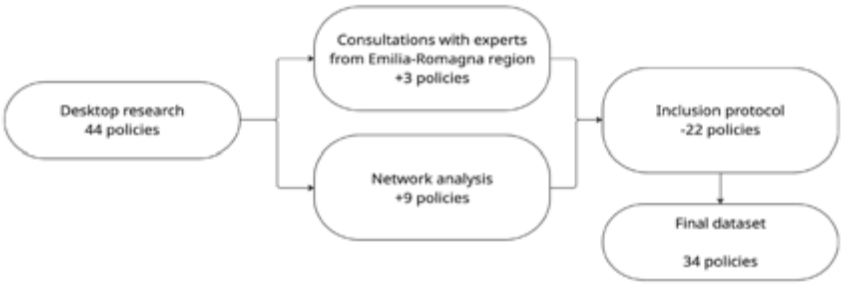

Figure 3. Policy mapping process, source: authors

Policies acted as nodes in networks, linked by references, legal hierarchies, or shared objectives, with their centrality indicating structural importance. Central hubs exhibit the highest degree, each spawning more than a dozen subordinate regulations and guidelines in the intermediate rings. Secondary hubs further translate these directives into territorially specific measures. In contrast, the sparsity of links in the upper- right sector corresponds to under- transposed objectives related to ecosystem- service valuation, suggesting a gap between strategic intent and operational uptake. Overall, the topology confirms a "command- and- translate" hierarchy: supranational norms initiate the causal chain, national legislation refines scope and enforcement, and regional plans supply context- dependent tools, yet the uneven distribution of subordinate ties highlights domains requiring additional transposition efforts to achieve full multi- level alignment.

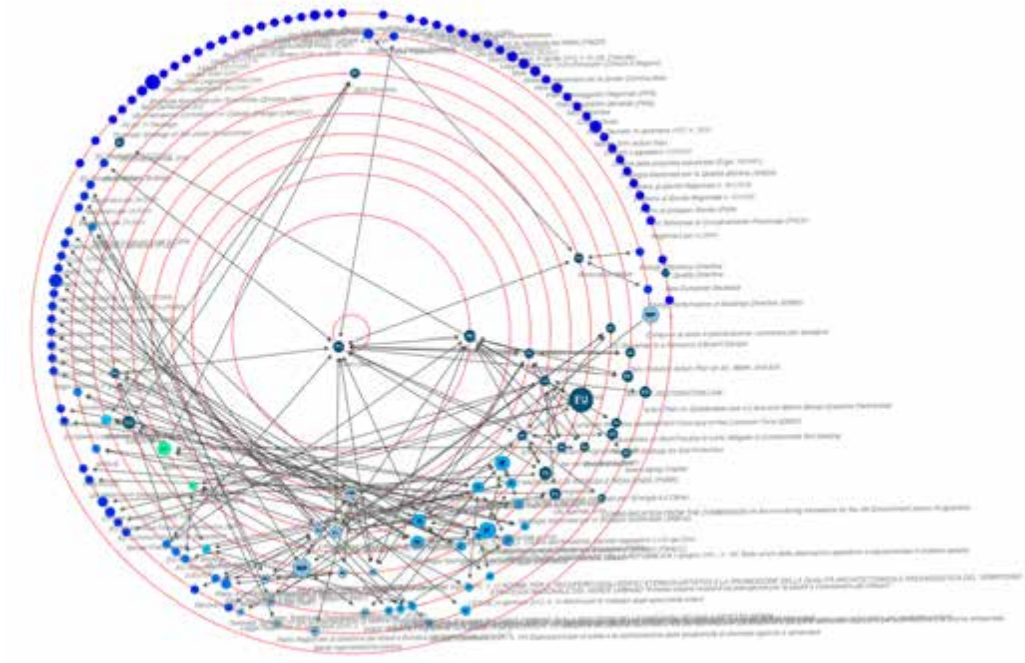

Figure 4. Policy network mapping, subordinated implementation links, source: authors (SocNetV tool)

The second radial graph shifts the lens from hierarchical subordination to horizontal connectivity, visualizing explicit cross- references and shared implementation clauses that bind the corpus into a cohesive governance web. In this layout, a dense inner core of EU- level strategies—including the European Green Deal, Biodiversity Strategy 2030, and Soil Thematic Strategy—functions as a multi- policy "switchboard" with the highest betweenness centrality, channeling over one- third of lateral edges. National framework laws (e.g., Italy's Climate Law 2020

and the Circular Economy Action Plan) occupy mid- rings, forming cross- sector bridges that synchronize energy, land- take, and restoration agendas. Outermost rings host specialized regulations—such as regional territorial plans and sectoral decrees—that derive operational guidance from multiple upstream sources, reflected in their high out- degree but low reciprocity. A pronounced edge density along the southeast arc highlights an execution "cluster" where climate- adaptation, brownfield redevelopment, and renewable- energy mandates reinforce one another, indicating strong integrative capacity in those domains. In contrast, the sparse link field in the northwest quadrant signals thematic silos around ecosystem- service valuation and social equity, showing these topics are weakly embedded in current execution chains. Overall, the topology reveals a governance architecture that is horizontally well- connected for mitigation and circular- economy objectives but remains fragmented for socio-ecological valuation, pinpointing strategic areas where future policy knitting is needed.

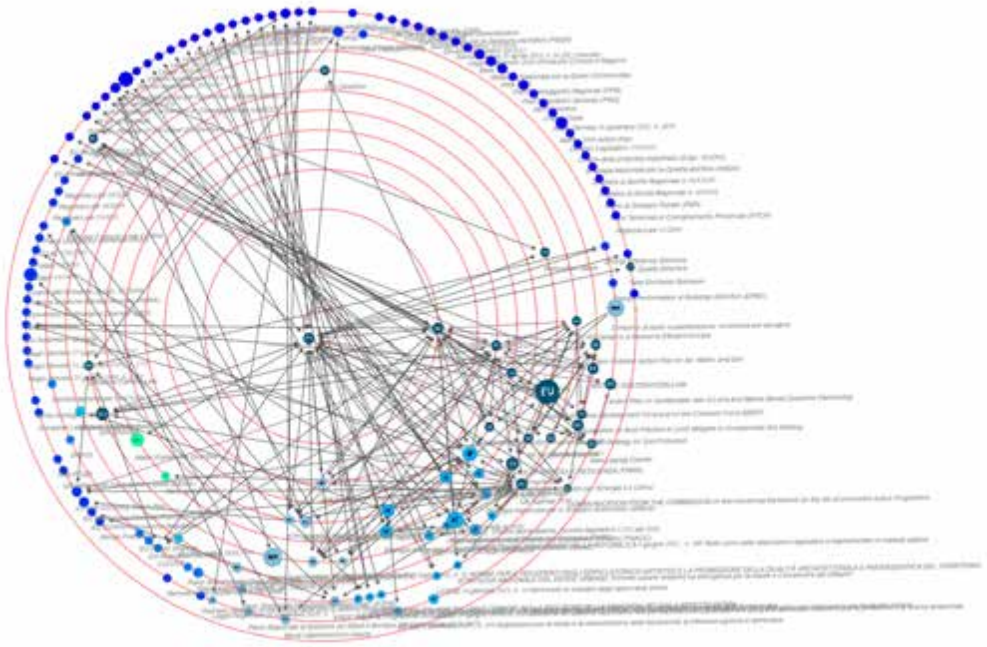

Figure 5. Policy network mapping, strategic execution links, source: authors (SocNetV tool)

The operational layer of the policy web comprises concrete instruments that translate strategic goals into codified procedures, monitoring schemes, or financing mechanisms. At the graph's centre lies a single dominant hub—a regulation with top- decile degree and highest betweenness—representing a cross- cutting implementation framework serving as the procedural backbone for multiple thematic domains. From this hub radiates a dense fan of edges to mid- tier policies forming an "execution cluster" in the south- eastern arc; their moderate betweenness but high degree indicates they collect mandates from the central hub and redistribute them into sectoral toolkits without bridging to other clusters. Conversely, the north- western quadrant contains smaller peripheral nodes with low degree and negligible betweenness, reflecting policy instruments operating largely in isolation and weakly institutionalized within mainstream operational machinery. Overall, the topology reveals a governance architecture dominated by a few procedural heavyweights, while several thematic areas lack robust linkages. Closing these gaps will require augmenting existing hubs' mandates or establishing new bridging instruments to align operational execution with strategic ambition.

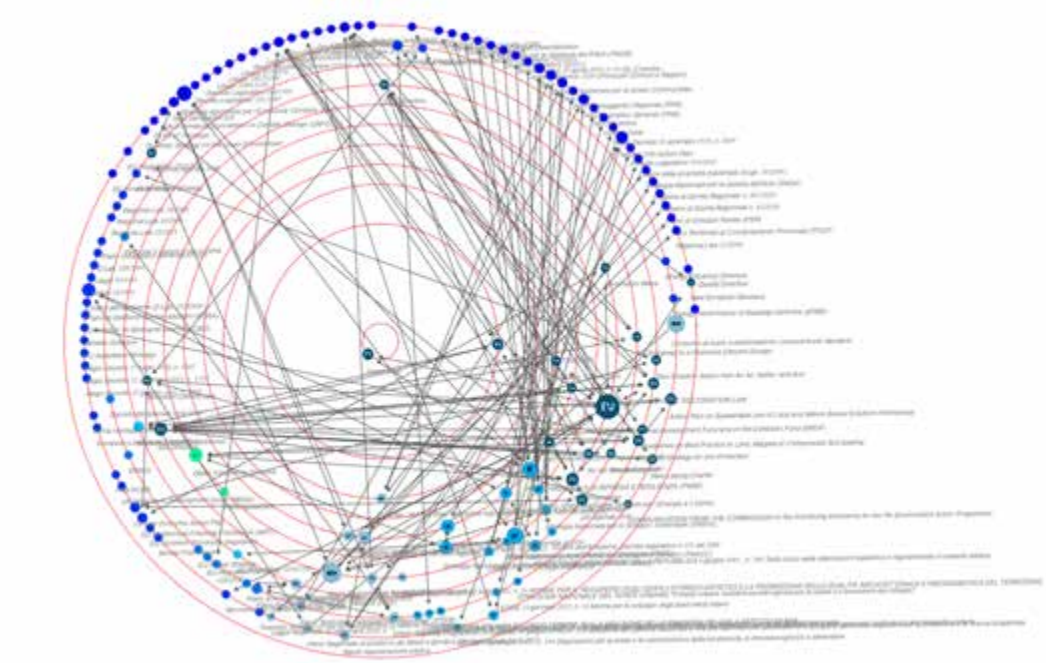

Figure 6. Policy network mapping, Operational execution links, source: authors (SocNetV tool)

The network analysis enabled the identification of prominent nodes both through visual inspection and quantitative centrality metrics (degree, betweenness, and eigenvector). High-scoring nodes that were not present in the initial corpus were flagged as omissions, resulting in the inclusion of nine additional policies. The full texts of 56 candidate policies were systematically reviewed to assess their fit to inclusion protocol and extract the necessary data. This screening process yielded a final dataset of 34 policies for all subsequent analyses (see Appendices).

3.1 ZNLT at the European Level

The concept of ZNLT has gradually evolved into a cornerstone of the European Union's environmental and spatial planning agenda. Anchored in the broader objectives of land degradation neutrality, biodiversity conservation, and sustainable urban development, the ZNLT goal aims to halt the net conversion of natural and agricultural land into artificial surfaces by 2050. The progression from soft strategic guidance (2006–2011) to operational planning (2020–2021) and finally to enforceable legal mandates (2024) represents a significant trajectory in EU land governance. Initially, the 2006 Thematic Strategy for Soil Protection set limits on soil sealing and promoted brownfield rehabilitation, introducing "limitation–mitigation–compensation" principles. The decisive milestone came with the EU Roadmap to a Resource Efficient Europe (European Commission, 2011), which introduced the 2050 ZNLT target. It also proposed the development of indicators (soil sealing and urban density) as tools for monitoring progress toward sustainable land use. Building upon this, in 2020, EU Biodiversity Strategy for 2030 emphasized land preservation for biodiversity, committing to restore 15 % of degraded land and mandating Urban Greening Plans. In 2021, EU Soil Strategy for 2030 reaffirmed ZNLT, recommending national soil management plans, land reuse incentives, and participatory governance, prioritizing degraded land and promoting land recycling rates above 70 %. Finally, in 2024 Nature Restoration Law introduced binding targets to prevent green urban area loss by 2030, expand green cover, and prioritize disused urban land for redevelopment, institutionalizing monitoring of urban tree canopy and habitat fragmentation. The law embedded the ZNLT concept within enforceable national restoration plans, marking a shift from strategy to obligation. It also institutionalized monitoring requirements on urban tree canopy, and habitat fragmentation, closing previous gaps in enforcement and transparency.

The analyzed final dataset includes 12 documents, functional typology of which reveals that strategic frameworks dominate: most texts set politically endorsed but non-binding objectives; three documents serve primarily as informational tools (providing monitoring guidance or methodological standards); and only the Nature Restoration Law constitutes a legally binding instrument, creating enforceable obligations. This distribution

forms an implementation pyramid, where a broad strategic apex funnels into a narrow base of binding regulations, potentially diluting enforcement consistency across the Union. Applying a categorical clustering to their policy objectives shows a predominant emphasis on land use and soil protection: of the twelve high-level instruments, five target land-use and soil protection, focus on biodiversity restoration, pollution prevention, urban regeneration, climate adaptation is less present, illustrating a strong corpus focus on soil governance.

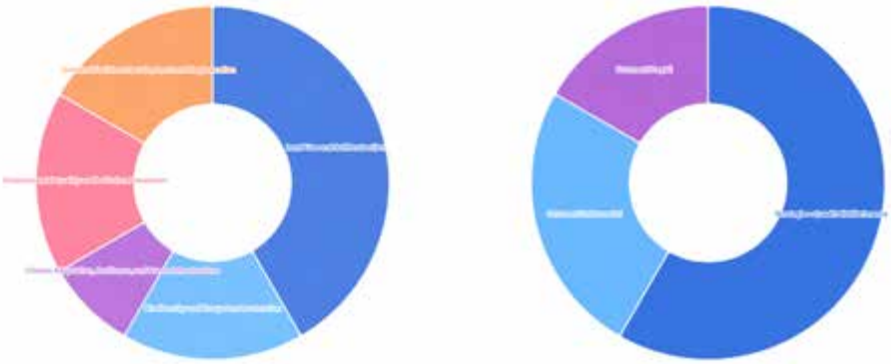

Figure 7 (from left to right) Categorical clustering and functional typology of supranational dataset, source: authors

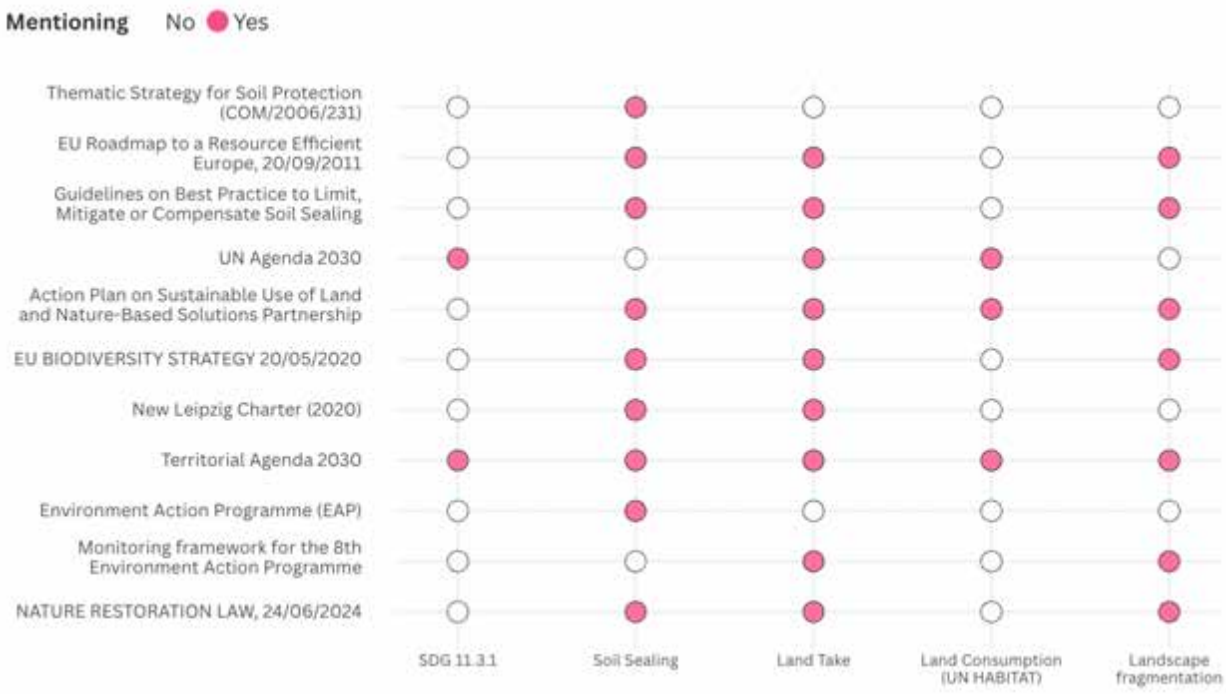
The content analysis highlights a significant presence of soil sealing and land take terms, which are addressed in ≈75% policies. In contrast, broader socio-ecological concepts such as land consumption (UN-Habitat) and SDG 11.3.1 appear in only 25% and 17% of documents respectively, while Landscape fragmentation is cited in ≈58%, mainly in biodiversity-focused instruments, but is mainly absent from soil or resource-efficiency strategies.



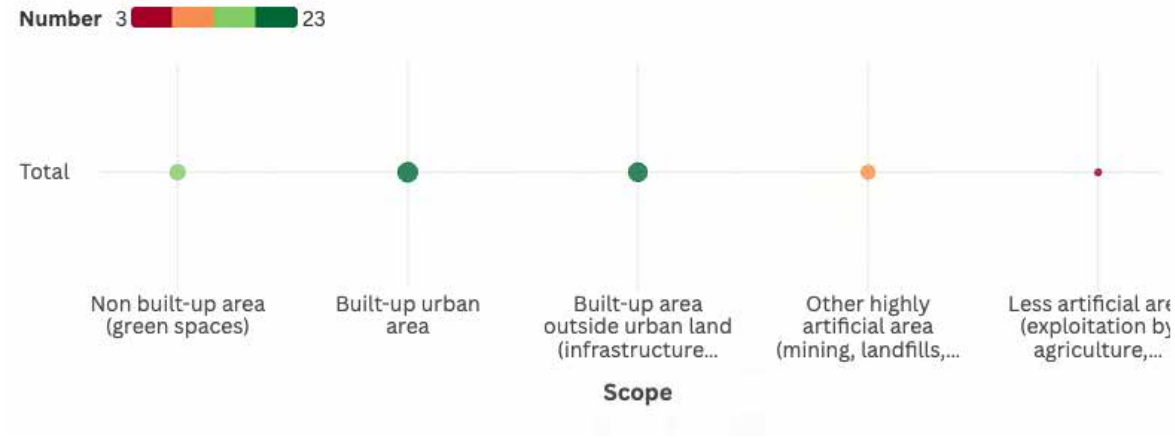


Figure 8: Terminology Trends (top) s and Spatial Focus (bottom) in EU ZNLT Policies, source: authors

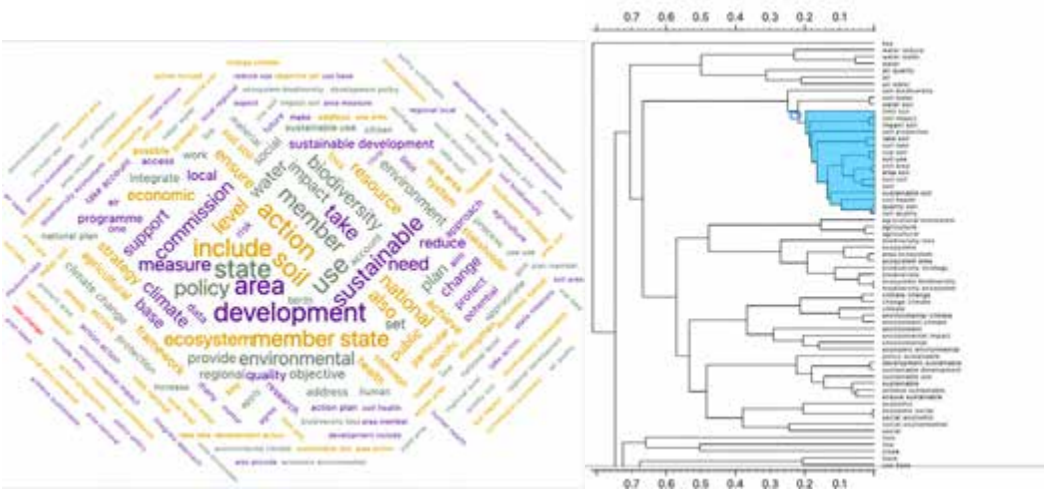

Figure 9. Machine learning text mining, supranational level, source: authors (Orange machine learning tool)

Tri- layer network analysis corroborates the textual findings by revealing stratified policy roles. Certain documents serve as normative hubs or "procedural spines" underpinning governance, i.e. EU Biodiversity Strategy functions as a hierarchical anchor, exhibiting high eigenvector centrality in both subordinated implementation (76.98 %) and strategic execution (94.48 %) layers, confirming its pivotal role in setting normative objectives across subordinate policies.

Figure 10. Policy network centrality analysis (supranational level), source: authors

In contrast, the Nature Restoration Law acts as an operational engine with the highest eigenvector centrality in the operational layer, translating strategic objectives into concrete procedures, monitoring requirements, and enforcement protocols. Between these poles lie strategic orchestrators, such as the EU Soil Strategy and Territorial Agenda 2030, which display elevated betweenness centrality in the strategic execution network, bridging high-level goals with implementing acts. Foundational texts like the Thematic Strategy for Soil Protection and the EU Roadmap to a Resource Efficient Europe retain moderate degree centrality in subordinated implementation, anchoring early policy cascades.

Network analysis reveals that several high-centrality documents, though silent on land conversion, serve as critical connectors in governance. The EU Green Deal leads in eigenvector centrality for subordinated implementation and strategic execution (100%), and in subordinated betweenness (≈9%), positioning it as the macro-framework for climate neutrality and the circular economy. The Floods Directive 2007 also emerges as a key vertical bridge linking soil and water governance. High strategic but low operational eigenvector centrality for UN Agenda 2030, the New Urban Agenda, and Territorial Agenda 2030 (≥17%–42% vs. <6%) underscores their role as agenda setters rather than direct implementers.

Overall, the corpus exhibits a multi- tiered topology: hierarchical anchors establish land- take targets, strategic orchestrators integrate cross- sectoral ambitions, and operational engines drive implementation, forming a resilient, though uneven, governance network.

3.2 ZNLT in Italy: National Framework

Over the last two decades Italy has moved from treating soil sealing as an indirect planning concern to recognising ZNLT as a core dimension of ecological transition. While a single framework statute is still absent, a review of national laws, strategies and investment plans reveals a cumulative layering of restrictions, incentives and monitoring duties that increasingly converge on the ZNLT logic.

The term *consumo di suolo* starts appearing in national policy documents only after 2010, while early 2000s statutes dealt with land take mainly through landscape- or contamination-related provisions. Earlier laws, such as Legge Urbanistica (Governo Italiano, 1942), addressed land take indirectly by mandating municipal master plans, promoting regeneration, and protecting green strips. Articles 13 and 20 directed growth toward degraded urban zones, mandating their redevelopment and allowing expropriation if owners failed to act. Article 18 empowered

municipalities to reclaim idle plots for public use, discouraging land speculation, while Article 25 protected private gardens and green strips, safeguarding permeable soil and urban vegetation. The Codice dell'Ambiente (D.Lgs. 152/2006) introduced precautionary and remediation principles for contaminated soils; Article 239 framed land degradation as an environmental liability, anchoring future anti- sealing debates (Governo Italiano, 2006). The policy narrative gained explicit soil-consumption language only after the EU Roadmap to a Resource-Efficient Europe fixed the 2050 ZNLT horizon. Domestically, a sequence of soft-law and targeted statutes began to translate that horizon.

In response to EU prompts, Italy made several attempts to approve a framework law to limit land take. The first, the "Catania" bill (2012), proposed capping agricultural land conversion caused by impermeabilization, urbanization, and non- agricultural construction (Naldi, 2012). The 2013 draft (Redazione Carteinregola, 2013) aimed to reduce soil consumption gradually, targeting zero by 2050 in line with European objectives. A 2014 proposal amending the Legge Urbanistica sought to encourage urban regeneration and discourage greenfield development to combat sprawl (ANSA, 2014). None of these drafts passed. In 2015, the Strategia Nazionale di Adattamento ai Cambiamenti Climatici (SNAC, 2015) identified soil sealing as a driver of hydrogeological risk and ecosystem fragmentation, linking climate adaptation with land- take control (Ministero dell'Ambiente e della Sicurezza Energetica, 2015). In 2016, the comprehensive bill "Contenimento del consumo del suolo e riuso del suolo edificato" (Atto C. 2039–A) was approved by the Chamber of Deputies on 12 May 2016 and transmitted to the Senate as Atto Senato 2383 (Senato della Repubblica, 2016). However, it did not receive final Senate approval before the end of the XVII Legislature and thus did not become law.

Concurrently, Law 132/2016 (Istituzione del Sistema nazionale a rete per la protezione dell'ambiente e disciplina dell'Istituto superiore per la protezione e la ricerca ambientale) established a national network comprising ISPRA and regional/provincial environmental agencies, which issued guidelines and annual reports quantifying land take via soil-sealing (imperviousness) indicators (Senato della Repubblica, 2016). The Strategia Nazionale per lo Sviluppo Sostenibile (SNSvS) formally adopted SDG-aligned soil-sealing indicators and designated ISPRA as the national monitoring hub, inaugurating a coordinated data regime for land take (Ministero dell'Ambiente e della Sicurezza Energetica, 2017). The Piano Nazionale Integrato per l'Energia e il Clima (PNIEC) advanced a "zero-additional-soil" criterion for renewable-energy siting (Ministero dello Sviluppo Economico, 2019). After 2021, Italy's Piano Nazionale di Ripresa e Resilienza (Presidenza del Consiglio dei Ministri, 2021), and Ecological Transition Plan (PNTE) (Ministero della Transizione Ecologica, 2022), have linked ZNLT to brownfield reuse, restoration, and advanced targets to 2030. The Strategia Nazionale del Verde Urbano (Ministero della Transizione Ecologica, 2021) promoted de-sealing and urban nature-based solutions, while the Strategia Italiana di Lungo Termine (Ministero dell'Ambiente e della Sicurezza Energetica, 2021) recognized conflicts between renewable energy rollout and soil conservation, proposing degraded-land restoration as a mitigation measure.

In 2023, a bill on soil consumption and urban regeneration titled "Disposizioni per il contenimento del consumo di suolo e la rigenerazione urbana" (Atto Camera 1179) was introduced in Parliament but did not reach a vote before dissolution (Camera dei Deputati, 2023). It is now under examination by the VIII Commissione Ambiente of the Chamber of Deputies, with review having begun on 3 October 2023. The proposal aims to create a national framework for progressively reducing land consumption in line with the EU's goal of zero net land take by 2050. Italy has developed robust indicators to track progress on land take. The National System for Environmental Protection (SNPA) – comprising ISPRA and regional environmental agencies – monitors land consumption annually using satellite imagery and GIS data. Their flagship report "Consumo di suolo, dinamiche territoriali e servizi ecosistemici" provides detailed statistics by region and municipality (SNPA, 2024).These data are published openly and serve as a basis for policy adjustment.

The collected corpus of 12 polices is predominantly of soft power: only 25% are binding, supplying juridical backbone for urban development controls, tree-planting mandates and environmental monitoring, but precede or stand apart from the EU-driven sustainability agenda of the last decade. The other 75%, such as SNAC, PNIEC, and PNRR, are non-binding but strategic, reflecting a model that promotes coordination but risks fragmented implementation due to weak enforcement mechanisms. Thus, Italy's land-use regulation rests on a robust legal base for basic controls, while its post-2015 sustainability objectives rely primarily on aspirational instruments whose effectiveness depends on their integration into regional and municipal law. Thematic analysis shows that half of corpus belongs to "climate adaptation, resilience, and green infrastructure".

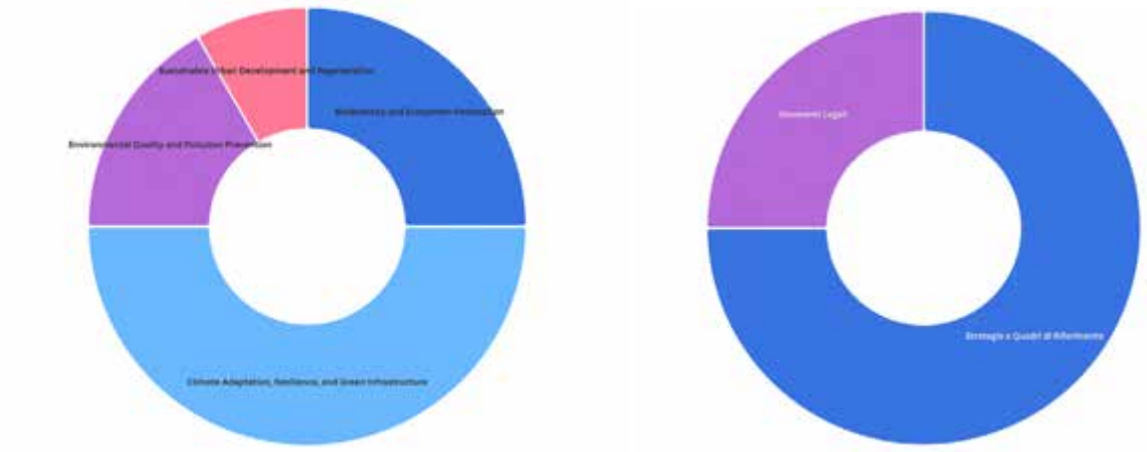

Figure 11 (from left to right) Categorical clustering and functional typology of national dataset, source: authors

In Italy is mainly used the term consumo di suolo, which according to ISPRA[1] refers to the transition from non-artificial to artificial cover, whether permanent (buildings, paved roads) or reversible (construction sites, ground-mounted PV, unpaved depots). Agricultural and forestry uses are excluded, as they retain biophysical cover; permeable greenspaces only count if the soil structure is irreversibly altered. ISPRA equates consumo di suolo with the EU's "land-take" indicator, while UN-Habitat's broader "land consumption" (SDG 11.3.1) includes intensive agriculture and cropland or forest expansion—highlighting ISPRA's narrower, sealing-focused approach. In this way, content analysis reveals land take, landscape fragmentation and soil sealing dominate Italian policy discourse, while "land consumption"and SDG 11.3.1 are less referenced.

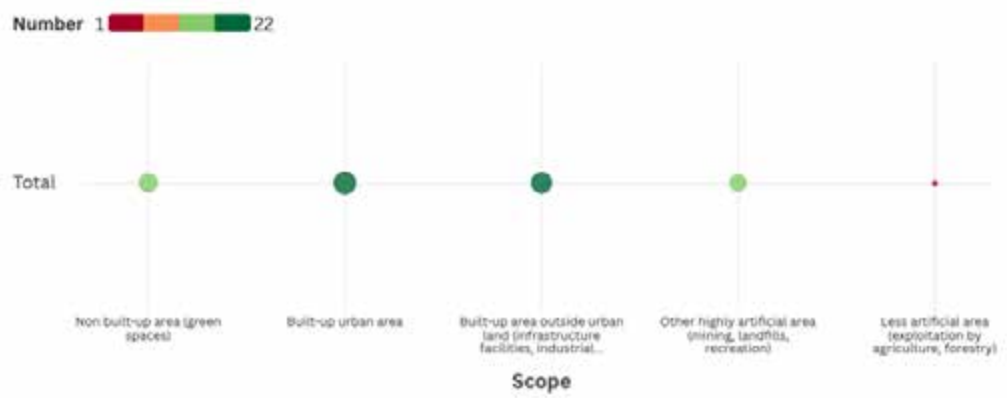

Figure 12: Terminology Trends (top) s and Spatial Focus (bottom) in IT ZNLT Policies, source: authors

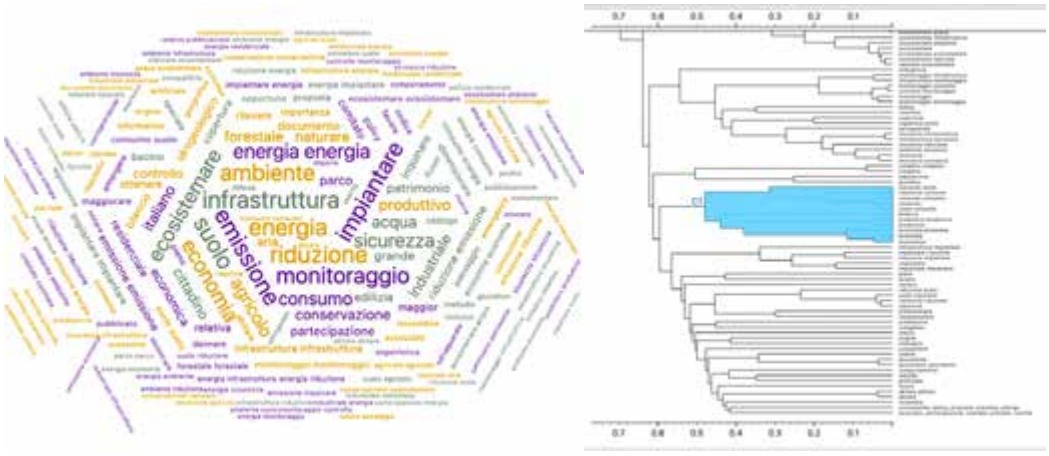

Figure 13. Machine learning text mining, national level, source: authors (Orange machine learning tool)

Network analysis reveals a stratified policy architecture. The SNSvS serves as a normative hub, with high eigenvector centrality in subordinated implementation (~9%) and strategic execution (~33%), unifying various statutes. The PNRR is the chief orchestrator, exhibiting the highest strategic-execution eigenvector (~53%) and high degree and betweenness. Operational engines like PNACC and SNAC show strong operational centrality (~3–4%) and betweenness, translating strategic objectives—such as sealing mitigation and flood-risk reduction—into local regulation and financing. Notably, several frequently cited statutes (D.Lgs. 42/2004, D.Lgs. 152/2006) occupy important procedural roles but lack explicit land-take clauses, creating "silent-but-central" gaps that undermine policy cohesion.

Figure 14. Policy network centrality analysis (national level, Italy), source: authors

This assessment indicates that Italy has advanced in embedding ZNLT principles, yet its policy architecture is still characterised by a mosaic of sector-specific measures and largely non-binding strategies rather than a single statutory backbone. Key statutes address land conversion peripherally, with climate-resilience strategies prevailing. The hub-and-spoke architecture depends heavily on multi-mission plans such as the PNRR, leaving gaps whereby absent soil-consumption clauses may permit indirect land take. Although the PNRR, PNIEC provide operational leverage and SNSvS, SNAC offer normative guidance, weak soft–hard integration might sustain fragmentation and regional inertia.

3.3 Regional Implementation: Emilia-Romagna Case Study

In the absence of a national land-take statute, regional governments took the lead in limiting land take, primarily using their planning powers. Emilia-Romagna's Piano Territoriale Regionale (PTR, Regione Emilia-Romagna, 2010), approved in 2010, provides the broad strategic framework for territorial development and coordination of local plans. By the time of its drafting in the 2000s, awareness of uncontrolled land consumption (consumo di suolo) was growing in Italy. The PTR embeds the principle of limiting land take as a key policy guideline. In fact, language echoed later in law can be traced to the planning ethos of that time – for example, treating land as a "bene comune e risorsa non rinnovabile" (common good and non-renewable resource) that must be preserved.

In 2013, a significant initial step was taken with the establishment of an interdepartmental working group, the "Valorization of Agricultural Areas and Containment of Land Consumption, that equipped with detailed knowledge of land consumption patterns and the status of rural territories, and proposed operational methodology that not only quantified existing soil consumption but also enabled a qualitative spatial analysis. Building on this foundation, Emilia-Romagna launched a pioneering soil consumption monitoring program culminating in the 2015 regional report (Consumo di suolo e pianificazione: conoscere per decidere, Regione Emilia-Romagna, 2015). A crucial conceptual advance was the precise definition of consumo di suolo: the irreversible conversion of agricultural, natural, or semi-natural areas into sealed or permanently artificialized surfaces (e.g., buildings, roads, industrial yards).

The set of land uses that lead to the loss of natural characteristics, resulting in an artificial surface whose purpose is not the production or harvesting of biomass. It was described as a dynamic process that alters the nature of the territory, moving from natural conditions to artificial conditions, of which impermeabilization represents the final stage. Importantly, the methodology excluded temporary or reversible uses and permeable green areas from the "consumed" category until conversion was made permanent.

The subsequent LR 24/2017, signaled a major shift toward achieving ZNLT by 2050 by capping new land take and prioritizing urban regeneration over greenfield development. The law restricts new construction to cases where all reuse or replacement options are exhausted and reinforces urban growth boundaries. Its provisions require that any new construction is permissible only after all feasible options for the reuse or replacement of existing buildings have been exhausted, effectively relegating greenfield expansion to a last-resort status. By reinforcing urban growth boundaries and explicitly demarcating built-up areas, the law curtails further encroachment on undeveloped land. The law limits new land take to a maximum of 3% of the urbanized land area (as of 1 January 2018) up to the year 2050. In practice, this functions as a "land take budget" for each municipality and the region as a whole. Importantly, LR 24/2017 defines "land take" in net terms, as the balance between newly urbanized areas minus any areas returned to natural state through de-sealing within urban boundaries.

Urban planning was restructured with the introduction of the Piano Urbanistico Generale (PUG), replacing prior municipal plans and emphasizing regeneration, with detailed zoning assigned to secondary instruments. Municipalities were required to adopt new PUGs by the end of 2020. By January 2025, dozens of new PUGs had been adopted or approved.

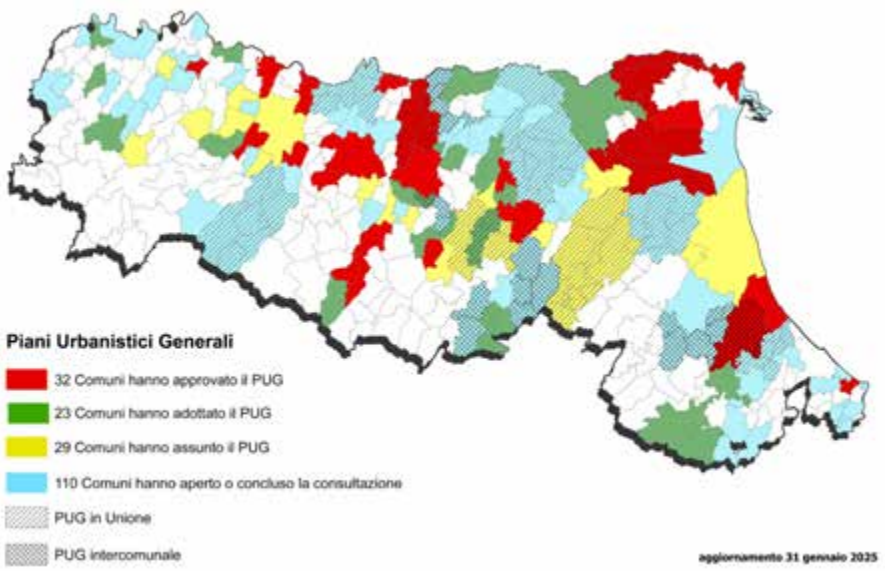

Figure 15. Level of PUG approvement at municipal level, source: Emilia-Romagna region

Emilia-Romagna has established a multi-layered governance system to monitor and enforce its land take policies. Municipalities are obliged to submit digital data on any land transformations. Each January, the region compiles the previous year's land take data and publishes the results. The region's open data portal also provides shapefiles of the officially recognized urbanized territory per the new plans. The success of LR 24/2017 led to the integration of ZNLT principles into subsequent regional policies. The Regional Strategy for Agenda 2030 commits to ZNLT, aligning with SDGs 11 and 15 and the EU's 2050 target, focusing on urban regeneration, brownfield restoration, and compliance with the 3% cap. The Piano Regionale di Gestione dei Rifiuti e Bonifica delle Aree Inquinate 2022–2027 prioritizes brownfield reuse for waste infrastructure, promoting regeneration in line with ZNLT goals. The ERDF Programme 2021–2027 incorporates land take reduction, using LR 24/2017 as a benchmark, funding urban transformation agendas that prioritize regeneration and reuse over greenfield development.

The functional typology and clustering of Emilia-Romagna's policy corpus reveal clear patterns in both legal force and thematic orientation. Binding instruments belong to Sustainable Urban Development and Regeneration and Land Use and Soil Protection clusters, respectively, reflecting their role as normative hubs that mandate redevelopment-first approaches and set soil- consumption ceilings. In contrast, non- binding strategies occupy the Climate Adaptation and Sustainable Urban Development clusters, serving primarily as high- level vision documents that lack enforceable provisions. Economic instruments, explicitly target Sustainable Urban Development and Regeneration. Lastly, informational tools, epitomized by "Consumo di suolo e pianificazione: conoscere per decidere", are classified under Land Use and Soil Protection, furnishing data for evidence- based decision- making without direct regulatory authority.

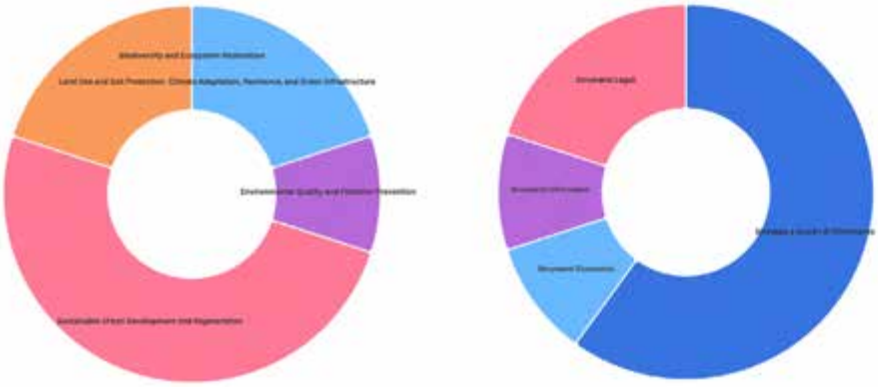

Figure 16 (from left to right) Categorical clustering and functional typology of regional dataset, source: authors

Across all ten documents, there are explicit provisions addressing land-take reduction. Although soil sealing appears in nearly all documents, its treatment differs markedly depending on the policy family. Land-take itself appears as a headline metric, signalling broad acceptance of this concept as the principal proxy for horizontal land conversion. However, only four instruments (e.g., L.R. 24/2017, PER 2030, the Regional Strategy for Agenda 2030, and PTPR) pair land-take with explicit restorative language such as de-sealing or ecological compensation. Equally significant is the limited uptake of the broader "land-consumption" concept as defined by UN-Habitat.

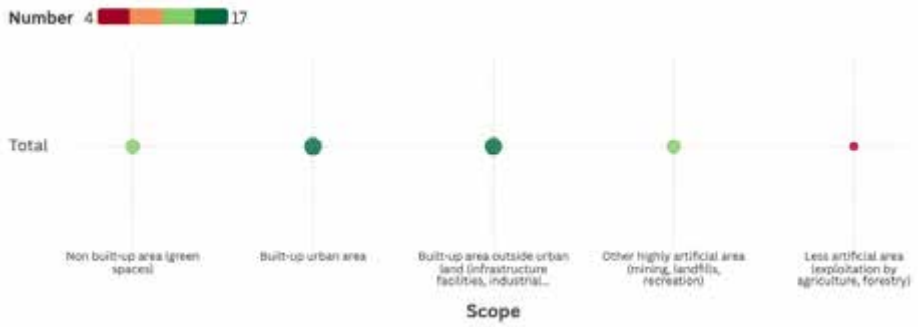

Figure 17: Terminology Trends (top) s and Spatial Focus (bottom) in ER ZNLT Policies, source: authors

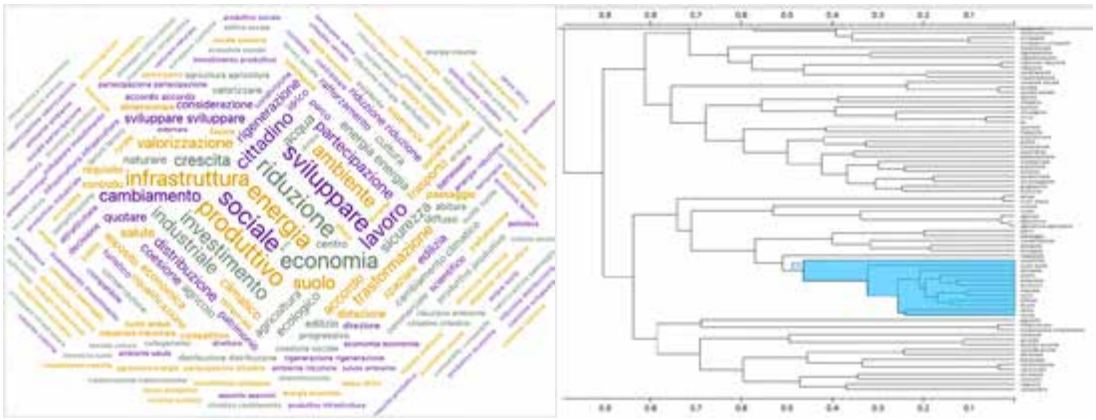

Figure 18. Machine learning text mining, regional level, source: authors (Orange machine learning tool)

Network-centrality metrics highlighted the following. The Regional Strategy for Agenda 2030 and LR 24/2017 show high betweenness and eigenvector centrality, acting as key orchestrators and hierarchical anchors that connect multiple policy tiers, even without directly addressing land consumption. In contrast, instruments like Bandi rigenerazione urbana and the Smart Specialisation Strategy suggest low centrality, indicating peripheral roles with limited integrative capacity. Secondary anchors, such as PRAP and Legge Regionale 16/2002, provide coordination but lack direct land conversion provisions, creating potential alignment gaps.

Bandi regenerazione urbana									
Piano Regionale di Gestione dei Rifiuti e Bonifica Siti Contaminati 2022–2027									
Regional Strategy for the Agenda 2030									
ERDF Regional Programme 2021-2027									
Law No. 24/2017, titled "Disciplina regionale sulla tutela e l'uso del territorio,"									
Piano energetico regionale 2030 (PER)									
Piano Territoriale Paesaggistico Regionale" (PTPR)									
Smart Specialisation Strategy (S3)									
Piano Territoriale Regionale (PTR)									
Consumo di suolo e pianificazione: conoscere per decidere.									

Figure 19. Policy network centrality analysis (regional level, Emilia-Romagna), source: authors

The analysis showcased institutional innovation and strong multi-level governance, embedding the ZNLT target through spatial analysis, monitoring, and land-take caps. However, gaps persist where non-binding fiscal tools lack explicit land-consumption metrics. The next policies revision (or the drafting) of peripheral to ZNLT, energy-transition or climate-adaptation policies, incorporating quantitative sealing thresholds (e.g., maximum km² of new impermeable surfaces), could enforce the net-gain logic that underpins ZNLT.

3.4 Cross-Level Analysis and Policy Gaps

In collaboration with Emilia-Romagna experts, the corpus was evaluated for relevance to the process of land take reduction and re-using abandoned or previously-used land in Emilia-Romagna. Combining scores with policies' legal bindingness, it allowed to map these scores onto a Power/Relevance matrix, where:

Key policies (High relevance and power) directly address land-take prevention or land-reuse through binding provisions (laws, directives, mandatory funding conditions). Rigorous execution and regular updating are essential, as gaps might pose immediate risks. Influential policies (high relevance, low power) provide technical guidance, strategic visions, or soft-law recommendations promoting ZNLT without binding force. Strengthening them requires converting these into binding obligations; until then, their impact relies on political will, peer pressure, and funding alignment. Contextual policies (low relevance, high power) are binding legal acts that have only secondary or indirect practical usefulness for the ZNLT processes. Often "sleeping giants," small amendments can produce major effects. Effective cross-sector coordination is needed to prevent these powerful instruments from unintentionally promoting new land take. Peripheral policies (low relevance, low power) — Soft-law or legacy documents that target adjacent sustainability objectives with minimal or no explicit focus on the regional ZNLT effort. They provide entry points to embed ZNLT terminology into wider policy contexts.

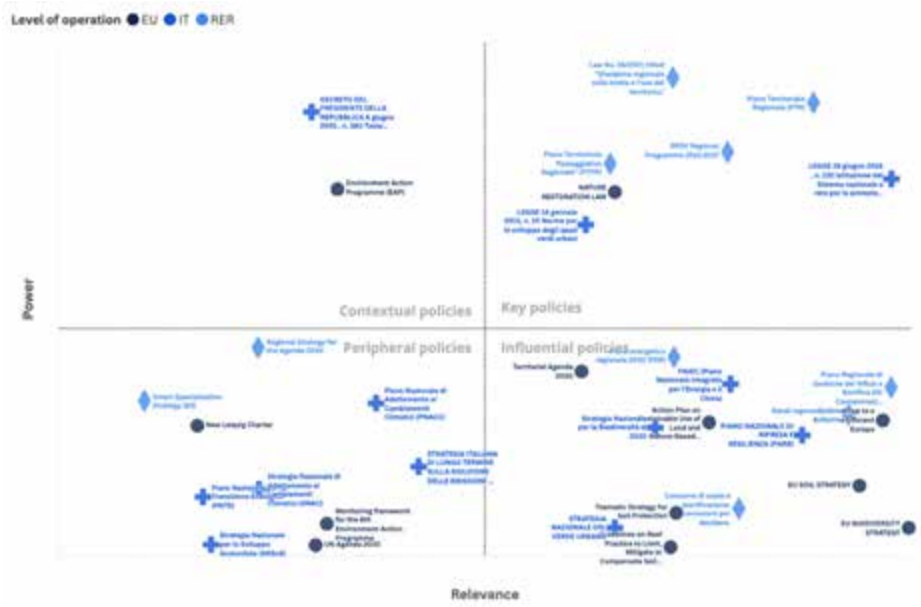

Figure 20. Policy Power/Relevance matrix, source: authors

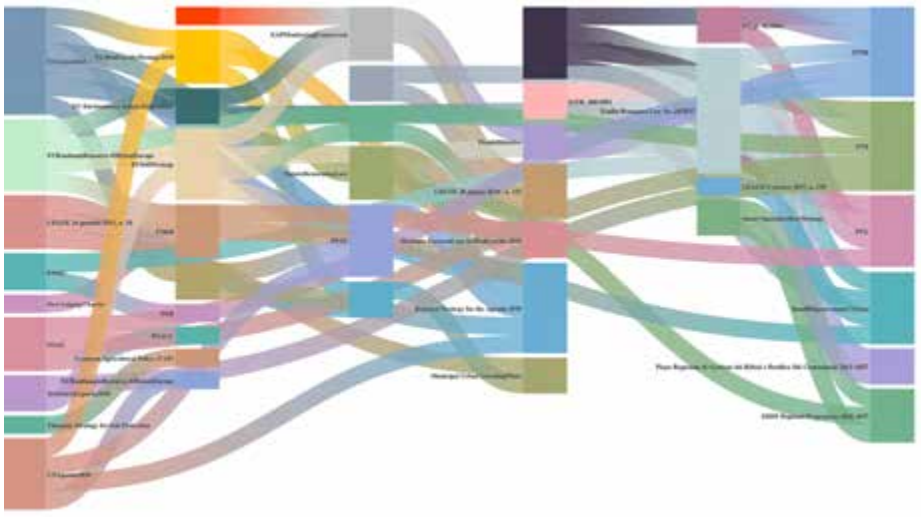
The self-evaluation revealed that only 21% of the corpus emerged as Key policies, that practitioners regard as directly operational for achieving ZNLT (e.g. the EU Nature Restoration Law 2024; LR 24/2017; the ERDF 2021-2027 programme; and the PTR/PTPR tandem). The largest cluster (44%) falls in the Influential quadrant, where soft-law strategies and thematic action plans can be widely consulted but lack coercive force. Finally, 29 % were deemed Peripheral: overarching frameworks (i.e. UN Agenda 2030, National Ecological Transition Plan and Regional Smart Specialisation Strategy, etc), which provide little concrete leverage for practitioners. And only two high-power texts were rated as Contextual (6%)—notably 8th Environment Action Programme and the national Consolidated Building Code (DPR 380/2001).

Network-analysis and expert-evaluation results were consequently onto the DPSIR framework. DPSIR was recalibrated, categorizing objectives as Drivers, Pressures, States, Impacts, or Responses to construct a governance-oriented causal network. Policies containing multiple objectives were mapped according to their most relevant DPSIR categories, enabling accurate representation across different analytical nodes.



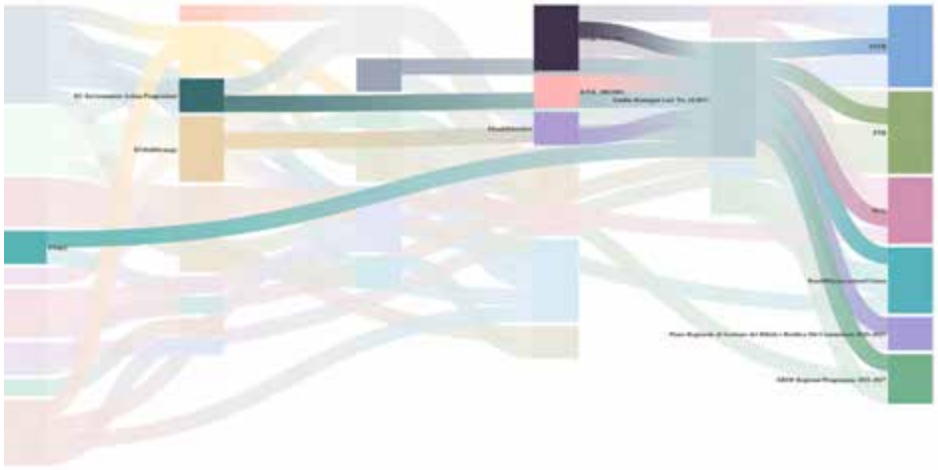


Figure 21. Sankey diagram (transition of policy objectives), source: authors

At the Driver level, agenda-setting strategies such as the European Green Deal, EU Biodiversity Strategy 2030, and EU Soil Strategy position land-take neutrality, ecosystem restoration, and soil health as central economic priorities. High strategic centrality scores reflect their ideational influence, but limited operational centrality signals persistent implementation barriers. Pressure policies, as Nature Restoration Law and LR 24/2017, translate strategic goals into enforceable quantitative limits. Urban regeneration incentives and brownfield prioritization in national and EU funding schemes further operationalize the "reuse before new take" hierarchy. State-focused instruments remain peripheral: few policies establish systematic monitoring of land condition or biophysical baselines. Notable exceptions are the 8th Environment Action Programme Monitoring Framework, Italy's Law 132/2016, and Emilia-Romagna's "Conoscere per decidere." Their low centrality underscores a monitoring deficit, weakening adaptive management. Impact-oriented measures are more consistent, targeting ecosystem and social consequences of land conversion. The EU Biodiversity Strategy and adaptation policies promote connectivity, habitat restoration, and nature-based solutions to mitigate flood and heat risks. Urban green space mandates and financial instruments (PNRR, ERDF) support mitigation and compensation, though most objectives remain qualitative, diluting their regulatory effect. Responses comprise a stratified layer of operational instruments and funding mechanisms translating prior targets into practice. High-relevance statutes such as LR 24/2017 and regional ERDF programmes drive implementation via updated local plans and dedicated investments, while non-binding strategies maintain high strategic influence but limited coercive force. Institutional mechanisms, including the SNPA monitoring system, enhance enforcement capacity and policy learning.

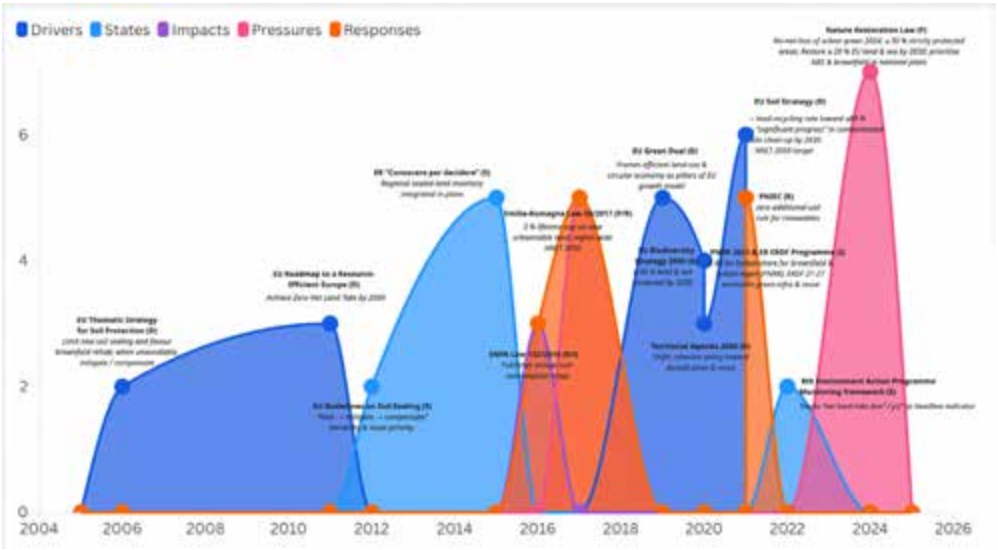

Figure 22. Sankey diagram (transition of policy objectives), source: authors

The longitudinal reconstruction of ZNLT corpus discloses a six-phase "policy stratigraphy" in Emilia-Romagna in which successive DPSIR nodes accrete rather than co-evolve. Early Driver texts—the EU Thematic Soil Strategy (2006) and the Resource-Efficient Roadmap (2011)—conferred a macro-narrative of circular growth and set a 2050 neutrality horizon, yet remained programmatic. Only after a distinct State layer (2012-15) had produced the first sealed-soil baselines did impact-mitigation pilots surface, linking annual soil-consumption reporting (SNPA, 2016) with modest urban-greening offsets. Hard Pressures arrived abruptly: LR 24/2017 imposed a 3 % lifetime land-take cap, while the 2024 EU Nature Restoration Law crystallised a 20 % ecosystem-repair mandate and an urban-green "no-net-loss" rule. An intervening consolidation wave (2019-21) re-embedded ZNLT within the Green Deal's climate-neutrality calculus and paired it with restoration (30 % strict protection; 20 % degraded-land recovery), thereby recasting neutrality from a stand-alone limit into a limit-plus-repair paradigm.

Overlaying temporal and functional layers reveals systemic discontinuities. Drivers precede enforceable Pressures by 6-8 years, creating windows of political drift in which implementation relies on voluntary Response finance (PNRR, ERDF 2021-27). Monitoring capacity remains front-loaded and stagnant: after 2016 no major State instrument has been added, jeopardising the evidentiary basis for the 2050 neutrality claim. Conversely, rhetoric on ecological and social impacts proves catalytic, synchronising surges in mitigation funding with the 2016 and 2021 policy waves.

3. Conclusions and Recommendations

This study has demonstrated that ZNLT ambition is embedded within a richly textured but uneven multi-level governance architecture. Clear vertical alignment emerges through the top-down diffusion of EU objectives, such as no net land take and land degradation neutrality, explicitly reflected in national strategies. At the supranational level, flagship initiatives such Biodiversity Strategy 2030, and Soil Thematic Strategy serve as powerful "normative anchors," diffusing the 2050 neutrality target through hierarchical subordination and strategic execution networks. Yet the translation of these objectives into binding national and regional instruments varies markedly: Italy's national framework remains a patchwork of soft-law strategies and piecemeal statutes, while Emilia-Romagna has pioneered one of the most coherent subnational approaches with its LR 24/2017 cap and advanced de-sealing pilots. This divergence vividly illustrates how policy innovation at one tier can catalyze—or be held back by—gaps at another, highlighting the need for stronger vertical coherence.

The analysis revealed some potential governance imbalances. The land-use policy landscape functions as a multi-level governance system, where interactions among European, national, and regional policies reveal alignment, redundancy, and governance gaps. Strategic "Drivers" dominate the policy topology, whereas "monitoring baselines and some quantitative thresholds are under-represented, weakening adaptive feedback loops. Enforcement of pressure measures are unevenly applied: Emilia-Romagna's 3 percent land-take budget exemplifies a clear cap, whereas national and EU funding programmes often offer only aspirational incentives. At the same time overlapping instruments might create administrative complexity and "strategy fatigue" unless well-integrated.

In summary, the linkages show a multi-level orchestration at work: when properly aligned (as in the case of the 2050 target cascading down to Emilia-Romagna's law), governance becomes coherent and mutually reinforcing. Where levels are misaligned – such as a national policy vacuum – adaptive governance suffers, as lower-level efforts may lack broader support and higher-level goals remain aspirational. The network of policies is densely interconnected, but the strength of those connections (alignment vs. fragmentation) greatly influences outcomes on land-use sustainability.

As the draft Italian land-take law moves forward, lawmakers face a choice: keep the narrow, sealing-centred metric for regulatory simplicity, or broaden the definition toward full land consumption to capture agricultural encroachment and forestry conversion.

Abstract
Collaborative governance of community regeneration is the essential need of the community as living space, and also provides an effective path for community spatial governance. This paper combs the connotation of collaborative governance and the necessity of community collaborative governance. Through the analysis of three typical cases of Nanning Love U Garden, this paper summarizes three types of community garden co-construction modes: external empowering type, internal and external collaboration type and internal autonomy type, and discusses three optimized mechanisms of the collaborative governance: whole-process participatory co-construction mechanism, flexible cooperation and co-maintenance mechanism, and differentiated co-financing mechanism. It has certain reference significance for other cities in China to build community garden networks, promote collaborative governance of community regeneration and promote sustainable development of communities.

Keywords: Participatory Community Planning; Collaborative Governance; Public Engagement; Love-U Garden

1 Introduction

Many cities in the world today are facing the slowdown in economic growth, the reduction in fiscal revenue, and the resulting challenges in public space governance. With the slowdown in China's economic growth, urban construction has also entered the stock regeneration era from incremental development. Community planning and community regeneration based on the built environment require the engagement of multiple local actors and the collaborative governance of multiple departments. So, how can different collaborative governance models be used to stimulate community engagement for different types of communities? How can actors play the role of catalyst and driver in community collaboration and engagement? How to optimize the mechanism of participatory community planning and collaborative governance based on the existing institutional environment? However, current research mostly stays in macro-framework design and isolated case studies, lacking networked practice and continuous observation. Therefore, it is urgent to sort out the multiple models of collaborative governance and the optimisation of participatory community planning mechanisms in combination with long-term systematic spatial practice.

The "Love-U Garden" action in Nanning, China, which began in 2021, has built a rare city-level garden network. Empowered and accompanied by social organisations, the Clover Nature School, it encouraged residents to build and maintain spontaneously, innovated collaborative governance mechanisms, and ultimately became a model for the regeneration and governance of urban community green spaces. This study sorts out the concept of "collaborative governance", combines Habermas's "life world" theory, analyzes the co-construction model and mechanism optimisation of Nanning Love-U Garden, and attempts to provide practical references for the old communities' regeneration.

2 Background

2.1 The connotation of "collaborative governance"

Collaborative governance is an administrative theory that has emerged since the 1990s. It still lacks a clear and unified definition. It is generally believed that collaborative governance originates from the intersection of synergy theory in natural science and governance theory in social science (Huang, 2023). Collaborative governance advocates that multiple governance subjects (including public departments, enterprises, social

Project supported by the Young Scientists Fund of the National Natural Science Foundation of China (Grant No. 52208077)

organisations and individuals) jointly participate in decision-making and jointly solve public problems based on the mutual dependence of resources and interests (Wikipedia, 2025). Collaborative governance can achieve more than any one sector could achieve on its own. The core of its theory is to emphasize the diversity and synergy of governance subjects, which contrasts with the monocentric governance power (Yu, 2013). The fields that use collaborative governance more frequently are political science and management, and most of them focus on the characteristics of collaborative governance as an alternative to managerialism and adversarial approaches. In the field of urban and rural planning, collaborative governance is also seen as an important tool to promote cross-regional and cross-departmental cooperation and to solve the difficulties in public service supply and social and economic development (Hu, 2014). At the same time, in recent years, the concept of "co-governance" has also been frequently used in China's urban planning field, often in the form of "multi-party co-governance" or "co-construction, co-governance and sharing", and its core is also to emphasize the diversity and coordination of spatial governance subjects. It can be said that the concept of "co-governance" in the field of urban and rural planning is basically equivalent to the connotation of "collaborative governance" in administrative science. In general, whether in the fields of political science, management science, or urban planning, scholars emphasize the differences between collaborative governance and traditional administrative management methods, but there are few studies that implement it in actual projects and put forward operational suggestions.

2.2 Community as "life world"

German philosopher Jürgen Habermas believes that modern society consists of two basic areas: life world and system (Finlayson, 2005). Life world refers to the ordinary world in which we live together with others. System is the accumulated structure and established instrumental behaviour type. The two have completely different rules, mechanisms and behaviour patterns, corresponding to communicative behaviour and instrumental behaviour respectively. Life world and communicative behaviour have the function of social integration, building consensus, preserving social significance, and carrying out social and cultural reproduction. System mainly includes two subsystems, money and power, whose main functions are to produce and circulate materials (products and services) and to systematically integrate behaviours. System is embedded in life world, but in fact it is parasitic on life world, so life world takes precedence over system (Habermas, 1990).

Community space is a typical life world, in which money and power are difficult to play a leading role, and the consciousness of "living community" based on daily life collaboration becomes the spiritual foundation of community cohesion (Liu, 2023). At the same time, community space is a typical public space that requires space governance and public services. Therefore, the governance of community space needs to obey the underlying logic of the life world - communicative rationality, which means respecting the diversity of communicative subjects in the community and the right to equal dialogue, so as to reach a consensus and form an orderly social structure. Therefore, "cooperative governance" is the essential requirement of community governance.

Collaborative governance is applied to the community space level, emphasizing the equal consultation and participation of all stakeholders in spatial renewal, which is different from traditional unitary management and bureaucratic management. Since China's community planning has not yet been included in the statutory planning system, the existing collaborative governance research on community renewal mainly focuses on macro, top-down framework design and academic discussion, lacking micro, bottom-up model induction and governance mechanism optimisation. Nanning Love-U Garden is a rare city-level community garden network in China. This article will study three cases from the perspective of collaborative governance to summarize its collaborative governance model and mechanism.

2.3 From Laoyou council to Love-U Garden

Nanning City officially launched the regeneration of old residential communities in 2019, and proposed a plan to complete the regeneration of old residential communities built before the end of 2000 by the end of 2025, involving about 1,270 residential communities and about 165,000 residential units. However, the regeneration of old residential communities in Nanning faces four major problems: 1) Low participation, and local residents lack subject awareness; 2) Difficult communication and coordination, diverse residents' needs, some residents are unwilling to give up vested interests, and it is difficult to reach a consensus; 3) Difficulty in raising funds, the demand for old regeneration funds is large, and in addition to government investment, residents also need to crowdfund part of the funds, which is difficult to raise; 4) Difficulty in management, the number of old residential communities is large, and most of them do not have property management and property committees, and lack

effective management mechanisms.

Therefore, the Nanning Municipal Government purchased services and introduced a professional team to establish the "Laoyou-council", and refined and formulated the "Twelve Rules of Laoyou-council" to standardize the work process and build a long-term community management mechanism. The functions of the Laoyou-council are to train community and council representatives, collect regeneration intentions, determine regeneration plans, collect personal contributions, coordinate regeneration conflicts, and supervise construction quality. As of April 2024, Nanning has established 1,024 Laoyou Councils, elected 6,723 Laoyou-councils' representatives, held 2,832 special consultation meetings on the regeneration of old residential communities, and solved more than 16,000 community regeneration issues. The Laoyou Councils allows residents to express their different opinions, promotes the community to reach a consensus, and gradually solves the difficulties of old residential community regeneration (Housing and Urban-Rural Development Department, 2020).

After the regeneration of old residential communities, on the one hand, the management team needs new forms of participation to mobilize residents more widely and promote the depth of participation in public affairs; on the other hand, the government hopes to promote the "Laoyou-council plus" working method and give full play to its long-term effect; in addition, the regeneration of old residential communities and the work results of the Laoyou-council also need to be presented in a more "visual" way to increase residents' sense of gain and satisfaction. Therefore, the municipal government and the Luobo team invited the Shanghai Clover Nature School team to mobilize residents to build community gardens in the communities that have completed the regeneration, called Love-U gardens.

3 Love-U Garden project

Love-U gardens are small community gardens in Nanning City, which are guided by the Nanning Housing and Urban-Rural Development Bureau, hosted by the Nanning Urban Renewal and Property Management Guidance Centre, and invited by the third-party professional team Shanghai Clover Nature School to empower and accompany the community during the regeneration of old residential areas in Nanning. It encourages residents to participate in the construction and maintenance of the gardens. Through the Laoyou Councils, discussions are held, and empowerment training is conducted by professional organisations. It aims to activate idle space, cultivate public spirit, and point to sustainable development (Clover Nature School, 2021).

The goals of Nanning Love-U gardens are as follows:

1) Improve physical space. Based on a survey of 155 communities in Nanning, a participatory design method of co-creation and construction with residents is used in front of and behind the doors of apartment buildings to realize the implementation of 1,000 community gardens of 3 to 5 square meters, improving the living environment of the community.
2) Cultivate a community of flower lovers. Through participatory design and construction, the team incubates a community of flower lovers locally, provides professional planting skills, cultivates a self-organized team of flower lovers, and encourages flower lovers to discuss, build and share together.
3) Activate autonomous action. Laoyou Garden has created a scene where everyone can discuss and work together to transform the public space, and has fostered the community's ability to reach consensus and act collaboratively. This ability helps to stimulate residents' sense of subjectivity and their enthusiasm for future participation in public affairs.

As of October 2023, Clover House has assisted in the construction of 1,020 Love-U gardens in 92 communities in Nanning. (Figure 1) According to the location and size of the garden, it can be divided into gate gardens, roof gardens, building gardens, central gardens and street gardens. A large number of gardens of different types have formed a city-level green public engagement network, fully mobilizing residents of different ages and classes to participate in it, and reconstructing the relationship between residents and the community and society.

Figure 1 Nanning Love-U Garden Network

4 Analysis

The co-construction of Nanning Love-U Garden is a process of tapping community resources, linking participating entities, multi-party collaborative actions, and establishing a long-term mechanism. It can be divided into three progressive stages: the first stage is external empowerment, with community R as a typical representative. Due to the weak local participation foundation and public awareness, the construction of Love-U Garden relies more on external empowerment, and social organisation plays the role of project leader. The second stage is internal and external collaboration, with community J as a typical representative. With the development of the work, citizens began to accept the concept of the community garden, and external forces such as social organisations, universities, and social actors began to intervene to achieve internal and external collaboration. The social organisation gradually changed from a leader to a co-builder. The third stage is internal autonomy, with community N as a typical representative. With the further enhancement of public awareness and internal motivation, professional teams retreated behind the scenes and turned into technical supporters, and local residents began to autonomously co-fund, realizing conscious initiation, spontaneous construction, and self-management. This study will select three typical cases to illustrate three different co-construction models.

4.1 External empowering type

As the community with the largest number of Love-U gardens and flower lovers in Jiangnan District, community R was built in 1999. It is the first batch of housing estates in Nanning City and the first community built by Ronghe Group as a real estate developer. The property management quality is good. Most of the owners were middle and high-income groups at that time, with a high average quality. In 2019, community R was included in the first batch of old community regeneration in Nanning City. In 2022, the external empowering team, a social organisation named the Clover Nature School began to build the first batch of Love-U gardens in community R.

4.1.1 Construction of the benchmark

In the early stage of the construction of the Love-U gardens, there were few responses and slow progress because residents did not understand the concept of the community garden. The Children's Garden in the first phase of community R is a turning point in the construction of the Love-U gardens in the community. The backyard of Teacher Qin's children's picture book library in the community is full of construction waste and has serious rat infestation. He hoped that with the help of the Love-U Garden project, the green space downstairs will be transformed into a public rest space for neighbors and a venue for nature education. Through the demonstration

and leadership of a external professional team, the construction of the Children's Garden has attracted the attention and participation of other residents. In response to residents' questions about the publicness of the garden, the team patiently explained that all Love-U gardens cannot be closed to ensure that all the residents can share them, and that each garden requires at least three flower lovers to sign in order to gain support. In the end, the Children's Garden received unanimous praise from residents and triggered a wave of applications for Love-U gardens in the community (Figures 2 and 3).

Figures 2 Children's Garden

Figures 3 Public engagement

4.1.2 Spread of gardens

The benchmark effect has driven the discussion and dissemination of public issues. With the continuous empowerment of the external team, the community action of the Love-U Garden has spread with the help of the social network. Due to the limited number of applications, the team had to raise the standard. Each garden requires 20 residents to sign in order to obtain project support. The growth and spread of the garden are reflected in three aspects: 1) The cost of a single Love-U Garden is limited. The team encourages some flower lovers to crowdfund and purchase more beautiful and durable rest tables and chairs and other garden facilities, which are used as references in other gardens. 2) The team provides professional guidance to assist residents in expanding garden design and improving garden quality. 3) Residents who have not applied for the project are encouraged to learn from the experience of the Love-U Garden and improve their own gardens downstairs. By April 2023, community R has completed the construction of 228 Love-U gardens, cultivated 370 flower lovers, and built a systematic garden space network and a social network of flower lovers of all ages.

4.1.3 Negotiation of responsibilities

After the guidance and coordination of the external team, the residents and the property management company reached a consensus on the maintenance of the Love-U gardens: the property company equipped the core flower lovers with the public faucet key, the flower lovers were responsible for daily watering and maintenance, and the property company was responsible for the bottom and provided professional support. After the garden was built, there were also neighborhood conflicts. Some Love-U gardens added hard paving and seats due to the needs of socializing and resting, and other residents complained that the project reduced the greening rate of the community. Under the guidance of the professional team, the flower lovers quickly drafted and collectively signed an application to retain the existing Love-U Garden, which was supported by the government and finally successfully protected the achievements of the Love-U gardens. The Love-U gardens have become the common property of the community.

4.2 Internal and external collaboration type

Community J is the only large-scale Love-U Garden in Xingning District and also the community with the largest number of flower lovers in Xingning District. The community was built in 1999 and is one of the first batch of high-rise residential communities in Nanning. It consists of 4 high-rise buildings surrounding a central garden. However, due to its age, the greening design cannot meet the living needs of residents, and poor maintenance has caused some green spaces to become barren.

4.2.1 Space exploration

The construction of Love-U gardens adheres to the concept of companionship construction and gradual regeneration. In May 2022, the external team entered the community J. At the beginning, because residents, the community owners committee and the property management had low acceptance, the professional external team chose a messy corner next to the fitness area as the startup project. There are three reasons for this decision. Firstly, the difference between before and after is obvious. Secondly, it was close to the activity areas for children and the elderly. And thirdly, it was close to the residents' fitness area. As the project progressed, residents turned from bystanders to participants and put forward more demands for garden renovation. On the technical level, professional teams, social organisations and local residents jointly explored sustainable garden design, tried to grow local edible plants, experimented with kitchen waste composting technology, and used idle old items to make simple rainwater collection device system.

Figures 4 Love-U Garden in community J

Figures 5 Rainwater collection device system

4.2.2 Collaborative construction

The construction of the Love-U gardens attracted the participation of many partners. The environmental protection social organisation held 8 edible garden course trainings, which assisted the implementation of the garden and attracted other local participants. As a semi-open community, this community is also a playground for children from the nearby vegetable market. The destructive behaviour of outside children caused dissatisfaction among the children in the community. But when they participated in the Love-U Garden construction, the barriers gradually disappeared, and the previous opposition turned into concerted action. Guangxi Academy of Arts led residents to complete the construction of the Travel Garden and the Windmill Garden using on-site waste. The social organisation "Little Volunteers" collaborated with community children to upgrade rainwater collection devices, create stone paintings, and realize the implementation of the Colorful Garden and the Bubble Garden. From May to August in 2022, Community J cultivated 88 flower lovers and completed 64 Love-U gardens, including one large garden.

4.2.3 Continuous community action

During the design and construction process, residents put forward more practical suggestions, such as the installation of seats and irrigation facilities, and continued to negotiate and co-create in the maintenance of the garden. The Edible Garden designed a compost tower, but after it was built, residents thought its shape was unlucky and had a peculiar smell, and asked to remove it. After communication, the external team decided to dismantle the compost tower and transform the materials into round planting boxes, named "Bubble Garden", and the residents who originally opposed it also happily participated in the construction. After the overall completion of the garden, the co-construction team launched a guide training program to cultivate concept disseminators and community connectors for the community garden. At the end of August, Community J held the "Cooling Party", which not only spread the concept of the Love-U Garden, but also enhanced the residents' sense of community identity and cohesion.

4.3 Internal autonomy type

Community N, located in Qingxiu District, was built in 2003. It was once one of the highest-quality residential communities in Nanning at that time and was rated as an "advanced greening unit". However, over the past 20 years, due to poor operation and management of the community, the facilities have aged and it was listed as a "poor" community by the Nanning Housing and Urban-Rural Development Bureau in 2022. After several years of hard work by the community owners, a temporary owners' meeting was finally established in 2023, and the original property company was replaced by a state-owned property company under a commission system. Therefore, community N has a good foundation for community autonomy and public engagement.

4.3.1 Leverage of crowdfunding

In 2023, the Love-U Garden project team launched the Love-U Garden Seed Fund Plan, providing a menu-style material package to encourage the community to raise funds to build a small community garden. After the active introduction of property management company, a design workshop was organized in the community in July of the same year. More than 10 flower lovers discussed the garden plan with the designer to determine the site selection and bill of materials. Flower lovers began to spontaneously crowdfund funds based on the material package. After a building invested five material packages, residents not only raised about 30,000 yuan in construction funds, but also actively contacted nearby auto repair shops to use recycled tires to make garden scenery, and finally transformed the garden area to 30 square meters (Figure 6). As of the beginning of 2024, community N has invested a total of 30 material packages and successfully mobilized owners to raise a total of 70,300 yuan.

Figures 6 Love-U Garden in community N

Figures 6 Star Garden

4.3.2 Links of actions

The Star Garden is the first Love-U Garden in community N. It was initiated by an enthusiastic flower lover and built in advance (Figure 7). Driven by the pioneers, the community ushered in an unprecedented self-organized construction. In the end, a total of 22 Love-U gardens were applied for and built, with more than 200 residents participating. In the early stage of garden construction, there were also cases of tools and plants being lost, but some flower lovers took the initiative to provide help between the gardens. On one hand, it stimulated the public awareness of other residents. Everyone began to share plants and tools and help each other. Some white collars also participated in the construction until late at night after get off work; on the other hand, the construction action built a neighborhood network. The flower lovers' dinner after the construction made neighbors who had not communicated with each other become familiar with each other. The property company also actively supported and participated in the construction of the garden, and carried out daily cleaning and maintenance of the garden, becoming a part of the life community.

4.3.3 Co-creation of festivals

Love-U gardens in community N introduced digital community participation tools. Flower lovers used WeChat applet to record the process of garden construction, which not only preserved precious construction memories, but also became a platform for daily communication, sharing poetry creation and life details of the subsequent garden growth. While Love-U gardens improved daily rest space, they also inspired more public communication behaviours.

Some residents took the initiative to take out tea sets and invite neighbors to share and maintain. The owners spontaneously organised a community garden festival and invited the government, property management and professional teams to celebrate together. Flower lovers wrote lyrics to connect the names of all gardens and sang them on the spot.

Through the construction of Love-U gardens, the relationship in the community N has become more harmonious, and the sense of belonging and identity of the community has been further strengthened, becoming an "urban utopia" in the mouths of residents.

5.Conclusion

The three models of Love-U gardens summarized in this article each have their own applicability. The external empowering type mainly relies on the guidance, demonstration and long-term empowerment of professional institutions. It is suitable for communities with both aging infrastructure and population, weak public participation foundation, and scarce social resources. However, its limitation is that it requires high capabilities and investment from professional institutions. The internal and external collaboration type mainly relies on external diverse social forces for collaboration and co-creation. It is suitable for communities with relatively rich social resources, rich community age structure, and strong participation potential. Its limitation is that it requires high resource integration capabilities of the community, and it is necessary to improve the later maintenance and co-management mechanism of the garden. The internal autonomy type mainly relies on the endogenous power of the community and the self-driving force of residents. It is suitable for communities with a good public engagement foundation, relatively complete infrastructure, and strong community self-organizing ability. Its limitation is that it requires high community autonomous management capabilities and the coordination of owners.

The concept of collaborative governance is introduced throughout the entire process of Love-U gardens. In the planning and design stage, Laoyou-councils' meetings are held to summarize the real needs of residents. In the construction stage, designers plant plants with residents to stimulate residents' physical participation. In the maintenance and management stage, the external team guides internal residents and other parties to clarify responsibilities, co-create a long-term maintenance mechanism, and determine different maintenance models for gardens of different sizes. The external team accompanies the entire process, hoping to use Love-U gardens as a starting point to allow the community to generate more internal spontaneous public actions.

For the application of different community garden construction models, the specific operational suggestions are as follows: 1) The external empowering type should further promote the construction of the entire process. Through the construction of an integrated mechanism of planning, construction, management and operation, the dual improvement of "material" and "non-material" in old communities can be achieved. 2) The internal and external collaboration type should actively link the participation of all age groups, create an all-age friendly participation path by linking multiple resources, cultivate a self-organized team of flower lovers, and promote the sustainable growth of community gardens. 3) The internal autonomy type should focus on encouraging multi-channel fund raising, introducing social forces to create inclusive projects, leveraging residents' independent co-funding and self-empowerment, and achieving continuous construction and long-term operation and maintenance.

As a city-level community garden network construction practice, Nanning Love-U Garden is also a social experiment in community space collaborative governance based on community deliberation. The Love-U gardens not only improve the living environment of old residential areas, but also reshape local social interactivity through public engagement, enhance residents' subjectivity and sense of belonging, mend and repair community social networks, and promote the formation of community consciousness, becoming the finishing touch of Nanning old residential area regeneration. At the same time, the practice of Nanning Love-U gardens also has certain theoretical guidance and practical reference significance for other Chinese cities to create community garden networks, promote collaborative governance of community regeneration, and promote sustainable development of urban communities.

PARTICIPATION AFTER DISASTER: CENTRAL GOVERNMENT APPROACH TO PARTICIPATION PLANNING

Beyza Kurt
Affiliation: ITU Faculty of Architecture, Urban Planning Master's Program
Email: kurtb24@itu.edu.tr

Abstract
The 21st century is an era of crises, driven by the increasing impact of climate change and successive crises ranging from environmental degradation to social and economic inequalities. This multi-crisis environment has necessitated the adoption of holistic, inclusive, and participatory approaches in managing disaster risks. The focus of this study is to examine the participation perspective in Türkiye's recovery process after the February 6, 2023, Kahramanmaraş earthquakes from the institutionalized participation understanding in the world. In this context, the stakeholder participation plan in the Rural Areas Earthquake Recovery and Reconstruction Project (KADİYAP) carried out by the Ministry of Environment, Urbanization, and Climate Change was examined, and the central government's approach to managing the participation process was evaluated in line with the determined criteria.

Keywords: Disaster Management; Participation; Stakeholders; Inclusivity; Central Administration

Introduction

The crisis period that emerged in the early 21st century, after the concept of the Anthropocene was defined the successive crises experienced in the world. The world continues to experience crises related to each other due to the irreversible impact of humanity on the environment. Şengül (2023) points out a complex structure and interaction, and groups global crises under the following six main headings: Economic/Financial, Social Welfare, Ecological, Border/Refugee, Urban, Governance/Democracy. Just as the governance systems of all countries have difficulty adapting, Turkey's governance system is also struggling with crises. The current governance system is expected to overcome the crisis by intervening with short-term policies in the face of crises. However, the crisis experienced by complex social, economic, spatial, and environmental relations networks causes other crises. According to Lister and Wilde (2020), governance systems that can adapt to the constantly changing needs, expectations, rights, and abilities of all actors and institutions that make up our societies need to be created. Such a system will require deliberative dialogue and engagement with many actors (business, civil society, politicians, communities, trade unions) and political coalitions at all levels.

Turkey, like the rest of the world, has had to deal with economic crises, epidemics, fires, floods, and earthquakes one after another. Especially after the February 6, 2023, earthquakes, it was observed that the central government's ability to respond to disasters from a single source was not possible due to related crises. Therefore, responsibility should be shared with local governments, communities, and the central government in response to disasters and the recovery process. All actors are expected to participate in the process to meet their needs.

Methods

Effective disaster management relies on the active involvement and collaboration of governmental bodies, civil society organizations, and the general populace. Engaging local communities in the recovery efforts following a disaster can mitigate the risk of future crises. However, the central government needs to adopt a deliberate political system that facilitates the participation of various actors. This study aims to evaluate the approaches included in the stakeholder participation plan prepared by the central government during the post-disaster recovery process and to develop a guiding framework with new strategies that will enhance social participation.

The research topic focuses on how the central government addresses social participation in post-disaster recovery processes. This necessitates asking the following questions:

How does the central government approach social participation in post-disaster recovery processes?
Does the strategy for community involvement in post-disaster recovery align with the established principles of participation as outlined in existing literature?

The first section explains the concepts of participation and disaster management and evaluates their relationship with each other. This paper examines societal-focused strategies in disaster management, providing both conceptual frameworks and methodological insights, while also identifying key principles essential for engaging

communities in post-disaster recovery, based on a thorough review of existing literature on these strategies. The second section examines how the central government involved local communities in the rebuilding after the February 6 earthquakes. The final section presents a conclusion and evaluation based on the assessments of all previous sections.

Within the scope of the study, concepts and approaches were examined to create a conceptual theoretical framework. As a result, the parameters affecting participation in contemporary Turkey and the issues that need to be considered were identified. As a result of these examinations, the stakeholder participation plan in the Earthquake Recovery and Reconstruction in Rural Areas Project (KADİYAP) carried out by the Ministry of Environment, Urbanization, and Climate Change with the financing of the World Bank was examined and the central government's approach to managing the participation process was evaluated. All information regarding the meetings to be attended by the public and the reports prepared after the meetings was announced on the General Directorate of Construction Works website. The data sources obtained from these reports are;

- Participation methods of the Stakeholder Groups determined within the Scope of the Project,
- Complaint Methods,
- Number of people attending official meetings held after the disaster,
- Question-and-answer sections of the meetings.

This data was evaluated using the participation principles determined from the literature.

Conceptual framework

The Concept of Participation and Participatory Processes

The term participation has been discussed and used in literature in various ways by different authors throughout history. Western authors have used it to understand the relationship between citizens and state institutions. Arnstein (1969) examined citizen participation and its relationship with the social imperatives of the time. In answering these questions, he created a participation ladder consisting of 8 levels of participation. Each step in these eight levels of participation corresponds to the degree of citizens' power to determine the final product (Figure :

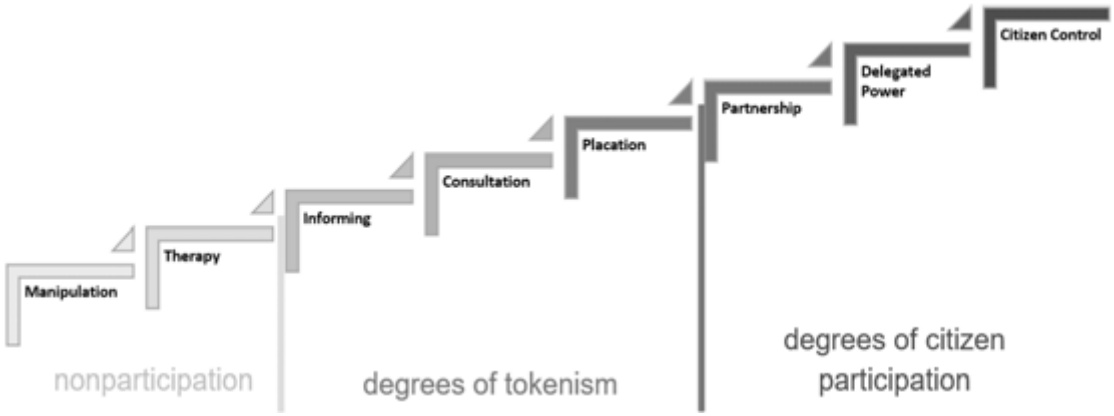

Figure 1: Arnstein's participation ladder

Many organizations, such as the International Association for Public Participation (IAP2), are inspired by Arnstein's participation ladder and propose a public participation spectrum. However, there are criticisms about these participation spectrums that do not cover all segments of the population in the world. For example, Cornwall and Goetz (2005) emphasize fairness to marginalized groups, especially women, in the radical redistribution of resources and power relations. According to authors such as Cornwall, Goetz, and Arnstein, one of the criteria to be considered in a participation process is to ensure a fair sharing of power.

From a planning theory perspective, efforts should be made to ensure that all interests are considered and met in a general plan during participation (Innes & Booher, 2002). This can only be achieved if the process includes all segments of society.

As Arnstein also mentioned in the participation ladder, participation is, in theory, the cornerstone of democracy. The OECD (2001) provided information on the elements that indicate the quality of democracy in its report on participation. Governments demonstrate the success of democracy through the transparency, accountability, and effectiveness of their policies and decision-making processes by increasing information, public consultation, and active participation. Governments must be responsible for using citizens' input received through feedback, public consultation, and active participation. In short, governments are expected to manage a transparent and accountable process by creating an area where citizens can actively participate.

Disaster Management and Post-Disaster Recovery Processes

To determine the criteria for post-disaster participation, scientists from various fields working on disasters were considered. Quarantelli, one of the pioneers of disaster sociology, considered disasters to represent fragility, reflecting "weaknesses in social structures or social systems" (Rodriguez, Quarantelli, & Dynes, 2006). In the same book, he mentioned that disasters are not just physical events. They affect individual coping patterns and the inputs and outputs of social systems. They are also rooted in the social structure and reflect the processes of social change. Due to the characteristics of the social system, it is fragile against disasters (Rodriguez et al., 2006). To better understand the vulnerabilities and responses of the social system during disasters, including local communities in the process, ensures a more effective and fair recovery. Geographer Cutter (1996) addresses the fragility of the social system by relating it to space. When addressing fragility spatially, he evaluates it according to its proximity to the disaster, the frequency of the event, its magnitude, and its duration. In the social system, factors such as infrastructures that meet basic needs, populations with special needs, poverty indicators, gender, and race are addressed (Cutter, 1996). It is of great importance to include all affected community groups, especially women, children, the elderly, the disabled, and ethnic minorities, in post-disaster processes.

Earthquakes have also been evaluated in terms of their impact on administrative processes and their effects on society. The United Nations Office for Disaster Risk Reduction (UNDRR) has prepared the Sendai Framework (2015) for disaster risk management at national and local levels, focusing on earthquakes. It emphasizes the shared responsibility between the central government and national authorities, sectors, and stakeholders, following national conditions as one of its basic principles. UNDRR has prepared a guide to support the implementation of the Sendai Framework, ensure the participation and ownership of all stakeholders in action, and strengthen accountability in disaster risk reduction. Another international organization, IFRC (2011), emphasizes transparent information sharing, meaningful beneficiary participation, effective and efficient use of resources, learning systems, and responding to concerns and complaints in line with accountability.

Oliver-Smith (2018) has studied the lack of such coordination in post-earthquake displacement processes. The basic approach of the post-disaster government is to maximize the number of houses built based on the idea of housing, leaving only a physical object to be transferred to the residents, who are given little opportunity to participate in the process. There was also harsh criticism of corruption and politically motivated aid distribution. In explaining the difficulties faced by both people and planners, he argues that a fully participatory approach is necessary because resettlement has inherent complexity, with "a range of factors from different orders such as cultural, social, environmental, economic, institutional, and political being interrelated." From Oliver-Smith's critiques of the post-disaster process, the importance of transparent information sharing in the participatory process emerges.

The conceptual framework (Figure 2) developed to evaluate the effectiveness of participation in post-disaster recovery processes is based on the principles of justice and power sharing, transparency and accountability, and inclusiveness. This framework aims to ensure equal access to decision-making processes for all stakeholders and to strengthen communities based on social equality. Transparency ensures that decision-makers are accountable to communities through the open and understandable flow of information, i.e., a responsible process. The principle of inclusiveness ensures the participation of all segments of communities in the processes. In addition, feedback mechanisms and continuity of processes enable more responsive and long-term solutions to be provided to the needs of communities. This framework is a one-to-one guide for effectively evaluating participation processes.

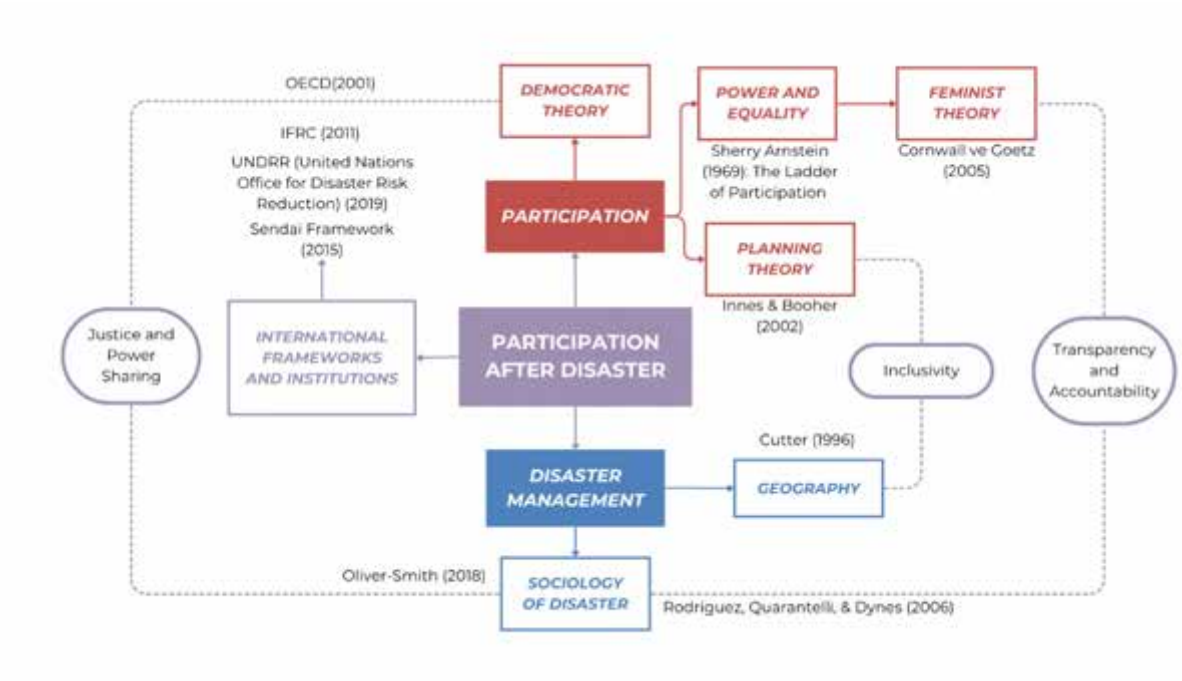

Figure 2 Conceptual Framework Created Based on Literature

Recovery process after the February 6 Kahramanmaraş earthquake

On February 6, 2023, two earthquakes centered in Kahramanmaraş with magnitudes of 7.7 and 7.6 Richter occurred, affecting 11 provinces and more than 14 million citizens. As 22 months have passed since the earthquakes, the government has begun to deliver the houses built after the disaster.

The Turkey Earthquake Recovery and Reconstruction Project (TDİYP) was developed for housing to be built in rural areas, managed by the Ministry of Environment, Urbanization and Climate Change (ÇŞİDB) and the Disaster and Emergency Management Presidency (AFAD). Financed by the World Bank, this project has prepared a Stakeholder Engagement Plan (SEP) per the ESS10 standard titled "Stakeholder Engagement and Disclosure of Information". The project aims to ensure continuous participation and consultation of its stakeholders throughout the project period.

The project aimed to conduct meaningful consultations with the stakeholders on;

i) designs,
ii) scope of agreements and financial obligations,
iii) identify other needs of stakeholders that can be considered/supported and match these with the existing support provided by the government.

After the damage assessment studies were completed, information meetings were held with the participation of the local people, mukhtars, NGOs, and district governors (Figure 3). The Q&A section of these meetings, where the concerns and suggestions of the people were received and housing designs were presented, was not reported because there was no ministry staff. As can be seen in the photograph in Figure 3, it was observed that there was little female participation in these meetings held in the first two months of the earthquake. In addition, the lack of reporting of Q&A shows a lack of transparency in participation.

Figure 3 Malatya-Akçadağ-17.03.2023

Project Stakeholder Participation
Project stakeholders and interested parties with a stake in the project are directly or indirectly affected. The implementation is aimed at being implemented with three basic principles;

- Openness and life cycle approach
- Informed participation and feedback
- Inclusiveness and sensitivity

It is planned that the participation activities of the determined stakeholders will continue throughout the project. All information regarding the meetings to be attended by the public has been announced on the YİGM website. Meetings are also held to receive the feedback of the muhtars for the houses whose construction process has been completed.

Inclusivity is A common theme in the participatory planning literature and project principles. Efforts have been made to provide participation support according to needs to include disadvantaged groups affected by the project, but cannot convey their concerns or understand the project outcomes (Table 1).

Table 1 Participation Methods of Stakeholder Groups Determined within the Scope of the Project (H: High; M: Medium; L: Low)

Stakeholder Group		Interest Level	Impact Level	Participation Method	Additional Resource Support
Direct Stakeholders	Rights holders whose houses were damaged	H	H	High Consultation meetings, Face-to-face meetings, CSIDB website, Digital communication tools, social media, Project information brochures/flyers, Online meeting, Grievance Mechanism (CM)	
	CSIDB, KTB, SB, UAB, ETKB, TOB, TB, Presidency of Religious Affairs	H	H	One-on-one meetings Official meetings, Consultation meetings	
Indirect Stakeholders	Landowners and land users adjacent to buildings, the Municipality, and neighborhood residents	M	H	Consultation meetings, CSIDB website, Digital communication tools, social media, Project information brochures/flyers, Online meetings, Grievance Mechanism (GMM)	
Other Relevant Parties	Governorships/District Governorships and municipalities	H	H	Communication (Letter, Phone, Emails) One-on-one meetings	
	Construction companies and workers, Consultants, controllers	H	M	Face-to-face meetings	
	NGOs – Associations at local and national level, Media, General public	L	M	Communication (Letter, Phone, Emails) One-on-one meetings Official meetings Consultative meetings CSIDB website Digital communication tools social media	

Vulnerable individuals or groups	Individuals with disabilities	H	M	Face-to-face meetings Audio devices Accessible platforms etc.	Special education needs Special education coordinators, Sign language interpreters/ Translators
	Elderly individuals	H	M	Face-to-face meetings Communication methods in inaccessible areas	Not required
	Immigrants, refugees, and non-native Turkish speakers	H	M	Face-to-face interviews Translated documents Special interpreters Communication in inaccessible areas	Translators
	Pregnant women and/or Women with young children Female-headed households	H	M	Face-to-face meetings Communication in inaccessible areas and methods	Not relevant
	Children	H	M	Face-to-face meetings Trained facilitators	Specially designed communication environments and approach
	People with post-traumatic Stress Disorder (PTSD) / mental health issues.	H	M	Face-to-face meetings Trained facilitators Psychologists	Psychological support

The fact that the disadvantaged group is treated differently in the project's stakeholder groups brings another question. While the beneficiaries whose houses were damaged are the ones who are directly affected and interested, the level of impact on the disadvantaged groups is at a medium level. No additional source has been provided regarding the inclusion of women whose houses were damaged, especially the women heads of the family. In addition, although it is stated in the report that regional organizations and NGOs representing the rights of the disabled will be discussed, these institutions and NGOs are not included in the report.

Stakeholder Engagement Activities

The report published in November 2024 includes information on the participation of stakeholders in the meetings. A table is provided where we can see the distribution of the participating stakeholders by gender. In this context, the information in Figure 4 from two different districts of the 4 cities where the meetings were held

is summarized. As seen in Table 1, although additional resource support is not deemed necessary for women's participation, women's participation varies from place to place. For example, in Malatya, women's participation is very low in the Pütürge district, while in the Ören district, women's participation is higher than men's. The same situation applies to Elazığ and Diyarbakır. In Adıyaman, it is seen that women's participation was very low in the first meetings that had just started. Table 2 also shows the number of houses to be built in the neighborhoods where these meetings were held. Here, there are neighborhoods where total participation is very low compared to the number of houses to be built.

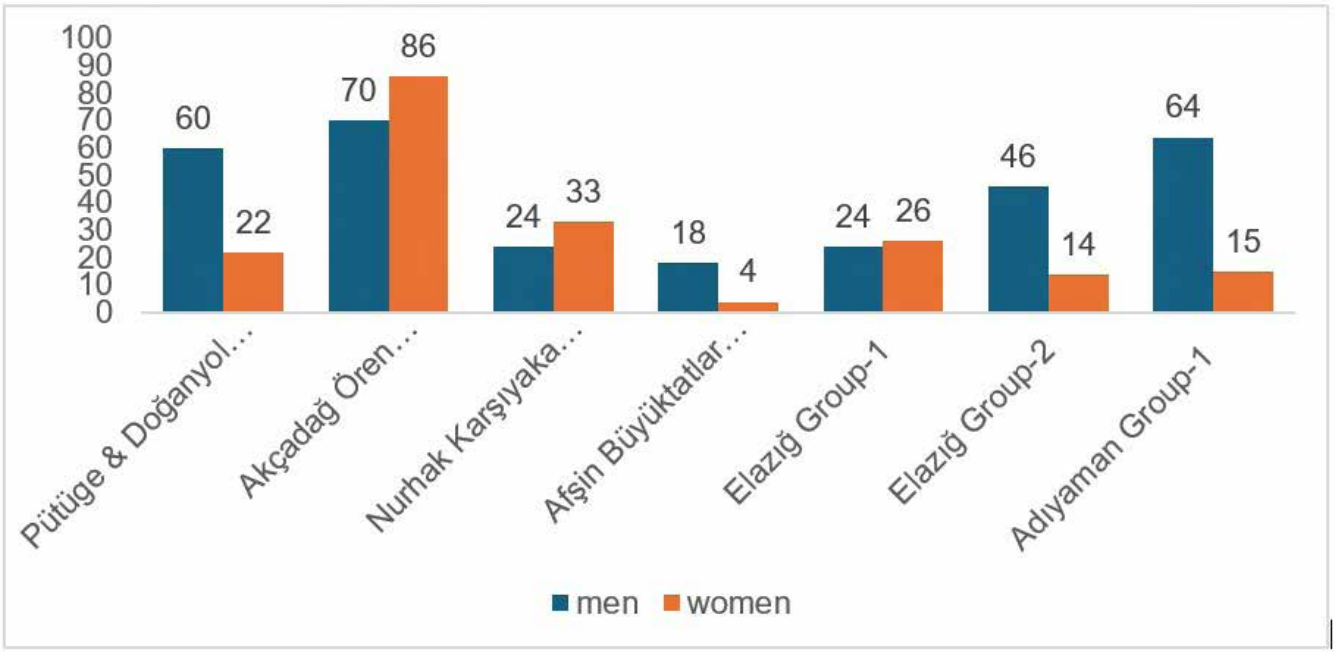

Figure 4: Number of male and female meeting attendance

Table 2: Participation in meetings and the number of houses to be built

	men	women	total	Number of houses to be built
Pütürge & Doğanyol /Malatya	60	22	82	105
Akçadağ Ören Mahallesi /Malatya	70	86	156	287

Afşin Büyüktatlar neighbourhood / Kahramanmaraş	18	4	22	23
Elâzığ Group-1	24	26	50	79
Elâzığ Group-2	46	14	60	172
Adıyaman Group-1	64	15	79	80

Most of Dessup's reports are on the website under Environmental and Social Management Plans (ESMPs). These reports also include Q&A sessions from village-based meetings.

Dessup – 01 Malatya

The summary of the Q&A session at the meeting held in Malatya Ören Neighborhood on November 9, 2023, is given in Table 3. The ESMP prepared for the project was hung at the Neighborhood Headman's Office entrance in Container City for 1 week (Figure 5). In the face-to-face meeting,

- Social Expert from the Administration;
- Social Expert from the Audit Consultant (Koltek);
- Technical team;
- Construction Site Manager from the Contractor (Pekintaş);
- Neighborhood Headman participated.

Table 3: Public Participation Meeting – Questions and Answers

Questioner	Question	Answer
Neighborhood Resident	The application was rejected because the warehouse was not demolished and registered as a house.	The delivery process of the house is related to AFAD. It was suggested that he meet with AFAD.
Neighborhood Resident	Cost / Credit	to be determined by the President
Neighborhood Resident	Natural gas in new housing Infrastructure requested	It is not included in the current plan. However, the Ministry of Energy and Natural Resources may direct a revision of the plan.
Neighborhood Resident	An increase in the number of housing units was requested	AFAD determines it
Neighborhood Resident	It was stated that the debris removal works were not completed, and there was a health risk due to asbestos among the rubble.	It was stated that the previous debris removal contractor left the job unfinished shortly after starting. A new contractor has been selected and is expected to arrive on-site soon.
Neighborhood Resident	Tenants	It was recommended that the tenants apply to TOKİ.
Neighborhood Resident	Suitability of houses for disabled individuals	It was mentioned that the interior arrangements can be made after the houses are allocated if an application is submitted to the Administration.

As mentioned above, questions were asked about the many mistakes that went wrong in the village areas. It was also stated that the number of houses was insufficient for the neighborhood. Guidance was given by saying that these two issues were under the responsibility of AFAD. Since the fees and installment method of the houses were not determined, questions were directed about this issue, but no clear information was given by the authorized persons on this issue. Natural gas infrastructure was requested for the houses, but it was conveyed that it was not included in the project and that the project could be revised if the Ministry of Energy and Natural Resources decided. It cannot be said that a healthy question-and-answer process was experienced due to the absence of state institutions that were the addressees of all these questions.

Figure 5 ESMP Suspension Photos (November 3, 2023) and Public Participation Meeting Photo
Dessup-02 Kahramanmaraş

Dessup-02 Kahramanmaraş
The Environmental and Social Management Kahramanmaraş reports dated May 2024 stated that the meetings had not been held yet, and there was no information about them. In the Stakeholder Participation Report published in November 2024, only photographs of the meetings were included (see Figure 6).

Figure 6 Dessup-02 Kahramanmaraş PKT photos

Dessup-03 Elazığ
In Elazığ, villages were divided into three groups based on proximity, and meetings were held accordingly. The ESMPs were hung in the mosques, Mokhtar's offices, and village construction sites (Figure 7). Who will have access to the hangar hung on the construction site is unknown.

Figure 7 Kambertepe and Altınkuşak ESMP Hanger Photos

In the face-to-face meetings, authorized names from the construction came as in Dessup 1. Therefore, the problem of not having people to whom the questions were addressed in Dessup 1 continued. The inquiries posed during the meeting exhibit a greater degree of reproach compared to those in Malatya, primarily due to the involvement of individuals who experienced a loss of rights following the 2020 earthquake. Individuals who were unable to acquire legitimate ownership of the earthquake-constructed residences from late 2020 to 2023 were once more referred to officials at AFAD. Another sensitive issue was that the barn for animal husbandry, a vital source of income for the villagers, was not included in the project. Due to the nature of the emergency, officials consistently emphasized that only shelter would be provided. Despite the presentation showcasing various homes, attendees were more focused on inquiries regarding payment options and costs rather than selecting a property. A further concern involved religious venues and community amenities. Just like the barn issue, they are not included in the scope of this project.

Table 4 Public Participation Meeting – Questions and Answers

Questioner	Answering the question	Question	Answer
Village Resident (Saman)	EMAY (Social Expert)	The barn is our main source of income; how will we survive without it if the project does not include one?	Since this is an "emergency" project, priority has been given to housing construction. Unfortunately, the barn is not included in the project.
Village Resident (Halkalı)	Administration (Environmental Expert)	We, as a family, are victims of the 2020 earthquake. Our houses were also destroyed along with the houses that were determined to be severely damaged in the 2023 earthquake, and we were not given the right of ownership; we were left homeless.	This situation is within the authority of AFAD. There is nothing we can do about it as the Ministry.
Village Resident (Çakmakkaya)	Administration (Social Expert)	Why is our village being built somewhere else, everything we have will remain here. We, as a people, are not happy with the new settlement.	You can also submit this to the complaint mechanism as a request. The parcel will probably not change, but let's talk to the Ministry
Village Resident (Kambertepe)*	Administration (Social Expert)	The Site Plan has changed, our houses are being built in a different place than the parcel we previously accepted. We want the previous site plan.	There are conditions for changing the Site Plan, it cannot be changed without reason. It cannot be changed without the knowledge of the Contractor and Consultant. Please put your complaints in the complaint boxes.
Village Resident (Kambertepe)	Administration (Social Expert)	Everything needs to be rebuilt in the new place. These (mosque, imam house) need to be built urgently. Will these be built?	Places of worship and other social facilities are not within the scope of this project. All needs are evaluated in the site plans, and planning is done accordingly.

*Participants in Kambertepe did not sign the participant list because if they had, the location of the parcel would have been considered accepted.

Figure 8: Stakeholder Participation Meeting Photos

Complaint Resolution Mechanism:
The World Bank has established a transparent and accountable process for stakeholders to voice their complaints, concerns, and suggestions regarding projects it finances. This mechanism aims to document complaints and systematically provide feedback and learning. Table 5 outlines the various methods for stakeholders to file complaints related to this project's framework.

Table 5 Grievance Redress Mechanisms by Level

Level/Area	Implementation Details
PIU Level CCM	Confidentiality and Anonymity: The right to file a complaint is guaranteed. Registration Process: Complaint information is recorded in a complaint log by trained personnel. a. Stakeholder name and contact information (personal information is not shared with third parties). b. Details how and when the complaint was submitted, accepted, responded to and resolved.
National Level SCM	Complaint Channels: a. Presidential Communication Center (CİMER) b. Foreigners Communication Center (YİMER)
World Bank Grievance System	All projects financed by the World Bank have a Grievance Service (GRS).
Worker Grievance Redress Mechanism	Workers may use a separate grievance mechanism to report: a. Working conditions b. Financial concerns c. Child labor/forced labor d. Legal issues e. Workplace gender-based discrimination and sexual harassment.
Sexual Exploitation and Harassment Management	Grievance Line: A grievance line has been established to address SSI/ST cases arising from project activities. Labor Management Procedures (LMP): The August 2023 report details behavioral guidelines for contractor personnel to prevent sexual assault.

Ongoing KADİYAP Feedback:
The KADİYAP project has received significant feedback from stakeholders through the PIU. The most common complaints, suggestions, and concerns include:

- Issues with property rights.
- Dust generated by construction machinery.
- Damage to village roads from heavy equipment.
- Lack of appreciation for project implementation.
- Requests for additional housing.

The complaints received from the feedback are also common in the meetings. However, the central administration has made no new decisions regarding these complaints during the process. The process continues as it started. This mechanism is limited to listening to citizens only. In addition, if the responses given to the complaints received are in the form of directing them to another institution, as in the meetings, this participation will be put in a vicious circle.

My request for information via Cimer for the writing process of this statement has been left unanswered for 2 months. All these are elements that disrupt the transparency of the process. Finally, the feedback system for harassment management, which is explained in detail in the labor procedure, raises new concerns about the participation of women in rural areas.

Evaluation and conclusion

The stakeholder participation plan prepared by the central administration for the accountability of the KADİYAP project, financed by the World Bank, has been examined. It is the first study conducted in Turkey to ensure participation in a disaster of this scale. In addition, the World Bank announced in its press release published in December 2024 that it approved new financing to support the Improvement of the Agricultural Sector in Earthquake-Affected Regions of Turkey. This participation plan, aligned with KADİYAP, seems to lead the way for other projects. To eliminate the errors and deficiencies made in line with the literature for plans, 3 main criteria for participation should be emphasized.

The main goal of international organizations such as UNDP is to ensure democratic participation where stakeholders can have power in recovery through the participation process. However, in this project, stakeholders are content with only receiving information about the process. Most of the statements cannot be eliminated from being one-sided, such as not doing anything other than referring AFAD officials to the housing ownership situation, which is the most common issue in the Q&A section of the meetings. Power sharing between the central administration and the local government is achieved through mutual dialogue. Otherwise, as Arnstein mentioned in the participation ladder, the participation process is only manipulation. The participation process has been seen as a procedural requirement only, and no extra work has been done to include all disaster victims in the process fairly. Regarding the fair distribution of power, it is striking that Adana, Diyarbakır, Gaziantep, Hatay, Kilis, Osmaniye, and Şanlıurfa, out of the 11 provinces that experienced the earthquake, were not included in the reports, and there was no reason for not including them.

This brings us to another problem: the process is not being inclusive. As Cornwall and Goetz mentioned, marginalized groups should be worked with to distribute resources and power equally. Given that women's participation differs from one village to another, it is essential to assess field-specific strategies, and collaborating with village associations or NGOs could prove beneficial. Furthermore, the established complaint mechanisms can serve as excellent models of inclusivity globally. Nonetheless, the effectiveness of these mechanisms relies on the central government, leading to citizens' apprehensions about their involvement. Thus, it is crucial to align the complaint mechanisms more closely with the efforts of NGOs and local governments.

Another issue is transparency and related accountability. The project prioritizes this objective, leading to the establishment of meetings and the implementation of complaint resolution systems. However, there is a power dynamic created by a complaint mechanism that is completely dependent on the central administration. Gathering complaints directly under the central administration transforms participation into a system where the government controls the citizens. Communicating grievances directly to the government is a symbolic means of involvement. Their goal is to calm the public reaction against the administration rather than real change. Finally, for this plan to be interactive and participatory, it needs to create areas where stakeholders can negotiate among themselves, and it is expected to be a flexible and transformative process for the upcoming process.

Abstract
Low-rise, low-density housing continues to dominate Ireland's housing sector, despite policy ambitions and climate targets that promote compact urban growth (CUG). This study investigates the persistent gap between national planning goals and actual housing delivery. Using a qualitative approach, semi-structured interviews were conducted with developers, architects, and housing experts to examine barriers to implementing CUG. Key themes that emerged include typology viability, embodied carbon, and future housing trajectories. Findings highlight regulatory constraints, car-centric planning practices, and market preferences for low-density housing as key barriers. These insights reveal a critical misalignment between policy and practice, offering a foundation for more targeted interventions to support sustainable, low-rise, medium-density housing in Ireland.

Keywords: Compact urban growth, housing delivery, planning barriers, embodied carbon, Ireland

Introduction

Ireland is experiencing an ongoing housing crisis (Ibec, 2023), with a system that fails to meet the needs of its growing population. Despite sustained policy efforts, housing output continues to lag behind demographic demand (OECD, 2025). In 2022, Ireland's population surpassed five million for the first time since 1851 and is projected to reach seven million by 2057 (Central Statistics Office, 2022). National policy currently targets the delivery of 33,000 new homes annually over the next decade, though recent analysis suggests that this figure may need to rise (The Housing Commission, 2024). However, if these dwellings are provided using a 'business as usual' approach to embodied carbon and a 'target achieved' operational carbon reduction scenario, Ireland will fail to reach its carbon targets (O'Hegarty & Kinnane, 2023).

Currently, the most delivered housing typology is low-rise, low-density, often located on greenfield sites on the edge of urban areas (SCSI, 2023). This model generates roughly 30% more embodied carbon per unit compared to infill alternatives, due to the additional infrastructure required (Brady et al., 2024). Shifting toward low-rise, medium-density infill housing could significantly reduce emissions while making more efficient use of land (Brady et al., 2024).

Irish government policy strongly supports compact urban growth. The *National Planning* Framework 2040 prioritises high-quality urban places and compact settlement, with 'Compact Growth' as the lead objective in the *National Development Plan 2021–2030*. Action 16 of *Town Centre First* promotes local TCF Plans aligned with this approach. The Sustainable Residential Development and Compact Settlements (SCSG): Guidelines for Planning Authorities (DHLGH, 2024) further support CUG through changes such as reduced back-to-back distances and lower parking requirements near public transport. Yet in practice, compact housing delivery remains limited: in 2022, 64% of homes were detached or semi-detached, while terraced homes—aligned with compact forms—accounted for just 19% (Central Statistics Office, 2022).

These patterns reflect Ireland's history of dispersed, low-density urban development (Mccafferty, 2019), marked by segregated land use, car dependency, and weak coordination between housing, transport, and planning (Mccafferty, 2019; O'Driscoll et al., 2023) . Despite policy commitments, spatial practices shaped by historic norms and infrastructure continue to dominate (Rau, 2009).

This paper examines the barriers to implementing compact, low-rise, high-density housing in Ireland. Interviewees were asked to identify current obstacles to delivering such housing, defined here as approximately 80 dwellings per hectare over four storeys on appropriate sites (RIAI, 2022). Drawing on semi-structured interviews with planners, policymakers, developers, architects, and housing experts, the study highlights the regulatory, institutional, and market challenges that constrain delivery. It offers a practice-based, multi-stakeholder perspective that contributes to ongoing debates on sustainable urban development and climate-responsive housing.

Literature Review

Defining Compact Urban Growth

The OECD (2012) frames CUG as a model that promotes efficient land use while reducing energy consumption and car dependency. In the Irish context, the Royal Institute of the Architects of Ireland (RIAI) defines compact urban growth as a strategic approach to urban development that prioritises building within existing cities and towns, rather than expanding into low-density greenfield areas. This concept focuses on optimising land use, enhancing sustainability, and improving the quality of life for residents (RIAI, 2020).

Complementing this, the *Sustainable and Compact Settlements Guidelines for Planning Authorities* (2024) frame compact growth as a key policy objective aligned with the National Planning Framework. The guidelines aim to accommodate 50% of housing growth within the existing built-up footprint of Ireland's five main cities, and 30% in other settlements, primarily through infill and brownfield redevelopment. This supports the creation of integrated, connected, and liveable urban environments that efficiently utilise existing infrastructure and contribute to national climate (DHLGH, 2024). To facilitate this, the RIAI promotes a low-rise medium-density housing typology, defined as own-door homes delivered at densities of 35–80 dwellings per hectare, which supports sustainable urban consolidation while maintaining compatibility with existing suburban contexts (RIAI, 2022).

Impacts of Compact Urban Growth

Empirical studies demonstrate clear environmental and energy-related benefits of compact urban forms. Zeng et al. (2022) show that compact growth significantly reduces carbon emissions by clustering development near services and infrastructure. Gaur et al. (2024) reinforce these findings in the Irish context, noting that dense urban areas exhibit lower energy demands due to reduced reliance on private vehicles and individual heating systems. Literature also supports a correlation between increased building height and lower embodied carbon. Drewniok et al. (2022) found that buildings with 4–6 storeys strike the optimal balance in terms of material efficiency and embodied emissions. Increasing urban density can further support sustainable development by reducing travel needs, enabling resource efficiency, and preserving land for agriculture.

Studies across major European cities, including London, Paris, Berlin and Istanbul, confirm that compact or taller residential buildings consume less energy than low-density, detached housing forms (Ding et al., 2022; Iddon & Firth, 2013). In Chinese cities, Ding et al. (2022) show a similar trend, with $CO\Delta$ emissions decreasing in compact urban configurations, though moderated by specific density thresholds. Iddon & Firth (2013) also highlight that apartment buildings tend to have lower operational energy use, particularly in temperate climates, while detached homes offer better potential for renewable energy integration in warmer regions.

Compactness also supports shared infrastructure, reduces land take, and facilitates more efficient public transport (Ding et al., 2022; Iddon & Firth, 2013). Beyond environmental performance, compact urban growth can deliver social benefits such as improved access to amenities, equitable transit, and more inclusive communities (Ahlfeldt et al., 2018; Burton, 2001). These benefits, however, are contingent on high-quality spatial design and governance. Anderson (2015) shows that shared outdoor spaces can significantly enhance community interaction and liveability, provided they are thoughtfully integrated.

Economically, compact urban development supports productivity through agglomeration effects and reduces infrastructure costs. Research by Glaeser and Resseger (2010) and Litman (2015) shows that mixed-use, high-density environments increase land value, commercial activity, and tax revenue. In the Irish context, Wall & Crowe (2024) find that centrally located coworking spaces in compact towns stimulate local economies by boosting footfall and supporting service-based businesses, reinforcing the broader economic value of compact urban growth.

Barriers to Implementing Compact Urban Growth

While the benefits of CUG are well established, its implementation is consistently challenged by institutional, regulatory, and market constraints. Zu Ermgassen et al. (2022) warn that without a shift away from low-density development, emissions targets will remain out of reach. Barriers such as restrictive zoning, high land prices, and fragmented governance continue to favour suburban expansion, even where policy supports more compact forms (Farris, 2001; Rode, 2018).

Developers face increased costs and unclear sustainability expectations, while planning systems often prioritise high-rise, small-unit models over diverse, medium-density formats (Candel & Törnå, 2022; Parker et al., 2023). Suburban aspirations, outdated tools, and undervaluation of compact housing further reinforce low-density ((Gilbert et al., 2020; Haarhoff et al., 2013). Suggested responses include zoning reform, pilot projects, and cross-sector collaboration to enable more responsive and viable housing strategies (Parker et al., 2023).

Parker et al. (2023), examining the case of Ontario, show that even where demand for mid-density, family-oriented housing exists, entrenched development practices and investor preferences sustain a high-rise-dominated model. Their findings highlight how institutional inertia and market logic can override both policy intentions and public needs. This evidence supports growing calls for more grounded, stakeholder-focused approaches to planning reform.

Despite strong policy backing for compact growth in Ireland, there is a notable gap in research on how those delivering housing experience its barriers. Most existing literature emphasises policy or spatial modelling, offering limited insight into real-world implementation. This study addresses that gap by exploring how planners, developers, architects, and policymakers in Ireland perceive and navigate the practical challenges to delivering compact, low-rise, medium-density housing.

Materials & Methods

Qualitative Research

This research employed a qualitative methodology, using semi-structured interviews to explore the research questions in depth. Semi-structured interviews occupy a middle ground between structured and unstructured formats, combining a predetermined set of questions with the flexibility to explore emerging themes based on participant responses (Robson & McCartan, 2016).

Study Design & Participants

Primary data was collected through ten semi-structured interviews carried out in May and June 2023. Interviewees included five home builder developers (private and semi-state), one approved housing body, two architecture practices, one estate agency and one quantity surveying practice. Participants were selected based on their membership of the Irish Green Building Council (IGBC) and Construct Innovate (CI), along with their experience in the delivery of housing at scale in Ireland (>100 unit developments). A full list of interviewees can be seen in Table 1.

All conversations were carried out online and lasted approximately 1 hour. They were recorded to enable verbatim transcription, and each participant was allocated a pseudonym. An academic peer review was carried out in advance to ensure ethical compliance.

Table 1: A List of Study Interviewees

Position	**Type of Organisation**
Quantity Surveyor, Director	Quantity Surveying Practice
Architect, Urban Design Team	Architecture Practice
Architect, Director	Architecture Practice
Head of Sustainability	National Developer
Managing Director	Estate Agent Company
Head of Design	Approved Housing Body
Architect, Director	Architecture Practice
Planner	National Developer
Architect, Design Manager	Semi-State Developer
Director of Design	National Developer

Interview Structure

To explore contemporary challenges in delivering compact urban growth in Ireland, a series of semi-structured interviews were conducted with housing industry professionals. The purpose of the interviews was to investigate three core themes: the viability of different housing typologies, strategies to reduce embodied carbon, and anticipated future trends in housing delivery. These themes were selected to align with national policy priorities and to understand practical barriers and opportunities from the perspective of practitioners.

A common set of guiding questions was developed (see Table 2), with additional prompts available to expand on specific responses. Each session began with a brief introduction to the research project and the interview team (a lead and a supporting interviewer), followed by a short self-introduction from the interviewee. This approach ensured consistency while allowing for flexibility to follow emerging insights in real time.

Table 2: Interview questions
Viability 1. What type(s) of housing developments do you find viable to build in Ireland within the regulations and density guidelines at present? **Barriers** 2. What are the current barriers to building low-rise, medium-density housing of circa 80 dwellings per hectare over 4 storeys on these sites? **Embodied Carbon** 3. Who is measuring carbon in the housing development industry at present in Ireland? 4. How can embodied carbon be reduced in the construction of housing developments in Ireland? 5. Are home-buyers concerned about carbon and/or Building Energy Rating (BER)? **The Future** 6. How do you see these housing developments evolving by 2030?

Results

Interview Results & Discussion

This section presents the results of the interview process, followed by a discussion of key findings and methodological limitations. Interviews were conducted via Zoom and transcribed using Otter.ai. The transcripts were then imported into NVivo for coding and thematic analysis. The discussion is organised around the key themes that emerged during this process and is supported by direct quotations from participants. Particular emphasis is placed on Question 1, due to the strength and relevance of the responses it generated.

Part 1: Viability

The first question asked of participants was what type(s) of housing developments they find most viable to build in Ireland within the regulations and density guidelines at present? Nine out of ten respondents stated that single-family dwellings in semi-detached or terraced format on greenfield sites at a density of 30-40 dwellings per hectare (dph) are most viable.

Architect 1 stated, "*The developer's answer to this is going to be houses, houses all day long. They can be built in a timber frame system, can be rolled out quickly, can be completed in phases and sizes that suit them; they can sell them incrementally, which works with their funding model.*"

Developer 5 echoed this sentiment, "*In an ideal world for us, it would be housing, pure traditional terraced housing... at the moment, because of interest rates and all the rest, the only thing that's viable is owner-occupied housing. Duplexes or apartments just aren't viable for the private market.*"

However, in order to achieve densities dictated by policy, higher-density models are also built as part of these developments. Two of the nine noted that, given the availability of the State as a buyer, these higher-density models are equally viable at present.

Developer 2 noted, "*In terms of low density, [we've] no issue selling privately all day long but having said that, there are other routes to market, which are available at the moment, which means that the high density schemes are perfectly viable in the current political or economic climate....*

What we're seeing now is that entire schemes or certainly entire blocks will be purchased by either the LDA [Land Development Agency] or an AHB [Approved Housing Body]."

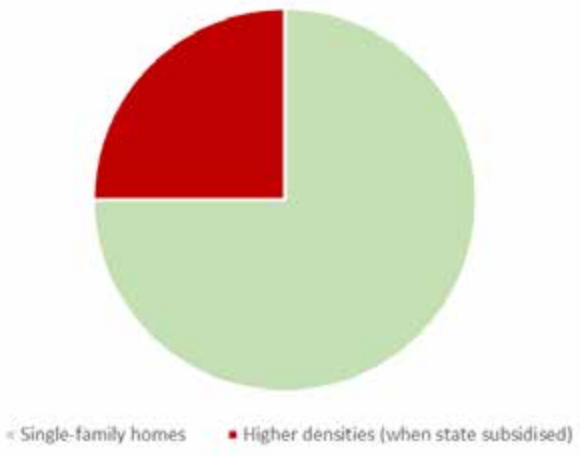

Figure 1: Industry Expert Responses to the Question: "What Is Currently Viable?"

Barriers

Interviewees were asked to identify the current barriers to delivering low-rise, medium-density housing, defined here as approximately 80 dwellings per hectare across four storeys on suitable sites. The two most commonly cited challenges were the difficulty of accommodating car-related infrastructure in line with stakeholder expectations identified earlier, and the increased costs associated with additional regulatory requirements. One underlying tension relates to the application of the Design Manual for Urban Roads and Streets (DMURS) — a national guidance document first published in 2013 and updated in 2019, which promotes street design that prioritises pedestrians, cyclists, and public transport within compact, walkable neighbourhoods (Government of Ireland, 2019). While DMURS supports reduced car dominance in urban areas, its principles are not always fully reflected in practice, where conventional standards around car access and parking continue to shape development layouts. This can limit the feasibility of delivering denser, low-rise housing formats on available urban sites.

Car-Related Infrastructure

The provision of, on average, two parking spaces per dwelling and associated roads limit achievable density. The reasons referenced for providing this quantum of parking, however, varied across interviewees; some attributed the issue to local authority requirements, while others related it to market preferences.

According to Architect 1, *"developers are very comfortable in the shared surface space and with DMURS and the reduction of the percentage of site that is occupied by road infrastructure."* Said architect noted the conflict between *"many development plan standards and DMURS and the conservative attitude of particularly the engineering departments within those local authorities"*.

This sentiment was echoed by Developer 5, who stated, *"Notwithstanding official policy, a lot of local authorities will still look for two parking spaces per house. We can live with one parking space per unit, but a lot of the time, they're looking for two. The planners will never override the role of engineers. The road engineers are still kind of the kings."*

Similarly, AHB1 noted a *"pushback from local authorities"* with regard to a reduction in the quantum of parking. Developer 1 stated, *"DMURS makes much more sense than the way we're forced to build roads around these estates. They are still predominantly car-focused rather than people."* One particular local authority dictates that houses are only built upon one side of a road: *"One of the issues we have from a density point of view is the requirement for roads that only have houses on one side."*

On the contrary, several interviewees stated that market preferences are the driver behind the quantum and type of car parking provided.

Developer 2 noted, *"Generally, we put a relatively high figure against the parking."* For example, in relation to Strategic Development Zones where there is a cap on parking, they stated that their *"marketing team are having to work hard to get their heads around how we sell something which doesn't have a dedicated parking space with it."*

Meanwhile, Architect 1 relayed anecdotal evidence from a homebuyer: *"If I can't see the headlights of my car from the sitting room, I don't want the unit."* However, it was added that this attitude is changing in well-connected locations.

Similarly, Estate Agent 1 noted that attitudes are changing within the market. *"The last six months have been transformative in terms of how people think around sustainability and their footprint. Last October [2022], nearly every other sale was cancelled because people were saying "we can't just deal with one car space", but there's an awareness now that it's the right thing to do, so it's less of an issue."* They also noted that *"Car charging is a much bigger issue now, so if you've off-curtilage parking, how do you charge your car?"*

Developer 3 described how these two issues of local authority requirements and market preferences are linked. *"The local authorities can say no. Fingal now wants 0.5 space for a 2-bed house. Now, that's all very well, in principle, but people are still going to buy two cars or at least a car, so it's going to be abandoned on the street, so your streetscape is going to be dire, there's no way of controlling that. Unless it's infrastructure-led, it just won't work."*

Costs

Respondents stated that higher density typologies (including duplexes and apartments) cost more to construct than houses and sell for less.

Developer 3 described the situation: *"A 2-bed apartment costs twice as much to build as a 2-bed house. A 2-bed apartment on average will cost €400,000 plus to build, a 2-bed house would be around €200,000/220,000."*

Estate Agent 1 echoed this sentiment: *"Typically, the guidance we're getting is that the duplex construction cost is somewhere between an apartment and a house. Then depending on where the policy supports are, the duplex will trade below a house".*

Developer 2 noted, *"If we had our way, we probably wouldn't want to build duplex blocks. They have a lower value than a house, and they're more complicated to build, so therefore, the return on them is lower than on the house."* The key factors contributing to the higher construction cost for denser typologies are outlined below in order of frequency mentioned.

a) Building regulations/Technical Guidance Documents (TGD)

According to respondents, when units are stacked to increase density, compliance with the building regulations becomes more complex. For example, accessibility requirements (TGD M) mean larger staircases and the introduction of lifts, while additional fireproofing between dwellings dictates a change to floor build-ups (TGD B).

Developer 2 stated, *"The regulations will dictate that we deliver a really high quality product. It makes them very expensive to build, and there's no getting away from that. If you had a four storey walk-up and you didn't have to put in lifts and so on and so forth, is that going to bring the price down? Yes, of course it is."*

Architect 2 backed this up *"What we're advocating for is that we make allowances to keep the existing provisions of Part M, to allow a duplex with an apartment on top or an apartment on the bottom with a duplex on top or duplexes stacked and also allow up to four floors with a Part M residential type staircase in the centre, which allows you to go 1800mm between breaks of landings, with two apartments per floor. That would really open up a much more economical way of doing housing with a provision to put a lift in at a later date if required."*

Architect 1 noted, albeit with an acknowledgement of the importance of the regulations, "*Over the last 10 years, nearly every aspect of the Building Regulations has become more onerous... the cumulative effect of all those things does make things more expensive. What would be useful is if there were percentages where there could be latitude. If you had, for example, 20% of units in a scheme that had a lower level of Part M accessibility, you will begin to see a different pattern emerging.*"

The method of construction for houses is familiar and quick. Much of the construction can take place off-site and is not reliant on specialist subcontractors or external design teams. Many respondents noted complexities associated with achieving compliance with TGDs when constructing duplexes and apartments using a timber frame system but stated that they are currently trialling solutions.

Developer 5 stated: "*Traditionally, for housing for a long time, we've been doing timber frame, but that's more of a cost decision rather than a green decision....I think it's challenging to do duplexes with timber frames. If we could do three and four-storey buildings in timber frame, I think that'd be a useful thing.*"

Developer 2 stated, "*We have trialled a model of using a fully timber-framed duplex unit.*"

Developer 1 noted, "*We'd like to go down the mass timber route for some of those [higher density schemes], but then we fall into the fire regulation limitations on that. That's something that is definitely holding back that side because we can find a business case for building with mass timber from the cost point of view, but it's something that just isn't as feasible at the moment with those fire regs.*"

b) Space standards

Back-to-back distances and garden sizes were noted by 40% of respondents as a barrier to compact urban growth. These interviews occurred during the summer of 2023, in the period when the Sustainable Residential Development and Compact Settlements (SCSG): Guidelines for Planning Authorities (DHLGH, 2024) released in January 2024 remained in draft (known then as the Sustainable Compact Settlement Guidelines). Discussions acknowledge the reductions in garden sizes and back-to-back distances proposed by the draft document.

Developer 4, who had examined the changes proposed by the draft SCSG noted, "*When we looked at it, it resulted in wider houses, your garden is shorter because they've reduced the back to back, but in order to get the minimum area, you end up building wider houses.... You end up losing out in the other dimension in terms of the density.*"

Developer 2 noted, "*At the moment, for a house, you have to [have] over 45 square metres of private open space etc. Whereas, for an apartment, you only need 7 square metres of balcony. Is there something that can happen there?*" They also stated the impact of these guidelines on typologies. "*Typically, to get over 35 or 40dph, you would have had to build some duplex blocks. With the compact growth [proposed SCSG guidelines], you may no longer need to build a duplex block; you could potentially do a scheme of all housing, quite compact housing onto a site now, just over 35dph.*"

Equally, regarding the internal layout of dwellings (and storage in particular), respondents noted the multiple standards and differing criteria depending upon whether a dwelling is classified as a house or an apartment. For example, as outlined in the '*Design Manual for Quality Housing*' and consistent with the 2022 '*Sustainable Urban Housing: Design Standards for New Apartments, 2022*', a 3-bed/5P House requires internal storage of 5 square metres while an equivalently sized apartment requires 9 square metres.

As Architect 1 noted, "*If you're providing a three-bedroom duplex, and you have to provide nine metres squared of storage internally within that unit, then it ends up being bigger than a house.*"

Developer 3 stated, "*The fact is, we have our minimum house area, but then we have about eight other sub-standards, minimum living room area, minimum living room width, and they don't relate to each other. So to deliver all those sub-standards, we have to inflate our house by 20% above the minimum.*"

With regards to apartments, Developer 4 has addressed this issue through the exclusion of en-suites. *"The way the areas have been set for apartments is if you don't have an ensuite, largely they're achievable. If you have an ensuite, it can be quite challenging to get down to the minimum areas."*

c) Financing

The manner in which the construction of lower-density houses is financed usually differs from that of multi-unit apartment or duplex developments. Houses can be built in small numbers and sold off incrementally to finance subsequent phases, whereas developers are often reliant on external sources of financing for longer periods of time when constructing higher-density typologies.

When referring to apartment schemes Architect 2 noted, *"All of those schemes depended on international funding, largely because you had to build the entire scheme out, and you have to finish the whole damn thing and pay the interest costs on borrowings etc, until the whole scheme is finished."*

While Developer 3 stated, again with reference to apartment schemes, *"So a lot of developers have to carry or forward fund that for up to two years before you get any profit, whereas, in a housing development, you can subdivide it and release sections."*

With regards to traditional low-density, low-rise houses, QS 1 noted, *"They can build 10, sell 10, build 10, they can self-fund."*

d) Planning risk

Due to the lengthy timescales associated with achieving planning permission, respondents were reluctant to take any risks in this area.

Architect 1 stated, *"At the moment, what our clients are saying to us is that it takes them multiple times longer to get planning permission than it does to build something. They can build a scheme in six months or a year, but it might take them two or three years to get to the point where they have planning permission, and that's a real problem."*

Developer 5 reflected this position: *"We know what the mix is, what the market is looking for, we know the local authorities, we have a relationship with individuals within local authorities, and we know what they look for."*

Developer 2 stated, *"We need to have a better agile planning system to give us more transparency in terms of timelines and more guarantees as well."*

Developer 2 noted, *"Do we just stick to what we know? There is a certain element of that, and there is a risk associated with bringing something new to market... It'd be safe to say that we don't take on planning risk very lightly."*
Architect 1 elaborated upon the relevant complexities within the planning system. Although these points were not raised in this manner by others interviewed, it is recognised that they are key regulatory drivers of issues noted by others, and as such, the information is included here.

A recurring theme among interviewees was the disconnect between national policy and local implementation, with local development plans often taking a more conservative stance driven by local objectives. As one interviewee noted, *"One of the benefits of the SHD (Strategic Housing Development) system was that when you were sitting in a tripartite meeting with the board and the Local Authority, the board was very, very clear that national policy was the primary legislation."*

In contrast, planning mechanisms such as Strategic Development Zones (SDZs) were viewed positively by developers for offering greater certainty and predictability in the planning process. One developer observed, *"I think the SDZ might be the favourite form of development model for a lot of developers. It gave them such security, making the planning process timely and predictable."*

Similarly, there was early enthusiasm for Urban Development Zones (UDZs) , though some uncertainty remains about their implementation: "*There was genuine excitement from developers when the idea of the UDZ first came out.*"

However, uncertainty around the release of updated planning guidance and standards is having a chilling effect on development. Several interviewees described how this lack of clarity is leading developers to delay or scale down projects. As one architect explained, "*Do we not think at scale until such a time as we have a new set of standards and some clarity on what has been achieved before 2030 in terms of sustainability and decarbonising?*" Finally, participants emphasised the need for a more agile mechanism for making small amendments to planning applications, arguing that the current process is overly bureaucratic and time-consuming. As one developer put it, "*So instead of a six-week turnaround on a quick change, which might be the trigger to releasing your project, it just doesn't happen at all because nobody has the appetite to go through that process for small changes.*"

e) Market preferences

A reluctance amongst home-buyers to purchase higher density own-door typologies such as duplexes or maisonettes beyond metropolitan centres was stated by almost all respondents as a barrier to compact urban growth. Respondents noted that semi-detached dwellings are seen as 'premium products'; end-of-terrace units sell for more than mid-terrace; and duplex units sell for less than houses. These market preferences influence site layouts and dictate terrace lengths.

Although duplex units or small apartment blocks are built as part of these developments to achieve densities dictated by planning regulations, developers' business model relies upon these units being sold back to the state for use as social and affordable housing due to a lack of appetite within the private market.

Developer 3 described this process: "*At the moment, with the current development standards, own door housing maxes out at about 31 units per hectare, so that falls short of the minimum 35 for Celbridge or Lexlip. You always have to introduce the apartments and duplexes to bring it up. Now, it's alright. We can offload a portion as social housing, but again, there is less demand for that.*"

Architect 2 elaborated upon the reason these typologies [duplexes and apartments] are favoured neither by estate agents nor the market. "*There is a predisposition in house builders against duplexes....Estate agents don't like them because basically, you've got quite a nice unit just upstairs, but the problem is you only get balconies, so you've effectively got an apartment over two floors with balcony accommodation.*"

Developer 5 stated, "*Traditionally, we haven't liked duplexes, I think largely because the ones that were built in the 90s and the naughties weren't very sophisticated. They were pretty ugly, looking very basic. We steered away from them, but we can't avoid it now. So we are looking at different ways of doing it. We are looking at things like perhaps a shared garden area at the back, rather than traditional back gardens of 60 square metres; that you would have courtyards that would be shared by families. That could address a lot of the bin store and bike store problems....*"

AHB 1 noted issues in accessibility associated with duplex units: "*...the problem with duplexes is my client is very different to what the private sector client is; there might be two or three young kids. If we have a ground floor unit for an elderly person and we have a 2/3 bed duplex above that, I'm asking someone to drag a buggy, or their shopping, up two or three flights of stairs potentially.*"

Of the private developer home builders interviewed, all relied upon a combination of in-house team expertise (customer research teams) and Estate Agents' knowledge to inform typologies. Developer 1 described this process, "*I have arguments with them [Estate Agents] about whether we should have heat recovery ventilation in a house. They say oh no, people would prefer an extra toilet.*"

While Estate Agent 1 noted the lack of built examples of compact urban growth available to inform home buyers of possibilities. "*We've been advocates of low rise medium density, we've been in Cambridge a couple of times, but we can't bring all the buyers to Cambridge to show them it.*"

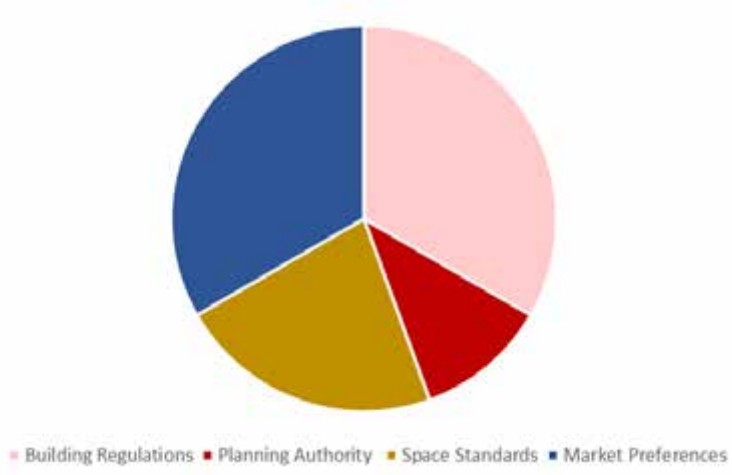

Figure 2: Industry expert responses to the question of what are the barriers to Compact Urban Growth?

Part 2: Embodied carbon
Interviewees were then asked three questions on the extent to which the stages of whole life carbon assessment influence design and construction decisions for these housing developments.

Firstly, when asked "Who is measuring carbon in the housing development industry at present in Ireland?", all developers, both private and public, responded that they are currently calculating the carbon associated with their developments; however, in most cases, this information has not yet started to inform any changes. Of the two architects interviewed, both stated that they are not currently calculating carbon, while the quantity surveyor we spoke to suggested that their profession is best placed to calculate embodied carbon.

Architect 1 referred to a first principles approach: *"We smuggled in a lot of thinking around this kind of stuff because it wasn't really on anybody's agenda."* They noted, *"Developers, from my point of view, are not really there yet. They're not forced to be there. Compliance with all the regulatory regimes is still very much their preoccupation."*

Architect 2 stated, *"Disappointingly no. We'd love to, but we haven't because we're mostly working in the private sector and haven't been asked to do it."*
Developer 4 stated *"We're asking our design teams to provide some analysis under embodied and operational carbon. We're still in the data collection stage of it.... we'd obviously see an alignment between reduced carbon and reduced cost in that sense."*

QS1 noted, *"Last year, we developed a tool to do the upfront embodied carbon calculation...We're now rapidly developing a tool to model the whole life because the conversations have changed so quickly from just the upfront embodied to the whole life assessment. It will be part of our remit, as QSs, anything that needs measuring and quantifying should sit with us."*

Secondly, when asked "How can embodied carbon be reduced in the construction of housing developments in Ireland?", the majority of respondents stated that they had not commenced addressing this issue but suggested solutions.

Developer 2 noted, *"I think it has to be legislation. If not, carbon tax. That'd be another big stick to threaten people with."* Similarly, developer 5 noted, *"I think the general assumption is that there's going to be a carbon tax, which is going to impact the cost of concrete. We're trying to move away from concrete."*

All developers interviewed stated that they were looking at solutions relating to the embodied carbon of the dwellings alone. Developer 3 noted, *"Infrastructure is going to be a challenge because that's where we haemorrhage a lot of our money and a lot of our carbon, below the ground. We're looking at solutions for the house at the*

moment but we need to come up with solutions for the infrastructure.... We're focusing on the units themselves and the houses and getting our typologies right so we can enhance our pre-manufacture value on those."

Three out of the four private developers interviewed cited Modern Methods of Construction as a means of reducing carbon associated with these developments. Developer 3 noted, *"We are removing the brick outer leaf because it is a high carbon offender. We want to go with a lightweight product"* in this with a synthetic product to mimic brick in order to *"bring the consumer on the journey."*

Architect 1 noted, *"Our clients from the private side are more aware of it now, but the decarbonising of transport as a solution is their main interest."*

Finally, when asked "Are home-buyers concerned about carbon and/or Building Energy Rating (BER)?", Estate Agent 1 summarised *"Of course, we want to buy organic if you could afford it, but if you can't, you can't."* implying that a higher cost is associated with a lower carbon home. In terms of their marketing strategy, they noted, *"It is less carbon footprint and more around community, diversity and biodiversity. There's a total acknowledgement in terms of the climate crisis, but we're not selling houses on the basis of the climate crisis."*

On the matter of BER ratings, Estate Agent 1 discussed the low impact from a cost perspective of different A ratings. *"When BER came in, there was a differentiation, and we'd be asked, and we're still asked, the difference between an A3 and an A1 or an A1 and an NZEB. To achieve those levels is really, really hard. It's nice to have, but it doesn't drive the value."*

This question was not discussed with other interviewees in any detail; however, developer 3 noted that *"millennials are very much invested in sustainable development and a reduction of carbon."*

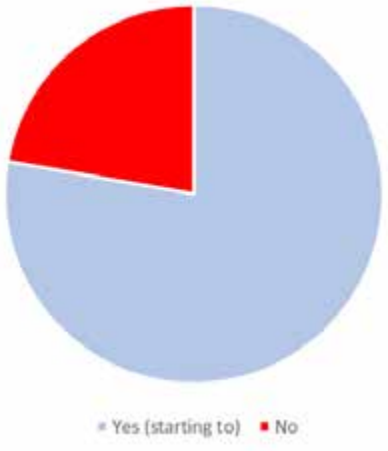

Figure 3: *Industry expert responses to whether embodied carbon associated with developments is currently counted?*

Part 3: The Future

Respondents were asked how they see these housing developments evolving by 2030.

The use of more modern methods of construction (MMC) was the most noted response to this question. Reasons noted for employing MMC included a diminishing labour force and the streamlining of the construction process. The ability to measure carbon was a secondary benefit of this approach. On MMC, QS 1 stated, *"I think the catalyst of carbon, the greater accuracy, and the reduction in waste.... It brings a cost benefit as well because of the efficiency, so it's a win-win. Higher quality, lower carbon, lower cost, quicker. It needs the economies of scale."* Developer 4 stated, *"We are trying to get our standardisation in place and then the next element of that would be to pursue a lot more MMC, which will hopefully improve the embodied carbon within the projects as well."*

Issues with the certification of new materials (such as more natural insulation or alternatives to brick cladding) are limiting options for innovation. Developers 1 and 3 spoke of the lengthy timelines and high costs involved in this process. Developer 1 noted that *"The certification process is so slow and so costly, we're looking at 18 months*

to get something approved, and then it is going to cost €60-70,000. So people decide to just keep going as we are.... it is a big restriction on how much innovation we can actually put into the homes." Likewise, developer 3 stated, *"certification could take you three to five years, it's quite constrained at the moment just to get one material certified in Ireland through the NSAI certification process."*

Developer 3 also noted the need to increase density. *"We need to increase density. At the moment it's 30 to 50, now that's changing to 40 to 80. I'd be cautious about going up to the 80. ... You can't have a low density housing scheme and then a very high density scheme right beside it in an area where there's no public transport."* Developer 1 referred to a reduction in dwelling sizes, *"It's also about reducing the size of our homes because the size of our homes in Ireland is crazy compared to the rest of Europe. So if we can reduce that, then we're reducing materials but yet giving people the same functionality in the home."*

Developer 2 focused on operational carbon, stating that energy efficiency is where they see the largest impact, *"the biggest dial turner that I can see now, based on what we know today, is energy efficiency."* Developer 5 also noted their attempt at addressing this issue: *"We have been unable to do anything in terms of district heating to date, not for the lack of asking the question on our side."* Developer 1 noted, *"We are definitely looking at more terraced houses because you can have more energy-efficient homes as they don't have as many exposed facades to lose heat through; that's something we're actively looking at."*

Key Findings and Their Implications

This study identifies a significant gap between Ireland's policy ambitions for CUG and the realities of housing delivery. Interviewees consistently pointed to low-rise, low-density, single-family homes on greenfield sites as the most viable option under current market and regulatory conditions. This preference is shaped by developers' funding models, construction efficiencies, and market demand for housing types that can be built and sold incrementally. While higher-density models are occasionally feasible, particularly when state bodies act as buyers, these remain exceptions.

Two principal barriers constrain CUG implementation: car-related infrastructure and regulatory costs. Although the DMURS promotes pedestrian-friendly, low-car environments, dominant expectations around car access and parking continue to shape planning and development practices. This car-centric approach inflates land and infrastructure costs, reducing the financial viability of medium-density schemes.

The regulatory environment also poses challenges. High compliance costs and vague sustainability requirements introduce uncertainty for developers. Fragmented governance and institutional inertia further reinforce traditional low-density development, stalling innovation. These findings echo international research pointing to zoning, land costs, and market preferences as persistent obstacles to compact growth.

Broader Context and Contribution

This research offers a grounded, practice-based perspective on sustainable urban development in Ireland. While existing literature outlines the benefits of compact growth, such as reduced emissions, infrastructure efficiency, and improved liveability, this study highlights the enduring gap between policy frameworks and implementation. It reveals how legacy planning practices, car dependency, and market dynamics continue to drive low-density outcomes despite national goals.

Achieving Ireland's housing and climate targets requires more than strategic plans. Addressing practical barriers is essential. This includes reforming parking and road standards to align with DMURS, streamlining regulatory processes, and fostering collaboration across sectors to encourage viable medium-density development.

Limitations

The study's small sample size of ten participants limits the generalisability of findings. Developers made up half the respondents, which may have biased the results. Future research should involve a broader range of stakeholders, including Approved Housing Bodies, planners, architects, and local authority staff.
Additionally, the qualitative approach carries the risk of bias, both from interviewees and interviewers, all of whom were trained architects. Despite efforts to maintain neutrality, this shared background may have influenced how responses were interpreted.

Nonetheless, the study provides valuable insight into the barriers to compact urban growth and offers a foundation for further research.

Conclusion

This paper outlines the regulatory, infrastructural, and market challenges that hinder compact urban growth in Ireland. It demonstrates how car-centric planning standards, regulatory complexity, and entrenched preferences for low-density housing continue to shape development patterns, despite policy commitments to more sustainable urban forms.

Although frameworks like the National Planning Framework and Town Centre First advocate compact, climate-responsive development, fragmented governance and policy-practice disconnects impede implementation. Addressing these issues requires coordinated action to reform planning norms, clarify regulatory expectations, and shift market dynamics.

With targeted interventions, Ireland can foster low-rise, medium-density housing that aligns with climate targets and urban liveability goals. Further research should evaluate the impact of recent policy changes, incorporate a wider range of stakeholder views, and examine the long-term implications of CUG strategies to inform evidence-based reforms.

Navigating Conflicts and Paradoxes: Analyzing the Interaction of Urban Regeneration, Local Governance, and Public Policy in the Tirana Riverside Project

Doriana Musaj
Polis University, Tirana, Albania
doriana_musaj@universitetipolis.edu.al

Abstract
This paper critically examines the Tirana Riverside Project as a paradigmatic case of post-disaster urban regeneration in Albania, unfolding amidst the dual crises of the 2019 earthquake and the COVID-19 pandemic. These emergencies catalysed a shift toward centralized governance and fast-track planning, enabling the implementation of large-scale projects with limited community consultation. Drawing on five intersecting theoretical frameworks—rational planning, advocacy planning, collaborative planning, the just city paradigm, and post-disaster urbanism—the study interrogates the paradoxes between technical innovation and social justice. Using a mixed-methods approach, which includes policy analysis, spatial documents, grey literature, and resident's interviews, the study reveals deep disjunctions between the project's smart-city vision and the lived experiences of displacement, exclusion, and institutional opacity. The findings demonstrate that resilience-oriented planning, when detached from democratic governance and procedural fairness, risks reinforcing inequality and transforming into an alibi-urbanism. The paper advocates for a post-crisis urbanism grounded in transparency, participation, and equitable recovery, particularly in contexts of fragile and contested governance and transitional countries like Albania.

Keywords: Post-disaster urban regeneration, centralized planning, Tirana Riverside Project, governance and community engagement, urban complexity and policy innovation.

Introduction

Albania went through two crises in a row only a few months apart from each other: the earthquake on November 26, 2019, and the Covid-19 pandemic lockdown in march 2020. The human tragedies triggered by these dual crises and their post-disaster consequences, significantly transformed the policies toward the urban environment. Justified by the necessity of rapid responses in governance decision-making, the rebuilt process forced rapid innovation in governance structures and regeneration strategies. The reconstruction of the earthquake-affected areas and the strategy to expand into new territories, required a new *ad hoc* legislative framework. The new norms and regulations, approved by the Council of Ministers, as action plans were issued by the *ad hoc* Ministry of Reconstruction, working closely with local governments and the National Territorial Planning Agency (AKPT). Its ad hoc creation, transitioned decision-making on the urban environment into a more centralized, top-down planning model. Justified by the urgency of the situation and articulated within an exceptional legal system, the *ad hoc* norms and instruments utilized fast-track urban planning tools for disaster recovery and public necessity, establishing also a precedent for managing emergencies related to urban growth in the future.

One of the first decisions of the Council of Minister after the earthquake of 2019, was passed on December 24, 2019DCoM No. 887), aimed to expedite the formulation and ratification of the "*Mandatory Local Plan (PdyV)*"[1] in the targeted regions chosen as post-disaster rebuilding zone. This legislation enabled authorities to bypass existing planning procedures, prescribed by the Planning and Development Law 107/2014 (Kuvendi, 2014) identify new development zones (even on private land), and sanction urban designs without public consultation or municipal council approval.

The "5 Maji" area renewal masterplan, was approved on March 3, 2020. The Municipality of Tirana altered the zone's classification from "development" as approved by Tirana 2030 General Local Plan, to "redevelopment". This redesign of the general local plan, designed as a green isolated neighbourhood disregarded the city infrastructure, network, history and identity. Individual property rights were disregarded also, while compelled residents to relinquish their homes via a non-negotiable contract, frequently lacking transparent information regarding compensation or subsequent housing arrangements.

This research examines the Tirana River Project case study, the renewal project that was designed to replace the existing neighbourhood. Located in the northern part of the city, alongside the river of Tirana, the "5 Maji"

1 The Mandatory Plan was an ad hoc new instrument, that was added to the Planning legislative framework after the Earthquake of 26 November 2019.

neighbourhood, was organically created after the 90s, and was home to communities that migrated in the capital after the communist regime fell (Aliaj et al., 2003)which is continuous, and incorporates mixed structures and historical events. Tirana is a symbol of urban culture between the sea and the mountain, preserving Illyrian, Roman, Byzantine cultures in a Oriental atmosphere;... between European elements and those typical Mediterranean' and Balkans' ones; surviving from the most authoritarian urban planning discipline of fascism and communism to the most anarchist chaos of medieval and modern times of 21-st century...\n\nIn short, Tirana is actually one of the most dynamic cities in Europe and obviously represents a city of a typical and prolonged transition, which remains still the main and most dramatic challenge of the present days.\n\nStarting from 1920, Tirana city has been always subject to studies and works to improve its architectural and urban development. Several studies are carried out recently also since 1994 and today, the most significant to be are \"The Strategic Plans for the Greater Tirana and Kamza Municipality\", which constitute a full set of documents including the complexity of the numerous social-economical issues, land use principles as well as future activities, infrastructure needed for normal development, what represents so far, the most recent urban research work for Tirana and Albania.\n\nIn the eve of the new millennium Municipality of Tirana initiated important urban operations that are completely changing the image of the Albanian capital. Tirana Municipality's goal is to prepare a vision of development that is flexible and adaptable to the rapid changes of the city. This necessarily requires the complete reformation of the town planning legislation as a process that should go side by side with the development of the city. The new urban regulation of Tirana can serve as good starting point for the new package of laws on Town Planning, which the country needs desperately. The drafting of this new regulatory plan as a process and in partnership with many specialized institutions and other interested groups and communities, regardless of the differences that might exist, is likely to be efficient and not prone to raise contestations or create obstructions and urban chaos as it's been the case so far. Let us hope for a positive change in the future.\n\nIt bears stressing also that authorities of Tirana Municipality have realized that developing a new urban development plan should not be over estimated, for this plan cannot resolve automatically all the complicated problems of Tirana, except for it will raise transparency and will guide better the municipal administration in the process of outlining a clear vision for the city's development by considering improving the logic of development in the hope that distortions similar to those we have witnessed so far will be minimized and prevented.\n\nFollowing the lessons learned from the urban planning in the past, taking into consideration the current urban phenomena, as well as the new proposed urban plans for Tirana Region (what is described in this Guide. Approved as a mandatory local plan (PdyV), the ambitious 29-hectare urban regeneration project (Figure 1), designed by the Italian architect Stefano Boeri, aimed to transform this low rise, low density, into a dense and smart city district, "*an accessible and self-sufficient district from the point of view of clean energy, water, food, and all urban public services*" (Boeri, n.d.). According to the architect, this renewed district would be self-sufficient in energy and would have the necessary infrastructure to guarantee supply and quality of life even during lockdown periods (Boeri, n.d.) (Figure 2).

As part of the new development plan, the Municipality of Tirana required residents to sign a compulsory agreement to relinquish their property without acknowledging their properties development rights. Residents strongly opposed the demolition of their homes, citing a lack of trust, as accused the municipality for non being transparent on the aims and decisions made, particularly regarding the property "exchange" agreement, which lacked clear information about how the re-allocation would happen. Many reported they were only notified about the evacuation date, without any further details on where they would live in the meantime, their housing arrangements or even the procedures of their displacement.

To the government, this large-scale urban renewal project was necessary because it would house more than 12,000 people, many of whom were homeless due to the earthquake, while the others would be the new families and social housing (Figure 3).

The public interest discussion made room for the arguments used by both local and central governments to justify the project. Suddenly in December 2021, the municipality gave a short notice to the residents to empty and leave their houses while inviting them to apply for a rent bonus, but without success, as the residents refused to leave their houses and didn't agree to the budget for rent, which was half of what an apartment rent used to be in Tirana at the time. This situation triggered a daily protest from the residents, gathering at the entry of the main road reaching their neighbourhood.

"*The Masterplan, planned to accommodate 12,000 people, is a 29-hectare green neighbourhood, equipped with all the technologies of a Smart City and able to guarantee the safeguards and health safety requirements necessary to face contemporary seismic and pandemic emergencies.*" (Boeri, n.d.)

The Tirana Riverside Masterplan case study, is one of the 43 designated post-earthquake rebuilding and redevelopment zones declared by the Council of Ministers. It is chosen as through it we could analyse the interaction between technical planning, (presented as smart planning), and political policies during intricate recovery phases. It aims to answer the question of how centralized planning instruments in post-disaster contexts affect procedural justice and community agency in urban regeneration projects.

The article draws on a range of critical urban planning theories to frame the analysis of post-earthquake renewal and rebuilding in the case of the Tirana Riverside project in Tirana. The theoretical framework used for this research is organized around five main ideas that helped us think critically about the Tirana Riverside project. First the rational planning, then followed by advocacy planning, collaborative planning, the Just City concept, and the post-disaster urbanism. Jane Jacobs' critique of orthodox planning's is also part of the discussion. It addresses a significant deficiency by examining how post-crisis rebuilding in Albania, an EU-aspiring yet governance-challenged state, serves as a platform for *ad hoc* urban planning, democratic manipulation, and controversial regeneration. It contributes to a nascent yet underexplored domain that examines how disasters function as both spatial disruptions and political catalysts, particularly within weak democracies.

These situations, characterized by weak institutions, mixed governance practices, and informal land tenure systems, hinder fair and democratic recovery in these countries were achieving democracy is both a struggle and a challenge. There is a notable gap in research regarding post-disaster urbanism in transitional and post-socialist states, despite extensive studies in developed and institutionally stable countries like Italy and the United States. There is limited understanding of how crisis-driven regeneration interacts with political instability and spatial inequality, primarily due to the lack of focused studies in these contexts. Therefore, the case of Tirana, Albania, following two significant post-disaster events, is particularly relevant to the discussion on post-disaster urbanism.

The study employs a mixed-methods approach to investigate the complex dynamics of post-disaster urban regeneration, with a focus on the Tirana Riverside Project case study. Combining qualitative insights with quantitative analysis and documentary evidence, the research aims to provide a multi-layered understanding of governance practices, spatial transformation, and community impact. The governance practices are studied through the examination of institutional practices and decisions, while the spatial transformation is investigated through planning documents and site observation. To address the challenges of the community impact, interviews were carried out with the members of the community and urban activists involved in the process. Media articles from that period, public declarations by government officials have all served as sources of information for the research. The content analysis was the main framework used to analyse documents, and responses of the interviews.

Theoretical Framework

The philosophy of urban planning has changed a lot in the past hundred years. It was once technocratic and rationalist, but during time shifted to be now, more dialogic, participative, and justice-focused. The transitioned from the rational planning paradigm, which was popular after World War II, and saw planning as a linear, scientific, and expert-led process, to participatory raised a wide debate in the West scholars and researchers. This paradigm emerged as predominant in the post-war decades, influencing both the role of planners and expectations of planning outcomes.

According to Taylor (1998), objectivity and technical efficiency were essential to rational planning, as it was based on the positivist philosophy, which made it all about looking at data, setting clear goals, and finding the best solutions. The rational plan helped things recover back to normal quickly after the war, as it changed the way people thought about planning, especially when coming up with quick fixes after war-related disasters. The rational planning decision-making was a logical and rational series of steps based on facts, evidence, and a clear goal. This model of planning leads people to believe that only planners can engage in the planning process, viewing it as a scientific and technical endeavour.

Planners were seen as value-neutral (see Davidoff, page); as a result, they were in charge of finding the best and most practical solutions by gathering information and using logical reasoning. This planning model used to look at numbers and scientific facts, disregarding other problems like injustice, oppression, gentrification, and marginalization (Taylor, 1998). In the years following WWII, the 1960s-1970s, more and more people spoke out against this way of thinking, as it didn't include people in the process, which meant it didn't take into account real-life problems and local knowledge.

Jane Jacobs, in 1961, wrote an important critique in her book "Death and Life of Great American Cities" of what she called "orthodox planning" (Jacobs, 2002). She attacked rational planning at the very first pages of the book as a top-down model that ignores the complexity, spontaneity, and social life of real urban neighbourhoods. Jacobs criticized planners for being too abstract and for being detached from the day-to-day realities of city life. To the author, forced redevelopment often destroys the real things that make cities alive, like community networks, informal economies, and social diversity.

In 1965, another scholar, Paul Davidoff, came up with the idea of "advocacy planning. He stated that planners should speak up for groups that are underrepresented and disadvantaged instead of staying neutral. To the author, the planner has to take a normative statement, like a lawyer does for his client, to push for fairness and diversity in the process of making public decisions (Davidoff, 1973). Thus, planners should help groups that don't receive enough attention by changing the way the project is set up to ensure that to include their voices and to make sure everyone can participate and by making rules and changes.

To Davidoff, it is impossible to suggest appropriate planning from a value-neutral perspective because "*values are inescapable elements of any rational decision-making process*." (Davidoff, 1973, p. 423), and to do its job well, "*the planning profession must engage itself thoroughly and openly in the debate surrounding political determination*."(Davidoff, 1973, p. 423). To the author, fair notice and public hearings, which are meant to gather supporting evidence for further cross-examination, are important ways to find the truth and make sure that the decision is not biased (Davidoff, 1973).

After that, planning became more collaborative and communicative. According to Patsy Healey, *communicative planning* is a planned and cooperative process meant to help stakeholders reach an agreement with the inhabitants. Patsy Healey's collaborative planning theory changed the approach to planning from instrumental rationality to communicative rationality (Healey, 2003). It was based on Habermas's idea of communicative rationality but used in a real-world planning system, dealing with normative objections, building on them, and coming up with a new way of looking at planning as a communicative and negotiated process. To Healey, the planning process should be open, clear, and ongoing, and it should take into account local values and knowledge (Healey, 2003). The author put more value on talking, being open to everyone, and learning from others than working only on technical knowledge. This model of planning is especially important in communities that are broken up because it's easy to question the legitimacy of authority (Healey, 2003).

Fainstein's "Just City" thesis extends beyond the planning process to encompass the outcomes of such planning (Fainstein, 2010). According to the author, we should evaluate urban development based on fairness, democracy, and diversity, particularly when evaluating "green" or "smart" initiatives. When dealing with these initiatives, we should look at how well they redistribute resources, reduce unfairness, and extend power to marginalized groups. The author believes that this model is especially useful when dealing with a situation after a disaster because redevelopment can hide social and spatial exclusion by using progressive language. Susan Fainstein's "just city" view makes the collaborative framework better by saying that urban planners should work hard to achieve their goals, which should include diversity, fairness, and participation in democracy. According to Fainstein's lens, we need to look at smart cities and sustainable master plans and see if they really do promote fairness and give everyone the same chances (Fainstein, 2010, p. 117)democracy, and diversity are important considerations. This is in contrast with the city as growth machine. Fainstein examines three cities: New York, London, and Amsterdam. She provides a history of post–World War II planning and then focuses on fairly recent cases of development in each. Her goals, though modest, are important if growing inequality in urban areas is to be reversed. Recommended.\"— ChoiceFor much of the twentieth century improvement in the situation of disadvantaged communities was a focus for urban planning and policy. Yet over the past three decades the ideological triumph of neoliberalism has caused the allocation of spatial, political, economic, and financial

resources to favor economic growth at the expense of wider social benefits. Susan Fainstein's concept of the \"just city\" encourages planners and policymakers to embrace a different approach to urban development. Her objective is to combine progressive city planners' earlier focus on equity and material well-being with considerations of diversity and participation so as to foster a better quality of urban life within the context of a global capitalist political economy. Fainstein applies theoretical concepts about justice developed by contemporary philosophers to the concrete problems faced by urban planners and policymakers and argues that, despite structural obstacles, meaningful reform can be achieved at the local level.In the first half of The Just City, Fainstein draws on the work of John Rawls, Martha Nussbaum, Iris Marion Young, Nancy Fraser, and others to develop an approach to justice relevant to twenty-first-century cities, one that incorporates three central concepts: diversity, democracy, and equity. In the book's second half, Fainstein tests her ideas through case studies of New York, London, and Amsterdam by evaluating their postwar programs for housing and development in relation to the three norms. She concludes by identifying a set of specific criteria for urban planners and policymakers to consider when developing programs to assure greater justice in both the process of their formulation and their effects.","event-place":"Ithaca","ISBN":"978-0-8014-7690-7","language":"English","number-of-pages":"224","publisher":"Cornell University Press","publisher-place":"Ithaca","source":"Amazon","title":"The Just City","author":[{"family":"Fainstein","given":"Susan S."}],"issued":{"date-parts":[["2010"]]}},"locator":"117","label":"page"}],"schema":"https://github.com/citation-style-language/schema/raw/master/csl-citation.json"} . The author believes this is crucial when people are forced to leave their only homes or are pushed out of society.

Vale and Campanella's (2005) theory of post-disaster urbanism provides us a new way to think about how the Tirana River Project came to be. This model of planning shows how disasters in cities can be both political triggers and physical barriers at the same time and space. The authors of the book "*The Resilient City: How Modern Cities Recover from Disaster*" (Vale & Campanella, 2005) argue that disasters are more than just physical breaks; they are "critical junctures" in the history of cities. (Vale & Campanella, 2005, p. 7) Disasters are rarely neutral; instead, they act as catalysts that bring out and worsen existing inequalities, making it easier for political and spatial agendas to be put into action quickly, even if they would have faced opposition otherwise (Vale & Campanella, 2005). To the authors, post-disaster governance, often under the pretense of urgency, enables bypassing regulations and consolidating authority through centralized control. In these situations, it can even employ emergency powers to change the urban configuration in ways that favor strategic or commercial interests. Thus, reconstruction is not merely about putting things back together the way they were before; it is selective, strategic, and often exclusionary, and the governmental actors and urban elites often use the crisis narrative to redesign and rebrand long-standing programs as essential for recovery. Their approach is called "opportunistic urbanism" (ibid.).

In addition to the five main planning theories, the case of Tirana's Riverside reflects also some elements of Austerity Urbanism (Peck, 2012)selectively targeting the social state, is a long-established trait of neoliberal governance, but it has been enforced with renewed systemic intensity in the period since the Wall Street crash of 2008. The paper develops the argument that these conditions are defining a new operational matrix for urban politics. Examining some of the leading and bleeding edges of austerity's 'extreme economy' in the USA, the paper seeks to locate these developments in the context of mutating processes of neoliberal urbanism, commenting on some of its social and spatial consequences.","container-title":"City","DOI":"10.1080/13604813.2012.734071","ISSN":"1360-4813","issue":"6","note":"publisher: RSA Website\n_eprint: https://doi.org/10.1080/13604813.2012.734071","page":"626-655","source":"Taylor and Francis+NEJM","title":"Austerity urbanism: American cities under extreme economy","title-short":"Austerity urbanism","volume":"16","author":[{"family":"Peck","given":"Jamie"}],"issued":{"date-parts":[["2012",12,1]]}}},"schema":"https://github.com/citation-style-language/schema/raw/master/csl-citation.json"} which finds its place when urban crises legitimize extraordinary governance and reduce citizens' participatory rights in decision-making. Originally characterized by the transformation of cities in the US and Europe during periods of financial constraints, today it can used to refer to the impact of emergency narratives on urban governance, which potentially undermine democratic norms, instruments, and principles accepted before the emergency. Although Albania's situation does not arise from fiscal cuts, the political logic of using the crisis as an opportunity for governance closely resembles how austerity regimes function in Western cities. These regimes often bypass democratic norms and impose technocratic control under the guise of innovation and recovery.

This notion was particularly relevant in the areas recovering from disasters or crises, where it is essential to employ both analytical methodologies and participatory decision-making. Patsy Healey's collaborative planning pays attention to inclusion, conversation, and accessibility and shows us how important communicative rationality and the persuasion of many stakeholders are. Participatory planning inherently conflicts with technocratic, top-down approaches to planning, while Susan Fainstein's concept of the "just city" provides a framework for assessing whether democratic outcomes are equitable and diverse and that planning should be evaluated not only for its effectiveness but also for its impact on underrepresented groups.

The state of the art triggered some more questions regarding the case under study. Is the mandatory rebuilt master plan technically effective and at the same time socially equitable? Does the Tirana Riverside master plan embody inclusivity and participatory engagement by local stakeholders, replacing traditional top-down planning, or does it represent a form of "authoritarian greenwashing" that is justified by post-disaster emergencies?

These theories helped us to understand how community members navigate urban complexity after a post-disaster and the conflicts generated through the crise in transitional countries like Albania. The investigation allowed us to assess whether the Tirana Riverside project represents a democratic paradigm of post-disaster urban planning, or functions as a mechanism for centralized governance under the pretext of sustainability and innovation.

To ground these theoretical reflections in a real context, the following section examines the Tirana Riverside Project as a representative case study of post-disaster renewal in Albania.

Case Study: Tirana Riverside Project

The Tirana Riverside Masterplan is one of the 43 post-earthquake rebuilding zones, part of the governmental strategy to tackle post-earthquake disasters. The masterplan aimed to create a resilient and smart urban area that included smart mobility infrastructure, affordable housing, green spaces, high density, and integrated public transport access (Boeri, n.d.). The project was presented as a state-led initiative with centralized oversight, yet its success depended (and still does) on navigating the local governance environment and inhabitants' expectations.

The master plan, designed by Stefano Boeri Architetti and SON-Group, planned to accommodate 12,000 people in a 29-hectare "*green neighbourhood, equipped with all the technologies of a Smart City and able to guarantee the safeguards and health safety requirements necessary to face contemporary seismic and pandemic emergencies*," according to the architect's masterplan description (Architetti, 2020). Its concept advocated mixed use, mixed housing, cultural integration, public administration buildings, schools, playgrounds, and even cult buildings (Figure 1). Public services were organized into three pedestrian-friendly hubs, creating a zero-emission, polycentric community that included schools, administrative offices, and a university center (Architetti, 2020). The project also sought to achieve the involvement of local SMEs, facilitating economic revitalization and setting new benchmarks for urban excellence (Architetti, 2020).

Figure 1: Tirana Riverside Master Plan Layers and functions. Source: Stefano Boeri Architetti https://www.stefanoboeriarchitetti.net/en/project/tirana-riverside/

Presented as a post-disaster innovative project, the new redesigned neighbourhood promoted smart urban design capable of withstanding both seismic events and health crises. The new plan emphasized the creation of open green spaces, intelligent infrastructure, low-emission transportation, and sanitary facilities, which collectively reflect an advanced approach to urban planning (Figure 2).

Pandemic Governance and Its Influence on Urban Planning

Albania was already in a state of emergency due to the earthquake of 29 November 2019 when the COVID-19 pandemic emerged in early March 2020, exacerbating the situation. The Albanian Parliament declared a national state of calamity, imposing a lockdown on public life. This empowered the government to implement specific measures on health, territory, and administration, while the prolonged emergency persisted for several months, grounding terrain for facilitating expedited urban planning and development decisions (Këshilli i Ministrave, 2019).

The government, compelled to revise its urban development strategies to tackle the earthquakes and later the epidemic, used "normative acts" as the main policy documents alongside executive orders. With the power set by the emergency of both legislative and executive, to design expedited laws and by-laws, the council of ministers approved a new set of norms and new plans for the post-disaster crisis. This new legal framework seeks to govern the operations of entities tasked with the rehabilitation and reconstruction of towns and regions impacted by natural or other disasters, in addition to the development of new territories (Këshilli i Ministrave, 2019).

The new policies, positioned as recovery instruments, necessary and obligated by the disasters in a few days, redesigned and replanned massive parts of the urban and rural territories. 43 post-earthquake rebuilding zones were approved by the normative act No. 9, dated 16.12.2019, new neighbourhoods that would host the affected families. In this setting, governance evolved into a top-down, emergency framework that facilitates the rapid advancement of urban innovation, thereby normalizing accelerated design methodologies and allowing the rebirth of the broad, atypical metropolitan territory (Këshilli i Ministrave, 2019).

A Disjunction Between Vision and Lived Experience

"Tirana Riverside overlooks a river park dedicated to the community and designed to preserve an ecosystem capable of increasing biodiversity in the urban environment, becoming a refuge and biological habitat for non-domestic species, and promoting the creation of microclimates useful for the surrounding civic well-being." (Architetti, 2020)

The Boeri masterplan, was designed to be implemented in an existing built neighbourhood at the north of Tirana. Positioned alongside the river Tirana, the district labelled as "5 Maji" was home to hundreds of families. Some architectural magazines published at the time several articles about the Tirana Riverside Project as a good example of how to reconstruct cities after disasters by integrating smart technologies, green infrastructure, and mixed-use design (Ravenscroft, 2020). But the individuals who live in the vicinity of these rebuilding zones witnessed that there is a wide difference between what the project says it would do and what people really see. The difference brings up crucial questions about who will create the future of cities and who will be left behind in the process. It also shows how planning is done poorly in transitional societies following a disaster.

This 29-hectare area, 35 years before, was predominantly a suburban region characterized by low-rise structures and some collective housing. It functioned primarily as an agricultural zone, frequently of a semi-rural nature. After the fall of the communist regime in 1990, the authorities lacked the capacity to cope with people migrating within the country, while hundreds of families moved from rural areas toward the outskirts of the capital. One of the area affected by the migration displacement was 5 Maji zone.

Figure 1: Tirana Riverside Master Plan 3D Image. Source: Stefano Boeri Architetti https://www.stefanoboeriarchitetti.net/en/project/tirana-riverside/

In the absence of week institutional presence, they built their own homes by themselves, without any pre-approved projects or permits. Some of them even occupied the land, while others bought it but didn't have clear legal papers. In 2005, these buildings attempted to navigate via the legalization process and were declared as being built informally. But, unlike the gradual and negotiated substitution processes observed in Kashar and Astir (Kacani, 2024), the transformation in the 5 Maji neighbourhood was imposed more abruptly through top-down decisions.

The objective of the Boeri masterplan to transform, with the principle of *tabula rasa*, the current neighbourhood into a smart city meant tearing down the homes of more than 300 families. People who lived in the area didn't accept the idea of tearing down their houses, as they didn't see why they should tear down what wasn't damaged by the earthquake. They said they weren't briefed about the project or allowed to be part of the design process, and no negotiations were made possible for them.

Most of them declared that they found out about it through the news.

At the time of the project's approval, some homeowners were still seeking to legalize their properties and secure full ownership rights, but the government proceeded with the project's implementation and, due to the lack of legal ownership of the site, exercised eminent domain only partially, interest thus expropriation was easier as the compensation was not obligatory. This logic mirrors broader patterns observed in Albania, where informal settlements are often overlooked as legitimate socio-urban formations, and their residents are treated as obstacles to development rather than holders of urban rights (Aliaj & Kacani, 2020).

The municipality claimed that would be in the "public interest," arguing that the new neighbourhood will also be home to those who lost their houses in the earthquake. Even though they were considered "illegal residents" and had no recognized rights to the land, the government promised to facilitate their return to the neighbourhood once the rebuilding was complete. Through a contract of understanding, those who would sign would be granted a rent bonus of 180 euros and, afterwards, an apartment. Data from a structured survey of residents from the former "5 Maji" neighbourhood demonstrates that none of the respondents reported being meaningfully consulted at any stage of the planning or implementation.

From Displacement to Precarity

The negotiation process between the residents and the government unfolded in a tense atmosphere, characterized by early morning police operations that forcibly displaced individuals and demolished some houses. The government referred to this initiative as "displace by force and demolish" (Figure 5; Figure 6). Citizens. al, an online media outlet, has provided a detailed account of the forced displacement of individuals and the demolition of structures in the "5 Maji" district of Tirana in early 2022. The empirical analysis incorporates these real-time articles from the operation.

Under police protection, the Territorial Protection Inspectorate (IMT) demolished twelve residences on February 22, 2022. The operation commenced prior to dawn, while residents resisted by nonviolent protests, forming human chains, and confronting police, who deployed tear gas and made arrests. The on-site journalist sources narrate the violent demolishment of the "5 Maji" district to make room for the Tirana Riverside Project from the perspective of eyewitnesses. The article, "Five Stories from 5 Maji," complements this legal and procedural analysis with the personal testimonies of the individuals impacted (Ndrevataj, 2022).

A young man handcuffed himself to the rooftop of his house as a sign of the last resistance while the police forcibly removed him; an elderly woman who had to leave her home of thirty years and an emigrant couple who lost their life savings invested in informal housing frame the operation's narrative by highlighting the human cost of development under duress, where affected citizens are treated not as stakeholders but as obstacles to be cleared. Through these accounts, the Tirana Riverside project emerges not only as an urban planning case but as a socially and ethically contested terrain.

Figure 5: The demolishment operation of 5 Maji neighborhood. Source: Citizens.al, Facebook 09.02.2022

Figure 6: Police presence during demolishment process. Source: Citizens.al, Facebook 09.02.2022

None of the individuals impacted had executed contracts for compensation. Their attorneys asserted that the proposed contracts were inequitable and that their notarization was unlawful. The ombudsperson criticized the absence of explicit documentation, the deficiency of legally mandated compensation, and the employment of emergency legal measures to circumvent public consultation.

We conducted 10 semi-structured interviews with displaced residents in April 2025 to investigate issues related to displacement, institutional transparency, and community involvement. We performed an examination of urban density measures, land-use change patterns, and transportation accessibility indices in the areas before

and after the project. We performed a comprehensive examination of pertinent urban design plans, legal documents, policy briefs, municipal resolutions, and planning records. Attention was directed towards the normative legislation employed during the period of emergency and the formal redevelopment framework. We employed the triangulation of data to enhance the validity and dependability of the results. This integrative methodology facilitated the juxtaposition of official narratives with the experiences of impacted communities, revealing deficiencies in participatory governance and spatial equity.

A majority of respondents still live in temporary, substandard, or overcrowded housing, while the promised "smart neighbourhood" remains either inaccessible or unaffordable. Only a handful had signed return contracts, and even fewer had been reinstated. Nearly 60% of participants rated their current quality of life as worse than before displacement. Interviews uncovered material hardships, such as insufficient rent bonuses and legal barriers to property registration, and emotional and psychological stress due to prolonged uncertainty, social fragmentation, and the loss of community networks.

From Plan to Practice: Evaluating Tirana Riverside through a Theoretical Lens

As part of Albania's recovery plan after the earthquake, the Tirana Riverside masterplan, approved in 2020, promotes a smart and sustainable neighbourhood that can hold 12,000 people on 29 hectares. Stefano Boeri Architetti in charge of the masterplan, promoted smart housing, green transportation, biodiversity, and renewable energy systems, which all worked together and composed a resilient smart neighbourhood. On the surface, it fits with the rational planning model of Taylor, (1998), a target-oriented and data-driven, centralized, and efficiency-focused plan to deal with urban environments after crises. However, when viewed through the lens of Advocacy and Collaborative Planning, the project's legitimacy appears diminished.

Applying Patsy Healey's theory of Collaborative Planning (1997) to the Tirana Riverside Project is compelling, especially in light of Albania's post-disaster environment, which is characterized by institutional fragility, political centralization, and profound social heterogeneity. The goals and meaning of urban transformation are jointly shaped by a variety of actors, including citizens, public institutions, technical experts, and civil society, in Healey's lens, which views planning as a deliberative and inclusive process rather than a technocratic exercise. This approach stands in stark contrast to top-down, rationalist models, which place a higher value on efficiency, speed, and centralized control—frequently emphasized in post-crisis situations. The urgency of the COVID-19 pandemic and the 2019 earthquake in Albania resulted in a highly centralized planning response that left little room for local knowledge, dissent, or discussion.

Healey's caution is especially pertinent in this case: planning techniques that avoid candid discussion and consensus-building run the risk of losing their social acceptance and usefulness in fractured societies. The Tirana Riverside project kept away impacted communities from meaningful engagement, rather than encouraging a participatory dialogue on reconstruction. According to Healey's perspective, this case required not only physical reconstruction but also an institutional process based on equity, openness, and cooperative visioning—elements that were mostly lacking during the project's execution.

Healey says that the complexity of cities shouldn't be seen as a problem but as a chance to come up with new policies. Tirana Riverside shows how collaborative ideas at first glance can be questioned, changed, or used in a limited way.

Adding to this study, Susan Fainstein's (2010) idea of The Just City, we can look at both the processes and results of Tirana's rebuilding after a disaster. Collaborative planning puts a lot of weight on participation, discussion, and coming to an agreement through negotiation, while Fainstein argues that planning must also achieve substantive justice, especially in cities that are changing quickly and becoming more unequal while following neoliberal principles. Feinstein says that fairness, democracy, and variety should be the main ideas that guide decisions made in cities. The Tirana Riverside Project raises some important questions about these ideas. Has the improvement of the area made it easier for everyone to get to homes, public places, and services? Have people who used to live in the area gotten the right amount of money, been included, or been made full beneficiaries? How much does the project encourage people to interact with each other, and how much does it encourage people to stay away from others by making green spaces look nice?

While the Boeri smart project emphasizes eco-friendly mobility, rooftop gardens, and digital infrastructure, the social infrastructures necessary for just urbanism, such as housing rights, participatory accountability, and redistributive equity, remain critically underdeveloped. From a Fainstein (2010) perspective, the project fails to deliver on the core principles of the "just city," namely, that urban development must be evaluated not only by its design but also by its equitable outcomes and ability to empower the most vulnerable. This contradiction is especially salient in the context of the post-disaster urban redevelopment process, as Vale & Campanella (2005) have argued; crises often serve as catalysts for pre-existing political agendas, enabling the fast-tracking of plans that may otherwise have met community resistance.

In the case of the Tirana Riverside project, there is strong evidence that the earthquake was used to accelerate elements of the previously approved 2017 Tirana 2030 Masterplan, bypassing deliberative norms and replacing informal communities with formal architectural visions not shaped by those who lived there (Bateman, 2021). Further, this process reflects what Swyngedouw (2005) and Gunder (2010) critique as "post-political" urbanism: the masking of contentious political decisions under the language of resilience, innovation, and sustainability. The danger, they warn, is that "smart" cities become new mechanisms of exclusion, where design excellence is decoupled from social justice. The Tirana Riverside project is a good example of what Swyngedouw (2005) calls "Janus-faced governance. This implies that even though public discourse promotes new technologies, sustainability, and inclusivity, the planning process itself is still quite bureaucratic and exclusive. Both city and government officials told to the public stories about the 5 Maji, citizens that were both bullying and exclusionary, often labeling them "usurpers," "illegal," or suggesting they cared more about the interests of the opposition political party than their own family, while Boeri's project was shown as a solution to fix things after the earthquake and as a plan for a smart and powerful city. This behavior of both local and central authorities generated a "post-urban politics" where decisions were decided centrally and people became spectators of a growth tale that is shaped from top-down and imposed by force.

The government (both central and local) made decisions that were often communicated through general announcements in the media or on social media. These announcements didn't give enough information or allow for personal interaction with local government and its constituents. The fact that there aren't many ways for people to get involved is a major criticism of technocratic planning models by Healey (1997). She argues that these models always ignore the importance of local knowledge and different ways of thinking. People didn't see co-creation or meaningful consultation; instead, they saw what Miraftab (2009) calls "invited spaces," which are places with strict rules where community participation is predetermined, shallow, or non-existent (Miraftab, 2009).

Citizens.al (2021) investigative reports reveal that the transition from the "5 Maji" neighbourhood to the new smart and green city was characterized by a lack of transparency and the exclusion of residents. Important documents, such as the Compulsory Local Plan, were not made available to the public, and no public hearings or consultations were conducted. As a result, residents were unaware of decisions that would impact their homes and lives. Many residents were uncertain about whether they would need to relocate, receive compensation, or become part of the new community.

Many of the residents who were interviewed said that they were not allowed to legalize their homes before they were torn down, even though they were waiting for decades and even paid for the legalization procedure. This meant that they lost their property rights, and besides the fact that they lived there for more than 20 years, according to the civic code, they were eligible to be declared as owners. This goes against Davidoff's belief that planning should clearly recognize and support the rights of people who are politically disenfranchised. These testimonies strongly support Vale and Campanella's thesis on post-disaster urbanization, in which disasters are used to justify carrying out pre-existing development plans that often ignore justice, transparency, and citizen involvement.

Besides the right to the property and the right to an adequate house, the imposed plan, the violent arbitrary intervention, and forced redevelopment, according to Jane Jacobs's lens, destroy the things that make cities lively, like community networks, informal businesses, and a mix of different types of people.

The case of 5 Maji shows that centralized smart-city plans took the place of a neighbourhood that was built by the community but didn't involve the community. Jacobs' criticism is in line with what people in this study said, which shows that functional homes are being torn down without following the rules in the name of urban progress.

This critical lens let us look behind the appealing language of "green" and "smart" planning and instead focus on how these words were used in larger political and economic goals. The Tirana Riverside Project was shown as a symbol of forward-thinking urbanism, but our research shows how planning processes may be made less political and less democratic. It wasn't just a question of infrastructure or new ideas, instead it was also a question of fairness, inclusion, and power. These ideas make us think more about how post-disaster urbanism works in shifting and post-disaster situations and how planning, as both a field of study and a way to run a city, has to deal with the conflict between ambition and recklessness.

Conclusions and some final thoughts

The Tirana Riverside Project is a good example of how to rethink the stories, tools, and effects of urbanism after a disaster, especially when governments are changing and institutions are weak. At initially, the project was sold as a smart and forward-thinking redevelopment zone that would show how cities might be more resilient, adapt to climate change, be more resilient to pos-disaster, be adaptable for pandemic situations and come up with new innovative lifestyle. But doing it highlighted how hard it is to follow planning rules when they are enforced in a strict and top-down approach.

Our research shows that the project's official vocabulary, which included words like "smart," "green," and "resilient," was not backed up by processes that included everyone and focused on community involvement, spatial justice, or transparency. Instead, these ideas were used to justify actions that moved vulnerable people, ignored informal tenure, and went around deliberative governance. What was promised as change turned out to be a tightly controlled removal of informal urbanism, organized by business interests and hidden behind the language of innovation.

Masterplans and visualization techniques were useful technical tools, but they were also ideological tools that let people make cities without politics. This raises further concerns about how urban planning is being deployed in post-disaster contexts, not to protect or empower communities, but to control and reshape them. In moments of crisis, urgency is often manipulated to justify interventions that shut down negotiation and weaken democratic oversight. In the long run, planning shifts from being a tool for public good to a mechanism for state-led accumulation and investor confidence—frequently in conflict with the lived realities of those most affected by the disaster.

To truly understand post-disaster urbanism today, especially in transitional countries like Albania, we need to do more than just look at design frameworks. We need to ask important questions such as: Who decides what is an emergency? Who decides what to do? Who gains from the it, and who pays for it? These are not just questions about how things work or how to run things; they are questions about fairness. To rethink how cities work after a disaster, we need to face the hard truth that planning is often used as a way to keep people out of politics. It is important to stop the depoliticization of space and bring planning back to democracy, collective memory, and social repair.

Planning as a Field: Between Desire and Anger

The Tirana Riverside example illustrates a fundamental issue in the realm of urban planning: how to achieve an optimal equilibrium between the objectives of democracy and its function as an instrument of institutional aggression. Urban planning aspires to provide greener cities, equitable infrastructure, and adaptable lifestyles, on the other hand, it remains essential to the power structures that create the injustices it seeks to eliminate.

This contradiction increases in areas recently affected by a calamity, particularly in transitional democracies. When people experience a necessity for rapid action, planning frequently becomes expedited, more technical, and less sensitive to the social and physical contexts it influences. Projects are defined by polished presentations, global best practices, and indicators that are useful for investors. The complexity of local lives is either obscured or utilized as a mechanism.

Tirana Riverside not only demonstrated planning logic but also employed it: a progressive ideology that masked displacement, a narrative of inclusivity that concealed elite consolidation, and an aesthetic that rendered suffering invisible.

This indicates that the discipline is going through a more profound crisis. Planning is always subject to bias. It involves more than merely creating spaces or preventing rapid urban expansion. It constitutes a political act, a narrative concerning culture, and frequently serves as a means of exclusion. We must closely examine the frameworks employed to instruct, implement, and validate planning. What do our instruments represent? Whose voices are reflected in our plans? Whom are we assisting, and what is the expense involved?

To restore planning as a democratic and ethical endeavor, we must resist its allocation by market dynamics and governmental propaganda. It signifies acknowledging its role in exclusion while also advocating for its capacity to nurture, correct, and collaboratively create. A significant gap exists between aspiration and assertiveness that necessitates serious rethinking. In this context, planning is not imposed or removed, but conducted collaboratively with those who will be most impacted by its consequences.

In this domain, planning can initiate assistance not just for the city as an entity but also for the urban experience as a collective condition rooted in memory, conflict, belonging, and hope.

The TRP Dilemma and Post-Socialist Urbanism

The Tirana Riverside Project exemplifies post-disaster planning and the aftermath of socialism, all under the guise of authoritarian modernity. The initiative is formally designated as a "state-of-the-art urban regeneration project," although its execution illustrates how calamity can serve as a pretext for major changes in urban environments. The transition from ambitious masterplanning to social conflict indicates that knowledge of technology alone cannot substitute for ethical governance.

In the absence of explicit legislation and mechanisms for public engagement, regeneration is executed upon individuals rather than in collaboration with them. Our analysis indicates that the obligations related to inclusion and improvement were not fulfilled. New edifices and thoroughfares were constructed; yet, for several residents who previously inhabited the area, access to public services decreased. A significant number of individuals were compelled to relocate to the periphery or to temporary accommodations characterized by inadequate infrastructure and connectivity. The public transportation system is inadequate, and expenditures on walkability and social infrastructure have not increased correspondingly.

The majority of residents received inadequate compensation and poor alternatives. Standardized contracts, frequently signed under pressure, stripped individuals of their rights to negotiate, capitalize on increasing urban values, or maintain ties to their dwellings. A multitude of individuals possessed unsettled tenure claims, complicating their negotiation efforts. Engagement was superficial and hierarchical, with economic advantages going to private developers rather than the displaced populations.

Urban planning post-disaster must be equitable and inclusive of all stakeholders. This necessitates the implementation of planning strategies which are transparent, collaborative, and respect the rights and values of inhabitants. The increased density of residences and enterprises in Tirana Riverside Masterplan imposes greater pressure on the city's current infrastructure, particularly its roadways. Insufficient funding for public services may exacerbate traffic congestion and marginalize individuals from society.

The master plan orchestrated by Boeri promotes sustainable mobility, verdant thoroughfares, and cohesive transportation; yet, it lacks detailed information regarding the practical implementation of these systems. It displays roads, but not the traffic conditions. Public transit appears to prioritize managing the present rather than anticipating the future. It fails to consider the hundreds of thousands of square meters of dwellings that will shortly be occupied. The project may become an isolated enclave without multimodal, high-speed transit linking Tirana Riverside Masterplan to the northern periphery of Tirana.

The inconsistent utilization of public transit and infrastructure raises concerns around greenwashing and symbolic. It illustrates the compatibility of a progressive style with retrograde politics and underscores the paramount importance of critical, justice-oriented planning.

Public-Private Joint Ventures in Urban Area Development: Identifying and Governing Value Tensions

Paul van den Bragt
Affiliation: Delft University of Technology, Department of Management in the Built Environment, section Urban Development Management
Email: p.vandenbragt@tudelft.nl

Abstract
Public-Private Partnerships have been widely applied across Europe. However, critical perspectives question whether PPPs can safeguard public values or prioritize private interests over societal goals. Public-Private Joint Ventures (PPJVs) face particular criticism for governance designs that benefit efficiency while potentially undermining transparency and accountability. This paper examines Dutch PPJVs in area development. By adopting theoretical perspectives on contractual and relational governance, the study explores how these shape value tensions. Evidence from interviews suggests that although value tensions are not explicitly governed as such, they are affected by contractual and relational governance aimed at securing interests, mitigating risks, and managing opportunism, indicating reciprocity: underlying values give rise to diverging interests, which actors manage through contractual and relational governance—that, in turn, shapes how value tensions emerge and are addressed throughout the collaboration.

Keywords: urban development, Public-Private Partnerships, value tensions, Public-Private Joint Venture, public value

1.Introduction

Public-Private Partnerships (PPPs) are often seen as promising governance strategies for tackling complex urban challenges by leveraging the complementary strengths and resources of public and private actors — particularly in the European context, where PPPs have been widely applied since the 1990s (Ansell & Torfing, 2021; Hodge and Greve, 2007; Kort and Klijn, 2011). Meanwhile, literature raises critical perspectives on PPPs, particularly regarding their ability to safeguard public values. Scholars question whether PPPs foster public value creation, or whether they risk prioritizing private interests over broader societal goals, especially when governments take on a primarily facilitating role (Mazzucato and Ryan-Collins, 2022). Public-Private Joint Ventures (PPJVs), in particular, face criticism for governance designs that distance local politics from operational decision-making, benefiting progress and efficiency on the one hand, but potentially undermining values such as democratic legitimacy, transparency, and accountability on the other (European Commission, 2004; Reynaers, 2014; Tasan-Kok *et al.*, 2019). Another critique is that the differing organizational cultures and objectives of public and private actors can lead to conflicts over priorities and decision-making processes, potentially undermining the effectiveness of the partnership and putting public goals or values at stake (Van der Wal, 2008).

While much of the existing research on PPPs focuses on infrastructure or public service delivery, there is comparatively less attention for PPPs for urban development projects, specifically area development—as governance process towards realizing area-based spatial projects that includes important planning work. Moreover, there is limited empirical insight into how value tensions are experienced by stakeholders in planning practice, and how they manifest in partnerships. The first aim of this paper is therefore to identify value tensions through literature and empirically explore how they become evident within Dutch area development PPJVs.

By framing the Netherlands as exemplary context, this paper provides nuanced insights into the governance of value tensions in area development. Rather than seeking definitive solutions, the paper seeks to contribute to a better understanding of the influence of relational and contractual governance on value tensions in PPJVs, and to inform ongoing discussions about governance models that can support public value creation by governing tensions assumed to be inherent to these partnerships.

The Dutch context is illustrative for a declining trend in number of PPP projects across different sectors throughout Europe (European Investment Bank, 2016, 2024). Following a period of pioneering with PPPs under the Fourth Memorandum on Spatial Planning Extra (Vierde Nota Ruimtelijke Ordening Extra: Vinex) policy programme since the 1990s, the financial crisis of 2008 led to a decline in the use of PPPs in area development in the Netherlands, with many partnerships being dissolved or restructured (Heurkens, 2012; Buitelaar, 2014). Recently, there has been renewed interest in PPPs as Dutch area developments seek to address challenges such as housing shortages, sustainability, and social equity (BPD, 2023; Hümmels, 2017; Ten Have *et al.*, 2017).

This renewed attention prompts questions about what can be learned from earlier partnerships, particularly regarding the management of value tensions: how can governance arrangements in this new phase of PPPs be improved to better accommodate the inherent value tensions that arise in such collaborations?

This paper adopts theoretical perspectives on both contractual governance—emphasizing formal agreements to structure exchanges between actors—and relational governance—focusing on relational aspects such as trust, communication, and shared norms (Cao and Lumineau, 2015; Warsen *et al.*, 2019). While both approaches are seen as relevant to explain the performance of partnerships, their interplay and influence on value tensions in area development PPPs remain underexplored. The second aim of this paper is therefore to demonstrate empirically how contractual and relational governance mechanisms shape the emergence of value tensions in Dutch area development PPJVs.

2.Method

Empirical material for this research was collected through eight in-depth, semi-structured interviews conducted in 2024 with professionals engaged in joint ventures for large-scale area development projects in the Netherlands. While the primary focus of the study was not on contractual or relational governance or value tensions, the interviews did address these themes and thus offer valuable insights into stakeholder perspectives within Dutch PPPs. The interviewees were selected based on their extensive experience in joint venture developments and included three directors of PPJVs—either operating independently or seconded from municipal organizations—two senior executives within PPJVs, two professionals serving as supervisory board members or shareholders, and one senior manager with broad experience in PPPs from a major urban development firm.

These interviews were conducted and coded using Atlas.ti as part of the first phase (focused on the evolution of PPJVs from an institutional perspective) of the author's PhD project. The analysis of value tensions presented in this paper offers an initial empirical exploration of this theme. While the findings help to formulate and ground hypotheses, further empirical research is planned to deepen these insights.

In addition to the interviews, the research was informed by a literature review and by informal conversations with professionals throughout the research process. These included discussions with practitioners during thematic sessions at professional conferences, which provided further context and helped to validate and nuance emerging insights.

3.PPPs: Value tensions and governance challenges

3.1 (European) perspectives on PPPs and tensions

Despite the widespread application of PPPs, their impact on public values remains a subject of debate among scholars. This section discusses both the arguments in favour of PPPs and the main criticisms, and identifies several value tensions that can arise in PPJVs.

Proponents argue that PPPs can create synergies between public and private sectors, leading to improved efficiency, innovation, and value for money in public service delivery (Hodge and Greve, 2007). The involvement of private sector expertise and financing is seen as a way to overcome public sector resource constraints and deliver projects more efficiently (Kwak *et al.*, 2009). Some scholars suggest that PPPs can enhance public value by accelerating developments, improving service quality, and generating wider social benefits (European Investment Bank, 2011). Advocates claim that PPPs can improve risk allocation by transferring risks to the party best equipped to handle them (Grimsey and Lewis, 2002). This risk transfer, combined with private sector incentives, is argued to result in more realistic planning and improved project management (Verweij *et al.*, 2021). The long-term nature of many PPP contracts is also seen as encouraging a life-cycle approach to asset management and service delivery (Roehrich *et al.*, 2014).

However, critics have raised concerns about the impact of PPPs on public values. Some argue that the profit motives of private partners may conflict with public interest objectives, potentially leading to a prioritization of financial returns over social outcomes (Hodge and Greve, 2010). The complexity and long-term nature of PPP contracts can also make it difficult for governments to maintain flexibility and adapt to changing public needs over time (Willems and Van Dooren, 2016).

There are also concerns about the transparency and accountability of PPPs. The confidentiality often surrounding PPP negotiations and contracts can limit transparency and democratic oversight (Siemiatycki, 2007). Critics argue that this lack of transparency can increase the risk of corruption and reduce public trust in decision-making processes (Boardman and Vining, 2012).

The impact of PPPs on public sector capacity is another area of debate. While proponents argue that PPPs can bring in private sector expertise, critics worry about the potential hollowing out of public sector expertise. Over-reliance on private partners for critical functions can diminish institutional knowledge within the public sector, leaving governments less capable of independently managing future projects (Jooste and Scott, 2012; Osborne *et al.*, 2010).

Based on the discussion above and additional literature, several value tensions are relevant in Public-Private Joint Ventures in particular and displayed in table 1. These value tensions illustrate the governance challenges that PPJVs face in aligning the objectives of public and private sector partners.

Table 1: Key value tensions between public and private partners in Public-Private Joint Ventures.

Value Tension	Public Sector Perspective	Private Sector Perspective	Source(s)
Public value vs. profit maximization	Focus on equity, accessibility, and long-term social benefits; public interests are central	Primarily concerned with profitability and efficiency; financial outcomes are key	Osborne *et al.*, 2010; Greve and Hodge, 2010
Accountability and transparency vs. confidentiality & efficiency	Must be transparent and accountable to citizens; open decision-making is important	Prefer confidentiality to protect competitive position and avoid political interference	Forrer *et al.*, 2010; Willems and Van Dooren, 2016
Risk transfer vs. risk minimization	Seeks to transfer significant risks to private partners but wants to keep control over key services	Tries to minimize own risk while maximizing returns; prefers clear limits on risk exposure	Burke and Demirag, 2017; Greve and Hodge, 2010
Bureaucratic stability vs. market-driven agility	Follows stable, bureaucratic processes and formal procedures	Values flexibility and quick decision-making; prefers agile approaches	Huxham and Vangen, 2010; Villani *et al.*, 2017
Public control vs. private governance	Wants to maintain strategic control to ensure public goals are met	May have more influence over governance due to financial input or expertise	Hodge and Greve, 2010
Social impact vs. financial performance	May define success by social outcomes and long-term benefits	May define success by financial performance and measurable returns	Grossi *et al.*, 2017
Public ethics vs. private interests	Guided by public sector ethics and pursuit of public value	Driven by profit, which may sometimes conflict with public sector ethics	Reynaers and De Graaf, 2014

3.2 Contractual and relational governance

The value tensions outlined above illustrate the complex challenges that PPJVs face in balancing public and private interests. To better understand how these tensions are addressed in practice, it is essential to examine the governance mechanisms that underpin these partnerships.

The following section explores the role of both contractual and relational governance arrangements in shaping the dynamics and outcomes of PPJVs.

Traditionally, many PPPs are structured around detailed contracts that define risk allocation, responsibilities, performance metrics, and provisions for sanctions if performance is inadequate (Solheim-Kile and Wald, 2019). While PPPs are often associated primarily with their contractual nature, they actually encompass more than just these formal agreements between public and private partners. These partnerships also rely heavily on relational elements, such as trust, communication, commitment, and mutual respect, which can play a crucial role in the success of the collaboration (Cao and Lumineau, 2015). Such relational factors are key in managing project uncertainties and changes. A strong partnership enables the parties to address issues that go beyond what the contract stipulates. This relational dimension is slowly gaining more recognition in PPP research (Warsen *et al*., 2019). Literature identifies numerous critical success factors to explain the performance of PPPs, which can be traced back to two main theoretical perspectives on performance: contractual and relational.

The contractual perspective, rooted in economic institutionalism, principal-agent theory, and transaction cost theory, has traditionally dominated PPP research and practice (Lowndes and Roberts, 2013; Williamson, 1996). This approach views PPPs as a principal-agent relationship, with the public partner acting as the principal and the private partner or consortium as the agent. Both parties are considered rational actors pursuing their own interests in a relationship that is characterized by diverging preferences and information asymmetry. In this context, the principal relies on the agent for information about performance, creating potential for opportunistic behaviour. The agent may attempt to misuse the information asymmetry to their advantage. To mitigate these risks, contractual governance emphasizes the importance of well-written contracts, clear performance indicators, appropriate risk allocation, and the ability to apply sanctions (Warsen *et al*., 2019). However, the complexity of how exchanges take place between different actors makes it impossible to anticipate and structure all aspects through contracts beforehand, leading to incomplete contracting.

The relational governance approach suggests that instead of making contracts endlessly detailed, incomplete contracting is 'managed' by social relationships. The relational perspective is inspired by relational contracting, sociological institutionalism and governance (Deakin and Michie,; Lowndes and Roberts, 2013). This perspective emphasizes the process of cooperation and relational interplay. It highlights the significance of trust, informal communication, and openness for the successful functioning of PPPs (Warsen *et al*., 2019). This perspective views PPPs as collaborative partnerships instead of purely principal-agent relationships, emphasizing joint problem-solving and collaboratively addressing unexpected events that may arise during the contract period (Barretta *et al*., 2008; Reeves, 2008).

It is important to note that these two perspectives are not mutually exclusive. Rather, they can be seen as complementary lenses to look at how the complexities of PPPs are managed. Combinations of contractual and relational mechanisms are more likely to explain the success of partnerships (Warsen *et al*., 2019; Weihe, 2009). By looking at the behaviour of actors in PPPs from both perspectives, it is recognized that while contracts do shape interactions between partners, they do not entirely determine them .

3.3 Hypothesizing a reciprocal relationship between values, interests, and governance practices

This study assumes that value tensions are inherent to Public-Private Joint Ventures (PPJVs) and persist throughout the collaboration. It is expected that these tensions are not typically the object of explicit negotiation. Rather, public and private actors primarily focus on securing their respective interests within the collaboration and on managing risks—particularly where those interests diverge. In doing so, they seek to mitigate opportunistic behaviour, ensure implementation, and maintain control over critical issues, often without framing these challenges in terms of normative value tensions.

Nonetheless, these governance challenges are related to underlying values. For example, efforts by public actors to ensure transparency and accountability reflect concerns about legitimacy, while private actors' wish for confidentiality stems from commercial risk management and protecting competitive advantages. It is hypothesized that while actors do not explicitly govern for *values*, the contractual and relational governance mechanisms they adopt to govern *interests* do shape how value tensions emerge and are managed. For instance, formal governance structures—such as clear decision-making procedures or oversight mechanisms—can

address tensions around transparency and accountability, even if public and private actors prioritize legitimacy and efficiency differently. Similarly, contractual elements such as performance indicators or risk-allocation can help align expectations on what constitutes success, balancing social impact and financial performance.

Simultaneously, relational governance plays a role in mitigating tensions throughout the partnership that cannot be fully addressed contractually. For example, it can mitigate cultural frictions between bureaucratic stability and market-driven agility, and support mutual adjustment when unforeseen developments challenge initial agreements.

This study hypothesizes that while value tensions are continuously present in PPJVs, their occurrence is influenced by (contractual and relational) governance aimed at securing respective interests and managing risks in practice. Although value tensions stem from differences in public and private values, they become visible through the ways in which actors pursue and protect their respective interests. These tensions are not static, but shaped over time by how actors try to manage their interdependence. Governance arrangements—both contractual and relational—are primarily aimed at securing respective interests and managing risks (opportunistic behaviour, conflicts). In doing so, they also influence how value tensions manifest throughout the collaboration. This reflects a reciprocal relationship: underlying values give rise to diverging interests, which actors manage through governance practices—practices that, in turn, shape how those value tensions emerge.

4.Exemplary context: PPJVs in Dutch planning practice

The Netherlands has a longstanding tradition of employing PPPs as governance strategy to achieve urban policy objectives, such as housing provision and infrastructure development. Since the mid-1980s, public-private collaboration has been integral to Dutch spatial planning. Over time, various PPP models have emerged and evolved within Dutch planning practice, including PPJVs, each reflecting different levels of integration, responsibilities and risk-sharing between public and private actors.

PPJVs represent a distinctive form of PPP within Dutch urban development practice. Unlike traditional contractual PPPs—where governments set clear terms for private service provision—PPJVs involve the creation of a jointly governed legal entity. In these ventures, public and private actors cooperate intensively over a prolonged period, often merging governance structures and sharing both risks and responsibilities throughout nearly all phases of the development process (Klijn and Van Twist, 2007; De Zeeuw, 2018). Notably, PPJVs are long-term in nature, typically spanning 15 to 20 years.

PPPs in general have been highlighted as potential solutions to the increasing complexity of area development, where projects are required to address a growing range of societal challenges such as sustainable energy, climate adaptation, and social inclusion (Heurkens *et al.*, 2020; Janssen, 2024). This increasing complexity and interdependence between public and private actors has led to renewed calls from policymakers, developers, and academics for a revival of PPPs as suitable governance strategies for area development (BPD, 2023; Hümmels, 2017; Ten Have *et al.*, 2017).

5. Empirical findings: Value tensions in Dutch PPJVs

As a first main insight of this study, the interviews underscore that value tensions are inherent to PPPs, particularly in 'strong' PPP models such as joint ventures. The findings reveal a core tension between the need for transparency and democratic legitimacy on one hand, and the desire for progress and efficiency on the other. While transparency and accountability—especially towards municipal councils—are critical for legitimacy, an overemphasis can slow down decision-making and reduce the ability to act swiftly in complex area development projects. Conversely, prioritizing efficiency and progress may come at the expense of public oversight and trust. There is a continuous search for the right balance between keeping politics at a sufficient distance to allow for efficiency, while safeguarding legitimacy and transparency.

Another persistent tension is found between societal and financial returns. Public actors are primarily concerned with contributing to societal demands, whereas private partners focus on financial returns. The interviews underscore the importance of openly acknowledging and balancing these differing expectations at the outset, thus preventing future conflict and fostering a more sustainable partnership.

Finally, risk allocation is another recurring source of tension. When risks are divided unequally, distrust can arise, undermining the partnership. Interviewees stress that a more balanced risk distribution, even if private actors initially seek to minimize their exposure, is essential for fostering a sense of shared responsibility and long-term collaboration. A balanced risk allocation fosters greater trust and a more equal relational basis among partners, as everyone shares similar stakes and potential losses.

5.1. Governing value tensions in PPJVs

As a second main insight from this study, it became clear that the relationship between contractual and relational governance is central to understanding value tensions in Dutch PPJVs. These tensions are not only inherent to the public-private dynamic but are also shaped by how formal agreements and trust-based practices are combined. Interviewees point out that contractual governance provides the structural backbone for managing expectations and reducing opportunistic behaviour. Mechanisms such as exit strategies, clear and equal risk allocation, and supervisory boards are mentioned to become increasingly applied, especially following the financial crisis, as actors learned the importance of flexibility and the ability to adapt to changing circumstances. Well-designed contracts clarify roles, responsibilities, and dependencies, which can help prevent disputes and foster a sense of fairness. However, if contracts are too rigid or detailed from the outset, they can create an atmosphere of suspicion and inflexibility, undermining the collaborative spirit that is essential for long-term projects.

Relational governance, on the other hand, is built on trust, mandate, and informal cooperation. Trust enables partners to navigate uncertainties and adapt to unforeseen developments, which is particularly crucial in the long-term context of area developments. Giving project managers sufficient mandate and fostering open communication channels can accelerate decision-making and help balance the need for transparency with the demand for progress. Yet, too much reliance on informal trust without adequate contractual safeguards can lead to discomfort or even mistrust, especially from political stakeholders who require accountability.

The interviews reveal that the most effective PPJVs strike a balance between these two dimensions. For example, a 'light' contract that focuses on essentials, combined with regular informal engagement and clear channels for political input, can both safeguard public values and enable operational efficiency. Control mechanisms like dual-directorates, (internal) four-eyes principles, and external (financial) audits are seen as protective, ensuring transparency and enhancing trust without necessarily obstructing collaboration. Moreover, interviewees noted that, although private partners may have a preference for carrying less risk, a more balanced allocation of risks is generally considered preferable from a business strategy perspective. This is because such balance encourages a sense of shared responsibility, which can strengthen collaboration within the partnership and is viewed as advantageous for achieving long-term success and future business opportunities.

Moreover, the interviews suggest that actors in Dutch PPJVs do not appear to consciously govern value tensions as explicit objectives within their collaboration. Instead, their primary focus lies on securing their respective interests, mitigating risks, and managing potential conflicts to ensure successful implementation. This pragmatic orientation towards governance aligns with the hypothesized perspective that value tensions remain largely implicit rather than explicitly addressed.

Nevertheless, the contractual and relational mechanisms employed to manage interests and risks inherently shape how value tensions emerge and are handled in practice. For instance, efforts to allocate risks clearly and to establish trust-based cooperation influence the balance between values like transparency and accountability, and values such as confidentiality and efficiency. Thus, even though actors do not explicitly state that their governance activities are aimed at addressing value tensions, their governance practices have impact on how these tensions manifest and evolve throughout the collaboration.

This finding supports the hypothesis that governance arrangements in PPJVs are primarily interest- and risk-driven but simultaneously affect how value tensions emerge and are managed, confirming the earlier formulated reciprocal relationship.

5.2. Lessons and evolving perspectives in Dutch PPPs

The Dutch PPP landscape is evolving in response to both external pressures and internal learning. The complexity of area development has increased due to stricter regulations, broader societal challenges, and more demanding financial and risk management requirements, for example due to EU legislation (Basel III & IV). In this context, actors are innovating in structuring PPPs and governance arrangements after a period of decline.

The interviews indicate a shift towards lighter, more flexible partnership structures. Instead of transferring all land and responsibilities into a single joint venture, area developments now seem to seek governance designs that are suitable to accommodate more segmented developments, with responsibilities divided among smaller, task-specific entities (e.g., for energy, mobility, or above-plan infrastructure). Cost-allocation organizations are mentioned as vehicle to manage shared expenses (for example for construction of public space) and phased development approaches are adopted to reduce risk and allow for adjustment over time.

These innovative governance designs reflect a move away from the independent and rigid structures like PPJVs, which often struggled with inflexibility and demanded large investments upfront. The lessons learned from past joint ventures—such as the benefits of working out exit strategies, balanced risk-sharing, and the importance of combining contractual clarity with relational flexibility—influence the design of contemporary PPPs.

The interviews suggest a prevailing perspective that emphasizes the need for adaptability, mutual trust, and a careful balance of public and private values, with governance structures that can evolve in response to changing institutions and societal demands.

6.Conclusion

This paper has argued that we can currently observe a 'new phase' of PPPs in Dutch area development—a governance process around area-based spatial projects that includes important planning work—marked by adaptations that respond to contemporary challenges like increased financial constraints and the need to integrate multiple disciplines to address a wide range of societal issues. We set out to explore to what extent this new phase also addresses the value tensions inherent in PPPs, i.e. long-term collaborations between public and private actors. As PPPs are yet again emerging in the field because of the need for joint action to address contemporary urban development challenges, the central question seems not how to eliminate the tensions inherent to the partnerships, but how to acknowledge and 'govern' them within their evolving structures.

The findings indicate that PPJVs can mediate value tensions while maintaining effectiveness by finding the right combination of contractual and relational governance. Structured agreements play a crucial role in aligning financial objectives with societal goals, for example through balanced risk-sharing and contractually defined objectives. At the same time, keeping contracts as lean as possible helps preserve efficiency and flexibility, allowing actors to navigate the partnership based on relational norms and trust. Contractual control mechanisms—such as the appointment of an independent director, the use of external financial audits, and internal checks—can safeguard public values like transparency and accountability, reduce the likelihood of opportunistic behaviour, and help mitigate value tensions. Empirical evidence suggests that relational governance—embodied in mutual trust, open communication, and adaptability—can mediate or even compensate for the limitations of formal contracts, especially in a long term development process in which not all contingencies can be specified in advance. Conversely, well-designed contracts can provide a stable foundation that enables the development of relational norms and trust, particularly in the early and more vulnerable phases of a partnership. The Dutch context shows that managing value tensions in PPJVs requires a mutually reinforcing mix of formal agreements and trust-based practices, tailored to the specific context while leaving room to jointly adapt to changing circumstances. This dynamic interplay between contractual and relational governance offers actionable perspectives for managing value tensions in area development partnerships.

Empirical evidence also supports the hypothesis that actors do not explicitly govern value tensions, but primarily aim to secure their interests, manage risks, mitigate opportunistic behaviour, and maintain control. In doing so—often without consciously framing their actions in terms of value tensions—they still influence how value tensions are managed. This confirms the hypothesized reciprocal relationship: underlying values give rise to diverging interests, which actors manage through contractual and relational governance arrangements—arrangements that, in turn, shape how those value tensions emerge and are addressed throughout the collaboration.

Taken together, these insights indicate that value tensions can be managed to a certain extent through a thoughtful combination of contractual and relational governance. Embracing these inherent tensions, rather than seeking to eliminate them, is crucial for developing governance models that support public value creation in the complex context of area development.

Abstract
Integration of spatial planning systems across the EU's fringe regions is often challenged by institutional asymmetry, fragmented governance, and uneven territorial capacities. These conditions hinder the development of coherent evaluation tools capable of capturing the complexity and evolving nature of integration processes in such contexts.

This paper proposes a methodological framework that combines theoretical insights from territorial capital with a time- and process-sensitive evaluation logic. Inspired by the conceptual modelling techniques, the framework aims to assess spatial planning integration by linking contextual conditions, institutional dynamics, and cooperative processes. The South Balkan region is used as a contextual reference to guide framework development, offering illustrative territorial and institutional complexities, without serving as an empirical test site.

The approach is intended to support flexible, multiscalar, and temporally aware assessments of integration efforts, especially in regions where formal alignment may not reflect substantive cooperation or institutional readiness. By reframing spatial planning system integration as a dynamic and relational process, the framework offers an adaptable tool for future empirical research and policy evaluation in territorially diverse European regions.

Keywords: Spatial Planning System Integration, Territorial Capital, Indicator System, EU's Fringe Regions

1.Introduction

Integration of spatial planning systems is often seen as a complex, yet critical challenge in achieving meaningful territorial cohesion. During the late XX century and especially since the turn of this century, conditions for urban and regional development have been changing dramatically for countries and cities in Central, and more recently in Southeastern Europe. The process of integration has created new settings for capital flow, mobility of labour forces, and exchange of goods and services, consequently triggering new potentials and problems. Fuelled by the increasing globalization of economic activities, the pressure of competition between countries and cities/ regions has grown significantly thus making it crucial force in shaping the development paths of territories.

These problems seem to be even more intense in the EU's fringe regions. The territories in question are often characterized by complex socio-economic conditions, deep historical and cultural legacies, specific techno-political dynamics, and diverse governance structures, all of which are reflected in the regional territorial capital. Therefore, understanding the interplay of these tangible and intangible elements within the unique local contexts, together with accurate assessment of the extent and impact of Europeanisation processes on the planning systems, becomes fundamental for defining paths towards sustainable territorial development, grounded in the integration and cohesion.

However, conventional methodologies that provide frameworks for understanding and leveraging regional assets seem to face significant hurdles in these dynamic environments. The concept of "territorial capital" (TC), notably advanced by Roberto Camagni, has played a critical role in categorizing the diverse assets. Coming from an economic perspective Camagni (2007, 2008) discussed the term in a comprehensive way, introducing different types of territorial capital and essentially paving the way for further research. As Moretta (2021, p. 104) notes, "The originality of this concept lies on the fact that, for the first time, the attention focuses on the analysis of a certain place in a more holistic and comprehensive way, considering a wider set of tangible and intangible assets located in it".

Yet, applying such frameworks to the EU fringe regions, especially those encompassing mixed membership statuses, reveal several gaps, either from a contextual or structural perspective. The discussion of these gaps, asks for a new methodological approach, one that will enable an indicator system in support of an evidence-based spatial planning system integration. Therefore, the aim of this research is to address these limitations by providing a structured, adaptable, and solution-oriented methodology of identifying the relevant components as assets of the TC in the fringe regions and suggesting more dynamic understanding of how territorial potential is activated, leveraged, and transformed through policy interventions and governance processes.

Methodologically, this involves critically engaging with the concept of territorial capital but augmenting it with a process-oriented approach capable of capturing dynamics, evaluating performance, and informing adaptive strategies. We propose integrating the diagnostic strengths of TC taxonomies with evaluative and dynamic framework of Input-Output-Outcome-Process (IOOP). This combination provides complementarity in a way where understanding the existing capital will provide context for policy design, while the IOOP model will allow evaluation of how effectively, specific policies mobilize or enhance that capital to achieve desired outcomes. The IOOP framework formalizes the pathways that are supported by the assets and resources (Inputs), then are activated through governance mechanisms and institutional practices (Processes), will lead to tangible short-term results (Outputs) and, ultimately, will provide long-term transformations (Outcomes).

The primary geographical focus of this study is the South Balkan region, selected for its representative complexities, commonly found in the EU's fringe areas characterized by mixed membership, diverse developmental trajectories, and significant integration challenges. Here, it is worth noting that the paper develops a comprehensive indicator system, where the proposed case-study plays the role of contextual anchor - a reference that helps inform the structure and logic of the proposed system. However, it does not report on the application or findings of this framework, which will be the focus of future empirical work.

2.Conceptual Framework and Methodology

2.1.*Territorial capital: challenges*

The concept of territorial capital (TC) closely tied to debates of urban competitiveness (Begg, 1999; Boddy & Parkinson, 2004) and integration policies, was introduced by the OECD (2001) and further developed by Camagni (2007, 2008). It highlights the role of endogenous assets alongside exogenous factors in unlocking development potentials. To systematize these assets, Camagni proposes a taxonomy based on two axes: rivalry (private, impure or club, and public goods) and materiality (tangible, mixed, and intangible). This approach, eventually results in a 3x3 matrix of nine types of capital, all contributing to local competitiveness and, if accumulated positively, to sustainable development. At its corners, within the so-called "traditional square", the matrix identifies the following capital forms: private fixed capital (tangible, high rivalry), natural/cultural resources and infrastructure (tangible, low rivalry), human capital (intangible, high rivalry), and collective action (intangible, low rivalry). The remaining five types of capital, form an "innovative cross" in the matrix center, including proprietary networks, university spin-offs, agglomeration economies, relational capital, and governance networks. Within this taxonomy, the relational capital and cooperation networks highlight the social and policy-driven dimension of TC, thus emphasizing place-specific qualities and comparative advantages that go beyond purely functional assets.

However, applying the territorial capital (TC) methodological approach directly to EU fringe regions for assessment purposes reveals significant limitations, broadly falling into two categories: contextual and structural challenges. The first, come from misalignment between the framework and socio-political, economic, and cultural realities of the EU fringe regions, while the latter, stem from the internal design and operational limitations, particularly in its application to diverse and data-scarce contexts.

Over the years, contextual criticism has challenged Camagni's framework for being too static and failing to capture the dynamic evolution of territorial capital in response to global shifts like digitalization, migration, or climate change (Rodríguez-Pose, 2018), specifically for the regions experiencing rapid socio-economic transitions (e.g. EU integration processes). Some have found the taxonomy's Eurocentric bias, rooted in Western institutional models, to overlook the unique historical and cultural contexts of non-EU states, where informal institutions and power dynamics play significant roles (Marques & Morgan, 2018)and the economic crisis that ensued, have exposed even further the persistent pattern of uneven development which has plagued the European Union (EU.

In this context, TC taxonomy appears to be irresponsive to the effects and underdeveloped roles of institutions in these states, primarily in regard to the institutional quality, trust, and governance capacity. These are vaguely categorized, limiting the framework's ability to address the complex institutional landscapes of fringe regions, where alignment with EU standards is a priority for candidate countries (Cojanu & Robu, 2019). Namely, Camagni's framework assumes harmonious mobilization of territorial assets, underestimating political conflicts and power asymmetries, deep ethnic divisions and contested borders within and between territories (Rodríguez-Pose, 2013). In the fringe regions for example the governance capacities significantly differ between EU members and candidates, consequently leading to oversimplifying the challenges of cross-border cooperation and resource allocation (Medeiros et al., 2024).

Camagni's taxonomy has been confronted in structural terms too. Pike et al. (2016) discuss the empirical application challenges posed by blending of physical, human, relational, and institutional assets, which often result in blurred boundaries. Terms like "social capital" and "relational capital" lack rigorous operational definitions, complicating their measurement in diverse contexts such as the South Balkans, where trust and cooperation vary significantly across borders (Storper, 2005). Finally, the largely normative nature of the taxonomy, offering few concrete indicators for measuring territorial capital across regions (Affuso & Camagni, 2010) is emphasized as critical gap in these fringe regions, where data availability is inconsistent, and comparable metrics are essential for evidence-based policymaking.

In response to these challenges, aforementioned scholars have expanded their research on the dynamics of the regional development processes and relational dependencies. For instance, Storper (2005) highlights relational assets and untraded dependencies, through a context-specific, path-dependent lens; Boschma and Martin (2010) emphasize historical trajectories and local capabilities in their "evolutionary economic geography"; and Rodríguez-Pose (2018) introduces the "Geography of Discontent", linking underdevelopment to inequality, discontent and governance failures. Martin and Sunley (2015) focus on institutional thickness and fit, addressing Camagni's underdeveloped treatment of institutions; Faludi (2010) and Davoudi (2003) promote polycentric development as an alternative to agglomeration models, aligning territorial capital with spatial planning and providing a policy-oriented lens to operationalize assets like infrastructure and relational networks. Barca (2008) stresses place-based, participatory approaches that operationalize territorial capital through stakeholders engagement; Moulaert et al. (2013) explore community driven solutions, Capello et al. (2009) offer frameworks for fringe-regions innovation ecosystems, and Servillo (2010) investigates governance innovation – all enhancing Camagni's model with tools for institutional alignment, collaboration, and policy relevance.

The extensive engagement of scholars with Camagni's territorial capital taxonomy (Camagni, 2007, 2008, 2009) affirms its status as cornerstone in regional development, offering multidimensional lens to classify, both tangible and intangible assets that drive territorial competitiveness and cohesion. However, all these takes on Camagni's taxonomy have limited application to complex contexts, such as the EU fringe regions. As Morretta (2021) argues, the taxonomy's strength lies in its integrative approach, which combines endogenous and exogenous forces to enhance local resources and improve well-being. The framework successfully moves beyond the limitations of purely top-down strategies that overlook local dynamics, while avoiding the narrow scope of bottom-up approaches focusing solely on local actors. However, its effectiveness relies on more nuanced and context-sensitive application of the taxonomy or as Morretta's observes: "... territories are endowed with different local actors and types of tangible and intangible resources of variable quantity and quality. Although both types of resources are important in determining and shaping the territorial characteristics and potential of a certain place, intangible forms of capital such as governance, innovation, networking and entrepreneurship are crucial to release this potential and trigger the process of endogenous development" (Morretta, 2021, p. 111).

2.2.*Structural support of evidence-based indicator system*

The discussion above, clearly underlines that, designing a comprehensive indicator system for spatial integration in EU fringe regions requires more than a static mapping of territorial assets; it demands a dynamic, adaptive, and politically sensitive framework capable of capturing the evolving, contested, and multilayered nature of territorial development. In contrast to specific and narrow conceptual frameworks, such as Storper's relational assets, Boschma and Martin's evolutionary economic geography, Rodríguez-Pose's geography of discontent, and Barca's place-based development, this study will focus on the Input-Output-Outcome-Process (IOOP) model, as operationally complete and strategically more flexible approach.

The discussion above, clearly underlines that, designing a comprehensive indicator system for spatial integration in EU fringe regions requires more than a static mapping of territorial assets; it demands a dynamic, adaptive, and politically sensitive framework capable of capturing the evolving, contested, and multilayered nature of territorial development. In contrast to specific and narrow conceptual frameworks, such as Storper's relational assets, Boschma and Martin's evolutionary economic geography, Rodríguez-Pose's geography of discontent, and Barca's place-based development, this study will focus on the Input-Output-Outcome-Process (IOOP) model, as operationally complete and strategically more flexible approach.

Grounded to some extent in the Logic-Model Theory (Kellogg, 2004; Wholey, 1979) and Program Theory (Chen, 2012; Rogers, 2008; Weiss, 1995), Figueiredo et al. (2018) in the OECD document titled as "Indicators for Resilient Cities" provided one of the first major application of the so-called IOOP model in European urban policy evaluation. While the traditional logic models are often linear and do not provide feedback loops for policy evaluation, the program theory prioritizes causal and contextual logic, but when it comes to practical adaptation, it lacks operational and policy-focused loops. The IOOP model (Figueiredo et al., 2018) aligns with Logic models by using the same categories: inputs, processes (as activities), outputs, and outcomes as core components, tailoring them into a framework, specific for territorial policy in complex, multi-scalar contexts. It also draws from Program Theory's outcome orientation and iterative evaluation but formalizes a more operational, policy-oriented structure. The strong practical applicability of this model has been acknowledged by many scholars including Giffinger and Kramar (2023) who developed an indicator system of distinct components for liveable cities, and in his later work, Giffinger (2024) expands the IOOP model with learning processes by adopting a phase-specific, processual approach.

Drawing from the literature review and driven by an overarching objective to address the complexities of spatial planning system integration in the EU's fringe regions, we argue that combining Camagni et al.'s TC taxonomy (2007, 2008) and Figueiredo et al. (2018) IOOP model will provide structural framework for building comprehensive indicator system. This framework isn't driven by the compatibility of the two methodological approaches, rather by their complementarity, as they answer different questions. Camagni et al. focus on the statics of potential (territorial assets) while Figueiredo et al. focus on dynamics of intervention, as input describing the policy performance. Understanding the territorial capital provides the context for designing relevant policies and evaluating those policies could show how effectively that capital is being leveraged or enhanced to achieve direct outputs and ultimately, as outcomes of policy interventions. In other words, the complementarity of these models lays not in its common denominator, rather in what each doesn't primarily focus on:

- Gap from Policy Evaluation Perspective: The Figueiredo et al. (2018) approach, while evaluating a policy, might not explicitly account for the underlying territorial context defined by its specific mix of territorial capital. The success or failure of a policy (it forms of its output) can be heavily influenced by the pre-existing territorial capital (e.g. a skills policy will have different outcomes in a region independent of its initial level of human capital). Hence, this framework measures policy results but doesn't inherently diagnose the underlying territorial conditions that shape those results.
- Gap from Territorial Capital Perspective: Camagni's taxonomy provides a rich diagnosis of a territory's assets and potentials (which are outcome of former development) but doesn't inherently evaluate how specific policies are mobilizing, utilizing, or changing that territorial capital. It describes the potential but doesn't measure the effectiveness of actions taken to leverage it. We know what capital exists, but not necessarily how well certain policy is using or building the corresponding types of capital.

Table 1: Key differences

FEATURE	FIGUEIREDO ET AL. (2018) (policy evaluation)	CAMAGNI (territorial capital)
WHAT IT LOOKS AT	A specific policy or program	A territory (region, city)
MAIN GOAL	Evaluate policy performance/impact	Diagnose territorial potential/assets
FRAMEWORK	Performance Measurement Logic Chain	Asset Taxonomy / Classification
NATURE	Evaluative (How did X perform?)	Diagnostic (What does Y possess?)
ELEMENTS	Inputs, Process, Outputs, Outcomes	Types of Capital (Human, Social...)

Figueiredo's emphasis on feedback loops and adaptive cycles provides a crucial upgrade of Camagni's TC taxonomy. Evolutionary economic geography adds an important temporal dimension, but adaptation often appears organic rather than structured. In the IOOP model, feedback from Outcomes provides necessary information for the reassessment of Inputs and Processes, thus creating an explicit mechanism for learning and reconfiguration.

In the context of the EU's fringe regions, where fragmented histories, contested borders, and uneven economic transitions define spatial dynamics, designing a robust indicator system for spatial integration demands an approach that captures not only territorial assets, but also ways these assets are activated and transformed through policies. As a result, conceptualization of these policies is directly rooted in the outcomes of the feedback loops, provided by the IOOP model.

Table 2: Complementarity of Camagni's taxonomy and Figueiredo et al. IOOP methodology

ASPECT	CAMAGNI'S TAXONOMY	ENHANCED BY IOOP	WHY CRITICAL FOR FRINGE REGIONS
CORE LOGIC	Static typology of territorial capital	Dynamic sequencing (Input - Output – Outcome-Process)	Fringe regions need dynamic assessment of activation, not just listing assets
RELATIONAL ASSETS HANDLING	Acknowledged but not operationalized	Focuses on relational activation mechanisms	Detects failures to mobilize existing tangible networks and infrastructures
GOVERNANCE EVALUATION	Implicit, general	Explicit assessment of processes and capacities	Identifies governance gaps, common in politically fragmented fringe regions
CONTEXT ADAPTABILITY	Assumes stable institutional contexts	Includes feedback loops, adaptive to shocks	Captures rapid socio-political and economic changes typical of fringe areas
PLAN VS OUTCOME MEASUREMENT	Largely descriptive	Tracks discrepancies between plans and outcomes	Exposes implementation bottlenecks, crucial where planning often underdelivers
INSTITUTIONAL SENSITIVITY	Eurocentric stability bias	Sensitive to hybrid, informal, evolving institutions	Suitable for fragile, mixed-governance settings of fringe regions
MULTI-LEVEL, CROSS-BORDER FIT	Territory	Accommodates multi-scalar, cross-border dynamics	Fits the transnational, cross-border realities of EU peripheries

2.3.***Identifying key territorial dimension for SPSI in EU's fringe regions***

In the ever-evolving landscape of European spatial governance, the notion of spatial planning system integration (SPSI) has become increasingly central. As the European Union has expanded eastward and southward, it has incorporated a broader array of political traditions, institutional cultures, and territorial challenges, only to instigate re-definition of the term integration. In the theoretical discourse, the act of spatial planning system integration refers to the processes and mechanisms aimed at enhancing coherence, coordination, and cooperation between distinct spatial planning systems across different administrative levels (vertical integration) and policy sectors (horizontal integration) (Davoudi & Strange, 2008; Stead, 2014; Stead & Meijers, 2009)this book examines spatial planning at different places throughout the British Isles. Six illustrative case studies of practice examine which conceptions of space and place have been articulated, presented and visualized through the production of spatial strategies. Ranging from a large conurbation (London. Yet, the realities of integration differ substantially between EU core regions, endowed with mature planning institutions and dense territorial capital

and fringe regions, where fragmented governance, asymmetrical institutional capacity, and geopolitical tensions frequently complicate integration efforts. While in both cases, the ultimate goal is to create a more harmonized and synergistic approach to territorial governance that transcends administrative borders (Moulaert et al., 2010), we observe key differences in the properties of these two types of regions. By employing previously established methodology as a guiding analytical framework, we will explore how different forms of capital, condition the nature and success of spatial planning system integration. The main objective is to identify the key component(s) for successful SPSI in EU's fringe regions.

In contrast to the EU core regions, which often exhibit high relational capital in form of well-positioned logistical and economic networks, EU's fringe regions, particularly those along the eastern and southeastern peripheries face a distinctly different reality. Here, SPSI efforts contend with historical legacies of centralized governance, weak planning institutions, limited policy coherence, and geopolitical fragmentation. Examples include the Western Balkans, and to some extent already integrated parts of Eastern Europe and Baltic states, which exhibit fragmented and underdeveloped territorial capital, resulting in weak spatial planning integration. Furthermore, centralized governance legacies, limited administrative capacities, and sectoral fragmentation constrain institutional capital and cross-border coordination (Nienaber & Wille, 2020). The results of the ESPON COMPASS project (2018) find that many of these systems are "proto-conformative" or "erroneously performative" planning systems, in which policies exist in formal documentation, but are weakly implemented in practice and often subordinated to investor interests. Path dependency, rooted in professional and institutional inertia, further hampers reform (Dąbrowski & Piskorek, 2018), while market-led development with weak public oversight defines the "neo-performative model" common in the areas (Berisha et al., 2021).

Economic capital remains central to integration, yet disparities in infrastructure and investment undermine planning capacity, especially in the Eu's fringe, cross-border regions (Perkmann, 2003), which is why Jakubowski (Jakubowski, 2020) stresses that gaps in physical infrastructure demand tailored, place-specific policies. In addition, the limited market access weakens relational capital, thus hindering the implementation of strategic visions (Zonneveld, 2005), which escalates the necessity of data harmonization and infrastructure systems for effective cross-border planning (Frank et al., 2017). Finally, as Perkmann (2003) notes, low social capital, driven by historical divisions, weak trust, and fragile regional identities further obstructs cooperation, which underscores the importance of fostering shared identity and trust.

All of these shortcomings across different components of the territorial capital in the fringe regions greatly impede the integration of spatial planning systems and therefore addressing them efficiently requires targeted interventions. But what actually constitutes effective spatial planning system integration and what are the key territorial dimensions? Literature review, shows that scholars seem to agree on several key properties:

- Policy Coherence: Alignment of strategic objectives, policies, and instruments across different planning systems and levels (Stead, 2014; Stead & Meijers, 2009);
- Inter-administrative Cooperation: Established formal and informal mechanisms for joint working, communication, and decision-making between planning authorities (Zonneveld & Stead, 2024);
- Shared Territorial Vision: A collectively agreed-upon understanding and set of goals for the future development of the shared territory (ESPON, 2018);
- Harmonization of Frameworks: Efforts to align legal, regulatory, and procedural aspects of planning systems to facilitate joint action, though full harmonization is often complex and not always the primary goal (Janin Rivolin, 2008);
- Joint Implementation and Monitoring: Collaborative execution of planning strategies and projects, supported by shared monitoring and evaluation systems (Waterhout, 2008);
- Adaptive Capacity: The ability of the integrated system to learn from experience and adapt to changing socio-economic, environmental, and political contexts (Healey, 2006).

While, SPSI relies on synergy among various forms of territorial capital, the aforementioned properties of effective spatial planning system integration are intrinsically linked more to certain types of territorial capital, mostly: Relational Capital, Institutional Capital, Cooperation Networks & Governance, Social Capital and Human Capital.

Camagni et al. define relational capital as "bilateral and multilateral linkages" rooted in trust, shared values, and the ability for cooperation and collective action (2011, p. 5). As a key form of intellectual capital, its intangible and flexible nature makes it crucial in navigating diverse planning cultures, especially in cross-border contexts (Nienaber & Wille, 2020; Purkarthofer, 2018). Its "club good" nature means that benefits are shared mainly among active participants, underscoring the value in joint planning efforts, where cooperation yields both direct and wider regional benefits. In fringe regions, relational capital helps overcome cognitive and cultural gaps, promotes socio-cultural integration and enables knowledge sharing (Camagni et al., 2011; Fogarsi, 2024). Unlike human capital, which is rivalrous and private, relational capital enables transformation of potential into effective cooperation and by doing so it addresses Boschma's "proximity puzzle" (Boschma, 2005). Thus, while social capital reflects the slow-building trust of a community, relational capital centres on active, strategic linkages between actors.

Institutional capital is also essential for SPSI, particularly in cross-border regions, where fragmented governance hinders spatial collaboration (Nelles & Durand, 2014)the number of cross-border cooperation structures in Europe has exploded owing to political and financial support by the European Union aimed at encouraging cohesion and developing peripheral regions. These policies are part of processes of de-bordering and political rescaling that have profoundly affected cross-border areas by creating new institutional territories and political structures. The purpose of this paper is to study the institutional history of cross-border metropolitan governance in Europe through the comparison of two of the most advanced cross-border metropolitan regions: Lille and Luxembourg. This paper asks how these cross-border structures have developed and changed. What can their patterns of institutional evolution contribute to understanding governance in other cross-border regions? Are these new spaces evidence of political rescaling? This paper presents and redefines cross-border governance as a cyclical and a long-term process and also explores the challenges that these partnerships face in becoming functionally effective and autonomous policy actors. Ultimately, we find that there is no replicable ideal of cross-border governance and that even long-standing partnerships are in a period of exploration and reinvention. Establishing a competitive and coherent cross-border metropolitan region is ambitious and complex, and it necessitates the coordination of policies at multiple scales and across institutionally diverse territories. This project requires the modification and/or construction of new institutional and legal frameworks. This reorientation of political attention has resulted in a reconceptualization of political space but not the empowerment of new political actors, indicating that the process of rescaling may be a work in progress.","container-title":"European Urban and Regional Studies","DOI":"10.1177/0969776411431103","issue":"1","page":"104-122","title":"Political rescaling and metropolitan governance in cross-border regions: comparing the cross-border metropolitan areas of Lille and Luxembourg","volume":"21","author":[{"family":"Nelles","given":"Jen"},{"family":"Durand","given":"Frédéric"}],"issued":{"date-parts":[["2014"]]}}],"schema":"https://github.com/citation-style-language/schema/raw/master/csl-citation.json"} . Although Camagni's taxonomy doesn't list it as separate entity, institutional capital intersects with both social and cultural capital, blending tangible infrastructure with intangible norms and governance "software" (Giffinger et al., 2007). Institutions function as public goods but face limitations in light of different scales of legal harmonization and Europeanization. This means that institutional capital can create enabling frameworks, yet it does not ensure stakeholder action or capacity. In fact, it is often determined by the political will and bureaucratic rigidity (Camagni, 2019; Jakubowski, 2020). Thus, formal structures alone are insufficient without strong relational dynamics and adaptive governance practices.

Considering the discussion above, while we recognize that SPSI is a multifaceted process influenced by a variety of territorial capitals, we underscore the prevalent comparative importance and favourability of relational capital. Its ability to activate and sustain mechanisms of cooperation, particularly in fragmented and asymmetric governance environments, alongside its embeddedness in trust-based linkages, joint action, and shared learning proves that the relational capital is the most context-sensitive and policy-relevant component of territorial capital for enabling meaningful spatial integration. Therefore, in the following section, we turn to explore how relational capital can be systematically integrated into the IOOP model, enabling us to assess not only the presence of territorial assets, but also their activation through strategic cooperation, collective competence, and adaptive planning practices.

2.4.***Integrating Relational Capital into the IOOP model for SPSI***

In order to provide operational completeness, embedded feedback mechanisms, and capacity for theoretical integration we will implement the Input-Output-Outcome-Process model, thus enabling more coherent integration policy evaluation. By doing so, we align with Giffinger and Kramar's path-oriented approach, which considers "the urban dynamics over time and therefore provides evidence on speciΔc transformation processes" and their recommendation that designing a comprehensive indicator system should be "based on a place-based and process-orientated understanding of urban development, which can be expressed by appropriate indices for measurable trends"(Giffinger & Kramar, 2023, pp. 45, 50).

In the context of EU's fringe regions, this means understanding the temporal dynamics of relational capital, or how trust, cooperation, and institutional embeddedness emerge and evolve. Therefore, our first challenge will be to map the relational capital across the four stages in this model and try to identify how relationships are built, operationalized, tested, and matured throughout the integration process in spatial planning or governance. Emphasizing the importance of policies when designing indicators, comes from the following objectives: creating goal-oriented framework, providing effective policy discussion, supporting comprehensive evaluation, delivering evidence-based recommendation and encouraging meaningful, stakeholder engagement. Consequently, full integration of the relational capital into the IOOP model necessities discussion over what should be addressed by the selected indicators, what should be acknowledged and what should be measured.

The Input phase lays the relational foundation for cooperation by building trust, aligning norms, and identifying stakeholders (including underrepresented groups like: local authorities, civil society, cross-border institutions). Early recognition of asymmetries in power dynamics, resources, and knowledge is essential to prevent dominance by stronger actors later. Understanding divergent governance cultures, harmonizing planning terminologies, and comparing legal frameworks and policy cycles supports conceptual alignment. It is during this phase that acknowledgement of past cooperation or conflicts will inform setting realistic agenda and joint visioning.

The Output phase shifts to tangible deliverables: strategies, agreements, instruments to name a few, that reflect coordination across sectors (horizontal) and governance levels (vertical). Outputs gain legitimacy when embedded in laws or administrative procedures, which in later stages should be accompanied by clear implementation plans (timelines, funding, responsibilities). These must reflect local socio-economic realities and include feedback loops for monitoring and revision, ensuring adaptability. In contrast, outputs that are technically sound but socially or institutionally fragile indicate that the system remains fragmented under the surface.

The Outcome phase demonstrates the transformative value of the entire process. As noted by Figueiredo et al. (2018), this is where the maturity of relational capital is assessed via policy changes, service improvements, or greater territorial cohesion. Indicators of success include formalized cross-border institutions, aligned procedures, and joint governance bodies. Spillover effects, like regional synergies or transferable planning models signal systemic change. Additionally, signs of healthy trust, stakeholder engagement, and public satisfaction confirm that integration is continuing beyond project cycles.

Finally, the Process phase tests the authenticity of collaboration. As Healey (2006) describes, planning is an "arena" where actors negotiate and coordinate. It is only foreseeable that relational capital will be activated through joint decision-making, adaptability, and conflict resolution, whereas symmetrical power dynamics, mutual accountability, and inclusion of smaller actors reveal the depth of cooperation. This phase depends on strong human and institutional capital: facilitators, secretariats, and support structures, all important to sustain momentum and resilience.

Table 3: Indicator properties per stages of IOOP model

IOOP Stage	What Should Be Addressed	What Should Be Acknowledged	What Should Be Provided / Measured
INPUT	- Identify actors, mandates, and willingness - Build trust foundations - Mobilize shared resources	- Power asymmetries - Trust gaps - Lack of shared vision or institutional continuity	- Stakeholder mapping - Shared intent statements - Initial trust scores - Cross-border legal/financial provisions - Baseline network connectivity
OUTPUT	- Generate co-produced outputs - Institutionalize learning and procedures - Ensure shared ownership	- Imbalance in workload or influence - Superficial or symbolic outputs	- Number and quality of co-produced plans - Legal standing of outputs - Follow-through rate on commitments - Process quality reflected in outputs
OUTCOME	- Institutionalize cooperation culture - Sustain long-term relationships - Support mutual learning	- Political turnover - Fragile institutional memory - Risk of "project fatigue"	- Long-term policy alignment - Survival of partnerships - Stakeholder satisfaction trends - Adaptive capacity - Indicators of spatial cohesion and trust continuity
PROCESS	- Enable coordination platforms - Align decision-making practices - Ensure transparency and inclusivity	- Informal leadership and champions - Conflicting routines or vocabularies - Participation fatigue	- Frequency and diversity of joint meetings - Equitable participation metrics - Joint task forces - Conflict resolution practices - Decision autonomy and reciprocity

Understanding each of the phases of the IOOP model in regard to the relational capital, provides us with means to address its main components: cooperation capability, collective action capability and collective competence. Here, we utilize the following understanding of the components: Cooperation capability – the ability of actors to engage, communicate, and maintain relationships, Collective action capability – the capacity to coordinate and act jointly toward shared objectives and Collective competence – the shared knowledge, routines, and skills enabling effective joint problem-solving and adaptation. These components could be connected to particular phases of the IOOP model. Cooperation capability is most crucial in the Input and Process stages, as without it, partnerships lack trust and fail to activate; Collective action capability peaks in the Process and Output stages, when entities must act jointly and Collective competence becomes visible in Output and Outcome phase, as it reflects whether knowledge, routines, and learning are institutionalized. However, this categorization is very tentative, as the components are interdependent, not isolated; they are iteratively evolving across all IOOP phases and reinforce themselves over time through feedback loops. For example, key identifier of cooperation capability is trust-building, which starts in input phase, but is continually tested and reinforced in Process, Output, and only proves sustainable in the Outcome phase; collective action capability begins as coordination attempts in process phase, but its real expression is in joint delivery (Output) and long-term policy embedding (Outcome); and collective competence emerges from shared learning and experience, which is built in the Process and Output phase, but has its maturity reflected in the Outcome phase. This is why rather than exact mapping of the components at certain stage of the IOOP process, we should trace their development and expression across time.

Table 4: Relational capital components integration in IOOP model

RC Component	INPUT (effort)	PROCESS (action)	OUTPUT (efficiency)	OUTCOME (effectiveness)
Cooperation Capability	Build trust Align visions	Sustain dialogue Encourage openness	Coordinate authorship Ensure shared visibility	Institutionalize trust Measure stakeholder confidence
Collective Action Capability	Define shared intent Negotiate roles	Coordinate tasks Resolve conflicts	Deliver together Monitor contribution balance	Sustain cooperation Enable continuity of actions
Collective Competence	Recognize skills Identify learning needs	Share knowledge Create joint procedures	Co-produce strategies Document learning	Adapt policies Embed learning into governance culture

3.Multilayered system of relational capital and indicators

Building on the preceding discussion and methodological framework, the next step is to identify indicators linked to key components of relational capital relevant for Spatial Planning System Integration (SPSI). Here, we underline that indicator selection is context-sensitive, differentiating core EU regions, which can rely on outcome-oriented indicators, from the fringe regions, which benefit from indicators measuring input and processes.

Considering the fringe-specific pre-conditions, it becomes evident that a comprehensive indicator system for evaluating SPSI should be grounded in a multi-layered conceptual structure that runs across the IOOP Cycle. At its foundation, the system must be built upon place-dependent factors that reflect the unique spatial, institutional, socio-economic, legal, and cultural characteristics of each region. This makes them cross-cutting as they influence all four IOOP phases. While they are mainly anchored in the Input phase, where they describe the foundational conditions but their effects are most visible in the Output and Outcome phase. In essence, these factors provide the structural core that ensures any policy development process is territorially anchored, context-sensitive, and capable of addressing the real conditions and constraints of a given region.

The use of policy-oriented concepts as the organizing logic, indicators should be designed to assess fundamental goals of spatial planning integration, such as institutional coherence, subsidiarity, alignment of planning instruments, stakeholder participation, and governance efficiency. The indicators for this layer of our system, define the normative orientation of the planning system which makes them valuable for establishing the preconditions and guiding principles. As expected, they are mainly located in the Input phase of the IOOP Cycle, although some indicators like stakeholders' engagement could indicate results in Process and Output phase too. Indicators based on these concepts help evaluate readiness and capacity, they reflect the strategic cognition of actors, in terms of how they understand integration, what they prioritize, and what they perceive as barriers or enablers. Nevertheless, though framed around normative policy objectives, these types of indicators must be reflective to the specificities of place, allowing the system to maintain both, comparability and local relevance. Misplacing the indicators for policy-oriented concepts into the output or process phase, exposes a risk of treating the guiding values as results, which inverts the logic of a policy design.

Finally, to operationalize and evaluate the development of SPSI over time, the system must adopt a path-oriented framework. Such a framework enables the analysis of trajectories, institutional learning, and cumulative capacities through all stages of the IOOP model. However, the key indicators for this framework are primarily anchored in the Outcome phase because there, they capture the cumulative, long-term, and emergent effects of integration. This dimension of our system, consequently ensures that the SPSI is evaluated as a dynamic and historically contingent process, not just a snapshot of plans or actions.

In sum, the integration of place-dependency as the structural core, policy-oriented concepts as the design framework, and path-orientation as the temporal-evaluative logic provides us with a comprehensive system of relevant indicators evaluation of spatial planning system integration in EU's fringe regions.

Having established the structural framework of the system and indicator relevancy filters, the next step is to run the system across the three dynamic components of relational capital: cooperation capability, collective action capability, collective competence.

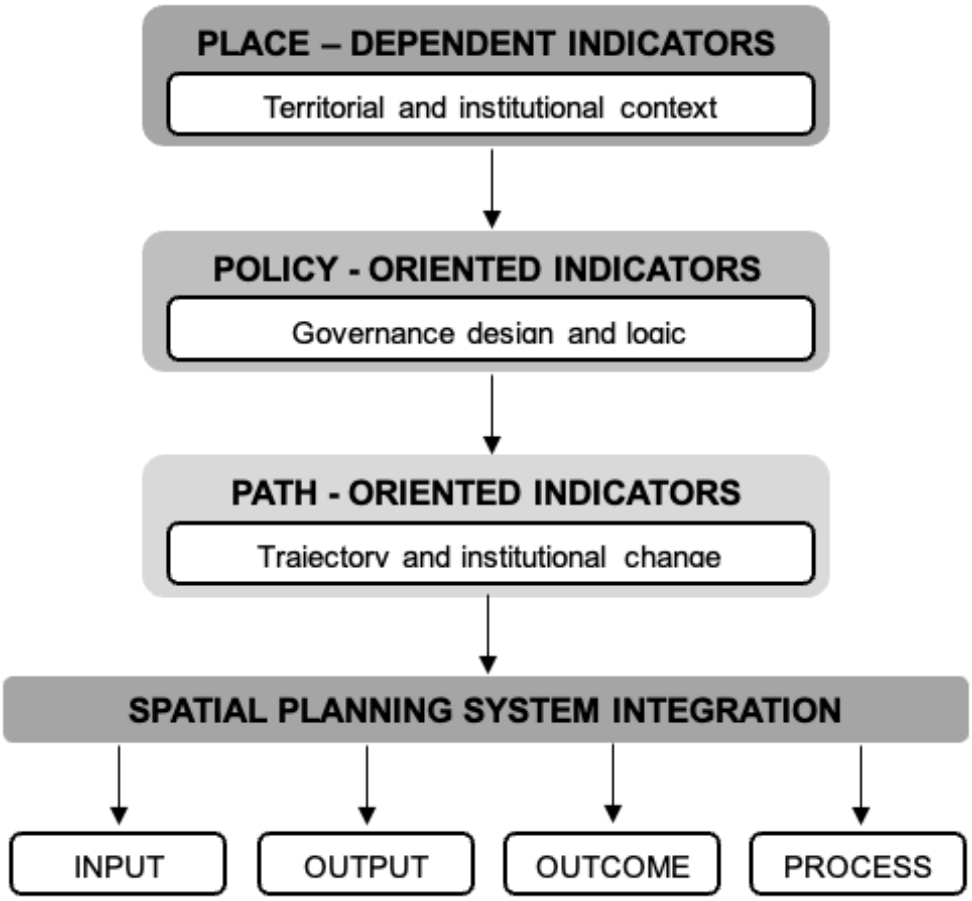

Figure 1: Indicator relevancy filters

The relationship between these components vis-à-vis indicator types and the IOOP phases is mostly horizontal and cross-cutting, although some relational capital indicators are inherently phase-dependent, meaning they are not strictly independent and interact with all phases. Accordingly, we adopt the understanding of this relationship as cross-phase and interactive, dependent on two analytical dimensions and one sequential. This means that relational capital can be analysed as transversal dimension: it is activated in the Process phase, shaped in Input, reflected in Output and Evaluated in Outcome phase. Indictor types (place-dependent, policy-oriented and path oriented) as diagnostic lens, shape the temporal logic, that is they organize how we observe relational capital, not when it happens; and finally, the IOOP model gives structure to systemic change, from conditions to coordination to outputs and implications.

In Table 5, we provide graphic interpretation of Indicator relevancy for each component of relational capital per particular phase within the IOOP model. The different shades of colour, along with descriptions above, indicate the analytical role and relevance of each indicator type within the IOOP model. The values (strong, cross-cutting and not applicable) help clarify how each indicator is used in evaluating SPSI and where it holds the most analytical weight. So, when certain indicator is anchored then it is directly connected to its relevancy, meaning it is fully applicable, and designed to measure variables or dynamics specific to that phase. For example, place-dependent indicators are anchored in the Input phase, because they measure initial conditions like institutional maturity, legal structure, or governance asymmetry, whereas the path-oriented indicators are anchored in the Outcome phase, because they assess trajectory, learning, and long-term change, which are only visible over time. The cross-cutting indicators provide interpretive insights, helping to understand, contextualize, or explain variations in that

phase. In this case, the place-dependent indicators are cross-cutting in the Output phase, as they help explain why some regions produce better-integrated plans or agreements than others, based on territorial conditions but they don't measure the outputs themselves. Similarly, the policy-oriented indicators are cross-cutting in the Outcome phase because they help interpret whether governance design influences long-term results but they're not designed to measure impact over time. Finally, when indicators are marked as "not applicable" or "not yet observable", then they are inapplicable in that particular phase, usually because the conditions they measure, don't exist yet. In this case, we cannot apply path-oriented indicators in the Input phase because there hasn't been any time or activity yet to observe change or evolution. The different shades, tentatively indicate the indicator importance in this particular phase.

Table 5: Indicator relevancy for each component per stage

IOOP Phase	Relational Capital **Component**	Place-dependent Indicators	Policy-oriented Indicators	Path-oriented Indicators
INPUT	**Cooperation capability**	**Strong importance (anchored)** Defines regional preconditions for cooperation	**Strong importance (anchored)** Design of institutional cooperation mechanisms	**Not applicable** Requires time-based data
	Collective action capability	**Strong importance** Maps asymmetries and capacity gaps	**Strong importance** Assesses subsidiarity and alignment	**Not yet observable**
	Collective competence	**Strong importance** Institutional maturity and knowledge base	**Strong importance** Evaluates the system's readiness to learn	**Not yet observable**
PROCESS	**Cooperation capability**	**Cross-cutting (interpretative)** Explains ease/difficulty of cooperation	**Relevant importance** Assesses participatory and procedural norms	**Emerging importance** Early signals of trust or coordination evolution
	Collective action capability	**Cross-cutting** Explains coordination feasibility	**Relevant importance** Joint mechanisms and decision-making structures	**Emerging importance** Initial changes in coordination dynamics
	Collective competence	**Cross-cutting** Explains variation in learning speed	**Relevant importance** Procedural adaptability	**Emerging importance** Learning-in-action
OUTPUT	**Cooperation capability**	**Cross-cutting** Explains variability in output quality	**Moderate importance** Embedded collaboration tools	**Visible importance** Institutionalization of cooperation over time
	Collective action capability	**Cross-cutting** Explains delivery variation	**Moderate importance** Output relevance to joint goals	**Visible importance** Depth of coordination output (e.g., cross-sector plans)
	Collective competence	**Cross-cutting** Explains technical and strategic output quality	**Moderate importance** Responsiveness of tools and institutions	**Visible importance** Adaptation based on implementation feedback
OUTCOME	**Cooperation capability**	**Cross-cutting (moderate)** Long-term enabling conditions	**Cross-cutting (moderate)** Explains outcome durability	**Strong importance (anchored)** Trust durability, embedded norms
	Collective action capability	**Cross-cutting (moderate)** Explains long-term coordination success/failure	**Cross-cutting (moderate)** Gaps in governance design affecting delivery	**Strong importance** Expanded joint implementation capacity
	Collective competence	**Cross-cutting (moderate)** Explains differences in outcome sustainability	**Cross-cutting (moderate)** Effectiveness of institutional learning structures	**Strong importance** Institutional learning, policy adaptation, system change

We believe that the proposed tri-layered indicator system offers a comprehensive and adaptive framework for evaluating Spatial Planning System Integration (SPSI), especially in complex, EU's fringe contexts. By integrating place-dependence, policy orientation, and path-dependence, the indicator system reflects territorial diversity, institutional logic, and long-term transformation. Its design supports evidence-based learning, strategic adaptation, and feedback loops, which are key elements for building an explicitly resilient planning system. Finally, being tested by the components of relational capital, throughout different stages of the IOOP model, allows the framework to be more time-sensitive and process-aware.

4.Discussion

The main objective of this paper is to design a methodological framework for evaluating Spatial Planning System Integration (SPSI) in EU fringe regions. The main outcome is a tri-layered indicator system, that combines Camagni's territorial capital taxonomy with the IOOP (Input-Output-Outcome-Process) model, that addresses a critical gap in current spatial planning literature: the lack of operational tools capable of systematically evaluating integration efforts in structurally weaker and politically diverse European regions. Rather than focusing narrowly on outcomes or institutional forms, the proposed system allows for process-aware, time-sensitive, and territorially grounded assessment. The analytical strength of the system lies in its capability to enable evaluators to move beyond static measures of policy alignment, and instead to trace the evolution of spatial integration as a dynamic interaction between territorial resources, institutional processes, governance culture, and cooperation mechanisms.

Although the South Balkan region is referenced throughout the text, this paper does not provide empirical findings instead, the region serves as a contextual anchor - a reference frame that helps inform the structure and logic of the proposed system. The multitude of different planning environments in this region reflect the challenges faced by similar EU fringe regions, including: historical legacies of centralized planning, fragmented and asymmetrical administrative structures, and uneven EU integration. Therefore, the design process of the indicator system was informed by the spatial and institutional properties of this area, thus ensuring that the framework would be relevant, grounded, and sensitive to real-world constraints, without being limited by the specifics of a single case.

During the development of the indicator system, a notable methodological insight emerged: its potential for diagnostic reversibility. Originally designed to evaluate SPSI from inputs to outcomes or starting with the presence of enabling conditions and tracking their transformation into cooperative practices and strategic results, the model was found to also function effectively in reverse. This is especially relevant in contexts where spatial planning outputs appear formally aligned with EU objectives, but lack systemic grounding in territorial capital, institutional continuity, or cooperative capacity. This is why, when designing the system, our focus was turned towards the indicators capturing key dimensions of relational capital: relational capabilities, collective action capabilities, and collective competence, whose observation from regional context was informative and not of empirical nature. Ultimately, they signaled the type of questions that this framework is designed to provoke in future studies: Are planning outputs anchored in shared diagnostics and institutional memory? Are relational processes maintained beyond individual projects and/or funding cycles? Are integration practices embedded in legal and organizational routines? These questions demonstrate how the framework functions, not only as an evaluative tool, but also as a diagnostic lens for deeper institutional reflection.

Finally, similar to any other conceptual framework, the proposed indicator system has its own limitations. The effectiveness of the system depends on the availability and quality of data, particularly concerning the intangible forms of capital such as trust, cooperation, and institutional behaviour. What is more, some indicators will have to rely on proxies or qualitative assessments, which potentially could affect standardization and comparability. When it comes to the IOOP model's complexity, it may also require simplification in regions with low planning maturity or limited administrative capacity. Therefore, any future research should prioritize empirical testing, beginning in the South Balkans and extending to other EU fringe regions such as the Baltic states and Eastern borderlands. This would help evaluate the system's scalability, adaptability, and diagnostic precision, while refining indicators for diverse territorial contexts. In cases where institutional readiness is limited, simplified applications or pilot testing could support incremental uptake. Additionally, future work might expand the framework to include indicators on digital planning, resilience, and cross-sectoral integration, enhancing its relevance for emerging policy challenges.

5.Conclusion

This paper presents a novel and adaptable framework for evaluating Spatial Planning System Integration (SPSI), developed through a tri-layered indicator system rooted in Camagni's territorial capital taxonomy and structured via the IOOP (Input-Output-Outcome-Process) model. The system integrates three interrelated layers: place-dependency as the structural core, policy-orientation as the design logic, and path-orientation as the temporal-evaluative dimension. These are filtered through the dynamic dimensions of relational capital to produce a context- and time-sensitive, process-aware, and stage-reversible tool for assessing integration, especially in EU's fringe regions, where systemic coordination remains a challenge.

Rather than offering a case-based analysis, the study uses the South Balkan region as a contextual anchor, with the explicit objective not to demonstrate results, but to ensure the system's relevance to the complexities commonly found in EU fringe territories. In doing so, the territorial and institutional diversity of the region in question was leveraged to reinforce the framework's potential for broader application.

In this paper we emphasize the relational dynamics, institutional coordination, and temporal progression, so that we can provide framework that moves beyond conventional, output-focused evaluation methods. By doing so, we rely on multidimensional territorial indicators and diagnostic reversibility which in our view deepens the understanding of the systemic drivers and constraints that influence the spatial development processes. As a result, the paper contributes to academic discourse and policy practice, by addressing a long-standing methodological gap in European spatial governance.

At the end, three key takeaways emerge from this work. First, effective SPSI evaluation requires frameworks that incorporate relational, institutional, and procedural dimensions, not just static outcomes. Second, the system's diagnostic reversibility provides a powerful tool to assess whether formal planning outputs are truly supported by or result of meaningful cooperation and systemic readiness. Third, while the conceptual framework of the indicator system is theoretically strong, future empirical testing and iterative adaptation will depend on data quality and availability.

Abstract
The implementation of the EU's ambitious goals for ecological transition and climate adaptation calls for a paradigm shift toward systemic, inclusive, and nature-based governance models for managing environmental assets. Recognizing the growing strategic relevance of the interdependence between governance and stewardship, this contribution offers a critical reflection on the implementation and outcomes of several EU-funded projects (LIFE and Interreg) led by the Roma Tre research group in the Agro Pontino. These projects have fostered the development of an innovative, collaborative, and adaptive governance framework that integrates formal regulatory mechanisms with voluntary agreements (Pacts and Environmental Contracts) and community-driven initiatives (Land stewardship agreements). Operating across multiple governance levels, this approach aims to enhance participatory environmental management, strengthen institutional capacity, and support long-term socio-ecological resilience.

Keywords: collaborative governance, land stewardship, environmental contract

Introduction: Integrating Collaborative Governance and Environmental Stewardship for Climate Resilience in Europe and the Mediterranean Basin

Climate change represents one of the most pressing and complex challenges of the 21st century, with profound implications for ecosystems, societies, and economies worldwide. Nowhere is this more evident than in the Mediterranean Basin, a region identified as a global climate change hotspot due to its accelerated warming – approximately 20% faster than the global average (IPCC, 2022). This region is increasingly vulnerable to extreme weather events, prolonged droughts, biodiversity loss, and land degradation, all of which threaten ecological integrity and socio-economic stability (EEA, 2020).

In response to these escalating threats, the European Union (EU) has articulated a comprehensive policy framework aimed at fostering climate resilience and ecological sustainability. Key initiatives such as the European Green Deal (European Commission, 2019), the EU Biodiversity Strategy for 2030 (European Commission, 2020), and the EU Strategy on Adaptation to Climate Change (European Commission, 2021) underscore the need for systemic, inclusive, and nature-based approaches to environmental governance. These strategies emphasize the restoration of degraded ecosystems, the expansion of protected areas, and the integration of biodiversity considerations across all sectors of policy and planning.

However, the implementation of these ambitious goals necessitates a paradigm shift in governance models. Traditional top-down approaches, while still relevant, are increasingly being complemented by collaborative governance frameworks that emphasize co-production of knowledge, shared decision-making, and multi-actor engagement (Ansell & Gash, 2008). Collaborative governance is particularly well-suited to address the multifaceted and cross-sectoral nature of climate adaptation and biodiversity conservation, where ecological, social, and institutional dynamics intersect in complex ways.

The collaborative governance model, as defined by Ansell and Gash (2008), involves formal, consensus-oriented, and deliberative processes in which public agencies engage non-state stakeholders in collective decision-making. This model is characterized by iterative cycles of trust-building, shared understanding, and incremental successes that reinforce stakeholder commitment and deepen collaboration. In this context, the adaptive governance approach incorporates learning, monitoring, and feedback to enhance governance effectiveness over time (Folke et al., 2005; Westerink et al., 2017).

In parallel, the concept of environmental stewardship has gained prominence as a complementary framework for implementing governance strategies at the local level. Environmental stewardship refers to actions undertaken by individuals, groups, or networks to protect, care for, or responsibly use the environment in pursuit of both ecological and social outcomes (Bennett et al., 2018). These actions are deeply embedded in local contexts and are influenced by a range of factors, including social, cultural, financial, and institutional capital.

The interdependence between governance and stewardship is increasingly recognised in the literature. While governance structures provide the institutional scaffolding necessary to mobilize actors and allocate resources, stewardship actions operationalize these strategies through concrete, place-based interventions. Johnson et al. (2020) highlight the critical role of civil society in environmental governance, emphasizing that local stewards – often organized in formal and informal civic networks – play a pivotal role in managing and transforming local environments.

This synergy is particularly vital in hybrid landscapes characterized by overlapping peri-urban, rural, and natural components. In such contexts, governance processes must be coordinated across multiple scales and sectors, requiring the activation of diverse stakeholders and the transparent management of shared resources. The landscape approach advocated by Westerink et al. (2017) exemplifies this need for spatially coordinated multi-actor governance arrangements in agri-environmental management.

Moreover, the effectiveness of both governance and stewardship is contingent upon the capacity of local actors. Capacity encompasses a range of assets, including social networks, cultural traditions, financial resources, physical infrastructure, human skills, and institutional frameworks (Bennett et al., 2018). External actors such as governments and NGOs can play a facilitative role by enhancing local capacity, providing incentives, and fostering partnerships.

A critical component of this integrated approach is the co-production of knowledge. Effective environmental governance requires the integration of scientific and local knowledge systems, a process that is often hindered by communication barriers, trust deficits, and institutional constraints (Rodela & Swartling, 2019). Transdisciplinary collaborations and social learning processes are essential for overcoming these challenges and for building a shared understanding of environmental issues and solutions. Social learning is a powerful mechanism for fostering inclusive and context-sensitive governance. It enables individuals and groups to learn collectively by sharing knowledge, experiences, and perspectives.

In this context, this article proposes to address climate and environmental challenges facing Europe and the Mediterranean Basin, applying an integrated approach that combines collaborative governance with environmental stewardship. Such an approach must be adaptive, inclusive, and grounded in local contexts. It must also prioritize the co-production of knowledge and the empowerment of local actors.

Specifically, this contribution explores the multi-layered governance model developed and tested in the Agro Pontino (Italy) from the perspective of the research group actively involved in EU-funded projects highlighting critical tensions, challenges, opportunities and potential trajectories emerging from the intersection of collaborative governance and stewardship practices fostering transformative action for environmental sustainability and climate adaptation.

Methodological approach

The methodological approach adopted is grounded in an innovative multi-level governance model structured on two interrelated levels: a territorial level with a strategic function and a local level with an operational function. This framework enables the integration of formal regulatory instruments with voluntary mechanisms, fostering inclusive, adaptive, and action-oriented decision-making processes that are essential for addressing environmental sustainability and climate adaptation challenges.

The first, strategic and territorial level is implemented through two main governance instruments: Pacts and Environmental Contracts. These tools operate under the principles of vertical and horizontal subsidiarity through voluntary commitments promoting cohesion between institutions across multiple levels and sectors. Specifically, the Pact is an open and permanent working group where a plurality of actors – including public authorities, associations, small enterprises – define shared goals for environmental sustainability and climate adaptation. Likewise, the Environmental Contract is a voluntary governance tool that engages institutions, local authorities, associations, and citizens in a participatory process to promote the sustainable management of a water basin, integrating water resource protection, hydrogeological risk prevention, ecological and landscape enhancement, and socio-economic development (Bastiani, 2011).

The second, operational and local level is realised through Land Stewardship Agreements (LSAs), a voluntary public-private collaborative tool that fosters cooperation between landowners and users (farmers, foresters, shepherds, hunters, fishers, passive recreationalists) to promote the sustainable management and conservation of natural and cultural landscapes through long-term, participatory commitments involving a wide range of civil society groups (Sabaté et al., 2013). LSAs – typically lasting ten years – formalize the commitments of stakeholders for the implementation, management, and maintenance of green infrastructure in peri-urban and rural areas, providing the necessary institutional and financial scaffolding to ensure their durability. By sharing a management model and objectives for landscape maintenance and biodiversity conservation, landowners and users become active players (Magaudda et al., 2020).

The innovative contribution of the model lies in the structurally and functionally integrated relationship between the two levels. Pacts and Environmental Contracts serve as strategic coordination frameworks, aligning planning instruments, policy priorities, and institutional efforts across sectors in a coherent and systemic manner. LSAs, on the other hand, serve as implementing tools that translate strategic goals into concrete actions, strengthening the operational dimension of climate adaptation by embedding resilience and ecological connectivity at the community scale and ensuring their long-term effectiveness and continuity. This governance system is based on an iterative, flexible and participatory process involving networking activities, stakeholder consultations, joint drafting of strategies and agreements, definition of planning and incentive criteria, and identification of funding resources.

Case studies: LIFE BEEadapt and Interreg Euro-MED Coastrust in the Agro Pontino

Study area

The Agro Pontino, a vast coastal plain in southern Lazio bordered by the Lepini Mountains and the Tyrrhenian Sea, is the result of a radical transformation of both its natural and cultural landscapes. This transformation occurred during the 1930s through the implementation of the so-called 'Great Reclamation', a major hydraulic engineering effort that drained extensive marshlands and converted them into arable land. The intervention profoundly altered the region's ecological systems, land use patterns, and settlement dynamics, giving rise to a landscape now dominated by agricultural infrastructure and a dense network of drainage canals. The territory also includes a significant stretch of coastline, encompassing ecologically valuable systems such as sandy dunes, coastal lakes (including Fogliano, Monaci, Caprolace, and Paola), and wetlands, many of which are protected within the boundaries of Circeo National Park. These areas are biodiversity hotspots and represent highly sensitive ecosystems that are increasingly vulnerable to anthropogenic pressures. While agriculture remains the dominant land use, tourism has emerged as a growing component of the region's socio-economic profile. The coastal zone, with its unique natural features, historical settlements, and recreational amenities, attracts a wide range of visitors throughout the year. However, the expansion of tourism – particularly in the absence of adequate regulation – can exacerbate land use conflicts, contribute to habitat fragmentation, and place additional stress on water resources and waste management systems. Thus, balancing economic development with environmental sustainability poses an ongoing challenge for regional planning and governance. Despite

the historical significance of its agricultural matrix, the Agro Pontino is currently facing multiple environmental challenges (Magaudda et al., 2019). The unchecked expansion of urban and rural settlements, coupled with the intensification and industrialization of agricultural practices, has led to a progressive decline in the ecological functionality and biodiversity of the landscape. These dynamics are eroding the resilience of the region's agroecosystems and exacerbating the impacts of climate change.

In this context, the coastal and peri-coastal zones of the Agro Pontino emerge as a particularly relevant case study for analysing the interactions between agriculture, tourism, urbanization, and ecological conservation. The pressing need for integrated landscape management strategies – capable of reconciling productivity, biodiversity conservation, and climate adaptation – is increasingly evident, especially considering the threats posed by sea-level rise and the growing fragility of coastal ecosystems (Fig. 1).

Figure 1 – Coastal ecosystem of the Agro Pontino (Giovanni Mastrobuoni).

Over the past two decades, the Province of Latina has played a central role in initiating a process of environmental recovery and territorial requalification across the Agro Pontino. Recognizing the potential of green and blue infrastructure systems – such as windbreak strips, canal banks, and riparian buffer zones – as ecological connectors, the Province has promoted a planning approach aimed at restoring landscape continuity and enhancing ecosystem services (Benelli et al., 2022). In alignment with the objectives of the EU Water Framework Directive (2000/60/EC) and the Habitats Directive (1992/43/EEC), the Province has undertaken numerous studies and monitoring activities focused on the region's environmental conditions and challenges. This commitment culminated in the adoption of the Provincial Territorial Coordination Plan (*Piano Territoriale Generale Provinciale* – PTGP) in 2010, which formally integrated the Provincial Ecological Network as a strategic planning tool. This network represents a key instrument for the conservation of local habitats and the restoration of ecological processes, with particular attention to agricultural landscapes through targeted strategies aimed at reducing pollution and re-establishing ecological continuity.

This wide-area planning framework has been reinforced through a series of EU-funded projects that have mobilized territorial stakeholders and supported demonstrative interventions. These projects – LIFE Rewetland (2010 - 2014), LIFE Greenchange (2018 - 2023), Interreg MED Coasting (2018 - 2019), LIFE BEEadapt (2022 - ongoing), and Interreg Euro-MED Coastrust (2024 - ongoing) – have collectively contributed to an evolving model of integrated governance for environmental regeneration (Fig. 2).

They emphasize collaboration, the valorisation of natural capital, and the operationalization of green and blue infrastructure as key elements for sustainable land management and climate resilience.

The Agro Pontino thus represents a dynamic laboratory for exploring innovative approaches to regional governance that combine ecological restoration, sustainable agriculture, and inclusive territorial development. Through a gradual yet continuous process, the region is moving toward a more balanced relationship between human activity and the environment, underpinned by strategic planning, multi-actor engagement, and an increasingly structured framework for ecological connectivity.

Figure 2 – Agricultural and natural landscape of the Agro Pontino (LIFE Greenchange).

Life BEEadapt

The LIFE BEEadapt project "A Pact for Pollinator Adaptation to Climate Change" (LIFE21CCA-IT-LIFE BEEadapt/101074591) is funded under the LIFE Programme's Climate Action subprogramme and coordinated by the National Park of the Tuscan-Emilian Apennines. It brings together a diverse network of institutional, scientific, and civil society actors, including the Institute for BioEconomy of the National Research Council (CNR-IBE), the Sustainable Development Foundation, the University of Camerino, Legambiente, RomaNatura, the Municipality of Aprilia, Confagricoltura Latina, U-Space srl, and the Department of Architecture at Roma Tre University. The project addresses the increasingly severe impacts of climate change on wild pollinators – such as bees, hoverflies, moths, and butterflies – by adopting an integrated approach that combines ecological, agronomic, and territorial governance measures. These actions aim to strengthen the adaptive capacity of pollinator communities in response to climate-induced stressors. LIFE BEEadapt is situated within a broader context of declining pollinator populations across Europe and the Mediterranean, a trend largely attributed to altered phenological cycles and the growing frequency and intensity of extreme weather events (Gordo & Sanz, 2010; IPBES, 2016; ISPRA, 2023). In this regard, the project places pollinators at the centre of local adaptation strategies by promoting ecological connectivity and habitat diversity. This is operationalized through the development of flower meadows, shelters, and other green infrastructure interventions within urban, peri-urban, and rural areas, thereby extending flowering periods, re-establishing synchrony between floral and pollinator phenology, and ensuring the availability of refuge habitats. These ecological interventions are integrated with agronomic and land-use practices that enhance resource availability and functional landscape management.

Pilot activities are being implemented in five target areas across Italy: the Tuscan-Emilian Apennines National Park, the Torricchio Nature Reserve in the Marche region, the agricultural landscapes of the Agro Pontino, the Municipality of Aprilia, and protected areas within the city of Rome managed by RomaNatura. To facilitate

the implementation of these interventions, the project fosters a collaborative multi-level governance model, articulated through two primary instruments: Pacts for the Adaptation of Pollinators to Climate Change and LSAs. In the Agro Pontino, the Pact is coordinated by Confagricoltura Latina and is conceived as a strategic governance instrument to coordinate and promote the active participation of territorial stakeholders in climate adaptation initiatives, both during and beyond the LIFE BEEadapt project period. The Pact seeks to integrate existing planning and programming frameworks to improve access to funding opportunities for local actors, support environmental management through technical documentation, and enhance the territorial effectiveness of ecological interventions through a network-based logic. Land stewardship agreements are identified as the primary implementation mechanism for the on-the-ground management of pollinator-friendly green infrastructures. The governance process underpinning the Pact is guided by key principles, notably the activation of an open and inclusive participatory process to ensure the comprehensive identification of challenges and the co-definition of actionable solutions, which are essential for achieving durable and measurable outcomes. Furthermore, the Pact is designed to align with the specific territorial, social, and institutional contexts in which it operates, ensuring coherence with existing regulatory frameworks, planning tools, and strategic programs. A central output of the Pact is the development of a Local Agenda, comprising a dynamic and evolving set of actions aimed at achieving the Pact's objectives. This agenda is structured as a living document, designed to be continuously updated and expanded based on the evolving needs and contributions of stakeholders.

The governance framework established by LIFE BEEadapt builds upon the foundation laid by the previous LIFE Greenchange project, which was coordinated by Province of Latina. LIFE Greenchange aimed to enhance the ecological integrity of the Agro Pontino, as well as northern Malta and Gozo, by restoring ecological connectivity and increasing the availability of natural habitats within agricultural landscapes. These efforts sought to mitigate the effects of fragmentation caused by infrastructure development, urban sprawl, and intensive farming. A key component of LIFE Greenchange was the creation of a governance mechanism – the Pact for Biodiversity – signed on September 3, 2020, by representatives of regional and local institutions, environmental authorities, and farmers' associations. This Pact functioned as an open and permanent forum for dialogue, aiming to coordinate the management of agricultural areas through the sharing of practices, tools, and knowledge. It also sought to harmonize priorities and funding mechanisms for ecosystem conservation and restoration (Magaudda et al., 2020).

Within this context, LIFE BEEadapt continues and expands upon the governance architecture established by LIFE Greenchange in the Agro Pontino region.

On one hand, through a renewed participatory process, the project organizes targeted stakeholder workshops addressing pollinators and sustainable agricultural practices – such as the event on Eco-Scheme 5 (March 31, 2025, held with Confagricoltura Nazionale and ANSA, with 50 farmers in attendance) – to develop a shared strategy for strengthening pollinator resilience to climate change and promoting the adoption of LSAs. Key stakeholders involved in the Pact include Province of Latina, representatives from agricultural associations (Confagricoltura, CIA, Coldiretti), Circeo National Park, Municipalities of the Agro Pontino (Latina, Sabaudia, San Felice Circeo, and others), farmers and environmental NGOs.

On the other hand, LSAs function as the operational tools of the Pact, facilitating the on-the-ground implementation of conservation measures. To date, six LSAs have been signed by farms directly involved in pilot interventions. These agreements include three key parties: the beneficiary of the LIFE BEEadapt project (Confagricoltura Latina), which is responsible for the implementation of green infrastructure using LIFE funds and serves as the designated landscape stewardship organization; the farms tasked with the management and maintenance of the green infrastructure; and the landowners, when distinct from both the beneficiary and the farms, whose participation is essential for the legal and operational validity of the agreements. The participating farms serve as demonstration sites for adaptive land management practices aimed at enhancing pollinator conservation. By signing the LSAs, farmers formally commit to managing the green infrastructure developed through the LIFE project in accordance with jointly defined principles and standardized protocols. Additional LSAs will be formalized throughout the project's duration, with the expectation that many will remain active beyond the project's conclusion. This ongoing engagement underscores the long-term sustainability and potential for broader replication of the governance model established by LIFE BEEadapt.

Interreg Euro-MED Coastrust

The project Coastrust "Promoting shared stewardship for Mediterranean Coasts, led by the Region of Western Greece, was funded in 2024 by the Interreg Euro-MED Programme 2021-2027, under the priority 'Greener MED', Specific objective RSO2.7 'Enhancing protection and preservation of nature, biodiversity and green infrastructure'. It is framed within the Mission 'Protecting, restoring and valorising the natural environment and heritage' and will run until 2026. The project consortium is composed of nine partners from seven countries (Croatia, Greece, Italy, Malta, Spain, Albania, Bosnia and Herzegovina), ensuring a wide geographical coverage within the Programme area. Partners consist of a variety of organisations with complementary roles and expertise, belonging to the public administration (Region of Western Greece, Regional Development Agency of the Dubrovnik-Neretva County, Institute for Nature Conservation in Albania, Office of The Prime Minister of Herzegovina - Neretva Canton Government, Andalusian Federation of Towns and Provinces), the non-profit sector (SUBMON, Nature Trust Malta, Sustainable Development Foundation) and the academia (Roma Tre University). Additionally, nine associated partners (mostly local authorities) take part in the project, with different roles ranging from advisory, to dissemination and replication of results, to operational support to pilot actions implementation.

Coastrust addresses the need to sustainably use, manage, protect or restore ecosystems with the involvement of stakeholders and citizens, consistently with the European orientations promoting participatory approaches to biodiversity conservation. It is a 'Testing' type of project, i.e. intended to 'experiment common instruments, policies, strategies and action plans already developed to validate concrete solutions to be transferred' (Interreg Euro-MED, 2022). To this aim, the project applies the environmental stewardship concept to coastal areas undergoing anthropogenic pressures and aims to test and establish multi-level and multi-stakeholder governance mechanisms to support the sustainable management of natural resources at land and sea. The composition of the consortium mirrors this multi-level approach, by involving public institutions with different scopes and jurisdictions (a Macro Region, a Regional authority, an association of Municipalities in Spain, a Regional Development agency) in order to shed light on the diverse administrative, organizational and management challenges posed by participatory governance models.

The project works on both the strategic/methodological level and at the implementation/operational one. At the first level, it intends to establish the necessary conditions to enable environmental stewardship and to develop a methodology for defining common goals for sustainably manage coastal areas through stewardship. A preliminary version of this methodology has already been released and will be further refined throughout the project lifetime to be ready for transferring and replication within the Programme area. At the implementation/ operational level, the project supports the development of pilot activities, including both a strategy and a set of actions for each of the 8 coastal areas targeted, developed with the engagement of institutions and private actors at all scales and consistently with the areas' specificities and needs. Target areas were chosen so as to feature the widest range possible of site-specific environmental, geographical and socioeconomic issues, in order to allow for the design of more comprehensive stewardship strategies: river mouths (i.e. the Neretva Delta in Croatia and Bosnia y Hezergovina and the Buna River in Albania), protected coastal and marine areas (i.e. the Circeo National Park in Italy and the Ċirkewwa Marine Park in Malta), coastal lagoons, sandy beaches, etc.

In the Province of Latina, the activities that are being carried out by the Department of Architecture of Roma Tre University were designed to build on the outcomes and actions of previous initiatives, which since 2010 have been testing multi-level governance tools and mechanisms for improving the sustainability and effectiveness of the management of local assets: the LIFE projects Rewetland and Greenchange, the River Contracts of Cavata – Linea Pio, Amaseno and Ufente, and the Coast Contract developed within the framework of the Interreg MED Coasting. All these initiatives had served to mobilize the local stakeholders' network and engage different categories (local authorities, protected areas management bodies farmers, NGOs) in co-design processes, raising awareness on environmental protection issues and on the need of a change of paradigm in territorial governance.

Coasting specially builds on the Coasting experience, which in turn aimed to capitalize previous experiences of multi-stakeholders' contractual tools for sustainable and collaborative territorial governance (such as the *Contrat de Baie* of Marseille and the River Contracts), by applying their methodology to the coastal tourism sector in the Mediterranean area. This was achieved through participatory workshops involving both public and private actors, which in the area considered led to the development of the Agro Pontino Coast Contract, the first practice transferring the River Contract tool to a coastal area in Lazio region (Magaudda et al., 2021). Promoted by the

Lazio Regional Government and coordinated by the Province of Latina, the process acknowledged the synergic connection between biodiversity, landscape, climate change and tourism (Magaudda et al., 2021) and aimed at developing an integrated strategy for the management of the coastal area, balancing the improvement of the tourism sector and the maintenance and enhancement of the area's environmental quality.

As a matter of fact, the Coast Contract has been taken as a reference strategic framework to give continuity to: thus, the Roma Tre team is working to use environmental stewardship as an operational tool to implement those parts of the Contract that are most suitable to actively mobilise the local civil society – environmental associations, schools, neighbourhood committees, etc. Members of these target groups will be encouraged and tutored into presenting concrete stewardship initiatives to be supported by the project and implemented in the Circeo National Park by means of stewardship agreements involving the park authority and other interested parties (i.e. beach concessionaires).

In order to proceed with the target groups mobilization, the Roma Tre team, in collaboration with the Province of Latina (that is associated partner in the project) has organized a series of meetings to explain the project rationale, build the participants' capacities on environmental stewardship, and establish and operate a Local Action Group to develop the coastal stewardship strategy and the actions to implement it. The main actors targeted, besides local authorities, were relevant entrepreneurial associations (beach resorts managers, fishermen, etc.), small enterprises, and especially non-profit organizations already active in the protection and enhancement of the environmental assets of the area. Attendance to the meetings was deemed satisfactory, and the process was particularly successful in establishing contacts among NGOs, which often work separately, unaware of each other's activities.

Nevertheless, meetings attendance and involvement were negatively affected by widespread feelings of saturation, on one hand, and disappointment, on the other. Saturation is here intended as a condition of over-stimulation of territorial actors, which have been called to engage in numerous consecutive projects that, from their standpoint, have still not led to concrete results. Despite the organizers' effort to clarify the specific scope of Coastrust and highlight its continuity with previous initiatives, this feeling persisted especially in 'veteran' stakeholders. Moreover, the fact that the Coast Contract was virtually shelved, due to multiple reasons including lack of coordination, political input, and dedicated funding, generated a sense of disappointment that can ultimately put at risk the project success. In a wider perspective, these criticalities can even rise questions about the effectiveness of using EU-funded projects for the gradual implementation of governance mechanisms. In fact, in the case of Coastrust, the promoters' willingness to resume and bring forward the work done so far is now clashing with some stakeholders' disappointed expectations towards public authorities, which are blamed for not giving course to the decisions taken with the local community, somehow downplaying past participation efforts.

Conclusion and future perspectives

Collaborative learning processes are crucial to address contemporary environmental challenges and support resilient socio-ecological transitions.

The experience gained through the LIFE BEEadapt and Interreg Euro-MED Coastrust projects in the Agro Pontino confirms that combining multi-level collaborative governance models and land stewardship tools is a promising way to carry out this process. Strategic instruments (Pacts and Environmental Contracts) and operational mechanisms (LSA) can be mutually reinforcing and, when properly integrated, can help overcome common challenges in environmental governance, such as institutional fragmentation, discontinuous stakeholder engagement, and lack of coordination among sectoral policies. In fact, while the governance framework provides the institutional architecture for collective learning, coordination, and adaptive management, stewardship operationalizes these principles on the ground through concrete actions and incentives. Together, they create a dynamic system capable of fostering community empowerment, aligning public and private interests into dynamic collaborative networks to respond to environmental pressures, and promoting shared responsibility in the management of common goods.

However, structural limitations persist that may put collaborative learning at risk and ultimately jeopardize the long-term sustainability of these processes. Chief among them are the dependence on project-based EU funding, the weak institutionalization of Pacts as formal governance tools, and the risk of stakeholder disillusionment and desertion in the absence of tangible follow-up.

The case studies analysed suggest that the implementation of the model should imply an intentional, well-structured process that cannot be confined to the boundaries of EU projects, which are limited in terms of both duration and funding. Such projects, though able to trigger the process, should be framed within a clear long-term vision and engagement system, adaptive and flexible enough to include non-traditional actors in the management of environmental assets, and able to overcome institutional and epistemological barriers, as well as to acknowledge the value of the local communities' knowledge and initiatives. These challenges call for a rethinking of the mechanisms used to support and enhance land stewardship, including the structural integration of stewardship practices into public plans and programmes, their continuous, adaptive monitoring and follow-up, and the introduction of payment schemes for ecosystem services (PES) to reward stakeholders' engagement.

In conclusion, the convergence of collaborative governance and land stewardship represents a promising pathway for advancing the EU's goals for climate resilience and biodiversity, and for ultimately building resilient socio-ecological systems. It aligns with the EU's vision of a just and green transition, where local communities are empowered to shape their environmental futures and contribute meaningfully to global sustainability goals. However, in the light of the experiences analysed, there is a clear need to strengthen the institutional and social infrastructure of territories through tools capable of linking strategic vision with concrete action. This entails investing not only in pilot projects, but also in capacity-building pathways, regulatory recognition, and incentive mechanisms. Collaboration between practitioners, public officers and academia, as demonstrated in the case of the Agro Pontino, can support this transition.

Abstract
Wetlands are vital ecosystems, hosting 40% of global biodiversity and providing services such as flood regulation, carbon storage, and water purification. Despite their importance, wetlands face severe threats, with over 35% lost globally in the past 50 years due to urbanization, agriculture, and pollution. The Mediterranean region is particularly affected, requiring urgent action to ensure wetland preservation and sustainable management. This paper aims to explore the potential of Wetland Contracts as participatory governance tools for wetland conservation. It focuses on the WE GO COOP project, which scales Wetland Contracts through a Mediterranean Community of Practice (CoP) and adapts them to new contexts. The paper also highlights the role of a virtual collaborative platform in fostering stakeholder engagement and knowledge exchange, showcasing its effectiveness in addressing wetland challenges through innovative governance.

1. Wetlands governance in the Mediterranean

Mediterranean wetlands, as defined by the Ramsar Convention (1971), are "areas of marsh, fen, peatland or water, whether natural or artificial, permanent or temporary, with water that is static or flowing, fresh, brackish or salt, including areas of marine water the depth of which at low tide does not exceed six meters." These ecosystems, while covering only 2-3% of the Earth's surface, host 30% of vertebrate species, highlighting their extraordinary biodiversity and ecological significance. Beyond their ecological value, wetlands provide essential ecosystem services that benefit both the environment and human society. These services include water purification, flood regulation, carbon sequestration, climate change mitigation, and the provision of habitat for a wide variety of species. Wetlands also support vital economic activities such as fisheries, agriculture, and tourism, which are especially important in the Mediterranean region.

The Ramsar Convention, formally known as the Convention on Wetlands of International Importance, was adopted in 1971 in Ramsar, Iran. This international treaty focuses on the conservation and sustainable use of wetlands worldwide, recognizing their ecological, economic, and cultural value. Ramsar mandates that member states promote the protection of wetlands through direct conservation measures and encourage sustainable use of these vital areas. A key aspect of the Ramsar Convention is the establishment of the List of Wetlands of International Importance, which includes sites recognized for their global ecological significance. These sites are specially protected to safeguard biodiversity and the essential ecological functions they provide, such as water purification, climate change mitigation, and habitat for numerous species of flora and fauna.

Despite their importance, Mediterranean wetlands face severe degradation, with their surface area having declined by nearly 50% since the 1970s (Ramsar Convention Secretariat, 2018). This loss is driven by anthropogenic

pressures, including urbanization, agricultural land conversion, water abstraction, and disruptions to hydrological cycles. These stressors have been compounded by the absence of an integrated governance framework, resulting in fragmented conservation efforts and inadequate spatial planning.

Effective spatial planning is critical to addressing these challenges and ensuring the sustainable management of wetlands. Often, wetlands face the challenge of being governed by a patchwork of regulations and authorities, each focusing on narrow, sectoral interests, such as agriculture, urban development, or water management, without considering the holistic ecosystem dynamics. To avoid further degradation, spatial planning must be more integrated and ecosystem-based, recognizing the interconnections between wetlands and surrounding environments. A coordinated approach to land use, water management, and conservation is needed to balance human activities with ecological preservation.

In recent years, the EU Nature Restoration Law has brought wetlands into the spotlight as critical ecosystems to restore. The law, which was proposed by the European Commission in June 2022 and approved in June 2024 by the EU Parliament, sets ambitious targets for the restoration of Europe's degraded ecosystems, habitats, and species, including wetlands. The law is designed to ensure the restoration of biodiversity across the EU, addressing the severe degradation of ecosystems due to human activity, pollution, climate change, and over-exploitation. Wetlands are explicitly included as key ecosystems to restore due to their crucial role in environmental health (European Parliament and Council, 2024).

The Nature Restoration Law emphasizes that many of Europe's wetlands have been lost or degraded over previous centuries, primarily due to drainage for agriculture, infrastructure development, pollution, and climate change. However, wetlands are invaluable in achieving the EU's broader environmental, climate, and biodiversity goals. They provide vital ecosystem services, such as filtering pollutants, securing clean drinking water, reducing flood risks, and supporting biodiversity. Moreover, wetlands help mitigate and adapt to climate change, making their restoration essential for the EU's climate and social objectives.

By including wetlands in the Nature Restoration Law, the EU aims to unlock the potential for wetland restoration, which can have far-reaching benefits for both nature and society.

In this framework, this paper aims to highlight how the Interreg Euro-MED WE GO COOP – *Improving WEtland GOvernance through a COmmunity Of Practice* project attempts to address these governance challenges by promoting multilevel, ecosystem-based management approaches (Muccitelli *et al.*, 2023). The project is based on the capitalization of the Wetland Contract, facilitates collaboration among diverse stakeholders to harmonize wetland conservation with sustainable use. This approach seeks to mitigate conflicts between development and preservation, creating a common framework for addressing the complex dynamics of wetland management and for reaching the European and international goals (EC, 2020).

2. Wetland Contracts as a collaborative tool for e governance in Europe

In the last decades of the 20th century, under the broader framework of the European Union, relevant processes of devolution and transfer of competences were initiated.

The principle of subsidiarity, formally established by the Treaty on European Union (TEU), asserts that decisions should be made as close as possible to the citizen, with regular assessments to ensure that action at the EU level is warranted considering the capabilities at national, regional, or local levels.

Several countries in Continental Europe, operating under the so-called *civil law system* rooted in Roman law, have been encouraged to reconsider their traditional centralized legal frameworks. This has led to the incorporation of numerous contractual arrangements. Within this context, private stakeholders are explicitly involved, with recognized opportunities to influence change and participate in decision-making processes (Table 1).

Table 1. Civil Law System vs Common Law System

	Civil Law System	Common Law System
Geographical Areas	Predominantly in Continental Europe	Predominantly in Anglo-Saxon countries
Entities Responsible for Public Interest	Public authorities are entrusted with general interest matters, following a hierarchical institutional structure	A broad range of actors – including universities, non-profit organizations, foundations, and trade associations – are encouraged by social, economic, and cultural milieu to enter into binding agreements with public authorities
Written Constitutions	Always present	Not always present
Judicial Decisions	Not binding on third parties; however, administrative and constitutional court rulings on laws and regulations are binding on all	Binding on future cases (precedent applies)
Influence of Legal Scholarship	Legal scholars have significant influence in certain jurisdictions	Minimal influence from legal scholars
Freedom of Contract	Limited – many legal provisions are automatically implied into contracts	Extensive – very few legal provisions are automatically implied into contracts

Decision-making and managerial input have assumed particular significance in environmental governance. It is not merely the rigidity of regulations but rather the architecture of the decision-making framework that shapes expectations and obligations. This approach was notably implemented in France during the 1980s through the introduction of *Contrats de Rivière* (River Contracts). These contracts are defined as technical and financial agreements aimed at the comprehensive and sustainable management of a coherent hydrographic unit. They represent a shift toward participatory and multi-stakeholder governance in water resource management.

Inspired by this French model, wetland contracts have gradually gained traction across Europe. These instruments clearly express the necessity for participatory governance by facilitating coordinated action for the conservation and sustainable management of wetland ecosystems. Their increasing adoption reflects the growing awareness of the crucial role wetlands play in climate change mitigation, biodiversity conservation, and water cycle regulation.

The evolution and dissemination of such governance tools are closely linked to the development of European environmental policy, particularly the Water Framework Directive (2000/60/EC). This directive emphasizes participatory planning at the river basin level and introduces the objective of achieving a "good ecological status" for all water bodies. It thus encourages integrated, locally driven approaches to resource management. Throughout the years, the Contract has proven effective in France and Belgium, offering a structured yet flexible tool that enables stakeholders, including landowners, local authorities, and private organizations, to define and pursue shared goals for wetland conservation and sustainable use (Bastiani, 2011; Scaduto, 2016). These contracts exemplify a bottom-up approach to governance, aligning biodiversity preservation with sustainable practices such as eco-tourism and agriculture.

In Italy, the implementation of wetland contracts is relatively recent, since the beginning of the 2000s, but expanding rapidly, supported by a favorable regulatory environment and experience gained through river contracts.

Also in this case, the Italian Environment Code focuses mainly on rivers, having formalized the river contract in 2015 as "a voluntary tool of strategic and negotiated planning for the protection and better management of water resources, valorization of river landscape and mitigation of hydraulic risk, contributing to the local development." (Italian Environment Code, 2006/2015)

Many Regions have been actively promoting these tools through their legislation and dedicated calls and programs. These processes are often initiated by local governments or regional environmental agencies, in collaboration with environmental associations, universities, and land reclamation consortia. The wetlands involved are typically under significant anthropogenic pressure, such as intensive agriculture, fishing, urbanization, or tourism, underscoring the need for a shared, multi-level vision for their protection (Ernoul *et al.*, 2021).

The governance model of wetland contracts is based on a participatory and multi-level structure, involving a broad range of public and private actors. A typical framework includes a Coordinator and a Management Board with a political role, supported by the Technical Secretariat tasked with developing studies and operational proposals and conducting the participatory process. Finally, the Assembly includes all the stakeholders involved in the process.

Community engagement is facilitated through active participation tools, including forums, territorial workshops, public consultations, and co-design sessions. The formal signing of the contract by participating entities is voluntary yet binding, with each signatory committing to responsibilities in line with their competencies and resources.

From a spatial planning perspective, the wetland contract serves as a catalyst and integrator for existing policies. It operates in synergy with urban, landscape, environmental, and agricultural plans, offering a cross-cutting and coherent vision of the challenges and opportunities related to wetlands. As such, the contract acts as a strategic coordination platform, helping to overcome institutional fragmentation and enhance the value of existing regulatory tools. Furthermore, it facilitates access to European and national funding by providing a structured and monitorable framework for concrete actions.

3. The Interreg Euro-MED WE GO COOP project: partnership and objectives

Building on the increasing relevance of wetland contracts across Europe and their evolution into strategic tools for integrated territorial governance, the WE GO COOP project represents a pivotal step toward the institutional consolidation and geographical expansion of this governance model. Funded under the Interreg Euro-MED programme, the project is designed to strengthen, transfer, and coordinate Wetland Contract experiences at both transnational and local levels across the Mediterranean.

WE GO COOP addresses the need to move beyond isolated pilot cases by structuring a shared framework for wetland governance, rooted in participatory planning and multi-level collaboration. It responds to the growing urgency to protect and restore wetland ecosystems facing anthropogenic pressures, ecological degradation, and policy fragmentation.

Central to the project is the promotion of the Wetland Contract, a voluntary agreement among public institutions, private stakeholders, and civil society organisations aimed at the sustainable management and enhancement of wetlands. This tool fosters local ownership and shared responsibility through the co-definition of objectives, action plans, and governance mechanisms. Although the model has already been implemented in several Mediterranean regions, WE GO COOP seeks to consolidate, harmonise, and scale its application, addressing both the need for institutional coherence and the diversity of territorial contexts.

The project adopts a dual strategy. On one hand, it seeks to scale up the Wetland Contract model by establishing a Community of Practice (CoP) at the Mediterranean level, a transnational platform of exchange and coordination. This community brings together public authorities, academics, NGOs, and technical experts to capitalise on existing experiences, share methodologies, and promote integrated approaches to wetland management. On the other hand, WE GO COOP aims to scale down the model by transferring it to new implementation areas, specifically Albania, Croatia, Portugal, and parts of the Southern and Middle Eastern Mediterranean, while also reinforcing its application in countries where it is already active, such as Italy, Greece, and Spain.

The initiative is organised around two main work packages: the first dedicated to the development and facilitation of the CoP, and the second to the transfer and contextualisation of Wetland Contracts in the designated pilot areas. These components are supported by transversal activities such as stakeholder engagement, knowledge dissemination, and alignment with regional and EU policy frameworks.

The partnership (Figure 1) is led by ANATOLIKI S.A. – Organisation for Local Development (Greece), and includes:

- MedWet Initiative (France), leading the CoP and overseeing the extension of project activities in Middle East and North Africa (MENA) regions;
- Department of Architecture of Roma Tre University (Italy), providing scientific insight into collaborative planning and stakeholder engagement processes;
- FAMP – Andalusian Federation of Towns and Provinces (Spain), contributing long-standing expertise with environmental contracts in wetland contexts;
- Nature Park Vransko Lake (Croatia), piloting actions in a vulnerable Ramsar site;
- PPNEA – Protection and Preservation of Natural Environment (Albania), adapting the methodology to the Vjosë-Nartë Protected Landscape;
- RCDI – Development and Innovation Network (Portugal), targeting wetlands influenced by agriculture and tourism dynamics in the Alentejo region.

Figure 1. Interreg Euro-MED WE GO COOP: partnership and main project data.

The consortium is complemented by a wide array of associated partners, including municipalities, universities, and protected area authorities, which enhance the territorial reach and thematic scope of the initiative.

Importantly, WE GO COOP builds upon the outcomes of a series of EU-funded projects that, over the past decade, have contributed to shaping and testing the Wetland Contract model in various environmental and institutional settings. These include:

- Interreg MED WETNET (2016–2019), which pioneered Wetland Contracts in six Mediterranean countries through coordinated multi-actor agreements;
- Interreg MED COASTING (2018-2019) and COASTING PLUS (2021–2022), which expanded the participatory governance model to coastal areas and sustainable tourism planning;
- Interreg IT-HR CREW (2018–2021), which focused on coordinated wetland management in the Italy-Croatia transboundary context;
- Interreg MED TUNE UP (2019–2022), which translated the Wetland Contract methodology into the marine domain, targeting Marine Protected Areas (Palazzo *et al.*, 2021).

By integrating and systematising these diverse experiences, WE GO COOP contributes to the consolidation of a common governance culture. It develops a transferable framework capable of accommodating ecological variability, socio-economic diversity, and policy asymmetries across the Mediterranean.

With a total budget of €999,784, of which €799,827.20 is provided by Interreg Euro-MED funds, and a duration of 27 months, the project actively supports European objectives in biodiversity, water protection, and climate adaptation. By enhancing collaborative capacity, facilitating cross-border cooperation, and fostering inclusive governance structures, WE GO COOP represents a key milestone in the advancement of a Mediterranean-wide, participatory approach to wetland conservation and sustainable territorial development.

4. Towards the Wetland Contracts Community of Practice

At the heart of the project's upscaling efforts is the creation of a Community of Practice (CoP) dedicated to Wetland Contracts in the Mediterranean, encompassing both EU and MENA regions. This transnational network brings together policymakers, researchers, practitioners, and local communities to foster dialogue, exchange knowledge, and disseminate best practices. It supports the development and implementation of participatory governance tools such as Wetland Contracts and provides a collaborative space where stakeholders can bridge the gap between scientific research, policy frameworks, and community action, promoting multi-level and multi-stakeholder cooperation.

The CoP was intentionally designed as a bottom-up initiative, building on existing experiences with Wetland Contracts across the Mediterranean. Its framework responds to the needs of organizations that face challenges in wetland governance and view the Wetland Contract as a promising opportunity for change.

A kick-off event, "*Gathering the Community of Practice*," was held in Seville in October 2024, bringing together an initial group of over 30 experts and organizations interested in launching the CoP. The participants focused on shaping a Mediterranean-specific vision of the Wetland Contract model and integrating it into the CoP. Three guiding questions structured the discussion:

- *Why establish a Mediterranean CoP on Wetland Contracts?*
- *Who should join the CoP?*
- *What should the CoP do?*

The session adopted a participatory approach, engaging both in-person and online attendees. The Mentimeter tool was used to conduct a live survey, capturing real-time responses that reflected participants' expectations and shared visions for the future of the CoP. The survey results highlighted key values such as cooperation, governance, sustainability, and community, underscoring participants' commitment to a collaborative approach to wetland management. Among the CoP's priority objectives, capacity building (15%) and networking (13%) were ranked highest, demonstrating a shared need to strengthen knowledge and foster stronger connections among actors. Other emphasized areas included monitoring, learning, and mentoring, positioning the CoP as a platform for ongoing improvement and engagement. The main perceived benefits of joining the CoP included enhanced management skills, expanded networks, and increased recognition of the Wetland Contract's value. Participants indicated that their main contributions would be intangible knowledge (27%) and introducing new stakeholders (27%), reflecting a strong emphasis on sharing experiences and broadening the community. To ensure its effectiveness, participants suggested tools such as a repository of best practices, regular meetings, online platforms, and strategic planning mechanisms to facilitate continuous information exchange and cooperation.
Another key milestone was the first thematic seminar, "*Framing the Community of Practice*", held in Rome in January 2025. This event provided a space for stakeholders to discuss common challenges, define governance goals, and explore strategies for improving wetland management. It emphasized the need for tools that enable cross-sectoral collaboration and the integration of diverse perspectives in decision-making. Using the World Café methodology, participants contributed proposals in three thematic areas to help shape the vision and objectives of a Mediterranean CoP focused on Wetland Contracts (Table 2).

Table 2. Thematic areas, guiding questions and key outcomes discussed during the World Cafè session in Rome to shape the objectives of the Mediterranean CoP on Wetland Contracts.

Topic	Guiding questions	Key outcomes
Legal Acknowledgment and Advocacy	*How can legal frameworks for Wetland Contracts be strengthened?*	Analyze national regulatory frameworks for Wetland Contracts
	What advocacy actions are needed to increase recognition?	Highlight links between Wetland Contracts and the Nature Restoration Law
		Engage policymakers in the CoP
		Promote leadership coaching to support Wetland Contract dissemination
Knowledge Sharing and Capacity Building	*What tools or platforms can facilitate knowledge exchange?*	Emphasize the benefits of Wetland Contracts
	How can training enhance stakeholder capacity?	Deliver know-how through the MedWet platform
Finance for Governance and Action	*What are the most effective funding mechanisms for governance?*	Develop a business plan for the CoP
	How can long-term financial sustainability be ensured?	Promote new EU-funded projects on Wetland Contracts
		Define a quality certification for Wetland Contracts

The second part of the Rome seminar focused on defining key elements of a forthcoming policy paper, aimed at promoting the integration of Wetland Contracts into European environmental strategies and frameworks. The seminar marked the beginning of a collective reflection on necessary recommendations, as well as challenges and opportunities that should be addressed. A brainstorming session helped identify priority policy areas where Wetland Contracts can play a meaningful role, namely:

- Climate change adaptation
- Landscape and socio-cultural heritage
- Nature restoration and biodiversity protection

In each of the aforementioned areas, Wetland Contracts can empower local communities to take action by sharing responsibilities and commitments. By providing a shared vision and a practical action plan, Wetland Contracts can also support effective investments through greater integration and synergy across all sectors. Wetland Contracts has been acknowledged as able to promote integrated governance by engaging stakeholders in shared decisions and actions. They support climate adaptation, biodiversity restoration, and cultural heritage by aligning local priorities with broader environmental goals through participatory and place-based strategies.

5. A web platform to assess the current implementation of Wetland Contract at Med level

One of the key activities supporting the creation of the Community of Practice (CoP) for wetland governance in the Mediterranean is the development of a virtual collaborative web platform. This platform serves as a transnational hub designed to monitor, document, and disseminate good practices and data related to signed Wetland Contracts across the region. It is conceived as an open and interactive tool that fosters knowledge exchange among CoP members, while also facilitating continuous interaction and capacity-building processes.
The structure and tools of the platform are inspired by previous Mediterranean experiences that have contributed to building shared knowledge on wetland management. The data were primarily collected and selected from open-source datasets such as:

- *Gest'eau*, the French platform that promotes integrated and sustainable water resource management. It provides information on planning tools such as SDAGE, SAGE, PTGE, and basin contracts, facilitating cooperation among local stakeholders. It is managed by the International Office for Water with support from the the Ministry of Ecological Transition. A dedicated section focuses on the *Contrats de Milieu* (Environmental Contracts).
- The Mediterranean Wetlands Observatory (MWO) that monitors the health of Mediterranean wetlands, providing data and indicators to guide conservation efforts. It supports sustainable water and biodiversity management. Established in 2008, it is coordinated by Tour du Valat.
- The Interreg Italy-Croatia CREW Observatory that is a transnational hub focused on monitoring and sharing best practices and data related to coastal wetlands in the Italian-Croatian cross-border region. It promotes sustainable wetland management through tools like the Wetland Contract, encouraging collaboration among public and private stakeholders.
- The inventory of Environmental Contracts in Mediterranean Ramsar and marine sites, developed within the framework of the Interreg MED TuneUp project.
- The inventory of Wetland Contracts signed in Italy provided by the Italian Board of River Contracts (*Tavolo Nazionale dei Contratti di Fiume*).

The WEGOCOOP platform, currently under experimentation, is organized into different sections that enable key environmental governance actors to interact through tools such as a repository, a WIKI, and a WebGIS. The core of the platform is the WIKI, which include river, lake, wetland, coastal, marine, and aquifer agreements, are categorized by typology and georeferenced for spatial analysis (Figure 2).

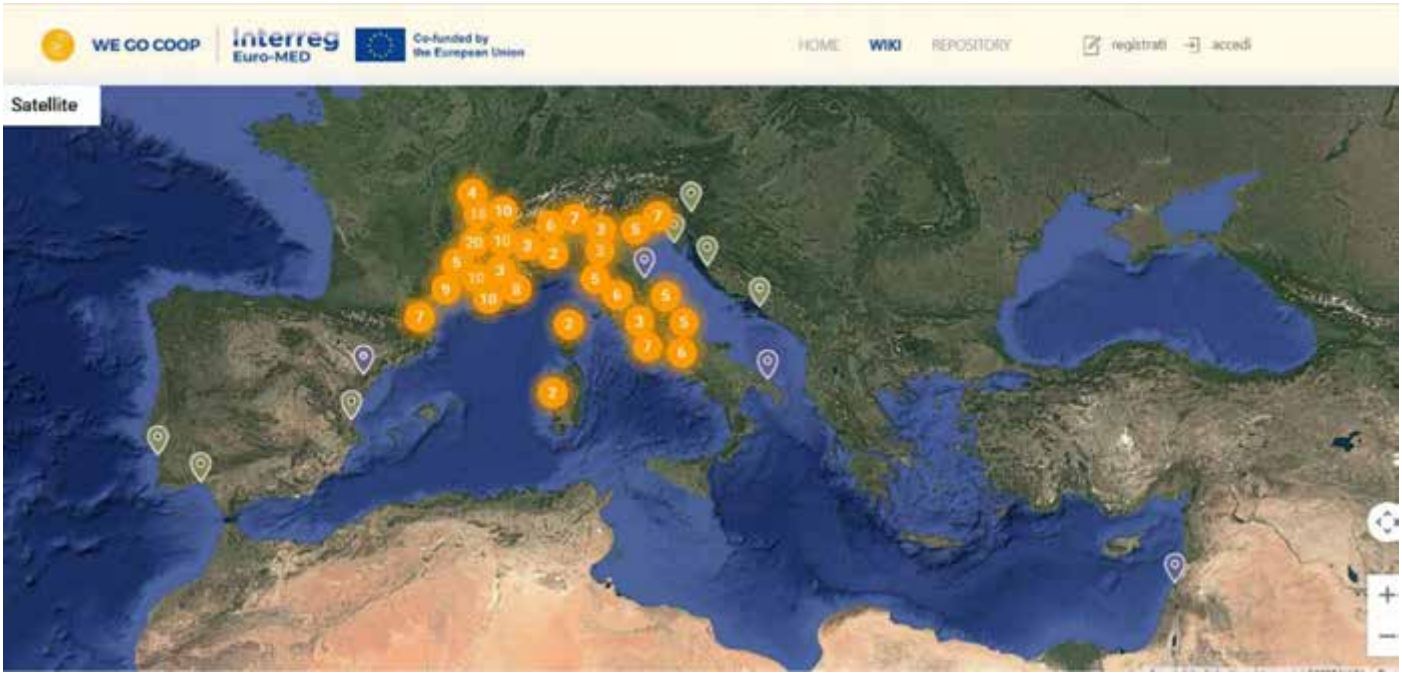

Figure 2. Current state of updating of the WE GO COOP virtual platform.

Each case study is documented through a standardized set of fields that capture both institutional and ecological dimensions. Key descriptors include the location (longitude and latitude of the centroid), contract's name, year of signature, and the main source of funding, ranging from international and EU programs to national or local funds. The platform also records the typology and identity of the reference organization, contact details, and the geographical and ecological context of the water body involved, including whether it falls under nature protection regimes such as Natura 2000 or regional parks. Governance characteristics are detailed through the number and type of signatories (public/private), sectors involved (e.g., agriculture, tourism, fisheries), and thematic priorities such as flood management, pollution control, and biodiversity conservation. Financial aspects are addressed through estimates of required and activated funding, while qualitative insights are captured via self-assessment metrics on stakeholder engagement, knowledge sharing, and strategic planning. Finally, each contract entry may include links to official documents and lessons learned, offering a comprehensive and comparative view of environmental governance practices in the Mediterranean region.

By integrating these resources into an accessible digital space, the platform enhances the effectiveness, scalability, and transferability of collaborative governance practices. This work presents the initial outcomes of the WE GO COOP project and demonstrates how the virtual platform functions as a pivotal tool for advancing wetland governance. By enabling the CoP to access, share, and co-create knowledge, the platform plays a central role in addressing the ecological and socio-economic challenges faced by wetlands in the Mediterranean and beyond.

6. Perspectives and ways forward

Wetland Contracts represent a forward-looking governance instrument, specifically designed to support the conservation, restoration, and sustainable management of wetlands and associated ecosystems. Developed within the framework of key European environmental policies, such as the Water Framework Directive and the Nature Restoration Law, they offer concrete means of advancing the European Green Deal's biodiversity and climate adaptation objectives. These policies emphasize the need for integrative, inclusive, and multi-level governance approaches capable of addressing the ecological degradation of aquatic and terrestrial environments while promoting socio-economic resilience.

At the heart of Wetland Contracts is a participatory model of governance that mobilizes a broad spectrum of territorial actors, including public authorities, environmental NGOs, private landowners, scientific institutions, and local communities. This collaborative framework enables the co-production of knowledge and the alignment of diverse interests around shared ecological and socio-economic goals. Through coordinated interventions, Wetland Contracts support actions such as the removal of artificial barriers to restore hydrological connectivity, wetland re-naturalization to enhance carbon sequestration and flood mitigation, and the establishment of ecological corridors to combat habitat fragmentation.

Despite their innovative potential, the implementation of Wetland Contracts still presents several critical challenges. These include the need for stable funding mechanisms, the variability in institutional capacities across regions, and the complexity of coordinating heterogeneous stakeholder interests over the long term. In some cases, the lack of clear legal frameworks or integration with existing planning instruments can also hinder their full operationalization.

In this context, the Community of Practice (CoP) promoted by the WE GO COOP project plays a crucial role. It serves as a collaborative environment in which these challenges can be openly addressed through the exchange of experiences, joint problem-solving, and the development of shared methodologies. By facilitating structured dialogue among practitioners, policy-makers, researchers, and local actors, the CoP fosters mutual learning and contributes to the progressive refinement of Wetland Contracts as effective governance tools.

Beyond their immediate ecological and social benefits, Wetland Contracts may also contribute to broader biodiversity conservation frameworks, particularly to the definition of the so-called *Other Effective Area-Based Conservation Measures* (OECMs). Recognized under the Convention on Biological Diversity (CBD), OECMs refer to areas that, although not formally designated as protected, achieve sustained biodiversity outcomes through effective and enduring governance (CBD, 2018; IUCN-WCPA. (2019).

The governance architecture of Wetland Contracts, emphasizing long-term engagement, adaptive management, and inclusive participation, can help identify and support such areas, especially where conservation objectives are achieved through locally driven processes.

By embedding Wetland Contracts within a dynamic and structured Community of Practice, governance is strengthened on multiple fronts: horizontally, by fostering collaboration and knowledge exchange among diverse actors; and vertically, by aligning local actions with national and European policy frameworks. This multi-level configuration enhances institutional coherence, improves implementation capacity, and ensures that wetland restoration efforts are both scientifically grounded and socially legitimate.

In conclusion, the combined approach of Wetland Contracts and the CoP promoted by WE GO COOP represents a robust and adaptable governance innovation. By addressing existing implementation challenges, supporting participatory and evidence-based decision-making, and contributing to broader conservation strategies such as OECMs, this model advances Europe's goals for biodiversity restoration, climate resilience, and territorial cohesion. It offers a replicable and scalable pathway for sustainable ecological governance in diverse socio-ecological contexts.

Abstract:
Climate change exposes vulnerabilities in water-agriculture governance by straining information flows, collaboration, and norms. This study couples Social Network Analysis (SNA) with resilience theory to examine how Murcia's actor configurations enable absorption of shocks, adaptation, and transformation. Using COSMIC—a platform co-developed with HDA that integrates multilingual surveys, real-time validation, and instant network visualization—stakeholders provided organizational profiles, mapped inter-actor ties, and identified leverage points. COSMIC generated an undirected graph and computed node metrics (degree, betweenness, closeness, eigenvector) plus network indicators (density, modularity). Preliminary findings reveal a polycentric structure: a core of interconnected institutions sustains redundant pathways (absorptive resilience), while clusters suggest opportunities for cross-sector collaboration (adaptive resilience). Qualitative interviews confirm public and academic actors perceive high cohesion—validating hubs' buffering roles—whereas civil society's lower cohesion ratings expose outreach needs. Divergent views on sustainability versus productivity highlight "intent"-level leverage points requiring value-focused dialogues. COSMIC's survey-to-analysis workflow enables rapid diagnosis of structural strengths and weaknesses, guiding parameter-level (data-sharing), feedback-level (incentives, mediation), and intent-level (value alignment) interventions. These preliminary insights will be tested and refined across remaining FARMWISE case studies.

Keywords: Climate Resilience, Social Network Analysis (SNA), Leverage Points, Water Management, Agricultural Governance

1.Introduction

The intertwined challenges of climate change and water scarcity are redefining the boundaries of sustainability in agriculture. Nowhere is this more evident than in semi-arid regions like Murcia, in southeastern Spain—a territory characterized by structural water stress, increasingly erratic precipitation, and intensifying socio-environmental pressures. With an average annual rainfall of only 300–350 mm and a historical dependency on intensive irrigation systems, the region has long been on the frontline of adaptive water governance (García-Ruiz et al., 2011; Iglesias & Garrote, 2015). Compounding the issue, Murcia has experienced at least 17 extreme weather events associated with DANAs (Depresiones Aisladas en Niveles Altos) since 2000, including the devastating floods

of 2019, which brought more than 500 mm of rainfall in a matter of days (Pérez-Morales et al., 2021; Zabalza et al., 2018). These disruptions underscore the urgent need for governance systems that can anticipate, absorb, and adapt to climatic shocks.

Remarkably, Murcia has also emerged as a global reference in water reuse and efficiency. It currently recycles approximately 98% of its treated wastewater, compared to 9% in the rest of Spain and just 5% across Europe (Esamur, 2022). This performance reflects a sophisticated network of infrastructures and actors—ranging from public water authorities like the Confederación Hidrográfica del Segura and the Mancomunidad de los Canales del Taibilla, to regional administrations, farmer cooperatives, water user associations (WUAs), and municipal operators. Yet, despite this apparent success, the very complexity of this governance landscape may become a liability in times of crisis. Fragmented responsibilities, institutional inertia, and weak coordination mechanisms often erode the system's adaptive potential (De Stefano et al., 2015; López-Gunn et al., 2012).

Most research to date on Murcia's water governance has emphasized technological and infrastructural solutions. What remains underexplored is the role of actor configurations and network structures in shaping adaptive capacity. In other words, *how resilience is organized*, and not merely what technical tools are deployed. To address this gap, this paper adopts a relational perspective grounded in Social Network Analysis (SNA), resilience theory, and the concept of leverage points (Meadows, 1999; Bodin, 2017). We argue that understanding who interacts with whom, and how, is essential to revealing hidden vulnerabilities and unlocking transformative potential within governance networks.

Our case study draws on the ongoing Horizon Europe project FARMWISE, which aims to support climate adaptation in agriculture across eight European regions, both through the use of digital models and the inclusion of water innovations in each of the 8 case studies (Spain, Poland, Italy, The Netherlands, United Kingdom, Sweden, Finland and Ukraine). In this paper, we start by applying our methodology to Murcia - a region that exemplifies both institutional innovation and structural tension in water management - to later extend the approach to the other case studies in subsequent phases of the research. Our objective is threefold: (1) to map the actor networks involved in water-agriculture governance in the Murcia region; (2) to identify structural leverage points that may enhance system-wide resilience of the network; and (3) to offer strategic insights for more adaptive and inclusive governance arrangements in the region.

The study addresses three core questions:

- How are actors in Murcia's water-agriculture governance system interconnected, and what structural network patterns emerge?
- Where are the leverage points—nodes or relationships—that hold potential for amplifying resilience?
- How can these insights inform adaptive governance interventions in climate-vulnerable regions?

To operationalize this analysis, we developed a digital tool—**COSMIC (Collaborative Stakeholder Mapping of Interactions and Collaborations)**—built from the ground up through a collaboration between the Universitat Politècnica de València (UPV) and the University of Applied Sciences Darmstadt (H_DA). COSMIC facilitates the participatory mapping of governance networks through structured surveys, enabling the quantification and visualization of stakeholder relations. Governance networks refer to relatively stable configurations that emerge from the interactions of interdependent yet operationally autonomous actors, operating within a self-regulating framework shaped by external forces. These networks contribute to the collective attainment of public goals through ongoing coordination and collaboration (Isett et al., 2011; Kapucu, 2015; Sørensen & Torfing, 2005). Combined with qualitative data from interviews and focus groups, this mixed-methods approach allows us to trace not only the structure but also the meaning of interactions, what they enable, constrain, or fail to deliver.

By reframing resilience as an emergent property of relational dynamics, rather than a fixed institutional trait, this study contributes to ongoing debates on how to govern complex socio-ecological systems under increasing uncertainty (Folke et al., 2010; Chaffin et al., 2014; Biggs et al., 2012). Our findings have the potential to inform new strategies for leveraging collaboration, amplifying adaptation,driving reflection among stakeholders, and fostering long-term system transformation through governance.

2.Theoretical Framework

In this study, we are using 3 theoretical frameworks: SNA, Leverage points and resilience theory. The notion of leverage points is used as a conceptual bridge between network analysis and resilience theory. By identifying actors or relational patterns that play a disproportionately influential role in shaping collective behavior—such as brokers, connectors, or isolated subgroups—we aim to locate critical entry points for policy and intervention. These leverage points may not only signal opportunities for enhancing communication, trust, or legitimacy, but may also reveal deeper barriers to transformation, such as power asymmetries, siloed mandates, or entrenched mental models (Westley et al., 2011; Pereira et al., 2018).

2.1 Social Network Analysis in environmental governance

Social Network Analysis (SNA) has become an increasingly influential tool for understanding the relational underpinnings of governance in complex socio-ecological systems. Moving beyond static or institutionalist views, SNA conceptualizes governance as a dynamic web of interactions among diverse actors—government agencies, civil society organizations, private entities, and knowledge institutions—whose positions and relationships shape decision-making, knowledge circulation, and adaptive capacity (Wasserman & Faust, 1994; Prell et al., 2009; Janssen et al., 2006).

In the domain of environmental governance, SNA enables researchers to uncover not only *who* is involved, but *how* they are positioned relative to each other, *what kinds of ties* connect them (e.g., collaboration, authority, knowledge exchange), and *which structural properties, at the individual and network level* —such as centrality, density, or modularity—facilitate or constrain collective action (Bodin & Crona, 2009; Ingold & Balsiger, 2015). At the individual level, for instance, actors with high *degree centrality* often serve as visible influencers due to their numerous connections, while those with high *betweenness centrality* act as brokers or gatekeepers, strategically positioned to control the flow of information across otherwise disconnected subgroups (Burt, 2005; Bodin et al., 2006; Long et al., 2013). These positions can greatly influence the distribution of power, the legitimacy of decisions, and the ability to coordinate across scales or sectors (Knoke & Yang, 2008; Crona & Parker, 2012).

At the network level, measures such as *density* (the extent to which all possible ties are realized), *reciprocity* (mutuality of interactions), *modularity* (degree of clustering), and *centralisation* (unevenly a network's ties are concentrated on one or a few nodes rather than being evenly distributed) provide insight into how well-connected or fragmented a governance system is (Newman & Dale, 2005; Scott, 2017; Gava et al., 2025; Sandström, A. & Carlsson, L., 2008). Cohesive networks may promote trust, shared norms, and institutional learning (Henry & Vollan, 2014), while the presence of weak ties or bridging connections across clusters—what Granovetter (1973) famously called "the strength of weak ties"—can be crucial for accessing novel information and enhancing adaptive flexibility (Bodin, 2017; Sayles et al., 2019).

Empirical studies have demonstrated the relevance of SNA for water and agricultural governance. In Zimbabwe, Manzungu and Machiridza (2005) used SNA to expose how informal hierarchies and poor coordination among irrigation users led to inefficient water allocation and conflict, rooted in a lack of structural cohesion. In coastal Kenya, Crona and Bodin (2010) showed that actors occupying central and bridging positions were essential for linking ecological knowledge with governance processes, particularly in fragmented watershed contexts. Meanwhile, Berardo and Scholz (2010) analyzed U.S. estuarine policy networks, revealing how the *density* and *multiplexity* of ties—actors interacting across multiple domains—fostered cooperation and trust in conditions of uncertainty. Their "risk hypothesis" posits that actors facing high interdependence are more likely to establish stable, cooperative ties, thus enhancing the system's capacity to self-organize.

Methodologically, SNA provides a versatile platform to examine both the **structural** properties of governance systems (who is connected, how, and how often) and the **functional** implications of those structures—how power, influence, or knowledge circulate; where bottlenecks or gaps exist; and which nodes or relationships are most critical for systemic change (Reed et al., 2009; Borgatti et al., 2009). Moreover, by incorporating *tie content* (e.g., cooperation, conflict, funding, regulation), researchers can analyze not only the form but also the quality of interactions—an essential dimension in climate governance, where institutional misalignment and power asymmetries often hinder transformative action (Stein et al., 2011; Bodin, 2017).

2.2 Leverage points in complex systems

In the context of complex socio-ecological systems, the question of *where* to intervene is often more consequential than *how* to intervene. This idea lies at the heart of the concept of *leverage points*, introduced by Donella Meadows (1999), who argued that certain elements within a system exert disproportionately high influence over system behavior. Leverage points are strategic locations where a small change can catalyze substantial and lasting transformations across the whole system.

Meadows (1999) proposed a hierarchy of leverage points, ranging from shallow interventions—such as adjusting numerical parameters—to deep interventions that shift the goals, structures, or paradigms of the system itself. While shallow leverage points may offer immediate results, they are often insufficient to address persistent or structural problems. Deep leverage points, by contrast, target underlying causes and worldviews, and therefore hold greater transformative potential, even if they are more politically or institutionally challenging to access (Abson et al., 2017; Fischer & Riechers, 2019).

This distinction has gained increasing relevance in sustainability science, where the complexity of environmental challenges calls for change processes that go beyond technical fixes or incremental adjustments. Abson et al. (2017) identify four realms of leverage—design, intent, parameters, and feedbacks—and argue that interventions targeting design (e.g., governance architectures) and intent (e.g., normative goals) are more likely to result in transformative change than those focused on parameters or feedback regulation. Similarly, Fischer and Riechers (2019) contend that leverage points must be approached relationally, as interacting across different system levels—material, institutional, and cognitive—in ways that either reinforce or obstruct change.

In governance contexts, leverage points are not limited to technical solutions but include shifts in institutional arrangements, collective behaviors, and underlying narratives. For instance, transformative governance may emerge from changes in how problems are framed, how legitimacy is distributed, or how power asymmetries are addressed (Westley et al., 2011; Blythe et al., 2018). Transformative potential also depends on timing and context; socio-political shocks, crises, or policy windows can act as catalysts for deeper shifts if actors are prepared to engage with them strategically (Herrfahrdt-Pähle et al., 2020; Patterson et al., 2017).

Importantly, the identification of leverage points is not a purely analytical task—it is deeply normative. What constitutes a desirable intervention point depends on whose values, interests, and visions of change are prioritized (Meadows, 1999; Leach et al., 2010). This insight has led scholars to advocate for participatory and reflexive approaches to leverage points research, emphasizing inclusion, imagination, and collective learning as vital components of any transition process (Pereira et al., 2018; O'Brien, 2012).

Ultimately, leverage points thinking invites a fundamental reorientation in how we approach change. Instead of treating symptoms, it seeks to act on root causes. Instead of managing systems, it asks how systems can evolve. And instead of focusing solely on action, it also engages with intention—shifting not only what we do, but what we aim for, and why (Table 1).

Table 1. Leverage Points for Sustainability Transformation (Adapted from Abson et al., 2017)

Leverage Point Depth	Type of Intervention	Description	Examples	Transformative Potential
Shallow	**Parameters**	Adjustments to measurable variables within the system without altering its underlying structure or goals.	Tax rates, efficiency targets, emission limits	Low
	Feedbacks	Modifications to feedback mechanisms that regulate the system's behavior over time. They can dampen or reinforce systemic patterns.	Environmental fines, subsidies, performance incentives	Moderate
Deep	**System Design**	Changes to the institutional architecture, decision-making rules, and power relations that shape how the system functions.	Multi-level governance, participatory platforms	High
	System Intent (Goals & Paradigms)	Shifts in the overarching purpose, values, or dominant paradigms that define what the system is for and how success is measured.	From GDP growth to wellbeing, degrowth narratives	Very High

2.3. Resilience as a property of governance networks

The concept of resilience has become central to the analysis of socio-ecological systems and the governance arrangements that shape their capacity to withstand, adapt to, and transform in response to shocks and long-term stressors. Originally rooted in ecological theory (Holling, 1973), resilience has evolved into a multi-dimensional concept encompassing the ability of systems not only to absorb disturbances and maintain function (*persistence*), but also to adapt their structure (*adaptability*) and even shift into new regimes when needed (*transformability*) (Folke et al., 2010; Walker et al., 2004).

When applied to governance systems, resilience entails more than technical robustness or institutional efficiency. It reflects the degree to which institutional configurations, actor relationships, and decision-making processes can respond flexibly and innovatively to emerging challenges—particularly those associated with climate change, resource scarcity, or socio-political conflict (Biggs et al., 2012; Pahl-Wostl, 2009). In this view, governance networks are not merely instruments of control or regulation, but dynamic arenas in which resilience is continuously negotiated, reproduced, or undermined.

A resilient governance network is characterized by features such as diversity of actors and knowledge systems, redundancy in roles and responsibilities, modularity to contain cascading failures, and the capacity for learning and self-organization (Berkes et al., 2003; Janssen et al., 2006). Polycentricity—the coexistence of multiple centers of authority—is also considered a key feature, as it enables more adaptive and context-sensitive responses across scales and sectors (Ostrom, 2010; Huitema et al., 2009).

Critically, resilience is not a neutral or universally beneficial property. Scholars have warned against uncritically celebrating resilience without examining *what* is being made resilient and *for whom* (Cote & Nightingale, 2012; Béné et al., 2012). Systems can be resilient in maintaining unsustainable or unjust arrangements, such as elite capture of resources, exclusionary institutions, or maladaptive dependencies.

Therefore, assessing resilience in governance networks requires a normative lens—one that interrogates not only the system's capacity to endure, but also its ability to evolve toward more equitable, democratic, and sustainable configurations (Westley et al., 2011; Chaffin et al., 2014).

In the context of climate adaptation and water governance, resilience is increasingly conceptualized as a relational property that emerges from the interactions among actors, institutions, and ecological processes (Pahl-Wostl, 2009; Bixler et al., 2016). The structure and quality of relationships—trust, accountability, shared visions—are essential to understanding how governance systems mobilize collective action, coordinate across fragmented mandates, and navigate uncertainty. It is within this relational perspective that the integration of resilience thinking with network-based approaches finds its relevance: not as a static attribute of institutions, but as a dynamic, distributed, and contested capacity that is embedded in governance configurations.

3.Murcia As Case study

The Region of Murcia is one of Europe's most water-stressed agricultural areas, with irrigation withdrawals totaling nearly 1.7 billion m^3 per year—over 80 % of regional use—and a structural deficit of roughly 20 % covered by the Tagus–Segura inter-basin transfer and advanced wastewater reuse schemes (FAO, 2021; Confederación Hidrográfica del Segura, 2021). Remarkably, Murcia reclaims and reuses approximately 98 % of treated wastewater for irrigation—well above the EU average—underscoring its position at the forefront of agricultural water reuse (Regional Government of Murcia, 2018; European Commission, 2020).

Despite these innovations, water quality remains a critical concern: nitrate concentrations in Segura-basin aquifers frequently exceed the 50 mg/L limit of the Nitrates Directive (91/676/EEC), while phosphate runoff drives eutrophication events in the Mar Menor coastal lagoon, fueling stakeholder conflicts between irrigation communities seeking expanded transfers and desalination and environmental groups demanding stricter fertilizer controls and reuse quality standards (Confederación Hidrográfica del Segura, 2021). This combination of extreme scarcity, pioneering reuse, and contested water-quality challenges makes Murcia an ideal case for exploring how governance networks and technological interventions co-evolve under these constraints.

This analysis will be complemented by comparative case studies in the Netherlands, Poland, the United Kingdom, Sweden, Finland, Italy, and Ukraine, in future stages of the study.

4.Methodology

The methodology of this study is supported by COSMIC1, an open-access, interactive virtual platform that integrates data collection, actor-network visualization, and social network and leverage point analysis. COSMIC serves as both an academic research resource and a practical tool for multi-actor governance, centralizing data from the eight FARMWISE case studies (ES, IT, FI, ND, UK, UKr, PO, SW). As introduced before, in this work in progress paper, only the Spanish case study, in the Murcia region, will be introduced.

The sampling universe varies according to each case study's territorial context, acknowledging that an innovation system may be either regional or national: in the Murcia region in Spain, stakeholders are selected at the autonomous-community level - NUTS2 (regional)[2].

The number of participants was established according to a qualitative representativeness criterion validated jointly by the pilot coordinator and relevant local organizations, rather than through a strict statistical sampling method. Respondent recruitment was based on lists provided by regional leaders, supplemented by contacts identified through the iterative interview process, with explicit recognition and assessment of potential snowball bias (a sampling bias in which participants refer to similar contacts; Bethlehem, 2010). The study employed a

1 https://sus.media.h-da.de/ Developed jointly with the Darmstadt University of Applied Sciences.

[2] NUTS1/2 (national/regional): in countries with smaller administrative subdivisions, such as the Netherlands, where the study is conducted at the national level. / NUTS1 (national): in contexts covering one or more NUTS2 regions within a larger administrative framework, such as those used in Italy.

bottom-up mapping approach, progressively incorporating new stakeholders as they emerged during the interviews. Specifically, representatives of organizations such as irrigation communities, water-and-agriculture innovation firms, public research bodies, agricultural development agencies, farming cooperatives and federations, and journalists and media outlets specialized in environment and agriculture, among others, were surveyed. This iterative process continued until theoretical saturation was reached, ensuring the capture of the diverse perspectives essential for the analysis without relying on formal probabilistic estimates.

Using a multilingual questionnaire through the COSMIC platform, that will be available in eight languages, we collected three types of data structured in three sections: (1) nodes: general organizational information (10 items); (2) edges: description of key interactions among actors (7 items); and (3) leverage points: assessment of water-management leverage points (12 items) using a Likert scale. The main objective of the survey is to provide a robust database for analyzing both social networks under the Social Network Analysis framework (SNA; Wasserman & Faust, 1994) and leverage points from a systems perspective (Abson et al., 2017), thereby visualizing the complexity of the innovation and water-management ecosystem across the FARMWISE regions. Information about the actor network allows the researchers to get qualitative information about the actor network.

This survey was reviewed in a pilot phase by experts in agriculture, sustainability, and governance at the Polytechnic University of Valencia, ensuring coverage of the hydric innovation system's dimensions and internal consistency of the scales, and validating linguistic adaptation with each case-study leader (Dillman, Smyth & Christian, 2014).

Data collection is currently underway only for the FARMWISE Case Study in Spain, specifically in the Murcia region, carried out between February and April 2025. Surveys are administered by telephone during business hours, while simultaneously introducing the data in the COSMIC platform, with an average completion time of 15–18 minutes.

Raw data is stored in a JSON file feeding COSMIC's visualizations. This workflow enables calculation of key metrics—degree, betweenness, density, and modularity—and the creation of force-directed layouts that highlight the most significant interactions (Wasserman & Faust, 1994). All procedures comply with ethical and data protection regulations: participants sign informed consent under the GDPR, with advice from the UPV Data Protection Delegation.

5.Results (under construction

As the network remains under development, the following serves as a provisional illustration of the conclusions that may emerge.

5.1 The use of COSMIC platform

Data collection and preliminary social network computation were executed through the COSMIC (Collaborative Stakeholder Mapping of Interactions and Collaborations) platform, which implements a semi-automated pipeline from survey dissemination to metric extraction:

- **Questionnaire distribution**

A unique, multilingual survey link is generated for each case study and disseminated to identified stakeholders. Respondents provide organizational attributes and enumerate inter-organizational ties via structured fields. This standardized digital instrument reduces measurement error and enhances comparability across contexts (Dillman et al., 2014).

- **Automated data parsing and validation**

Submitted responses are encoded in JSON format. The platform performs syntactic and consistency checks—flagging incomplete metadata or implausible tie entries—and prompts researchers to resolve discrepancies, thus preserving data integrity.

- **Network construction and visualization**

Upon validation, COSMIC automatically interprets the JSON edge list, instantiates an undirected graph, and generates a force-directed sociogram. This immediate visual feedback facilitates iterative sampling adjustments and early detection of structural anomalies.

- **On-the-fly metric computation**

Core SNA metrics at node/individual-level (degree, betwenness, closeness cenetralities) and at network level (node and edge counts, density, average degree, and modularity via the Louvain algorithm) are computed server-side and logged alongside raw data.

- **Data export for advanced analysis**

Processed networks and attribute tables can be exported in interoperable formats (e.g., GEXF, GraphML, CSV), enabling seamless integration with external analytic environments (e.g., Python's NetworkX, R's igraph).

- **Automated workflow with human intervention**

COSMIC transforms a single shared survey link into a parameterized network model with minimal manual intervention. Nevertheless, because stakeholder identification and response completeness rely on participant engagement, rigorous follow-up protocols—including reminder communications and targeted outreach—are required to achieve sufficient coverage, mitigate snowball bias, and satisfy theoretical saturation criteria.

5.2 Murcia's water and innovation social network

Rank	Degree Centrality	Betweenness	Closeness	Eigenvector
Explanation	Proportion of all possible direct ties an actor actually has; high values identify "hubs" with many immediate connections for rapid information/resource exchange.	Extent to which an actor lies on the shortest paths between others; high values flag "brokers" or gatekeepers controlling key communication channels.	Average proximity of an actor to all others (via shortest paths); high values mark those who can reach every stakeholder in a few steps, ideal for quick mobilization.	Influence via association: actors connected to other well-connected peers score highly, marking them as indirect opinion leaders whose reach is amplified by powerful neighbors.
Notes	Identifies actors with the most direct ties, key hubs for transmitting information or resources.	Pinpoints actors that bridge otherwise disconnected groups—critical brokers for cross-cluster coordination.	Highlights actors best positioned for rapid outreach—efficient conduits for time-sensitive communication.	Reveals actors whose influence is amplified by connections to other influential peers—ideal targets for indirect opinion-leader interventions.
1	CEBAS-CSIC	CEBAS-CSIC (171.67)	COBET Tratamientos del Agua SL (1.00)	Universidad Politécnica de Cartagena (1.00)
2	ESAMUR	ESAMUR (100.33)	ESAMUR (0.607)	CEBAS-CSIC (0.954)
3	Confederación Hidrográfica del Segura	Confederación Hidrográfica del Segura (72.00)	CEBAS-CSIC (0.595)	ESAMUR (0.944)
4	Comunidad de Regantes Campo Cartagena	Comunidad de Regantes Campo Cartagena (64.00)	Confederación Hidrográfica del Segura (0.565)	Comunidad de Regantes Campo Cartagena (0.835)
5	AZUD	AZUD (40.67)	SAT #557 (0.554)	Confederación Hidrográfica del Segura (0.760)

Concerning degree centrality, which represents the proportion of all possible direct ties that an organization actually has (i.e., a measure of its immediate interconnectedness), the five highest-scoring actors were CEBAS-CSIC, ESAMUR, Confederación Hidrográfica del Segura, Comunidad de Regantes Campo Cartagena, and AZUD.

This means that these organizations maintain the greatest number of direct relationships within the Murcia governance network, positioning them as key conduits for exchanging information, coordinating activities, and mobilizing resources across stakeholders.

Concerning betweenness centrality, which captures how often an organization lies on the shortest paths linking other pairs of actors (i.e., its potential to broker or gatekeep information flows), the top five and their scores were: CEBAS-CSIC (171.67), ESAMUR (100.33), Confederación Hidrográfica del Segura (72.00), Comunidad de Regantes Campo Cartagena (64.00), and AZUD (40.67). This indicates that these organizations occupy pivotal intermediary positions in the network, controlling key channels through which information and resources traverse between otherwise disconnected stakeholders.

Concerning closeness centrality, which quantifies an organization's average proximity to all other actors in the network (i.e., its capacity for rapid outreach), the highest values were observed for COBET Tratamientos del Agua SL (1.00), ESAMUR (0.607), CEBAS-CSIC (0.595), Confederación Hidrográfica del Segura (0.565), and SAT #557 (0.554). This means that these organizations are, on average, fewer steps away from all other stakeholders, enabling them to disseminate information or coordinate actions across the network more quickly than their peers.

Concerning eigenvector centrality, which reflects influence via connections to other well-connected actors (i.e., indirect prestige or endorsement power), the leading organizations were Universidad Politécnica de Cartagena (1.00), CEBAS-CSIC (0.954), ESAMUR (0.944), Comunidad de Regantes Campo Cartagena (0.835), and Confederación Hidrográfica del Segura (0.760). This indicates that these organizations are not only well-connected themselves but are also linked to other highly connected stakeholders, granting them enhanced indirect influence and prestige within the governance network.

Together, these centrality measures paint a consistent picture of Murcia's water-governance network as a polycentric yet hub-driven system. A small group of organizations—most notably CEBAS-CSIC, ESAMUR, and the Confederación Hidrográfica del Segura—occupy the most direct ties, broker the majority of indirect exchanges, and sit closest on average to all other actors, making them essential for coordination, information flow, and rapid outreach. Meanwhile, the Universidad Politécnica de Cartagena and CEBAS-CSIC extend their reach even further by connecting to other highly central stakeholders, amplifying their indirect influence across the network. This overlap of high-degree hubs, high-betweenness brokers, high-closeness disseminators, and high-eigenvector influencers underscores the critical role of a core group in maintaining network cohesion, facilitating cross-cluster links, and accelerating the spread of innovations or policy directives. At the same time, it points to potential vulnerabilities should any of these central organizations be disrupted, as well as to strategic opportunities for leveraging their positions to achieve system-wide impact.

5.3 Murcia's stakeholders perception about the about their network

Stakeholders from five sectors provided Likert-scale ratings (1 = "completely disagree" to 5 = "completely agree") on three dimensions of network leverage points. Table 6 summarizes, for each sector, the number of respondents (N), mean score, and standard deviation (SD) for each survey item. In each sector, all items received between 1 and 5 ratings, with most sectors providing 2–4 responses per item.

Sector-specific descriptive statistics for network perception items

SECTOR	ITEM	N	MEAN	SD
Surface level				
Academia	The network is strong and cohesive.	2	4.50	0.71
	The network is very diverse.	2	4.00	0.00
	Efficient coordination mechanisms exist.	2	3.50	0.71
Comunicación	The network is strong and cohesive.	1	5.00	–
	The network is very diverse.	1	4.00	–
	Efficient coordination mechanisms exist.	1	4.00	–
Private sector	The network is strong and cohesive.	4	3.50	1.73
	The network is very diverse.	4	4.00	0.82
	Efficient coordination mechanisms exist.	4	3.25	1.50
Sector Público	The network is strong and cohesive.	3	4.00	1.00
	The network is very diverse.	3	4.33	0.58
	Efficient coordination mechanisms exist.	3	3.67	0.58
Sociedad Civil	The network is strong and cohesive.	2	2.50	0.71
	The network is very diverse.	2	3.00	1.41
	Efficient coordination mechanisms exist.	2	3.00	1.41
Intermediate level				
Academia	I would like to collaborate more.	2	4.00	0.00
	Influential actors facilitate sustainable practices.	2	3.50	0.71
	Conflicts impede innovation.	2	2.50	0.71
Communication	I would like to collaborate more.	1	3.00	–
	Influential actors facilitate sustainable practices.	1	3.00	–
	Conflicts impede innovation.	1	2.00	–
Private sector	I would like to collaborate more.	4	4.25	0.96
	Influential actors facilitate sustainable practices.	4	3.50	0.58
	Conflicts impede innovation.	4	3.25	1.50
Public sector	I would like to collaborate more.	3	4.33	0.58
	Influential actors facilitate sustainable practices.	3	3.67	0.58
	Conflicts impede innovation.	3	3.00	0.00
Civil society	I would like to collaborate more.	2	3.50	0.71
	Influential actors facilitate sustainable practices.	2	3.00	1.41
	Conflicts impede innovation.	2	3.00	0.00

Deep level				
Academia	Network prioritizes sustainability over productivity.	2	2.50	0.71
	Ecosystem ready for collaborative governance.	2	4.00	0.00
Communication	Network prioritizes sustainability over productivity.	1	3.00	–
	Ecosystem ready for collaborative governance.	1	4.00	–
Private sector	Network prioritizes sustainability over productivity.	4	2.25	0.83
	Ecosystem ready for collaborative governance.	4	2.25	0.83
Public sector	Network prioritizes sustainability over productivity.	3	2.67	0.58
	Ecosystem ready for collaborative governance.	3	3.67	1.15
Civil society	Network prioritizes sustainability over productivity.	2	3.00	0.00
	Ecosystem ready for collaborative governance.	2	3.50	0.71

Stakeholder groups differed in how they rated the cohesion, diversity, and coordination of the Murcia governance network ("surface level"). Academic and Public Sector respondents consistently rated network strength and diversity highly (mean scores ≥ 4.0 out of 5) and judged coordination mechanisms to be moderately efficient (3.5–4.0). Private Sector actors provided more varied answers, with average scores of 3.5 for cohesion, 4.0 for diversity, and 3.25 for coordination. Civil Society gave the lowest surface-level ratings (2.5–3.0), while the sole Communications respondent rated all three dimensions between 4 and 5.

On the "intermediate level," which addresses actors' willingness to collaborate, the role of influential organizations, and the impact of conflicts, Public and Private Sector participants expressed the strongest desire to work more closely with the network (means slightly above 4.0). Academics' willingness to collaborate was similarly high (4.0), whereas Civil Society and Communications scored this item at 3.5 and 3.0, respectively. Across sectors, opinions were moderate on whether key actors facilitate sustainable practices (means around 3.5) and on whether conflicts obstruct innovation (means ranging from 2.5 to 3.25).

At the "deep level," concerning the network's underlying goals and readiness for new governance models, all groups gave lower ratings on whether sustainability takes priority over productivity (means between 2.25 and 3.0). In contrast, perceived readiness for a more collaborative, sustainable governance approach was rated highest by Academia and Communications (4.0) and lowest by the Private Sector (2.25), with Public Sector and Civil Society falling in between (3.5–3.7).

6.discussion: qualitative integration of stakeholder's network perceptions (under construction)
Drawing on resilience theory and leverage-point concepts, stakeholder perceptions help us understand Murcia's governance network in three ways: its ability to absorb shocks, to adapt over time, and to transform fundamentally.

Absorptive capacity (surface-level perceptions & parameter levers)
High ratings of network cohesion and diversity among Academia and Public Sector actors align with a capacity to absorb disturbances through redundant ties and multiple information channels (Berkes et al., 2003). These perceptions corroborate the high-degree centrality of CEBAS-CSIC and ESAMUR, suggesting that immediate "parameter" interventions—such as enhanced data-sharing protocols—can be readily deployed via these hubs to buffer short-term shocks. In contrast, Civil Society's lower ratings suggest some groups may be left out, pointing to areas where we need focused outreach to strengthen these weaker points.

Adaptive capacity (intermediate-level perceptions & feedback levers)
Strong expressed willingness to collaborate (especially in Public and Private sectors) reflects a positive feedback orientation—actors are ready to adjust practices in response to evolving conditions (Pahl-Wostl, 2009). This theme resonates with high-betweenness metrics: brokers like ESAMUR occupy positions to catalyze adaptive loops by convening multi-stakeholder working groups or piloting iterative policy-learning exercises. However, moderate

concern about conflicts suggests that without clear feedback mechanisms—like performance-based incentives or mediation forums—adaptation may stall.

Transformative capacity (deep-level perceptions & intent levers)
Views diverged on whether sustainability goals outweigh productivity goals. Some actors remain focused on traditional mandates, while others are open to deeper change, despite both actors can be innovating and fostering paradigm shifts (Folke et al., 2010). These normative divergences correspond to Meadows' "intent" leverage points: changing goals and paradigms is inherently political and requires deliberate engagement of central institutions (e.g., Confederación Hidrográfica del Segura) to convene reflexive dialogues. The relatively higher readiness perceived by Academia and Communications suggests pockets of transformative potential that can be activated through strategic framing exercises and co-creation workshops.

7.Preliminary conclusıons
The COSMIC platform was pivotal in this research, providing an end-to-end, semi-automated pipeline from survey deployment to network visualization and metric extraction. Its multilingual interface, real-time validation checks, and built-in SNA computations enabled rapid development of a fully parameterized network model from a single questionnaire link.
However, ensuring that peripheral actors were included—and thereby mitigating snowball bias—required diligent follow-up by the research team.

Overall, the combination of COSMIC-enabled network analytics and qualitative insights offers a scalable, replicable methodology for diagnosing resilience and guiding multi-level interventions: simple "parameter" fixes via data-sharing protocols, "feedback" instruments like incentives and demonstration projects, and "intent" dialogues to realign system goals. Future research should broaden stakeholder engagement, track network dynamics over time, and pilot the identified leverage-point interventions to assess their impact on adaptive capacity and transformative change.

How meaningful is formal participation in environmental assessments? Examining the case of large-scale linear infrastructure projects in Germany.

Philipp Kerschbaum
Affiliation: Environmental Assessments Research Group, Faculty VI – Planning, Building, Environment, Technical University Berlin (Germany)
Email: philipp.kerschbaum@tu-berlin.de

Abstract
Public participation informs and underpins the authorities' decision-making in the approval of large-scale energy and mobility infrastructure projects. Despite well-established knowledge on the prerequisites for meaningful engagement, participatory practices frequently remain limited to fulfilling minimum legal obligations.

This contribution examines which requirements for public participation in impact assessments are currently fulfilled and which aspects remain in need of improvement. The analysis focuses on the German approval processes for motorways, railways, and electricity transmission grids.

The analysis reveals that, although formal participation requirements remain limited in scope, they offer potential entry points for more meaningful engagement. Particularly, the dimensions of communication, mutual learning, and procedural innovation emerge as key areas for authorities to experiment with and advance participatory practices.

Keywords: environmental assessment; public participation; meaningful stakeholder engagement, large-scale infrastructure; energy and mobility transition

Glossary
MSE – Meaningful Stakeholder Engagement
EA – Environmental Assessment
E(I)A – Environmental (Impact) Assessment (project level)
SEA – Strategic Environmental Assessment

1.Research interest and relevance
Measures to accelerate the planning and approval processes for energy and mobility projects have become a heavily discussed topic in political debates worldwide (Enríquez-de-Salamanca, 2021; Fischer et al., 2023). In the German context, there is an urgent need to expand infrastructure to support climate goals and reduce greenhouse gas emissions. On top of that, the country's ageing infrastructure demands immediate attention and maintenance (Dullien et al., 2024; Schroeder, 2020). Policymakers are under increasing pressure to drive progress on both fronts simultaneously. The widely perceived lengthy timespans between the initiation and final approval of infrastructure projects have intensified public and political calls for faster approval processes and led to the implementation of new policies[1,2]. However, accelerating these processes without consideration of trade-offs may harm the environment and democratic standards (Bond et al., 2014; Geißler and Jiricka-Pürrer, 2023).

When discussing barriers to accelerated infrastructure development, one instrument frequently takes centre stage: environmental assessments (EA)[3]. Originating in the 1970s, EAs have since become the globally recognised standard for assessing potential impacts of infrastructure projects and guiding informed, environmentally conscious decision-making (Hanna and Arnold, 2022). However, five decades later, EAs are increasingly under pressure.
As Bond et al. (2024, p. 410) note, the instrument "is under threat in many jurisdictions" due to a growing perception that it has "failed to convince sceptics that it represents value for money.

1 Recommendation for a resolution and report by the Committee on Transport (15th Committee) on the Federal Government's draft bill - printed matter 20/6879 - Draft law to speed up approval procedures in the transport sector and to implement Directive (EU) 2021/1187 on streamlining measures to accelerate the realisation of the trans-European transport network (original language: German)
2 DIRECTIVE (EU) 2023/2413 OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 18 October 2023 amending Directive (EU) 2018/2001, Regulation (EU) 2018/1999 and Directive 98/70/EC as regards the promotion of energy from renewable sources, and repealing Council Directive (EU) 2015/652
3 Environmental Assessments are a type of Impact Assessments

Despite the worldwide implementation and success, EAs are perceived as being „too expensive, take too long, get in the way of development, and are ineffective in helping protect the environment or to meet environmental objectives" (Fischer et al., 2023, p. 181; Sinclair and Burdett, 2024). Despite the lack of empirical evidence, participation processes and appeals against permits are often cited as one of the main reasons for delays. Therefore, measures to accelerate approval processes often focus on weakening participation processes (Geißler and Jiricka-Pürrer, 2023; Zschiesche and Grünberger, 2024).

Fischer et al. (2023, p. 181) define environmental assessments as a "(...) participatory ex-ante assessment framework for policies, programs, and projects (...)", highlighting the central role of participation. The involvement of diverse actors – including the general public – enhances the quality of environmental assessments by contributing to well-informed decision-making (i.a. Sinclair and Diduck, 2017; Glucker et al., 2013; Morrison-Saunders et al., 2023; Suškevičs et al., 2023). Early and continuous participation is thus essential for democratic decision-making and plays a crucial role in ensuring transparency, legitimacy, and public acceptance (Doelle and Majekolagbe, 2023). Particularly, the legitimacy and societal acceptance of projects related to the energy and mobility transition(s) hinge on the meaningful engagement of stakeholders (Kamlage et al., 2018; Rehhausen et al., 2018). However, there seems to be a consensus that these transitions, and therefore the planning and approval of respective projects, need to be accelerated (Skjølsvold and Coenen, 2021).

Discussions about the adaptation and development of approval processes, both in academia and practice, are as old as the instrument itself (Bonnell, 2025). Sinclair et al. (2022) highlight the discrepancy between the theoretical goals of the instrument and the differing implementations in practice. They argue for a „next-generation impact assessment" to close this gap. While public participation is increasingly subject to rationalisation and adaptations, next-generation impact assessments underscore the value of meaningful public participation (ibid). The normative concept of Meaningful Stakeholder Engagement (MSE) promotes participatory approaches centred on the needs of affected communities (Buhmann et al., 2024).

This contribution adds to the discussion on stakeholder participation and EA. It will be examined to what extent participation in the current formal approval system in Germany (organised by competent authorities) can meet the criteria of MSE. Informal forms of participation and the possibilities of stakeholders other than authorities to steer the participation process were not the object of the analysis. Furthermore, it reflects and discusses whether MSE is a valuable concept for analysing national EA systems.

The text is structured into four parts. First, characteristics of MSE in EA processes are outlined. Second, the German EA system is introduced as a case. An initial overview is presented, followed by a focused examination of approval procedures for large-scale linear infrastructure projects and associated participation mechanisms. Key debates surrounding the acceleration and streamlining of these procedures are also addressed. Third, a set of elements and requirements of MSE is applied to the German context. Finally, the findings and broader implications are drawn.

2.Method, data collection, and case

The methodology consists of two parts. First, a structured literature review (Bryman, 2012) on public participation and the acceleration of planning and approval processes. Second, a document analysis of legal documents using the case of Germany (Bowen, 2009). The categories of analysis are defined by elements and requirements of Meaningful Stakeholder Engagement (MSE), as proposed by Sinclair and Burdett (2024).

Case selection: The selected case is the legal framework for environmental assessments (EA) of large-scale infrastructure projects in Germany. Germany serves as a valid case regarding its dynamic discussion on the adaptation of approval processes and consequences for participation (Geißler and Jiricka-Pürrer, 2023; Zschiesche and Grünberger, 2024). Moreover, the country's geographical position in Central Europe, as well as its size, offers the possibility to build on the experience of many large-scale and highly controversial infrastructure projects (Hellmuth and Jakobs, 2021).

This analysis focuses in particular on three types of linear infrastructure projects: railways, motorways, and electricity grids. They provide useful cases due to the scale of the projects, the public debate and disputes

surrounding them, as well as the environmental impacts (Gharehbaghi et al., 2022).

Literature review: The procedure for collecting relevant literature is based on highly cited publications and documents such as handbooks[4]. Based on these, the snowball method (backward citation tracking) was applied to gather documents in this field (Hirt et al., 2023). The seed element of the citation tracking (through Scopus and Google Scholar) built the most recent articles (published before April 2025). Finally, a keyword search of Scopus and Google Scholar was carried out to check whether further relevant documents weren't covered by previous steps (keywords used: "meaningful" AND "public participation" AND "environmental assessment" OR "impact assessment"). While the international literature was mainly collected via the Scopus database, documents on the German national context were also found via Google Scholar or via relevant institutions such as the German Federal Environmental Agency.

Analysis of participation in the EA: An existing framework (Sinclair and Burdett, 2024) was used to analyse participation in the context of impact assessment. This framework comprises ten distinct elements, organized into 31 requirements that form analytical categories (see Appendix 1). Based on these categories, laws were analysed and assessed. Four different categories were introduced to show the degree of fulfilment (see more in the results chapter). The attribution of the relevant parts of the documents to the categories is based on the descriptions of the categories and of the respective parts in the documents.

3.Participation in Environmental Assessments

Discourse and challenges

Environmental assessments (EAs) serve as a bridge between the technical design of infrastructure projects and their real-world environmental and societal impacts. The inclusion of diverse stakeholders and their perspectives is essential, as assessment outcomes cannot be based solely on technical considerations (Ulibarri et al., 2019). Public participation in EA has been the subject of extensive scholarly discussion. Suškevičs et al. (2023) show that participation focuses mainly on formal arenas, whereas „(...) guaranteeing public/stakeholder impact in decision-making and timing of the participatory process are still among the most problematic issues in the EA context" (ibid, p. 13). Despite the existence of extensive legislation and numerous guideline documents, participation often remains at a consultative level, which may lack sufficient depth or significance to ensure a meaningful impact on final decisions.

While Suškevičs et al. (2023) focus on the European context, Buhmann et al. (2024, p. 3) highlight a „(...) growing frustration with (...) public participation in the decision-making processes of (...) projects and plans proposed or implemented by companies or governments" at a global level. The concept of Meaningful Stakeholder Engagement (MSE) has emerged in response to these challenges (Buhmann et al., 2024, p. 3). MSE emphasizes the inclusion of affected stakeholders and the consideration of their needs in planning, assessment, and approval processes. As such, it offers an analytical lens for examining existing legislation on EA.

Conceptualisations of (meaningful) public participation

The conceptualisation and current debates on MSE build upon and are closely linked to key contributions from earlier conceptual frameworks. In particular, two publications have been highly influential in shaping the discourse on public participation in (environmental) impact assessments. Glucker et al. (2013) expand upon O'Faircheallaigh's (2010) earlier framework by distinguishing three central rationales of participation: the instrumental (leads to legitimacy and resolving conflict), the substantive (contributes to a „better" outcome), and the normative rational (reflects democratic ideals and fosters empowerment).

MSE contributes to the ongoing discourse on participation in environmental assessments (EA). In this context, the essential elements of public participation identified by Sinclair and Burdett (2024) serve as a framework for analysis. Drawing on both practitioner and scholarly experience, as well as insights into assessment systems, the authors highlight "(...) meaningful public participation, starting early, continuing throughout (...)" as a key element,

4 Handbook of Environmental Impact Assessment (edited by K. Hanna 2020).

Handbook of Environmental Impact Assessment (edited by A. Fonsecca 2022)
Handbook on Meaningful Stakeholder Engagement (edited by Buhmann et al. 2024)

Handbook of Public Participation in Impact Assessment (edited by Burdett and Sinclair 2024)

framing stakeholder engagement as a "(...) core feature of assessment deliberations." Although the conception is rooted in the Canadian context, the authors emphasize its broader relevance, "(...) to inform assessment improvement efforts anywhere" (Sinclair et al., 2022, p. 4).

Sinclair and Burdett (2024) differentiate ten elements (see Table 1), which are further specified through 31 detailed requirements (see Appendix 1). Together, they provide a comprehensive set of analytical categories for the analysis. Table 1 shows that all elements cover the rationales mentioned above (Glucker et al., 2013) and therefore align with the existing literature on the requirements of public participation.

Table 1 - Central elements of MSE in combination with basic rationales of public participation, based on Glucker et al. 2013, Sinclair and Burdett 2024, and own attribution

Element-No.	Elements of MSE Sinclair and Burdett (2024)	Instrumental (What leads to legitimacy and resolving conflict?)	Substantive (does the element contribute to a "better" outcome?)	Normative (Does the element reflect democratic ideals and foster empowerment)
1	Adequate notice			√
2	Access to information			√
3	Participation assistance		√	√
4	Opportunity for public comment	√	√	
5	Access to public hearings			√
6	Early and ongoing participation	√	√	
7	Deliberative forums	√	√	√
8	Decision Impact	√		√
9	Learning oriented		√	√
10	Fair and open	√		√

The allocation of elements to the respective rationales was made deliberately, based on Glucker et al.'s (2013, p. 106 ff) description and guiding questions, presented in the first row of Table 1. The attribution was strict; e.g., the element „opportunity for public comment" alone does not necessarily lead to the achievement of the normative rationale. However, it can be seen that the normative rationale covers most of the essential elements, while the instrumental and substantive rationales could be attributed to only half of the elements. This aligns with the normative aspirations and the claim of MSE to be a concept centred on the needs of those affected by projects (Buhmann et al., 2024).

As the conceptualisation of Sinclair and Burdett (2024) is relatively recent, no publicly available scientific studies were identified that apply this approach to the analysis of a specific national EA system[5]. This study can therefore be regarded as an exploratory effort to assess the applicability and analytical utility of the framework in a national context.

4.Case: Approval, environmental assessments and participation for linear infrastructure in Germany

Overview of participation in the German EA system

Both contestations and implementations of international law shaped public participation in environmental assessments (EA) in Germany. One of the most influential policies is the Aarhus Convention. Ratified in 2007, it guarantees public participation, access to justice, and access to information[6]. Additionally, the implementation of EU law led to the obligatory standardised assessment of projects and plans (Schütte et al., 2023).

5 besides a Master's thesis of one of A. John Sinclair's students (Bayuelo Gonzalez (2025) on the national case of Colombia) at the University of Manitoba, Canada

6 https://unece.org/environment-policy/public-participation/aarhus-convention/text, last call May 2025

Initially, the global rise of „environmental movements" led to increased public awareness of environmental values and fostered growing opposition to large-scale infrastructure projects (Odparlik and Köppel, 2013; Ohlhorst, 2018; Wende, 2018). Schütte et al. (2023) state that public participation and awareness of the impacts of projects in Germany developed particularly through highly confrontative cases. The Stuttgart 21 railway project is a notable example of civic resistance, public protest, and demands for more progressive participation processes (BMVI, 2014; Böhm, 2011). Such large-scale infrastructure projects have come to symbolise what Schütte et al. (2023, p. 23) describe as "non-functioning and ineffective participation processes" (own translation). In response to persistent conflicts and legitimacy deficits, participatory processes have been gradually expanded. One key reform introduced the possibility of early public participation[7] – a process initiated before the formal application for approval. As a result, competent authorities are now required to actively promote preliminary public involvement in the planning phase (Ziekow, 2018).

A range of legal frameworks governs the depth and scope of public participation in EA in Germany. Among these, the Environmental Impact Assessment Act (UVPG) and the Administrative Procedure Act (VwVfG) constitute the core legal foundations for participatory processes within the EA system. Additionally, various sector-specific laws – depending on the type of project and the jurisdiction (i.e. federal state) – further define participation requirements and procedural steps (Köppel et al., 2004, p. 241; Ziekow, 2018).

Participation in linear energy and mobility infrastructures in Germany

The focus on linear infrastructure enables a cross-sectoral analysis across three distinct yet comparable domains: motorways, railways, and electricity grids. While these sectors differ in terms of responsible authorities, they are similar regarding their socio-environmental impacts, the public discourses they generate, and the regulatory framework of project approval (Biasotto et al., 2022; Gharehbaghi et al., 2022). Each project type plays a significant role in political debates surrounding the transition to sustainability and economic development. Moreover, they are of national and international relevance (European Parliament, 2024).

In the German context, linear infrastructure projects follow a comparable planning and approval logic. A specific project requiring formal planning approval (the so-called "Planfeststellung") typically reflects a series of preliminary decisions made at various strategic planning levels. These processes range from demand assessments to corridor selection (see Table 2). EAs, such as strategic environmental assessments (SEA) and environmental impact assessments (EIA), are embedded in these steps. Consequently, the legally mandated participatory steps associated with EAs also apply throughout the entirety of the approval procedure.

Derived from the legal documents, four essential steps can be differentiated:

Table 2 - overview, evolution from strategy to project of railway, motorway and electricity grid projects (BMVI, 2014; Bundesnetzagentur, 2021)

Step	Instrument	Participation
The strategic level – necessity and demand – strategic plan	Grid development plan[8], National plan of traffic routes[9]	SEA - Mandatory through EIA law (UVPG)
Fixing of connections (starting and endpoint)	Demand plan[10]	Law process
Planning of corridors and alternatives	Specific plan[11]	SEA, mandated by EIA law (UVPG)
Planning and permit - final project	Planning approval[12]	EIA and approval process, mandated by EIA law and Administrative Procedure Act (UVPG & VwVfG)

7 German term: „frühzeitige Öffentlichkeitsbeteiligung" (§25 VwVfG)
8 Netzentwicklungsplan
9 Bundesverkehrswegeplan
10 Bedarfsplan
11 Fachplan
12 Planfeststellung

Each of the steps listed in Table 2 applies chronologically to all three linear project types. Between the strategic level and the final project, there are several opportunities for participation (BMVI, 2014; BMWi, 2021). At the same time, considerable time lags often occur between the initial idea and final implementation.

Participating in every single step or keeping track of the entire process and the decisions made at each step is a difficult task, especially for non-experts. Participation thus becomes a complex and challenging exercise in itself (Fung, 2015). If concerns are not addressed at an early stage, conflicts or resistance could arise at a very late stage. Typically, by the time major decisions are made, the possibility of influencing the project is already low (Mathur et al., 2008). This highlights the importance of a transparent and comprehensive summary of the preliminary process, significant decisions, and opportunities to influence the projects at an early stage. It is evident that the earlier participation starts, the more concerns can be raised, addressed, and conflicts prevented. Accordingly, various guidance documents (BMVI, 2014; BMWi, 2021) and academic literature (i.e. Doelle and Majekolagbe, 2023) highlight the need for early and continuous participation.

However, this aspect is not broadly reflected in the law. During the approval process, formal participation is limited to the opportunity for stakeholders to submit comments and participate in a public hearing. Additional steps, such as preliminary public participation before the application for approval, are mentioned in law, but not mandatory (Ziekow, 2018).

Discourses on streamlining and simplification in Germany

Discussions about adapting and simplifying EAs are as old as the instrument itself (Faith-Ell, 2023; Noble, 2023). EAs are assumed to be too expensive, too long, and don't provide value for money. The debate is further fuelled by the urge to implement projects that boost the economy and facilitate the transition to renewable energy and mobility systems (Bond et al., 2014). Enríquez-de-Salamanca (2021) argues that discussions on streamlining are driven by a "(...) political trend that sees EIA as an obstacle to necessary investments". While various actors hold differing views on streamlining processes, it's commonly understood that acceleration is required (Skjølsvold and Coenen, 2021). The challenge, however, is to determine the acceptable trade-offs for achieving this speed.

In the German context, the primary reasons for accelerating approval processes are the urgency of the climate crisis (coal and nuclear phase-out, energy transition), the aging infrastructure, the need to become independent of Russian gas, and the desire to boost economic growth (Deutscher Bundestag, 2023).

In recent years, numerous measures have been implemented to accelerate processes, primarily through new EU Directives and Regulations (mainly for electricity grids and renewable energies) and national laws (also for mobility projects) (Zschiesche and Grünberger, 2024; Geißler and Jiricka-Pürrer, 2023).

Starting in 2018, several "acceleration" laws were implemented, unfolding impacts on the infrastructure sector, including rail, road, and the electricity grid. Measures include, for example, excluding certain project types from EIA, defining a special public interest for projects relevant to the energy and mobility transition, shortening timeframes, adapting public participation, changing material standards, modifying requirements for mitigation and compensation measures, or limiting opportunities for legal challenge and appeal. Further on, there is a tendency towards a stronger focus on the strategic level[13]. This tends to lead to simplification of assessments at the project level or even to no mandatory assessment at all (Geißler and Jiricka-Pürrer, 2023; Zschiesche and Grünberger, 2024). Two recent projects demonstrated radical measures to accelerate the assessment and approval process. The first was a project that began construction before the final approval had been issued. Simultaneously, a large number of human resources within the authority were mobilised (Tesla Giga Factory, see: Kühn, 2023). And second, a project that did not require an EIA at all because it was considered by law to be of high public importance (LNG terminal, see: Kment and Fimpel, 2022).

All in all, many measures tend to weaken the EA instrument and public participation. Furthermore, there is an increasing complexity in determining which assessment is applicable in a given case. Last but not least, for some types of projects, the opportunities for stakeholders to participate and raise concerns were weakened. The

13 Directive (EU) 2023/2413 of the European Parliament and of the Council of 18 October 2023 amending Directive (EU) 2018/2001, Regulation (EU) 2018/1999 and Directive 98/70/EC as regards the promotion of energy from renewable sources, and repealing Council Directive (EU) 2015/652

ongoing and dynamic discourse, along with concrete measures to accelerate processes, shape the possibilities for public participation.

In Germany, adaptations to EA legislation that weaken participation structures often lack sufficient empirical evidence of their effects (Geißler and Jiricka-Pürrer, 2023). To help address this gap, the following analysis evaluates if and how existing legal provisions incorporate the requirements for MSE.

5.Meaningful stakeholder engagement in the German environmental assessment system

The conceptualisation of a Meaningful Stakeholder Engagement (MSE) by Sinclair and Burdett (2024) was applied. The set consists of ten elements, further divided into 31 specific requirements. Each element comprises at least one requirement (see Appendix 1). For each requirement, corresponding statements in relevant German law were identified. Different categories were assigned based on how well each requirement was met. (1) Fulfilled, (2) partly fulfilled, (3) not required by law but the possibility exists, (4) or not part of the law and not within the competence of the authority.

Results

No element completely fulfils the means of the MSE concept (this would be the case if all requirements were fulfilled). Zooming in on the requirements, a heterogeneous picture emerges. Four requirements fully meet the criteria, while only one requirement cannot be met by the authorities and laws. The vast majority of the requirements are either partially met (11) or not met but possible (15).

The classifications for the different categories are discussed below chronologically from 1 (fulfilled) to 4 (not part of law and competency). Table 4 presents the category of partly fulfilled requirements, accompanied by an argumentation. This category is of particular interest because improvements could be addressed within the existing legal framework.

(1) Fulfilled

Fulfilled requirements relate to the communication about the process itself and the opportunity to raise concerns and receive feedback. As required by constitutional principles as well as the pillars of the Aarhus Convention and subsequently ratified into German law, the principles of natural justice and procedural fairness are followed. Those elements reflect fundamental principles of participation.

Table 3 - requirements identified as "fulfilled" (based on Sinclair and Burdett 2024)

Element	Requirement
Adequate notice	notice about assessment, where future information is located and where comments can be directed to
Decision impact	Input can impact and change the course of the decision at hand - no treated as advisory only
Learning oriented	Feedback to participants about how their input has, or has not, been used
Fair and open	Public participation processes follow principles of natural justice and procedural fairness

(2) Partly fulfilled

The requirements categorised as „partly fulfilled" deal with: the access to and transparency of processes and decisions, the means and forms of communication, as well as different forms and depth of stakeholder engagement.

Table 4 - requirements identified as "partly fulfilled", (based on Sinclair and Burdett, 2024 and the author)

Element	Requirement	Argumentation
Adequate notice	direct notice to affect individuals and organizations	This depends on the stakeholder, who can be notified indirectly through the EIA-portal and a newspaper. In general, the authority can achieve this requirement through various means of notice. *(§73 VerwVfG)*
Access to information	Easy access through a public registry or other means	By law, it must be officially accessible during the public consultation period. A digital EIA-Portal exists, but not all information is available at all times. Consists only of the documents necessary for the application – no internal documents of the authority on the process. *(§20 UVPG)*
Opp. for public comment	Open to all interested parties and individuals	Yes, generally speaking, everyone who wants can address issues (but not everyone has the same rights). Those affected and those who have raised official concerns can participate in the entire process. Others who didn't raise a concern are precluded at a later stage. *(§18 & §19 UVPG)*
	Allows for consideration of „need for" and „alternatives to"	Yes – one part of the EIA-report (but often not negotiable because already preset). Questions on alternatives and „need for" are part of preliminary strategic steps, before an EIA is started. The EIA report provides a more comprehensive conclusion of those preliminary steps. *(§16 UVPG)*
Access to public hearings/ADR	Transparency and timely written decision	Whether it is „timely" is hard to assess. However, there must be a written decision at a transparently communicated time. (Literature and stakeholders often criticize that there is too little time) *(§24 UVPG, §69 VwVfG)*
Early and ongoing participation	Stakeholder involvement in many assessment choices	Depending on what is understood by „many" and „assessment choices", stakeholder involvement in EIA is formally limited to statements. At the same time, rail, road, and electricity offer different levels of strategic opportunities for participation. *(Own attribution based on the author's knowledge)*
Deliberative forums	Open dialogue in a non-judgmental environment	Depends on how „open dialogue" is defined. Public debate opens space for a dialogue and discussion, but often in a very formal setting. Authorities can potentially work towards enhancing the openness. *(Own attribution based on the author's knowledge)*
	Establishing sustainability as a concept and a goal	This criterion itself is subject to extensive debate, so it would be necessary to clarify what is meant by sustainability first. To some extent, it can be argued that EIA law incorporates forms of sustainability with its goals and mitigation hierarchy. *(§2 UVPG)*

Fair and open	Transparent	The formally mandated participation process is transparent in that it is communicated publicly, allowing affected parties to participate and ensuring that a final decision is made publicly. All statements have to be commented. Other aspects, such as the planning process, are in the hands of the proponent; authorities cannot directly influence transparency in this regard. *(Principles of Constitution and Aarhus Convention)*
	Open to all interested parties and individuals	Yes, generally speaking, everyone who wants can address issues (but not everyone has the same rights. Later in the process, only those who filed a statement can formally take part. *(§18 UPVG)*

Table 4 illustrates the connection between the requirements and the relevant sections of the German law. This category indicates that many requirements allow authorities to meet them. Qualitative and normative wordings like "easy access", "open dialogue", or "timely" don't offer explicit categories for evaluation.

(3) Not required by law, but the possibility exists

The results within this category (see Table 5) show opportunities to expand and innovate participation practices. These include the use of diverse communication channels such as phone, email, or social media; the provision of inclusive and informal spaces for deliberation; the involvement of the public in designing the participatory process itself; and the implementation of interactive formats that go beyond conventional tools like open houses or online submissions.

Table 5 - requirements identified as "Not required by law but the possibility exists", (based on Sinclair and Burdett, 2024)

Element	Requirement
Adequate notice	use of phone, email or social media
Participant assistance	Need for assistance because of complex issues (focus on funding)
Opp. For public comment	Interactive modes of participation beyond open houses and website submissions
Access to public hearings/ADR	Frequent and creative use of the hearing process
	Inclusive, informal venues for deliberation
	Negotiation and mediation
Early and ongoing participation	Public engaged in the design of the participatory program to be followed
	Extension of participation to the follow-up stage
	Reasonable timelines established
Deliberative forums	Emphasis on knowledge integration
	Face-to-face decision-making
	Incorporate future methods such as visioning and scenario development
Learning oriented	Promotes learning "about" and "through" IA
	Fosters mutual learning among all participants
	Ensures lessons from past ass. as well as process experiences are considered in future ass. & ass reform

In addition to experimenting with participatory formats, another key set of requirements concerns the recognition and integration of diverse forms of knowledge, as well as the promotion of mutual learning throughout the assessment process.

(4) Not part of the law and not within the competence of the authority
One aspect could be identified as not being required by law and not within the authority's remit: „transparent, ongoing and timely exchange of information between all parties". Much information, especially at the planning stage, is held by the proponent. It is the proponent's choice when the first information is made public. Authorities can work towards an exchange and provide means of communication, but they cannot mandate it. Furthermore, it is unclear what is meant by "all parties". As soon as the proponent gets in contact with the authority and applies for permission, this requirement is within the competence of the authority.

Discussion
Most of the requirements fall into categories that are partly fulfilled or not mandated, but could be put forward by authorities. Referring to the above-mentioned rationales of public participation (Glucker et al., 2013), current legislation doesn't cover the instrumental and normative rationales. This shows that aspects of legitimacy and conflict resolution, as well as the fulfillment of democratic ideals and empowerment, fall short. The findings align with existing research, which suggests that formal participation processes tend to meet only the minimum requirements (Eckerd and Heidelberg, 2020; Fonseca and Fitzpatrick, 2024; Fung, 2015). It therefore reflects that the benefits of public participation, although intensively discussed in the literature, are still not sufficiently embedded in law.

Nevertheless, it was shown that participation is widely regarded as an essential component of environmental assessment (EA). Against this background, the results could also be seen in a more positive light. Despite the low number of fulfilled requirements, there are several opportunities to enhance participation. The analysis focused on the possibilities and competencies of the authorities responsible for the formal participation process. The allocation of resources (both staff and time) is crucial to design, organise, and sustain meaningful participation processes (see also Tryjanowski and Zschiesche 2020; Geißler and Jiricka-Pürrer 2023). To establish participation processes that extend beyond statements and public hearings, authorities need to analyse and reflect on their current routines. Meaningful participation processes can be better informed by combining experience from successful initiatives and existing expertise with an understanding of current systems' strengths and weaknesses, gained through learning and experimentation.

Communication is a key factor contributing to unfulfilled requirements. One important aspect is to recognise different worldviews, knowledge, and stakeholders' needs. Guidelines of German authorities (BMWi, 2021) already reflect these aspects to a certain extent. This points to an existing discourse and sensitivity regarding this topic. In summary, an EA practice that integrates participation as an essential part of successful approval processes must be willing to reflect on and modify existing routines. The results show that authorities need to act beyond the minimum legal requirements, for example, by experimenting with deliberative forms of stakeholder involvement. Furthermore, a focus on mutual learning reflects elements of experimental governance (Newig et al., 2019).

It was assessed whether the set of elements and requirements by Sinclair and Burdett (2024) offers a valuable tool to analyse the German EA system. Based on the knowledge of the logics of the EA system and the respective laws, all of the elements and requirements could be applied. With the help of the literature and own expertise, it was possible to draw primary conclusions. Those conclusions are in line with existing knowledge. Nevertheless, there is potential for improvement - e.g., it is not apparent how to assess and value normative elements such as "lengthy process", "sustainability as a goal", "easy access", or "timely response". Some aspects are formulated too generally and should be adjusted and complemented to fit the particular geographic context (for the German context, for example, with the elements of early participation or the various strategic steps). To increase the reliability and replicability of the results, a further refinement of the requirements is necessary. A preliminary consultation phase involving interviews or a Delphi method should be implemented to define the categories in more detail. Following the initial allocation, a second consultation phase with experts would facilitate further discussion and reflection on the results.

6.Conclusion

The objective of this contribution was twofold: first, to examine the German environmental assessment (EA) system for large-scale infrastructure projects in terms of its capacity to achieve meaningful participation processes. Second, to examine to what extent the framework developed by Sinclair and Burdett (2024) serves as a valuable analytical tool. The theoretical base for the analysis was the discussion of the discourse surrounding Meaningful Stakeholder Engagement (MSE) in EA in general. Further on, the main characteristics and challenges of the German context were outlined.

The analysis shows that there is potential for the development of environmental assessments that meaningfully engage stakeholders in Germany, although this potential is currently unrealised. At the same time, it is evident that most of the requirements are not fully met or mandated by law. To address this, the authorities would need to promote participatory processes that exceed minimum legal requirements.

Although the environmental impacts, approval procedures, and, consequently, participation processes of the three project types – motorways, railways, and electricity grids – are broadly comparable, different competent authorities can pursue distinct strategies and cultures of participation. The willingness and experience of authorities play a crucial role in implementing MSE, an aspect that warrants further investigation.

The elements and requirements of MSE by Sinclair and Burdett (2024) proved to be a useful analytical tool, as it incorporates the three main rationales of participation in environmental assessments (defined by Glucker et al., 2013) and consists of a comprehensive and detailed set of requirements. Some aspects were identified to develop the applicability of the concept further. For example, there is a need for an ongoing discussion about how to formulate and describe its elements and requirements. To ensure the replicability of attributions, it's important to clarify terms like "good," "timely," or "often," as they can be open to interpretation. This links closely the validation and discussion of the findings. Therefore, consecutive validation steps should follow the initial attribution.

Further research needs to consider additional policies that influence EAs. This also comprises guidelines and sub-statutory regulations. Further expert evaluation and practical insights are needed to effectively align policies with requirements. Furthermore, analysing different country contexts could help refine the set of requirements and foster transnational learning.

The "value for money" (Bond, 2014) of public participation must be communicated in a way that is tangible to a broad audience. Notably, early and continuous engagement is increasingly recognised not only as a democratic imperative but also as a key factor in achieving effective governance. It also serves as a medium- to long-term benefit for project proponents and authorities, as it can help prevent conflicts and gather valuable data about the project's impacts. This aspect becomes particularly significant in the context of current efforts to accelerate planning and approval procedures.

Remarks

The AI software: Grammarly AI, Chat GPT, and DeepL were used to refine writing style. No text was generated by AI.

Due to the limits on words, not all the arguments for the contributions (like Table 4) to the elements and requirements were mentioned in the text. The whole table of attributions can be submitted upon request.

Appendix 1 - Meaningful Stakeholder Engagement (MSE), Elements and Requirements

Essential elements	**Specific requirements**
Adequate notice	direct notice to affect individuals and organizations
	use of phone, email or social media
	notice about assessment, where future information is located and where comments can be directed
Access to information	transparent, ongoing and timely exchange of information among all parties
	Easy access through a public registry or other means
Participant assistance	Need for assistance because of complex issues (focus on funding)

Opp. for public comment	Open to all interested parties and individuals
	Allows for consideration of "need for" and "alternatives to"
	Interactive modes of participation beyond open houses and website submissions
Access to public hearings/ ADR	Frequent and creative use of the hearing process
	Transparency and timely written decision
	Inclusive, informal venues for deliberation
	Negotiation and mediation
Early and ongoing participation	Public engaged in the design of the participatory program to be followed
	Extension of participation to the follow-up stage
	Value judgments when choosing trade-offs
	Reasonable timelines established
	Stakeholder involvement in many assessment choices
Deliberative forums	Emphasis on knowledge integration
	Face-to-face decision-making
	Open dialogue in a non-judgmental environment
	Establishing sustainability as a concept and a goal
	Include forms of alternative dispute resolution
	Incorporate future methods such as visioning and scenario development
Decision imact	Input can impact and change the course of the decision at hand - no treated as advisory only
Learning oriented	Promotes learning "about" and "through" IA
	Fosters mutual learning among all participants
	Feedback to participants about how their input has, or has not, been used
	Ensures lessons from past ass. as well as process experiences are considered in future ass. & ass reform
Fair and open	Public participation processes follow principles of natural justice and procedural fairness
	Transparent
	Open to all interested parties and individuals

Abstract
While most studies on institutional capacities for social value in planning practice stem from public perspectives, contemporary European urban transformations often involve both public, private and civic actors. This paper presents a Dutch market-led practitioner's research project of four *ex post* evaluations on social sustainability in newly realized urban neighbourhoods, in which the author actively participated. From a collaborative governance perspective, the paper reflects on the project's contribution to building institutional capacity for social value in urban development practice. Preliminary findings reveal how the market holds specific—perhaps hidden—capacities in terms of mobilization, communication skills, shared knowledge production and development of relational networks, yet tends to hold on to a limited perspective on social sustainability and to make a more incidental than structural impact.

Keywords: institutional capacity, private sector capacity, civic capacity, citizen participation, social sustainability

1.Introduction

As many cities in Europe and beyond face social challenges such as socioeconomic segregation, loneliness or unequal access to services for different social groups, creating social value through urban planning and development is considered increasingly important in theory and practice. Social value is defined by the UK Green Building Council as "created when buildings, places and infrastructure support environmental, economic and social wellbeing, and in doing so improve the quality of life of people" (UKGBC, 2021). By promoting a broader understanding of value than monetary alone, social value closely aligns with the more specific policy ambition for social sustainability, i.e., the ambition to improve people's quality of life, individual and collective well-being, for generations living now but also in the future (Weingaertner & Moberg, 2014)

Moreover, researchers increasingly call for anthropological understandings of social sustainability in the built environment that go beyond its understanding through tangible—'traditional planning'—aspects such as adequate housing or public space, but also through human-oriented aspects such as well-being, agency and capability (Dissart & Ricaurte, 2023; Janssen & Basta, 2022; Woodcraft, 2016). In the same line of thought, the process of involving local communities has become central to debates on social value to understand the impact of decisions on people's lives (Social Value UK, 2023). Similarly, the many varied frameworks that exist in social sustainability literature mention participation and inclusion of local actors as a key indicator of social sustainability in the built environment (see e.g. Dixon & Woodcraft, 2013; Janssen et al., 2023; Kjeldsen & Stender, 2022).

Involving local communities not only leads to a better understanding of local needs and potentially more effective plans, but meaningful citizen-planner dialogues also help to foster trust and to enhance social cohesion (Othengrafen et al., 2024). A common challenge of participatory practices, however, is that they remain incidental and exclusive and fail to make a wider social impact. This challenge can relate to issues of capacity in planning practice—for example, the lack of regulatory frameworks, policy support, and financial or human resources are reasons why creating social value through citizen involvement fails to be embedded in regular governance processes.

While various studies reporting on capacities for social value focus on institutional capacities, thereby referring to public perspectives (e.g., Cuthill & Fien, 2005; Polk, 2011) contemporary European urban transformations often involve both public, private and civic actors. Although market actors are often seen as actors merely incentivized by maximizing profit, regulatory frames such as ESG policy by the European Committee motivate investors and financers in urban development to create social value or 'to make a social impact'. This shift has led market parties such as property developers and construction companies to develop programs in which they operationalize liveability, resident wellbeing or social equity goals – thereby increasingly experimenting with citizen participation approaches.

This conference paper reflects on a conducted participatory action research project in the Netherlands in which the author participated in a market-led practitioner's project of *ex post* evaluations on social sustainability in newly realized urban neighbourhoods. The paper aims to explore the contribution of this applied research project to institutional capacity building for social value creation in contemporary urban development practice. Meanwhile, the paper tests a preliminary framework to analyse capacities for social value creation in terms of different actors—either public, private, or civic— and different levels—either individual, collective or institutional. Finally, the paper defines questions for the continuation of this research.

2.Towards an analytical framework

2.1 Citizens as a serious actor in collaborative governance for social value

Citizen participation has been widely discussed in planning literature. Often forming part of the collaborative planning discourse (Healey, 1999; Innes & Booher, 2004) research foci range from public participation as an extension of local governance, as cocreation and coproduction as development forms where citizens exercise power and can co-decide on interventions (Rosen & Painter, 2019), or as citizen engagement as the activities that (groups of) citizens initiate and undertake themselves in the sphere of civic society, for example through voluntary, non for profit and cooperative activities (Knaps et al., 2024). While the strive after consensus in the communicative turn in planning has been criticized for its neglect of pluralistic worldviews (Mouffe, 1999; Young, 2015), involving citizens in planning practices remains to be considered an essential approach for various instrumental—i.e., better knowledge of local matters—and intrinsic purposes—i.e., enlarging citizen's voice or enlarging democratic capacity (Uittenbroek et al., 2019).

Normatively, participation is considered a key principle of what 'good governance' is about (OHCHR, 2025). More descriptively, conceptualising citizen participation as an essential part of collaborative governance for social value underscores that places are developed through the activities of not only public but also private and civic actors (Emerson et al., 2012). As such, considering citizens as actors in collaborative governance implies that citizens, next to other actors, are not only representing their self-interests (i.e., NIMBY-ism), but can also be oriented towards a public goal in planning practice— for instance, the transformation of an urban area, the perseverance of a liveable neighbourhood, or more general, creating social value.

2.2 Capacities for collaborative governance in urban development practice

In response to reconfiguring state-economy-civil society relations in governance practices in Europe and beyond in the early 21st century, Healey et al., (2003) developed a relational understanding of institutional capacity that concentrates on the shared responsibilities of actors for public purposes around the locality of a place. According to Healey (1998), institutional capacity includes knowledge resources, relational resources and mobilization capacity. Polk (2011), who applies this framework to sustainable development, defines:

- *knowledge resources* as formal and informal types of expertise and know-how, including formal, tacit and experiential types of knowledge.
- *relational resources* as "individuals gaining greater personal and professional relationships with colleagues within a wide range of organisations and agencies involved in local and regional planning. Some of the potential outcomes of social relations include the establishment of trust, respect and reciprocity between participants". (Polk, 2011, p188)
- *mobilization capacity* as the concrete impact, including less tangible long-term impact, that a governance area has in formal planning processes on the local and regional level.

Although Healey's (2019) sociological-relational understanding of institutions certainly does not limit her interpretation of institutional capacity to a governmental focus alone, recent notions of private sector and civic capacity from other authors can help to specify further what resources and abilities are needed for solving complex societal problems. In recent strands of literature on climate adaptation in public policy for example, the capacity of the private sector to influence policy agendas and to develop sector-specific operating procedures or technologies are mentioned as important pathways to achieve climate mitigation or adaptation goals (Sarzynski, 2015).

In addition, from a more normative perspective, civic capacity distinguishes from a general notion of capacity by including a dimension of agency and freedom of choice: "Civic capacity [...] as the extent to which the sectors that make up a community are (1) *capable* of collective action on public problems (the resource dimension), given the norms and institutional arenas for local action; and (2) *choose* to apply such capabilities (the dimension of effort, will and choice, or "agency")" (Briggs, 2008, p13). It is thus not only important that civic society possesses resources to be able to undertake action, but also that there is room for choosing to do so— think for example of a political climate in which it is safe as a citizen to decide to participate in urban discussions, or in which a citizen simply has time available to do so.

Adopting a collaborative governance perspective thus implies a broader interpretation of institutional capacity in which institutional is not limited to 'the public' but particularly includes private sector and civic capacities. Furthermore, the participatory approaches that urban social sustainability demands give reason to emphasize capacity in planning practice not only as occurring at an institutional, 'regulatory policy-level', but also at the individual (e.g., residents or professionals) and collective (e.g., local communities or other forms in which citizens unite themselves) levels where participatory interaction can take place. As such, Table 1 presents a preliminary framework of actors in urban development and their capacities that play a role in collaborative governance for social value creation. In contrast to the individual and collective ones, the structural level does not refer to *actors* in urban development but to long-enduring structures in society that shape and are shaped by those actors— such as rules, cultures, traditions and beliefs (Ostrom, 2009)

Table: Analytical framework (preliminary, by author): institutional capacity for social value creation in urban development practice

	Civic	**Private sector**	**Public sector**
Individual	**Actors**: Residents, users of urban areas **Capacities**: Personal abilities, skills, knowledge, choice	**Actors**: Professionals, developers, local entrepreneurs **Capacities**: Personal abilities, skills, knowledge	**Actors**: Civil servants, governors, politicians **Capacities**: Personal abilities, skills, knowledge
Collective - intraorganisational	**Actors**: Collective citizen groups, cooperatives, political groups, associations **Capacities**: Mobilization resources, relational resources, knowledge, choice	**Actors**: Companies, shareholders **Capacities:** Mobilization resources, relational resources, knowledge	**Actors**: Local, regional and national governments **Capacities**: Mobilization resources, relational resources, knowledge
Collective – interorganisational	**Actors**: Citizen group networks, platforms **Capacities**: Shared mobilization resources, shared relational resources, shared knowledge, shared choice	**Actors**: Professional networks and platforms **Capacities**: Shared mobilization resources, shared relational resources, shared knowledge	**Actors**: Governmental networks and platforms **Capacities**: Shared mobilization resources, shared relational resources, shared knowledge
Structural	**Structures**: Collective values, cultures, traditions **Capacities**: Collective culture, private law	**Structures**: Working culture, beliefs and assumptions **Capacities**: Working culture, private law	**Structures**: Public values **Capacities:** Public management culture, public law and policy instruments

3.Method

3.1 Empirical reflections of a participatory action research

This conference paper aims to reflect on the Back to the Neighbourhood-project's (BTTN) contribution to build institutional capacity for social value in urban development practice, and meanwhile, to test the suitability of the preliminary framework in Table 1 to understand such capacity building. The BTTN-project (see 3.2) concerns an applied research project in which four newly developed neighbourhoods in three large cities in the Netherlands (i.e., Amsterdam, Rotterdam, and The Hague) were evaluated in terms of social sustainability. The project was conducted via a cooperation between the Foundation for Knowledge on Area Development at TU Delft and a socially oriented property developer in the Netherlands, while also including various other public and private urban actors such as architects, urban designers, civil servants, and other property developers.

The author of this paper was actively involved in the project as co-developer and co-coordinator, for which this paper can be considered as participatory action research. The choice for this active involvement of the researcher in the practitioner's project served an adjacent objective of the BTTN-project— namely to test the value of a scientifically argued framework to evaluate social sustainability in urban areas based on the Capability Approach in Dutch urban development practice (see outcomes for this objective in Janssen, 2025). This paper does not elaborate further on the function and impact of this evaluative framework but intends to draw reflections that serve a new research agenda on institutional capacity. By actively participating in all the evaluations throughout the entire duration of the BTTN-project, the author was in the position to do many field observations and have abundant informal conversations with the participants of the project. No formal semi-structured interviews were yet conducted. The observations presented in chapter 4 should therefore be seen as preliminary observations that, although based on intensive participation, should be complemented by future interviews or focus groups with the participants.

3.2 The Back to the Neighbourhood Project

Between April 2024 and January 2025, a Dutch property developer initiated a program to perform ex post neighbourhood evaluations in areas that the company had developed in the recent decade. While such urban development projects are, after realization, typically evaluated in terms of costs and construction performance, the BTTN-project aimed to concentrate on how the qualitative goals of such projects— such as increasing people's quality of life, and stimulating social encounters— had come into practice. Whereas the project was thus initiated by a single market actor and focused on the urban development projects of this actor, the BTTN-project formed a collective learning program in which many partner organisations in the field, including municipalities, housing organisations, architects and urban designers, participated.

The setup of the BTTN-project was as follows. Four recent urban development projects that had specific goals regarding social sustainability were selected to be evaluated. Those goals were for example formulated as "this project needs to be a stepping stone for surrounding residents", or "this project needs to become an area where people feel at home, and neighbours meet each other and form a community". Per neighbourhood, a group of between 15-25 professionals were mobilized to perform interviews with residents living in the newly developed areas. The group of practitioners consisted of employees of the property developer itself—with various roles stretching over various development stages, from concept development to project execution— but also of practitioners from other (partner) organisations. As such, the project not only served to draw lessons on the performance regarding social sustainability but also to train practitioners in engaging with residents.

Each neighbourhood evaluation lasted for a period of approximately four weeks. This period started with a 'kick-off'-session in which the practitioners were briefed and had the opportunity to train their interview skills. This was followed by a period of two or three weeks in which the participants went 'back to the neighbourhood' and performed interviews with residents. Residents were approached on the spot, by ringing the doorbell or by being approach on the street or were approached via local social media channels. After this period, the practitioners came together for a feedback session to exchange the findings to which residents were invited as well. The findings were analysed by two researchers participating in the coordination team of the project.

4.Preliminary empirical findings: building capacities through the BTTN-project

This chapter discusses how specific capacities in the BTTN-project were relevant to the creation of social value. It also reflects on whether certain types of capacities were lacking, and on whether the project contributed to building new capacities relevant for social value in the Dutch urban development practice.

4.1 Capacities at individual, collective and structural levels

A first observation in the BTTN-project is that an important type of capacity for social value occurs at the individual level of professionals, namely in the communication skills of the practitioners who took part in the project. As citizen participation was not a daily task for most practitioners, conducting a qualitative semi-structured interview with a resident was a first experience for some. All participants received the same guiding material with the key questions, yet the quality and intensity with which practitioners engaged with citizens varied widely. It became clear how professionals who are in their regular jobs are responsible e.g., floor management, client communication or team leadership, benefitted much from their experience with daily 'social' work activities. Although such an empirical observation may not be surprising, it points out that a potential capacity for social value in the built environment is 'hidden' among professionals—yet would need to be made use of to create actual value in practice.

At the inter-organisational level, capacity building took place through shaping new relational resources among the various public and private urban actors in Dutch planning practice who participated. Although those actors, of course, already interacted in their regular work activities, the BTTN-project provided a platform where they intensively collaborated on a relatively simple assignment in a neutral setting (i.e., without interests or negotiations) and could collectively build trust. Moreover, the experiences that the practitioners gained from participating in the BTTN-project can be seen as contributing to a collective knowledge of social sustainability and citizen involvement among urban actors in the field. It had been an explicit objective of the BTTN-project to conduct the resident interviews with a large group of professionals—instead of a single researcher or consultant taking care of all interviews. This decision proved to be successful: many participating professionals feedbacked that simply 'doing it yourself' had made a true difference in their understanding of what citizen engagement is about and what social impact can mean to residents.

Finally, at the structural level, the project's contribution to capacities was found to take a small step in a transition towards new working cultures needed for social value in planning practice. By making the BTTN-participants enthusiastic about the neighbourhood evaluations, the BTTN-project aimed to normalize discussing social sustainability in urban debates and to normalize the engagement with citizens in urban development practice. Nevertheless, the enduring impact of the BTTN-project for the future can be questioned due to the incidental character of the project. As participation in the project was not formally commissioned nor financially rewarded, it was noticeable how practitioners already struggled with their available time to participate in one of the evaluations, limiting the project to making a more structural impact.

4.2 The specifics of private sector capacity

The fact that the BTTN-project was initiated and co-organised by a private actor seemed to have several advantages for social value. In one of the neighbourhoods, for example, it was observed how a local citizen initiative had grown into an important social infrastructure for the area. This concerned a not-for-profit café that performed social activities in a glasshouse such as urban greening, distributing food leftovers, and organizing workshops and weekly dinners for neighbours. After having engaged with this citizen initiative for some weeks, the property developer learnt that the initiative faced difficulties in receiving municipal budgets to insulate the physical space, which hindered it from performing the activities during the winter period. The market actor quickly responded to this observation by activating a fund and financing the retrofit of the glasshouse, enabling the initiative to widen the social activities in the neighbourhood.

While this situation illustrates how a combination of private actors being able to mobilize financial resources and being able to respond quickly to locally emerging needs can make a concrete impact on people, the private sector also has limitations for social value creation. It became clear during the BTTN-project, for example, that the leading interest of the property developer in social sustainability eventually mainly concerned their own clients, being the private buyers or investors renting out their rental apartments.

How quality of life was experienced by communities living just outside the newly developed housing areas, was less of a concern to the market actor—whereas this would be a main concern from an urban social sustainability perspective.

Moreover, it was noticeable how making enough time available to perform the neighbourhood evaluations was challenging, particularly for those participants working in the private sector. To them, participating in the BTTN-project meant doing something 'extra' on top of regular working priorities, in some cases giving up a free evening or day on the weekends. Although collaboration with local (governmental) actors who are more permanently active in the neighbourhoods was sought after, the BTTN-project failed to collaborate with those actors to ensure that the resident-professional relationships would last for a longer period of time. Beyond the one-off feedback session at the end of each evaluation period, the BTTN-project did not include further follow-ups with residents or other local actors in the neighbourhoods.

Finally, although a key element of the BTTN-project was to engage with residents of the new urban neighbourhoods, civic capacity was used or expanded only to a very limited extent. By choosing interviews as the main method of civic engagement in the BTTN-project, little attention was paid to the developing knowledge of residents or the mobilization of relational resources. Moreover, the specific notions of choice and agency, that are characteristic to civic capacity, played a minor role in the project—residents were mostly offered only one predefined way to participate in the project, at one moment.

5.Discussion: towards enlarging institutional capacity for social value in urban development practice

The overarching aim of this paper was to explore how collaborative governance practices can contribute to institutional capacity building for social value creation in planning practice. This contribution reflected on the Back to the Neighbourhood-project, a market-led project in the Netherlands in which a property developer evaluated four newly developed neighbourhoods together with the author of this paper and other public and private actors in Dutch planning practice.

Preliminary findings from the BTTN-project reveal how the market holds specific —perhaps 'hidden'—capacities that contribute to social value creation in urban areas in terms of mobilization capacity, communication skills, shared knowledge production and development of relational networks. The lack of specific policy frames and regulations on social sustainability benefit the private sector to be able to respond quickly to locally emerging needs once those are observed. Although this reflexive characteristic of the market is certainly an advantage for social value creation, it also risks steering exclusive interventions, for example when certain local needs are heard less than others.

Using an analytical framework to investigate institutional capacity among individual, collective and structural levels and public, private and civic spheres, helps to elucidate what the 'thicker' and the 'thinner' potential contributions of a planning practice to institutional capacity for social value creation are. The empirical findings for example show how private sector capacities in the BTTN-project are limited ('thin') in terms of adopting a comprehensive perspective on social sustainability that considers the wider communities living in cities, and in terms of making their 'best practices' for social impact creation more structural than incidental. It was also observed how the BTTN-project had a limited contribution in terms of building civic and public capacity.

Developing this framework further in future research can help to find out when exactly various capacities complement each other and lead to effective collaborative governance for social value creation. For this, it is needed to further investigate and define when participatory approaches 'create social value' to people living in urban areas and what conditions facilitate those approaches. European studies on for example neighbourhood planning in the UK (Wargent & Parker, 2018), Community-Led Local Development by the EU (Servillo, 2019), or the institutionalised *Gebietsbetreuungen* in Vienna (Janssen, 2024) can be discussed to explore what capacity elements help citizen participation to become more structurally embedded in planning practices.

Concluding, in a planning context where the market plays an increasingly dominant role, it is promising to strive after a collaborative governance for social value in which capacities of public, private and civic actors complement each other. Yet, several questions require further inquiry. What exactly are those specific capacities,

theoretically and empirically? Are they conditional or optional, are they generic or situation-dependent? When exactly are capacities complementary and do they foster successful collaborations among actors in practice? And in what form do those capacities enable true social value creation that aligns with the lived experiences of those whose policies are aimed?

The questions raised here will be addressed in the continuation of this research. The findings presented in this paper are based on the author's initial observations after participating in the Back-to-the-Neighbourhood-project. Although based on intensive participation, the findings should be validated by additional research methods, such as interviews groups with the participants, or by adding one or several comparative cases.

Abstract
The relevant transformation processes that affect contemporaneity require a radical transformative change across all fields in terms of relations among human activities and the environment. The research illustrated in this contribution addresses the issue of change through the lens of territorial planning, discussing the hypothesis that in practices of territorial self-government it is possible to define 'minimum units of bioregional planning' enabling virtuous co-evolutionary interactions between humans and the environment. Drawing on theoretical insights and empirical work in the Aniene River basin, the study emphasizes the need to transcend the institutional/non-institutional divide and support subsidiary planning processes. Within this framework, digital platforms, such as a GeoSocialWeb, are conceived as enabling environments for interaction, fostering relational governance processes and context-specific forms of territorial self-government.

Keywords: bioregion; natural resources; agreement tools; self-government; river contract

1. Introduction

This contribution presents the conceptual framework and some findings from the ongoing work of the authors within the italian PRIN (Research Project of Significant National Interest) "Bioregional planning tools to co-design life places. Empowering local communities to manage and protect natural resources"[1].

Based on the urban bioregion approach developed within the italian territorialist school, the research project's main goal is to contribute to the drafting of a framework for agreement tools for territorial planning, which could support collaborative forms of management and use of environmental resources directly empowering the communities that live in the territory.

These agreement forms of planning are intended as flexible environments in which the actors involved in each specific planning process are able to define the most suitable tools to allow effectively the implementation of the principle of vertical and horizontal subsidiarity, in the perspective of addressing at different scale both local and global challenges.

The focus of this contribution regards the concepts of urban bioregion approach, natural resources management, agreement planning tools, and interactive spatial planning as intended by the authors.

Moreover, it illustrates how within the research project a bioregion has been selected as case study in the area of the Metropolitan City of Rome Capital and the neighbouring Province of Frosinone, and the partial findings identified by the authors at the date, including the denotation of some experiences of territorial governance that, in different ways, extend beyond traditional institutional planning frameworks.

1 The project, funded by the PNRR (Recovery and Resilience Italian Plan) and running from October 2023 to the end of February 2026, is led by a Research Unity from the University of Florence (PI prof. Daniela Poli) and involves RUs from the University of Cagliari (Associated PI prof. Anna Maria Colavitti), University of Genoa (Associated PI prof. Giampiero Lombardini), University of Palermo (Associated PI prof. Filippo Schilleci), and University of Molise (Associated PI prof. Luciano De Bonis), to which all the authors are affiliated.

2. The urban bioregion approach

The concept of urban bioregion has been developed within the italian territorialist school, mainly through the work of Alberto Magnaghi. It represents an evolution of the bioregion concept, which emerged in the Sixties and Seventies in the context of northamerican ecological movements (Berg, 1978; Todd, 1984; Sale, 1985), and was based on its Greek-Latin etymology, combining "bios" (life) and "regere" (to govern), signifying a region governed by nature (Magnaghi 2014a).

The "urban" adjective, which distinguishes Magnaghi's approach from the above bioregional model, is aimed both at overcoming ineffective anti-urban opposition, recognizing the widespread nature of contemporary urban phenomena at their current geographical scale, and steer clear of deterministic view that tie human settlements solely to environmental factors (Magnaghi 2014a).

Additionally, according to Dematteis, Magnaghi employs that adjective to emphasize that the "return to the territory" civilization he advocates is inherently urban, in the particular sense of a "return to urbanity" as a space of relationship and proximity, and as a process capable of re-establishing the idea of the city in a new bioregional perspective (Dematteis, 2021).

Basing on the consideration of the social dimension of the bioregion (Berg, 1978), the socio-ecological and municipalist vision of Bookchin (1970), and with particular reference to the ecological geography studies (De la Blache, Martonne, 1903), as well as the experiences of the Regional Planning Association of America (Friedmann, Weaver, 1979) and Mumford's (1963) concept of the "region of the human community", Magnaghi (2014a) anchors the concept of the bioregion to the territorial project, i.e. he refers above all to the principle of coevolution between place, work and folk of the bio-anthropocentric Valley Section by Geddes (1915).

It is worth noting that Magnaghi (2014a) refrains from defining the urban bioregion by fixed territorial boundaries. Instead, he presents it as an analytical and, more importantly, planning tool for managing a territory, a concept that Dematteis (2021) identifies as the planning outlet of the entire territorialist theory.

In this respect, it is also important to emphasize that, once clarified that the physical boundaries of an urban bioregion are not fixed, but must be defined in a contextual manner, Magnaghi also states that in the governance of the territory the urban bioregion should translate into in interpretative and planning tool at the level of the of the "minimum units of territorial and landscape planning" of a large area of a region (Magnaghi, 2014a)

The definition of these minimal units remains a subject of debate among territorialist scholars. However, for our purposes — namely, opening the way to a form of living understood as a complex interplay between human societies and the environment that transcends mere habitation — we believe that, among the various components constituting a bioregional complex, political factors enabling forms of self-government hold particular significance (De Bonis, 2024). Therefore, identifying the "minimum units of bioregional planning" must first and foremost refer to such forms of self-government. These units should align with territorial areas governed by self-organized entities engaged in a productive and co-evolutionary relationship with their environment (De Bonis, 2024).

3. Natural resources management in the urban bioregion

The productive and co-evolutionary relationships that can take place between human societies and the environment within the area that we identify as the minimum unit of bioregional planning reflect an approach to the relational dynamics between human and non-human that seeks to overcome dualistic visions, which generally result in hierarchical and sterile forms of inter- and intraspecific interaction.

In fact, if the concept of urban bioregion were to be understood solely according to an ideal of "return to nature" in opposition to development models that are not environmentally sustainable, the transformative and planning potential that it intrinsically possesses would be significantly decreased, failing to counter those global political trends that reduce the environmental issue to the imposition of rules and limits on the use of environmental resources and the emission of polluting and climate-altering substances.

In addition to contributing to the creation of that "techno-fascist" scenario (Gorz, 2015) towards which contemporary society has predominantly oriented itself for several decades now, adopting a 'sterile' approach to the concept of urban bioregion would also foster a nostalgic vision of nature (Fabbri, 2019), conceived as incapable of self-regeneration, in need of human intervention to survive and return to an idealised, primordial and uncontaminated state, according to a form of "naturalist demagogy" (Baudrillard, 2019) which is far from the most intimate essence of nature itself.

The urban bioregion project, on the other hand, has the potential to enhance the relational continuum in which all organisms are immersed, including humans, avoiding both the initiation and perpetuation of processes of value extraction from natural resources (De Bonis, Ottaviano, 2024), and those approaches based on a "bad conscience" (Magnaghi 2010, citing the expression used by Françoise Choay in *L'Allégorie du patrimoine*, 1992), which manifest in strictly conservationist instances that tend to reduce or exclude the interaction between humans and ecosystems. Therefore, by overcoming the principle that the difference between human and non-human presupposes separating boundaries, and that human action is always imbued with an 'original sin' towards the environment, the urban bioregion project can interpret this difference as a relational interface within an osmotic environment, constantly seeking states of equilibrium between the components of the system.

It is widely reported in literature that the human role as an ecological factor goes well beyond the negative meaning to which it is generally associated in contemporary times. The long-term interaction between agro-forestry-pastoral activities and the environment has often produced highly diversified ecosystems that are now recognised as being of particular value (Gauquelin *et al.*, 2018), and the interruption of historical co-evolutionary processes can cause a decline in ecosystem richness (Conti, Soave, 2006).

Even the IUCN - International Union for Conservation of Nature - recognises[2] the value of OECMs (Other effective area-based conservation measures), i.e. those practices of land use and management that allow the achievement of positive results in the long term for biodiversity conservation and ecosystem functioning, also in association with cultural, spiritual and socio-economic values. Among the practices that can be recognised as OECMs, we include those involving the use of "rural commons", which we can certainly consider the most evident form of those "territorial common goods" that Magnaghi defines as "intergenerational collective products that are distinguished from natural common goods as they are entirely produced by human action as a human environment [..]" (Magnaghi, 2015, 139), and one of the most symbolic forms of territorial self-government found throughout history and across the world.

4. From institutional planning to planning through agreement tools

The need to develop tools that enable forms of territorial self-government is particularly relevant to the advancement of the urban bioregional approach, because it is by starting from areas in which such forms of self-government are exercised that we can identify the minimum units of bioregional planning.

Magnaghi notes that the process of progressive reconstruction of territorial common goods finds concrete expression in the activation of "multi-actor, multi-sector and multi-functional contractual and pact forms to address the governance of the territory as a common good" (Magnaghi, 2015, 151), in which the processes of self-organisation among local actors precede institutional involvement.

Furthermore, in the same text Magnaghi recognises a particular interest in the contractual forms aimed at the management of water resources (such as river contracts, which will be discussed in more detail in paragraph 5 as one of the components of the project's case study), because they invert the top-down logic of sectoral policies, paving the way for new forms of care and planning by the local community, which only subsequently extend upward, involving institutional sectors (Magnaghi, 2015).

Well, as already argued elsewhere (De Bonis 2024b; FC; De Bonis, Ottaviano, 2024), we reiterate here that Magnaghi's interpretation of these processes can not only be considered a potential evolution towards innovative institutions of collective action that generate commons, but also, in this context, provides a meaningful and distinctive

2 In December 2024, IUCN co-organised, together with ICCA Consortium, International Association for the Study of the Commons, and University of Lausanne, the event "The European Commons, Territories of Life and OECMs Conferences". <https://ruralcommons.eu/> (Last accessed: June 2025)

contribution from territorial planning. This contribution lies in the creation of 'collective rules for individual use', which form the core essence of the above non-state institutions (Ostrom, 1990).

It is also particularly interesting, in the context of this contribution and the research project outlined here, how Ostrom shifted the focus of her discussion from a purely theoretical level to the search for real-world experiences in which collective resource management practices were effective, and how the integration of her insights into the bioregional design approach enriches them with a generative dimension capable of producing entirely new commoning practices.

In the specific Italian regulatory context to which the research project refers, the possibility of implementing forms of territorial self-government must be sought within the spaces that the institutional planning system, rigid and hierarchical by nature, leaves open to actions grounded in the principle of subsidiarity (De Bonis, 2019). Article 118 of the Italian Constitution, following the 2001 reform, attributes all administrative functions to the Municipalities "unless, to ensure their unitary exercise, they are conferred to the Provinces, Metropolitan Cities, Regions and State, on the basis of the principles of subsidiarity, differentiation and adequacy" (clause 1). It also establishes that all the administrative bodies mentioned in clause 1 must promote "the autonomous initiative of citizens, individually and in association, for the performance of activities of general interest", based on the same principle of subsidiarity (De Bonis, 2019).

Furthermore, the Law on Local Authorities (Legislative Decree 267/2000, art. 3, clause 5), even before the constitutional amendment of 2001, establishes that Municipalities and Provinces, in carrying out both their inherent and delegated functions, perform their functions also through activities that can be adequately exercised by the autonomous initiative of citizens and their social groups, again in accordance with the principle of subsidiarity (De Bonis, 2019).

This means that experiences of "voluntary" planning and design, implemented by local communities even without involving the institutions, can be considered fully compliant with the constitutional and regulatory provisions, as an application of the principle of subsidiarity in the field of territorial governance (Ottaviano, De Bonis, 2021). Among the voluntary land planning tools, the river contract is arguably the one that has attracted the most attention in recent years[3], both from local actors and from institutions.

Formally introduced into the Italian legal system by Law no. 221 of 28 December 2015, through the addition of Article 68-bis to Legislative Decree 152/2006 (Environmental regulations), the river contract is defined as a voluntary tool "for strategic and negotiated planning" aimed at protecting and managing water resources and enhancing of riverine territories, with the goal of supporting local development. It also contributes to the definition and implementation of district planning tools at the level of the hydrographic basin and sub-basin.
This makes it a tool that complements institutional planning of river contexts (typically under the responsibility of River Basin Authorities, though it often incorporates broader, multi-sectoral aspects) by actively and non-hierarchically involving non-institutional actors such as associations, committees, businesses, and individual citizens. Furthermore, within the river contract framework, "variable geometries" of planning relationships between different actors frequently emerge, allowing for the overcoming of rigid administrative boundaries. These flexible, contractual, and voluntary arrangements often are more adaptable than the rigid structures of the institutional planning framework (Ottaviano, De Bonis, 2021).

5. The Aniene river basin as a case study of urban bioregion

In order to support the process of defining adequate forms of self-government of territorial resources that can be effectively implemented in bioregional areas, the research project included experimental analytical work in some areas identified as case studies.

The research unit of the University of Molise therefore examined the vast territory of the Metropolitan City of Rome Capital, also following up on previous research work carried out by a research group from the University of Florence[4], and in particular focused its research work on the bioregional sub-area corresponding to the

3 According to data from the National River Contracts Table observatory, in May 2024 more than 200 River Contracts were activated, of which 80 have been signed. Moreover, in all Basin Management Plans, drawn up by the District Basin Authorities, there are references to River Contracts.

4 The work, carried out under the scientific responsibility of Professor Daniela Poli, and which saw the participation of the

hydrographic basin of the Aniene river, in the eastern portion of the Metropolitan City.

This area is particularly interesting due to the variety of landscapes and socio-economic contexts that it traverses over its almost 100 km length, from its sources at about 1900 m above sea level on the Simbruini Mountains in the province of Frosinone to its confluence with the Tiber at the northern vertex of Villa Ada Savoia, just upstream of its entry into the consolidated city of Rome.

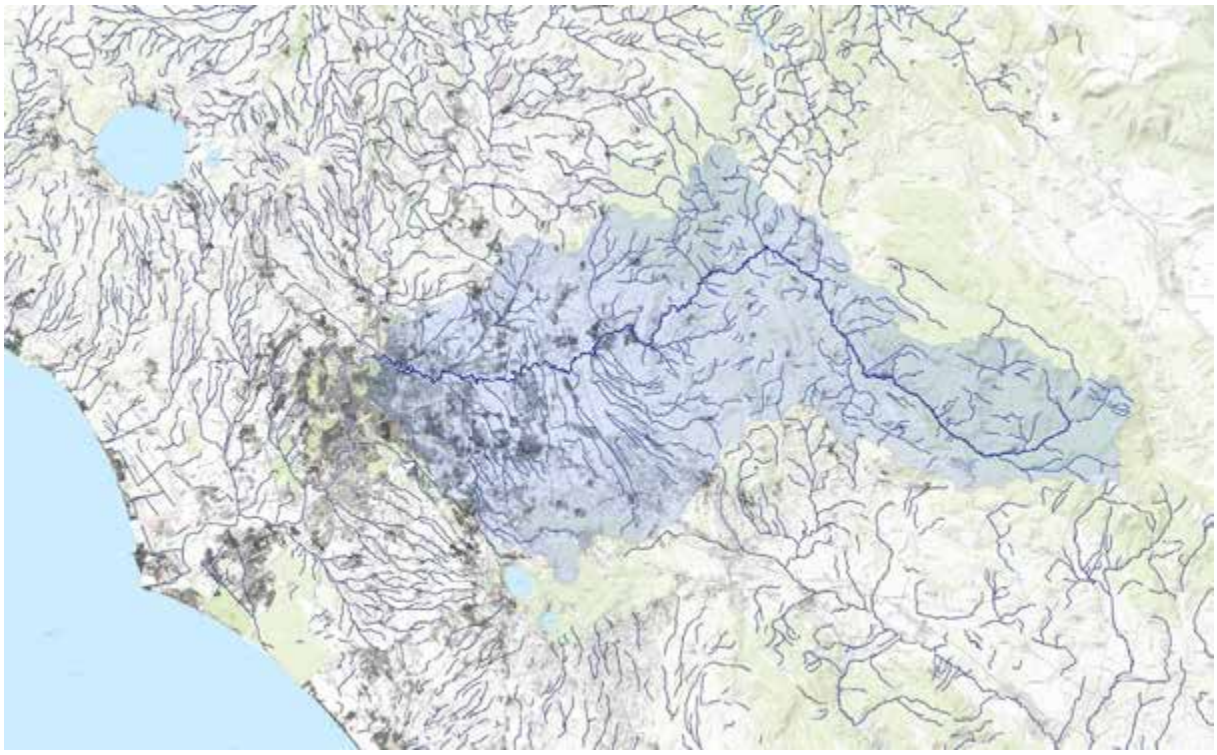

Figure 1 - The basin of Aniene river in the context of the hydrographic network (in blue) and the widespread urban fabric (buildings in black) of Lazio region. Elaboration by G. Ottaviano.

The Aniene has played a significant role in shaping the settlement structure of the territorial area that is headed by Rome, in particular along the linear axis of the ancient Via Tiburtina Valeria from the city to Tivoli, which acts as the valley outlet of the river and from which a polycentric network of numerous hill and mountain towns extends. The principal upstream element, in both historical and contemporary terms, is Subiaco.

The presence of a watercourse of significant flow enabled the development in ancient times of various productive activities that exploited its driving force, in addition to agricultural and fish farming practices that in some forms persist today. In the upstream section, which is largely consistent in social, economic and demographic characteristics with the broader context of Italy's inner and mountainous areas, grazing and forest use have also been historically significant.

A further element of interest within the ongoing research is the existence of a River Contract for the Aniene, which

scientific committee consisting of Professors Alberto Magnaghi (president), Alberto Budoni, Luciano De Bonis, Claudio Cerreti, Paolo Cesaretti, Carla Masetti, Claudia Mattogno, and the working group composed by Doctors Monica Bolognesi and Eni Nurihana, is presented in the research report "Studi, ricerche e linee strategiche per riorganizzare la Città Metropolitana di Roma in un sistema di bioregioni urbane resilienti e autosostenibili" ("Studies, research and strategic lines to reorganise the Metropolitan City of Rome into a system of resilient and self-sustainable urban bioregions").

concerns nearly the entire extension of its hydrographic basin[5], involving numerous institutional, economic and civil society actors.

The activities leading to the River Contract definition began in the early 2000s, well before this instrument gained recognition in practices and in the regulatory system. The Forum for the Aniene, which generated numerous meetings and events open to a wide range of entities interested in environmental and socio-economic issues relating to the river territory, can be considered as both the original nucleus and the catalyst of that associative dynamism which has expanded over the years and now comprises numerous actors with interest in actively participating in the management of the watercourse.

The formal River Contract process began in 2014, initiated by the Committee for the Aniene, to which numerous associations[6] belonged, also with the support of various individual actors. This initiative prompted the engagement of the Mountain Community X of the Aniene, which in 2016 assumed a leading role and broadened the group of institutional and associative actors involved, up to approximately 100 parties that, in 2018, formalised a Document of Intent outlining the objectives and governance structure of the River Contract.

In February 2020, the Lazio Region allocated funding to support the process, integrating the financial contribution of the Mountain Community X of the Aniene and enabling the definition of an Action Programme, comprising 94 project initiatives (Figure 2), and the formal signing of the River Contract in 2022.

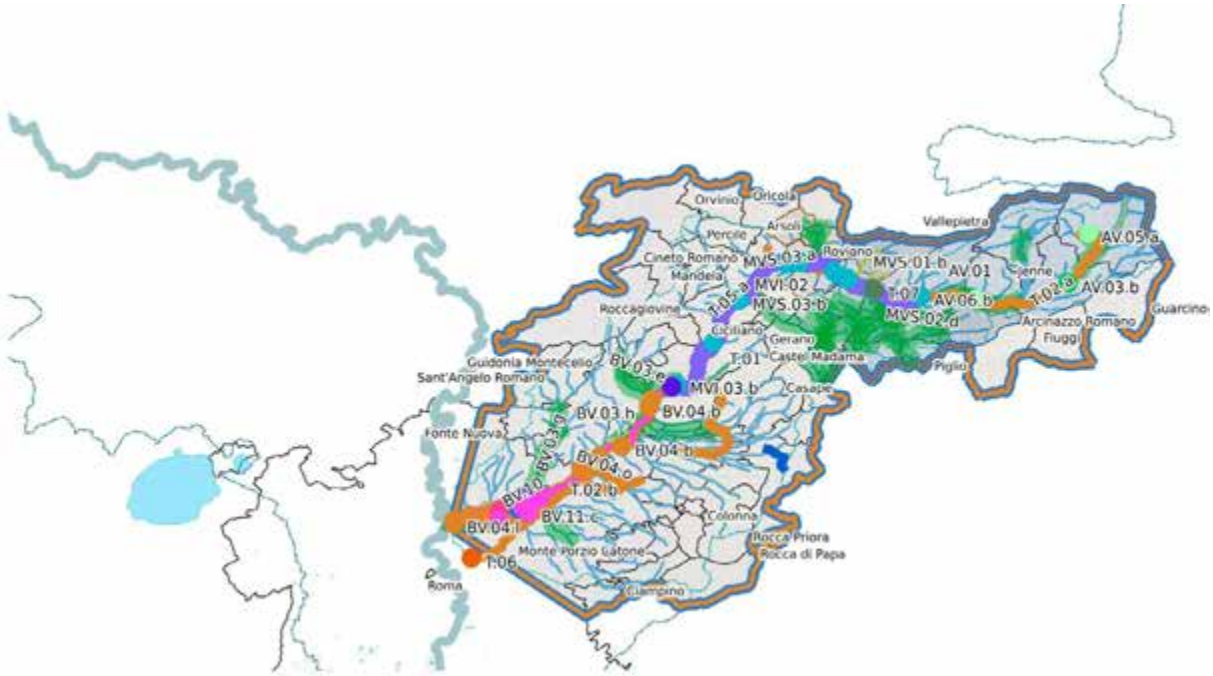

Figure 2 - The WebGis map of the project initiatives of the Action Programme. Source: WebMap of the River Contract, accessed 06 June 2025, <https://shorturl.at/9KTCi>

The initiatives within the Action Programme refer to four general objectives: i) mitigation and adaptation to hydrogeological risks; ii) environmental improvement; iii) sustainable use of environmental resources; iv) tourist-recreational enhancement of the environment. For each initiative, the Action Programme designates the responsible party (single or multiple) and additional actors potentially involved in implementation.
The analysis of the initiatives reveals that responsibility is distributed among 61 actors, predominantly with exclusive assignments. Shared responsibility is more common among associations. Responsible actors include

5 With the exception of a portion of approximately 2 km2 (equivalent to less than 0.15% of the entire surface area of the river basin) which falls within the administrative territory of the neighbouring Abruzzo region.

6 Associazione Insieme per l'Aniene Onlus, Canoa Kayak Roma Assex, Canoanium Club Subiaco, Associazione Sistema Ambiente (clubs of Tivoli and Subiaco), Legambiente, WWF, Italia Nostra (section Aniene - hub Vicovaro Mandela), Compagnia del Casone (Castel Madama), Associazione Amici dei Monti Ruffi, F.I.E. - Sentiero Verde.

22 municipalities, 20 local associations, 5 territorial bodies (such as managing authorities of protected areas, mountain communities, and basin authorities), 4 municipal districts of Rome Capital, 4 local sections of national associations, the Lazio Region, 2 companies or business networks, 2 professional orders, and the Autonomous Institute of Villa Adriana and Villa d'Este.

Across the 94 initiatives, 164 actors are cited as either responsible or involved in implementation. In addition to the aforementioned typologies, these include public service providers, universities and research centres, schools, public agencies and consortia, ministries, superintendencies, museums, local action groups, municipal unions, and the Metropolitan City of Rome Capital.

The most frequently cited actor is the Lazio Region, involved in a total of 58 initiatives, but designated as responsible in only two. Likewise, the two regional parks (Monti Simbruini and Monti Lucretili), the Regional Authority RomaNatura, the Mountain Community X of the Aniene, the municipal districts II, III, IV and V of Rome, the Basin Authority, and certain associations ("Insieme per l'Aniene" and "V.A.R.A. - Valle Aniene Rete Associazioni") participate extensively, but rarely as responsible parties.

Both the Municipality and the Metropolitan City of Rome Capital are involved in numerous initiatives (20 and 27 respectively), yet never with positions of responsibility, similarly to the public company managing the integrated water service Acea (involved in 29 initiatives).

In addition to the typological mapping of the involved actors and the relational geometries envisaged in the Action Programme, the research assessed the coherence of each initiative with the four general objectives, categorising each initiative accordingly.

Furthermore, a typological classification of the proposed interventions was conducted to analyse the project contents of the River Contract, resulting in the identification of 32 types of action.

The objective of tourist-recreational enhancement is the most prominent (68 out of 94 initiatives, including 33 where it can be considered as its exclusive objective), followed by the objective of environmental improvement (51 occurrences, of which 14 as an exclusive objective). Mitigation and adaptation to hydrogeological risks (19 total occurrences, 2 exclusive) and sustainable use of environmental resources (15 total occurrences, 3 exclusive) are significantly less represented.

Among the planned actions, the most frequents concern the restoration, improvement or enhancement of soft mobility infrastructure (e.g., paths, cycleways, pedestrian routes) with 44 occurrences; removal of environmental criticalities (19); creation of recreational or visitor spaces (16); river maintenance (12); restoration of buildings or structures (12); and environmental redevelopment (12).

The analysis results are substantially consistent with what can be hypothesised on the basis of the overall objectives of the River Contract, i.e. the environmental protection and management of the river area and socio-economic development, which in high-quality, environmentally sensitive contexts, is generally predominantly referred to tourist and recreational use only.

While acknowledging the preferability of protective and valorising territorial approaches over extractive and deteriorative practices, we argue that these do not fully restore the centrality of the relational continuum between human society and the environment necessary to sustain the processes of virtuous co-evolution that the urban bioregion project should aim for.

Points of interest do emerge from certain initiatives focused on reactivating sustainable production practices, such as agri-food and phytotherapeutic production, and local, multi-source energy generation integrated with other territorial management cycles.

Another noteworthy aspect from the Action Programme is the dynamism of non-institutional, and not exclusively associative, actors. Some entrepreneurial entities, both within and outside the formal framework of the River Contract, have initiated projects enhancing innovation, multifunctionality, and the valorisation of territories and

agricultural practices in Rome's urban area.

Moreover, ongoing research to identify practices within the Aniene basin that reflect reproductive and virtuous co-evolutionary relationalities between human society and the environment has highlighted some experiences that present interesting features.

One of them concerns the farmers' markets in Tivoli and Frascati, promoted by the Slow Food Foundation for Biodiversity, which aim to foster local agricultural production conducted according to methods ensuring quality and sustainability.

Additional relevant practices are the development of a network of urban gardens (which also intersects with some River Contract initiatives), a Solidarity Purchasing Group, and the process of establishing a renewable and solidarity-based energy community in Rome, promoted by an association with active citizen involvement.

6. Co-producing planning action: the project's GeoSocialWeb platform

The process of defining the minimum bioregional units, previously discussed, cannot disregard the enabling of forms of territorial self-government. They configure an "interactive context" characterised by "high complexity and instability" (Crosta, 2003), in which the actors "make themselves" during the implementation of the practices, and within the same process decide upon the tool that regulate them, whether through intentional or unintentional actions (Crosta, 2007).

In this way, paths are enabled that contribute, to some extent, to the "social production of the plan" within the broader "social production of territory", that is, a rethinking of planning action as a process of "self-formation that gives inhabitants the sense of belonging to a community and a place" (Giangrande, 1998) or, even more fittingly in light of the complexity of contemporary socio-geographical contexts and relations, a sense of simultaneous belonging to multiple communities and places, defined by the "variable geometry" of involvement in trans-scalar and trans-local processes of "differentiation of interaction spaces" (Crosta, 2003).

The activation of these social ecosystems of planning requires an opening of territorial governance practices to forms of "projects in planning", understood as the implementation of the principle of subsidiarity within the framework of territorial planning. As illustrated in paragraph 4, recognising the constitutional legitimacy of self-determined design practices would also support overcoming the "clear distinction between 'institutional' and 'non-institutional'" planning (De Bonis, 2019).

The agreement tools would allow the "transition from government to governance" (Micciarelli, 2014) and the emergence of those "forms of federalism from below" necessary for the "integral application of the principle of subsidiarity" (Magnaghi, A. in Becattini, 2015), through a network of relationships across multiple organisational levels, such that each issue can be addressed at its most appropriate level (Micciarelli, 2014).

It is clear that the most suitable form of self-government must be identified in each specific context, as any attempt to formalize or establish the forms in which communities can exercise their power of self-determination would lead to the paradox of "self-management of heteroregulated units", which Gorz (2015) describes as "a nonsense or a mystification".

The activation of planning action by local actors can be significantly supported through technological tools that lower the barriers to accessing technical skills and facilitate the exchange of information with planning potential. Research shows a spontaneous tendency among grassroots initiatives to leverage new technological tools, and in particular collaborative mapping in our case, as a means to construct new images of the territory (De Bonis *et al.*, 2020, 2019).

For this reason, and in continuity with approaches that the authors of this contribution have been developing over the years (De Bonis, 2009), the research project included the creation of an interactive web environment (GeoSocialWeb), interoperable with the information systems used in planning processes and based on the integration of GIS and WebGIS with emerging technologies in the field of neogeography, in the framework of a platform that allows asynchronous communication and peer-to-peer online production (Social Web) of content.

The choice to adopt this technology is based on the recognition that the production of geographic information has undergone a profound transformation in recent years. From being a specialized domain, it has evolved into a multi-actor and widespread process of information production. These forms of neogeography rely primarily on digital tools and the co-production of data through mobile applications and web-based platforms. This phenomenon is associated with the so-called data revolution (Kitchin, 2014).

Among the practices of collaborative mapping and location-based social networks, or geosocial (Kitchin, Lauriault, Wilson, 2017), there are experiences of integration between open source software for web mapping, collaborative writing, and communication, also based on DokuWiki platforms. These systems enable interaction among users for the collaborative construction and sharing of geographically referred analytical frameworks and territorial images (De Bonis *et al.*, 2020).

Such platforms foster interaction between users, facilitating the integration of different approaches and competences. They can be understood as socio-technical learning environments, which transcend the sectoralisation of specialised territorial knowledge production and incorporate other forms of spatial intelligence (Mattern, 2017).

GeoSocialWeb is therefore a tool to enable the production of cartography through collaborative approaches, and it is designed to facilitate decentralised and collaborative, bottom-up map-making processes that combine expert knowledge, contextual awareness, and creative expression from all kinds of users.

The system, currently under development, is conceived as an integration of existing tools for the production and sharing of geographic information with those that facilitate social interaction among users. It represents an environment of extensive online interaction aimed at sharing territorial knowledge and collective visions of the future: at the same time, a digital infrastructure and social space for encouraging action and interaction among researchers, territorial communities, and any user interested in contributing their vision of a place.

GeoSocialWeb functions as an environment of online interaction for territorial communities, aimed at experimenting processes of co-produced mapping apt to strengthen sense of place and "place consciousness" (Magnaghi, 2010), encouraging the drafting of bottom-up future scenarios oriented towards community self-government, thus overcoming the fragmentation typical of various "participatory planning" approaches.

While the initial population of the platform (i.e. the first set of maps) could be provided by the members of the research group, the key feature of the GeoSocialWeb lies in its openness to contributions from all registered users.

These users can create and share data about the territory and interact with other users around uploaded content. The platform is developed as a digital environment for the collaborative creation and management of interactive forums, based on the sharing of text (comments, discussion) and various media types (images, videos, audio). Use of the platform is open to any user, but full functionality (such as the ability to comment or modify content) is reserved for registered users.

Each forum is necessarily linked to a map embedded into the webpage (Figure 3). The platform under development is being optimised to allow interaction on cartographic bases generated through the uMap application[7], which enables the creation of interactive and shareable maps based on OpenStreetMap.

7 https://umap.openstreetmap.fr/

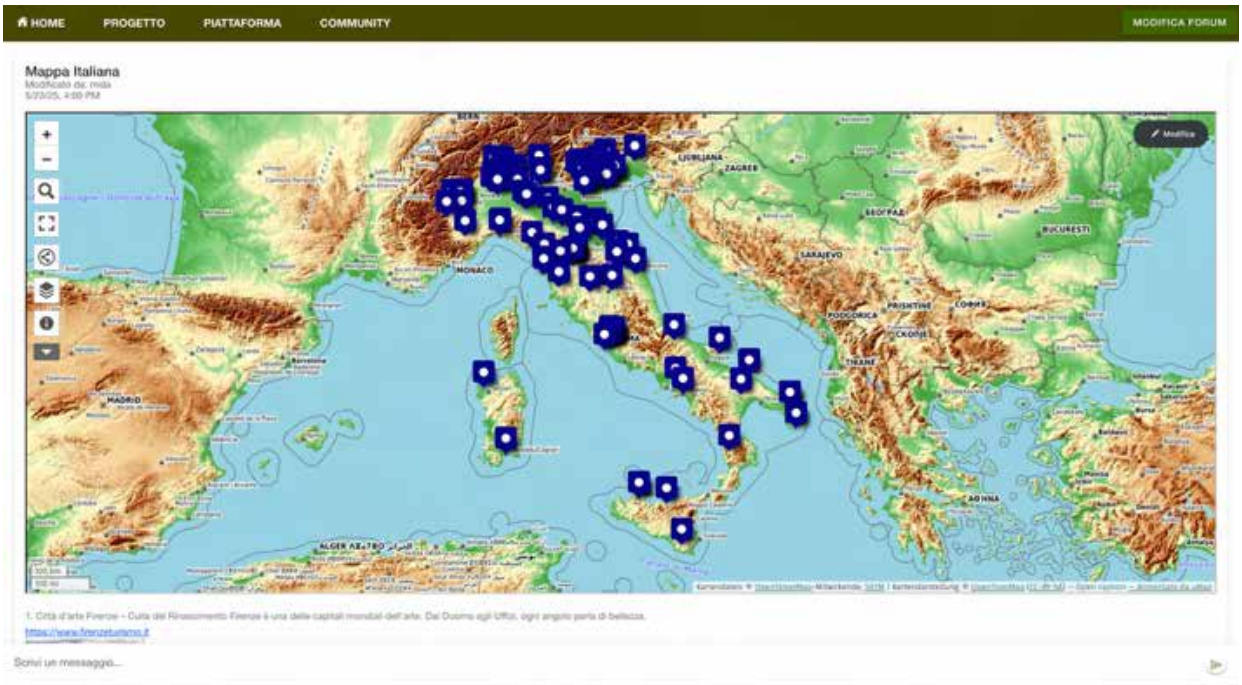

Figure 3 - Map embedding in a test forum page within the alpha version of the GeoSocialWeb under development. Courtesy of M. Daniele

Forums also include dynamic fields for inserting descriptive texts, external links, multimedia files, and customised iFrames (Figure 4). The platform integrates functionality for storing and displaying the history and attribution of changes to the forum, thereby allowing users to track the evolution of interactions around specific territorial issues.

7. Conclusions

Having as a general reference the theoretical insights expressed in paragraph 2, 3, and 4, the ongoing research in the Aniene River basin has revealed a number of elements worthy of deeper analysis and further development. Among these, the experience of the River Contract stands out as an example of an agreement tool that, although still largely framed within institutional logics, shows the potential to act as a complementary instrument to formal planning.

This is also demonstrated by the geometries of interaction between the actors, in which there is a greater involvement of subjects progressively as one moves towards the lower scale, with a particularly relevant role of local associations.

We suggest that the River Contract can be interpreted as a flexible and inclusive framework that may serve as a connection level between institutional planning and community-driven forms of self-governed territorial action. The process that led to the Aniene River Contract, from the wide engagement of associative networks to the subsequent institutionalisation of a participatory governance structure, highlights the complex dynamics behind subsidiary territorial governance.

The Action Programme of the River Contract, with its 94 project initiatives and over 160 involved actors, reflects both the strengths and limitations of the current participatory planning configuration. The prevalent focus on tourist-recreational valorisation suggests a relatively narrow interpretation of territorial enhancement, often disconnected from deeper, more transformative engagements with local socio-ecological systems.

On the other hand, certain project proposals (particularly those aimed at reactivating sustainable production cycles, e.g., local food and phytotherapeutic supply chains, local energy systems) and ongoing practices outside the formal framework (such as farmers' markets, urban gardens, and emerging energy communities) indicate a latent potential for self-organised, co-evolutionary planning practices. These initiatives, although still fragmented, offer promising ground for experimentation of territorial self-government.

In this evolving context, the GeoSocialWeb platform could support decentralised, collaborative mapping and the co-production of territorial images, fostering place awareness and the networking of place-based initiatives. In doing so, it may contribute to addressing one of the main challenges highlighted also by the Aniene case: the need to shift from participation understood as consultation or project delivery toward active forms of self-government that are grounded in local knowledge, relational engagement, and shared responsibility.

Abstract
The present paper proposes a methodology for the evaluation of participatory planning processes through an integrated lens that connects institutional design with civic experience. The model synthesises objective indicators – such as timing, access, and policy integration – with subjective dimensions – like trust, agency, and place attachment. This enables it to capture the interplay between governance structures and lived participation. The framework is situated at the intersection of institutional practice and democratic innovation, thereby facilitating cross-boundary learning between public actors, communities, and planning professionals. This exploratory study establishes the foundation for subsequent empirical validation. It provides a versatile instrument for evaluating and collaboratively designing participatory pathways that enhance citizen empowerment and fortify democratic resilience across various territorial contexts.

Key words: Process evaluation; Participatory planning; Civic Engagement; Agency.

Introduction

Public participation in decision-making is widely acknowledged as a foundational element of contemporary urban and territorial planning. It serves not only as a safeguard of deliberative democracy (Smith, 2006), but also as a mechanism for promoting more equitable, informed, and context-sensitive policies (Healey, 1997). In this perspective, participatory planning has assumed a central role in shaping urban policies that reflect social complexity and emerging territorial needs (Ansell & Gash, 2008; Fischer, 2012).

Despite its growing institutionalization, evaluating the effectiveness of participatory processes remains a complex task. Existing assessment models are often polarized between procedural approaches, focused on efficiency and organizational criteria (Rowe & Frewer, 2000), and experiential approaches, concerned with participants' perceptions, relational dynamics, and subjective outcomes (Bherer, Gauthier, & Simard, 2021; Quick & Feldman, 2011). This methodological divide limits the ability to frame participation as a systemic phenomenon shaped by both design quality and lived experience (Kapucu, 2021).

This study proposes an integrated evaluation framework that brings together structural and experiential dimensions. On the one hand, it considers process-related variables such as transparency, time management, accessibility, and the integration of participatory outcomes into planning decisions (Reed et al., 2018; Partidário & Mourato, 2020). On the other, it incorporates subjective dimensions including trust, motivation, agency, and place attachment (Zimmerman, 1995; Manzo & Perkins, 2006; Christens, 2012).

The framework is designed with two main objectives: first, to offer a comprehensive tool for evaluating participatory processes across diverse planning contexts; and second, to foster critical reflection on the relationship between structural design and democratic meaning in participatory governance.
The key contributions of this work are as follows:

- To test the hypothesis that participatory effectiveness results from the interaction between procedural efficiency and experiential engagement (Michels & De Graaf, 2017);
- To investigate how process characteristics shape participants' perceptions, particularly regarding institutional trust, sense of belonging, and civic activation (Baiocchi & Ganuza, 2017);
- To provide a transferable methodological model that can be adapted to evaluate a variety of participatory planning cases;
- To identify enabling and constraining factors that influence the transformative capacity of participatory processes;
- To highlight the critical role of perceived authenticity and the actual integration of public input in shaping long-term civic trust and engagement (Nabatchi & Leighninger, 2015; Voinov et al., 2022).

The paper is structured as follows: section 2 reviews the theoretical foundations and key approaches to evaluating participation; section 3 presents the proposed methodology and analytical tools; section 4 discusses potential applications and expected outcomes and offers critical reflections. Through this structure, the study aims to contribute a methodological foundation for more reflective and effective participatory planning practices, integrating both process quality and civic experience.

Background

Participation in territorial planning is now widely acknowledged as a key component of democratic and inclusive governance, aimed at the co-production of urban policies. Beyond mere consultation, participatory planning is conceived as a deliberative and transformative process, capable of redistributing decision-making power, fostering collective learning, and valuing local knowledge (Healey, 1997; Innes & Booher, 2004). It is rooted in a dialogical and pluralistic vision of urban space, where the co-construction of spatial decisions strengthens both civic identity and collective responsibility (Sandercock, 1998).

An effective participatory process not only broadens the decision-making base but also reinforces policy legitimacy, promotes socio-spatial justice, and enhances community capacity for stewardship. Collaborative planning enables forms of relational justice by recognizing cultural and social differences (Healey, 1997), while participation that acknowledges diversity contributes to a more equitable democracy (Young, 2000). The literature on collaborative governance (Ansell & Gash, 2008) emphasizes trust, dialogue, and mutual learning as essential to shared and sustainable outcomes.

Evaluating participatory effectiveness is thus central to understanding its real impact on territorial transformation. Participation yields both instrumental benefits, by incorporating local knowledge into better decisions (Innes & Booher, 2004), and normative ones, by enhancing democratic legitimacy and social capital (Fung, 2006; Smith, 2006). Effectiveness entails measuring not only tangible outputs but also relational impacts and civic empowerment (Michels, 2011; Nabatchi & Leighninger, 2015).

Fundamental participatory principles include inclusiveness, equity, transparency, mutual accountability, and informed deliberation (Smith, 2006; Fung, 2006). For these principles to be effective, they must be operationalized into procedural mechanisms that ensure meaningful influence on decision-making (Arnstein, 1969; Fung, 2006). This dual nature, both transformative and technical, demands evaluation tools that can capture both the experiential quality of civic involvement and the structural efficiency of the process.

Objective evaluation tools focus on structural, procedural, and organizational features, offering criteria to assess process coherence and efficiency. Key aspects highlighted in the literature include: well-calibrated timing that allows for reflection and input (Reed et al., 2018); clarity in roles and expected competences to avoid informational inequalities (Partidário & Mourato, 2020); accessibility in terms of physical, digital, and temporal dimensions (Voinov et al., 2022); the quality and traceability of outputs (Reed et al., 2018); and the degree to which outputs are integrated into subsequent planning phases (Partidário & Mourato, 2020). Such tools are instrumental for ensuring accountability and comparability, especially in complex institutional settings, and form the basis of evaluation models adopted by public agencies and international organizations (Abelson et al., 2003). More recent approaches propose multi-scalar frameworks that integrate formal criteria with indicators of relevance, impact, and sustainability (Voinov et al., 2022).

Among these procedural variables, time management is particularly significant: appropriately paced processes facilitate meaningful engagement while avoiding rushed or diluted participation (Reed et al., 2018). Clear definitions of roles and competencies foster equitable involvement, while transparent expectations and information access are prerequisites for informed engagement (Partidário & Mourato, 2020). Ensuring logistical and technological accessibility is equally critical (Voinov et al., 2022).

Effective participatory processes also produce outputs that are relevant, accessible, and verifiable. Transparent reporting and clear documentation enhance trust and process legitimacy (Reed et al., 2018). Moreover, the integration of these outputs into actual planning decisions is a key indicator of transformative capacity (Partidário & Mourato, 2020).

While objective tools are essential, they must be embedded within broader evaluation strategies that reflect on context, purpose, and long-term effects (Reed et al., 2018; Partidário & Mourato, 2020). Participatory evaluation itself can enhance democratic quality and empower communities (Voinov et al., 2022; Osei-Kyei et al., 2023). Frameworks such as MEPPP (Monitoring and Evaluation of Participatory Planning Processes) aim to support collective learning and address the complexity of knowledge co-production (Kusters et al., 2017).

Subjective evaluation, in turn, focuses on participants' experiences and perceptions, offering a complementary lens to structural analysis. It captures the relational and symbolic dimensions of participation, how citizens feel engaged, heard, and empowered. The literature emphasizes that beyond inclusive mechanisms, perceived authenticity is crucial to meaningful participation (Papadopoulos, 2012; Bussu & Bartels, 2014; Brandsen et al., 2018).

The concept of empowerment is central to subjective evaluation. It refers to individuals' perceived capacity to influence decisions, contribute meaningfully, and act effectively. Empowerment is multidimensional: intrapersonal (self-confidence and perceived efficacy), interactional (understanding and navigating processes), and behavioral (active participation and responsibility) (Zimmerman, 1995; Christens, 2012). These dimensions intersect with trust in institutions (Fung, 2006), personal and collective motivation (Bherer, Gauthier & Simard, 2021), and emotional place attachment (Manzo & Perkins, 2006).

Empowerment is not only individual but also contextual and relational. It reflects how a participatory process fosters authentic engagement, mutual recognition, and shared learning (Fischer, 2012; Baiocchi & Ganuza, 2017). In essence, it is about enabling citizens to move from passive spectatorship to active agency.

Subjective effectiveness thus lies not in strictly measurable parameters, but in the ability to generate meaningful involvement, recognition, and transformative learning (Fischer, 2012; Nabatchi, 2012). These experiences offer a privileged lens to assess whether participants feel empowered, develop new forms of engagement and trust, and perceive their contributions as valued.

Evaluating these elements requires appropriate methodologies that go beyond declared opinions to explore relational dynamics, dialogic quality, and emotional responses (Quick & Feldman, 2011; Baiocchi & Ganuza, 2017; Kapucu, 2021).

Objective and subjective evaluations are complementary and inseparable in assessing participatory effectiveness. Structural analysis reveals key procedural elements—such as timing, accessibility, and transparency—while subjective analysis captures lived experiences, perceptions of agency, and transformative outcomes.

Literature calls for integrated models that link process design to experiential outcomes (Michels & De Graaf, 2017; Bherer et al., 2021), recognizing that procedural features shape participation quality, and that citizens' perceptions, in turn, affect process legitimacy and impact (Kapucu, 2021).

In this light, integrated evaluation emerges as a crucial approach for capturing the complexity of participation. It requires mixed methods, capable of combining quantitative and qualitative, observable and interpretive data, and indicators that reflect both efficiency and civic engagement (Innes & Booher, 2004; Reed et al., 2018).

Only through such an integrated approach can we fully understand the dual nature of participation—as both a democratic arena and a technical device—and promote planning practices that are more equitable, reflective, and oriented toward collective learning.

Compared to existing evaluation frameworks such as the IAP2 Spectrum of Public Participation or the MEPPP (Monitoring and Evaluation of Participatory Planning Processes), the model proposed in this study offers a more integrated and flexible approach. While these models often prioritize either procedural phases or outcome indicators, our framework explicitly connects objective and subjective dimensions, placing equal emphasis on structural features and civic experiences. The added value lies in the model's capacity to adapt across contexts while maintaining a multidimensional focus that includes institutional design, trust-building, empowerment, and place-based engagement. It is conceived not only as a technical tool for analysis, but also as a reflective device to support the design of more meaningful participatory practices.

In order to clarify the distinctive contribution of the proposed evaluation model, it is useful to compare it with two of the most established frameworks in the field of participatory planning evaluation: the IAP2 Spectrum of Public Participation and the MEPPP (Monitoring and Evaluation of Participatory Planning Processes).

The IAP2 Spectrum is a widely used tool that classifies public involvement into five levels (Inform, Consult, Involve, Collaborate, Empower). While it provides a practical guide for designing participatory activities, it focuses primarily on the degree of control or influence granted to citizens, offering little insight into the quality or effectiveness of participation in terms of outcomes or experiential depth.

The MEPPP, on the other hand, adopts a more structured approach to monitoring and evaluating participatory processes, with attention to outputs, relevance, and sustainability. It proposes a multi-scalar model capable of assessing both the planning content and participation dynamics. However, MEPPP tends to concentrate on formal and procedural criteria, and while more robust than IAP2, it does not explicitly integrate subjective and experiential dimensions such as trust, empowerment, or place attachment.

By contrast, the framework proposed in this study explicitly aims to bridge this gap by integrating objective structural indicators (e.g. timing, access, use of outputs) with subjective experiential dimensions (e.g. trust, motivation, agency, place attachment). It provides a multidimensional and flexible instrument, adaptable to diverse contexts, and suitable not only for evaluation but also as a co-design support tool for future participatory processes.

As shown in Table 1, the three frameworks differ significantly in their integration level, focus, and intended use.

Table 1: comparative overview of participatory evaluation frameworks.

Framework	Evaluation Focus	Key Dimensions	Level of Integration	Adaptability	Primary Use
IAP2 Spectrum	Participation phase/type	Inform, Consult, Involve, Collaborate, Empower	Low – phase-based classification only	Medium – standardized model	Participation typology and design
MEPPP	Process monitoring and output analysis	Participation levels, outputs, sustainability, inclusiveness	Medium – procedural + some impact focus	High – scalable and modular	Monitoring and evaluation
Proposed Framework	Structural + experiential evaluation	Timing, Access, Trust, Agency, Empowerment, Place Attachment	High – combines objective and subjective	High – adaptable and reflective	Evaluation, learning, and co-design

Methodological proposal

Building on the theoretical foundations outlined in the previous section, this study proposes a methodology to evaluate the effectiveness of participation in urban and territorial planning. The approach adopts a dual perspective, objective and subjective, aimed at constructing an analytical framework that links the structural features of participatory processes with citizens' perceptions and lived experiences.

The objective evaluation focuses on structural and functional characteristics of participatory processes that influence their capacity to include, inform, and empower citizens. A first key dimension is time—not only the overall duration but also the process phasing and its alignment with planning stages. As Healey (1997) argue, a well-paced process fosters meaningful participation and collective reflection, avoiding symbolic or purely consultative forms of engagement.

A second dimension concerns required competences. Clarity of language, accessible content, and potential training opportunities are essential to ensure informed participation. Reducing cognitive asymmetries is central to inclusive processes. Providing clear and accessible information strengthens trust and comprehension (Mahajan et al., 2022), while training enhances participants' ability to contribute constructively, fostering individual and collective empowerment (Yamaguchi et al., 2024).

Accessibility extends beyond physical or organizational factors to include scheduling, communication methods, digital access, and outreach to marginalized groups. Authentic participation requires attention to access inequalities (Nabatchi & Leighninger, 2015), and inclusive digital tools can expand engagement to underrepresented populations (Pinto et al., 2023).

Another critical factor is the quality of outputs—defined by clarity, relevance, and consistency of results. Effectiveness depends not on the quantity of inputs but on their synthesis, feedback to participants, and transformative potential. Clear, coherent outputs support legitimacy and institutional uptake (Fung, 2006), and effective feedback mechanisms build trust and civic engagement (Mahajan et al., 2022).

Finally, use of outputs measures whether outcomes are integrated into subsequent planning or policy-making phases. This assesses institutional responsiveness and the coherence between participation and implementation. A process becomes transformative when outputs inform real decisions (Smith, 2009; Michels & de Graaf, 2021), marking a shift from symbolic consultation to substantive participation.

Table 2: structural criteria for the objective evaluation of participatory planning processes.

Criteria	Indicators
Time	Overall duration, process phasing, coherence with planning stages
Required Competences	Clarity of content, level of knowledge needed, support provided
Accessibility	Access methods, meeting times, information and digital inclusion
Process Outputs	Clarity, traceability, and relevance of participatory outcomes
Use of Outputs	Degree of integration into subsequent planning or programming

The subjective evaluation acknowledges citizens as active agents and focuses on their perceptions of the participatory experience. Several key dimensions underpin this perspective, while the corresponding structural indicators used to assess these aspects are summarised in Table 2. Trust in the process and institutions emerges through transparency, perceived coherence, and legitimacy of decisions. Transparent communication enhances trust (Fung, 2006), while coherence strengthens procedural legitimacy (Innes & Booher, 2004).

Motivation reflects the reasons driving participation—ranging from civic duty to personal interest or the desire to improve one's community. It is shaped by perceived efficacy and recognition of contributions (Bherer, Gauthier & Simard, 2021).

Agency refers to the perceived capacity to influence outcomes and be heard. It connects to empowerment, a multidimensional construct encompassing self-confidence, understanding of the process, and active engagement. Empowerment strengthens awareness and participation effectiveness (Yamaguchi et al., 2024).

Lastly, place attachment denotes the emotional and symbolic bond with one's environment. This connection fosters participation and care for local spaces. Recent research highlights how place attachment contributes to well-being and resilience (Kamani Fard & Paydar, 2024), making it a critical factor in participatory planning.

These dimensions are interdependent and collectively shape the perceived quality of the participatory process. To assess them, a structured questionnaire is proposed, based on validated or adapted scales from established literature:

- Trust: Measured using a 5-point Likert scale adapted from Fung (2006) and Innes & Booher (2004), focusing on perceived transparency, coherence, and institutional reliability.
- Motivation: Captured through items exploring extrinsic (e.g., civic duty, personal interest) and intrinsic (e.g., satisfaction, perceived contribution) drivers (Bherer et al., 2021).
- Agency: Assessed via perceptions of influence and capacity to express views, based on Christens (2012).
- Empowerment: Measured following Zimmerman's (1995) model, including intrapersonal (self-efficacy), interactional (process understanding), and behavioral (active participation) components.
- Place Attachment: Explored through statements on emotional connection, territorial identity, and care responsibilities (Manzo & Perkins, 2006; Kamani Fard & Paydar, 2024).

Table 3 uses Likert-scale responses (1 = strongly disagree to 5 = strongly agree), preceded by filter questions on process familiarity and participation frequency.

Table 3: dimensions and sample items for subjective evaluation of civic participation experience.

Construct	Sample Items
Trust	"The participatory process was transparent"; "Information provided was coherent and reliable"
Motivation	"I felt motivated to improve my community"; "My contribution could make a difference"
Place Attachment	"I feel emotionally connected to where I live"; "This place is part of my identity"
Agency	"My opinion was listened to and considered"; "I played an active role in decision-making"
Empowerment	"I feel more competent after participating"; "I gained tools to influence future decisions"

As highlighted by Fung (2006) and Innes & Booher (2004), effective participation balances procedural adequacy with participants' perceptions of being heard and valued. Baiocchi & Ganuza (2017) further show how public recognition of participants' views strengthens trust and agency. Similarly, Manzo & Perkins (2006) demonstrate that place attachment deepens civic engagement, especially when coupled with a participatory context that fosters empowerment.

Potential applications and critical reflections

This study offers a preliminary theoretical framework for evaluating the effectiveness of participatory processes in urban and territorial planning. As an exploratory contribution, it does not yet include empirical validation but is intended as a foundation for future applied research. Similar to other conceptual or methodological studies in the planning field, the aim is to develop a coherent evaluative model that can be tested, refined, and adapted across different case studies and territorial contexts (see e.g., Innes & Booher, 2004; Reed et al., 2018).

Recognizing the active role of local communities in territorial governance is essential to address the complex challenges of contemporary societies. Participation should not be confined to token consultation; rather, it must be seen as a structural component of governance, capable of enabling citizens to act as informed and responsible agents. This shift moves beyond the spectator-actor dichotomy, placing communities at the center

of local development strategies. Empowerment, in this perspective, is not a by-product but a core outcome of participatory inclusion, fostering civic awareness, decision-making autonomy, and access to tools for social and territorial transformation (Rota, 2023).

From this standpoint, territory should be conceived not merely as a physical space but as a common good requiring sustainable, inclusive, and collaborative management. Valuing local resources and strengthening cooperation networks emerge as crucial strategies for building cohesive and identity-driven development models. Promoting collaboration between public and private actors, and across urban and rural settings, is key to fostering resilient territorial systems. These dynamics call for the establishment of community learning networks to cultivate a culture of sustainability and active citizenship, equipping communities with knowledge and skills for collective decision-making.

In this view, sustainability becomes not only a goal but a guiding principle for reshaping territorial governance. It functions as a heuristic and educational device that steers collective choices toward fairer and more enduring models of coexistence. Addressing socio-economic transformations requires a holistic approach, where endogenous knowledge is integrated with participatory governance and adaptive management. Within this framework, cultural heritage plays a strategic role—not as a static legacy but as a dynamic force capable of enabling regeneration processes and reinforcing collective identity (Carta, 1999).

Future research should focus on how participatory governance can reframe the relationship between people and place, particularly in contexts affected by deterritorialization and the erosion of local identity. Reinforcing the idea of territory as a "common home" (Tanca, 2015) involves recognizing it as a relational space where social and cultural capital can generate resilience and self-determination. The organization of space according to local specificities and the valorization of endogenous resources are essential for ensuring long-term cultural and social reproduction.

Active participation is therefore a decisive element for building inclusive and resilient governance models. Through deliberative processes and participatory research methods, communities can cultivate a deeper sense of belonging (Ilovan, 2022). The interplay between territorial identity and place attachment becomes central in planning, as emotional and symbolic bonds to place directly affect levels of civic engagement. Shared narratives and collective memory transform space into an essential component of community life.

In this light, public policies must account for the relational dimension of governance, acknowledging how interactions between individuals, groups, and institutions influence territorial attachment. Standardized approaches risk neglecting the cultural and symbolic specificity of places. Qualitative methodologies—such as in-depth interviews and discourse analysis—are increasingly recognized as valuable tools to explore the emotional and experiential dimensions of civic engagement.

Future research directions should also address how global dynamics and growing mobility are reshaping local identities. Urbanization, labor market transformations, and digital interconnectivity are altering the ways individuals relate to their environments. It is therefore necessary to explore the ambivalent, and at times conflictual, relationships people develop with their lived spaces. This awareness is key to designing planning strategies that are more sensitive, inclusive, and attuned to local needs and experiences (Ilovan, 2022).

Despite the absence of empirical validation in this study, the proposed framework has the potential for a wide range of applications. For instance, it could be applied to participatory budgeting processes in medium-sized European cities, where evaluating both procedural transparency and residents' sense of agency is crucial. Alternatively, it could provide a framework for the evaluation of place-based cultural regeneration projects in rural areas, where community attachment and trust in institutions are significant variables. The following hypothetical applications illustrate how the framework can be adapted to different participatory settings, serving both as a diagnostic and a design-support tool.

This work is intended to be conceptual in nature and is presented as a proposal. It is argued that the proposal provides a foundation for a more nuanced understanding of participation as both a technical and democratic process.

It is imperative that future empirical studies are conducted in order to test the framework, evaluate its applicability across diverse contexts, and refine its indicators to ensure relevance, reliability, and transformative potential.

While the proposed roadmap outlines a coherent path towards empirical validation, further reflection is required on two critical aspects: scalability and the active involvement of local actors in the evaluation process.

Firstly, the scalability of the framework will be addressed through a modular and adaptable design. The framework has been designed to function at different scales, including project, neighbourhood, municipal and regional levels. It achieves this by allowing the selective use of indicators based on contextual relevance. The calibration of structural dimensions, such as timing or accessibility, is contingent upon the complexity of the process. Conversely, experiential components, including trust and place attachment, can be adapted through the utilisation of shorter or more in-depth instruments. Furthermore, the utilisation of digital tools and online platforms will be investigated to enhance the scope of data collection, particularly in multi-site or cross-country applications.

Secondly, the involvement of institutional stakeholders and local communities will be pivotal in both the testing and refinement phases. The framework is not merely intended as a tool "for" evaluation, but as a device "with" and "through" participants. In order to achieve this objective, the empirical phase will incorporate participatory validation methods, such as co-design workshops, focus groups, and deliberative feedback sessions with public officials, community leaders, and citizens. These interactions are designed to ensure contextual calibration of indicators, enhance legitimacy, and cultivate a culture of shared learning around participatory quality.

The dual strategy of modular scalability and embedded stakeholder engagement is set to be pivotal in ensuring the relevance, usability, and transformative potential of the framework across diverse territorial and institutional settings.

To guide future research and application, Table 4 presents a phased roadmap detailing the objectives, methodologies, and expected outcomes for each step of the empirical validation process.

Tables 4: future research pathways and empirical validation roadmap.

Phase	Objective	Methodology	Expected Outcome
1. Contextualization	Identify suitable case studies across different urban and rural settings	Case selection based on diversity of governance contexts and participatory models	Comparative insight into context-sensitive variables
2. Instrument Development	Refine and operationalize indicators from the proposed framework	Pilot testing of questionnaires and interview guides; expert validation via Delphi method	Reliable tools for assessing structural and experiential dimensions
3. Data Collection	Apply the evaluation framework to real participatory processes	Mixed-method approach: surveys, interviews, participant observation, document analysis	Comprehensive datasets combining quantitative and qualitative evidence
4. Analytical Integration	Test relationships between structural variables and perceived effectiveness	Statistical analysis (e.g. SEM, regression) + narrative synthesis of qualitative insights	Validation or refinement of hypotheses on effectiveness drivers
5. Cross-Case Comparison	Identify patterns and divergences across contexts	Comparative case study methodology	Generalizable lessons and adaptive model improvements
6. Participatory Validation	Involve local actors in reviewing results and recommendations	Feedback workshops, focus groups with stakeholders	Enhanced legitimacy and usability of the evaluation tool
7. Dissemination and Scaling	Share findings with academic, institutional, and civic audiences	Publications, policy briefs, training modules	Uptake of the model in planning practices and policies

Abstract
This paper explores the risks and opportunities of Albania's Just Green Transition (JGT) in the context of its post-socialist transformation. Drawing up an updated transition theory that accounts for the complexities of purposive change and multi-dimensional justice, the Albania's post-1990 reforms with the current push for climate neutrality under the JGT are compared. The analysis reveals common transition challenges and specific risks tied to JGT's environmental focus and urgency. By mapping the lessons from Albania's post-socialist era—such as the need for participatory governance, particularly in a context of "transitions fatigue"—the paper outlines strategies to address JGT-specific risks—such as governance gaps, social inequities, and economic disruptions—drawing on developments through 2025.

This paper, through a comparative lens, underscores the importance of inclusive policymaking, balancing socio-economic and spatial justice, and leveraging international support for a successful JGT.

Keywords: Purposive Transition; Just Green Transition; Governance Challenges; Risks and Benefits; Sustainability Transitions; Transition Theory

1.Introduction

The open-ended processes of power, political, and societal transformation that initiated with the fall of the socialist regime(s) around the beginning of the 1990s marked the so-called post-socialist transition ((Müller 2019); (Petrov 2014)). This period of profound change affected numerous Central-East European (CEE) countries, leading to the widespread adoption of the term 'transition' among scholars, policy-makers, and the general public to describe this historical epoch and to label these nations as 'transition countries' (Carothers 2002). This transition signaled an epochal shift, simultaneously ushering in uncertain futures for the economies involved, which subsequently embarked on diverse hybrid political models, often diverging from the paths envisioned by Western agencies that emphasized privatization, liberalization, and democratization (Müller 2019).

Within this broader regional context, Albania's journey has been particularly stark. The nation moved from an almost feudal system in 1945 to a highly centralized and autarkic economy. Then, in 1991, it experienced an abrupt transformation towards a liberal market economy[1]. After five decades of severe repression, the post-communist era was characterized by a vacuum in legislation, policies, and institutions. This transition was initially driven by a population desperate for democracy and liberalism. However, the first decade of the 1990s culminated in a climate of escalating informality, marked by problematic tenure recognition, illegal development, forced evictions, and rampant corruption. These issues were exacerbated by the failure of several 'political experiments,' contributing to the dominance of the extralegal economy in Albania, which encompasses more than half of the country's real estate and properties. This situation, while not typical for EU member states, remains a significant technical and political challenge for Albania as it pursues EU integration.

Crucially, by the time the transition began in mid-1992, Albania lacked a tradition of participatory governance. Given the severe abuses of the previous system, citizens often perceived participatory governance not as an opportunity for engagement but as an extension of the forced labor that had been a cornerstone of their oppression.1 As with other Eastern European countries, the radical changes of the early 1990s completely reshaped Albania's political, social, and economic realities. Albania's specific circumstances led to a volatile transition, punctuated by chaotic and dramatic events. Most notable was the unprecedented economic collapse caused by the infamous pyramidal investment schemes[2] and the subsequent social unrest in 1997, which left the

1 In line with the liberal policies, after massive expropriation of private properties by the collectivist communist state, the new pluralist authorities initiated a failed privatization process, trying to establish the rule of law but without a Cadastral Office. This has marked one of the most profound challenges, yet a pressing issue for the Albanian socio-economic context.

2 The Albanian pyramid schemes of the mid-1990s were among the most devastating financial collapses in post-communist Eastern Europe. By 1996, an estimated two-thirds of Albanian households had invested in these fraudulent investment schemes, whi-

country temporarily without a government and necessitated UN intervention and a multilateral peacekeeping force to restore order (Aliaj and Kacani 2024)..

It is essential to understand that Albania's transition has been uniquely complex and markedly different from that of most European countries. Unlike others, it emerged from the most rigid orthodox system of centralized planning in the former Eastern Bloc, making the shift to a market economy and democratic governance particularly challenging. The 1999 Kosovo War further strained Albania's fragile social fabric, as the country absorbed a massive influx of refugees, compounding existing economic and social pressures. However, with the end of the Yugoslav Wars, regional stability improved, allowing Albania to enter a period of relative progress. The early 2000s saw a notable shift toward stability, economic growth, and social development, with GDP expanding at an average annual rate of 6 percent and significant advancements in socio-economic indicators. Yet, problems began to resurface around 2010 as the global recession and the logic of 'stabilocracy'—underlying financial and security aspects—slowed both economic and democratization processes.

Despite these ongoing challenges, Albania joined NATO in 2009 and remains committed to progressing towards EU membership, navigating an increasingly unstable and unpredictable global landscape. While still grappling with numerous political and economic reforms, and arguably still in transition for many initiated processes, by the end ofthe 20th century, the Government of Albania, along with other Western Balkan governments, aligned as supporters and implementers of the European agenda for green transition. This is both a necessity for pan-European commitment to address climate challenges and ensure environmental sustainability, and a crucial requirement for EU integration.

The newly presented "green transition," as Geels (2011) might suggest, is equally "purposive" for all Western Balkan countries, considering its embeddedness within the EU green agenda, the EU integration process, and the structural and technical weaknesses in the region that inhibit the spontaneous emergence of bottom-up niches of change.1 The JGT is thus layered onto a society already weary and skeptical of grand, externally-driven transformation projects, a phenomenon that can be described as "transitions fatigue". This fatigue, born from past experiences with reforms that often fell short of their promises or were perceived as imposed, creates a challenging socio-political backdrop for yet another large-scale transition.

In this context, this chapter aims to examine the JGT within the broader framework of Albania's post-socialist transformation, drawing parallels between these two pivotal periods of systemic change. Firstly, it decodes the theoretical concept of transition(s) by incorporating recent scholarly advancements and critiques. Secondly, through a comparative approach, it examines Albania's post-1990 transformation, highlighting key governance, socio-economic, and spatial challenges, while identifying lessons relevant to the JGT and exploring its multifaceted implications. This comparative lens aims to identify shared challenges and distinct features of the two transitions to draw actionable insights. The final section synthesizes the conclusions, outlines a trajectory for further discussion, offers policy recommendations, and underscores the importance of inclusive, climate-sensitive governance for Albania's sustainable future, particularly in light of its complex transitional history and the evolving understanding of what constitutes a truly "just" transition.

2.Decoding Transition(s): A theoretical exploration of the term

Transition studies, originating in biology and population dynamics, have expanded to encompass demographics, health, and, significantly, organizational management and technological innovation scholarship (Rotmans, Kemp and van Asselt 2001). Transitions, broadly defined, are processes of profound and systemic change that reconfigure societal, economic, and environmental systems over time, presumably towards an improved state that incorporates new, desirable features or contributes to solving existing problems (Loorbach, Frantzeskaki and Avelino 2017). Within academic discourse, the term has been extensively analyzed through frameworks such as socio-technical transitions, governance transitions, and socio-ecological systems (Geels 2002); (Smith, Stirling and Berkhout 2005). The concept of socio-technical transitions, central to these studies, focuses on the co-evolution of

ch promised exorbitant returns but operated as classic Ponzi schemes. The schemes thrived due to weak financial regulation, political complicity, and a lack of public financial literacy, fueled by Albania's rapid and unregulated transition to a market economy. By early 1997, the schemes collapsed, wiping out an estimated $1.2 billion—equivalent to nearly half of Albania's GDP at the time. The crisis led to widespread social unrest, mass protests, and the near-total collapse of state institutions, culminating in an intervention by a UN-sanctioned multinational peacekeeping force (Operation Alba).

societal practices, technological advancements, and institutional frameworks. Frank W. Geels (2002) introduced the Multi-Level Perspective (MLP) as a foundational approach to understanding such transitions, emphasizing three interconnected levels: niches (spaces of innovation), regimes (dominant systems), and landscapes (broader socio-political and environmental contexts).

However, the traditional understanding of transition dynamics and the applicability of established theories are being increasingly questioned in the context of contemporary sustainability challenges. Notably, insights from past transitions may offer limited guidance for the current low-carbon transition. This is because historical financial risks often stemmed from speculation in rapidly rising industries driven by new, vastly more productive technologies. In contrast, the current transition necessitates policy interventions to rapidly render declining, yet currently productive, high-carbon industries unprofitable, leading to stranded assets and locating significant financial risks within these sunset sectors. This shift implies that the "problem" of transition is evolving; it is less about the "pull" of inherently superior new technologies and more about the "push" out of undesirable, deeply embedded existing ones, creating unique socio-economic and financial disruption profiles.

2.1.Critiques and Evolutions of the Multi-Level Perspective (MLP)

While the MLP remains a cornerstone of transition studies, it has faced critiques that highlight areas for development. Some scholars argue that the MLP primarily explains transitions through a temporal lens and is best suited for bottom-up analyses, potentially underemphasizing the role of top-down influences and broader power dynamics.5 A significant critique is its perceived focus on technological aspects at the expense of adequately considering the socio-political dimensions of transitions, including agency, power, and politics.

Recent scholarship seeks to expand the MLP to address these limitations. There is a growing emphasis on incorporating multi-level governance, recognizing that transition niches can emerge and be shaped by interactions across local, regional, national, and even global governance levels.5 This is particularly relevant for sustainability transitions, where international regulations and agreements (landscape pressures) can significantly influence national policies (regime dynamics) and the development of local innovative solutions (niche activities). For a country like Albania, heavily influenced by the EU agenda, understanding these top-down pressures and multi-scalar governance interactions is crucial for analyzing the JGT. The application of MLP to analyze the circular bioeconomy transition in Nordic regions, for instance, confirmed the unique challenges faced by peripheral areas and underscored the importance of innovation, consumer choices, and overarching environmental factors like climate change impacts as drivers of transition. This highlights the MLP's utility in understanding regional specificities when its analytical scope is appropriately broadened.

2.1.1Sustainability Transitions and Justice in Sustainability Transitions

Sustainability transitions are characterized by societal, multilevel, multi-institutional, and cross-sectoral changes that affect multiple regimes—socio-technical, socio-ecological, political, and governance—as well as societal values, ideas, perceptions, ethics, and morality.These transitions involve large-scale transformations, a focus on finite, collectively owned natural resources, and inherent tensions between growth-oriented sectors and public interests regarding resource management and ethical implications.1 The complexity and dynamic interplay of dimensions such as time, space, affected sectors, actors, and overarching goals make sustainability transitions highly complex and difficult to foresee, even with careful planning world (Cedergren, et al. 2022); (Hansen and Coenen 2015); (Kemp, Loorbach and Rotmans 2007); (Rotmans and Kemp, Managing Societal Transitions. Dilemmas and Uncertainties: The Dutch Energy Case Study 2003).

The transition to a low-carbon economy epitomizes such a large-scale structural change, necessitating the expansion of "sunrise" (low-carbon) industries and the contraction of "sunset" (carbon-intensive) industries (Hunsucker and Loos 1989). A comprehensive theoretical framework that fully links this structural change to financial stability, especially concerning the risks emanating from sunset industries, is still developing.4 Sustainability itself, often defined as meeting present needs without compromising future generations' ability to meet their own 1, is not a fixed state but an evolving goal. Sustainable development is a fluid, ongoing process of transformation, where sustainability transitions represent the continuous effort to balance changing human demands with the biosphere's adaptive capacity (Derissen, Quaas and Baumgärtner 2009).

"Sustainability "meets the needs of the present generation without compromising the ability of the future generations to meet their own needs" and is therefore neither a fixed state of harmony, nor an identifiable state, coping with both the certainty and the uncertainty of change. (Kemp, Loorbach and Rotmans 2007) , (United Nations 1987, 24), (Handmer and Dovers 1996)"

The imperative for "justice" in sustainability transitions has gained significant traction. The call for 'just transitions' originated in the 1970s and 1980s with trade unions in North America concerned about job losses resulting from environmental policies, linking to broader 19th-century discourses on income and wealth distribution. The concept is now firmly established in the International Labour Organisation (ILO) Guidelines for a Just Transition Towards Environmentally Sustainable Economies and Societies for All and is reinforced by the UN Sustainable Development Goals (SDGs) and the Paris Agreement.

The understanding and scope of "just transition" have evolved considerably, particularly since 2022. Initially, the Paris Agreement focused on the "just transition of the workforce and the creation of decent work and quality jobs".

However, subsequent developments, including the 2021 Glasgow Pact and discussions at various international forums, have broadened this definition to encompass wider societal impacts on diverse groups such as women, Indigenous Peoples, low-income households, and youth.7 There is a growing recognition that a just transition must address not only distributive justice (fair allocation of benefits and burdens) but also procedural justice (inclusive and participatory decision-making) and, increasingly, restorative and transformative justice, which aim to correct historical inequities and fundamentally alter power structures.

The UN Committee for Development Policy (CDP) at its 2023 plenary emphasized that countries need to develop context-specific approaches to just transition, reflecting their unique societal needs, priorities, historical responsibilities for climate change, and adherence to principles of global climate justice and common but differentiated responsibilities.8 An open letter from world leaders in June 2023 further underscored the commitment to "a green transition that leaves no one behind".8 The operationalization of the UNFCCC Work Programme on Just Transition Pathways and the ILO's establishment of a Global Coalition for Social Justice in November 2023 (which will feed into the 2025 World Social Summit) signal a deepening institutional commitment to this broader, more demanding conceptualization of justice.

This evolving understanding suggests a spectrum of approaches to implementing a just transition, ranging from:

- Status Quo: Maintaining existing systems while compensating for negative impacts (e.g., retraining for job losses)
- Managerial Reform: Facilitating change within the current economic system, often through social dialogue.
- Structural Reform: Implying institutional change and new governance structures that challenge existing power relations.
- Transformative: Aiming for an overhaul of economic and political systems, seeking alternative development pathways and empowering grassroots movements.

Furthermore, concepts like "energy justice" and "spatial justice" are becoming integral to the discourse. Energy justice considers fairness in energy production and consumption, access, and decision-making, while spatial justice examines the geographical distribution of environmental benefits and burdens, which is highly relevant given Albania's existing urban-rural and regional disparities. The role of local activism, exemplified by movements like "our energy, our rights" in other contexts, highlights the importance of community engagement in shaping just outcomes.

The following table provides an updated timeline of key milestones in the development of the "Just Transition" concept:

Table 1: "Just Transition" Timeline

Year(s)	Milestone
1990s	In the United States, unionists and activists advocate for mechanisms to address job losses from new environmental regulations. The Just Transition Alliance is founded.
2000s	International trade union coalitions introduce the Just Transition concept into global climate discussions, including at COP15 (Copenhagen, 2009).
2011	At COP17 (Durban), South Africa initiates national discussions on a Just Transition framework.
2015	The ILO Guidelines on Just Transition are adopted. The 2030 Agenda for Sustainable Development reinforces the concept, which is officially included in the Paris Agreement (workforce focus).
2018	The Solidarity and Just Transition Silesia Declaration is signed by 50 countries at COP24 (Katowice, Poland), emphasizing fair workforce transitions.
2019	At the UN Climate Action Summit, 46 nations commit to developing Just Transition strategies.
2021	Just Transition gains prominence at COP26 (Glasgow): The Just Transition Declaration is signed. The Global Accelerator on Jobs and Social Protection for Just Transitions is launched. Glasgow Pact expands JT definition.
2022	The IPCC report, High-Level Political Forum (HLPF), and UN Secretary-General's priorities reinforce Just Transition as a key component of global climate action.
2023	UN CDP Plenary discusses JT: emphasizes context-specific approaches, historical responsibilities, global justice. June: World leaders' open letter on "a green transition that leaves no one behind".
2023 (Nov)	ILO Governing Body endorses Global Coalition for Social Justice; establishes working party for 2025 World Social Summit. UNFCCC Work Programme on Just Transition Pathways operationalized.

Source: Authors own readings

Agreeing with Abram et al. (2022), the concept of just transition still lacks a single, unified theoretical definition, partly due to the long-standing debates surrounding "justice" itself and partly due to the ongoing evolution of theoretical perspectives on transitions. For the purpose of this chapter, the focus will be on "purposive transition" and how it manifested in Albania's post-socialist experience and is now re-emerging in the context of the JGT, informed by these richer, more demanding notions of justice

2.2.Defining Purposive transition

Stemming from Petrov's (2014) analysis of the term "transition" and its widespread use to characterize CEE countries, this type of transformation signaled epochal change while simultaneously unfolding uncertain futures for the affected economies.1 The post-socialist transition in the Western Balkans is what Smith, Stirling, and Berkhout (2005) define as a 'purposive transition'. This is characterized by a deliberate goal pursued from the outset of transformation, accompanied by an explicit set of societal expectations and a heavy reliance on external resources, aid, and political orientation. The Transition Management approach, as outlined by Rotmans, Kemp, and van Asselt (2001), draws significantly from this concept, analyzing, among other things, the role of external stakeholders and resources in initiating and carrying out such transitions.

Petrov (2014) further characterizes the post-socialist purposive transition in CEE countries as 'teleological'. In this view, regime change appears "purposeful, preordained, and therefore predictable, virtually unstoppable, and impelled by a future goal," which serves as the "defined end of the transition process" (p.30).1 However, he also notes that these transitions often did not progress along the pathways or towards the goals defined by Western agencies. Instead, the uncertain futures affecting these economies led to the emergence of varying hybrid political models, irrespective of the paths designated by external actors, which typically emphasized privatization, liberalization, and democratization.

This divergence between intended purpose and actual outcome can be attributed, among other factors, to the fact that the transition itself was often not adequately informed by its wider historical context. It was frequently reduced to a singular, joint model to be followed, regardless of the heterogeneity and idiosyncrasies within the region, or, as in this case, Albania's specific circumstances.1 The experience of Albania's post-socialist transition powerfully illustrates how the intended "purpose" can be significantly reshaped or even subverted by local realities, institutional path dependencies, and societal responses.

It is these contextual socio-cultural and territorial factors—what Carothers (2002) termed "the underlying conditions ... the economic level, political history, institutional legacies, ethnic make-up, sociocultural traditions, or other 'structural' features"—that should be meticulously accounted for when furthering efforts towards any new transition.1 These factors are critically important in defining how a potential new transition, such as the JGT, will unfold within a country. Utilizing the Multi-Level Perspective (MLP) framework, these underlying conditions correspond to the socio-technical landscape in which regimes are embedded and continuously change. They encompass the spatial structure of territories, economic growth patterns, social factors, normative values, environmental challenges, potential disasters, and political dynamics.

Spain's Just Transition Strategy (ETJ), approved in 2019, offers a contemporary example of a state-led "purposive" or "managed" transition. It explicitly links national energy and climate plans (PNIEC) with the ETJ to proactively manage socio-economic impacts, aiming to maximize social benefits and mitigate negative consequences of decarbonization.11 This illustrates a deliberate, goal-oriented approach that relies on strategic planning and anticipates socio-economic disruption, hallmarks of a purposive transition. However, the success of such strategies remains context-dependent.

In Albania, these underlying conditions, coupled with fatigue from a stagnating EU integration process, conflicting narratives stemming from the post-socialist era, dominant-power politics, institutional corruption, and deep territorial disparities, have cultivated a sense of a 'never-ending transition'.1 This "transitions fatigue" can significantly complicate the preordained nature often associated with purposive transitions, as public skepticism and institutional inertia may hinder progress towards externally defined goals.

Nevertheless, Albania's history does not suggest an inherent resistance to change; on the contrary, the country has demonstrated an openness to exploring different political, economic, and social trajectories. What has been consistently missing, rather, is a cohesive governance and policy framework capable of structuring and guiding change in a systemic and strategic manner.1 This absence of a clear governance skeleton has historically hindered Albania's capacity to follow a structured transition path. Unfortunately, similar gaps persist in the case of the Just Green Transition, suggesting that even with a clear "purpose" driven by the EU Green Deal, the actual JGT trajectory in Albania could be unpredictable and heavily shaped by its unique underlying conditions and historical path dependencies, risking further disillusionment if not carefully managed and locally embedded.

2.3.Albania's Post Socialist Transition vis a vie the "new" transition(s)

In the Albanian context, the post-1990 transition from a socialist to a market-driven economy exemplifies a regime shift precipitated by external pressures, including the collapse of socialist states in Eastern Europe and Albania's reintegration into global systems.1 Similarly, the current climate imperative under the Just Green Transition (JGT) represents a landscape-level pressure requiring systemic changes to governance, energy systems, and societal behaviors. A comparative lens offers a panoramic view of both transitions, revealing instructive parallels and crucial distinctions.

2.3.1 A retrospective on Albania's Post Socialist Transition

The collapse of Albania's communist regime marked one of the most dramatic transitions in Eastern Europe. This period of profound systemic change saw the country grapple with the challenges of democratization, economic liberalization, and the reorganization of its social and spatial structures. Albania's transition was characterized by political instability, rapid urbanization, economic hardships, and a significant shift in societal values, all of which left (and still has) a lasting impact on its development trajectory.

On a systemic level, Albania's transition was uniquely complex and distinct from that of most European countries. Emerging from one of the most rigidly centralized and repressive communist regimes in the former Eastern

Bloc, Albania's governance had been shaped by an extreme form of autarky, where decision-making was highly centralized, and citizens were systematically excluded from political processes. For 45 years, Albanians were denied fundamental freedoms of speech, religion, and movement, living under an isolationist regime often compared to present-day North Korea in terms of political and economic seclusion.

The shift to a multi-party democracy was turbulent, marked by political instability, frequent government changes, and contested elections, which further eroded public trust in institutions (Biberaj 1999). The adoption of a new constitution in 1998 was a critical milestone, laying the groundwork for Albania's gradual progress toward European integration. Simultaneously, efforts to decentralize governance sought to empower local authorities and promote regional development. However, these efforts were inconsistently implemented, with local governments lacking the necessary resources and institutional capacity to carry out their responsibilities effectively. Corruption and governance deficits further hindered the state's ability to implement coherent policies, fueling widespread public disillusionment with the transition process.

In the same time, the spatial landscape of Albania underwent one of the most profound changes. Under communism, strict migration controls and centralized planning had shaped the country's urban and rural dynamics. The removal of these controls in the 1990s led to rapid urbanization, with cities like Tirana and Durrës experiencing exponential growth as people migrated in search of better opportunities (Bejko 2015). This population surge strained urban infrastructure and services, leading to the proliferation of informal settlements and unregulated construction. At the same time, rural areas were left behind, experiencing depopulation and neglect. The urban-rural divide widened, as rural regions struggled with inadequate access to infrastructure, education, and healthcare. The lack of coordinated spatial planning and governance further exacerbated these inequalities, leaving Albania with deeply entrenched spatial disparities.

Economically, Albania's transition from a centralized to an open-market economy was abrupt and poorly managed. Privatization and liberalization were implemented rapidly but without proper regulatory frameworks, leading to widespread job losses and economic insecurity. The 1990s saw severe financial instability, with hyperinflation, currency devaluation, and the collapse of pyramid schemes in 1997, which devastated household savings and deepened poverty. The private sector remained weak, while remittances became a crucial economic lifeline. Limited foreign investment, weak institutions, and unclear property rights further hindered sustainable growth, leaving Albania's economy fragile and highly dependent on external support.

However, the 2000s saw modest recovery, driven by sectors such as agriculture and later, services and tourism. Remittances from Albanian migrant workers, particularly those in Greece and Italy, became a critical source of income for many households, highlighting the country's dependence on its diaspora for economic stability.

The social fabric of Albania underwent profound changes during the transition. The shift from a collectivist, state-controlled system to an individualistic, market-driven society disrupted traditional social structures. Rising unemployment, poverty, and inequality created a sense of social fragmentation, while mass emigration transformed the country's demographics. Between 1991 and 2001, an estimated 600,000 Albanians emigrated, primarily to neighboring countries. This exodus included a significant portion of the skilled workforce, leading to a brain drain that hindered Albania's long-term development prospects. While remittances provided short-term economic relief, the loss of human capital presented a critical challenge for the country's future.

Normative values also shifted as Albania embraced Western democratic ideals. However, the rapid modernization often clashed with entrenched patriarchal and rural traditions, creating tension between old and new societal norms. The process of adapting to these changes was slow and uneven, reflecting the complexities of transitioning from one ideological system to another.

As a result of all, the rapid urbanization of the 1990s further exacerbated environmental challenges. Under communism, the emphasis on heavy industry and large-scale agricultural production had left a legacy of environmental degradation. Deforestation, soil erosion, and pollution were widespread issues, particularly in industrial and mining areas. Informal settlements and unregulated construction contributed to waste accumulation, air pollution, and water contamination, particularly in urban centers like Tirana.

Meanwhile, the lack of environmental awareness or policies during the early years of transition meant that these issues were largely ignored.

Only by the 2000s, Albania began adopting environmental protection policies, driven in part by its aspirations for EU membership. These efforts included waste management reforms and the establishment of protected areas. However, implementation and enforcement remained weak, and significant gaps persisted in aligning environmental governance with sustainable development goals.

Additionally, starting with the signing of the Stabilization and Association Agreement with EU- 2006/2007, following with the NATO integration (2009), and in 2014 gaining the EU candidate status, Albania was offered a trajectory for integration into the European Union, a commitment for which the country is still working on. This process, however, again consists of a prescribed list of structural and political reforms (Commission 2018), that despite the financial and technical support provided, only recently has gained a new momentum, with the opening of negotiations for few of the chapters in 2024.

Table 2: Economic Context of Albania: Indicators.

Main Indicators	2023 (E)	2024 (E)	2025 (E)	2026 (E)	2027 (E)
GDP (billions USD)	22.82	26.13	27.99	29.92	31.85
GDP (Constant Prices, Annual % Change)	3.5	3.3	3.4	3.5	3.5
GDP per Capita (USD)	8,299	9,598	10,386	11,211	11,938
General Government Gross Debt (in % of GDP)	59.8	58.3	57.0	56.2	55.5
Inflation Rate (%)	4.8	2.2	2.4	2.6	3.0
Unemployment Rate (% of the Labour Force)	10.7	10.7	10.7	10.7	10.7
Current Account (billions USD)	-0.29	-0.21	-0.28	-0.36	-0.22
Current Account (in % of GDP)	-1.2	-0.8	-1.0	-1.2	-0.7

Source: IMF – World Economic Outlook Database, October 2021

To conclude, Albania's transition has unfolded (and still is) through three distinct yet interconnected phases: the political and ideological shift from a rigid monist system to pluralism and democracy in the 1990s, the economic transformation from a centralized economy to a market-driven system in the 2000s, and the ongoing transition towards European and global integration over the past two decades.

At a global scale, Albania's transformation aligns with the major historical transition shifts of the post-war world: first, the Cold War era (1945–1989), which was dominated by the ideological and security struggle between the USA and the Soviet Union; second, the post-Berlin Wall period (1989–2006), which championed neoliberalism, human rights, and environmental concerns under a USA-led global economic order; and third, the post-2006 global recession era, marked by the decline of liberal interventionism and the rise of digital economies, geopolitical realignments, and increasing global competition between the Western alliance (USA/NATO) and emerging powers such as China and BRICS nations.

Albania's trajectory reflects both the opportunities and contradictions inherent in these transitions. While political pluralism, economic liberalization, and EU integration efforts have set Albania on a progressive path, deep-rooted governance weaknesses, institutional inefficiencies, and socio-economic disparities have hampered its ability to fully capitalize on the benefits of transition. Unlike many post-socialist countries in Central and Eastern Europe, Albania has not undergone a linear or structured transformation, but rather a fragmented and often reactive adaptation to shifting global trends.

As the country now navigates the challenges of sustainable development and green transition, it faces yet another test of its institutional resilience and governance capacity.

2.3.2 Contextualizing the JGT in Albania

While Just Green Transition concept and approaches are embraced at a global level, the process towards this transition in the WBs is progressing at a very slow pace and little is done in regard to societal preparedness for JGT.

In Albania, contextualizing JGT (let aside conceptualization of it) is rather a complex task. Apart from requiring the involvement of several stakeholder and institutions from all countries in the region, both contextualization and conceptualization process is faced with the (i) theoretical gaps that subsist in the definition of basic concepts such as transition and justice, for which we try to navigate in the aforementioned chapter and (ii) lack of awareness in understanding the process it requires or the policy overview specter and the place based empirical evidences such transitions bring to the societal level.

The JGT, both as a concept and as a policy framework, is being introduced in the Balkans via the Green Agenda for the Western Balkan (GAWB). Formalized in 2020 with the Sofia Declaration, the GAWB is the basis for a new growth strategy for the region, embedded in the EU Economic and Investment Plan for the Western Balkans. The same year, during the Berlin Process Summit in Poznań, the WB Leaders (Albania's included) expressed their common willingness and readiness to meaningfully contribute to an ambitious Green Agenda.

This entails the adoption of EU directives and transposition of regulation across policy areas and on a wide range of issues, from climate law, meeting energy efficiency goals, air and water quality standards, to the waste management framework, limiting pollution, increasing circularity, etc. This first step needs to be followed by implementation, leading to 'real', tangible change in all industrial/economic sectors. Despite initial enthusiasm, the Western Balkan countries continue to lag behind the EU in their efforts to combat, mitigate, and adapt to climate change. This shortfall stems not only from inadequate progress in implementing climate actions but also from the absence of a comprehensive, integrated approach that transforms both national and regional policies into climate-sensitive frameworks capable of addressing the multifaceted challenges of environmental sustainability.

Reaching the aforementioned goals cannot be accomplished overnight, as the implementation of such an ambitious agenda comes with multifaceted implications across social, environmental, economic, financial, technological, and even [geo]political dimensions. These complexities present significant challenges both regionally and nationally, primarily rooted in the lack of political commitment to improve or transform policies and insufficient financial resources to support basic services and economic activities, let alone the additional costs required to foster or nourish innovation.

2.4. Emerging Challenges & Opportunities

For countries like Albania, embarking on the Just Green Transition (JGT) is not without significant challenges. Indeed, as continuously argued, it is particularly demanding for a nation still grappling with unaccomplished prior transitions—towards a consolidated democracy, robust governance, full EU integration, and widespread economic prosperity—to envision re-entering a new transition, albeit one with a different meaning and magnitude.

A primary hurdle is a mentality barrier, deeply connected to a stigmatized perception of "political transition." This skepticism stems from both the prolonged duration of past transitions and their often-ambiguous outcomes, which have included hybrid post-authoritarian regimes that diverged from the initially proclaimed objectives of market capitalism and liberal democracy. Over the past few decades, the promises of transitioning to a liberal democracy, a free-market economy, and eventual EU membership sparked high expectations. However, many citizens have become disillusioned by the inadequate performance of implemented economic and social policies and the uncertain future these have created. This situation, as argued in a related Policy Brief 1, has produced a pervasive 'transitions fatigue'. This fatigue manifests as a general sense of skepticism, or even mistrust, towards policies perceived as prescribed by external entities, as well as towards the capacity of the domestic political class to design and implement comprehensive, effective, and place-sensitive policies.

This pre-existing skepticism makes the JGT, another complex and potentially disruptive transition, particularly vulnerable to public resistance or apathy.

Overcoming this fatigue requires exceptional efforts in transparency, genuine participation (embodying procedural justice), and delivering tangible, equitable benefits early on to rebuild trust.

A second critical challenge for just transitions is securing adequate funding and resources and ensuring their fair and just allocation and distribution. The financial burden of the JGT—encompassing investments in green technologies, infrastructure upgrades, reskilling programs, social safety nets for affected communities, and support for economic diversification—is substantial. For Albania, with its limited fiscal space (as can be inferred from its economic indicators 12), meeting these costs domestically is a formidable task. This challenge is compounded by the financial risks inherent in transitions that involve phasing out "sunset" industries, which may lead to stranded assets and significant economic write-downs.3 Consequently, a heavy reliance on external funding, primarily from the EU and international financial institutions, is likely. While such funding is crucial, it can also perpetuate the "purposive transition" dynamic, where external agendas and conditionalities might overshadow local priorities or fail to ensure equitable distribution, thereby undermining the "just" component of the transition if not carefully negotiated and nationally owned.

Furthermore, the JGT will inevitably have significant impacts on workers, communities, and consumers. These arise from the transformation of involved sectors in terms of technologies employed, guiding policies, employment opportunities (both creation and loss), and the affordability of new green services and products. The evolving understanding of "just transition" now explicitly includes a broader array of societal groups beyond the traditional focus on the industrial workforce, such as women, youth, low-income households, and other vulnerable communities. Addressing these diverse impacts requires comprehensive strategies. Serbia's Just Transition Roadmap, for example, details measures for welfare support, extensive reskilling programs, and robust economic diversification plans for its coal-dependent regions, offering concrete examples of how such impacts can be proactively managed. These efforts to secure funding and mitigate negative impacts extend to entire territories, affecting the quality of life across personal and ecological spheres, from basic life enablers to dimensions of human flourishing.

In this challenging context, without significant, internally driven efforts to foster transformation, the Just Green Transition, advanced through the GAWB, risks becoming yet another unfulfilled promise in Albania's long history of transitions. Moreover, the burden of action – or, critically, inaction – could disproportionately fall on the most vulnerable segments of society, exacerbating existing inequalities and creating new ones.

However, addressing these challenges thoughtfully also presents opportunities. Effective and genuine stakeholder engagement, drawing lessons from initiatives like Serbia's extensive dialogue processes or the co-creation models used in Open Government Partnership local action plans, can build crucial trust, foster a sense of ownership, and improve policy design and legitimacy. Successful economic diversification in affected regions, as planned in Serbia, can create new, sustainable livelihoods and resilient local economies. Additionally, the emergence of frontier technologies such as artificial intelligence, advanced robotics, and biotechnology holds potential for sustainable development and green innovation. Yet, this too is a double-edged sword: these technologies could become powerful enablers of a green transition if managed for inclusivity and equitable access, but they also carry the risk of increasing inequalities and creating new digital divides if their deployment is not carefully guided by principles of justice. The key lies in harnessing these opportunities proactively to ensure the JGT is not only green but also genuinely just and contributes to a more resilient and equitable future for Albania.

2.5. Conclusions

The journey towards a Just Green Transition (JGT) in Albania is situated within a complex tapestry of historical legacies, ongoing transformations, and evolving global imperatives. Definitions of JGT vary, but there is widespread recognition of the importance of context-specific analysis and strategies. Today, "just transition" generally refers to strategies, policies, or measures designed to ensure that no one is left behind or pushed behind in the shift to low-carbon and environmentally sustainable economies and societies.

This concept, with origins in trade union activism focused on job losses from environmental regulations, has expanded significantly. As more countries and a broader range of stakeholders engage with the challenge, the definition now often incorporates diverse dimensions of justice—distributive, procedural, and even restorative

or transformative—and addresses impacts on a wide array of social groups beyond the workforce.1 The ILO's 2015 Guidelines defined just transition as "greening the economy in a way that is as fair and inclusive as possible to everyone concerned, creating decent work opportunities and leaving no one behind," emphasizing social dialogue, rights at work, gender equality, social protection, skills development, and international cooperation.1 Approaches now vary from status quo compensation to deeper transformations of political and economic systems aimed at correcting historical inequities.

Landing the narrative of a "new" transition in a country like Albania, which has been subject to several profound and often disruptive transitions throughout its recent history with questionable levels of success, remains a key concern. In these circumstances, the term "Just Green Transition" is, so far, often used as a buzzword, without fully generating the necessary societal awareness of the scale and transformative nature it implies.

The post-socialist transition, marked by abrupt shifts in governance, economy, and societal norms, left Albania grappling with systemic challenges, including persistent governance deficits, deep-seated social inequalities, and significant environmental degradation. These challenges have forged a legacy that continues to shape the country's capacity to undertake new, large-scale transitions. The JGT, much like the transitions that preceded it, is not merely a technical or economic transformation—it is a systemic, cross-sectoral, and profoundly societal process. However, unlike past transitions, the JGT carries the added urgency of addressing climate change and the imperative of achieving sustainability in a manner that is explicitly just and equitable. The enriched theoretical understanding of transitions, including critiques of the Multi-Level Perspective that call for greater attention to socio-political agency and multi-level governance, further underscores the complexity of steering such change.

At its core, the JGT represents both a significant opportunity and a critical test of Albania's resilience and readiness to embrace transformative change. The lessons from the post-socialist era—particularly the crucial importance of participatory governance, equitable policy frameworks, and robust, accountable institutional capacity—offer valuable insights for navigating this new transition. However, these lessons also highlight persistent risks, such as political inertia, a lack of societal preparedness exacerbated by "transitions fatigue," and the uneven distribution of resources and opportunities. Albania faces a "double challenge": the universal technical and economic hurdles of decarbonization compounded by the profound contextual difficulty of implementing such changes within a legacy of weak governance and societal mistrust.

For Albania, the success of the JGT will hinge on its ability to balance ambitious environmental goals, largely driven by the European Union's Green Agenda for the Western Balkans (GAWB), with the socio-economic realities of its population. This requires not only adopting EU directives but, more importantly, tailoring them to the country's unique context, learning from both its own past and the experiences of other nations in transition. The emphasis must be on fostering inclusive policymaking, strengthening institutions from the ground up, and bridging the urban-rural and other socio-spatial divides to ensure that no community is left behind.

Moreover, the concept of "justice" in the JGT must be operationalized beyond rhetorical commitments. It must translate into tangible actions that address existing inequalities and prevent new forms of exclusion. This involves providing targeted support to vulnerable groups, investing in education and awareness to build societal readiness, and creating robust mechanisms for meaningful stakeholder participation in all stages of decision-making processes.1 The forthcoming requirement for countries to detail their just transition strategies in their Nationally Determined Contributions (NDCs) by 2025 presents a critical opportunity for Albania to articulate a comprehensive, time-bound, and genuinely inclusive plan.

As this chapter has demonstrated, the JGT represents a critical juncture for Albania. It is an opportunity not only to align with global sustainability goals but also to redefine its development trajectory in a way that prioritizes environmental stewardship, social equity, and economic resilience. However, achieving this vision will require a concerted, coherent effort across all levels of governance, active engagement from civil society, and effective international cooperation that respects national ownership and context.

In conclusion, while Albania's journey toward a Just Green Transition is fraught with challenges, it also holds the promise of a more sustainable and equitable future. This transition must be understood not only as a national process but also within the broader framework of global climate justice and the principle of common

but differentiated responsibilities and respective capabilities, a point underscored by recent international discussions.1 Unlike high-income countries, many middle- and low-income nations, including Albania, grapple with high poverty rates, informal labor markets, limited institutional capacity, and restricted fiscal space, making the balance between economic stability, social equity, and environmental commitments particularly complex.

Therefore, the JGT should not be reduced to a mere technical exercise or a rhetorical commitment; it must translate into concrete measures that build resilience, empower local economies, and ensure social inclusion. Learning from past transitions, Albania must focus on creating sustainable economic alternatives, investing strategically in education and skills development aligned with future needs, and establishing transparent and effective mechanisms for meaningful stakeholder engagement. Further research is warranted on several fronts: exploring the political economy of JGT in contexts of "transitions fatigue"; conducting comparative analyses of JGT implementation in post-socialist Balkan states, focusing on governance models and stakeholder participation; assessing the effectiveness of different JGT policy approaches (from status quo to transformative) in specific Albanian sectors; and examining the role of frontier technologies in Albania's JGT, particularly their potential benefits and risks for equity. Only through a comprehensive, context-sensitive, nationally owned, and globally informed approach can Albania navigate its Just Green Transition successfully, ensuring that it does not become yet another unfinished transformation in its complex transition history.

Redeveloping military land into affordable housing through a public-public partnership. The case of Valladolid's La Rubia barracks

Abstract
This study examines the complex challenges inherent in the public-public partnership established by the Spanish government in 2023 between SEPES and the Ministry of Defence. The primary objective of this partnership is to repurpose decommissioned military sites for affordable housing, thereby fostering socially equitable urban regeneration. The transformation of these areas would necessitate enabling specific institutional aspects of planning governance (i.e. the rules, laws, and procedural requirements), as well as the possibilities opened by community practices and actors (co-)operating within these structural settings. By scrutinise the case of Valladolid's La Rubia barracks, the research uncovers the complex interplay between the stakeholders involved if ways forward are to be found in challenging the institutional capacity to achieve the public interest.

Keywords: urban regeneration; urban governance; institutional capacity; public interest; land-use planning.

Introduction

In recent decades, the progressive demilitarisation of certain territories, including Spain, has resulted in a significant amount of land left underused or abandoned by the Ministry of Defence (MoD). These include different kinds of facilities (e.g., barracks, batteries, manoeuvre fields, and warehouses) spread across the territory, located in urban, peripheral and non-urban sectors, so their management has become a subject of increasing debate in the fields of territorial planning, urban sustainability and democratic governance (Touchton and Ashley, 2019). Due to the difficulties tied to the redevelopment of such land, often conceptualised as specific type of brownfields (Bednář et al., 2024), the institutional capacity of performing appropriate solutions for enabling urban regeneration processes plays a remarkable role to foster appropriate sustainable urban development (Ural & Severcan, 2022).

A solution for triggering public benefits from disused military land and unlock many initiatives currently in stand-by, the Spanish Government launched in May 2023 an innovative public-public partnership (Ministerio de Transportes, Movilidad y Agenda Urbana, 2023a). It regards the collaboration between two state entities, SEPES[1] and the MoD, for devoting currently abandoned military facilities for residential use, particularly aimed to increasing the presence of affordable housing across the country[2]. The initiative encompasses the redevelopment of 8.25-million-m^2 50 MoD-owned assets, facilitating the construction of 19,876 affordable housing units in 34 municipalities within 15 of Spain's 17 Autonomous Communities (Figure 1), with an estimated public investment of €620 million. This project aligns with the broader state-led "Affordable Rental Housing Plan," which seeks to utilize public land for social housing development, ensuring equitable access to adequate housing as enshrined in the Article 47 of the Spanish Constitution[3]. The implementation of this specific public-public partnership entails the transfer of MoD land to SEPES, which is responsible for enabling participatory and inclusive land readjustment while integrating private-sector stakeholders into the redevelopment process.

1 SEPES is the State Public Land Entity, Entidad Estatal de Suelo in Spanish, was launched in 1965 and it currently depends on the Ministry of Housing and Urban Agenda.

2 This partnership, in turn, derived from the 2022 agreement between MITMA and SEPES to promote a national plan for affordable or social rental housing named "Affordable Rental Housing Scheme (Plan de viviendas para el alquiler asequible) (Ministerio de Transportes, Movilidad y Agenda Urbana, 2022).

3 Article 47 states "All Spaniards have the right to enjoy decent and adequate housing. The public authorities shall promote the necessary conditions and establish appropriate standards in order to make this right effective, regulating land use in accordance with the general interest in order to prevent speculation. The community shall have a share in the benefits accruing from the town-planning policies of public bodies" (Senado de España, 2024).

Successively, private investors are predicted to intervene to implement the project within the planning guidelines established for the former military land.

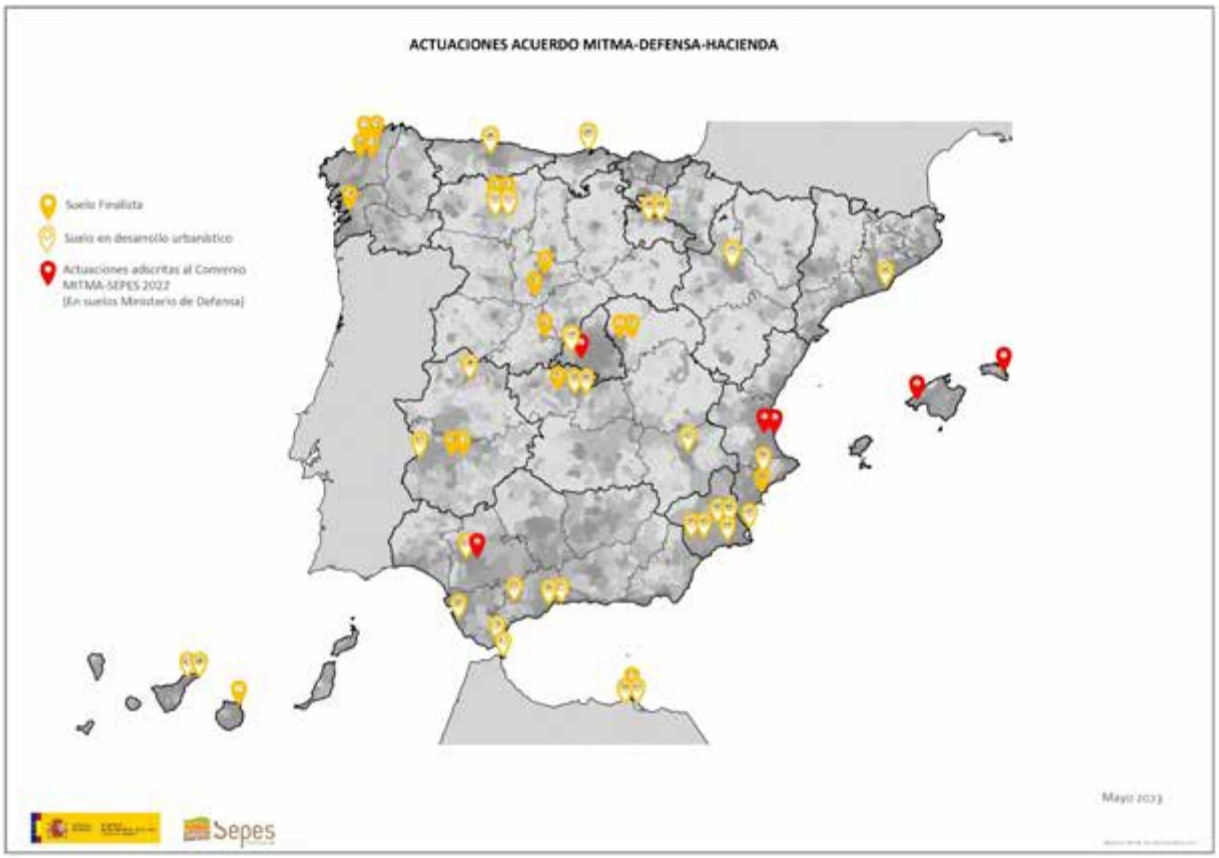

Figure 1. The map of the (*suelo finalista* is "land ready for urban development", *suelo en desarrollo urbanístico* is "land with ongoing urban development works", and *actuaciones adscritas al Convenio MITMA-SEPES 2022* corresponds to actions tied to the 2022 MITMA-SEPES agreement). Source: Ministerio de Transportes, Movilidad y Agenda Urbana (2023b).

This partnership constitutes a novel and paradigmatic example of how institutional capacity and the public interest can –and should– be articulated in the management of state assets, especially for the abandoned land that can be repurposed into sustainable and socially equitable housing solutions. This is even more urgent in the context of mounting territorial imbalances across Spain (Adalet McGowan and San Millán, 2019), along with real estate pressures and widespread challenges to accessing housing (Bonshoms-Guzmán, 2023).

In this context, both SEPES and the MoD occupy a position of considerable influence within the state apparatus, as they are equipped with legal, technical and financial resources that enable them to intervene in the territory with a strategic planning logic. Nevertheless, this capacity is neither uniform nor free of tensions, as it operates within a complex legal framework and in an ecosystem of actors, including local administrations, autonomous communities, private promoters and social entities, with diverse and sometimes conflicting interests. For instance, After the Spanish Ministry of Transport, Mobility, and Urban Agenda (MITMA) converted into the Ministry of Housing and Urban Agenda (*Ministerio de Vivienda y Agenda Urbana* in Spanish, MIVAU) in 2023, SEPES underwent a reorganisation process to become the State Public Land and Affordable Housing Entity focused on converting unused public land into public housing stock, which is still ongoing (SEPES, 2025). The consequence of this long-standing process is the delay in the implementation of the property transfer of the military land, thus undermining urban governance capacity (Healey, 1998).

The institutional capacity and the achievement of public interest in the conversion of military land into affordable housing

The 'institutional capacity' –i.e. the capacity of public administrations to effectively manage resources, coordinate actors and plan for the long term land-use of territories– has been identified as a determining factor in the success or failure for achieving the public interest in the conversion of military land to civilian uses (Ponzini and Vani, 2014). In Spain, this capacity has been affected by various structural factors, including the fragmentation of powers between administrations, the rigidity of regulations on state property and urban planning, and the absence of mechanisms for citizen participation in decisions regarding the utilisation of these lands after the military abandonment (Camerin and Córdoba Hernández, 2023b; De las Rivas Sanz, 2023).

One of the challenges of the institutional capacity is defining what 'public interest' is (Cassinelli, 1958) and this problem lies at the core of planning theories, addressing the fundamental question of the purpose and function of planning (Mazza, 1990: 48). However, the notion of the public interest is challenging to define (Moroni, 2004). Alongside the often interchangeably-used concepts of 'public good' (Deneulin and Townsend, 2007) and 'common good' (Mansbridge, 2013) the public interest can be understood as an essentially contested concept, "vague, imprecise and open to political manipulation" (Jade, 2017: 2).

By translating this to the real of military land to convert into new civilian uses, the public interest is thus manifested in the need to ensure that the redevelopment of military facilities responds to collective objectives, such as the provision of public equipment and services, the creation of affordable housing, the protection of the environment or the promotion of cultural and social activities. However, as demonstrated at both national and international level, a mercantile logic has been prioritised in these operations, driven by the search for fiscal profitability or market-oriented real estate operations (Christophers, 2018; Adisson and Artioli, 2020). This orientation has given rise to tensions with local communities, particularly in instances where opportunities to address social needs have been overlooked or spaces of high strategic and symbolic value have been privatised (Camerin, 2021).

These tensions are also at the centre of the debate between the supposed public/private dichotomy on temporalities, according to which the private sector's short-termism hinders public policy delivery, which should be all about long-term goals (Noring, 2019). However, despite the long-term goals of politicians in democratic regimes, it is important to acknowledge that these politicians are also constrained by the need to focus on short-term political goals. Such shortsighted behaviour and susceptibility to influences that go against long-term interests of the society often exacerbate the process associated with urban developments, whose process encompasses the timely execution of key tasks, including the endorsement of contracts, the initiation of projects, and the attainment of significant milestones (Hodge and Greve, 2019). This is imperative to ensure the timely delivery of planning-related programmes and the minimisation of procedural delays, which in turn will facilitate the mobilisation of the electoral support.

This is not only matter of political support, because it is pivotal to attract the private sector to the provision and management of affordable housing with an adequate balance of interests with the public sector (Canelas and Alves, 2024). This is true also for the case study of La Rubia barracks as the SEPES-Mod partnership targets the land ownership, but the redevelopment will involve private stakeholders, who will be responsible for the delivery of the project. As observed by Granath Hansson (2019), to guarantee a functional relationship, it is essential that adequate risk-return is offered to private actors to converge public and private interests, which significantly impacts delivery capacity. However, perceptions of risk-return vary due to several internal and external factors, such as the relationship between the public authorities involved and their continuous reorganisation (Adams and Tiesdell, 2010). Another salient issue is the correlation between policy stability and the attraction of private investment. The positive correlation that has been identified is partly explained by reasons related to investment planning, as well as by the upfront costs of learning to navigate new regulatory and fiscal frameworks (Raco, Livingstone and Durrant, 2019).

Methodology

The paper adopts a case study methodology to examine the changes occurred after the launch of the SEPES-MoD partnership in 2023 by the Spanish Government for the provision and management of affordable housing in the case of La Rubia barracks in Valladolid. We choose this case for three reasons. Firstly, although its innovative governance arrangement, that of a partnership between two public entities, this partnership has generated poor interest in the national and international literature. The analysis of this specificity can be relevant to understand the ways this partnership work and its impact on a specific case study. Secondly, the level of interest and

controversy this partnership generated in the public arena, as the state-led decision that may enter in conflict with Valladolid's spatial plan and the already settled agreements or procedures involved the redevelopment of the military land. Eventually, for reasons to do with data access and to keep updating the situation about La Rubia barracks after an initial attempt to approach this case study (Camerin and Córdoba Hernández, 2023a). A comprehensive understanding of the various objectives and timelines of the different stakeholders, and the manner in which these were influenced by each other, offers invaluable insights that transcend local idiosyncrasies, particularly with regard to institutional capacity, the concept of public interest, and the objectives and timelines of key stakeholders. The insights derived from this case study have the potential to inform the discourse surrounding the governance converting abandoned military land into affordable housing, thereby contributing to the enhancement of affordable housing delivery practices in the case of La Rubia and other contexts.

This paper draws on the semi-structured interview conducted in presence between January and April 2025 with two spokespersons of each Valladolid City Council, SEPES, Senate and the local grassroots association "La Rubia", culminated with the roundtable "Barracks in transformation: an opportunity for the La Rubia neighbourhood" (*Cuarteles en trasformación: una oportunidad para el barrio de La Rubia* in Spanish) held at the University of Valladolid on 24th April 2025. Additionally, through desk-based research, we identified relevant legislation and other policy documents (e.g., the 2020 general master plan, the so-called *Plan General de Ordenación Urbana* in Spanish; PGOU), including meetings from the executive and deliberative Valladolid City Council, and other material from media outputs. We identified our research participants by targeting the main bodies involved in the management of the barracks at state and local level, along with local citizens. This constitutes the basis for the interpretation of the redevelopment process before and after the launch of the SEPES-MoD partnership in 2023 to identify the impacts it has had on La Rubia barracks transformation. In particular, we categorised the information acquired on the case study in five main themes. They are the following:

- General characteristics of the barracks. Here not only the specific features of the case study are provided, but also the abandonment process the current state of the plot, the buildability, as well as the triggering factors of the redevelopment processes, such as their respective locations in the real estate market;

- Conflicts between the actors involved, including the owner (i.e. the MoD), the City Council and the citizens, even their different interests regarding new uses;

- Definition of the redevelopment costs for the public for the municipal coffers and/or derived from its environmental rehabilitation;

- Temporal evolution of the disposal process according to well-defined stages, agreed with the interested parties and framed in the context of the real estate market.

- What has happened after the launching of the SEPES-MoD partnership for converting La Rubia barracks into new affordable housing compounds.

General characteristics

La Rubia barracks, built in 1945, is situated in a predominantly residential urban sector of Valladolid, between the railway line and the Paseo de Zorrilla Avenue, in close proximity to the city's southern inner ring road VA-20 and the Vallsur shopping centre. The barracks are located within an area characterised by high-density development, with a density of 109.80 dwellings per hectare, with two primary categories of housing: closed blocks and open buildings. The neighbourhood population reaches 8,716 individuals with an average per capita income of €16,341, as reported by the National Statistics Institute (INE) for the year 2021.

In 2007, there was speculation that the barracks would be closed in 2011 and that between 500 and 700 dwellings would be built, of which 30% would be designated as social housing (Álvarez, 2007; Álvarez & Alrrúe, 2011). However, the military personnel belonging to the *Agrupación de Apoyo Logístico* nº 61 Operational Logistics Support Unit officially abandoned the barracks only in December 2014, being relocated to the military base "El Empecinado" in the surrounding municipality of Santovenia de Pisuerga. This displacement occurred in accordance with

the provisions of the PREPIDEF[4], which expected to benefit the military spending by saving €490,243 per year (Ministerio de Defensa, 2013b: 45). The situation of abandonment has persisted until the present day, resulting in the degradation of the built and open spaces within the military enclosure (Figure 2).

Figure 2. A view of the inside spaces of the military enclosure from outside. Source: photo by Federico Camerin (2025).

The surface area of the former barracks (106,866 m^2) corresponds to approximately one third of that of La Rubia neighbourhood (366,475 m^2). According to the current Valladolid's spatial plan approved in 2020 (Comunidad Autónoma de Castilla y León, 2020, pp. 2445-2447), the strategic importance of this urban void in La Rubia neighbourhood makes it a significant opportunity for territorial stitching on a city scale. In this particular instance, the barracks are located within the Urban Unit[5] no. 30 "La Rubia" (Comunidad Autónoma de Castilla y León, 2020: 19223-19226) and are conceived as the proper opportunity to improving the area to connect two relevant road axis currently separated by the disused military land, i.e. Paseo de Zorrilla and Carretera de Rueda. According to the 2020 PGOU, this strategic positioning facilitates also the introduction of new residential uses, tertiary activities and facilities, thereby generating a novel urban fabric comprising roads and pedestrian and coexistence roads.

4 The MoD set up in May 2013 the "Proposal for the rationalisation and efficient use of MoD estate" (PREPIDEF) to gradually abandon 163 sites in two steps, between 2014 and 2017 and 2018–2024 (Comisión de Defensa, 2013).

5 According to Article 85 of the Regional Planning Regulations (Reglamento de Urbanismo de Castilla y León in Spanish; Comunidad de Castilla y León, 2004), the 2020 PGOU incorporates the Urban Units as an instrument for urban regeneration. Urban Units permit a detailed approach to each part of the consolidated city, quantitatively and qualitatively specifying its urban planning parameters. By doing so, this facilitates the evaluation of actions that are executed in accordance with the PGOU, or that are proposed as modifications to it in the future.

Land-use planning and conflicts

There has been a notable change of opinion on the future of the old barracks on the part of the military that have accepted the unilateral decision taken by the City Council to assign a new use to the military land in the 2020 PGOU without a process of public participation nor with the residents or the MoD. Yet, there has been no demonstrations, protests or occupations of the area by citizens.

The 2020 PGOU classified the barracks as *suelo urbano no consolidado* (unconsolidated urban land) "SE(r).30.01 Acuartelamiento La Rubia" and as a *sector con ordenación remitida* (sector with remitted development) (Figure 3). This means that the 2020 PGOU establishes the overarching planning determinations (e.g., buildability and number of housing units), but the specific details remain to be delineated by a detailed plan, such as a special plan (*plan especial de ordenación urbana*) or a detailed study (*estudio de detalle*).

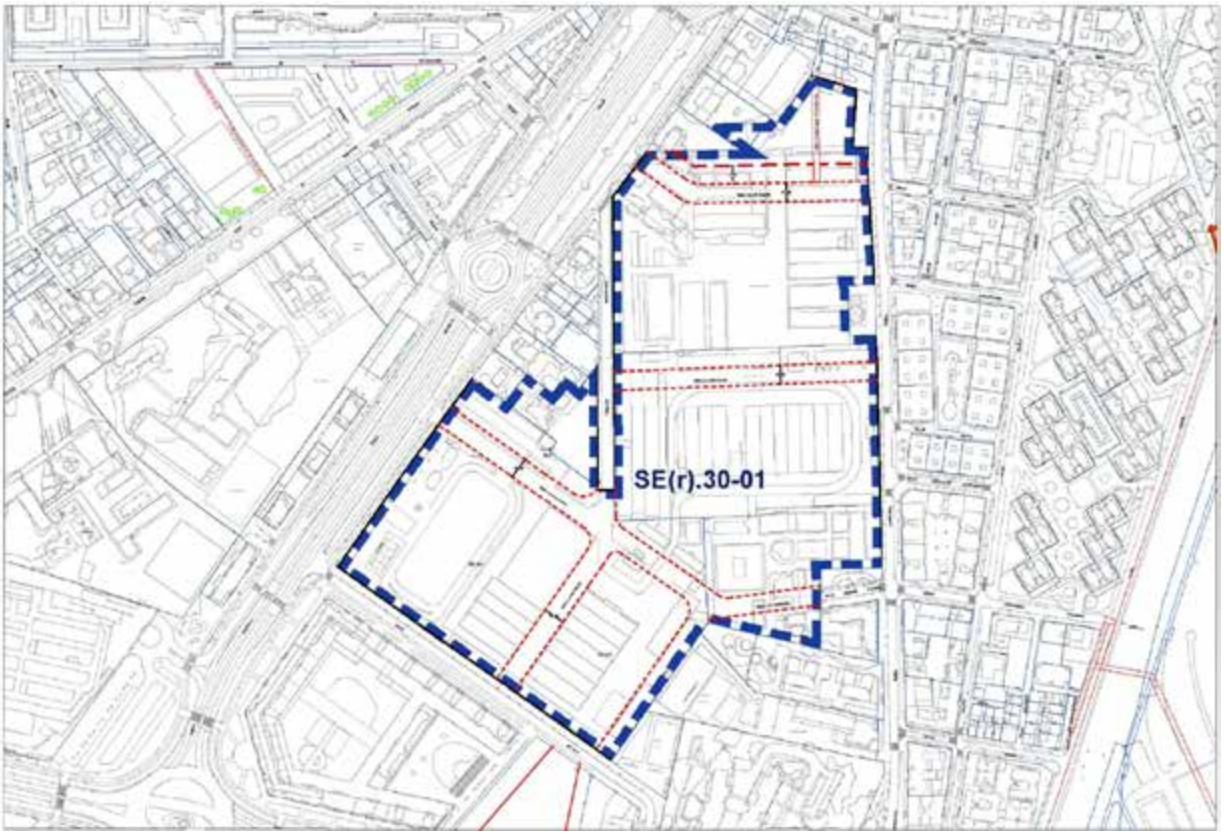

Figure 3. An image of the SE(r).30.01 Acuartelamiento La Rubia. Source: Comunidad Autónoma de Castilla y León (2020: 20456).

The objectives and criteria outlined in the 2020 PGOU included the establishment of new roads and pedestrian zones, with the intention of fostering social cohesion through mixed uses, mostly residential and productive. Three are the main contents. Firstly, the spatial plan establishes a new buildability of 64,119.53 m^3, of which 50% would be used for new 338 housing units. Of this amount, 70% will be designated as free housing (22,441.83 m^3), while the remaining 30% will be allocated for affordable housing (9,617.93 m^3). The remaining buildability (25,647.81 m^3) is earmarked for tertiary uses, including commercial and office spaces (Ministerio de Defensa, 2022, p. 14). Secondly, the developer obligations to transfer a part of the barracks to the City Council for local services (*cesiones mínimas de suelo para sistemas locales* in Spanish). A total of 6,411.95 m^2 of land would be devoted to a new equipment or facility, and 9,617.93-m^2 land to new uses –whether for additional housing or for other purposes– yet to be delineated by the local administration.[6] Eventually, the developer obligations in terms of land transfer for general benefits at city level (*sistemas generales exteriores, adscritos al sector* in Spanish) reaches 60,319.40 m^2 to locate not within the barracks' surroundings,

6 According to the Regional Planning Regulations, the total amount of new open public spaces will be at least 14 m^2/100 m^3 (art. 105), and 10 m^2/100 m^3 (art. 106) for public facilities.

but rather assigned to the "EL 05/24 Riberas del Pisuerga-Soto de Medinilla-Michelín" sector.

The MoD initially rejected these guidelines in May 2019 as the buildability was considered too low (Comunidad Autónoma de Castilla y León, 2020, 18684) but eventually accepted it in June 2020 (Comunidad Autónoma de Castilla y León, 2021, 15953) and, in turn, provides for a period of eight years to establish the detailed planning, i.e. 2028.

Redevelopment costs definition
The MoD is still to provide an adequate detailed analysis with regard to the current state of the buildings and open spaces inside the enclosure of La Rubia barracks (Ministerio de Defensa, 2022b, 4-5). The MoD's report provides unclear indications regarding the presence of polluting elements from an environmental point of view and the definition of rehabilitation costs of existing buildings. Furthermore, no study on the potential opportunities for preserving existing buildings has been considered, nor an overall analysis of the redevelopment costs.

With regard to the presence of pollution, the barracks contain buildings potentially at risk, although not quantified in terms of surface area. These include a petrol station with two buried fuel tanks, two elevated water tanks, one buried water tank, seven buried fuel tanks (including those of the petrol station), a semi-buried shooting gallery for testing with a single shooter's post, and some of the roofs of the buildings are made of asbestos-containing fibre cement slabs.

With regard to the presence of buildings earmarked for preservation, none of the existing buildings, which collectively occupy a surface area of 42,434 m^2 and range in height from one to two floors, are not listed nor considered to be protected from demolition. Many of these buildings are in a state of disrepair, necessitating comprehensive rehabilitation measures, unless their demolition is deemed the more feasible option. The 2020 PGOU proposes the demolition of these structures for the purpose of facilitating the redevelopment of the sector. Moreover, the barracks is also surrounded by a concrete block wall, which is to be demolished in order to facilitate the permeability with the urban fabric. The process of obsolescence of the buildings and shortening of their life cycle has not yet reached the point of being declared a ruin, and the area is not yet affected by notable processes of renaturalisation.

Temporal evolution
The absence of a definitive and collaboratively designed temporary programme can be attributed to the speculative approach adopted by the MoD, whose strategic intentions were evident in the retention of land that had become redundant for military purposes. The owner, in fact, waited for the City Council to approve a land-use change of the area in the new spatial plan to provide the military with the highest possible financial returns. The objective of maximising profits was made clear since October 2019, when the military organised a meeting with local businessmen to present the ways in which La Rubia could be exploited (No Author, 2019). The primary option discussed was a direct sale in the real estate market, with the secondary options of temporary assignment or rental due to the high payment that the potential buyer would have to face in a not particularly positive period for the real estate market.

However, the main challenge confronting the operation appears to be the absence of interest on the part of private entities and the paucity of public funding to develop the real estate project, as it is anticipated to be less lucrative than the one proposed in the initial conversion advances of a decade ago. As a matter of fact, from the supposed 500-700 new housing units, the 2020 PGOU established the building of just 338 dwellings. This lack of interest is being confirmed by the failure of the first auctions promoted by the MoD, published on 5 July 2022, with a bidding price of €8,280,948.74 (Ministerio de Defensa, 2022a: 33151). By the stipulated deadline of 7 September, no tenders had submitted for the barracks (Arrúe, 2022), consequently resulting in a decrease of the bidding price for the subsequent auction to €7,452,853.87.

The SEPES-MoD partnership and how it affects the redevelopment of La Rubia barracks. What's next?
In mid-June 2023 there has been various novelties having an impact on the redevelopment process. Firstly, on 6th June 2023, the MoD received a request for a direct sale from a private individual equivalent to the amount set in the second auction. In the subsequent days, on 23rd June, the applicant was notified that the transaction could not be executed because the property was included in the agreement of the Council of Ministers of 9th May 2023 for its

sale to SEPES (Estrada, 2025). Secondly, following the establishment of the new Spanish government in July 2023, the MIVAU was formed and SEPES, as it depends directly on MIVAU, has since been in a process of reconfiguring its teams and strategic priorities. Thirdly, in May 2023 the new grassroots association "La Rubia" (*Asociación vecinal La Rubia* in Spanish) was constituted. The impetus for this initiative stemmed from the necessity to revitalise the neighbourhood, necessitating the mobilisation of resources in response to unmet urban and environmental requirements, such as those related to the former military barracks.

The situation remained static until December 2024, at which point the Valladolid City Council passed a motion requesting that the central government expedite the redevelopment process (PP Ayuntamiento de Valladolid, 2024). Concurrently, the Spanish government initiated the Omnibus decree measures, encompassing Article 89 on the transfer of public assets (including military ones) to SEPES for the development of its policy on affordable housing (Jefatura del Estado, 2024: 179321-179322). However, this decree was eventually not approved, and the SEPES did not become the owner of La Rubia barracks, which still remains the property of the MoD.

In the first half of 2025, SEPES, Valladolid City Council, and La Rubia grassroots association started a dialogue based on the academic interest raised within the local Technical School of Architecture (*Escuela Técnica Superior de Arquitectura de Valladolid*, ETSAVA) belonging to the University of Valladolid, specifically in the subject "Urban rehabilitation and heritage" (*Rehabilitación urbana y patrimonio* in Spanish). The main goal of the subject has been developing specific urban policies to improve La Rubia neighbourdhood, including the former barracks. The roundtable entitled "Barracks in transformation: an opportunity for the La Rubia neighbourhood" (Figures 4 and 5) took place at ETSAV in April 2025 with the aim of discussing the current state of affairs (Alonso, 2025). In this instance, the representatives of the public authorities involved (State Housing Commission and Valladolid City Council) converged on the idea that the redevelopment of the barracks should contribute to a state-led social housing policy, and therefore to the construction of affordable housing in this area (Estrada, 2025).

As a result of the discussion, the public authorities' spokespersons agreed on the next two steps for initiating the redevelopment. The first one regards the free-of-charge property transfer of La Rubia barracks to SEPES once the internal reorganisation of the latter is completed. Only when the SEPES-MoD partnership will be executed, SEPES will be entrusted with the necessary competences to carry out the transformation process. However, this is not sufficient as the redevelopment process should also be detailed and even modified according to the fact that the 2020 PGOU can increase the urban density of the new city fragment by establishing a higher provision of housing units. Consequently, the second step is the establishment of a dialogue with the various parties involved as indispensable action for the formulation of the detailed guidelines of the redevelopment. This can take the form of an open participatory process with the local citizens to update the existing guidelines and the subsequent modification of the local spatial plan that includes the opportunity to increase the dwellings up to 600 units. This measure is expected to enhance the desirability of the real estate operation for private developers, but also to extend the benefits in terms of provision of affordable housing.

Conclusion: How does the institutional capacity evolve towards the public interest?

The purpose of this paper is to contribute to the ongoing debates surrounding the potential of a new kind of partnership to facilitate the delivery of affordable housing. In order to achieve this objective, the present study has two overarching goals. Firstly, to uncover the rationale behind the utilisation of the SEPES-MoD partnership for the provision of affordable housing, and the operational requirements for such partnerships, including in terms of spatial planning. Secondly, to pinpoint the intertwine between the various stakeholders involved and to understand whether the 2023 partnership has been a game changer in unblocking the multi-decade abandonment of the La Rubia barracks.

The novelty of the SEPES-MoD partnership regards the property transfer from one public body (MoD) to another one (SEPES), so the intervention the private sector is going to be entrusted with the redevelopment and financing of public infrastructures through capturing land value increases in such practice (Alterman and Kayden, 1988). When it comes to providing affordable housing, one contentious issue is who is best qualified to do so, with debates often falling into three broad categories: public sector (Hodkinson, 2019), private sector (Ball, 2009), or partnership provision (Benedict et al., 2022). In the context of the SEPES-MoD partnership, the institutional capacity demands that the public sector assumes the role of supervisor. This necessitates a significant degree of freedom for action, but this action needs effectiveness (Peters et al., 2018). This means that having the capacities is not equivalent to executing them or making use of them, because the Spanish government should be capable of creating efficient and effective public policies to address the problem in question.

Cases such as the former La Rubia barracks demonstrate the lack of effectiveness in the institutional capacity to achieve the redevelopment of this abandoned site because the introduction of the SEPES-MoD partnership has blocked the previous procedure, but it has consequently opened new paths towards reaching a more appropriate public interest. The case study analysis shows also the diversity of intervention models that illustrate both the potential and the limitations of the current system of public asset management, including former military land. It is evident that, following a period of several years characterised by dialogue not always transparent to the general public, the local administration has successfully negotiated with the MoD in order to obtain its support for the future new utilisation of La Rubia barracks in the 2020 PGOU. The new local spatial plan established the incorporation of this space into its neighbourhood by an urban regeneration intervention, although it was established with no proper citizens' involvement. In fact, the absence of proactive planning in the SEPES-MoD partnership has resulted in opaque and non-participatory processes that have apparently obscured the public interest. The case of La Rubia is significant because it demonstrates the disconnection between knowledge and policy, between planning and management, insofar as a planning and social "window of opportunity" is not fulfilled. This failure is hidden among abstract debates and bureaucratic illusions, without a coherent and well-founded environment.

In light of these considerations, there is an urgent need to enhance institutional capacity for the management of disused military land. This should be achieved through the implementation of more flexible regulatory frameworks, the establishment of inter-administrative collaboration mechanisms, and, most importantly, the introduction of tools that ensure transparency and citizen participation. The urban regeneration potentially triggered by the redevelopment of these kinds of spaces should be guided by an integral perspective that considers not only economic profitability, but also social and territorial sustainability. Rethinking the future of La Rubia neighbourhood entails the assumption that military land, far from being an exclusively technical or functional legacy, is part of the collective imagination and can become a key resource for the articulation of new urban centralities at the service of the common good.

To conclude, this research constitutes another step towards a better understanding of how SEPES can expand its capacity to act in the field of affordable housing in connection with previous situations characterised by the challenging intertwine between institutional capacity and public interests materialised through the guidelines of spatial planning tools. Further research should focus on the implementation of SEPES-MoD partnership in the other cases across Spain. This will be instrumental in continuing this examination of the fundamental roles and values guiding both the private and public sectors involved in each cases, as well as the nature of partnerships established to implement the planning guidelines for triggering urban regeneration processes.

ENVIRONMENT AND CLIMATE

Inspiration for Pathways towards Multi-Scale Green Urban Regeneration and Planning Construction under Dual Carbon Goals

Yufei Quan
School of architecture, Southeast University
qyf2011@126.com

Abstract
Facing climate crises, integrating green low-carbon strategies into urban regeneration proves crucial for carbon neutrality. This study examines multi-scale planning across urban agglomerations, cities, and communities through international case comparisons (US, UK, Germany, China, Japan, South Korea). Key insights: (1) Planning systems need tiered approaches - coordinating regional resources at agglomeration level, optimizing city spatial structures, and applying adaptable carbon-reduction measures locally. (2) Technology systems require ecological-industrial synergy through green corridors/renewables regionally, while focusing on microclimate improvement and green buildings locally. (3) Implementation demands multi-actor collaboration: expert committees for intercity coordination, standardised city-level frameworks, and community initiatives engaging residents and social capital. The research illustrates spatial planning's role in harmonizing economic development with ecological sustainability across spatial scales.

Keywords: Carbon peaking and neutrality goals; Multiple spatial scales; Green low-carbon regenerations; Urban planning pathways

1. Introduction

In the context of intensifying global climate change, cities, major contributors to carbon emissions (IPCC, 2022), have prioritised ecological governance and low-carbon transitions as essential pathways to achieving the "Dual Carbon" objectives of carbon peaking and neutrality. Data from UN-Habitat (2021) indicates that urban regions consume 78% of the world's energy and produce more than 60% of greenhouse gas emissions. China, undergoing one of the globe's most rapid urbanization processes, has witnessed its built-up urban area grow by over 200% since 2000 (National Bureau of Statistics, 2021). However, this expansion has amplified issues such as energy dependence, ecological fragmentation, and inadequate climate resilience, thereby demanding systematic resolutions. The 20th National Congress of the Communist Party of China underscored the importance of "coordinating industrial restructuring, pollution control, ecological conservation, and climate response," offering strategic direction for multi-scale green low-carbon regeneration.

In recent years, there have been multidimensional advancements in the field of green low-carbon urban regeneration research. At the level of urban agglomeration, Chen et al. (2021) developed a climate governance network model for European urban agglomerations, revealing nonlinear relationships between policy instruments and spatial performance. However, the applicability of this model to institutional contexts in developing countries remains unverified. At the city scale, Zhang et al. (2022) demonstrated that smart city technologies could reduce building energy consumption by 18–25% in megacities like Beijing and Shanghai, but they overlooked social equity issues in technology diffusion. Li et al. (2023) highlighted that transit-oriented development (TOD) combined with distributed energy systems could cut transportation emissions by 31% in London and Singapore, but they neglected spatial constraints in high-density built environments. For communities, Sorensen (2023) systematised Japan's Danchi regeneration model—"property rights restructuring, technological integration, and community co-creation"—showing a 42% reduction in carbon intensity through refined governance, though its transferability to land-public-ownership systems remains questionable. Marquina et al. (2024) introduced a dual-driven framework integrating low-carbon infrastructure and social capital activation in Latin American slum upgrades, but its technical solutions lack validation in temperate climates.

Despite these advancements, several critical shortcomings remain: (1) Institutional Obstacles to Cross-Scale Synergy: Most prior research has primarily centered on optimizing at a singular level. For example, Zhou et al. (2023) constructed a carbon metabolism model for the Beijing-Tianjin-Hebei region to examine industrial synergy at the regional scale. However, they did not create a vertical governance framework that connects national objectives, provincial breakdowns, and municipal execution. In another instance, Kim & Coseo (2022) introduced metrics for assessing green infrastructure performance at the community level but neglected to consider dynamic alignment with broader city-level climate goals. (2) Disparity Between Technology, Institutions, and Society: Wu et al. (2024) highlighted in the Yangtze River Delta Eco-Green Integrated Development Zone that fragmented property rights resulted in the implementation rate of technological solutions (e.g., building-integrated photovoltaics) falling

below 60% of the set targets. Additionally, Schwarz et al. (2022) found that limited public engagement reduced the efficiency of technical interventions in reducing emissions by 35–50% in the Ruhr industrial heritage regeneration projects in Germany. (3) Lack of Dynamic Adaptability: Gupta et al. (2022) showed in Chennai, India, that inflexible planning approaches were inadequate in addressing monsoon-induced failures of sponge city infrastructure. Furthermore, Yigitcanlar et al. (2023) developed a digital twin platform for real-time carbon monitoring in smart cities, but its decision-making algorithms did not incorporate feedback mechanisms for policy modifications.

Practical experiences exhibit three unique "objective-tool-actor" patterns in global green low-carbon regeneration practices. At the urban agglomeration level, the EU's Climate-Neutral Smart Cities Mission adopts a "cross-border agreement + industrial enclave" model. This model connects the industrial heritage regeneration of the Rhine-Ruhr region with the hydrogen transition in the Dutch Randstad ports, forming transnational low-carbon industrial chains (European Commission, 2023). These practices suggest that regional collaboration necessitates the disruption of traditional administrative barriers through a mechanism that encompasses mutual carbon accounting recognition, ecological compensation, and technology sharing. On the city scale, New York's 80×50 Plan innovatively links Floor Area Ratio (FAR) incentives to building carbon intensity, allowing developers to gain up to 20% additional FAR by installing rooftop photovoltaics or community microgrids (NYC Mayor's Office, 2017). This policy toolkit has led to a reduction in building-sector emissions by 23% from 2010 to 2020. At the community level, Singapore's HDB Green Towns Programme integrates "physical-digital-social" spaces through vertical greening (with a 15% annual carbon sequestration increase), smart meters (resulting in 62% resident energy-saving behavior adoption), and community carbon credit systems (with over 80% participation). This demonstrates the synergy of technological rigor, institutional flexibility, and social cohesion (HDB, 2022). However, practical challenges reveal disconnects between theory and implementation. Firstly, pervasive "data silos" are a significant issue—for instance, the Yangtze River Delta's carbon monitoring platform lacks access to 40% of enterprise-level microdata, which limits AI model accuracy (Liu et al., 2024). Secondly, policy innovation often lags behind technological advancements—hydrogen pipeline planning in Germany's Ruhr region has only achieved 65% of its 2030 green hydrogen supply target due to land acquisition regulations (RVR, 2023). Lastly, social cost considerations also pose a challenge.

This study presents an analysis of representative cases, including the Yangtze River Delta and Rhine-Ruhr urban conglomerations, transitional cities such as London and Tianjin, in addition to community-level practices like Japan's Danchi regeneration. These are utilised to construct a three-dimensional "planning-technology-implementation" framework. The paper addresses three scientific queries: (1) How can multi-level spatial governance facilitate the cross-scale transmission of carbon reduction targets? (2) What technological portfolios harmonise ecological restoration with industrial development? (3) How can collaboration among multiple stakeholders guarantee the long-term operation of regeneration projects? This research not only fills theoretical gaps in multi-scale integration but also provides replicable pathways for global urban low-carbon transitions within the framework of the Paris Agreement.

2. Methods and materials

2.1 Research framework

This study's research framework is organised in the following steps (Fig.1):

1. Case Analysis: This study systematically evaluates representative cases at the urban agglomeration, city, and urban area levels, employing three key dimensions—planning system, technical system, and implementation system.

2. Comparative Synthesis: This study provides a comparative analysis of strategic characteristics and divergences across various spatial scales, drawing on case studies. The focus is on examining different planning mechanisms, technological applications, and governance approaches.

3. Strategic Framework Development: Leveraging the aforementioned analysis, we have synthesised a goal-oriented strategic framework for green, low-carbon regeneration across various spatial scales. This framework provides actionable insights, enhancing practical planning and governance efforts.

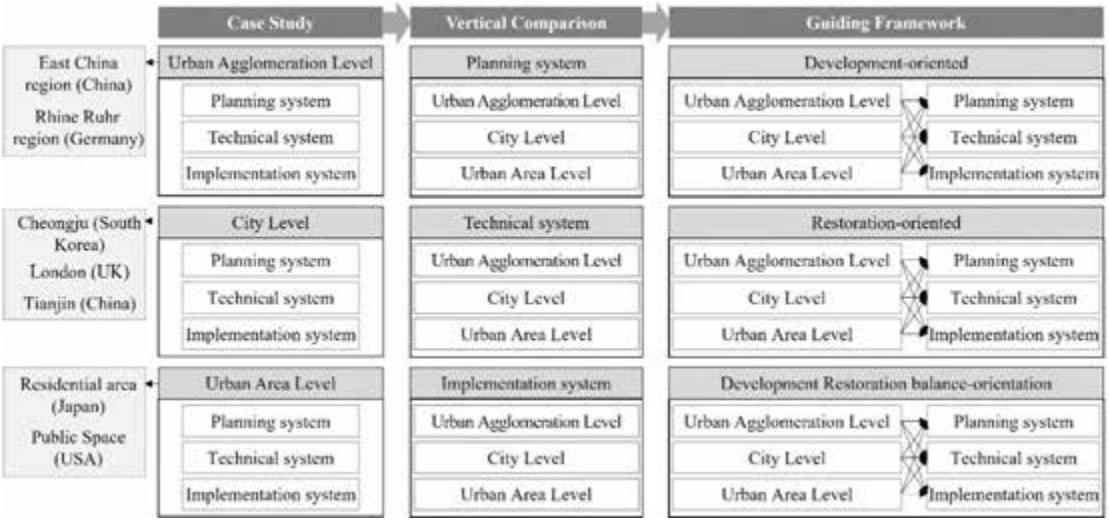

Fig. 1 Research framework

2.2 Illustrative cases of international green and low carbon regeneration efforts

This study conducts a comprehensive examination of representative cases by delving into their background, planning system, technical system, implementation strategy, and primary sources of inspiration.

2.2.1 Urban agglomeration

2.2.1.1 The Yangtze River Delta Urban Agglomeration

The Yangtze River Delta (YRD) urban agglomeration, encompassing Shanghai, Jiangsu, Zhejiang, and Anhui, represents China's most economically dynamic region, contributing 24.2% of the nation's GDP in 2023. Despite its rapid economic growth, the region faces significant carbon emission challenges. Data from the 2020 Multi-resolution Emission Inventory for China (MEIC) reveals that industrial and power sectors account for over 70% of total emissions (Liu et al., 2024). Key challenges include:

- Spatial imbalance: Emissions are concentrated in core cities such as Shanghai, Suzhou, and Hangzhou, with coastal areas exhibiting 30-45% higher emission intensity than inland regions.
- Ecological pressure: Rapid urbanization has fragmented critical ecological spaces (e.g., wetlands and forests), reducing carbon sequestration capacity by 18% since 2015.
- Policy urgency: Balancing economic expansion with dual carbon goals (peak emissions by 2030 and neutrality by 2060) requires urgent governance innovation.

(1) Planning system

To address these challenges, the YRD has adopted a dual-planning framework. First, a multi-level spatial governance system integrates cross-regional coordination at the provincial level—emphasizing ecological corridor protection and low-carbon industrial transitions through binding indicators (e.g., ≥23% forest coverage)—with localised urban-rural integration and low-carbon infrastructure development at the municipal level. Second, a spatial zoning system designates three functional areas:

- A core emission reduction zone (Shanghai-Suzhou corridor) restricting energy-intensive industries and promoting green transportation networks;
- An ecological conservation zone (southern Anhui) enhancing carbon sinks via wetland restoration;
- Carbon storage protection areas covering 30% of the territory.

(2) Technical system

The YRD employs data-driven tools, including a real-time carbon monitoring platform integrating MEIC data with transportation, energy, and land-use metrics. AI-powered scenario simulations project emission trajectories, identifying 2025 and 2028 as potential peaks under enhanced and baseline mitigation scenarios, respectively. Regional ecological networks are optimised using the InVEST model to pinpoint critical carbon sink nodes and restore blue carbon ecosystems.

(3) Implementation system
Implementation strategies combine policy innovation, industrial restructuring, and phased execution:

1. A carbon trading mechanism covering 1,200 enterprises and green finance initiatives supports market-driven decarbonization.
2. Industrial transitions target a 20% phaseout of coal-fired power plants by 2025 and promote "zero-carbon industrial parks," achieving 70% electrification of public transport by 2030, complemented by the Ningbo-Nanjing hydrogen corridor.
3. Phased actions prioritise coal consumption control and cross-city carbon sink protection during the peak period (2021–2030), transitioning to full energy system electrification and enhanced annual carbon sequestration during the neutrality period (2041–2060).

The YRD case exemplifies a globally replicable model for megaregional decarbonization, integrating systematic planning, data-driven decision-making, and market incentives. Its innovation lies in synergizing strategic top-down design with precision technical tools, balancing economic growth with ecological security to reshape sustainable development pathways for urban agglomerations.

2.2.1.2 The Rhine Ruhr urban agglomeration
The Rhine-Ruhr metropolitan region, a polycentric urban agglomeration in western Germany anchored by Cologne, Düsseldorf, and Essen, emerged as Europe's largest industrial hub, leaving a legacy of brownfields, ecological fragmentation, and carbon-intensive landscapes. Driven by the EU's Carbon Neutrality 2050 target and Germany's Federal Climate Protection Act, the region has adopted green infrastructure (GI) as a core instrument to integrate climate resilience, energy transition, and ecological restoration through multi-level planning. Key challenges include:

- Industrial brownfield regeneration;
- Cross-administrative ecological coordination;
- High-density urban regeneration.

(1) Planning system
The region integrates federal-state coordination and cross-city collaboration. At the federal level, the Spatial Planning Act establishes national ecological corridors (e.g., Rhine River), while the Federal Green Infrastructure Concept reserves renewable energy zones. North Rhine-Westphalia's State Development Plan designates Ruhr brownfields as transition zones with ≥30% green space targets. The Regional Association Ruhr (RVR) coordinates 21 cities under the Ruhr GI Master Plan, restoring the Emscher Valley and creating a "brownfield-green core-blue network." Cologne and Bonn jointly implement the Green Master Plan 3.0, forming a 200-km² Rhine-linked ecological network.

(2) Technical system
In terms of technical systems, three interconnected technical approaches drive transformation: Firstly, ecological network optimization through blue-green corridor restoration and brownfield regeneration. Secondly, climate-adaptive technologies leveraging GIS simulations to identify urban heat islands, enforce "cool islands" and ventilation corridors in high-risk zones, and deploy low-carbon infrastructure. Thirdly, renewable energy integration, including dedicated zones for wind/solar facilities and Europe's largest floating photovoltaic plant on coal-mining subsidence areas.

(3) Implementation system
Effective execution hinges on innovative policy development, active public participation, and astute monitoring and evaluation.

1. Policy innovation, exemplified by an ecological compensation mechanism requiring developers to purchase "eco-credits" for green space occupation (funding cross-regional wetland restoration) and climate budgeting aligning fiscal policies with emissions targets;

2. Public engagement, combining citizen science initiatives (e.g., mapping 5,000 protected heritage trees) and corporate partnerships (e.g., ThyssenKrupp converting 10% industrial land to public green spaces for carbon trading benefits);

3. Monitoring and evaluation via a GI performance platform tracking 12 indicators (green coverage, carbon sinks, etc.) and publishing annual resilience assessments.

The Rhine-Ruhr case demonstrates how multi-level governance, nature-based solutions (NbS), and cross-jurisdictional ecological compensation can transform post-industrial regions into climate-resilient models. Its integration of legal frameworks, technical innovation, and collaborative governance offers a replicable framework for global industrial urban agglomerations pursuing green transitions.

2.2.2 City

This study examines green-low carbon regeneration practices in three representative cities: Cheongju (South Korea), London (UK), and Tianjin (China), which exemplify central urban decay, megacity decarbonization, and industrial transformation, respectively.

Cheongju, the capital of Chungcheongbuk-do, faces urban decline in its central business district (CBD) due to population loss, aging infrastructure, and traffic congestion. Initiated in 2014, the Cheongju CBD Low-Carbon Green Regeneration Project redefined traditional high-carbon urban regeneration through systemic planning and technological innovation, establishing a Korean model for sustainable regeneration. London, the first global megacity to adopt a 2050 carbon neutrality target, achieved a 40% reduction in total emissions from 1990 to 2018. However, transportation (30% of emissions) and buildings (38%) remain critical decarbonization challenges. Tianjin, a major industrial hub in northern China, recorded a carbon intensity of 0.82 tons COΔper 10,000-yuan GDP in 2018, with fossil fuels constituting 97.4% of its energy mix (vs. China's national average of 82%), underscoring urgent energy transition pressures.

The analysis discerns context-specific challenges and contrasts strategies along three dimensions: planning systems, technical systems, and implementation systems. Key insights are succinctly synthesised (Table 1), providing valuable, transferable lessons for diverse urban environments embarking on low-carbon transitions.

Table 1. Comparative Analysis of Green-Low Carbon Urban Regeneration Strategies in Cheongju, London, and Tianjin

Aspect	Cheongju (South Korea)	London (UK)	Tianjin-China-
Key Challenges	•FAR incentives exacerbating housing affordability; mandatory affordable housing allocation. • Reliance on external carbon accounting expertise; high operational costs.	• Energy infrastructure constraints in historic districts. • Stakeholder conflicts in ZEZs implementation. • Long-term civic engagement needs.	•High costs of heavy-industry greening. •Water scarcity limiting circular economy. •Port-related freight emissions exceeding standards.
Planning Systems	• *Low-Carbon Green Growth Act* **(30% emission reduction mandate).** • TOD-driven regeneration and ecological corridor restoration.	• Three-tier system: *London Plan 2021* **designates 33 ZEZs; 15% stricter building energy standards; geothermal infrastructure planning.**	• Delineated green barrier; increased forest stock volume. • Pre-zoned offshore/onshore wind clusters; targeted non-fossil energy share. • Established industrial control lines + high-energy enterprise negative lists; phased out inefficient off-park enterprises.
Technical Systems	• Life-cycle carbon accounting (construction, transport, green spaces). • Mandatory eco-concrete, 30% BIPV coverage, hydrogen buses, rainwater recycling.	• *London Carbon Calculator Model* **(LCCM) with <5% error rate.** • Canary Wharf retrofit: Façade-integrated PV + geothermal heat pumps.	• Established a land-sea-air carbon sink monitoring network. • Piloted CCUS technology in Nangang Industrial Zone to increase CO storage volumes.
Implementation Systems	• PPP models + community-led "Low-Carbon Committees." • KETS carbon trading revenue + sub-market green bonds.	• Annual *Zero Carbon Progress Report* **(156 actions tracked).** • "Climate Action Fund" incentivizing civic participation.	• Statutory spatial planning for renewable land protection. • Tax incentives for certified low-carbon industrial parks.
Planning Insights	Demonstrates systemic "policy-space-technology-capital" integration for equitable regeneration. Highlights risks of social cost externalization in East Asian cities.	Validates "systemic policy-technology-civic governance" synergy for historic megacity transitions.	Establishes "ecological anchoring + industrial restructuring + port decarbonization" model. Proves heavy-industry cities can achieve eco-industrial symbiosis.

***Note:** TOD = Transit-Oriented Development; ZEZs = Zero Emission Zones; BIPV = Building-Integrated Photovoltaics; CCUS = Carbon Capture, Utilization, and Storage; KETS = Korea Emissions Trading Scheme.

2.2.3 The urban area

2.2.3.1 Public spaceβGreen infrastructure regeneration, US

As a high-density metropolis in the northwestern United States, Seattle faces the dual challenges of population growth and ecological conservation, including issues such as disrupted natural water cycles, intensified urban heat island effects, and uneven distribution of public spaces due to urban expansion. This study summarises the primary challenges in achieving green low-carbon regeneration of public spaces and outlines corresponding strategies across planning, technological, and implementation dimensions, as systematically presented in Table 2.

Table 2. Correspondence between Key Challenges and Systems in Seattle's Green Low-Carbon Public Space Regeneration

Key Challenges	Planning System	Technical System	Implementation System
Ecological Restoration (30% urban tree canopy by 2037)	**Macro-Micro Green Network** :• Macro: "One Core, Three Rings" framework (Central Waterfront Park, Urban Forest Ring, Neighborhood Greenway Ring, Rain Garden Ring). • Micro: Street retrofits into "Green Shared Corridors" to reduce carbon emissions.	**Nature-Based Solutions:**• Rain garden networks with "soil-plant-microbe" purification systems enhance carbon sequestration. • Smart urban forest management prioritises high-carbon-sequestration tree species.	**Cross-Department Collaboration** :• "Green Corridor Task Force" integrates road upgrades and stormwater management. • Green infrastructure (GI) integration into departmental performance evaluations.
Climate Resilience (90% stormwater facility coverage; 70% runoff pollution reduction)	**Naturalised Stormwater Management:**• Zoning based on "Infiltration Potential Maps": rain gardens (high infiltration), green roofs (medium), and underground cisterns (low).	**Digital Decision-Support Tools** :• GIS platform prioritises pocket parks in low-income areas. • Carbon footprint tracking via smart meters in public buildings.	**Policy-Financial Incentives:**• Mandatory "Stormwater Credit" purchases for developers. • Subsidies for household rain gardens and green roofs.
Social Equity (100% 5-minute park/greenway access; 50% green space equity index increase)	**Equitable Spatial Allocation** :• Neighborhood Greenways prioritise pedestrians and cyclists to reduce car dependency.	**Data-Driven Equity:**• GIS integrates demographic data to guide park distribution. • "Carbon-Neutral Corridors" enhance accessibility.	**Public Participation Mechanisms:**• "Green Home Lab" educates residents on DIY green infrastructure. • "Green Points" system rewards tree-planting with transit passes. • Participatory budgeting for funding allocation.

Seattle achieves green low-carbon regeneration of public spaces through a closed-loop framework integrating "target quantification, spatial retrofitting, technological modularization, and governance empowerment." The application of innovative technologies and broad societal participation serve as essential enabling conditions for the successful implementation of this initiative.

2.2.3.2 Residential area: Danchi regeneration, Japan

Japan has pinpointed the renovation of aging residential areas as a crucial component of low-carbon urban development. A prime example of this is the "Danchi Regeneration," primarily focused on centralised public residential areas constructed post World War II. This paper outlines the primary challenges encountered in this practice and pairs them with the corresponding strategies from the planning system, technical system, and implementation system. This pairing offers an intuitive understanding of the project's status (Table 3).

Table 3. Correspondence between Key Challenges and Systems in Danchi Regeneration

Key Challenges	Planning System	**Technical System**	**Implementation System**
Building Aging & High Carbon Emissions	Legal framework: The Low-Carbon City Promotion Act (2012) mandates emission reduction targets for old residential areas.	Building energy retrofitting: KSI housing system extends building lifespan to 100 years; solar power and ground-source heat pumps reduce carbon emissions.	Property-function replacement mechanism: Government retains public facility ownership; commercial land leases fund low-carbon retrofitting.
Community Aging & Declining Vitality	Specialised planning: Links with national plans to align spatial strategies (e.g., job-housing balance) with social sustainability goals.	/	Community co-creation: Resident participation in shared facilities (e.g., "community flower beds") lowers costs; elderly-friendly housing improves demographic balance.
Inefficient Land Use	Specialised planning: Promotes Transit-Oriented Development (TOD) to optimise land use.	Eco-restoration technologies: Permeable paving and 3D greening reduce heat island effects by 60%.	Chain-style regeneration: Phased relocation, FAR incentives, and reserved land for green spaces/public facilities enhance land efficiency.
Financial & Technical Bottlenecks	Independent management agency: UR Agency coordinates stakeholders and integrates cross-sector resources.	Resource recycling: 90% construction waste reuse; on-site composting reduces external resource dependence.	Green Bank platform: Social capital bids for low- carbon technology applications, balancing public subsidies and private investment.

Japan's "Danchi Regeneration" demonstrates that green regeneration of aging residential areas necessitates "institutional frameworks as the foundation, technological innovation as the tool, and community engagement as the core." By adopting refined planning, whole-process technological integration, and inclusive governance , this approach achieves carbon neutrality goals and provides a replicable paradigm for global low-carbon community development.

3. Results

This study performs a comprehensive analysis of representative cases across various spatial scales, aiming to delineate the common strategic features of green and low-carbon regeneration strategies within each spatial hierarchy. These strategies are examined in relation to three core systems: planning, technical, and implementation systems. Additionally, a vertical comparison is conducted to illuminate the distinct methodologies employed at different scales.

3.1 Comparative analysis of planning system

One strategic commonality across spatial scales is the adoption of multi-scale collaborative governance. Yet, there are strategic differentiations among spatial hierarchies. Urban agglomerations resolve scale mismatches with transboundary agreements and scenario modelling. Cities use statutory instruments for regulatory enforcement. Districts deploy metric-based spatial controls (Fig 2).

In urban agglomerations, planning for green and low-carbon regeneration is facilitated by a three-tiered governance framework that amalgamates national directives, regional coordination, and local implementation. Insightful case studies from the Yangtze River Delta and Rhine-Ruhr demonstrate clear organizational roles:

(1) National or Federal Policy Agencies, such as China's Ministry of Natural Resources and Germany's Federal Ministry for the Environment, establish overarching targets like carbon neutrality and provide funding for cross-regional projects; (2) Regional Coordination Bodies, for example, the Yangtze River Delta Integration Office and the Rhine-Ruhr Regional Association, arbitrate intercity infrastructure coordination tasks such as renewable energy grids and resolve jurisdictional disputes; (3) Provincial or State Governments translate national objectives into actionable plans, illustrated by Zhejiang's low-carbon industrial clusters and North Rhine-Westphalia's coal phaseout roadmap.

The implementation of the operational workflow involves three consecutive steps: (i) policy formulation, (ii) regional planning, and (iii) real-time monitoring. The federal/national level legislates emission reduction targets through climate protection acts that provide binding regulatory frameworks. Regional authorities develop spatially explicit action plans (e.g., renewable energy corridors) to ensure that the targets are met in line with local ecological and socioeconomic conditions. Multi-stakeholder working groups use common databases (e.g., GIS-based emission inventories) for implementation, monitoring and dynamic adjustment of strategies. The federal government provides legislation and financial instruments (e.g., carbon pricing) and regional authorities coordinate resource allocation. Local authorities implement site-specific projects (e.g., retrofitting green infrastructure) that link strategic objectives with their practical implementation on the ground. This hierarchical and integrated approach ensures vertical policy coherence while allowing for regional flexibility.

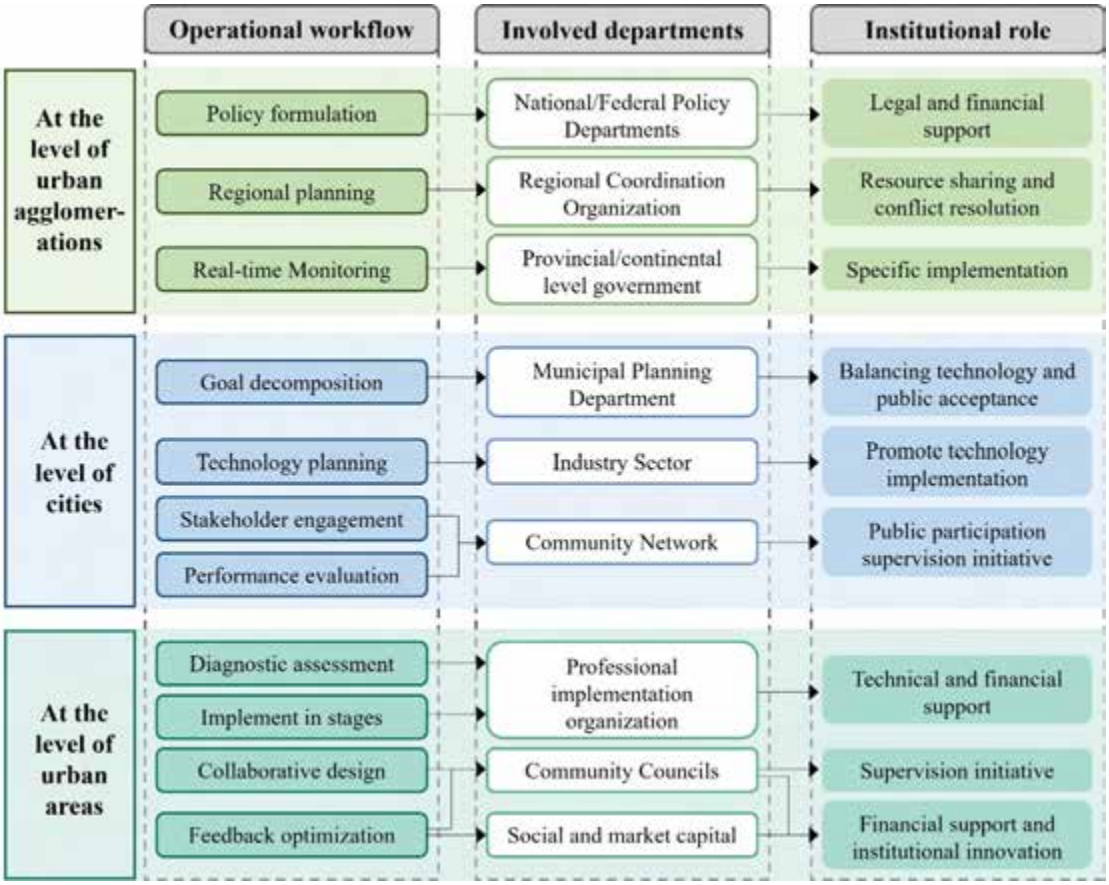

Fig. 2 Planning Processes Across Different Spatial Scales: Involved Departments and Their Roles

City-scale planning places a significant emphasis on cross-sectoral integration. Municipal authorities, such as the Greater London Authority, are responsible for formulating citywide strategies, such as the London Environment Strategy 2050. In contrast, sectoral departments like transport and energy are tasked with implementing domain-specific measures, such as Ultra-Low Emission Zones. Community networks, such as Sejong's Green Citizen Committees, serve to institutionalise participatory decision-making processes, including rooftop solar adoption. The urban planning workflow is comprised of four iterative phases: (1) the decomposition of national climate objectives into local targets; (2) the development of context-specific technical solutions, such as smart grids; (3) the embedding of social equity through stakeholder engagement, such as co-creation forums; and (4) progress tracking through digital platforms, such as IoT-enabled monitoring. This structured approach requires a delicate balance: municipal governments must reconcile technical feasibility with public acceptability, sectoral departments must drive innovation, and communities must ensure compliance with sustainability mandates.

In urban area-scale regeneration, tactical interventions are prioritised through the collaboration of multiple stakeholders. Specific agencies, such as Japan's UR Urban Renaissance Agency, oversee the entire project cycle, ranging from diagnostics to post-occupancy evaluations. Community councils like Tokyo Neighborhood Associations engage in co-designing solutions, such as energy-efficient retrofits. Meanwhile, private partners, including Mitsui Fudosan, offer their expertise and financial support, often through public-private partnership (PPP) models. The district-scale workflow is cyclical: (1) technical audits pinpoint vulnerabilities like aging infrastructure; (2) phased implementation reduces disruption by offering incremental upgrades, such as modular housing; (3) participatory workshops ensure that technical solutions align with socio-cultural priorities, including heritage preservation; and (4) the use of IoT sensors and post-occupancy surveys facilitates iterative refinements. Implementation agencies maintain technical rigor via lifecycle cost-benefit analyses, residents ensure social inclusivity via feedback mechanisms, and private stakeholders incorporate scalable technologies like prefabricated green systems. This holistic approach harmoniously blends technical precision with community adaptability in intricate regeneration scenarios.

3.2 Comparative analysis of technological system

Data-driven and modular technologies are amalgamated to establish a comprehensive hierarchical framework, spanning macro-scale simulation, meso-level integration, and micro-scale measurement. The prioritization of innovation varies across different spatial hierarchies: Urban agglomerations emphasise systemic interconnectivity. Cities have prioritised sectoral deep decarbonization, while urban areas are adopting replicable near-zero-carbon modules.

Carbon reduction strategies, when viewed across different spatial scales, exhibit hierarchical differentiation in their choice of indicators (Table 6):

Table 6. Multi-scale Carbon Emission Assessment: A Synthesis of Evaluation Dimensions and Indicators Across Spatial Hierarchies

Spatial Level	Indicator Category	Specific Indicator	Indicator Description
Urban Agglo-mera-ti-on **Level**	Energy Structure Optimization	Carbon emission intensity of industrial sectors (tons/10,000 CNY GDP)	Carbon emissions per unit of industrial output, reflecting the low-carbon transition level of industrial structure.
	Industrial De-car-bonization	Annual carbon reduction rate of ener-gy-intensive industries (%)	Annual carbon emission reductions in traditional industryies (e.g., steel, chemicals) through technological upgrades.
	Energy Networ-k Integration	Compatibility rate between renewable energy generation and grid stability (%)	Synergy between variable renewable energy (e.g., wind, solar) and grid peak-shaving capacity.
	Carbon Sink Ca-pacity	Total annual carbon sequestration in ecological spaces (mill-ion tons CO/year)	Annual carbon sequestration by forests, wetlands, and other ecological areas.
	Transportation Synergy	Intercity railway coverage rate (%)	Proportion of cities within the agglomeration connected by high-speed rail or intercity rail networks.
	Regional Carb-on Trading	Cross-city carbon quota tradin-g vol-ume (million tons/year)	Annual carbon quota transactions in regional markets, reflecting emission reductions driven by market mechanisms.

City Level	Ecological Agr-i-culture	Blue-green space ratio (%)	Proportion of water bodies (blue) and green spaces (forests, parks) in total urban land area.
		Forest stock volume (10,000 m³/ha)	Carbon storage per unit of forest area, indicating carbon sink capacity.
		Chemical fertiliser application intensity (kg/ha)	Fertiliser use per unit of agricultural land, reflecting efforts to reduce agricultural non-point source pollution.
	Energy Resou-rces	Share of locally generated renewable energy (%)	Proportion of renewable energy (e.g., wind, solar) in total energy consumption.
		Coverage rate of distributed energy supply centers (%)	Proportion of urban areas served by decentralised energy systems (e.g., combined heat and power plants).
		Installed solar PV capacity (MW)	Total solar power capacity installed on rooftops and vacant urban land.
		Coverage rate of district heating networks (%)	Proportion of urban areas served by low-carbon heating systems (e.g., waste heat recovery, geothermal).
	Industrial Deve-lopment	Proportion of value-added from strategic emerging industries in GDP (%)	Contribution of low-carbon industries (e.g., new energy, energy efficien-cy) to economic output.
		Reduction rate of energy-inten-sive enterprises (%)	Proportion of high-emission enterprises phased out through industrial restructuring.
	Transportation	Public transport modal share (%)	Proportion of trips made via metro, buses, and other green transit modes.
		Share of new energy vehicles (NEVs) in total vehicles (%)	Proportion of electric or hydrogen-fueled vehicles in the urban fleet.
		Bicycle lane density (km/km²)	Length of dedicated bicycle lanes per unit area, promoting non-motorised travel.
	Resource Circu-larity	Waste recycling and reuse rate (%)	Proportion of municipal solid waste and industrial by-products recycled or repurposed.
	Carbon Peak Tar-gets	Reduction rate of total carbon emis-sions relative to peak year (%)	Percentage reduction in total emissions by 2035 compared to the peak year (2005). Example: 5% reduction by 2035.
	Green Infrastru-cture	500-meter coverage rate of parks and green spaces (%)	Proportion of residential areas within a 500-meter walking distance of parks or green spaces.
	Building Energy Efficiency	Retrofitting rate of existing buildings (%)	Proportion of buildings upgraded with energy-saving measures (e.g., insulation, high-efficiency equipment).
	Building Decarbo-nization	Utilization rate of eco-friendly con-struction materials (%)	Proportion of low-carbon materials (e.g., recycled concrete) used in building construction.
Urban Area Level	Environmental Performance	CASBEE Community BEE Score (1–5)	Comprehensive assessment of environmental efficiency (BEE = Q/L), where Q = environmental quality and L = environmental load.
	Carbon-Neutral Communities	Number of certified carbon-neutral communities	Communities meeting standards for zero-carbon buildings and 100% renewable energy adoption.
	Energy Self-Suffi-ciency	Community renewable energy self-suf-ficiency rate (%)	Proportion of energy demand met by localised renewables (e.g., rooftop solar, geothermal).
	Resource Circu-larity	Greywater reuse rate (%)	Proportion of treated domestic wastewater reused for irrigation, toilet flushing, etc.
	Social Equity	Coverage rate of elderly-friendly facilities (%)	Proportion of residential units with age-friendly infrastr-ucture (e.g., barrier-free access, community clinics).
	Stormwater Ma-nagement	Permeable pavement coverage rate (%)	Proportion of paved surfaces using permeable materials to reduce runoff and enhance water infiltration.
	Biodiversity	Ecological corridor connectivity index (0–1)	Connectivity of green and blue spaces based on GIS n-etwork analysis (0 = fragmented, 1 = fully connected).
	Low-Carbon Buildings	Green roof coverage rate (%)	Proportion of building rooftops covered with vegetation to reduce ur-ban heat island effects.
	Low-Carbon Transportation	Share of new energy public transit routes (%)	Proportion of bus routes operated by electric or hydrogen-powered vehicles.

Urban agglomerations prioritise regional energy-industrial coordination and infrastructure-policy synergies. The Rhine-Ruhr region, for instance, exemplifies renewable energy-grid compatibility, such as wind-solar-grid matching rates, and engages in cross-border carbon trading to diminish industrial carbon intensity, particularly in sectors like steel and chemicals. These approaches tackle overarching challenges, such as energy network externalities, using collective metrics like carbon sink capacity and emission reduction ratios.

Cities are increasingly adopting multidimensional governance structures and localised transition strategies. For example, both Tianjin and London strive to balance economic growth with decarbonization objectives. They do this by maintaining blue-green space ratios of 30%, ensuring renewable energy self-sufficiency, and aiming for public transport modal shares of 40%. Their policy toolkits encompass incentives for green building and phased withdrawals from polluting industries, bolstered by moderate-granularity data such as COΔ emissions per unit of GDP.

In urban areas, technology-driven and resident-centric solutions are implemented. For instance, Japan's Danchi Regeneration and Seattle's green infrastructure projects use metrics such as per-meable pavement coverage (≥20%) and CASBEE community BEE scores (1–5) to gauge their performance. These initiatives seamlessly combine low-carbon technologies, like rooftop solar PV, with social equity measures, such as elderly-friendly facilities, and climate resilience strategies.

The hierarchical structure unveils a scalar transition from comprehensive systemic coordination to focused local action. In this context, national strategies, such as carbon markets, establish broad parameters that are then refined into city-specific objectives. These, in turn, cascade into precise community technical standards. Employing a nested governance model ensures complementarity across scales, harmonizing macro-level assessments with micro-level execution.

3.3 Comparative analysis of implementation system

Governance transitions have moved from bilateral relations between governments and markets (e.g., carbon trading in industry) to triadic relations that include civil society. Parallel to this, decision-making has shifted from strategic dominance to adaptive learning in iterative processes. The strategic differences across spatial hierarchies are as follows: Urban agglomerations focus on cross-border policy innovations for sustainability. Cities adopt market-based strategies to address financing issues.
Urban communities have been the vanguard of community-based instruments.

This study delves deeper into the analysis of disparities concerning green-low carbon transitions at various spatial levels. It does so by integrating perspectives from multiple stakeholders and employing mechanisms that balance interests (Fig. 3).

In urban conglomerations, coordination among multiple actors is underscored by cross-jurisdictional governance and industrial symbiosis. Collaboration between national/regional agencies, energy/manufacturing alliances, and research institutions is facilitated through legally binding frameworks, such as carbon trading, and shared infrastructure like renewable grids. The Rhine-Ruhr Metropolitan Association manages land-use zoning and sets emission caps, whereas East China utilises fiscal transfers to strike a balance between ecological conservation and industrial expansion. Interregional competition for resources is alleviated by compensation mechanisms, including carbon-sink subsidies, and technology-sharing platforms.

In cities such as Cheongju, London, and Tianjin, local governments use regulatory tools (e.g., low-emission zones) and public-private partnerships to steer markets toward sustainability, with planning/environmental departments, developers, utilities, and citizen assemblies often being key actors. For example, London's Ultra Low Emission Zone (ULEZ) sets stringent emission standards but provides subsidies for green retrofits. Meanwhile, Tianjin Eco-City incorporates resident input on green infrastructure design through digital platforms. To address conflicts between economic efficiency (e.g., developer profits) and equity (e.g., affordable housing), hybrid financing (e.g., green bonds) and community benefit agreements (CBAs) are used to ensure equitable distribution of benefits.

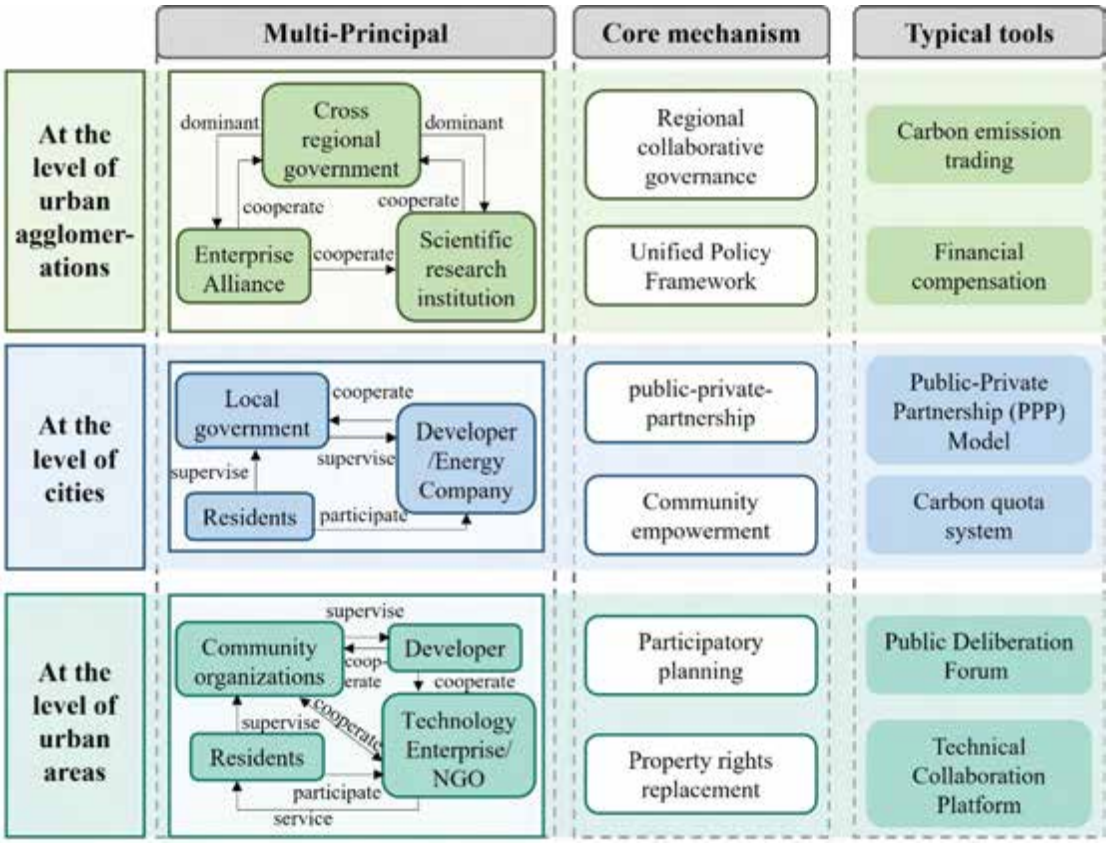

Fig. 3 Implementation Mechanisms Across Spatial Scales: Multi-Actor Interactions and Collaborative Dynamics

In urban areas, coordination among various actors is primarily focused on localised participation and micro-institutional innovation. The driving forces behind outcomes are resident committees, non-governmental organizations (NGOs), technical providers, and municipal agencies. For instance, Japan's UR Urban Agency restructures property rights in Danchi regeneration by compensating displaced residents with shared green spaces. Similarly, Seattle's grassroots organizations co-design rain gardens and pedestrian networks through citizen workshops. Land-use disputes are typically resolved through negotiated trade-offs, such as density bonuses for green roofs, and decentralised decision-making processes, thereby ensuring hyper-local legitimacy. In summary, the main features that distinguish hierarchies are as follows:

- Governance Authority: Urban agglomerations rely heavily on supranational frameworks, such as EU directives, while urban areas give precedence to community self-organization.
- Conflict Resolution: Macro-level conflicts are resolved utilizing economic tools such as carbon pricing. However, micro-level conflicts require social negotiations, for example, through the implementation of participatory budgeting.
- Actor Power Dynamics: Corporations exert a dominant influence on the agendas of city clusters, whereas non-governmental organizations (NGOs) and residents are pivotal in determining outcomes at the district level.

This structured synthesis illuminates the way spatial hierarchies shape stakeholder roles, institutional adaptability, and conflict resolution mechanisms during green-low carbon transitions. It offers concrete insights for the development of multi-scalar governance.

4. Discussion

4.1 Development-Restoration Balanced Strategies Across Scales

Green low-carbon regeneration is intrinsically connected to the strategic positioning of regional and urban development. It serves a dual purpose: the first aims to bolster urban sustainability via development-oriented interventions, and the second seeks to rehabilitate high-carbon-emission spaces that threaten urban

resilience, grounded in restoration-oriented priorities. These contrasting development orientations give rise to distinct strategic methodologies. Consequently, this study classifies strategies into three distinct typologies—development-oriented, restoration-oriented, and development-restoration balanced approaches—to cohesively summarise a multi-scale green low-carbon regeneration framework, thereby providing practical insights applicable to various spatial contexts (Fig.4).

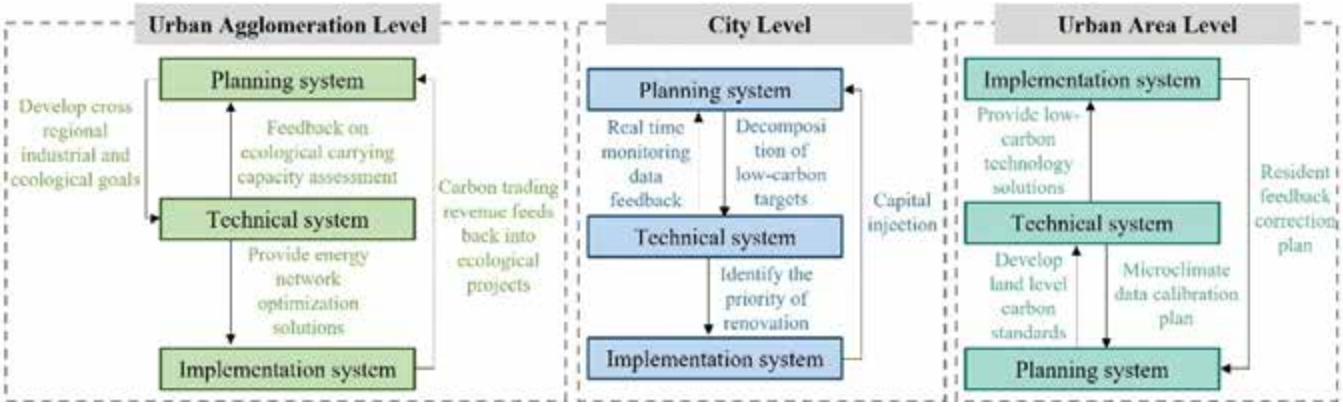

Fig. 4 Interaction mechanisms among multi-scale planning, technical, and implementation systems

4.1.1 Urban Agglomeration Level

(1) Planning system

- Development: The establishment of cross-regional renewable energy corridors and low-carbon industrial clusters is proposed as a strategy to decouple economic growth from emissions (Lin et al., 2022). Furthermore, the integration of "sponge city" principles into regional flood-resilient infrastructure planning is advocated (Yang et al., 2024).
- Restoration: Utilise circuit theory to design ecological security patterns, aiming to reconnect fragmented habitats and establish carbon sink protection redlines that encompass at least 30% of the territorial area (Liu et al., 2024).
- Integration: The implementation of a dual-control zoning system serves to strike a balance between industrial decarbonization and nature-based carbon sequestration (Bao et al., 2022).

(2) Technical system

- Development: Deploy AI-powered carbon accounting platforms for real-time monitoring of cross-border industrial emissions (error rate <5%) (Feng et al., 2022). Optimise multi-energy complementary systems (e.g., wind-PV-hydrogen storage) to achieve ≥75% renewable penetration (Wang et al., 2018).
- Restoration: Apply InVEST habitat quality models to prioritise wetland restoration sites and quantify carbon sink gains (Liu et al., 2024).
- Integration: Develop GIS-based conflict maps to resolve land-use disputes between energy facilities and protected areas (Sanchez et al., 2018).

(3) Implementation system

- Development: Initiate cross-city carbon trading markets and establish green finance hubs to facilitate funding for low-carbon transitions (Lin et al., 2022).
- Restoration: The implementation of ecological compensation mechanisms is proposed, whereby developers are required to finance off-site conservation efforts for greenfield occupation (Bao et al., 2022).
- Integration: Establish multi-stakeholder committees to synchronise industrial policies with biodiversity objectives (Xiong et al., 2021).

4.1.2 City Level

(1) Planning system

- Development: Implement transit-oriented development (TOD) mandates and 15-minute city frameworks with the objective of reducing transportation emissions by 40% (Deakin et al., 2012).
- Restoration: The process of restoring urban ecological networks and ensuring the implementation of 35%

blue-green space ratios within masterplans is imperative (Haase, 2024).
- Integration: The application of circular economy zoning is proposed as a strategy for co-locating waste recycling hubs within industrial parks, thereby enhancing sustainability (Jiang, 2024).

(2) Technical system
- Development: Enhance district heating networks through the integration of waste heat recovery systems, and ensure a minimum of 50% solar PV coverage on public buildings (Wang et al., 2015).
- Restoration: Utilise microclimate simulation tools, such as ENVI-met, to conceptualise urban forest designs capable of mitigating heat island intensity by 2–3°C (Sanchez et al., 2018).
- Integration: The process involves the creation of digital twins with the primary objective of optimizing the management of the energy-water-food nexus (Xiong et al., 2021).

(3) Implementation system
- Development: Implement carbon intensity quotas for industries and associate municipal bonds with green certification (Jiang, 2024).
- Restoration: The establishment of community land trusts is proposed as a strategic measure to safeguard green spaces against the encroachment of gentrification (Bouzarovski et al., 2018).
- Integration: Implement participatory climate budgeting to ensure congruence between fiscal policies and the priorities of citizens (Deakin et al., 2012).

4.1.3 Urban Area Level
(1) Planning system
- Development: Establish net-zero building codes and implement TOD-oriented land readjustment strategies (Wang et al., 2015).
- Restoration: The implementation of biophilic street design standards, such as having a minimum of 25% permeable surfaces and the use of native tree planting, can significantly enhance biodiversity (Sanchez et al., 2018).
- Integration: Utilise form-based coding techniques to align green infrastructure development with heritage preservation (Haase, 2024).

(2) Technical system
- Development: Scale building-integrated photovoltaics (BIPV) and shared energy storage systems to achieve 100% renewable energy blocks (Jiang, 2024).
- Restoration: Implement modular green walls and rainwater harvesting systems to decrease potable water consumption by 30% (Sanchez et al., 2018).
- Integration: Utilise IoT-enabled smart meters to monitor real-time carbon footprints of households and distribute green subsidies fairly (Bouzarovski et al., 2018).

(3) Implementation system
- Development: Provide tax rebates for environmentally friendly retrofits, such as a 20% reduction for the adoption of Building Integrated Photovoltaics (BIPV), and award density bonuses for affordable housing located near transit hubs (Wang et al., 2015).
- Restoration: The institutionalization of co-design workshops is recommended as an effective strategy for engaging marginalised groups in the planning process of green spaces (Bouzarovski et al., 2018).
- Integration: Establish eco-friendly asset management platforms to generate revenue from carbon savings and finance community initiatives (Jiang, 2024).

4.2 Theoretical Contributions and Innovations
This study advances existing literature in three dimensions:

1. Multi-Scale Vertical Comparison: Previous research has primarily centered on interventions at a singular scale, such as community-level Nature-based Solutions (NbS) (Wang et al., 2015) or city-level policy integration (Feng et al., 2022). In contrast, this study elucidates scalar interdependencies, showcasing how urban agglomeration carbon markets facilitate city-scale industrial transitions that subsequently finance district-level retrofitting. This addresses the pervasive "scale mismatch" criticism in sustainability governance (Haase, 2024).

2. Systemic Multi-Dimensional Framework: Differing from sector-specific analyses, such as energy systems (Lin et al., 2022) or social equity (Bouzarovski et al., 2018), this research amalgamates planning, technical, and implementation systems into a unified matrix. The Rhine-Ruhr case exemplifies this approach, showcasing how federal spatial planning (planning system) collaborates with regional GIS tools (technical system) and eco-credit mechanisms (implementation system) to realise comprehensive decarbonization.

3. Dual-Objective Strategy Framework: Previous research has predominantly focused on either growth-oriented strategy, such as green gentrification (Bao et al., 2022), or conservation-centric approaches like ecological restoration (Liu et al., 2024). This study offers a comprehensive strategy framework that harmonises both objectives. For instance, Tianjin's "ecological anchoring + port decarbonization" model concurrently promotes the upgradation of heavy industries (development) and the restoration of coastal wetlands (restoration), effectively addressing the dichotomy between economic progression and carbon neutrality (Xiong et al., 2021).

5. Conclusion

This study addresses urban ecological governance under climate change, exploring multi-scale green regeneration pathways aligned with Dual Carbon Goals. Through comparative analysis of urban agglomerations, cities, and communities across six nations, three key insights emerge: (1) A multi-tiered governance framework enables strategic carbon management – coordinating regional resource allocation (agglomeration scale), optimizing spatial structures (city scale), and implementing adaptive mitigation (community level). (2) Technical systems require horizontal integration of ecological restoration, industrial decarbonization, and smart governance, balancing anthropogenic-ecological synergies regionally while enhancing microclimates and green buildings locally. (3) Implementation necessitates policy-market-society coordination: expert committees for cross-regional evaluation, standardised planning protocols, and participatory models leveraging social capital. The research proposes a tripartite framework integrating planning, technical, and implementation systems, resolving fragmentation in traditional approaches through cross-scale carbon accounting and multi-stakeholder mechanisms. These findings advance sustainable urban theory and offer actionable strategies for cities at varying development stages to achieve low-carbon transitions.

This study also has two limitations. First, geographical coverage bias: the cases are concentrated in East Asia (China, South Korea, Japan) and Europe (Germany, UK), and lack representation from cities in the Global South which face distinct challenges (e.g., informal settlements in Africa). Future studies could expand the database with cases from São Paulo's favela electrification programs or Nairobi's slum-upgrading initiatives to enhance generalizability (Sanchez et al., 2018). Secondly, there are significant gaps in dynamic adaptation. The current framework prioritises static spatial strategies while neglecting the importance of temporal resilience. For instance, it reviews the phased coal phaseout in the YRD region compared to abrupt policy shifts. The inclusion of adaptive pathway methodologies such as climate-responsive zoning could enhance strategic flexibility (Yang et al., 2024).

Return of Mythical Bird · Reborn of Wetland — Conservation and Restoration Planning & World Heritage Site Application Preparation for Fujian Minjiang River Estuary

Zhaopeng Cheng, Chenxi Wang
Beijing Tsinghua Tongheng Urban Planning and Design Institute
chengzhaopeng@thupdi.com, chenxiwang0727@gmail.com

Abstract
The Fujian Minjiang River Estuary, a vital mudflat wetland along the East Asian-Australasian Flyway, serves as a sanctuary for numerous endangered species. In 2000, the reappearance of the Chinese Crested Tern *(Thalasseus bernsteini)*, long presumed extinct, brought new attention to the site. Today, from April to September each year, this 'bird of legend' returns, infusing the wetland with renewed vigor and vitality.

Despite ongoing restoration efforts, challenges such as marine aquaculture, invasive species, and human disturbance remain.

This paper outlines three strategies: defining protection zones, restoring waterbird habitats and hydrological system, and engaging local communities to support conservation and cultural recognition. These efforts contributed to the estuary's inclusion on the World Natural Heritage Tentative List in August 2022, marking a crucial step towards its recognition and protection on a global scale.

Key Words: world heritage; outstanding universal value; coastal wetland; habitat restoration; community development

1 Introduction

The Fujian Minjiang River Estuary, situated along the eastern coast of Fuzhou City, is a mudflat wetland formed through centuries of sedimentation from the Min River Basin(Figure 1). The area serves as a critical node on the East Asian-Australasian Flyway (EAAF) for migratory birds and provides refuge for numerous endangered species (RAMSAR, 2022).Twenty-four years ago, the reappearance of a mythical species added an element of mystery to this wetland. The Chinese Crested Tern (*Thalasseus bernsteini*, classified as Critically Endangered by the IUCN) was once believed extinct due to habitat degradation, typhoons, human interference, and low reproduction rates until its rediscovery in this area in 2000("Chinese crested tern", 2022).

Today, from April to September each year, this 'Bird of Legend' returns as expected, infusing the wetland with renewed vigor and vitality. While numerous restoration efforts have been implemented in recent years, challenges such as marine aquaculture, invasive species, and human disturbance persist(Lu, Y., D.D. Roby, Z. Fan, S. Chan, D.E. Lyons, C.-H. Hong, S. Wang, J. Yang, X. Zhou, D. Chen, H.-W. Yuan, S. Chen, 2020)especially colonies of terns (Subfamily: Sterninae. Consequently, there is an urgent need to establish graded protection zones, restore habitats for endangered waterfowl, and safeguard the ecosystem's integrity and authenticity(RAMSAR, 2022).

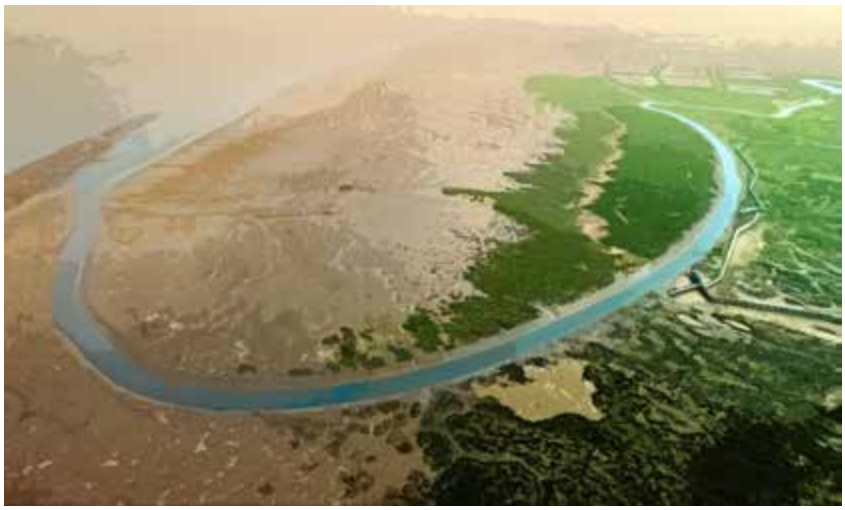

Figure 1 Minjiang River Estuary

This paper aims to introduce the restoration process, detailing how the project team managed to create a welcoming environment for returning wild birds and explore the potential for promoting harmonious coexistence between nature and humans.

The planning effort encompasses three key scopes (Figure 2): **'Research Scope'** covers the eastern coastal region of Fujian Province, extending north to Luoyuan Bay and south to Pingtan Island and Fuqing Bay, with an approximate area of 1,200 square kilometers. **'Conceptual Master Planning Scope'** is also the proposed World Heritage nomination area, covering approximately 267 square kilometers. **'Key Ecological Landscape Designing Scope'** focused primarily on the current Minjiang River Estuary Wetland Park and its surrounding areas, covering about 4.5 square kilometers.

According to each scope, the project contains three primary aspects:

1. Delineating the reservation area's boundaries, identifying Outstanding Universal Value and establishing graded control measures.
2. Optimizing the hydrological network, mitigating the impact of invasive species, and creating suitable habitats.
3. Fostering close cooperation with local communities to showcase the uniqueness and allure of a potential World Heritage Site.

As a significant milestone, the Fujian Minjiang River Estuary was successfully included in the World Natural Heritage Tentative List in August 2022(UNESCO, 2022), marking a crucial step towards its recognition and protection on a global scale.

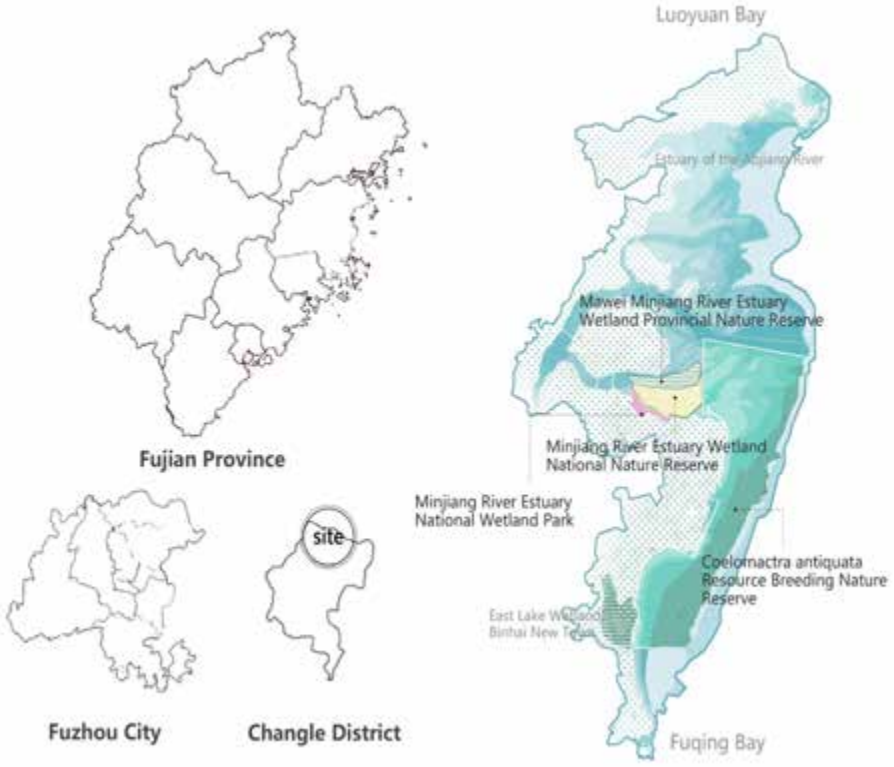

Figure 2 Project location and scope

2 Ecological Significance of the Estuary

The Fujian Minjiang River Estuary is a vital ecological zone where the Minjiang River meets the East China Sea. The estuary encompasses approximately 2,100 hectares of wetlands, including intertidal mudflats, mangrove forests, and shallow marine waters (F. Chen, H.P. Wang, Z.F. Zheng, P.H. Zhang, Y.Y. Ye,1998). As the most well-developed, natural and typical estuary delta in the East Asian subtropical region,

it was designated as a National Nature Reserve in 2013 and added to the Ramsar List of Wetlands of International Importance in 2022(RAMSAR,2022), making it reach a higher level of attention globally.

The ecological importance of the estuary can be summarized into three major aspects.

2.1 Biodiversity Hotspot

Known as the "mother river" of Fujian Province, the Minjiang River originates in the Wuyi Mountains, flows across the expansive plains of Fuzhou City, and ultimately merges into the East China Sea—where the Minjiang River Estuary is situated. (Wang, J.-Q., J. Li, Y.-J. Shih, L.-M. Huang, X.-R. Wang, T.-J. Chu, 2023)eight documents and surveyed data were collected and compared from 1990–2021. To obtain suitable analysis data, the content of the data was compared and evaluated. Explore the suitability of data based on several criteria. Among them, the bottom trawling survey carried out in 2006–2007, and non-parametric estimation methods such as Chao 2, Jackknife 1, Jackknife 2 and Bootstrap were used to estimate the fish species richness. The results of this case show that a total of 153 species of fish were caught in the trawling survey in the fourth quarter, belonging to 14 orders, 57 families and 101 genera. The 2006–2007 cruise is more complete for studying species richness. The Estimable expectations of fish species richness are: 250 (Chao 2

Located at the ecotone of two terrestrial biogeographic provinces and two marine ecological regions(D.Liu, 1995), the Minjiang River Estuary exhibits a high diversity of ecosystems and species with distinct regional characteristics, providing critical habitats for a numerous endangered species, including migratory birds, fish, large marine animals that migrating through the northwestern Pacific, and virous kinds of benthic animals (F. Chen et al.,1998).

2.2 Crucial Steppingstone of Migratory Birds

Situated along the East Asian-Australasian Flyway, the Minjiang Estuary serves as a key stopover and wintering site for numerous migratory birds. A recent survey conducted by Fujian Normal University in 2024 recorded 337 bird species in the Minjiang River Estuary Wetland, spanning 20 orders and 65 families (Fujian Normal University, 2024). Among these, 5 species are listed as Critically Endangered (CR), 10 as Endangered (EN), and 12 as Vulnerable (VU) on the IUCN Red List. Notably, the estuary is home to globally Critically Endangered (CR) species such as the Chinese Crested Tern (*Thalasseus bernsteini)* and Spoon-billed Sandpiper *(Calidris pygmaea)*, underscoring its significance as a critical node for global bird migration, biodiversity conservation, and ecological protection (Figure 5).

Figure 3 Representative Bird Species of Fujian Minjiang River Estuary

The Chinese Crested Tern *(Thalasseus bernsteini)* stands out as the most iconic species of the Minjiang Estuary. Once thought to be extinct for over six decades, it was rediscovered near Mazu Island—close to the Minjiang River Estuary—in 2000 (Lu, Y.et.al., 2020)especially colonies of terns (Subfamily: Sterninae and was given the name "Bird of Legend." Bearing the word "Chinese" in its name, the species is also imbued with cultural significance, often seen as a symbol of good fortune. Despite its symbolic status, the tern faces ongoing threats, including illegal egg collection, summer typhoons, and habitat degradation caused by sewage discharge, agricultural runoff, and industrial pollution(Lin, H., H. Lin, W. Chen, 2011). Enhancing habitat quality and expanding high-tide habitat areas are recognized as key strategies for safeguarding the future of this highly endangered species.

2.3 Coexistence of Ecosystem and Local Community.
Minjiang River Estuary has long been the central of the livelihoods, cultural identity, and heritage of surrounding communities. Exemplifies a gradient evolution of "mountains—human settlements—plain farmlands—saltwater fishponds—sea embankments—intertidal mudflats—river channels—open ocean"(Figure 4), the estuary reflects the natural landscape transition and the dynamic process of human settlement formation and development.

Figure 4 Mountain-to-sea Gradient of Minjiang River

Within the basin, the accumulated cultural activities, exchanges, and ethnic customs of settlements are linked through the Minjiang River. Over the course of history, these elements have fostered a diverse and hierarchically complete urban-rural settlement system, laying a robust foundation for the preservation and inheritance of historical and cultural heritage. By safeguarding the estuary, both cultural fabric and economic well-being of the region can be preserved, promoting a harmonious relationship between nature and local communities for generations to come.

3 Current Threats and Challenges
Over the past century, global warming, accelerated urbanization, and food insecurity have led to growing human encroachment on natural ecosystems(Chen, G., B. Fu, Y. Jiang, X. Suo, Y. Lai, Z. Chen, J. Li, L. Li, M. Lu, Y. Tang, H. Guo, R. Yang, B. Li, 2024). Recent studies indicate that natural World Heritage sites are increasingly at risk due to rapid climate change, particularly in the face of more frequent and severe climate extremes(Ke-Yi, J., W.U. Ming, S. Xue-Xin, 2011). The Minjiang River Estuary has not been immune to these pressures. Activities such as marine aquaculture, the spread of invasive species, and persistent human disturbances continue to pose significant threats to the health and stability of the wetland ecosystem, raising concerns about potential degradation.

Based on a thorough on-site investigation and a detailed evaluation against the criteria for World Natural Heritage, three key challenges have been identified in the study area. First, the ecological integrity and diversity within the existing reservation area is insufficient, and an effective control mechanism has yet to be established.

Second, the hydrological network is insufficiently connected, with ongoing threats such as invasive alien species. Additionally, critical high-tide habitats are missing, and existing waterfowl habitats are both small in scale and lacking in ecological diversity.

Third, Interaction between the wetland and surrounding communities has not been established, and there is a lack of display landmarks with heritage features.

Thus, how to protect the unique ecosystem of the Fujian Minjiang River Estuary, restore the 'home of the mythical bird', and assist in the application process for World Heritage has become a great challenge for both designers and all the other stakeholders.

4 Restoration Strategies and Implementation.
Landscape architects and engineers from various backgrounds gathered on this significant project. Starting from in-depth scientific ecological research, the project adopted nature-based solutions (NbS) to create suitable habitats for endangered water birds such as the Chinese Crested Tern, and strive to promote the regeneration of this wetland.

4.1 Solution 1: Delineate the scope of the reservation area & Establish control rules by grade
4.1.1 Analysis of Regional Uniqueness and Distinguish OUV
As part of this strategy, we began by analyzing the existing zoning framework and species survey data of the study area to distinguish its uniqueness based on its location and species. From the perspective of global terrestrial and marine biome classification systems, the project site lies within a transitional ecotone between two global terrestrial biogeographic regions—the China Subtropical Forest and the South China Rainforest—and two marine ecoregions—the Warm Temperate Northwest Pacific and the South China Sea(M.Holland,1991). Additionally, it falls within a national zoogeographic transition zone(D.Liu, 1995), highlighting its ecological and biodiversity significance.

Within this complex ecological context, multiple forms of ecosystem degradation have been observed (Figure 5). At the same time, the ecological gradient extending from the Wuyi Mountains to the East China Sea—traced by the course of the Minjiang River—has provide foundations for various ecosystems and habitat types(Wang, C., F. Cai, H. Qi, S. Zhao, G. Liu, Y. He, H. Lu, Y. Sun, T. Zhang, 2024). These include intertidal mudflats, salt marshes, shallow coastal waters and subtidal zones, scattered mangrove forests, freshwater wetlands and marshes, and chains of sandbanks and high-tide roosting islands(F. Chen, H.Wang, Feng.Z, P.Zhang, Y.Yan, 1998), providing shelters for numerous endangered species around the globe.

The regional uniqueness of the Minjiang River Estuary was defined through three key characteristics: its position at the convergence of major biogeographical provinces and marine ecoregions; its role as a critical habitat and migratory corridor for marine biodiversity; and its function as a vital staging site along the East Asian–Australasian Flyway. This conceptual framework—grounded in scientific evidence and ecological relevance—has been professionally endorsed by a group of experts, forming a solid foundation for articulating the Minjiang Estuary Wetland's Outstanding Universal Value (OUV).

Figure 5 Ecosystem types of Minjiang River Estuary

Through comparative analysis of analogous World Natural Heritage sites—such as the Wadden Sea, Suncheon Bay, and Phase I of the Yellow Sea–Bohai Gulf Migratory Bird Reserve—as well as key coastal wetlands across China, the Minjiang Estuary Wetland's exceptional value was defined (Figure 6). The site clearly meets UNESCO World Heritage Criterion (x) for its importance to in-situ biodiversity conservation and satisfies more than four Ramsar criteria for internationally significant wetlands. Based on this empirical evidence, its Outstanding Universal Value (OUV) was proposed as:

"One of the most critical natural habitats for in-situ biodiversity conservation globally"—a definition ultimately adopted in the official nomination dossier.

Comparative Analysis of Yellow Sea and Bohai Sea Heritage Sites

	Name	Criterion	Number of bird species	IUCN threatened species (birds)	Number of critically endangered species (birds)
Migratory Bird Sanctuaries along the Coast of Yellow Sea-Bohai Gulf of China (Phase I)	Yancheng Wetland Rare Birds National Nature Reserve, Jiangsu (YS-1)	x	415	17	1
	Yancheng Wetland Rare Birds National Nature Reserve, Jiangsu (YS-2)	x			
Migratory Bird Sanctuaries along the Coast of Yellow Sea-Bohai Gulf of China (Phase II)	Yellow River Delta National Nature Reserve, Shandong	x	381	30	3
	Liaohekou National Nature Reserve, Liaoning	x	292	22	3
	Dandong Yalu River Estuary National Nature Reserve, Liaoning	x	254	23	4
	Getbol, Korea Tidal Flats	x	118	22	1
	Fujian Minjiang River Estuary	x	312	25	5

Figure 6 Comparative Analysis of Minjiang River Estuary and other sites

4.1.2 Optimization of Protected Area and Control Rules by Region

Building upon thematic studies, the zoning of the heritage sites was reconfigured, by adding two extension area – Aojiang Estuary Wetland in Lianjiang County & Donghu Wetland in Binhan New City – the ecological integrity and biodiversity conservation of the wetland ecosystem was enhanced. At the same time, the area of the wetland park, where public interaction and education take place, was reclassified as the buffer zones of heritage site. These adjustments reinforce its function as both a long-term platform for regional ecological governance and a visible interface for World Heritage interpretation.

Following the clear demarcation of the heritage site boundaries, a zoned management system aligned with international conservation standards was implemented(Ringbeck, B. 2008):

1). Core Restricted Zone (Nominated Property): Enforces strict limitations on human activity and infrastructure, consistent with IUCN Category Ia (Strict Nature Reserve) guidelines.

2). Buffer Zone: Focuses on landscape protection and ecological coherence, allowing scientific research and education under regulatory oversight.

3). Co-Development Zone: Sets clear project thresholds and prohibited activity lists, promoting sustainable use through eco-industrial frameworks, green infrastructure, and carrying capacity monitoring (Figure 7).

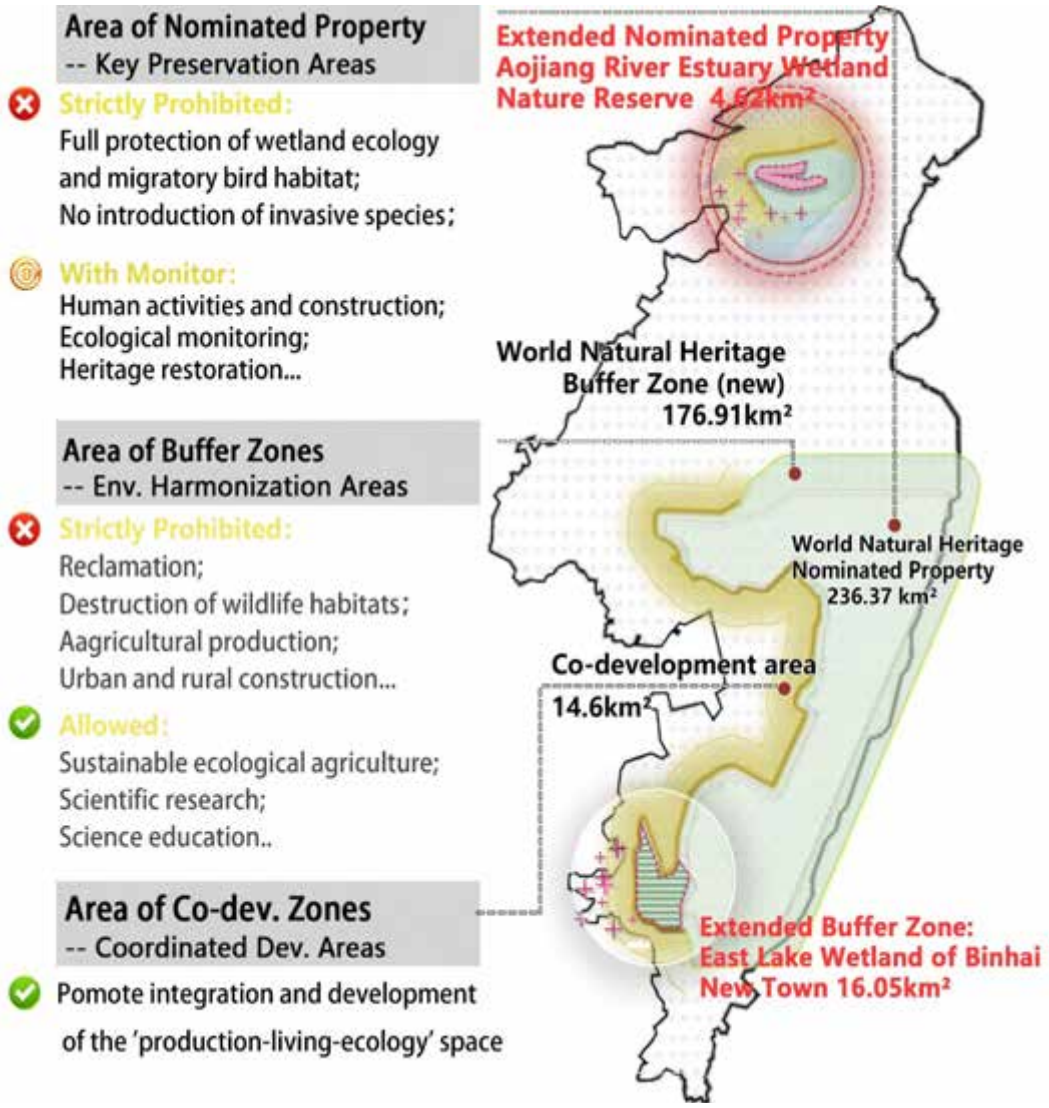

Figure 7 Reservation Area Optimization Plan

4.2 Solution 2: Systematically restore ecosystem & Create bird habitats

4.2.1 Optimization of Hydrological System

Wetlands are areas fundamentally defined by the presence of water, and water level is considered a key factor determining the species richness of waterbirds within these ecosystems(H.Liu, 2006). Fluctuating water levels can create diverse habitats that support various bird species -- for instance, shallow areas may provide feeding grounds, while deeper areas can serve as refuge during dry periods(Sánchez-Zapata, J.A., J.D. Anadón, M. Carrete, A. Giménez, J. Navarro, C. Villacorta, F. Botella, 2005)(A F Boshoff,1991). Given that the study area comprises not only natural habitats such as intertidal mudflats and mangrove forests, but also a substantial expanse of artificial environments like fishponds, designing and managing the hydrological system to provide more suitable habitats is essential to the success of our conservation efforts.

Currently, the hydrological conditions of research area are facing three major issues (Figure 8). First, there is no clearly defined mechanism for water replenishment between the internal fishponds and the adjacent open water, which puts limitation to the exchange of water that are critical for water quality, salinity balance, and the growth of benthic organisms. Second, the hydrological interconnection between each individual ponds are insufficient, leading to stagnation water conditions and signs of eutrophication. Third, the lack of a systematic hydrological regulation results in unpredictable water level fluctuations, undermining the stability and effectiveness of ongoing conservation efforts.

Figure 8 current fishponds of research area

To improve issues above, the project redefined hydrological units, managed the inlet and outlet water channels, added two smart water gates so natural exchange of water body can be realized with tides. By reshaping the pond topography, the internal water flow pathways within each individual pond can be optimized (Figure 9). For example, the northern section of Fishpond#1 has a relatively higher elevation what prevents natural drainage. The design excavates the overly elevated area thereby facilitating the water movement. Excess soil will be repurposed to consolidate the scattered habitat islands, expand the area of shallow zones and create a more coherent and efficient water flow network. In addition, water level regulation mechanism that meets the need of waterfowl habitats was developed, using monitoring data collected from 3 tide gauge stations nearby.

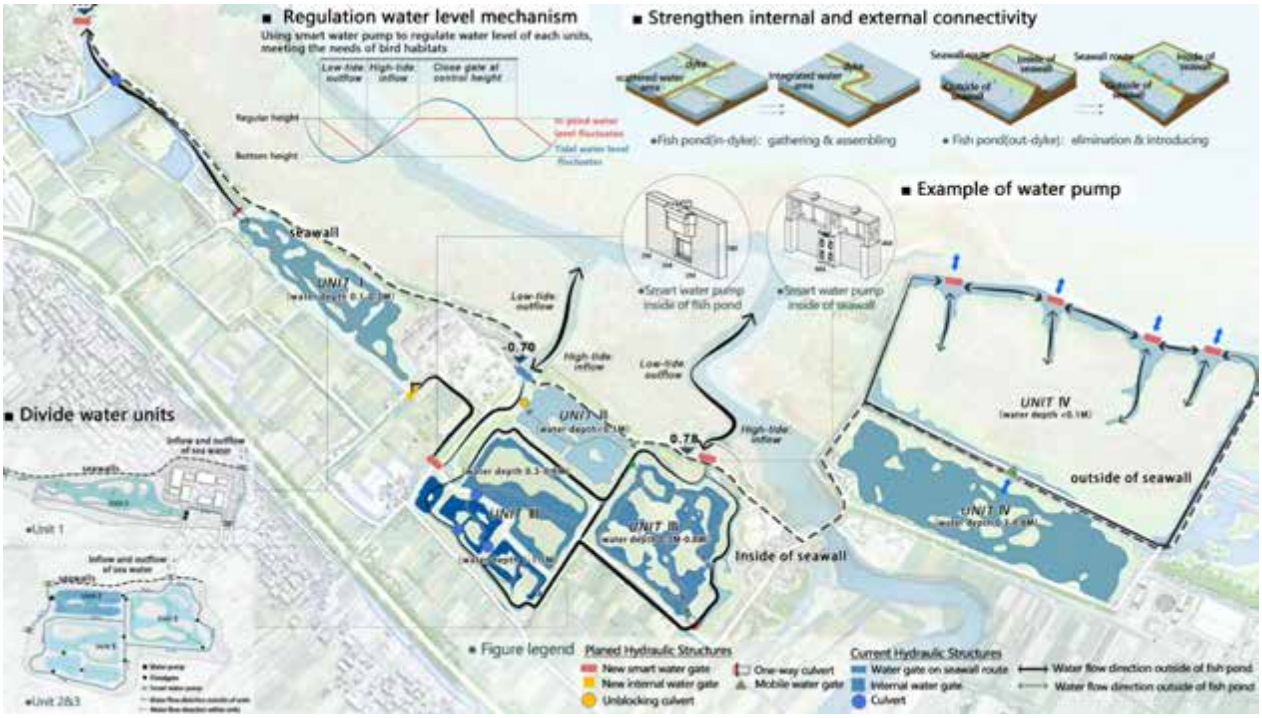

Figure 9 Optimization Efforts for Hydrological System

4.2.2 Replacement of the Occupied Ecological Niches

The Minjiang River Estuary, like other major coastal wetland along eastern China(An, S.Q., B.H. Gu, C.F. Zhou, Z.S. Wang, Z.F. Deng, Y.B. Zhi, H.L. Li, L. Chen, D.H. Yu, Y.H. Liu, 2007), has been significantly affected by invasive plant species, particularly smooth cordgrass (Spartina alterniflora) and common reed (Phragmites australis). S. alterniflora began to invade the Minjiang Estuary in 2002 and since then has gradually expanded its range(Feng, J., Q. Huang, H. Chen, J. Guo, G. Lin, 2018). Although efforts have been made to remove them and restore native vegetation – such as replanting with mangrove species like Kandelia obovata—the habitats of waterbirds remain at risk due to the invasive species occupying critical ecological niches(X.Xie, X.Sun, T.Wu, G.Jiang, L.Pu, Q.Xiang, 2020).

In the planning, a key area was designed for focused ecological management, covering approximately 1,250 hectares (Figure 10). By employing physical methods such as 'mowing, tilling, site preparation and plantation restoration'(Y.Zhu, 2025)(Figure 11), efforts would be made to manage invasive species like Spartina alterniflora (*Spartina alterniflora Loisel*) in this area. Local salt marsh plants such as mangroves, reeds *Phragmites australis*, Cyperus malaccensis *Cyperus malaccensis subsp. monophyllus*, and scirpus mariqueter *Bolboschoenoplectus mariqueter*are planted in suitable areas.

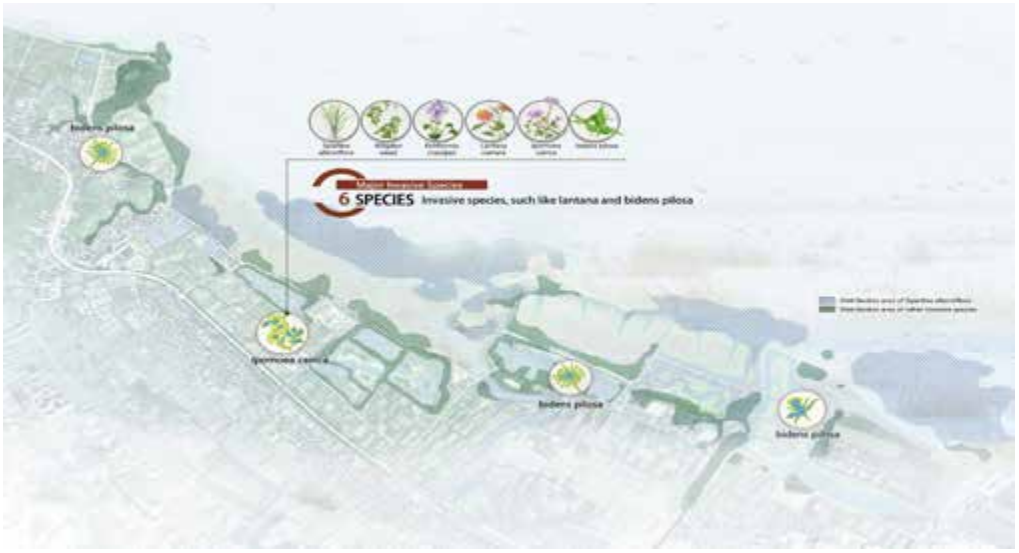

Figure 10 Restoration Area

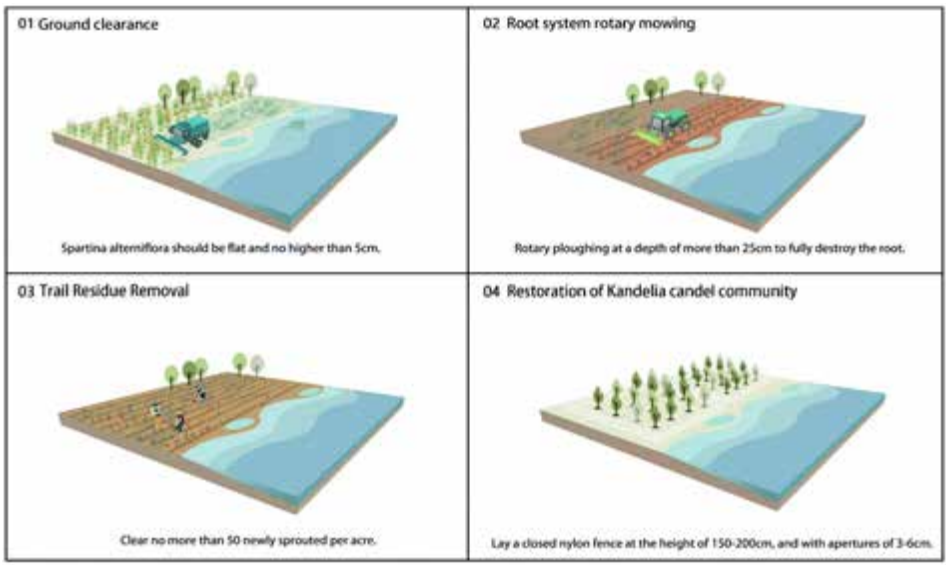

Figure 11 Management Mechanism of Spartina alterniflora

4.2.3 Creation of Diverse Waterbird Habitat

According to the 2020 winter avian monitoring data of Minjiang Estuary wetland, a total of 144 bird species were recorded across the entire area, including various groups such as shorebirds (*Charadriiformes*), geese and ducks (*Anatidae*), and egrets and herons (*Ardeidae*) (Fujian Normal University, 2024). If dividing the wetland into seven zones, labeled A through G, for statistical analysis, one could see that Zone B and E (tidal flats outside the embankment) had the highest volume of birds (Figure 12). Although the total bird counts in Zone C and D (artificial fishponds) was relatively lower, these areas exhibited higher species diversity. Based on our field investigation, the artificial fishponds serve as supplementary habitats for waterbirds during high tide times.

These habitats are moderately suitable for most species; however, due to factors such as poor habitat quality and a lack of suitable benthic organisms, the overall ecological carrying capacity of this area remains low.

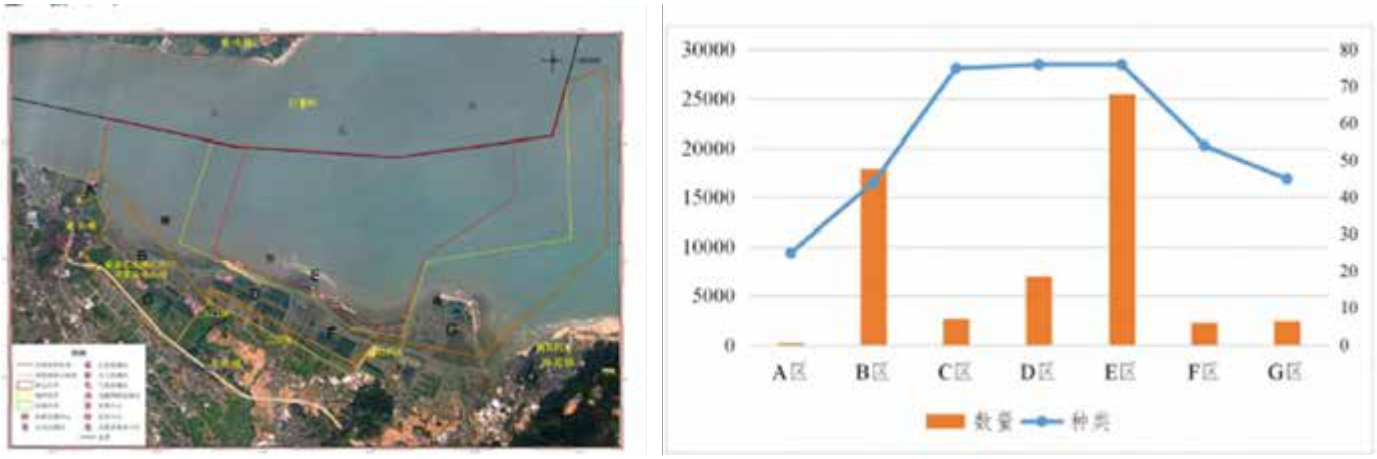

Figure 12 Bird Monitoring Data of Research Area (2020 winter)

To support the diversity of habitat and meet the ecological needs for various bird species, target conservation and management strategies were developed as follows:

For intertidal beach areas, a 100-hectoare core protected zones was designed to be the critical foraging and roosting habitats for migratory waterbirds, including the endangered 'Bird of Legend' Chines Created Tern (*Thalasseus bernsteini*). In addition, the plan suggested to actively manage invasive species to reduce the ecological competition and promote native biodiversity. Efforts such as restoring native wetland vegetation are made to enhance food availability. Tourist activities are prohibited in these core protected zones and only essential scientific research and maintenance work are permitted. In this way we could minimizes human disturbance to the greatest extent possible.

For high-tide habitats area (fishponds), an approximately 118-hectares of are tidal flats was developed to serve as supplementary habitats for waterbirds during vulnerable periods such as high tide and breading seasons. To enhance the ecological function of these restored zones, the plan removed pond dikes and barriers to restore natural water flow. In addition, benthic organisms have been introduced to enrich the food base, providing foraging resources for shorebirds and waterfowl,

Fishponds are in the wetland park, so in areas where tourists may come into close to bird habitats, protective forest belts are strategically planted, providing buffers serve to visually and acoustically isolated the bird habitat from human activity, thereby disturbance such as movement, noise, and light and be reduced.

A diverse range of habitats has been created through ecological reconstruction of selected fishponds. Water level is carefully regulated to fluctuate between 0.1 to 0.3 meters, which accommodates the foraging and nesting needs of wading birds(H.Liu, 2006). In addition, the bottom of the ponds is regraded to a gentle slope of no more that 3%, promoting sage access for birds and enabling gradual water transitions that support a range of aquatic and semi-aquatic species.

These reconstructed habitats are especially suitable for species such as the Black-winged Stilt (*Himantopus himantopus*) and the Pied Avocet (*Recurvirostra avosetta*), which require shallow water and open muddy or sandy substrates for feeding and breeding(H.Liu, 2006). The design not only increases habitat quality but also enhances ecological resilience, enabling the wetland to support a greater abundance and diversity of birdlife across different seasons and tidal cycles (Figure 13).

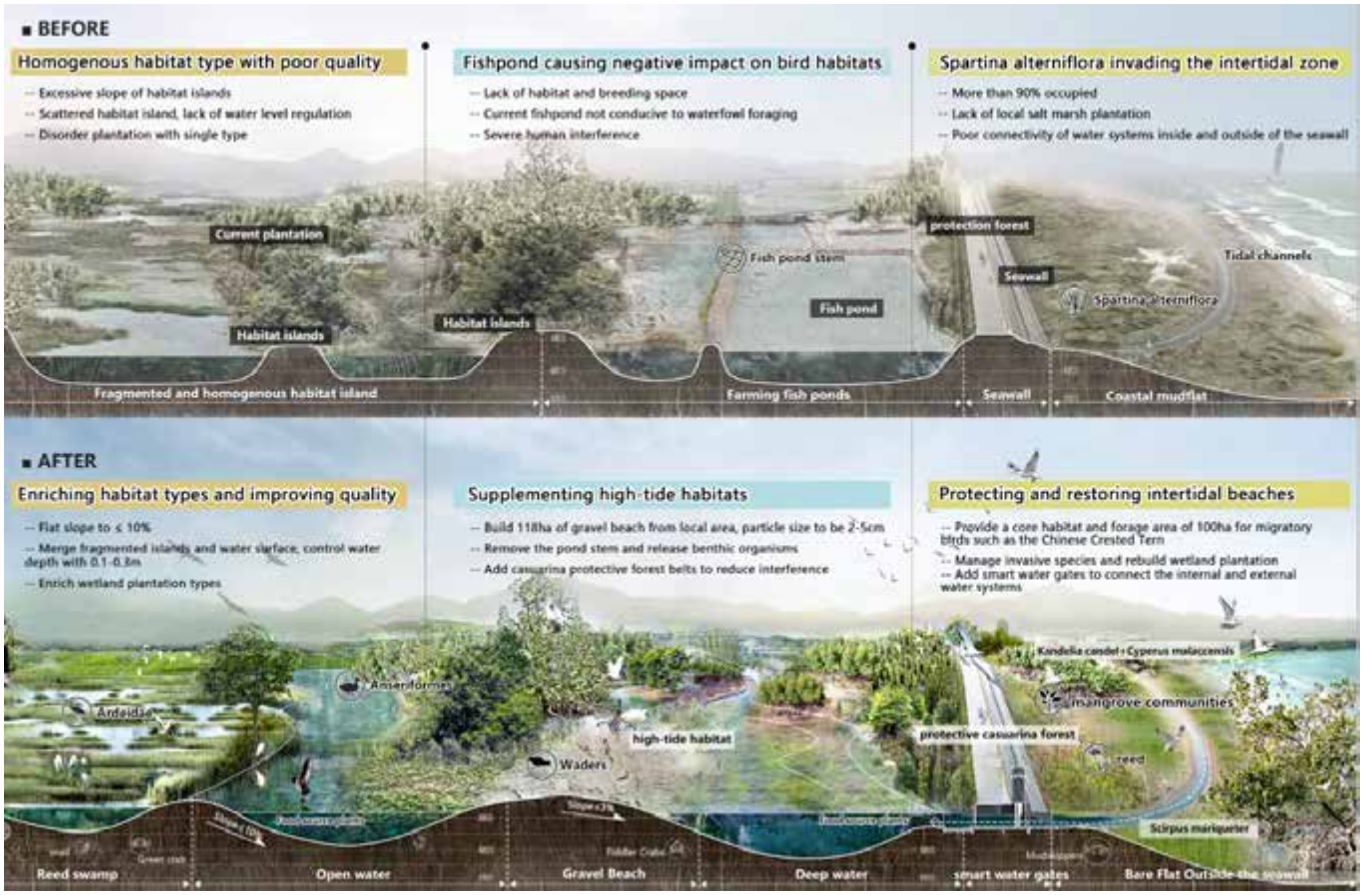

Figure 13 Landform engineering for habitat restoration

4.3 Solution 3: Collaborate with surrounding residents & Demonstrate a World Heritage Showcase

World heritage matters far more the protected area itself. The sustainability of heritage involves the sustainability of the heritage itself and its contributions to the sustainable development of the local population(Xu, L., G. He, L. Chen, 2024). According to UNESCO, World Heritage properties sustain biological and cultural diversity, which may support a variety of ongoing and proposed uses that are ecologically and culturally sustainable and which may enhance the quality of life and well-being of communities concerned(UNESCO,2024) (Lee, Y., R. Jayakumar, 2021).

4.3.1 Promoting a Synergistic Development with Surrounding Villages

The scattered villages and towns surrounding the Minjiang River Estuary Wetland serve as important settlements adjacent to this potential World Heritage site. By targeted environmental remediation and capacity building, actions plan that transform these communities into World Heritage villages were put into action. The transformation involves the strategic selection of dispersed land parcels for the establishment of facilities such as academicians' residences, research apartments, and research centers. Functional zones will be delineated based on the unique characteristics of each settlement – cultural tourism and recreation area, world heritage science and technology exhibition area and coastal leisure area. For example, Meihua Town on the eastern side of the wetland, once been an historic settlement known for its coastal defense heritage, will serve as part of 'cultural tourism and recreation area' and incorporate cultural tourism functions to create integrated pathways connecting local villages with the wetlands. This approach will also enable visitors to engage with both the region's historical and ecological assets, promoting the synergistic development of its natural and cultural heritage (Figure 14).

Figure 14 Creating a Synergistic Development with Surrounding Villages

Simultaneously, the action plan encourages creating sustainable employment opportunities by developing community-based tourism and heritage-related services. These initiatives not only stimulate the local economy but also contribute to the long-term vitality of the region. Invest in capacity building and vocational training to cultivate a new generation of skilled heritage stewards—individuals equipped with the knowledge, sense of responsibility, and practical skills needed to safeguard the site for future generations.

4.3.2 Demonstrate a Unique World Heritage Showcase

In addition to ecological restoration, the renovation of existing wetland infrastructure is a vital component of our broader project. As a symbolic gateway to the Minjiang River Estuary, the wetland museum functions not only as a visitor center but also as a crucial platform for public education and ecological awareness. Although the museum was constructed within the last decade, it suffers from several limitations—including a fragmented layout, an outdated exterior design, and overall underutilization—that falls behind the requirement the World Heritage site requires.

The renovation design draws inspiration from the nesting forms of migratory birds, particularly the iconic Chinese Crested Tern. With an outline resembling outstretched wings in flight, the new structure gently unifies the museum's once-scattered components into the protective embrace of a mythical bird, symbolizing both shelter and renewal(Figure 15).

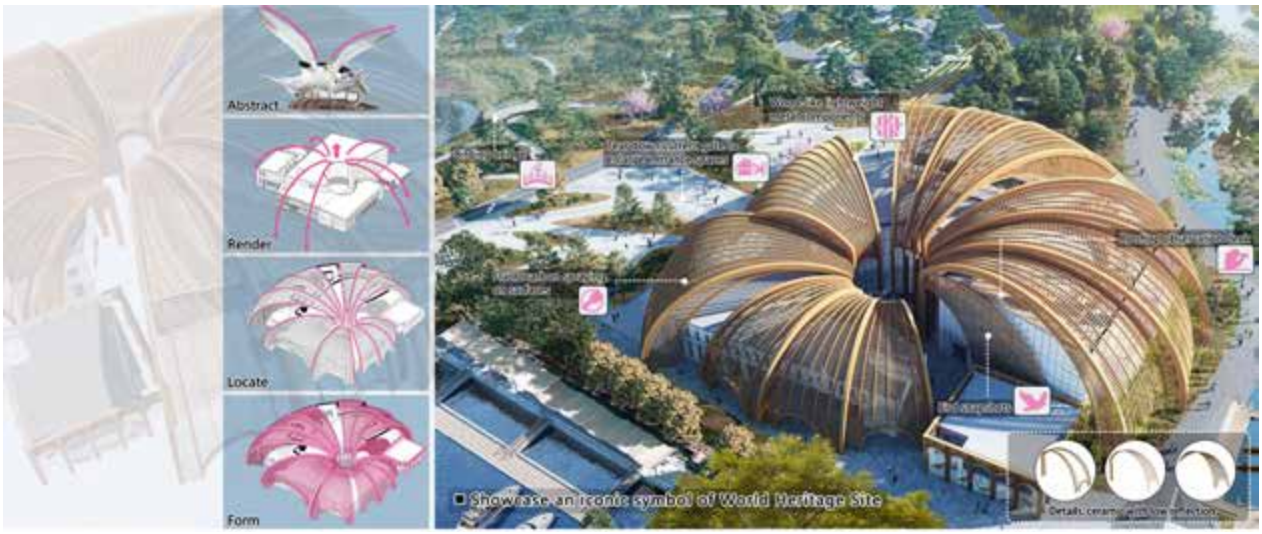

Figure 15 Renovation of Wetland Museum.

The park entrance is another focal point of the design. Inspired by the elegant wings of the Chinese Crested Tern, its fluid lines and graceful form create an inviting gesture—welcoming guests from all directions with a sense of movement, lightness, and warmth (Figure 16).

Figure 16 New design of park entrance

As part of the World Heritage application, this revitalized gateway demonstrates our commitment not only to conservation but to conveying the estuary's outstanding universal value— a shared spaces where human presence and natural life can flourish side by side.

5 Conclusion

The plan, if implemented successfully, would systematically restore 315ha waterfowl habitat, control 182ha of invasive species, supplement 118ha high-tide habitats, and lay out a 14.6km² heritage co-development zone, benefitting 20 surrounding communities and a total of 132000 residents. At the same time, the plan has greatly accelerated the process of the Fujian Minjiang River Estuary's application for Wetland of International Importance and World Natural Heritage sites. In August 2022, the 'Fujian Minjiang River Estuary: The ecotone between marine and terrestrial biogeographical regions' was successfully listed in the World Heritage Tentative List by UNESCO. In February 2023, it was included in the Ramsar Convention List of Wetland of International Importance, providing an important demonstration for the protection and restoration of natural heritage sites from a global perspective.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgement
This paper is based on the award-winning project "Conservation and Restoration Planning of Minjiang River Estuary Wetland Park", which was initiated in 2022 for the International Design Competition for the Minjiang River Estuary Wetland in Changle District, Fuzhou, Fujian Province, China. Our institution won the competition and was selected as the lead design team for this project. We extend our gratitude to the project team members—Yang Zhang, Xinyan Liu, Yidi Fu, Jinkun Dai, and Peng Qin—for their dedicated efforts in producing the figures and technical materials used in this paper.

Abstract
In the context of the increasingly severe global thermal environmental crisis, this paper examines 120 urban parks in Foshan, a representative water-network city in China's southern region. By using multi-methods integrating Boosted Regression Tree (BRT) modeling, Restricted Cubic Spline (RCS) threshold detection, and K-means clustering, the study explores cooling effectiveness of urban parks based on five metrics: Park Cooling Distance (PCD), Park Cooling Area (PCA), Park Cooling Efficiency (PCE), Park Cooling Intensity (PCI), and Park Cooling Gradient (PCG). Results reveal threshold-dependent cooling effects, with park area, blue-green ratio, and FAR as key determinant factors. Thresholds for optimal cooling efficiency occur at 2.31-4.03 km² park area, vegetation coverage exceeding NDVI 0.277, and blue-water ratio within 0.277-0.515. All the sampling parks could be clustered into four groups: high-efficiency, low-efficiency, medium-efficiency, and comprehensive cooling performance. The findings could provide reference to deeply understand the threshold mechanism in urban heat mitigation and evidence-based planning strategies for optimizing green infrastructure in water-network cities, supporting science-driven thermal environment optimization.

Keywords: Urban Heat Island Effect; Urban Parks; Green Infrastructure; Cooling Mechanism; Lingnan Water Network Cities

1. Introduction

1.1 Urban Heat Island Crisis and the Climate Regulating Role of Green Spaces

With the acceleration of global urbanization, the Urban Heat Island (UHI) effect has become an important environmental issue that threatens the health of urban ecosystems and the well-being of residents. (Oke & Maxwell, 1975; Rizwan et al., 2008). According to the 2021 IPCC report, urban surface temperatures in the 21st century have increased by 1.5-3.0°C compared to the pre-industrial period, with a significant increase in the frequency of extreme heat events (Masson-Delmotte et al., 2021). Urban green spaces have become a central vehicle for heat island mitigation through transpiration, shade effect and air flow regulation (Gong et al., 2024). A properly planned urban park can reduce the surrounding surface temperature by 1-5°C, and its cooling effect is closely related to the characteristics of park area, vegetation cover, and proportion of water bodies (GALLO et al., 1993; Kayet et al., 2016). However, the synergistic cooling mechanism of blue-green spaces in cities with dense water networks is not clear (Stewart, 2011; Zhang et al., 2024).

1.2 Thermal Environment Specificity of Lingnan Water-Network Cities

The Lingnan region is one of the fastest urbanising regions in China, with average annual temperatures 2-3°C higher than the national average and 60-90 days of high temperature in summer (Z. Yu et al., 2017). Foshan is located in the Pearl River Delta and is a typical water network city in the Lingnan region, with a hydrological pattern of the three river confluences of the West River, North River, and Sui River. Foshan has a river density of 0.8-1.2 km/km², creating a unique landscape of a water network city (Foshan Municipal People's Government, 2025). However, rapid urbanisation has led to fragmentation of green spaces and pollution of water bodies, weakening the synergistic cooling capacity of blue-green spaces (Gago et al., 2013). The cooling effect of water network urban parks is multiply affected by the distribution of water bodies, the structure of green space and the intensity of surrounding development (Bowler et al., 2010; Yang et al., 2020). However, studies addressing the threshold effect of their blue-green spaces still need to be supplemented.

1.3 Contradiction Between Threshold Deficiency and Planning Demands

Currently, urban green space planning faces challenges in the context of UHI. It is difficult to quantify the spatial cooling range and intensity of parks without comprehensive cooling performance indicators (Chang & Li, 2014; Feyisa et al., 2014). Measuring marginal effects and identifying thresholds for influencing factors such as park area and blue-green space need further research (Oliveira et al., 2011; Z. Yu et al., 2020). Local planning guidelines lack targeted strategies, leading to inefficient layout of blue-green spaces in water network cities (Ministry of Housing and Urban-Rural Development, 2020). Therefore, there is an urgent need to construct a complete framework of 'Indicators - Mechanisms - Thresholds - Strategies' to provide a scientific basis for thermal mitigation planning in water network cities.

1.4 Research Objectives and Innovations

In this study, 120 parks in Foshan City were used to quantify the spatial cooling effect of the parks by introducing five major indicators, namely PCD (park cooling distance), PCA (park cooling area), PCE (park cooling efficiency), PCI (park cooling intensity), and PCG (park cooling gradient). The non-linear relationship is resolved by identifying the marginal thresholds of factors such as scale, landscape pattern, blue-green space and the surrounding built environment. Finally, based on the k-mean clustering results, optimisation strategies are proposed for four different types of parks with different cooling performance. This study aims to reveal the mechanism of the cooling effect of water network city parks, provide a scientific basis for the optimisation of blue-green space layout, and contribute to the sustainable development of water network cities under the background of global climate change.

2. Materials and methods

2.1. Study area

This study took Foshan City (23°02'N-23°24'N, 112°51'E-113°23'E) as the study area, with a total area of 3797 km², which has a southern subtropical monsoon climate, with an average temperature of 28.5°C in summer (June-August), and extreme high temperatures of up to 39.2. The total length of urban rivers exceeds 6000 km, and the density of the river network is 1.58 km/km². In this study, 120 representative parks were selected from the screening of 382 parks larger than 1 ha. According to the park classification standard of Foshan City, the 120 parks cover five categories: community parks (36%), comprehensive parks (20%), wetland parks (8%), forest parks (12%), and special parks (24%).

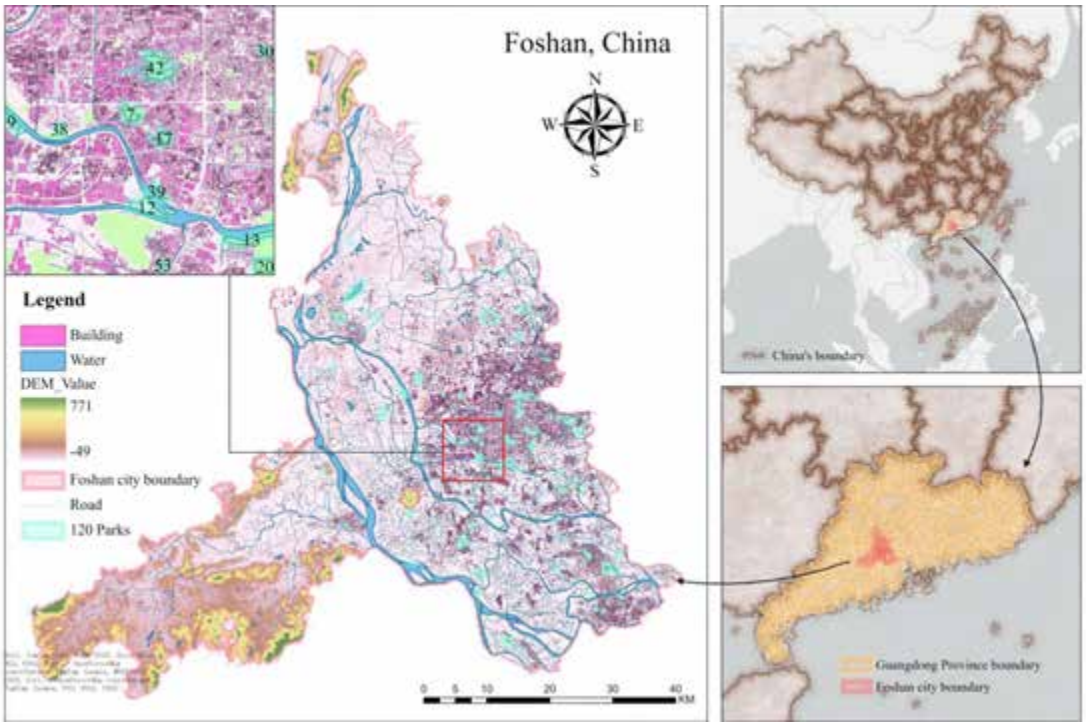

Figure 1 Distribution of the study area and 120 parks in Foshan City (Base map is from the standard map downloaded from the website of the Standard Map Service of the Ministry of Natural Resources (http://bzdt.ch.mnr.gov.cn/))

2.2 Data Sources

2.2.1 Inversion of Surface Temperature

This study used the radiative transfer equation method to invert land surface temperature (X. Yu et al., 2014) providing two adjacent thermal bands, which has a great benefit for the LST inversion. In this paper, we compared three different approaches for LST inversion from TIRS, including the radiative transfer equation-based method, the split-window algorithm and the single channel method. Four selected energy balance monitoring sites from the Surface Radiation Budget Network (SURFRAD. The basic principle involves estimating atmospheric effects on

surface thermal radiation, subtracting them from the total thermal radiation observed by satellite sensors to get surface thermal radiation intensity, and then converting it to land surface temperature.

$$L\lambda = [\varepsilon B(Ts) + (1 - \varepsilon) L-]\tau + L-$$

LΔis the thermal infrared radiation brightness observed by the satellite sensor; LΔis atmospheric upwelling radiance; LΔis the energy from atmospheric downwelling radiance reflected back after reaching the ground; B(Ts) is blackbody thermal radiation brightness; Δis atmospheric transmittance in the thermal infrared band. LΔ LΔ and Δwere obtained from the NASA website (http://atmcorr.gsfc.nasa.gov/). Δis land surface emissivity, calculated using the NDVI threshold method by Sobrino (Sobrino et al., 2004)three methods to retrieve the land surface temperature (LST. Ts is the actual land surface temperature.

$$Ts = K2 / \ln[K1 / B(Ts) + 1]$$

For Landsat - 8, K1 = 774.89 W/(m²·sr·μm) and K2 = 1321.08 K.

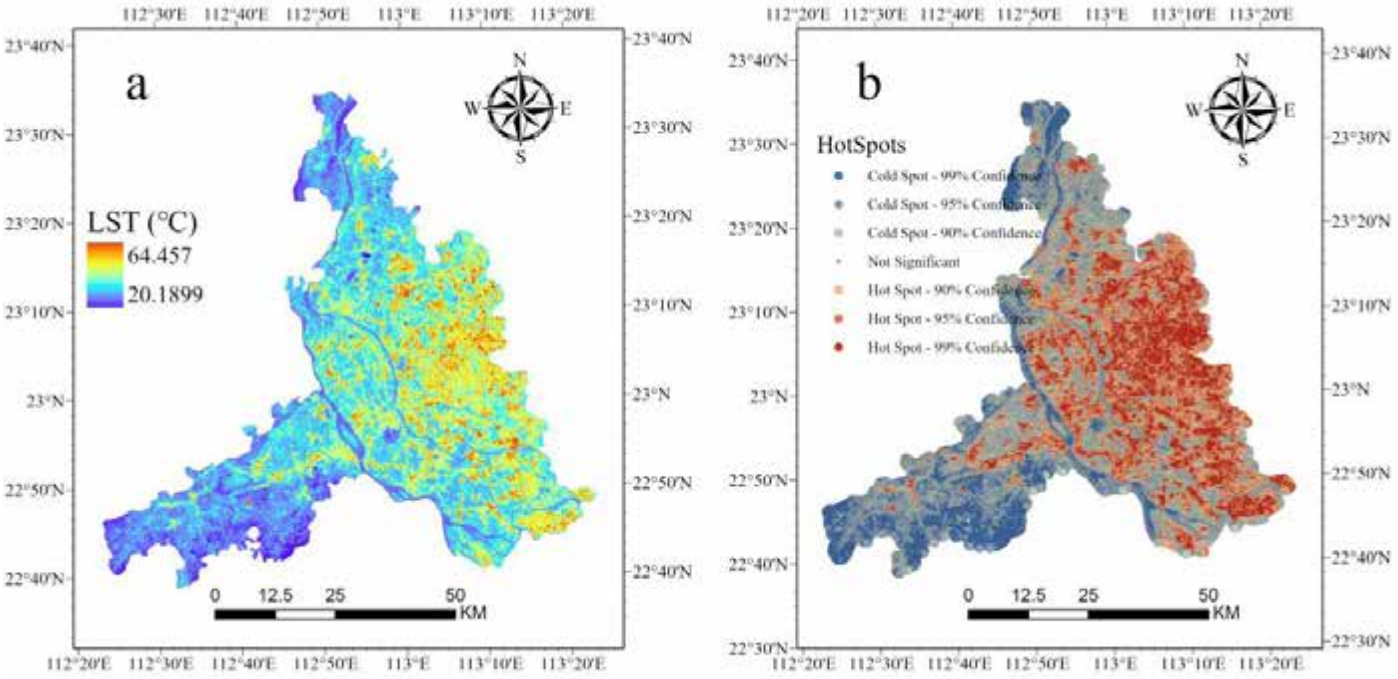

Figure 2 Mean surface temperature of the study area (a) and hotspot analysis map (b). (LST inversion in September 2022)

2.2.2 Data Sources

Remote sensing monitoring data, geospatial data, meteorological observation data and land use data were used in this study (Table 1). The surface temperature (LST) data were obtained from Landsat 8 OLI/TIRS satellite imagery, which was selected during the cloud-free period of September in the summer of 2022, and radiolabelled, atmospherically corrected, and inverted by the single-window algorithm to obtain the surface temperature distribution (Jimenez et al., 2010)thermal imagery at medium and high spatial resolution is useful in many environmental studies, such as evapotranspiration estimation from the energy balance equation, which is a key parameter when working in water resources management. In this sense, the launch in 1982 of the Thematic Mapper (TM. In addition, the field validation was carried out in September 2022, and the surface temperatures of 50 sample points were collected by portable infrared thermometers. Comparison with the satellite inversion results showed that the root mean square error (RMSE) was 1.2°C, and the absolute error was controlled within 1.5°C. The high resolution remote sensing images were collected using the GIS and the GIS. The high-resolution remote sensing image adopts GF-2 satellite data, and after orthorectification, image fusion and Support Vector

Machine (SVM) feature classification, it realises the interpretation of the landscape elements such as forest, grassland, water and impermeable surface of the park.

Table 1 Data Sources

Data Type	Source	Time Range	Preprocessing Methods
Surface Temperature (LST)	Landsat 8 OLI/TIRS (30 m)	Summer 2022 (September)	Radiometric calibration → Atmospheric correction (MODTRAN model) → Single-window algorithm inversion (Jiménez-Muñoz & Sobrino, 2003)
Remote Sensing Imagery	GF-2 Satellite (2 m)	July 2023	Orthorectification → Image fusion → Land cover classification (Support Vector Machine, SVM)
Park Vector Data	Foshan Natural Resources Bureau	2023	Boundary vectorization → Topological inspection → Attribute assignment (area, type, water body proportion, etc.)
Meteorological Data	Foshan National Benchmark Climate Station	2018–2023	Interpolation to generate 1 km resolution raster data (ANUSPLIN model)
Land Use Data	Guangdong Provincial Land Use Status Database	2022	Reclassification into 7 categories including construction land, green space, and water bodies (GB/T 21010–2017)

2.3 Methodology

2.3.1 Quantification of Park Cooling Performance

In this study, the ArcGIS multi-ring buffer model was used to quantify the spatial gradient changes and further quantify the attenuation pattern of the land surface temperature (LST) during the outward extension of the park boundary. A buffer zone is set every 30 metres from the park boundary, generating 40 concentric buffer zones covering a 1200-metre buffer zone. The buffer zone model is based on the Sanshan Forest Park, where the interior of the park is dark green, the area affected by the park cooling is mauve, and the unaffected area is yellow.

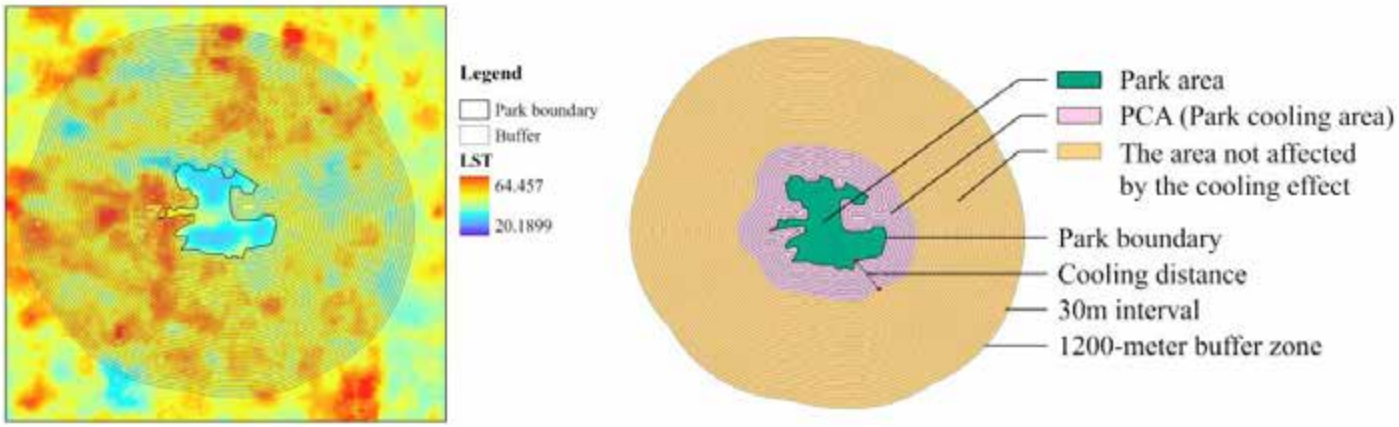

Figure 3 Schematic diagram of multi-ring buffer analysis (taking Sanshan Forest Park as an example, with 30 buffers extending to 1,200 m)

In order to quantify the thermal mitigation effect of the park on the city and to analyse the changing pattern of the park's cooling of the surrounding environment, this study fits a decay curve of the park's LST with distance from the park boundary. As shown in Fig. 4, the variation of buffer LST over the 1200 m buffer distance range of the park is depicted. The park temperature is at the starting point and represents the baseline average temperature within the park. As the distance increases, the average LST per 30 metre buffer goes from increasing to levelling off. The first turning point on the curve is a key metric that calculates park cooling intensity PCI and park distance distance PCD (Aram et al., 2019)..

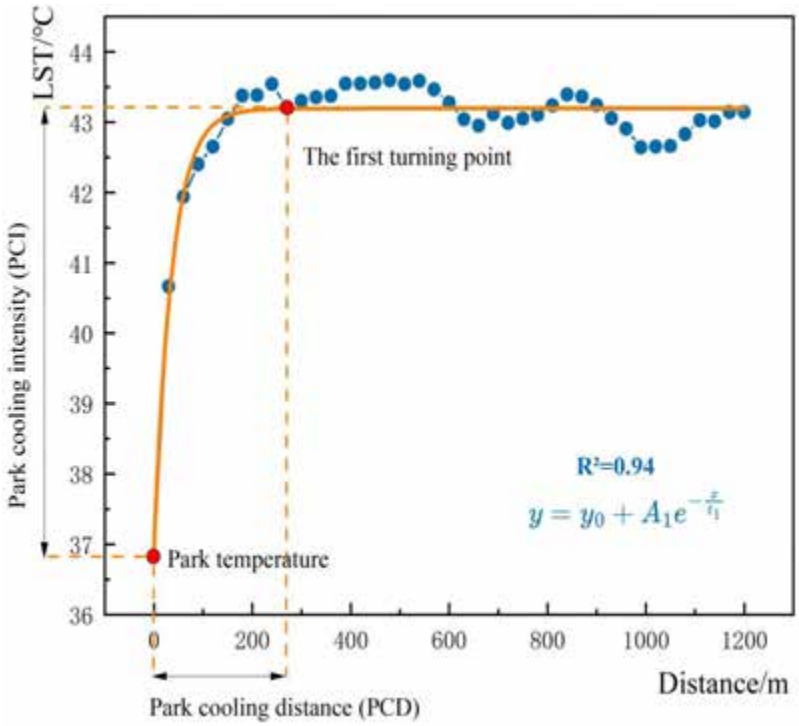

Figure 4 Curve fit of park thermal mitigation to the surroundings (average LST trend per 30 m buffer outside the park, in the case of Sansan Forest Park)

The park cooling effect evaluation system incorporates a multi-dimensional framework comprising five key metrics (Table 2): Park Cooling Distance (PCD), Park Cooling Area (PCA), Park Cooling Efficiency (PCE), Park Cooling Intensity (PCI), and Park Cooling Gradient (PCG). These indicators collectively provide a comprehensive quantification of urban parks' thermal mitigation capacity .

Table 2 Evaluation Index System for Park Thermal Mitigation Effects

Indicator	Definition	Calculation Formula	Unit
Park Cooling Distance (PCD)	Distance from park boundary to the boundary of the cooling effect	PCD = Distance from the first turning point to the park boundary (Figure 4)	m
Park Cooling Area (PCA)	Area within the park's influence range where temperature is significantly lower than the background value	PCA = Area of the buffer zone from the first turning point to the park boundary	km²
Park Cooling Efficiency (PCE)	Cooling area per unit park area	PCE = PCA / Park area	km²/km²
Park Cooling Intensity (PCI)	Average temperature drop within the cooling range	PCI = ΔT (Buffer zone LST - Park LST)	
Park Cooling Gradient (PCG)	Attenuation rate of temperature drop with distance from the park	PCG = ΔT / Distance	100m

2.3.2 Selection of Environmental Variables

In order to reveal the key drivers of thermal mitigation effects in urban parks, 20 variables were selected in this study from six dimensions: park morphology, distribution, structure, surrounding built environment, peripheral land cover and regional climate (Table 3). The first three dimensions are within the park, and the last three dimensions are located outside the park within the 1200 m buffer zone.

Table 3 Definitions and Calculation Methods of Influence Variables

Indicator Category	Specific Indicator	Abbreviation	Formula
Park Morphological Features	Park Area	PA	Vector data area
	Park Perimeter	PP	Vector data perimeter
	Elevation	DEM	Mean elevation within the park
	Normalized Difference Vegetation Index	NDVI	$NDVI = \frac{NIR - R}{NIR + Rw}$
Park Distribution Features	Impervious Surface Area Ratio	BR	$BR = \frac{\text{Impervious Surface Area in Park}}{\text{Total Park Area (PA)}}$
	Water Area Ratio	WR	$WR = \frac{\text{Water Body Area in Park}}{\text{Total Park Area (PA)}}$
	Forest Area Ratio	FR	$R = \frac{\text{Forest Land Area in Park}}{\text{Total Park Area (PA)}}$
	Grassland Area Ratio	GR	$GR = \frac{\text{Grassland Area in Park}}{\text{Total Park Area (PA)}}$
Park Structural Features	Landscape Shape Index	LSI	$SI = \frac{\text{Park Perimeter (PP)}}{2\sqrt{\pi} \times \text{Park Area (PA)}}$
	Aggregation Index	AI	$AI = \frac{\sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij}}{A} \times 100$
	Contagion Index	CONTAG	$CONTAG = 100 \times \frac{-\sum_{i=1}^{n} \sum_{j=1}^{n} p_{ij} \ln(p_{ij})}{2\ln(n)}$
Built Environment Surrounding	Building Density	BD	$BD = \frac{\text{Building Base Area}}{\text{Site Area}} \times 100\%$
	Floor Area Ratio	FAR	$FAR = \frac{\text{Total Floor Area}}{\text{Site Area}}$
Land Cover Surrounding Parks	Impervious Surface Ratio in Buffer	BBR	$BBR = \frac{\text{Impervious Surface Area in Buffer}}{\text{Total Park Area (PA)}}$
	Water Body Ratio in Buffer	BWR	$BWR = \frac{\text{Water Body Area in Buffer}}{\text{Total Park Area (PA)}}$
	Forest Ratio in Buffer	BFR	$BFR = \frac{\text{Forest Land Area in Buffer}}{\text{Total Park Area (PA)}}$
	Grassland Ratio in Buffer	BGR	$BGR = \frac{\text{Grassland Area in Buffer}}{\text{Total Park Area (PA)}}$
Climatic Conditions Surrounding	Surrounding Temperature	BLST	Mean LST in buffer zone
	Surrounding Wet	BWET	Mean humidity in buffer zone
	Surrounding Elevation	BDEM	Mean DEM in buffer zone

2.3.3 Analysis Models

(1) **Boosted Regression Tree (BRT) Model**

This study employed the Boosted Regression Tree (BRT) model to quantifie the influence of independent variables on dependent variables through relative Influence. This approach integrates multiple regression trees through a machine learning strategy to effectively capture complex interactions and threshold effects among variables (Elith et al., 2008; Friedman, 2001). The model's predictive accuracy was validated using the root-mean-square error (RMSE) and coefficient of determination (R^2) to ensure its reliability in quantifying the thermal effects of urban parks, providing data-driven support for subsequent spatial planning strategies.

$$RI_v = \frac{\sum_{m=1}^{M}\sum_{k=1}^{K_m}\Delta E_{m,k,v}}{\sum_{m=1}^{M}\sum_{k=1}^{K_m}\Delta E_{m,k}} \times 100\%$$

Where "v" is target independent variable (e.g., NDVI, BD); "M" is total number of regression trees; "K_m" is number of splits in the m-th tree; is reduction in squared error when variable v is used in the k-th split of the m-th tree.

(2) Restricted Cubic Spline (RCS) Curves and Threshold Identification

Restricted Cubic Spline (RCS) is a nonparametric statistical method that fits the nonlinear relationship between a continuous variable and a response variable by means of a segmented cubic polynomial function, with first and last linear constraints imposed to ensure the smoothness of the curve and the stability of the extrapolation (Govindarajulu et al., 2009; Zhao et al., 2024). The core advantage of RCS is its ability to automatically capture complex nonlinear patterns through segmental fitting and smooth connections. Its mathematical form is as follows.

$$f(X) = \beta_0 + \beta_1 X + \sum_{k=1}^{K-2} \beta_{k+1} \cdot h_k(X)$$

X is a continuous predictor variable; hk is the basis function; and tk is knots, usually taken as equidistant quartiles. In order to identify the thermal mitigation thresholds of the parks for the urban environment, the first order derivative (slope) and second order derivative (curvature) of the curves were calculated.The RCS curves allow for the identification of two critical inflection points (Fig. 5). The two critical inflection points are defined in the first-order derivative plot as the point where the slope of threshold 1 (T1) is 0 and threshold 2 (T2) is the point with the largest slope, when the rate of thermal mitigation of the park to the urban environment is likely to be optimal.

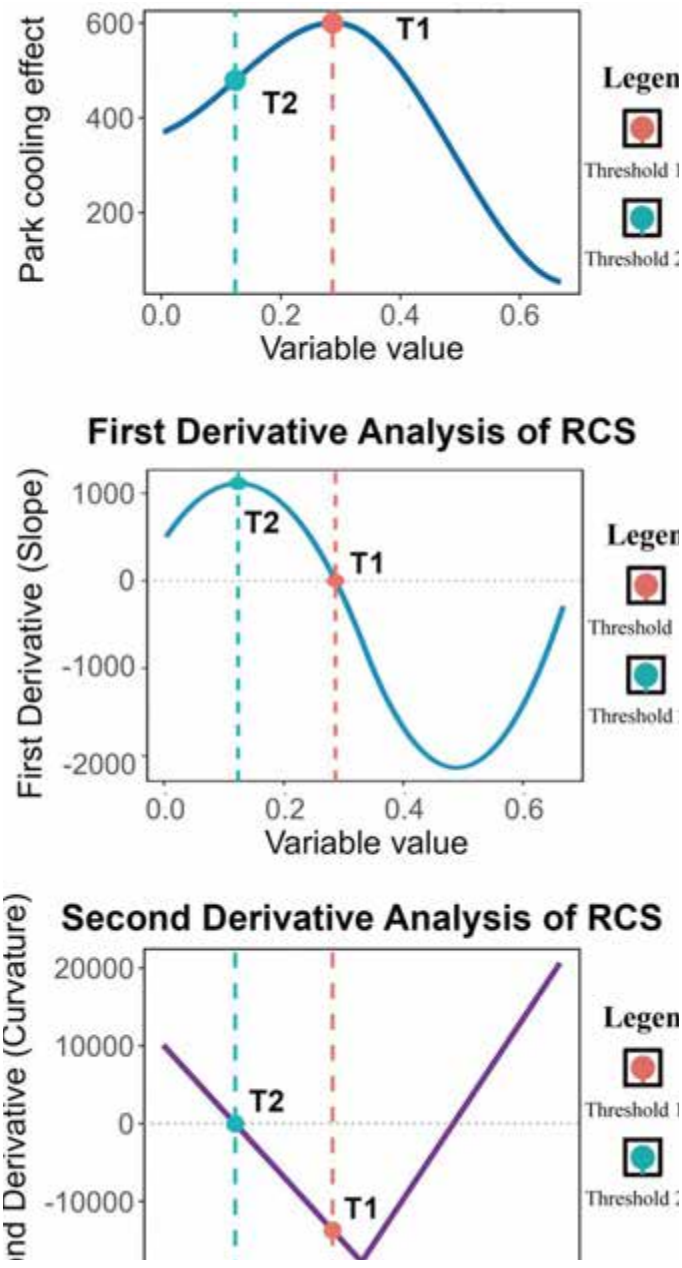

Figure 5 Schematic Diagram of Restricted Cubic Spline (RCS) and Thresholds

(3) K-means Cluster Analysis

In this study, a K-means clustering algorithm was used to classify the cooling performance of parks, with the aim of identifying clusters with similar cooling characteristics and quantifying their relative contributions (Kanungo et al., 2002)we are given a set of n data points in d-dimensional space R/sup d/ and an integer k and the problem is to determine a set of k points in Rd, called centers, so as to minimize the mean squared distance from each data point to its nearest center. A popular heuristic for k-means clustering is Lloyd's (1982. The optimal number of clusters was determined by the elbow rule in conjunction with the contour coefficient method. The elbow rule is based on the inflection point of the curve of the within-group sum of squares (WSS) with respect to the number of clusters, and the contour coefficient method is performed by calculating the average contour coefficient of 2 to 10 clusters (with values ranging from [-1,1], with larger values indicating better intra-cluster compactness and inter-cluster separation. The final result is determined (K = 4) as the optimal number of clusters.

3. Research Results

3.1 Spatial Patterns of Park Thermal Mitigation in Summer

3.1.1 Gradient Attenuation of Cooling Performance

In the spatial pattern of heat mitigation in parks in summer, the gradient decay of cooling effect showed significant regularity and spatial differentiation characteristics. Based on the buffer zone temperature analysis, all parks formed a significant cooling zone, with a mean park cooling distance (PCD) of 493.5 m and a mean cooling intensity (PCI) of 3.7 °C. The park cooling gradient (PCG) was 1.38°C/100 m, which means that the temperature drop decreased by 1.38°C with every 100 m increase in distance from the park, revealing the basic law that the park thermal mitigation effect exponentially decays with increasing spatial distance. The analysis of spatial heterogeneity shows that there are significant differences in cooling efficiency and coverage between parks of different zones and sizes. Wetland parks in the suburbs (e.g., Yundonghai Wetland Park in Sanshui, with an area of 4.35 km^2) had a park cooling area (PCA) of 6.21 km^2 and a park cooling efficiency (PCE) of 1.43 km^2/km^2, while community parks in the city centre (e.g., Zhongshan Park in Chancheng, with an area of 0.27 km^2) had a PCA of only 1.58 km^2, but their PCE was as high as 5.72 km^2/km^2. This suggests that although small parks have advantages in cooling efficiency, their absolute cooling coverage is limited due to their size (Figure 6).

The modulation of the cooling effect by the heat island background is significant. The mean surface temperature (LST) in the city centre area (Chancheng District) is 40.88°C, which is 7.3°C higher than that in the suburban area (Gaoming District), and as a result, the cooling gradient (PCG) in the city centre parks is 0.97°C/100 m, which is significantly lower than that in the suburban parks, which is 1.61°C/100 m. (Fig. 7), which suggests that the spatial decay rate of the cooling effect of the parks is weakened by the high intensity of the heat island environment. This indicates that the high-intensity heat island environment will weaken the spatial decay rate of the cooling effect in the parks, forming a spatial pattern of slowing down the cooling gradient in the thermal background.

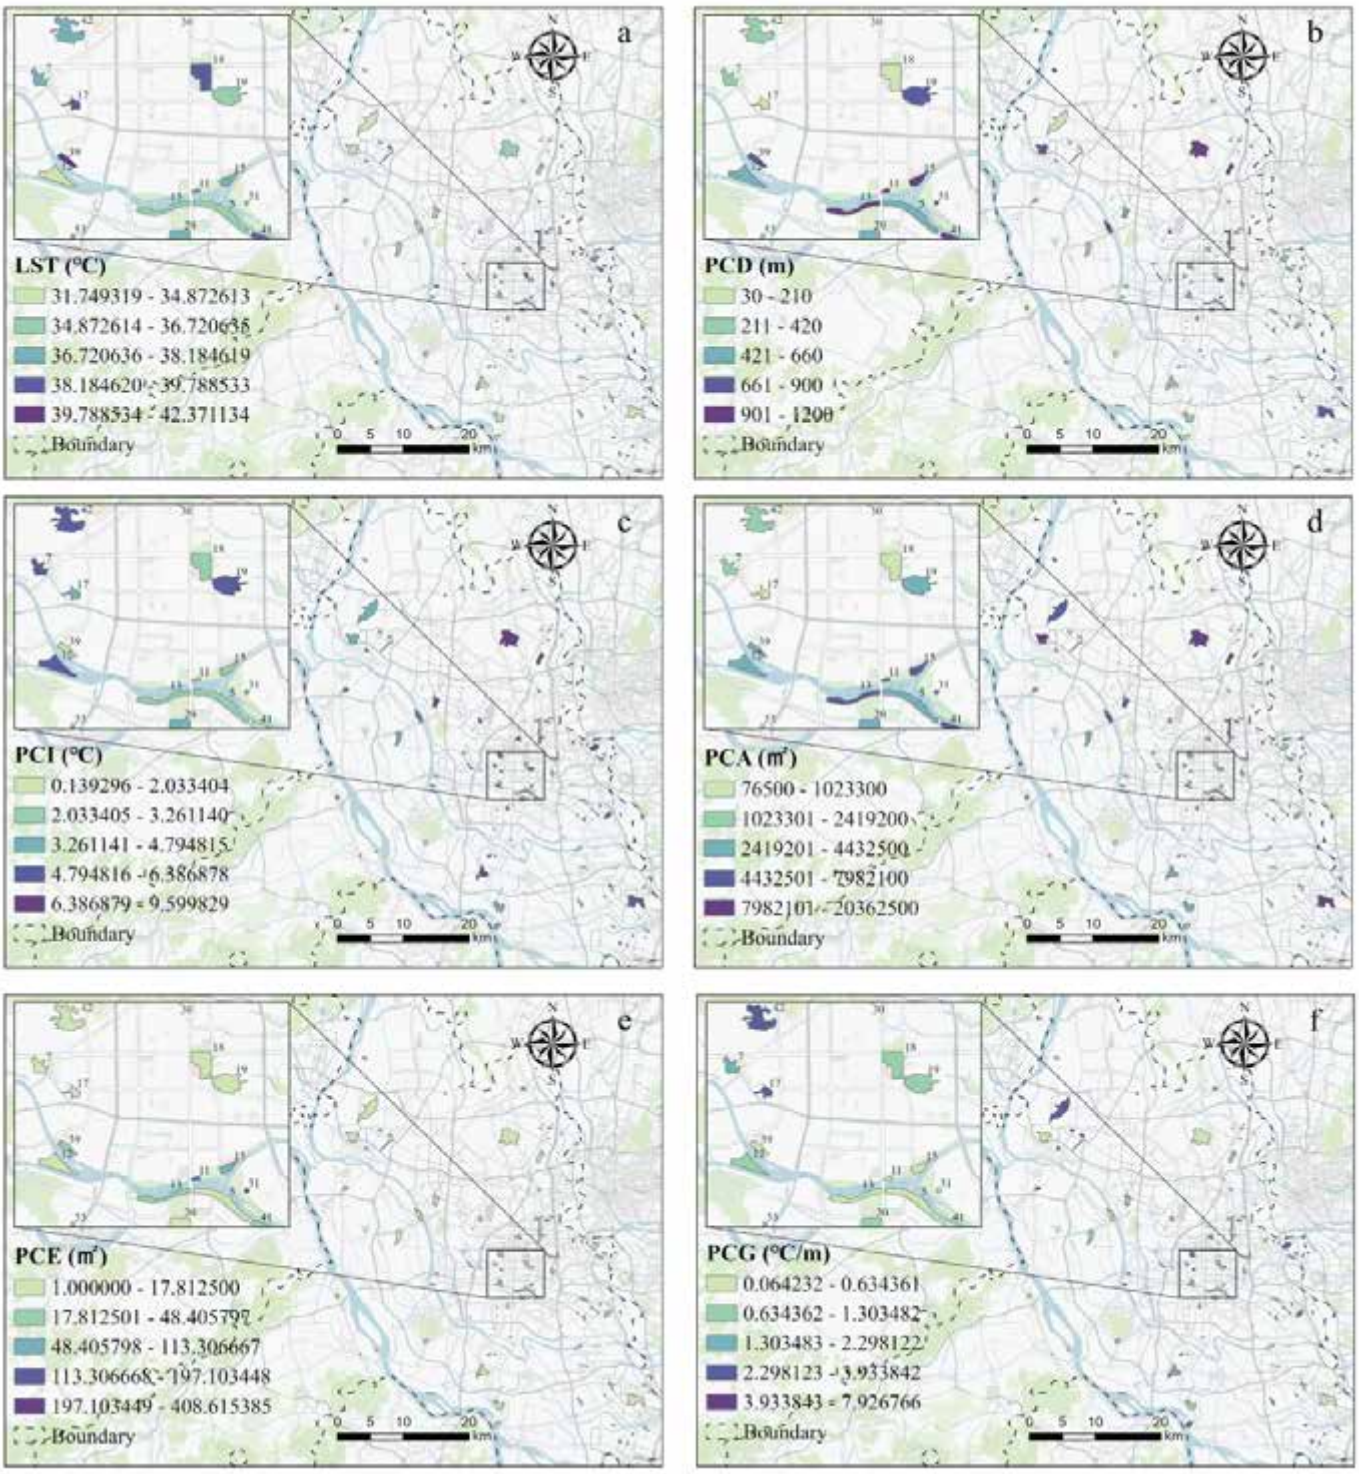

Figure 6 Spatial Distribution Maps of LST and 5 Park Cooling Performance Index for 120 Urban Parks: (a) Park LST, (b) PCD index, (c) PCI index, (d) PCA index, (e) PCE index, (f) PCG index.

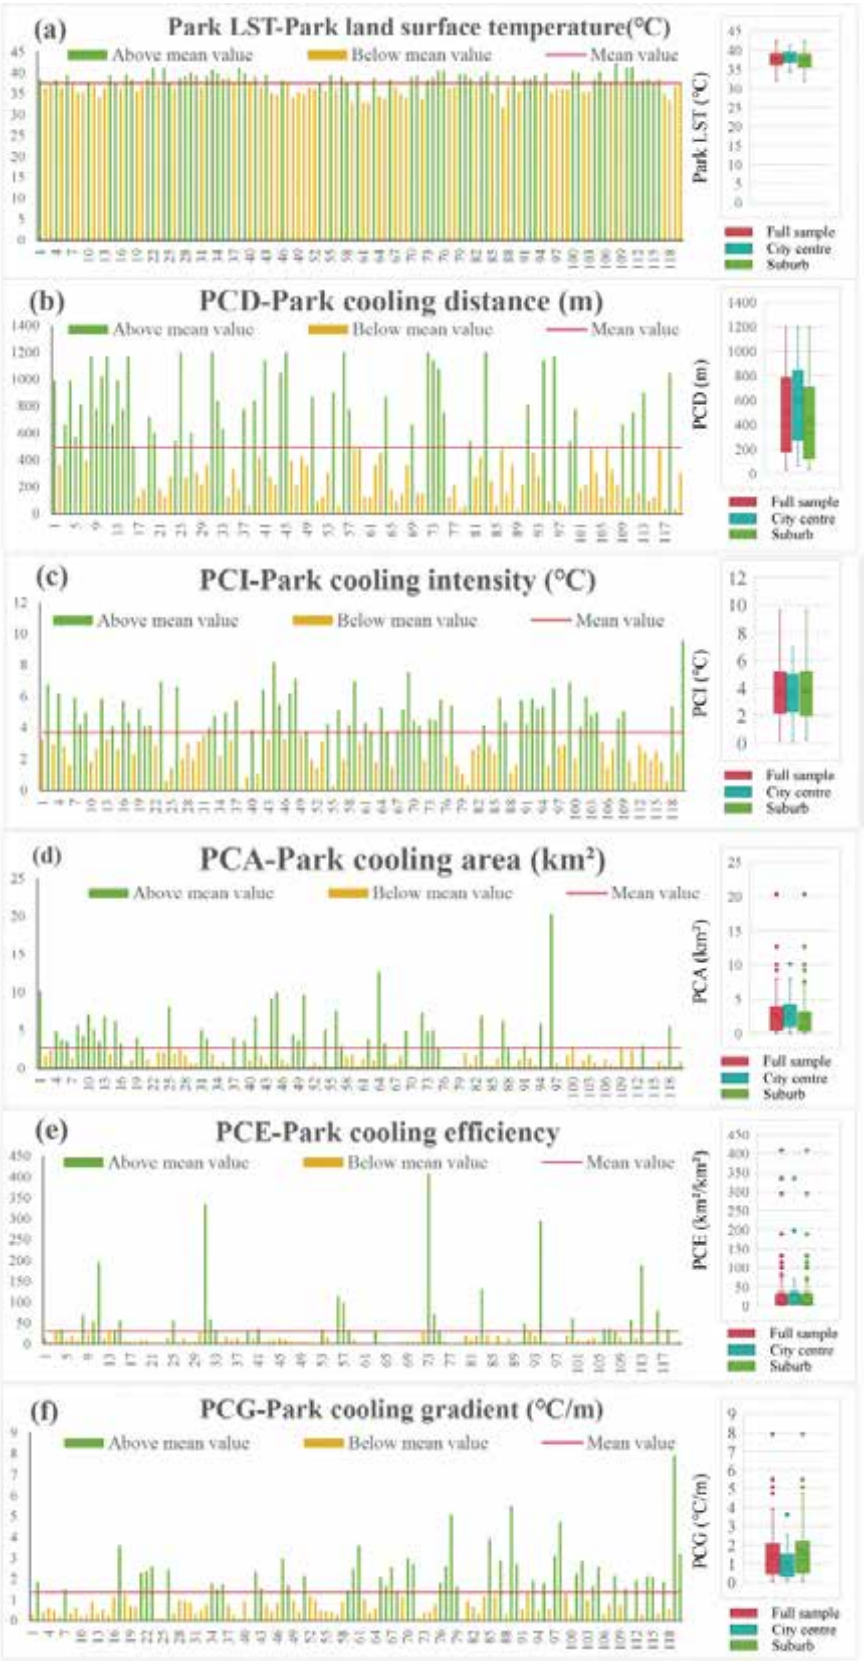

Figure 7 Bar Charts and Boxplots of Six Cooling Indices for 120 Urban Parks: The red boxplots represent the full sample, light green denotes downtown areas, and dark green indicates suburban areas.

3.1.2 Cooling Performance of Different Park Types

Based on the Foshan City park classification standard, the 120 parks included Community Parks, Comprehensive Parks, Wetland Parks, Forest Parks, and Special Parks. Among them, Forest Parks had an average PCI of 5.44±1.61°C, which was significantly higher than that of other types of parks, and their average PCA (4.84±5.38 km²) and PCG (1.8±1.4°C/100m) were higher compared with those of other parks, which was attributed to the synergistic effect of their large natural vegetation and complex ecosystems.Comprehensive Parks' PCA (4.36±3 km²) and PCD (743.75±287.75m), were outstanding, possibly due to their diverse landscaping with a large footprint. In contrast, the average PCI of specialised parks was only 2.23±1.62°C, but their PCE (43.58±98.84 km²/km²) showe1d high discrete characteristics, reflecting the differences in design elements such as vegetation configurations and water body areas in different specialised parks. Although the wetland park had a higher PCG (1.66±0.95°C/100m), its PCA was smaller (1.11±2.92 km²), which might be limited by the localised evapotranspiration of wetland water bodies.

Table 4 Cooling Performance of Different Park Types

Park Type	Sample	Mean PCI/□	Mean PCA/ km²	Mean PCE/km²/ km²	Mean PCD/m	Mean PC-G/□/100m
Community Parks	43	3.71±1.48	2.69±1.35	30.21±35.59	493.5±260.8	1.38±0.82
Comprehensive Parks	24	4.08±2.01	4.36±3	40.84±61.52	743.75±287.75	0.68±0.61
Wetland Parks	10	4.05±1.59	1.11±2.92	23.28±15.57	337.67±409.19	1.66±0.95
Forest Parks	14	5.44±1.61	4.84±5.38	11.49±18.72	555±414.32	1.8±1.4
Special Parks	29	2.23±1.62	1.81±1.81	43.58±98.84	393.1±380.09	1.56±1.88

3.2 Key Influencing Factors of Park Cooling Performance

3.2.1 Significance ranking of the Variables

Based on the BRT model results (Fig. 8), the model fit was generally satisfactory, with PCD (R^2=0.64), PCA (R^2=0.87), PCE (R^2=0.58), PCG (R^2=0.67), and PCI (R^2=0.83). Landscape pattern, land cover type, park morphological features and built environment were the core influences on thermal mitigation. Among them, in PCA, Park Perimeter (PP) was the most critical, reflecting the influence of park morphological boundaries on cooling diffusion, and Park Morphological Features accounted for 27.74%, indicating that the park's own morphological structure was the core factor determining PCA; on Cooling Efficiency (PCE), the importance of Park Area (PA) was prominent, showing that the scale effect had an impact on the cooling efficiency of unit area. Land Cover Types and Park Morphological Features together accounted for 81.98%.

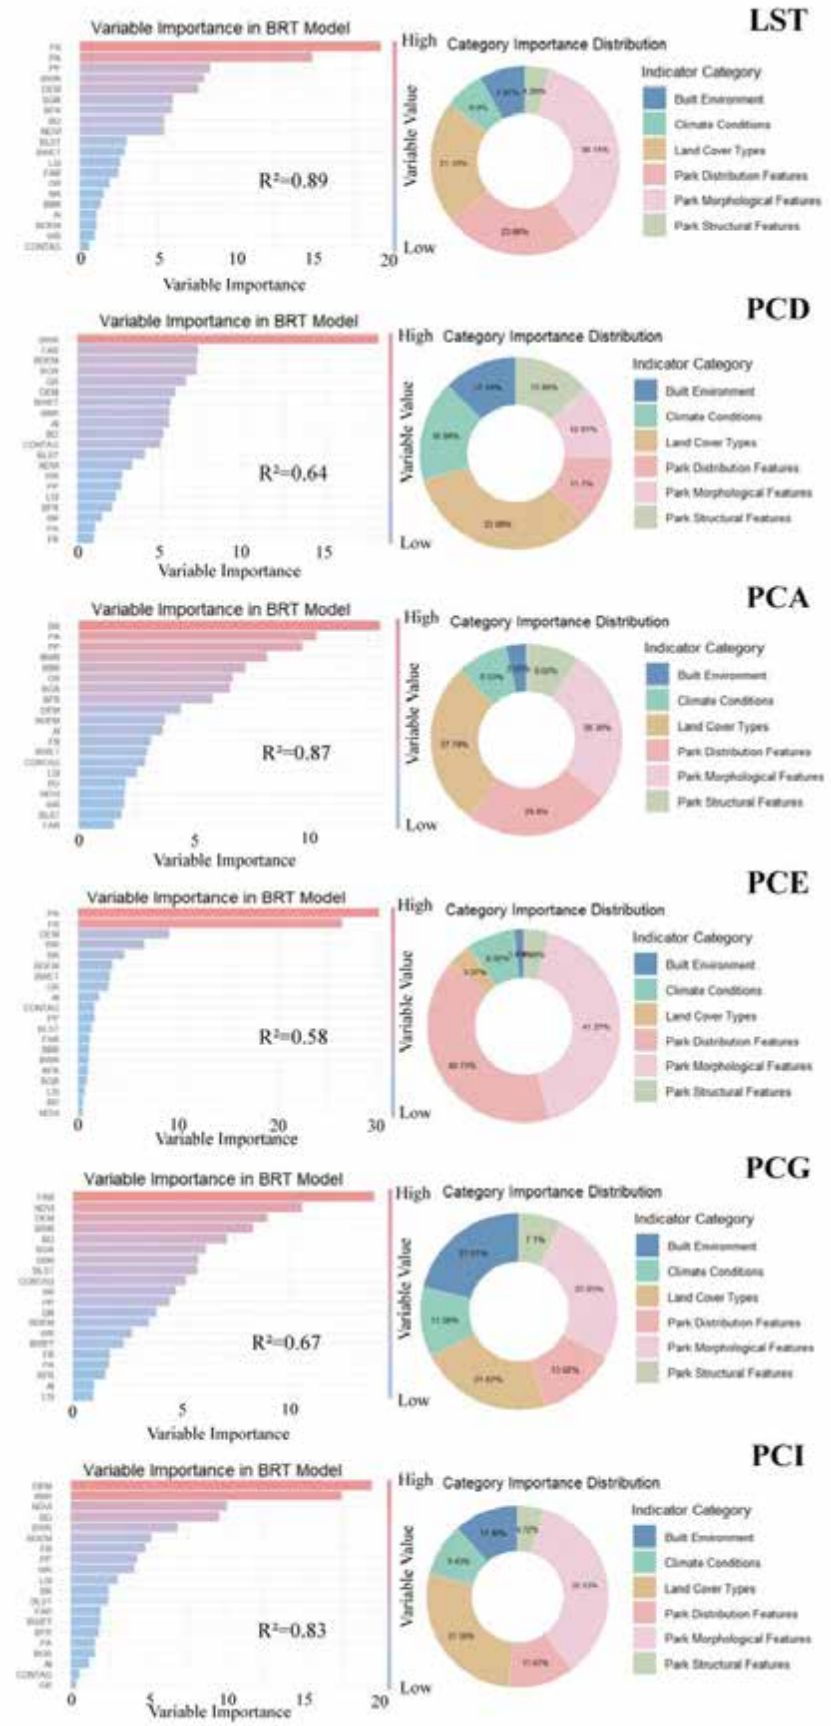

Figure 8 Importance Ranking of Influence Variables on Park Cooling Performance Based on BRT Model

3.2.2 Marginal Effect Analysis

Based on the BRT model, the study selected the five influencing variables with the highest variable ranking, constructed their restricted cubic spline curves (RCS curves) with the five park cooling performance indices (PCD, PCA, PCE, PCG, and PCI), and identified the thresholds (Figure 9). The park cooling performance index is mainly affected by various factors such as PA, DEM, FAR, NDVI, BD, BBR, BWR, etc., and shows a complex nonlinear relationship. Using the RCS curve, we can explore the increase and decrease of cooling intensity when the values of variables change, so as to guide the reasonable use of relevant variables to improve cooling intensity in park design, and then assist in determining the scope of variable control to improve cooling efficiency.

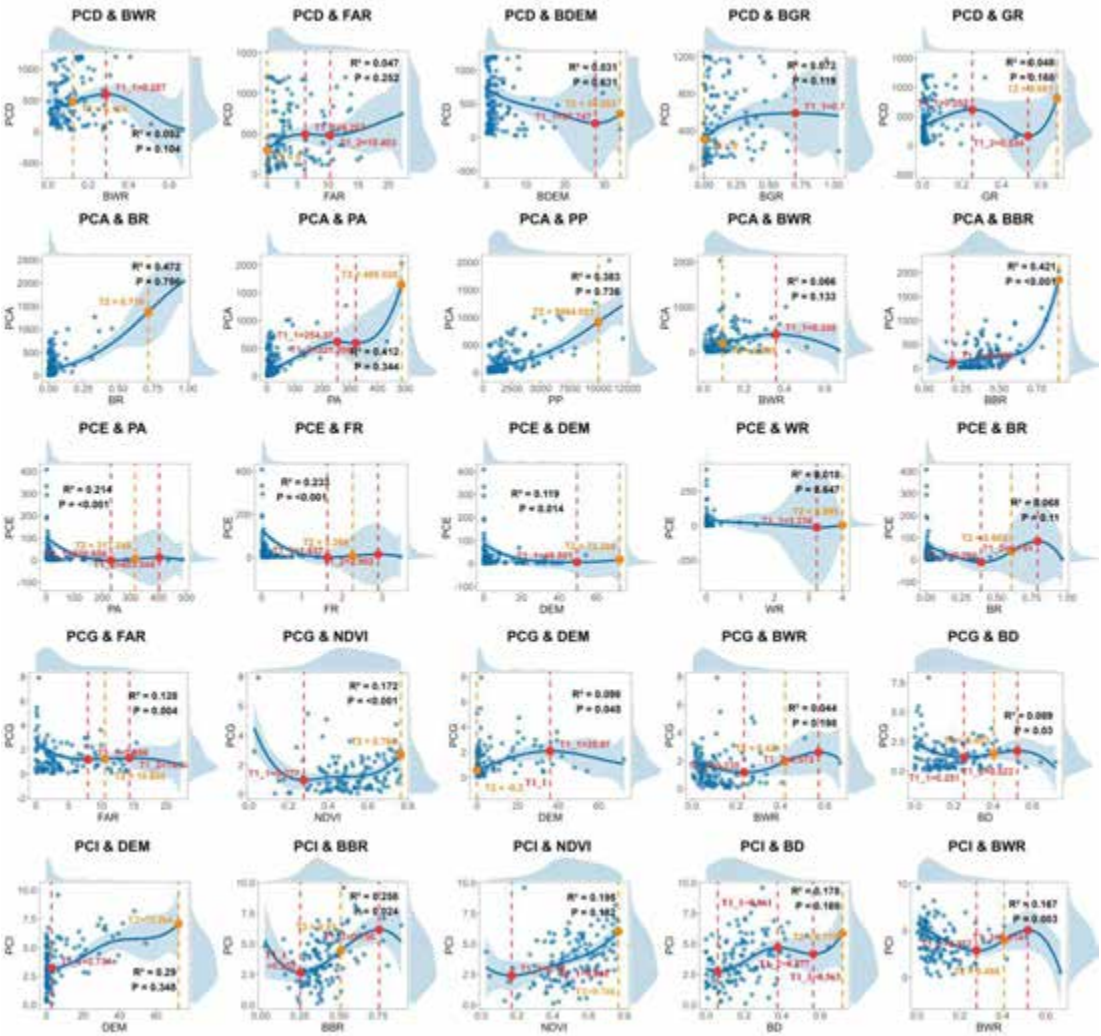

Figure 9 Restricted Cubic Spline (RCS) Curves and Threshold Identification for the Top Five Influencing Variables Ranked by the BRT Model and Five Park Cooling Performance Indices (Thresholds Marked in Yellow as T2 and Red as T1)

3.3 Threshold of Heat Mitigation Effects

Based on the RCS curve model, statistically significant thresholds were identified for 8 key variables (Table 5). Park area (PA) (R2 = 0.214, P < 0.001) showed increasing marginal utility of PCE in the interval [2.31, 4.03] k m², with the fastest growth rate at 3.17 k m², suggesting that moderately sized parks are favourable for the improvement of cooling efficiency.In terms of DEM, the effects on PCE (R2 = 0.119, P < 0.05) and PCG (R^2 = 0.098, P < (R^2=0.098, P<0.05) varied at different thresholds, with PCE changing from decreasing to increasing when the threshold exceeded 49.551m. Among the indicators of the built environment around the park, the building density (BD) (R^2=0.089, P 0.05) showed an increasing trend in the interval of [0.251, 0.523], and the fastest rate of change was observed at 0.403; the floor area ratio (FAR) (R^2=0.128, P 0.01) showed an increasing trend in the interval of [7.986, 14.34], and the

slope of increase was observed at 10.604, and the slope of increase at 10.604. The slope of the increase reached its maximum at 10.604. The NDVI (R^2=0.172, P<0.001), an indicator of vegetation cover, showed an increasing trend of PCG in the interval of [0.277, 0.766], with the maximum slope at 0.766. BBR (R^2=0.167, P<0.05) and BWR (R^2=0.167, P<0.05), positively affected PCA and PCI in the intervals [0.252, 0.756] and [0.277, 0.516], respectively, and reached the extremes of the rate of increase at the 51% and 40% thresholds.

Table 5 Thresholds of Key Variables for Cooling Performance and Their Ecological Significance

Variable	Cooling Performance Index	Threshold	Physical Meaning	Significance
PA	PCE	T1_1=2.31 km², T1_2=4.03 km²	When PA is within [2.31, 4.03] km², per-unit cooling efficiency (PCE) shows an upward trend (increasing marginal utility); outside this interval, PCE declines (decreasing marginal utility).	R^2=0.214, P < 0.001
		T2=3.17 km²	At PA=3.17 km², the slope reaches its peak, indicating the fastest growth rate of PCE.	
DEM	PCE	T1=49.551 m	Below 49.551 m, PCE decreases rapidly with elevation; above 49.551 m, PCE increases.	R^2=0.119, P < 0.05
		T2=72.266 m	At 72.266 m, the growth rate of PCE reaches its maximum.	
	PCG	T1=35.97 m	Below 35.97 m, PCG rises rapidly with elevation; above 35.97 m, PCG declines.	R^2=0.098, P < 0.05
FAR	PCG	T1_1=7.986, T1_2=14.34	When FAR is within [7.986, 14.34], PCG shows an upward trend; outside this interval, PCG declines.	R^2=0.128, P < 0.01
		T2=10.604	At FAR=10.604, PCG increases at the fastest rate.	
NDVI	PCG	T1=0.277	Below NDVI=0.277, PCG decreases with NDVI; above 0.277, PCG increases. This marks the transition point from decline to growth.	R^2=0.172, P < 0.001
		T2=0.766	Within NDVI [0.277, 0.766], PCG rises; at NDVI=0.766, the growth rate peaks.	
BD	PCG	T1_1=0.251, T1_2=0.523	Within BD [0.251, 0.523], PCG increases; outside this range, PCG decreases.	R^2=0.089, P < 0.05
		T2=0.403	At BD=0.403, the rate of PCG change reaches its maximum.	
BBR	PCA	T1=0.188	Below BBR=0.188, PCA decreases with BBR; above 0.188, PCA increases. This marks the transition from decline to growth.	R^2=0.421, P < 0.001
		T2=0.896	At BBR=0.896, PCA increases at the fastest rate.	
BBR	PCI	T1_1=0.252, T1_2=0.756	Within BBR [0.252, 0.756], PCI increases; outside this range, PCI declines. T1_1 marks the transition from decline to growth, and T1_2 marks the reversal.	R^2=0.167, P < 0.05
		T2=0.51	At BBR=0.51, the growth rate of PCI peaks, indicating the strongest positive effect.	
BWR	PCI	T1_1=0.277, T1_2=0.516	Within BWR [0.277, 0.516], PCI increases; outside this range, PCI declines. T1_1 marks the transition from decline to growth, and T1_2 marks the reversal (or significant trend change).	R^2=0.167, P < 0.05
		T2=0.405	At BWR=0.405, PCI increases at the fastest rate.	

3.4 Cluster Analysis of Four Cooling Patterns

In this study, 120 park samples were classified into 4 cooling performance clusters by K-mean clustering algorithm (Table 7, Fig. 10), revealing the differences in cooling mechanisms among different park clusters.The High-Efficiency cluster (28 samples) with PCI=0.430, PCA=1.299, PCE=0.094 and PCD=1.288, presented a high-intensity, large-area, far-radial pattern. The dominant factors of this cluster are the increasing marginal utility interval of park area (PA) over 2.31 kΔand NDVI over 0.766. Among them, Qiandeng Lake Park and Wanglugang Forest Park achieve efficient cooling through the layout of large water bodies and high vegetation cover, respectively.

The Low-Efficiency cluster (48 samples) has negative cooling indicators (PCI=-0.733, PCA=-0.432, PCE=-0.184), and is characterised by short cooling distances and gentle gradient attenuation, which is mainly due to the high BD (BD>0.523) or insufficient FAR (FAR<7.986), and insufficient NDVI (NDVI<0.277). In particular, the Half Moon Island Wetland Park had a limited cooling effect due to a high ratio of impervious surfaces in the buffer zone.

The Moderate Efficiency cluster (39 samples) had a moderate PCI=0.594 but a significantly positive PCG=1.026, with negative PCA and PCI, reflecting outstanding spatial heterogeneity. The dominant factors were DEM (DEM<35.97 m) and microtopographic differences under artificial intervention. Among them, Zhongshan Park in Chancheng formed a strong cooling gradient due to its close proximity to the built-up area but failed to reach an efficient level due to its size. Comprehensive clusters (5 samples) with PCE=4.199 were extremely high, such as the high evapotranspiration agricultural wetland model in Shuiteng Park.

Table 7 Cooling Characteristics of Four Park Clusters

Cluster Name	Samples	PCI	PCA	PCE	PCD	PCG	Typical Cases
High-Efficiency	28	0.430	1.299	0.094	1.288	-0.695	Qiandeng Lake Park, Yingyue Lake Park, Wangjiegang Forest Park
Low-Efficiency	48	-0.733	-0.432	-0.184	-0.352	-0.341	Banyuedao Wetland Park, Nan-hai National Fitness Sports Park
Moderate Efficiency	39	0.594	-0.487	-0.380	-0.706	1.026	Chancheng Zhongshan Park, Shiwan Park, Leigang Park
Comprehensive	5	0.000	0.673	4.199	1.671	-0.830	Yucun Cultural Park, Huahai Liuchao, Shuiteng Park

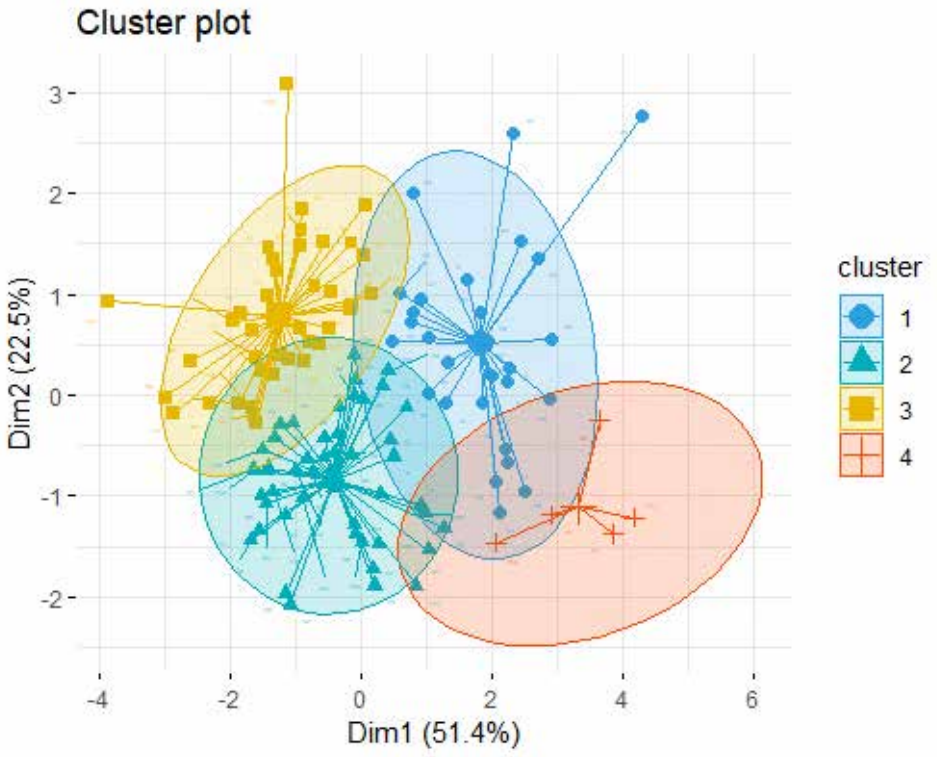

Figure 10 Cluster Diagram of Park Cooling Patterns Based on K-mean

4. Discussions

4.1Threshold Mechanisms for Heat Mitigation of Urban Parks in Water-Network Cities

The study reveals the nonlinear threshold relationship between the cooling performance of parks and key factors such as PA, NDVI, BD and BWR in water network cities, and constructs a methodological framework for the analysis of cooling performance indices and thresholds. The marginal utility of PA increases in the interval of [2.31, 4.03] km², which is a breakthrough from the traditional perception that the larger the size of the park, the better the cooling effect. It is proved that a moderate-sized park can achieve more efficient thermal mitigation by optimising the spatial layout. In addition, the decreasing and then increasing effect of NDVI with 0.277 as the turning point reveals the critical relationship between vegetation cover and cooling intensity. For the blue-green spatial indicators (BBR, BWR) of the buffer zone in the water network city, it was found that there was a threshold interval for the cooling effect. the PCI of BWR rose at [0.277, 0.516]. It provides a quantitative basis for the synergistic cooling of blue-green and enriches the thermal mitigation research on the coupling of urban ecohydrological elements.

4.2 Threshold-Based Planning Strategies

4.2.1 Hierarchical Control: Threshold Adaptation for Medium and High Efficiency Cooled Parks

For High-Efficiency Cooling Performance Parks (Cluster I), large parks with a PA greater than 2.31 km² and an NDVI greater than 0.766 should be strictly protected from fragmented development. For example, the Qiandeng Lake Park should maintain a balance between the thresholds of water body area and vegetation cover, and avoid the impervious surface ratio (BBR) of the buffer zone exceeding 0.188. For high-density built-up area parks (e.g., Wenhua Park) with BD greater than 0.523 or FAR less than 7.986 in Low-Efficiency Parks (Cluster II), the NDVI should be increased to 0.277 or above by removing walls to allow greening, vertical greening and other measures, while controlling the density of the new buildings to be ≤0.251 (Gill et al., 2007; Keeler et al., 2019)and changes to hydrology such as increased surface runoff of rainwater. Such changes are, in part, a result of the altered surface cover of the urban area. For example less vegetated surfaces lead to a decrease in evaporative cooling, whilst an increase in surface sealing results in increased surface runoff. Climate change will amplify these distinctive features. This paper explores the important role that the green infrastructure, i.e. the greenspace network, of a city can play in adapting for climate change. It uses the conurbation of Greater Manchester as a case study site. The paper presents output from energy exchange and hydrological models showing surface temperature and surface runoff in relation to the green infrastructure under current and future climate scenarios. The implications for an adaptation strategy to climate change in the urban environment are discussed.","container-title":"Built Environment (1978-. Moderate Efficiency parks (Cluster III) can use microtopography and artificial water bodies to optimise the cooling gradient, based on the PCG rise when the DEM is less than the 35.97 m threshold. For example, Zhongshan Park in Chancheng can make up for the lack of area by enhancing the temperature difference with the surrounding heat islands through the extension of the water system.

4.2.2 Spatial Optimization: Synergy between Blue and Green Networks

The blue-green network construction strategy based on horizontal and vertical threshold synergy provides a multi-dimensional spatial optimisation path for thermal environment management in water network cities. In terms of horizontal synergy, waterfront buffer zones with BWR ≥ 0.277 are combined with vegetation corridors with NDVI ≥ 0.277 in urban planning. A composite cooling chain is formed through the coupling of water evaporation and vegetation transpiration. Foshan Riverside Wetland Park enhances the PCI by 32% through the synergistic configuration of BWR=0.405 and NDVI=0.65. Secondly, vertical synergy, in the area of undulating terrain, the vegetation communities with staggered heights can be laid out. When the DEM was in the interval of 49.55-72.27 m, the effect of elevation on PCE showed a tendency of decreasing and then increasing. The cooling gradient is enhanced through the difference of transpiration in three-dimensional space. For example, the cooling efficacy of different elevation intervals was effectively enhanced by the vertical layering configuration of mountain vegetation in Wang Luegang Forest Park.

4.2.3 Optimization Strategies: Threshold Enhancement for Inefficient Parks

For the Low-Efficiency parks in cluster Δ the three-threshold priority transformation path requires systematic integration of ecological restoration and spatial planning strategies. Firstly, taking the green space threshold as the priority transformation guide, for the parks with NDVI<0.277, the vegetation cover is improved through high-density planting of native tree species, and the transformation target of NDVI≥0.4 is set. Native plants in Foshan City occupy an important position in urban greening, and the plan requires that no less than 70% of the

plant species applied in urban greening are native species. For example, Ficus microcarpa, Ficus alpina, Camphor, Viburnum, Bombax, etc. are commonly used native species in Foshan.

At the same time, the buffer zone BBR control is limited to a threshold of 0.252, and measures such as softening of the hard interface are taken to weaken the heat-reflecting effect and enhance transpiration. Optimisation through density threshold. For the area around the park with a BD greater than 0.523, planning policy tools such as volume ratio transfer will guide the building setbacks to regulate the BD to a reasonable range of [0.251, 0.523], and release ventilation corridors to promote air circulation. By implementing water body threshold supplementation, for small green spaces with PA less than 2.31 km², raising BWR to above 0.277 by introducing micro water features such as fountains and rain gardens (Keeler et al., 2019) can increase PCI by 15-20%. This progressive intervention pathway can form a chain of inefficient park renovation techniques from ecological substrate restoration to spatial structure optimisation.

4.3 Validation and Comparative Analysis of Thresholds for Park Cooling Performance

This study validates research related to thermal mitigation in parks. It has been suggested that NDVI needs to exceed 30% for significant cooling (Gill et al., 2007). This study validates this conclusion through a threshold of 0.277 NDVI and refines the mechanism of the negative effect in the low-coverage zone. In contrast to the subtropical water network city study, this study quantified the inverted U-shaped relationship between BWR and PCI (T1_1=0.277, T1_2=0.516), which complements the explanation that excessive concentration of water bodies inversely leads to a decrease in cooling efficiency. In addition, the PA marginal utility intervals found in the study were highly consistent with the optimal scale of 2-5 km² for thermal mitigation in urban parks proposed by the U.S. Environmental Protection Agency (EPA) (Wong et al., 2021), further validating the universality of the thresholds.

4.4 Research Limitations and Future Directions

The limitations of the study are that the thresholds are based on remote sensing data from a single city in a single season, and their applicability in cities with significant differences in climate zones has to be verified. Second, socio-economic variables such as population density and energy consumption were not included, making it difficult to analyse the impact of human-environment interaction on cooling performance. In the future, we can expand the sample to more cities in the Yangtze River Delta and Pearl River Delta, and construct a cross-regional threshold model. The combination of UAV thermal imaging and ground-based measurements can improve the data accuracy, and the introduction of SD models to simulate the evolution of the thermal environment under the threshold regulation can provide a tool to support dynamic planning.

5. Conclusion

In the context of the global urban heat island effect dilemma, this study reveals the mechanism of urban heat mitigation by urban parks through multi-indicator assessment and machine learning modelling. This study found that high-intensity urban heat island environments attenuate the spatial decay rate of park cooling effects. The BRT model and RCS curves revealed that there are key thresholds for the core drivers: the optimal scale of heat mitigation in urban parks is 2.3-4 km²; the NDVI of parks needs to be over 27.7% to achieve significant cooling effect; the BWR has an inverted U-shape relationship with PCI, and the optimal blue spatial threshold is 40%. Finally, 120 parks were classified into four categories, High-Efficiency, Low-Efficiency, Moderate Efficiency and Comprehensive by K-means clustering algorithm. The study proposes targeted planning strategies for the four categories of parks, among which the low-efficiency parks can improve the cooling performance by increasing the vegetation cover and controlling the building density, and optimising the blue-green space layout. This study can provide useful guidance for the development of blue-green landscape spaces in water network cities to address global climate change.

Research on Energy-saving Renovation and Energy Consumption Correlation of Historical Residential Districts under the Background of Urban Renewal: A Case Study of Hehua Tang District in Nanjing City

Lin Lin, Jin Xing
Affiliation: School of Architecture, Southeast University, Nanjing, Jiangsu Province, China
Email:17816377669@163.com ; jxining@163.com

Abstract
Amid rising global energy demands and China's shift toward urban stock optimisation, this study investigates low-carbon renewal strategies for Nanjing's Lotus Pond Historical District using parametric modelling and energy simulations. Integrating Rhino/Grasshopper with a simulated annealing algorithm, multiple building height schemes were generated and evaluated for solar potential. Results demonstrated optimised schemes reduced energy use intensity (EUI) by 5.6–25 kWh/m² versus baseline. Shape coefficient strongly correlated with EUI (r=0.997), while floor area ratio (FAR) showed inverse correlation (r=-0.989). Vertical building distribution critically influenced solar gains, with self-shading reducing potential by 22%–28% in select cases. Balancing heritage preservation with energy performance, recommendations advocate limiting heights (1–2 stories), optimising shape coefficients (≤0.55), and integrating solar systems. The methodology offers data-driven insights for sustainable historical district renewal in stock-optimisation contexts.

Key words: Energy-efficient Retrofitting Historic Residential District Building Morphology Building Energy Use Intensity

Introduction

According to data from the International Energy Agency (IEA, 2022), global energy consumption increases at a rate of 6% every five years. In China, building energy consumption accounts for 28% to 30% of total societal energy use, with residential buildings contributing 61.7% of this figure[1]. The energy efficiency and emission reduction challenges in China's building sector remain a persistent focus.

Existing studies demonstrate a strong correlation between urban morphology and building energy consumption. Mutual shading between buildings influences the distribution and reflection of solar radiation, thereby affecting energy demands for lighting, cooling, and heating[2]. For instance, Mengju et al. investigated urban morphological parameters of dormitory blocks at Wuhan University, revealing that block topology and urban morphology significantly impact energy consumption and solar potential at the neighbourhood scale[3]. Similarly, Shen et al. evaluated urban morphological factors affecting photovoltaic potential and energy consumption in residential areas in Wuhan, proposing sustainable planning strategies for central China through regression analysis[4]. Researchers have introduced quantitative metrics, such as coverage ratio, average building height, and floor area ratio (FAR), to directly assess relationships between urban form and energy use. Y. Li et al. found that increasing FAR reduces heating energy density, particularly in its initial stages[5], while H. Leng et al. identified FAR as the most critical factor influencing heating energy consumption in office buildings in Harbin[6]. However, existing studies primarily focus on early-stage urban design for new developments, failing to address China's current emphasis on stock optimisation through "retention, renovation, and demolition" (RRD).

Hui et al. analysed the impact of retrofitting strategies on individual building energy consumption in Shanghai's existing residential areas using Grasshopper, ENVI-met, and EnergyPlus, recommending priority measures for hot summer and warm winter zones[7]. Ning et al. proposed microclimate-based design strategies—such as green spaces and activity zones—to enhance thermal comfort in Beijing's traditional courtyards[8]. While these studies address building-level retrofitting, few explore the energy implications of morphological and layout adjustments at the planning scale.

China's urbanisation has transitioned from large-scale demolition to RRD-based stock optimisation. In alignment with human-centric urban development principles, cities are prioritising the renovation of ageing residential areas. Historical districts, as carriers of traditional architectural heritage, require preservation of street patterns and morphology while integrating organic renewal strategies. Under the "dual carbon" goals, energy consumption during renovation must also be addressed.

Since Nanjing's designation as a National Historical and Cultural City in 1982, the municipality has accumulated extensive experience in preserving traditional residential areas. This study selects a plot in Nanjing's Lotus Pond Historical District for parametric modelling, exploring RRD-based renewal strategies to reduce energy use intensity (EUI) and analysing correlations between morphological parameters and energy consumption. The findings offer guidance for low-energy retrofitting of historical residential districts.

1. Study Scope

The Lotus Pond Historical District, located in Nanjing's southern Shuangtang Subdistrict, represents a Ming-Qing dynasty residential and silk-weaving neighbourhood. The Lotus Pond Conservation Plan mandates protection of historical streets, courtyards, and architectural heritage while permitting adaptive reuse to enhance sustainability.

The study focuses on a 6,231.35 m² northwestern plot (Figure 1), bordered by Yingao Lane (north), Mingyangli (south), Mingyang Street (west), and Xiaoshunli (east). Of the 33 buildings within the plot, 28 are traditional or general structures targeted for renovation (Figure 2). Parametric models in Rhino simplified buildings to flat-roofed forms with uniform 4-metre floor heights.

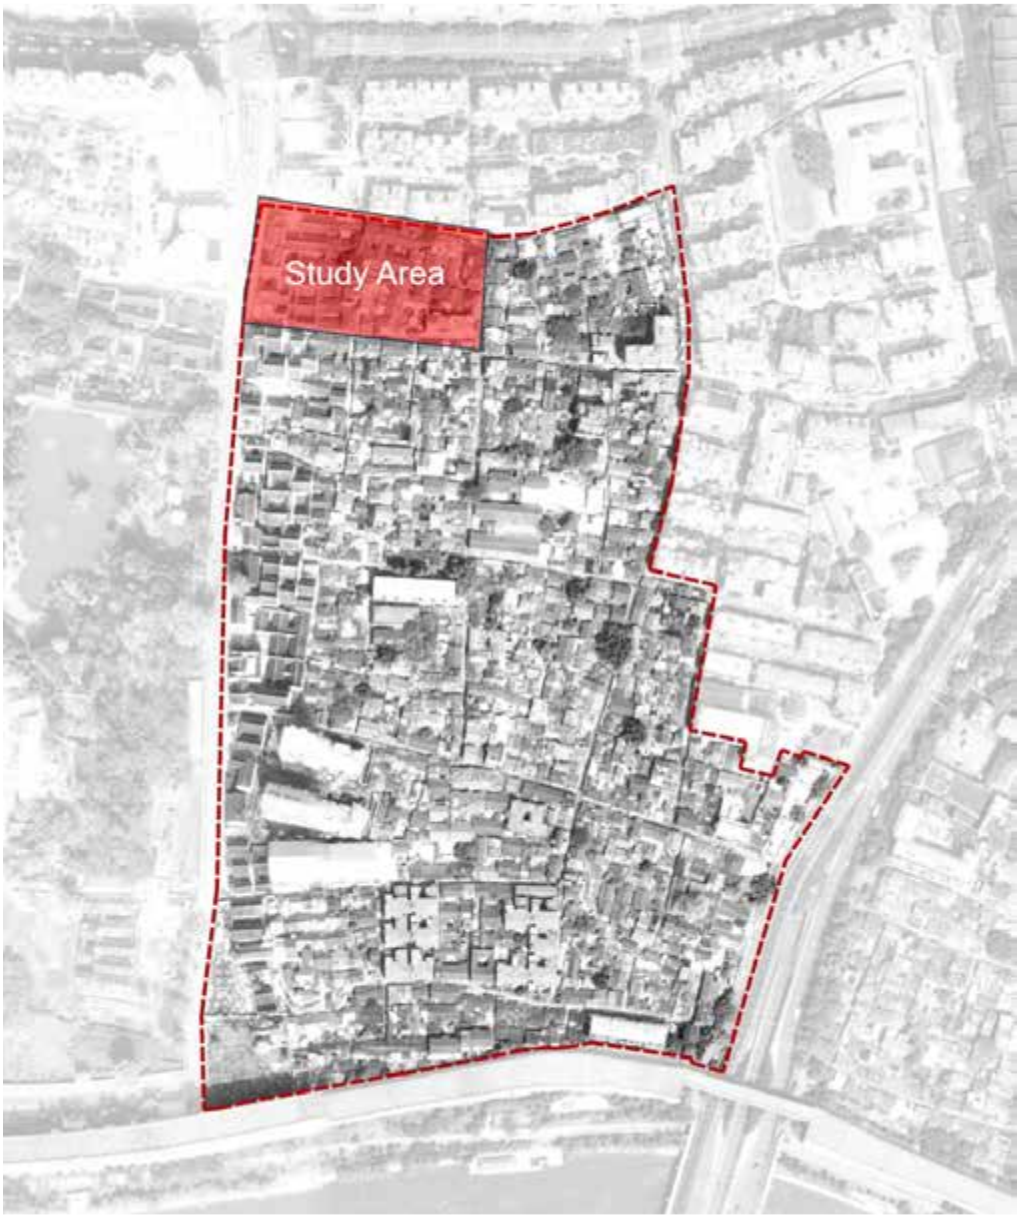

Figure 1 Study Area Boundary

Figure 2 Site Modeling and Renovation Scope Map

2. Simulation of Renovation Schemes

2.1 Height Adjustment Optimisation for Low EUI

The simulation and optimisation processes were conducted entirely within the Grasshopper platform in Rhino. Using the HB Model to OSM component in Grasshopper, Honeybee models were converted to OpenStudio models. Inputting Nanjing's meteorological parameters enabled the calculation of annual total energy consumption, including heating, cooling, indoor lighting, and equipment usage. Heating and cooling temperature thresholds in Honeybee were based on the ASHRAE 55 adaptive thermal comfort model, triggering heating below 18°C (64.4°F) and cooling above 28°C (82.4°F).

The building morphology generation logic retained the original building footprints, with randomised seed numbers controlling floor count variations (1–4 stories). The Annealing Solver in the Genome component (a simulated annealing algorithm) optimised schemes for low EUI. Simulated annealing, inspired by physical annealing processes, is suited for single or few-parameter optimisation. During the initial high-temperature phase, the algorithm explores a broad search space to avoid local optima. In the low-temperature phase, it refines solutions within a narrower range, converging toward the global optimum. Parameter settings for the simulated annealing algorithm are detailed in Table 1.

Table 1. Simulated Annealing Algorithm Parameters

Simulation parameters	Numerical value
Meteorological parameters of Nanjing City	chn_jiangsu.nanjing.582380_cswd
Building type	Midrise Apartment
Simulation cycle	From 00:00 on January 1st to 24:00 on December 31st
Floor height	4 meters
The range of changes in the number of layers	1-4 floors /1-2 floors
Gene	Random number of seeds (1-100)
Objective	Low EUI
Initial temperature	100%
Cooling rate	0.8
Drift rate	50%

2.2 Solar Radiation Potential Assessment of Renovation Schemes

To investigate the specific causes of EUI reduction during optimisation, solar radiation across all schemes was evaluated. Morphological changes, such as building height adjustments, may alter self-shading effects, reducing solar heat gain and thus cooling demand. Additionally, height modifications influence the shape coefficient (*S/V*), defined as the ratio of building surface area to volume, which affects thermal loss or gain. Therefore, solar radiation analysis is critical for each scheme.

For intuitive comparison of solar potential, the Zhejiang Provincial Construction Standard DB33/1105-2014 Code for Renewable Energy Application Accounting in Civil Buildings (Article 4.1.2) stipulates: "Roof areas with annual solar radiation exceeding 625 kW·h/(m²·a) should be prioritised for solar collector or photovoltaic panel installation." Given Nanjing's proximity to Zhejiang, this threshold was adopted.

Meteorological data, simulation periods, sensor locations, grid resolution (2m), and surface reflectivity parameters were configured as detailed in Table 2. The models and parameters were input into the Grasshopper workflow to simulate solar radiation, with results statistically analysed.

Solar radiation simulations were conducted using the Ladybug and Honeybee plugins integrated into Rhino's Grasshopper platform, leveraging the Radiance calculation engine. This method holistically accounts for building dimensions, orientation, ground reflectance, and adjacent structure reflections, generating accurate radiation values for roofs and façades across the case study (Figure 3).

Table 2. Settings of Solar Radiation Simulation Parameters

Simulation parameters	Numerical value
Meteorological data	https://climate.onebuilding.org/WMO_Region_2_Asia/CHN_China/JS_Jiangsu/CHN_JS_Nanjing.582380_TMYx.zip
Simulation cycle	From 00:00 on January 1st to 24:00 on December 31st
Measurement point position	100mm above the grid
Grid size	2 mx2 m
Building surface reflectivity	0.2
Average ground reflectivity	0.2

In this study, solar radiation potential was determined by calculating the ratio of the area exceeding the solar radiation threshold to the total exterior surface area of buildings across different simulated schemes. Using Grasshopper's component settings, measurement points surpassing the threshold were visually highlighted in the model (Figure 3). The proportion of highlighted points relative to the total measurement points served as a comparative metric for evaluating solar energy utilisation potential.

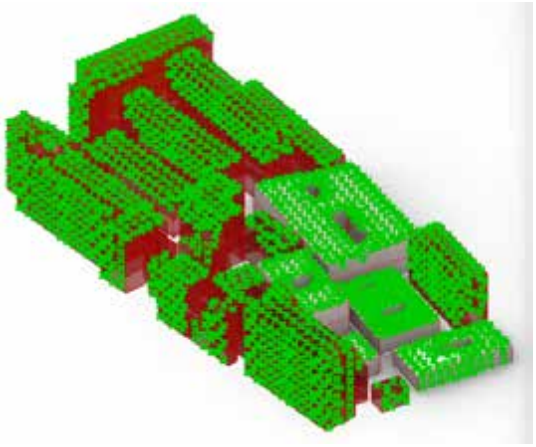

Figure 3 High-Radiation Zones (Threshold: 625 kWh/m²/a)

2.3 Correlation Analysis

Building morphological parameters and simulation results for all schemes were recorded and imported into SPSS software. Pearson correlation analysis was conducted between indicators to investigate the causes and logic behind EUI reduction in optimised schemes. The Pearson correlation coefficient (*r*) ranges from -1 (indicating a perfect negative linear correlation) to 1 (perfect positive linear correlation), with 0 signifying no linear correlation. A significance level of rat 0.01 (two-tailed) indicates statistically significant correlations.

3. Research Conclusions

3.1 Optimisation Results

The baseline EUI of the original scheme was 303.354 kWh/m². Simulation results identified 22 optimal schemes (Table 3), with unchanged energy consumption for indoor lighting (8.866 kWh/m²) and equipment (32.119 kWh/m²). The EUI of optimal schemes decreased by approximately 25 kWh/m² compared to the baseline.

Under heritage conservation guidelines—"strict protection of existing heights for heritage conservation units and historical buildings; new buildings restricted to ≤2 stories with eave heights ≤7 metres"—a secondary simulation constrained building heights to 1–2 stories. This achieved a further EUI reduction of 5.6 kWh/m².

Solar radiation potential (Table 4) decreased across low-EUI optimised schemes. The baseline potential (31.23%) was reduced post-height adjustment. Schemes 14, 16, and 22 exhibited relatively higher potential (>28%), while Schemes 2, 4, 5, 9, and 12 showed lower potential (<22%). This decline likely stems from increased self-shading effects resulting from taller building heights in optimised schemes.

3.2 Correlation Analysis

A Pearson correlation analysis between EUI results from two height adjustment phases and the shape coefficient (*S/V*) revealed a strong positive correlation (Figure 4). Further analysis of energy consumption data, morphological parameters, and annual solar radiation simulations (via SPSS) yielded the following key results (Table 5):

1 Floor area ratio (FAR) exhibited significant negative correlations with solar radiation potential, EUI, and heating/cooling energy demands.

2 Shape coefficient (*S/V*) showed significant positive correlations with solar radiation potential, EUI, and heating/cooling energy demands.

3ΔSolar radiation potential correlated positively with EUI, cooling energy consumption, and *S/V*.

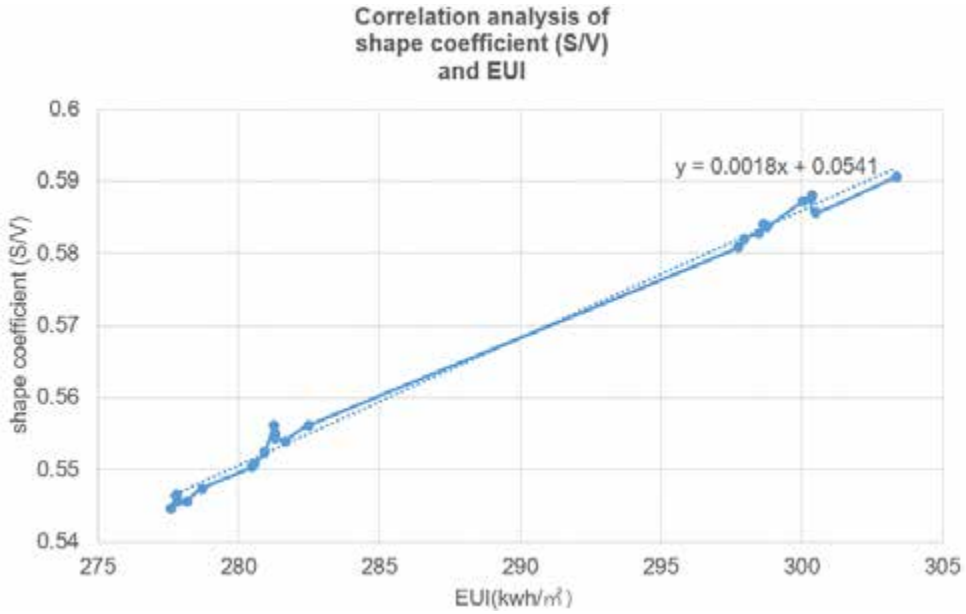

Figure 4 Correlation analysis of shape coefficients and EUI

3.3 Optimisation Recommendations

Floor area ratio (FAR) and shape coefficient (S/V) are critical morphological parameters influencing energy consumption. Reducing FAR (<1.2) and S/V (≤0.55) significantly decreases heating and cooling demands.

Adjusting building heights reduced EUI by 8.3% (approximately 25 kWh/m²). However, solar radiation potential decreased by 9.4% due to increased shading. Designs must balance energy efficiency with solar utilisation.

High solar radiation zones (>28%) should prioritise photovoltaic installations, but shading effects caused by taller buildings must be mitigated.

Adopt the "retain, renovate, demolish, and rebuild" (RRD) approach to preserve traditional urban fabric while optimising morphological parameters. Integrate parametric tools for precise energy consumption prediction and scheme optimisation, supporting green renewal of historical districts under China's "dual carbon" goals (carbon peaking and neutrality).

Abstract
Urban wilderness areas—natural spaces minimally impacted by human activity—are increasingly vital in China's rapidly urbanising cities. They offer key ecosystem services such as air and water purification, carbon sequestration, and urban cooling, while supporting biodiversity and providing public recreation. This study explores how integrating urban wilderness into Chinese urban planning can balance development and ecological preservation. Using interdisciplinary methods to assess wilderness contributions to resilience and livability. Case studies from Hangzhou, Shanghai, Lanzhou, and Yueyang illustrate effective strategies including native vegetation restoration, sustainable recreation infrastructure, and environmental education. Public accessibility and awareness are emphasised to foster environmental stewardship. Aligning wilderness conservation with China's urban planning goals supports ecological health and long-term sustainability, offering insights for policymakers, planners, and communities seeking greener, more resilient urban futures.

Keywords: Urban wilderness; ecological resilience; sustainable urban development

1. Introduction

Urbanisation has become a defining characteristic of the 21st century, with cities expanding at unprecedented rates. This rapid urban growth often leads to the degradation of natural environments, resulting in diminished biodiversity, increased pollution, and reduced quality of life for urban residents. In response to these challenges, the concept of urban wilderness has emerged as a vital component in urban planning and environmental conservation.

Urban wilderness refers to natural areas within or adjacent to urban environments that remain relatively undisturbed by human activity. These spaces, which can include forests, wetlands, grasslands, and other ecosystems, serve as critical habitats for wildlife and offer numerous ecosystem services. They play a significant role in air and water purification, carbon sequestration, climate regulation, and provide recreational and psychological benefits to urban dwellers. Moreover, urban wilderness areas contribute to the ecological resilience of cities, enabling them to better withstand environmental stresses such as climate change and natural disasters (Emily P. Zefferman, 2018) .

In the context of China, the importance of urban wilderness is increasingly recognised. Rapid industrialisation and urban expansion have led to significant environmental challenges, including habitat loss and fragmentation. However, initiatives such as the National Forest City program demonstrate a growing commitment to integrating green spaces into urban development. These efforts aim to enhance biodiversity, improve air quality, and provide residents with accessible natural areas, thereby promoting sustainable urban living (Xiaoqin Xie, 2023).

2. The Primary Objectives

This study aims to explore the role of urban wilderness in promoting sustainable urban development in China (Table 1).

Table 1: The Primary Objectives

The Primary Objectives				
To define and contextualise urban wilderness	To examine the historical evolution of urban wilderness in China	To assess global perspectives on urban wilderness protection and creation	To identify strategies for integrating urban wilderness into city planning	To evaluate the benefits of urban wilderness
Understanding the characteristics and significance of urban wilderness within the framework of urban ecology and planning.	Analysing how urban wilderness areas have developed over time and their current status in Chinese cities.	Reviewing international practices and policies that can inform China's approach to urban wilderness management.	Proposing methods for the protection and creation of urban wilderness areas, considering ecological, social, and economic factors.	Investigating the ecological services provided by urban wilderness and their impact on urban resilience and residents' well-being.

The scope of this study encompasses a comprehensive analysis of urban wilderness in China, drawing comparisons with international examples to identify best practices. It involves an interdisciplinary approach, incorporating ecological analysis, urban planning methodologies, and community engagement strategies. The research aims to provide actionable insights for policymakers, urban planners, and environmental advocates to effectively integrate urban wilderness into the fabric of Chinese cities.

3. Research approach

3.1 Interdisciplinary Approaches: Case Study; Literature Review

To effectively address the complexities of urban wilderness protection and creation, an interdisciplinary approach is essential. This involves combining insights from ecology, urban planning, sociology, and cultural studies to understand the dynamics of urban ecosystems (Table 1).

Table 2: Research approach

Research approach	
Case study	Research progress review
Case studies serve as critical tools for examining real-world examples of urban rewilding and ecological restoration. By selecting representative sites and analysing them through field observations, spatial analysis, and policy review, case studies reveal the interactions between natural systems and human interventions.	Research progress reviews synthesise existing theoretical and empirical research, identifying key themes, gaps, and debates within the field. A systematic review of scholarly articles, policy documents, and technical reports enables researchers to contextualise case findings within broader academic and practical discourses.

By integrating case study and literature review, these methods provide a robust framework for investigating the ecological, social, and planning dimensions of urban wilderness initiatives, ensuring a holistic and sustainable understanding of urban nature.

3.2 Case Studies

3.2.1 The display of cases in different parts of China

The selected case studies are geographically distributed across diverse ecological and cultural regions of China, offering a comprehensive view of urban wilderness practices in varying urban contexts (Table 3).

In Hangzhou, located in the Yangtze River Delta of southeastern China, Jiangyangfan Ecological Park showcases a low-intervention model of natural succession, where wetland habitats have been restored with minimal human alteration, emphasising biodiversity and public education.

Shanghai, as a leading coastal metropolis, showcases ecological planning at scale through Heqing Country Park, where rewilding strategies are applied within a high-density urban environment to balance biodiversity, recreation, and spatial equity.

Moving westward, Lanzhou's Yellow River riverside rewilding project addresses the ecological degradation caused by urban and industrial pressures, combining habitat restoration, community engagement, and sustainable tourism to reestablish both environmental function and cultural identity.

Meanwhile, Yueyang, located in southern China near Dongting Lake, highlights species reintroduction efforts, particularly the rewilding of Père David's deer in Junshan Houhu, contributing to both biodiversity restoration and wetland conservation.

Collectively, these geographically dispersed cases illustrate how urban wilderness practices are shaped by differing environmental conditions, cultural values, and planning frameworks across southern and northwestern China.

Table 3: Recreation of Urban Wilderness Cases in China

Case studies					
Project	**Study Area**	**Rewilding Strategies**	**Outcomes and Significance**	**Conclusion**	**Visual Representation**
Jiangyangfan Ecological Park	Hangzhou, Zhejiang province, Southern China,	a.Embracing Natural Succession b. Ecological Environment Construction	a. Ecological Restoration b. Public Education	Jiangyangfan Ecological Park demonstrates how urban rewilding and ecological restoration can transform degraded areas into biodiverse, educational natural spaces.	
Shanghai Heqing Country Park	Shanghai, Southern China	a. Minimising Human Intervention b. Habitat Restoration	a. Biodiversity Enhancement b. Ecotourism Development	Shanghai Heqing Country Park exemplifies urban rewilding by integrating ecological restoration into urban planning, enhancing biodiversity, and offering educational and recreational opportunities.	
Lanzhou's Yellow River Riverside	LanzhouΔGansu Province, Northwestern China	a. Habitat Restoration b. Community Engagement c. Sustainable Financing	a. Ecological Improvement b. Cultural Heritage Preservation	Lanzhou's Yellow River rewilding integrates habitat restoration, community engagement, and sustainable financing, transforming degraded urban riverfronts into vibrant ecological and cultural corridors.	
Rewilding of Père David's Deer in Junshan Houhu, East Dongting Lake National Nature Reserve	Yueyang, Hunan Province, Southern China	a. Habitat Assessment and Selection b. Monitoring and Adaptive Management	The reintroduced Père David's deer population shows adaptation and growth, but faces challenges from human disturbance and disease outbreaks.	Père David's deer rewilding in Junshan Houhu exemplifies effective habitat restoration and adaptive management, though challenges like human disturbance and disease persist.	

3.2.2 Strategies for Urban Wilderness Protection and Creation in China

Urban wilderness areas—natural or semi-natural spaces within or adjacent to urban environments—are vital for ecological balance, biodiversity conservation, and the well-being of urban residents. In China, rapid urbanisation has posed significant challenges to the preservation and creation of such spaces. However, various strategies have been implemented to address these challenges, focusing on native vegetation restoration, integration of sustainable recreational facilities, promotion of environmental education and public awareness, and the establishment of robust policy frameworks and governance structures (Figure 1).

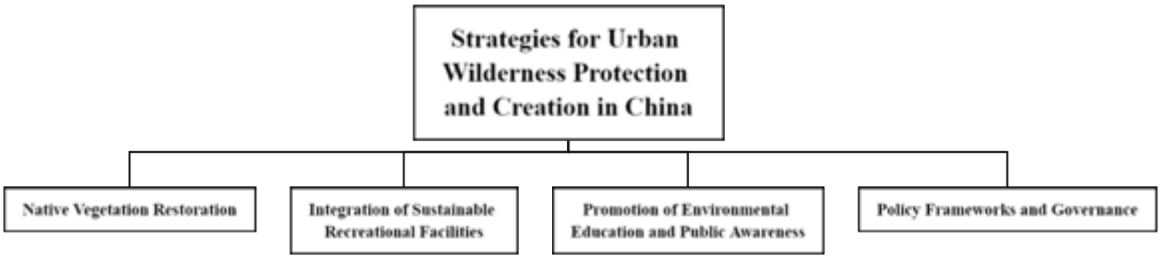

Figure 1: Strategies for Urban Wilderness Protection and Creation in China

Native Vegetation Restoration

Restoring native vegetation is a cornerstone of urban wilderness conservation in China. Programs like the "Grain for Green" initiative, launched in 1999, have converted over 15 million hectares of farmland and 17 million hectares of barren mountainous wasteland back to natural vegetation, aiming to mitigate soil erosion and flooding (Claudio O. Delang, 2015).

Similarly, the "Three-North Shelterbelt Program," also known as the "Great Green Wall," has been instrumental in combating desertification by planting over 30 million hectares of trees, increasing national forest coverage to over 25% (Reuters, 2024).

While these large-scale afforestation efforts have expanded green cover, challenges remain regarding biodiversity. The proliferation of monoculture plantations, often comprising fast-growing non-native species, has led to a decline in native forests, which have decreased by 6% due to the replacement of diverse ecosystems with single-species plantations (Kelly, 2018). To enhance ecological resilience, future restoration efforts should prioritise the use of native species and promote mixed-species plantings that support a broader range of wildlife.

Integration of Sustainable Recreational Facilities

Integrating sustainable recreational facilities within urban wilderness areas enhances their accessibility and utility for urban residents while preserving ecological integrity. Designing trails, observation decks, and educational signage using eco-friendly materials minimises environmental impact and encourages public engagement with nature. For instance, the Kubuqi Desert restoration project in Inner Mongolia transformed a barren landscape into a green area with tourism and agriculture industries, demonstrating the potential for ecological restoration to support sustainable economic development.

Moreover, incorporating green infrastructure such as eco-roofs and community herb gardens, as implemented by Future Generations China in Beijing, combines recreational and educational functions, fostering community involvement and environmental awareness. These initiatives exemplify how urban wilderness areas can serve multiple purposes, including recreation, education, and biodiversity conservation.

Promotion of Environmental Education and Public Awareness

Environmental education and public awareness are critical for the long-term success of urban wilderness initiatives. China has made significant strides in this area, establishing formal environmental education systems and integrating environmental topics into primary education curricula. Organisations like the China Environmental Education Centre (CEEC) have been pivotal in conducting environmental education and publicity activities, serving government departments, the public, enterprises, and media (Mee Young Choi, 2008).

Additionally, non-governmental organisations (NGOs) such as "Friends of Nature" and "Global Village of Beijing" have played a vital role in raising environmental awareness and promoting hands-on environmental activism since the mid-1990s. These organisations focus on education, awareness-raising, and community engagement, contributing to a more environmentally conscious society.

Despite these efforts, challenges persist, including a lack of motivation to incorporate environmental education in teaching and a contradiction between economic growth and environmental protection (Youyi Tian, 2016). Addressing these issues requires a concerted effort to enhance the quality and reach of environmental education programs, ensuring that they effectively foster environmental stewardship among the public.

Policy Frameworks and Governance

Robust policy frameworks and effective governance are essential for the protection and creation of urban wilderness areas. China has implemented various ecological restoration policies that have significantly impacted the country's terrestrial carbon balance, demonstrating the effectiveness of policy-driven environmental initiatives (Chao Yue, 2024). These policies include land management changes aimed at enhancing carbon sequestration and promoting sustainable development.

Furthermore, integrating nature-based solutions (NbS) into ecosystem restoration efforts provides both theoretical foundations and practical guidance for enhancing conservation efforts and promoting sustainable development. By incorporating NbS into policy frameworks, China can address environmental challenges more holistically, ensuring that urban wilderness areas are preserved and enhanced in the face of ongoing urbanisation.

Public participation and NGO activity are also crucial components of effective governance. Analysing the degree and types of public participation in NbS projects in China reveals the importance of engaging communities in environmental initiatives. Encouraging public involvement ensures that urban wilderness projects align with community needs and values, fostering a sense of ownership and responsibility among residents.

3.3 Research Progress Review

3.3.1 Definitions and Concepts of Urban Wilderness

The term "urban wilderness" refers to natural areas within or adjacent to urban environments that remain relatively undisturbed by human activity. These spaces, which can include forests, wetlands, grasslands, and other ecosystems, serve as critical habitats for wildlife and offer numerous ecosystem services. They play a significant role in air and water purification, carbon sequestration, climate regulation, and provide recreational and psychological benefits to urban dwellers. Moreover, urban wilderness areas contribute to the ecological resilience of cities, enabling them to better withstand environmental stresses such as climate change and natural disasters.

In the context of China, the importance of urban wilderness is increasingly recognised. Rapid industrialisation and urban expansion have led to significant environmental challenges, including habitat loss and fragmentation. However, initiatives such as the National Forest City program demonstrate a growing commitment to integrating green spaces into urban development. These efforts aim to enhance biodiversity, improve air quality, and provide residents with accessible natural areas, thereby promoting sustainable urban living.

3.3.2 Historical Evolution of Urban Wilderness in China

The development of wilderness aesthetics in China has undergone a profound and evolving cognitive process shaped by philosophical, religious, and cultural influences throughout different historical periods (Table 4).

Table 4: The Development of the Cognitive Process of Chinese Wilderness Aesthetics

The Development of the Cognitive Process of Chinese Wilderness Aesthetics		
Dynasty	Characteristics of the Era	Description
Pre-Qin Dynasty	Deification of nature; reverence for wilderness	During the pre-Qin Dynasty, the wilderness was regarded as a mysterious space associated with divine spirits. People revered and feared it. Aesthetics of wilderness focused on nature and mysticism. Thinkers described it as "nameless Dao," "non-being," "formless," and "silent."
Han Dynasty	Emphasis on forest grace and wilderness rhythms; new harmony	In the Han Dynasty, wilderness became important in Confucian moral practice. Confucian wilderness aesthetics emphasised rational beauty and ordered qualities, highlighting how wild landscapes could inspire moral reflection, e.g., the "Dao of governance" in The Analects.
Wei-Jin Dynasty	Emphasis on mountain tranquillity; wilderness as Zen transcendence	In the Wei-Jin Dynasty, wilderness aesthetics greatly influenced poetry and landscape painting. The appreciation of wilderness became more refined and integrated with natural emotions.
Sui Dynasty and Tang Dynasty	Pursuit of wild beauty and mystery; wilderness as sublime and fantastic	After the Wei-Jin Dynasty, wilderness aesthetics merged with religious and metaphysical beliefs. Mountains and waters represented the divine. Aesthetics were infused with Buddhist, Taoist meditation, focusing on quiet contemplation and transcendence.
Song Dynasty	Emphasis on mountain and water landscapes; wilderness as serene and deep	In the Song dynasty, wilderness began to be seen as shaped by human emotion and thought. It became central to poetic and landscape painting creation. Aesthetic focus shifted to secluded, elegant scenes.
Ming Dynasty and Qing Dynasty	Emphasis on mountain spirit and naturalness; wilderness as pure and natural	During the Ming and Qing periods, wilderness aesthetics spread to the public and became symbolic in literati sentiment and self-identity. Aesthetics turned toward individuality.

Together, these stages illustrate a continuous redefinition of wilderness aesthetics in Chinese thought, moving from divine reverence to humanistic integration, from metaphysical abstraction to personal expression.

China's relationship with wilderness has been shaped by a complex interplay of cultural, historical, and political factors. Traditional Chinese philosophy, particularly Taoism and Confucianism, emphasises harmony between humans and nature. The concept of "Unity of Man and Heaven" reflects an intrinsic value placed on natural landscapes (Mark, 2006). However, the 20th century witnessed significant shifts in this perspective. The rapid industrialisation and urbanisation during the mid-20th century led to extensive environmental degradation, with natural areas being converted for agricultural and industrial use (Weller, 2006).

In response to growing environmental concerns, the Chinese government initiated several conservation efforts. The establishment of National Forest Parks (NFPs) in the 1980s marked a significant step towards preserving natural landscapes. The first NFP was created in Zhangjiajie, Hunan Province, in 1982, and by 2009, China had established over 2,400 NFPs (National Forest Parks in China, 2013). These parks aimed to protect biodiversity, promote tourism, and enhance public awareness of environmental issues.

In recent years, urban wilderness has gained prominence in China's urban planning discourse. Cities like Shanghai and Chengdu have implemented initiatives to integrate natural spaces within urban environments. For instance, Shanghai's Heqing Country Park and Chengdu's "Garden City" initiative exemplify efforts to create urban wilderness areas that serve both ecological and recreational functions. These projects reflect a growing recognition of the importance of urban wilderness in enhancing urban livability and sustainability.

3.3.3 Global Perspectives on Urban Wilderness Protection and Creation

Globally, urban wilderness has been recognised for its multifaceted benefits, including biodiversity conservation, climate regulation, and human well-being. Cities worldwide have implemented various strategies to protect and create urban wilderness areas, often tailored to their unique ecological and socio-cultural contexts.

In Singapore, the "Garden City" vision has guided urban development since the 1960s, emphasising the integration of green spaces throughout the city. The establishment of nature reserves, park connectors, and rooftop gardens has transformed Singapore into a model for urban greening. These efforts have enhanced biodiversity, improved air quality, and provided residents with accessible natural spaces.

In the United States, the concept of urban wilderness has been explored through initiatives like the Urban Wilds Program in Boston. This program identifies and protects remnant natural areas within the city, recognising their ecological and cultural significance. Similarly, cities like Portland and Seattle have implemented green infrastructure projects that incorporate urban wilderness elements to manage stormwater, reduce urban heat islands, and enhance biodiversity.

European cities have also embraced urban wilderness as a component of sustainable urban planning. In Berlin, the concept of "urban wildness" has been promoted to preserve spontaneous vegetation and wildlife habitats within the city. These areas, often located on abandoned industrial sites, provide opportunities for ecological succession and community engagement (Kowarik, 2011). Such initiatives highlight the potential of urban wilderness to contribute to urban resilience and cultural identity.

These global examples demonstrate the diverse approaches to urban wilderness protection and creation, underscoring the importance of context-specific strategies. They also illustrate the potential of urban wilderness to address pressing urban challenges, including climate change, biodiversity loss, and social well-being.

3.3.4 The Role of Urban Wilderness in Sustainable Urban Development

Urban wilderness areas—natural or semi-natural spaces within or adjacent to urban environments—play a pivotal role in promoting sustainable urban development. These areas provide a multitude of ecosystem services that contribute to environmental health, biodiversity conservation, climate regulation, and the well-being of urban residents.

Ecosystem Services Provided by Urban Wilderness
Ecosystem services are the benefits that humans derive from natural ecosystems. Urban wilderness areas offer a range of these services, which are crucial for maintaining ecological balance and enhancing the quality of urban life.

Air and Water Purification
Urban vegetation, including trees and shrubs, plays a significant role in improving air quality by filtering pollutants such as particulate matter, nitrogen dioxide, and ozone. Through processes like deposition and absorption, plants remove harmful substances from the atmosphere, thereby reducing respiratory ailments among urban populations (David J. Nowak, 2006).

In terms of water purification, urban wilderness areas contribute to the filtration of stormwater runoff. Vegetated surfaces absorb and slow down rainwater, allowing for the removal of pollutants before they reach water bodies. This natural filtration process mitigates the risk of waterborne diseases and protects aquatic ecosystems (Davis AP, 2006).

Carbon Sequestration
Urban forests and green spaces act as carbon sinks by absorbing carbon dioxide during photosynthesis and storing it in biomass and soil. This process helps offset greenhouse gas emissions from urban activities, contributing to climate change mitigation. Although the carbon sequestration capacity of urban vegetation is lower compared to large natural forests, it still represents a valuable component of urban climate strategies (Churkina, 2010).

Climate Regulation
Urban wilderness areas influence local microclimates by providing shade, releasing moisture through evapotranspiration, and reducing surface temperatures. These effects help combat the urban heat island phenomenon, where urban areas experience higher temperatures than surrounding rural regions due to heat-absorbing surfaces like concrete and asphalt (Bowler, 2010). By moderating temperatures, urban green spaces reduce energy consumption for cooling and enhance thermal comfort for residents.

Enhancement of Biodiversity
Urban wilderness areas serve as habitats for a diverse array of flora and fauna, supporting biodiversity within city landscapes. These green spaces provide food, shelter, and breeding grounds for various species, including birds, insects, and small mammals. Maintaining biodiversity in urban environments is essential for ecosystem resilience, as it ensures the continuation of ecological processes and services (Goddard, 2010).

Moreover, urban biodiversity has educational and recreational value, fostering a connection between residents and nature. Exposure to diverse species can enhance environmental awareness and promote conservation efforts within communities.

Recreational and Psychological Benefits for Urban Residents
Access to urban wilderness areas offers significant recreational opportunities, encouraging physical activity such as walking, jogging, and cycling. Engagement in these activities contributes to improved physical health and reduces the risk of chronic diseases.

Beyond physical benefits, urban green spaces have profound psychological impacts. Exposure to natural environments has been linked to reduced stress, anxiety, and depression levels among urban dwellers. Studies indicate that individuals living near green spaces experience greater well-being and healthier cortisol profiles, highlighting the mental health benefits of urban nature (Maas, 2006).

Furthermore, urban wilderness areas promote social cohesion by serving as communal spaces where people can interact and engage in collective activities. This social interaction fosters a sense of community and belonging, which are vital components of mental health and societal well-being.

4. Results

China's rapid urbanisation has led to significant challenges in balancing urban development with ecological preservation. The expansion of urban areas often encroaches upon natural habitats, leading to biodiversity loss and environmental degradation. For instance, studies indicate that urban expansion in China is likely to affect habitats and biodiversity by 2030, with most provinces expected to experience urban growth near protected areas or biodiversity hotspots (Seto, 2012) .

To address these challenges, China has introduced the concept of "Ecological Civilisation," aiming to integrate ecological considerations into economic and social development. This policy framework promotes sustainable urban planning practices that prioritise ecological preservation alongside urban growth (Meng, 2021).

Climate change poses additional challenges to urban wilderness areas in China. Rising temperatures, altered precipitation patterns, and increased frequency of extreme weather events threaten the integrity of urban ecosystems. Urban areas contribute significantly to greenhouse gas emissions, exacerbating climate change impacts (Maizland, 2021).

In response, China has implemented initiatives such as the "Sponge City" program, which aims to enhance urban resilience to climate change by improving water management and reducing flood risks through the integration of green infrastructure (Li, 2017). These efforts demonstrate China's commitment to mitigating climate change impacts on urban environments.

Effective urban wilderness conservation requires active community involvement and stakeholder engagement. Public participation in environmental decision-making processes enhances the legitimacy and effectiveness of conservation initiatives. However, challenges persist in engaging diverse stakeholders and ensuring equitable participation (Chen, 2015).

To foster community engagement, educational programs and awareness campaigns are essential. For example, environmental education initiatives in urban areas have been shown to increase public awareness and support for conservation efforts (Tian, 2016). Additionally, involving local communities in the planning and management of urban green spaces can lead to more sustainable and inclusive outcomes.

5. Discussion of Results

China has implemented various policies aimed at promoting sustainable urban development and ecological preservation. The "Ecological Civilisation" framework serves as a guiding principle for integrating environmental considerations into urban planning. Additionally, initiatives like the "Sponge City" program and the establishment of national parks reflect efforts to enhance urban resilience and conserve biodiversity (Li, 2017).

While these policies demonstrate progress, challenges remain in their implementation and effectiveness. For instance, inconsistencies in policy enforcement and limited coordination among governmental agencies can hinder the success of conservation initiatives (Chen, 2015). Moreover, balancing economic development goals with ecological preservation continues to be a complex issue.

Comparing China's urban wilderness conservation efforts with international practices reveals both similarities and differences. For example, the concept of integrating green infrastructure into urban planning is common in countries like Germany and the Netherlands, where policies emphasise the multifunctionality of urban green spaces (Kabisch, 2015). Similarly, China's "Sponge City" program aligns with global trends in nature-based solutions for urban resilience.

However, China's rapid urbanisation and unique socio-political context present distinct challenges. The scale and pace of urban development in China necessitate tailored approaches to urban wilderness conservation that consider local conditions and governance structures. Learning from international experiences while adapting strategies to the Chinese context is crucial for effective conservation outcomes.

Based on the analysis of challenges and current practices, the following recommendations are proposed for enhancing urban wilderness conservation in China:

Enhance inter-agency collaboration and ensure consistent enforcement of environmental policies to improve their effectiveness.

Develop participatory planning processes that involve local communities in decision-making and management of urban green spaces.

Incorporate climate adaptation strategies into urban planning to mitigate the impacts of climate change on urban ecosystems.

Implement educational programs to raise public awareness and foster a culture of environmental stewardship.

6. Conclusion

This study has examined the multifaceted role of urban wilderness in China's sustainable urban development. Urban wilderness areas provide critical ecosystem services, including air and water purification, carbon sequestration, climate regulation, and biodiversity enhancement (Xie, 2019). Case studies from cities like Hangzhou, Shanghai, Lanzhou, and Yueyang illustrate successful integration of green spaces into urban planning, demonstrating the potential for ecological preservation alongside urban growth. However, challenges persist, such as balancing rapid urbanisation with ecological conservation, addressing climate change impacts, and ensuring equitable access to green spaces (Seto, 2012) .

The findings underscore the necessity for urban planning policies that prioritise ecological considerations. Integrating green infrastructure into urban development plans can mitigate environmental degradation and enhance urban resilience (Li, 2017). Policies should promote community involvement in the planning and management of urban green spaces to ensure that these areas meet the needs of diverse populations (Youyi Tian, 2016). Furthermore, adopting adaptive management approaches can enable cities to respond effectively to the dynamic challenges posed by climate change and urbanisation.

Future research should focus on evaluating the long-term effectiveness of urban wilderness initiatives in China. Comparative studies between Chinese cities and international counterparts can provide insights into best practices and innovative strategies for urban ecological conservation. Additionally, interdisciplinary research combining ecological science, urban planning, and social sciences can inform more holistic approaches to urban wilderness management. Emphasis should also be placed on developing metrics to assess the social and health benefits of urban green spaces, ensuring that these areas contribute to the well-being of all urban residents.

Enhancing Sustainable Cities Through Comparative Carbon Sink Benefits of Blue-Green Spaces: Evidence from Multi-Source Data

Zhihan ZHANG, Yuyue HUANG, Xun ZHANG, Qingxin YANG, Junyan YANG*
Affiliation: Southeast University
Email: zhangzhseu@163.com

Abstract
Cities, characterized by the coexistence of carbon emissions and sinks, face escalating climate challenges. This study advances carbon sink research by examining integrated blue-green space benefits, emphasizing neighbourhood scales as critical nexus points for intervention, combining ArcGIS and quantitative methods, we measured carbon contributions from green (e.g., vegetation) and blue spaces (e.g., water bodies), identifying green spaces—particularly arboreal vegetation—as dominant carbon sinks. Spatial aggregation of blue-green elements was identified as key determinants. We propose neighborhood-scale climate-adaptive strategies to enhance carbon sink performance and support sustainable urban development..

Keywords: Blue-Green Infrastructure, Sustainable Cities, Carbon Sinks, Climate-Adaptive Planning

1.Introduction

Urban areas constitute primary sources of carbon emissions whilst concurrently retaining substantial carbon sink potential. As complex spatial systems wherein emissions and sinks coexist, advancing sustainable urban development through emission mitigation and sink enhancement represents a critical pathway towards achieving China's "dual carbon" goals [1-5]. Contemporary research on urban carbon emissions predominantly focuses on building lifecycle energy consumption [6], extending analyses across multiple scales through interdisciplinary methodologies [7] and has yielded mature technical approaches. Nevertheless, high-density urban development has fragmented natural carbon sink spaces—primarily vegetated areas—diminishing their efficacy.

Scholarly investigations into urban carbon sinks face limitations arising from scale-induced methodological inconsistencies and intricate operational mechanisms, resulting in a "multi-dimensional dilemma": challenges in identifying sink components, delineating sink processes, and quantifying sink benefits. Within this context, targeted research has addressed carbon sink identification and performance. Zhou et al. [8] examined forest carbon sinks and storage in Guangzhou, whilst Liu et al. [9] quantified carbon sequestration capacity within Beijing's central urban parks, revealing that urban green space sink efficiency is influenced by vegetation typologies, habitat composition, and various determinants. Regional-scale carbon sink studies benefit from robust theoretical foundations, enabling established measurement and simulation techniques including the CITYgreen and i-Tree Eco models [10-19], alongside biomass methodologies and regression-based calculations [20-28]. These contributions have significantly advanced urban carbon sink research [29-30].

However, amidst escalating global warming and extreme weather phenomena, singular carbon sink spaces prove inadequate to address contemporary complexities. Research has consequently evolved from isolated examinations of green or blue spaces towards integrated analyses of composite urban blue-green space systems [31,33]. As fundamental ecological carriers for carbon sequestration, blue-green spaces demonstrate pronounced sink potential, extensively validated within the existing literature [31-33].

Collectively, current scholarship exhibits three salient characteristics:
(1) Prevailing studies compartmentalise blue and green spaces [34], overlooking synergistic carbon sink benefits [4];
(2) Technical constraints (e.g., limited data precision, ambiguous boundaries) and theoretical limitations (e.g., complex influencing mechanisms) impede accurate quantification of the carbon sink efficiency of blue-green spaces;
(3) Urban carbon sinks constitute a multi-scale challenge wherein measurement criteria—detection methods, computational formulae, and evaluation standards—diverge significantly across macro-, meso-, and micro-scales, necessitating explicit calibration of scale-induced variations.

Consequently, developing scientifically rigorous, high-precision carbon sink measurement methodologies that account for scalar heterogeneity forms the principal focus of this research.

Neighbourhoods—the minimal spatial units holistically encompassing blue-green infrastructure elements and built infrastructure—are prioritised as the optimal scale for urban carbon sink investigation. Functionally, neighbourhoods integrate city-wide carbon sink systems whilst informing site-specific components, serving as critical spatial nexuses. This study therefore adopts the neighbourhood scale, integrating macro-scale remote sensing with micro-scale field data to mitigate single-source limitations. We quantify integrated carbon sink benefits and influencing factors within Nanjing's Yuejianglou neighbourhood. Subsequently, we propose climate-adaptive optimization strategies for blue-green space planning at this scale.

2.Materials and Methods

2.1 Study Area and Data Sources

This study selected the Yuejianglou neighborhood in Nanjing, China—a representative hot-summer/cold-winter climate zone—as the research case study. Nanjing possesses superior natural conditions as one of China's inaugural National Garden Cities, with built-up areas attaining 45.04 per cent green coverage by the end of 2023, establishing a robust carbon sequestration foundation. The Yuejianglou neighborhood exemplifies typical urban characteristics, incorporating blue-green infrastructure components including mountain parks (Shizishan Park), waterfront parks (Xiuqiu Park), street greenery (green space along the street), pocket greens (green space beside the street), community internal greens, and hydrological features (river system) (Table 1). Its significant low-carbon development potential renders it a representative case for investigating urban neighborhood-scale blue-green infrastructure carbon sinks.

Table 1: Spatial Types and Areas of Carbon Sink Elements in the Yuejianglou neighborhood of Nanjing

Spatial type	Vegetation type	Land area (m^2)	Area proportion
Mountain Park	Trees,	140,000	Green Space Along the Street	shrubs,	24,300	
Internal Green Space	grasslands,	123,000	
Waterfront Park	Trees,shrubs,	95,600	
Green Space Beside the Street	grasslands, aquatic plants	13,000	
River system	Aquatic plants	135,355	

We extracted urban green space data using a generic deep learning framework [33] integrated with remote sensing. ENVI software facilitated preprocessing of green space elements, encompassing boundary delineation and area calculation, supplemented and validated through field surveys to ensure data completeness and accuracy. Vegetation typologies were catalogued via on-site investigations and statistical records; hydrological data originated from OpenStreetMap, with coordinate transformation and boundary extraction executed in ArcGIS. Carbon sink components comprised two categories: green spaces including mountain parks, waterfront parks, street greenery, pocket greens, and internal greens exhibiting point, linear, and areal spatial configurations; and blue spaces including lakes and rivers (e.g., the moat) displaying areal and linear distribution patterns. All data were standardised to uniform coordinates and units, culminating in a foundational geospatial dataset for the Yuejianglou neighbourhood's blue-green spaces (Figure 1).

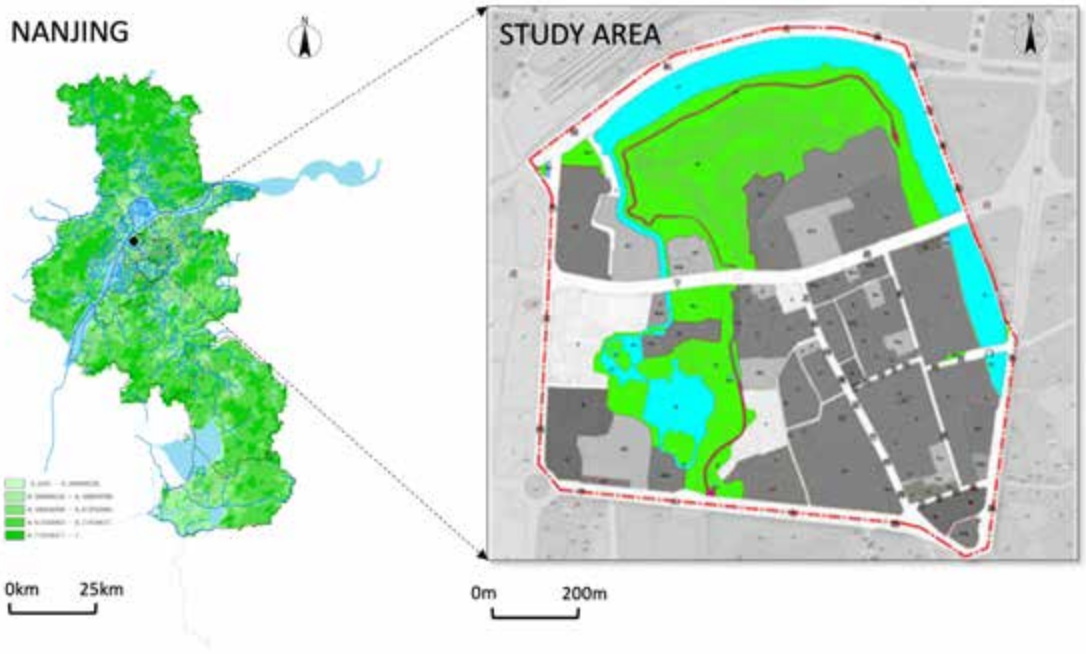

Figure 1: Distribution of Blue-Green Spaces in the Yuejianglou neighbourhood

2.2 Carbon Sink Calculation for Distinct Elements

Carbon sink quantification for neighborhood blue-green infrastructure encompassed two components.

1) Arboreal carbon sequestration: Calculated using the Landscape Performance Series (LPS) National Tree Benefit Calculator (NTBC) .

2) Shrub/herbaceous layer sequestration: Derived from established methodologies [35].

3) Aquatic carbon sinks: Computed using lake carbon sink methodologies [36-37], distinguishing contributions from water bodies and hydrophytes, with unit area sequestration rates categorised by waterbody type.

Spatial overlay analysis integrated biomass-based methods to quantify synergistic carbon sink enhancement in blue-green spatial interfaces. This approach incorporated vegetation-specific carbon sink coefficients and coverage areas, formalised as:

$$E = PVxBxVS$$

where:

E = Vegetation carbon sink (kg)

VS = Vegetation coverage area (m^2)

B = Carbon sequestration per unit area (kg/m^2)

PV = COΔpotential value (standardised to 1)

2.3 Influencing Factors of Blue-Green Space Carbon Sinks

We compiled carbon sink components (green spaces, water systems, soil, vegetation) and influencing factors, constructing a correlation model to examine their interrelationships. Influencing factors emphasised spatial patterns and configurations of components (Table 2) to inform design strategies. Pearson correlation analysis generated matrix of correlations between components and influencing factors, with statistical validation ensuring analytical objectivity.

Table 2: Constituent Elements and Influencing Factors of Blue-Green Space Carbon Sinks

Constituent elements		Influencing factors	Abbreviation
Green space	park green space area	Green space concentration degree	GSCD
	street green space area		
	internal green space area		
Water system	Water system area	Concentration degree of water system	CDWS
Soil	Permeable ground area	Vegetation richness	VR
Vegetation	Vegetation canopy width	Permeable ground coverage rate	PGCR

Note: Constituent elements refer to the elements that generate carbon sinks in the space, and the influencing factors refer to the elements that affect carbon sinks in the space

3.Results

3.1 Carbon Sink Benefits and Comparisons of Blue-Green Spaces

As illustrated in Figure 2, Shizishan Park—a mountainous park within the neighborhoods—exhibits rich vegetation communities, yielding an annual carbon sink of 806.92 t (tons), representing Yuejianglou's primary carbon sequestration zone. Street trees (predominantly Platanus spp., Cinnamomum camphora, and Celtis sinensis) contribute 79.50 t annually. Pocket greens generate 45.55 t/yr(tons/year), with vegetation including trees (Cinnamomum camphora, Celtis sinensis), shrubs (Pittosporum tobira, Loropetalum chinense, Photinia spp.), and herbaceous cover (Lolium perenne). Internal neighbourhood greens (residential greenspaces, flower beds) yield 56.24 t/yr, dominated by shrubs, herbs, and sparse trees.

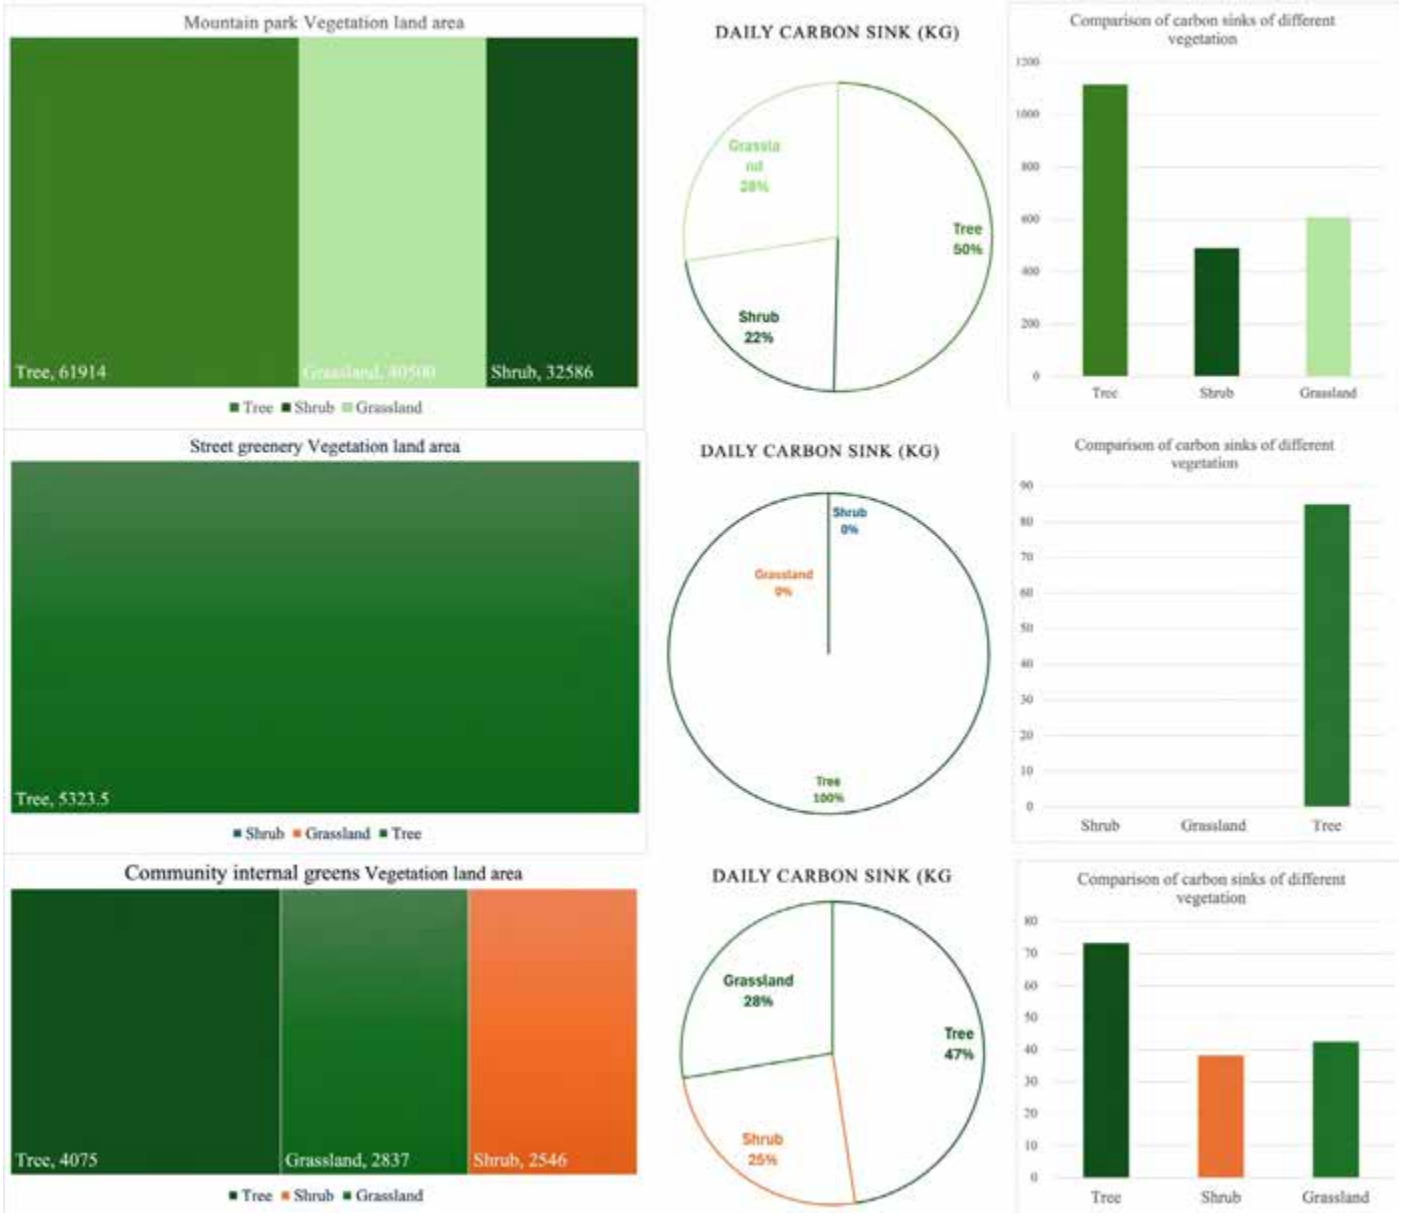

Figure 2: Area Proportion and Carbon Sink Benefits of Green Space Types (Mountain Park, Street Greenery, Internal Greens))

Blue space carbon sinks comprise lakes and rivers. Xiuqiu Park (Figure 3), a waterfront park, achieves 355.64 t/yr through integrated blue-green sequestration. However, its lake carbon sinks (79.05 t/yr) derive primarily from hydrophytes (Lythrum salicaria, Schoenoplectus tabernaemontani, Pontederia cordata, Phragmites australis), with negligible contributions from the water body itself. The moat's ecological ponds sequester 27.20 t/yr Hydrophytes account for 51% of aquatic carbon sinks despite occupying only 17% of water surface area, indicating their dominant role.

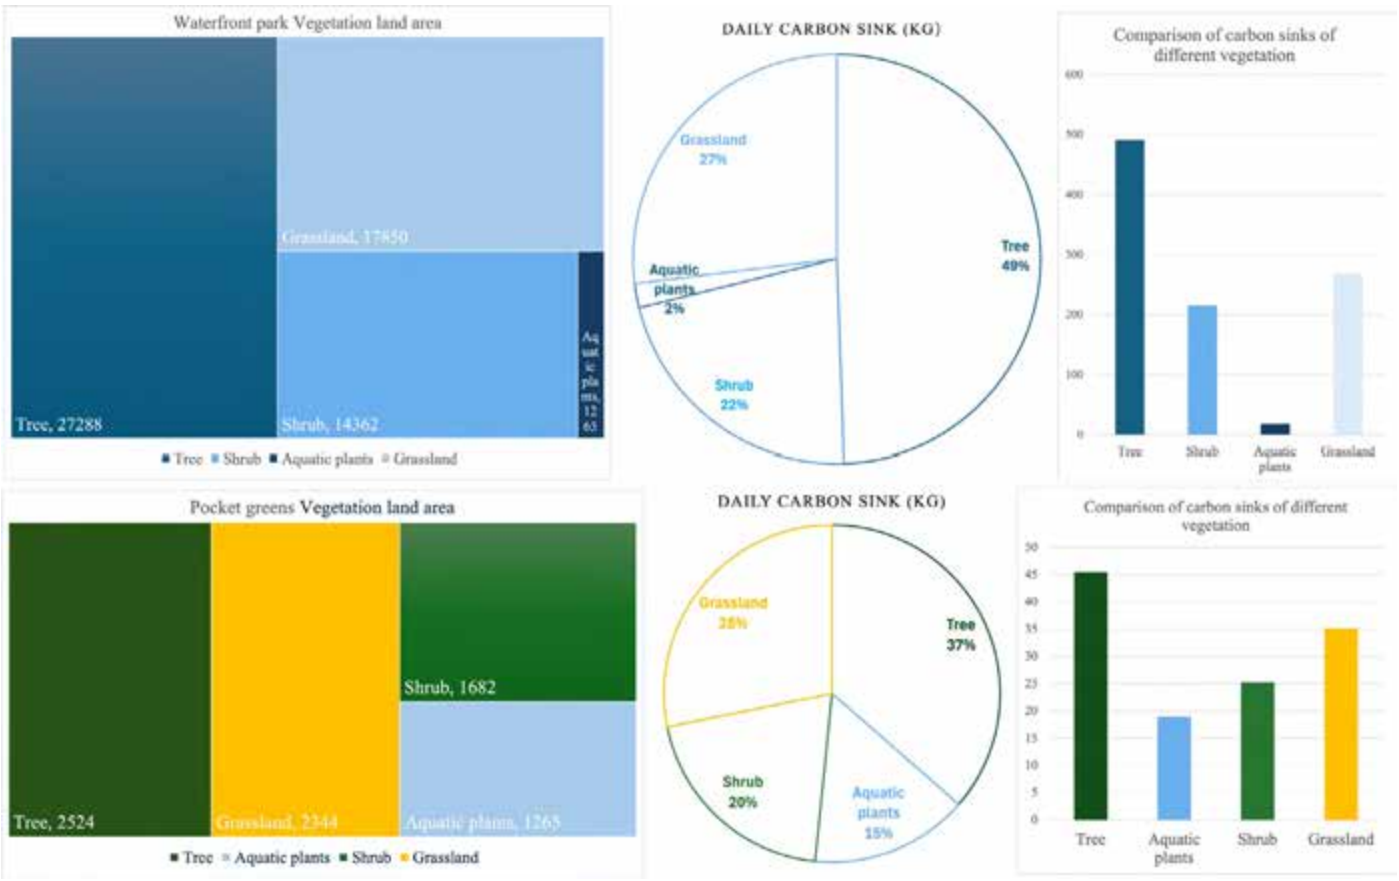

Figure 3: Area Proportion and Carbon Sink Benefits of Blue Space and Associated Riparian Greenspaces (Xiuqiu Park, Moat Riparian Zone))

Figure 4 illustrates the integrated relationship between spatial coverage and carbon sink benefits across diverse carbon sink typologies within the Yuejianglou neighbourhood.

Our analysis reveals two distinct carbon sink modalities: singular and composite systems. Shizishan Park, street trees, pocket greens, and internal neighbourhood greens constitute singular sinks predominated by green infrastructure, whilst the moat represents a singular blue-dominated system. Conversely, Xiuqiu Park and riparian green spaces along the moat exemplify composite blue-green systems, integrating lakes, hydrophytes, and terrestrial vegetation.

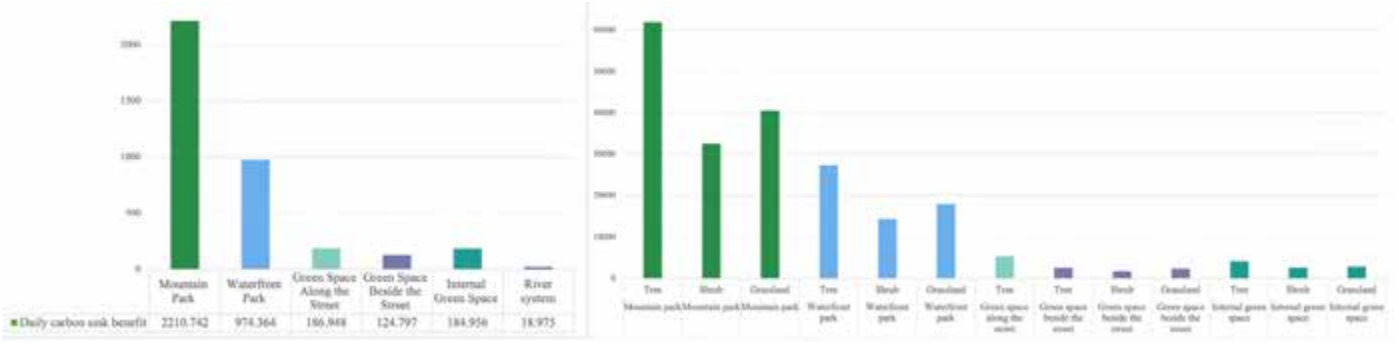

Figure 4: Relationship between Spatial Coverage Area and Carbon Sink Benefit by Space Type

3.2 Correlation Between Blue-Green Space Components and Carbon Sink Benefits

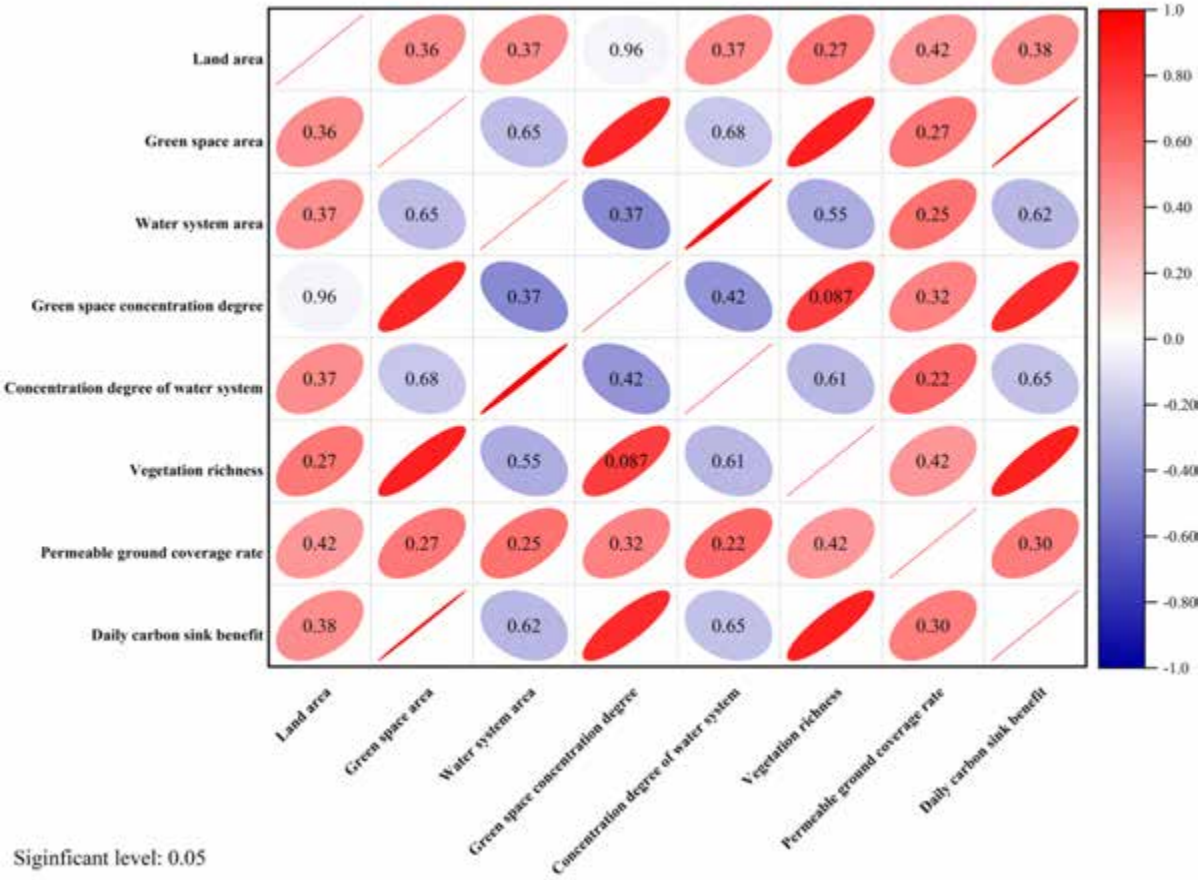

Figure 5: Correlation Analysis of Carbon sink Benefits of Blue and Green Spaces in the Yuejianglou Block

Correlation analysis (Figure 5) reveals carbon sink efficiency is jointly influenced by water system aggregation (as measured by CDWS) (r = 0.65) and green space aggregation (as measured by GSCD) (r = 0.62). Concentrated distributions of water bodies (e.g., lake-river connectivity) and green patches positively enhance overall carbon sequestration. Aggregated blue-green configurations promote efficient carbon sink functionality, with water aggregation (CDWS) exhibiting marginally stronger effects than green aggregation (GSCD).

Key correlations include:
1) Green space area and aggregation (GSCD): Strongest correlation (r = 0.96), indicating larger areas facilitate clustered green patches.
2) Total study area: Weak positive effects on water coverage and carbon sinks, but is less significant than green aggregation.
3) Water coverage: Marginal positive impact on carbon sinks.
4) Vegetation richness (VR) and water aggregation (CDWS): Moderately weak correlation (r = 0.55), suggesting aquatic clustering may mildly enhance plant diversity.
The neighbourhood's total annual carbon sink (1,314.36 t) displays significant spatial heterogeneity.

Key findings:
1) Green Spaces Dominate: Shizishan Park contributes 61.4% (806.92 t), confirming green infrastructure as the primary carbon sink component.
2) Blue Space Enhancements: Hydrophytes and riparian zones significantly boost aquatic sinks. Xiuqiu Park's water body contributes only 6% (79.05 t), but ecological riparian zones exhibit higher carbon density (1.2 t/h(tons/ha)) than hardened banks (0.4 t/h). Riparian interfaces correlate positively with terrestrial vegetation.

3) Linear Street Greenery Optimisation: Street trees (79.50 t) demonstrate a strong "tree size-carbon sequestration" relationship (R^2 = 0.73). As arboreal vegetation yields the highest per-unit sequestration, streetscapes—particularly tree-lined corridors—constitute critical optimisation spaces in high-density urban contexts.

4. Discussion

Our findings indicate that vegetation carbon sinks within green spaces predominantly contribute to overall carbon sink benefits (e.g., Shizishan Park's annual carbon sequestration of 806.92 t surpasses all other spatial types). Among vegetation categories, arboreal species—particularly large-specimen trees—demonstrate superior carbon sequestration capacity. This substantiates the principle posited by the National Tree Benefit Calculator that tree carbon sink potential correlates positively with dimensions. Concurrently, vegetation type significantly influences carbon sink efficiency, with distinct tree species exhibiting variable carbon sink coefficients. Consequently, trees characterised by high coefficients and substantial dimensions markedly enhance integrated green space carbon sink performance. Nevertheless, this remains contingent upon total green space area. Street tree selection and optimisation should therefore prioritise large-specimen trees with elevated carbon sink coefficients.

Regarding spatial correlations, water system aggregation (CDWS) (r = 0.65) and green space aggregation (GSCD) (r = 0.62) constitute primary determinants of integrated carbon sink benefits, further evidencing that carbon sink research necessitates combined analysis of blue and green spaces. More aggregated spatial configurations of water bodies and green patches enhance carbon sink functionality. Notably, water aggregation (CDWS) exerts marginally stronger effects than green aggregation (GSCD). Additionally, blue and green spaces exhibit synergistic spatial patterning, evidenced by a significant moderate positive correlation between water aggregation (CDWS) and green aggregation (GSCD) (r=0.68).This reveals that clustered aquatic areas frequently coexist with aggregated green zones (or vice versa), potentially influenced by shared topographic, planning or ecological processes. Spatial design should thus strategically adjust blue-green ratios to optimise carbon sinks within constrained areas.

Concerning influencing factors, vegetation structure and composition principally govern singular carbon sinks. For instance, broadleaf trees (e.g., Platanus spp.) sequester 12.6 kg/m² annually, which is 4.1 times the capacity of grasslands. [31] Secondly, spatial connectivity critically influences integrated sinks; blue-green ecological corridors (>30m width) elevate carbon density by 18–22%. Moreover, soil carbon sink contributions warrant attention: permeable surfaces exhibit 40% higher efficiency than impervious surfaces, while each 1% increase in organic matter boosts sequestration by 7.3%. These findings advocate incorporating "grey space" (permeable surfaces) into integrated sink frameworks, extending analysis from blue-green to blue-green-grey systems. Future research should quantify permeable soil carbon sinks and integrate them as design elements to substantially enhance neighbourhood-scale sequestration.

Optimisation Strategies focus on two dimensions: Sink enhancement: Blue spaces: Introduce hydrophytes (Lythrum salicaria, Phragmites australis) to augment aquatic contributions. Green spaces: Increase neighborhoods tree coverage from 30% to 50%, projecting 15–20% annual sink gains. Prioritise aggregated, interconnected blue-green spatial configurations.

Multifunctional synergy: Transform moat riparian zones into "carbon-neutral landscape corridors" integrating ecological, aesthetic, and recreational functions. Implement community carbon sink trading mechanisms to incentivise public engagement.

Technological advancements—particularly AI-enabled dynamic carbon flux monitoring, automated vegetation identification, and high-resolution data analytics—will refine future research precision, enabling robust, objective conclusions.

5.Conclusions

This study employed multi-source datasets to identify spatial distributions of carbon sink components in Nanjing's Yuejianglou neighbourhood, utilising ArcGIS and quantitative calculations to evaluate carbon sink benefits from green and blue spaces, establish correlations among influencing factors, and analyse determinants across spatial typologies. Climate-adaptive optimisation strategies were subsequently formulated. Key findings demonstrate

that green spaces constitute the primary carbon sink domain, with arboreal vegetation exhibiting superior sequestration capacity. Spatial aggregation of blue-green elements and green space area emerged as dominant influencing factors, with water aggregation (CDWS) exerting marginally stronger effects than green aggregation (GSCD). Notably, soil contributions—exhibiting sink benefits analogous to green spaces—were identified as a significant yet previously underemphasised dimension. Consequently, spatial design strategies are proposed: optimising blue-green ratios, enhancing street tree efficiency, adjusting aquatic plant communities, expanding riparian green areas, and establishing carbon-neutral landscape corridors.

Nevertheless, limitations persist regarding the precision of blue-green infrastructure component identification and the exclusion of carbon emission calculations during sink processes. Future research should integrate artificial intelligence algorithms for digital vegetation recognition to improve survey efficiency and accuracy. Concurrently, dynamic models capturing temporal variations in emission-sink processes would enhance the objectivity and scientific rigour of blue-green space assessments. Furthermore, incorporating microclimatic influences (e.g., urban heat island effects) through multi-scale validation via atmospheric inversion data (e.g., COΔ monitoring stations) presents a critical avenue for advancement.

Abstract
Historic cities embody rich cultural heritage and a long-standing relationship with nature, yet they are increasingly vulnerable to climate change. This study examines the intersection of heritage preservation and climate adaptation in Siena, a UNESCO World Heritage Site. Developed through the ISOCARP YPP Workshop "Valleys of Siena," the project addresses urban overheating within the city's dense historic core. Drawing on fieldwork, GIS analysis, and case studies, the research identifies key challenges, including a lack of green space and fragmented green valley systems. Inspired by initiatives such as Paris's "Oasis Schoolyards" and Barcelona's "Streets for Kids," the study proposes context-sensitive strategies—micro-greening, water-sensitive design, thermal regulation, and inclusive public spaces—rooted in community engagement. This approach offers a replicable model for the climate-resilient transformation of historic urban environments.

Keywords: Cultural Heritage, World Heritage Sites (WHS), Siena, UNESCO, Climate Change, Climate Adaptation

Introduction

Cities evolve through a dynamic interplay between human adaptation and their natural landscapes (Izzati & Ikaputra, 2022). While some urban areas undergo rapid transformations, others, like Siena—a UNESCO World Heritage city—have maintained a remarkable continuity, preserving a unique repository of built heritage deeply intertwined with their historical ecology. During the medieval era, Siena thrived by strategically leveraging its natural valleys for resources and microclimate regulation. However, the pressures of modern urban development on the city's fringes are now causing climatic transformations that risk disconnecting new areas from these vital historical and natural roots. Therefore, understanding and leveraging Siena's historical context is crucial to ensure that future developments remain harmoniously integrated with its enduring character and ecological balance.

Climate change, characterized by long-term shifts in temperatures and weather patterns primarily driven by human activities such as the burning of fossil fuels (United Nations, 2024), poses a significant global threat. Despite commitments to net-zero emissions by 2050, global greenhouse gas emissions continue to rise. Cities, though they cover only a small portion of the Earth's surface, are major contributors—accounting for over 70% of global greenhouse gas emissions and consuming over 65% of the world's energy (European Union, 2024). Limiting global warming to 1.5°C is essential for a sustainable future (IPCC, 2022). This warming trend presents significant risks to cultural heritage sites, demanding the implementation of targeted and adaptive conservation strategies to mitigate adverse effects while respecting their intrinsic value. Moreover, climate-related hazards such as flooding, rising sea levels, and increased erosion pose serious threats to cultural heritage sites that were not built to withstand these risks (Prabowo & Salaj, 2023). Siena, as a heritage city, reflects the deep ties between urban form and nature, raising key questions about climate resilience today.

The growing adversities of climate change threaten the identity of historically significant sites globally. Historic urban landscapes (HUL) need integrated adaptive measures to preserve their cultural and natural heritage from climate-induced risks (Fatoric, 2017). The UNESCO Recommendation on the HUL (2011) promotes a landscape-based approach that recognizes the layering of cultural, natural, and built values, encouraging adaptation that respects heritage integrity. Planning, regulatory systems, financial design, and community engagement are the four pillars of an inclusive heritage-based sustainable development and management strategy (UNESCO, 2011). The HUL recommendation (2011) exemplifies landscape-based and community-led preservation and safeguarding strategies that integrate traditional ecological wisdom with contemporary planning. It recognizes tangible aspects—such as historic built fabric and environmental factors—and intangible aspects—such as socio-cultural and economic elements—as well as the engagement of key stakeholders and their governance (Donato and Lohrasbi, 2017). These approaches emphasise blue-green infrastructure, passive cooling, and water-sensitive design while maintaining the morphological and symbolic fabric of historic cores of HULs.

Various studies from European contexts underscore the potential for combining resilience with conservation practices (Pereira Roders & Oers, 2011), acknowledging these as embedded adaptive responses to environmental stress (Mehrotra, 2016).

Historic urban landscapes, like Siena, represent a delicate balance between human culture and the natural environment, and understanding these man-nature ecosystem dynamics is crucial for effective urban management. Siena's unique urban fabric and its historical climate resilience were shaped by a sustainable mechanism that integrated its natural valleys into the city's functioning, likely through careful water management and ventilation strategies inherent in its medieval design. Consequently, the city's growth and transformation over time are inextricably linked to its historical context, forming a rich heritage urban landscape (Adishakti, 2017). While mapping serves as a valuable inventory technique for tracking urban change, this study aims to delve deeper into the qualitative aspects of this evolution in Siena, particularly concerning its climate vulnerabilities within its dense historical fabric.

A significant turning point in Siena's urban development was the approval of its general master plan in 1956 (locally) and 1959 (nationally) (Maggi, 2011). This plan made a deliberate decision to direct new urban growth outside the medieval walls, preserving the "green valleys" within and restricting further construction inside the historic centre (Maggi, 2011) (Figure 1). This commitment to preservation contributed significantly to Siena's historic centre being designated a UNESCO World Heritage Site in 1995, recognized for its exceptional preservation of medieval architecture and urban planning (UNESCO, 2024).

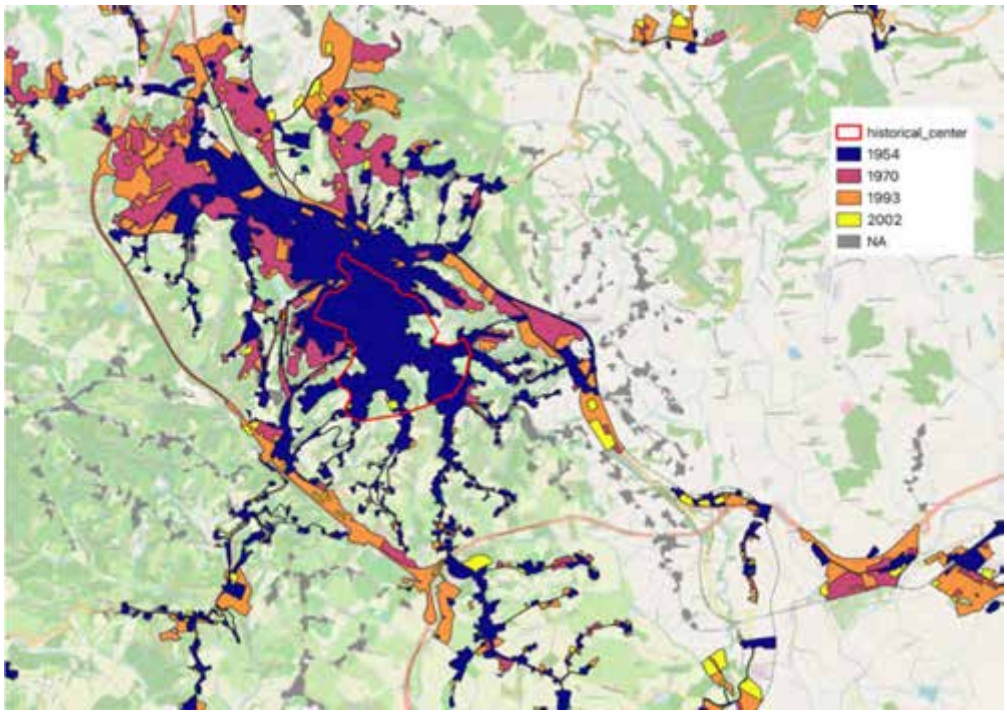

Figure 1. Spatial development of Siena. Author's elaboration.

This study, titled "Preserving the Past or Protecting the Future? Harmonizing Cultural Heritage and Climate Adaptation in Siena," emerged from the ISOCARP YPP (Young Planning Professional) Workshop "Valleys of Siena: Global Ideas for Local Connectivity." Recognizing climate change as a critical threat to the Siena region's ecological balance and its esteemed cultural heritage site, this research is inspired by Italo Calvino's *Invisible Cities*. We interpret the 'invisible' climate-related challenges—such as the intensifying urban heat island effect within Siena's dense historical structure—as being deeply embedded in its heritage-built setting, and we aim to uncover and address them. Ultimately, this project seeks to provide valuable insights for Siena by showcasing how other culturally significant sites have successfully adapted to climate change while maintaining comfortable living conditions for both residents and visitors. It aims to contribute to a more resilient and sustainable future for the city.

Materials and methods

This research employed a mixed-methods approach, combining quantitative spatial analysis with qualitative field research and comparative case study analysis to develop a practical toolkit for climate adaptation in Siena (Figure 2). The methodology was structured to: (1) diagnose the key climate-related challenges facing Siena, (2) study potential adaptation strategies from case studies all around the world, (3) define families of adaptation strategies which can preserve the cultural heritage and adapt to climate change, and (4) contextualize these strategies within Siena's specific historical, social, and environmental context.

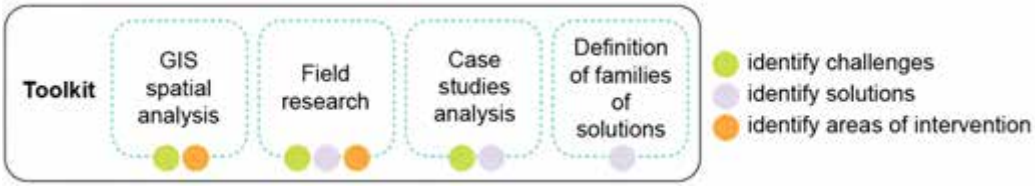

Figure 2. Scheme of the mixed-methods approach used to conduct the study.

GIS spatial analysis was conducted to map urban heat islands (UHIs), evaluate urban density, measure the distribution and quality of green spaces using NDVI, and perform an initial risk assessment to prioritize areas for intervention. **Field research** was undertaken to validate the GIS findings (Figure 3). This involved capturing visual documentation of areas with significant heat stress, extensive paved surfaces, and a lack of green spaces, as well as observations on the disconnection between the city centre and the valleys. Informal conversations with local residents and stakeholders offered valuable perspectives on their experiences and perceptions of Siena's current challenges.

Figure 3. Visual documentation from field research in Siena. This figure presents a selection of images captured during field research. Picture 1 - exploration of the surrounding valleys by bus; Picture 2 - on-foot observation within the valley areas; Picture 3 - the view of the Siena city centre as seen from the valleys; Picture 4 examples of small green interventions, such as potted plants, noted for their potential to contribute to microclimate cooling; Picture 5 - on-site perception of the urban environment; Picture 6 shows the *Tartarugone* parking area, identified as a potential site for future intervention.

A **comparative case study approach** was applied, selecting other UNESCO World Heritage Sites that have successfully implemented climate adaptation strategies, with a focus on urban heat island mitigation and small-scale, temporary interventions.

Based on the challenges identified through GIS, fieldwork, and the UNESCO case studies, we defined several **"families of solutions"**, including: Water Management, Ecosystem Enhancement, Community Engagement, Heat Control, and Places that Foster Belonging. These were then adapted to Siena's context.

By cross-referencing the spatial and qualitative findings with the solution families, we prioritized context-sensitive interventions that align with Siena's heritage values and spatial constraints.

Results

The presentation of the findings begins by outlining Siena's specific challenges. This is followed by an analysis of international case studies from contexts facing similar issues, particularly the intersection of cultural heritage and climate change impacts. Finally, we present defined solution families along with specific proposals for Siena, aimed at harmonizing heritage preservation with climate change adaptation.

Siena's Challenges

Despite Siena's renowned surrounding green valleys, its city centre presents a dense urban structure. Calculating the building coverage ratio within the city walls reveals that approximately 70% of the area is not occupied by buildings, leaving around 30% as built-up. While this relatively low building footprint might initially suggest a "green" centre, the city's valleys, encompassing public and private gardens and orchards, along with larger green spaces like "La Fortezza," are largely disconnected from the daily life within the historic core due to existing barriers. Furthermore, there is a noticeable scarcity of small green spaces integrated within the urban fabric itself. When recalculating the building coverage ratio for the central urban fabric, excluding these larger, often isolated green areas, the figure increases significantly to 47% (Figure 4A). This neighbourhood-level coverage ratio is considerably high, comparable to Densely built areas such as some neighbourhoods in Manhattan (according to the Density Atlas, 2020). The space not covered by building footprints is predominantly composed of impermeable pavements in streets and piazzas. These factors collectively contribute to the emergence of the urban heat island effect, a phenomenon that is projected to become increasingly pronounced as climate change progresses.

Analysis of the historic centre for the urban heat island effect indicated that approximately 30% of its area (excluding the green valleys, specifically 1.946–2.365 and 2.365–2.989 in the legend) is significantly affected by elevated temperatures (Figure 4B).

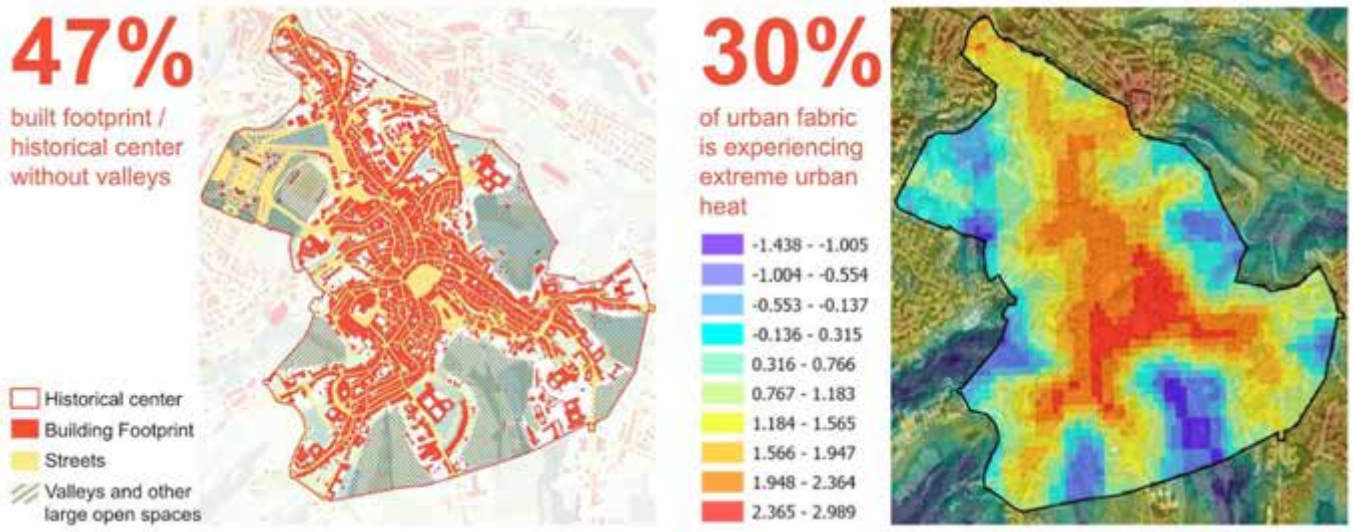

Figure 4. Built-up density and urban heat island (UHI) effect map. Author's elaboration.

Recognizing the stringent UNESCO regulations governing historical sites, we understand that the potential for large-scale interventions within such urban centres is limited. Direct alterations to the historical urban fabric and the creation of extensive greening infrastructure are often challenging. Therefore, our focus will be on small-scale interventions and temporary structures that strategically utilize existing urban spaces. GIS analysis and field research enabled the identification of several hot-spots within Siena's city centre—specific areas experiencing persistent issues requiring prompt attention (Table 1).

Table 1. Hotspots within Siena's city centre and their key challenges.

Picture	Type	Key challenges
	Larger squares	Heat absorption, lack of shade.
	Small squares	Occupied by cars, no greening or shading, lack of seating to stay instead of walking by.
	Main Streets	No or limited shade, lack of vegetation, high contribution to heat effect.
	Schools and public buildings	Fully artificialised, no or limited greening, closed to the public.
	Parking lots	Low urban quality, high contribution to heat effect, impermeable - limit water infiltration, disconnect valleys-city canter.
	Existing valleys	Prevalence of private space (gardens, restaurants, vineyards etc), lack of walkable trails, absence of urban furniture, physical disconnection.

Short interviews with local citizens and experts broadened our perspective beyond the factual data obtained through GIS analysis and documentation of climate challenges, incorporating a crucial social dimension. The Contrada communities' active role in urban life highlights the potential for citizens to act as key drivers in the adoption of sustainable greening initiatives. Considering the challenges that newcomers (e.g., students, migrants) may encounter upon arriving in Siena, we emphasize the necessity for spaces that foster social cohesion and gathering, providing opportunities for meaningful interaction among diverse individuals.

Case Studies Analysis

To address Siena's challenges, we researched potential actions implemented globally to combat similar issues. We compiled a list of relevant case studies: projects that integrate water management, reduce the heat island effect, enhance biodiversity, increase community engagement, and improve the liveability of public spaces. Based on these case studies, our aim was to identify solutions adaptable to Siena's context, enabling the city to confront its challenges while preserving its heritage. These solutions are conceived not only to help the city address its climatic challenges but also to encourage community engagement and create spaces where individuals from diverse backgrounds can meet and participate in common actions.

To address Siena's challenges, our research explored global initiatives tackling similar urban issues. We identified several relevant case studies offering adaptable solutions for water management, heat island reduction, biodiversity enhancement, community engagement, and improved public space livability (Figure 5).

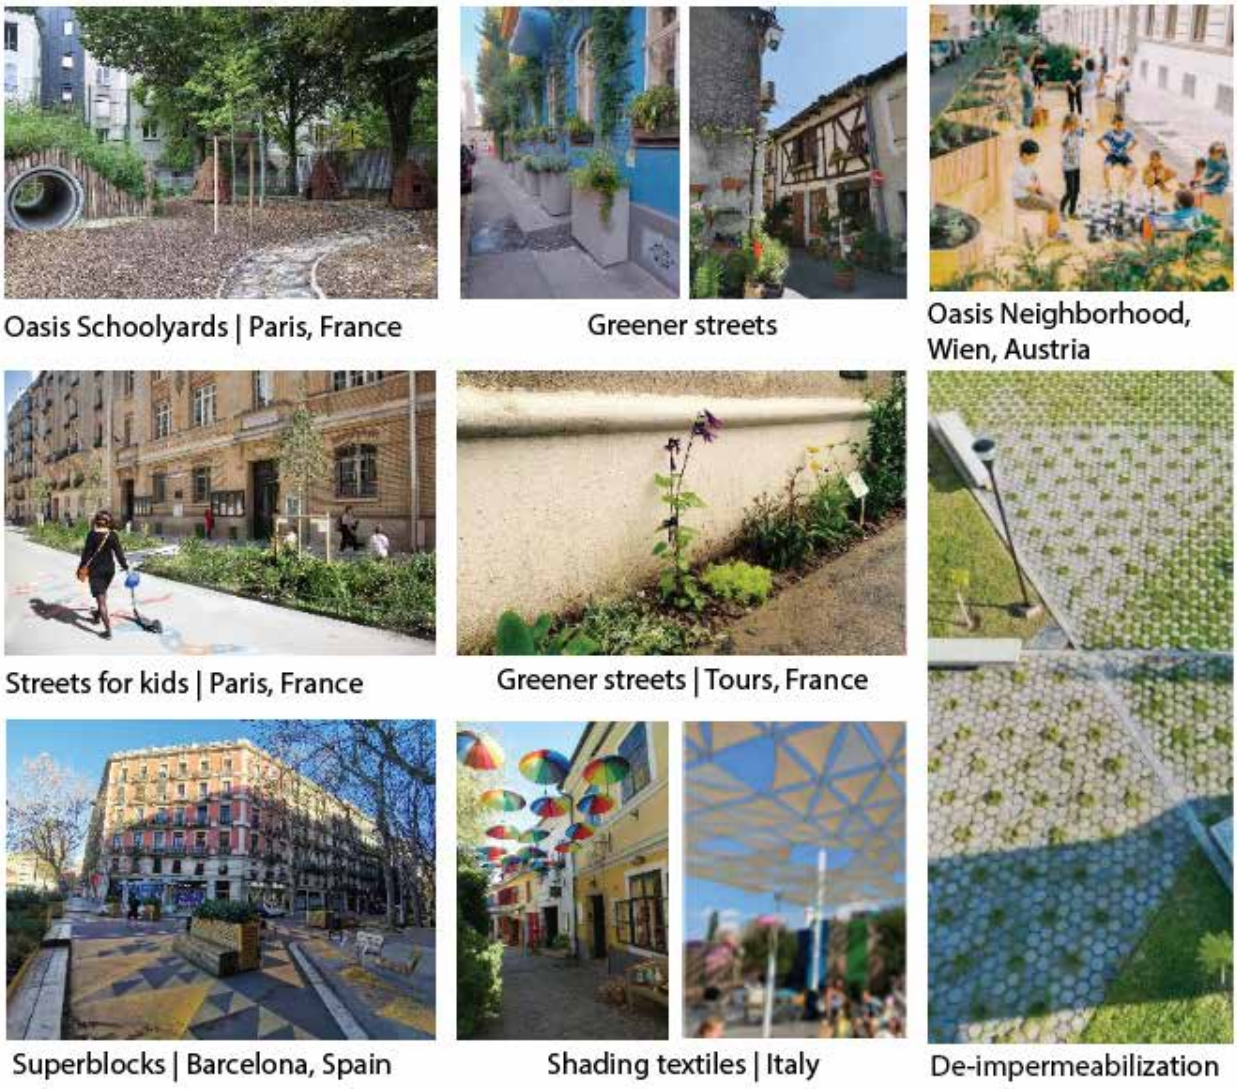

Figure 5. Case studies of cities adapting to climate change with temporary, soft, or green solutions.

One compelling example is the Paris Oasis - Openness, Adaptation, Sensitisation, Innovation, and Social Ties - Schoolyard Programme in France (Climate-ADAPT, 2022). Following the devastating heatwaves of 2003 and 2017, and in response to limited green public spaces, poor water absorption, heat island effects, biodiversity loss, and air pollution, Paris transformed schoolyards by de-impermeabilising surfaces and introducing extensive greenery. By opening these revitalised spaces to the public outside school hours, the city has encouraged community engagement, created vital social hubs, reduced urban heat, enhanced water management and biodiversity, lowered pollution levels, and improved the overall urban experience.

Similarly, the "Streets for Kids" initiative in Paris addressed the scarcity of green spaces, poor permeability, and limited biodiversity (Baierl, 2025). By reducing traffic and introducing greenery through de-impermeabilised streets and tree planting, the city created safer and more welcoming spaces for children and families. This not only reduced the heat island effect but also fostered community well-being and improved the urban ambiance.

Barcelona's "Superblocks" offer another exemplary model. Faced with limited public green space, excessive traffic, and biodiversity decline, the city reimagined car-dominated zones as pedestrian-centred green spaces (C40, 2018). Through the addition of street furniture and vegetation, Barcelona promoted social interaction, improved microclimates, enhanced biodiversity, and increased pedestrian safety.

Vienna's Vienna – Grätzloase initiative exemplifies a citizen-driven response to similar urban challenges (Lee Kuan Yew World City Prize, 2020). Temporary transformations of parking spaces into green community areas empowered residents to reclaim public space. These interventions contributed to heat island mitigation, water management, biodiversity support, and the creation of safer, more inclusive urban environments.

Simple yet impactful solutions, such as the use of plant pots or encouraging residents to green their streets, have been employed in various cities. For example, in Tours, France, the municipality enabled residents to cut through pavements and plant directly into the ground . This initiative tackled impermeability, water runoff, and heat effects while enhancing biodiversity and fostering community care for public space.

In Italy, some municipalities have addressed excessive heat in public spaces by installing temporary **shading textiles** across squares and streets (Fabbri et al. 2023). These installations reduce surface temperatures and promote the use of public spaces for social and cultural activities.

Other effective solutions include de-impermeabilising parking areas using permeable paving systems, such as concrete grids that allow grass to grow. These systems improve water absorption, reduce heat, and increase green cover in highly artificialised environments.

Collectively, these international case studies demonstrate that even modest, low-impact interventions can have wide-reaching benefits. When adapted to Siena's context, such strategies can contribute to a more climate-resilient, liveable, and socially cohesive city, all while respecting and preserving its cultural heritage.

Definition of Solutions

Drawing upon the insights gained from the analysed case studies, several families of solutions have been defined for potential implementation in Siena (Figure 6). These interconnected families are specifically designed to address the city's unique challenges while drawing inspiration from successful climate adaptation strategies observed in other UNESCO World Heritage sites. The proposed solutions are organized around five key areas of intervention. Firstly, **Water Management** strategies aim to enhance water retention and improve drainage systems, thereby playing a crucial role in reducing the risk of flooding and mitigating the adverse effects of the urban heat island. Secondly, **Ecosystem Enhancement** focuses on the restoration and improvement of natural ecosystems within and around Siena, with the goal of increasing biodiversity and improving overall air quality. Thirdly, **Community Engagement** initiatives are designed to empower local communities to actively participate in climate action through collaborative projects and shared stewardship. The fourth area, **Heat Control**, encompasses the implementation of various strategies to reduce heat absorption within urban areas and increase cooling mechanisms, thereby improving thermal comfort. Finally, the creation of **Places that Foster Belonging** is a key focus, aiming to develop accessible and welcoming public spaces that encourage social interaction among diverse groups and ultimately enhance the overall well-being of Siena's residents.

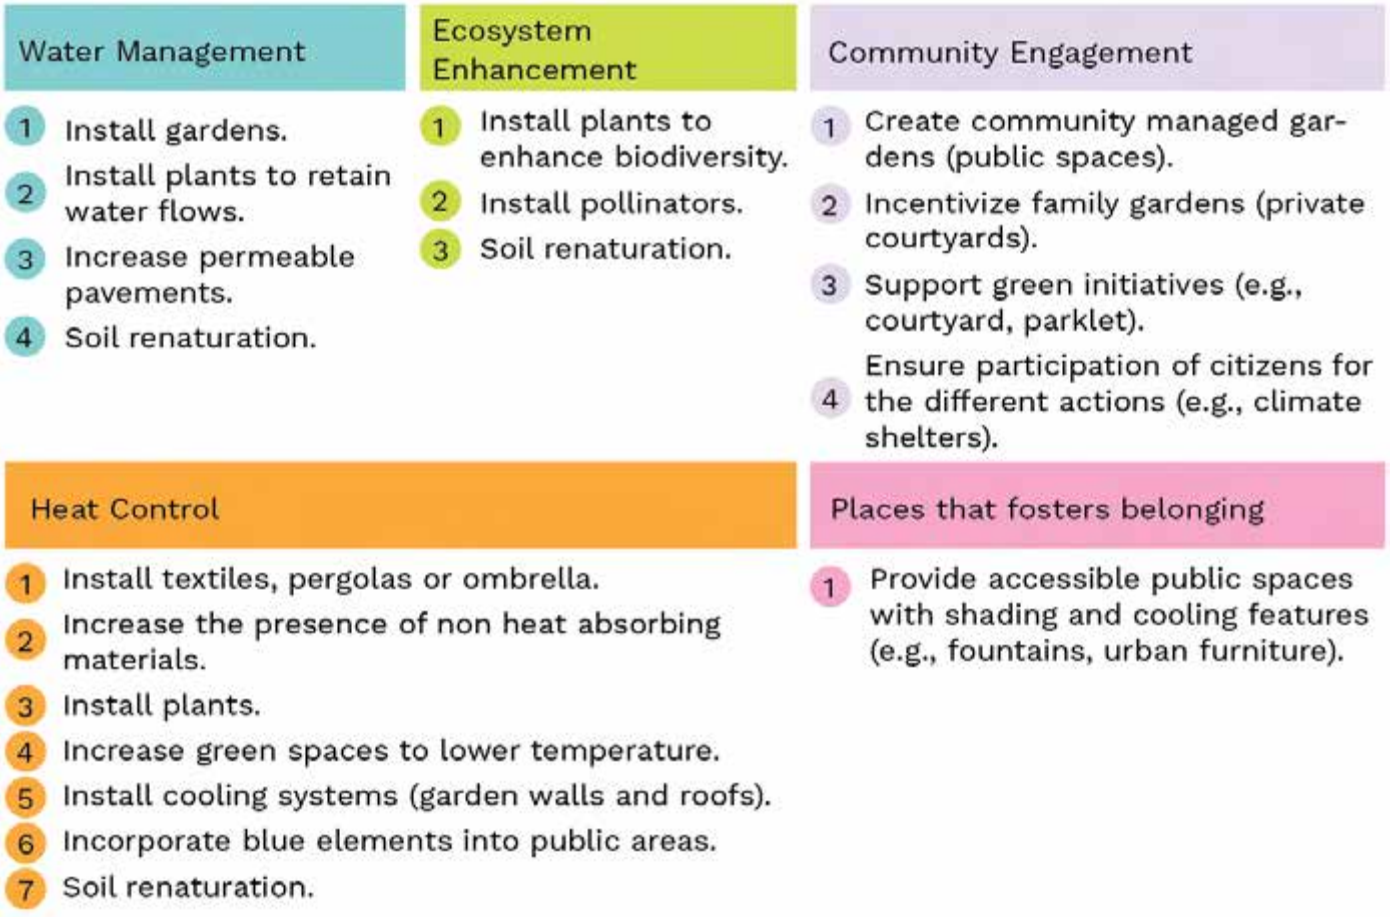

Figure 6. Families of solutions.

Furthermore, we have visually represented these solutions in a matrix (Figure 7) to assist decision-makers in understanding the relationship between specific areas in the city, their identified challenges, and the proposed solutions.

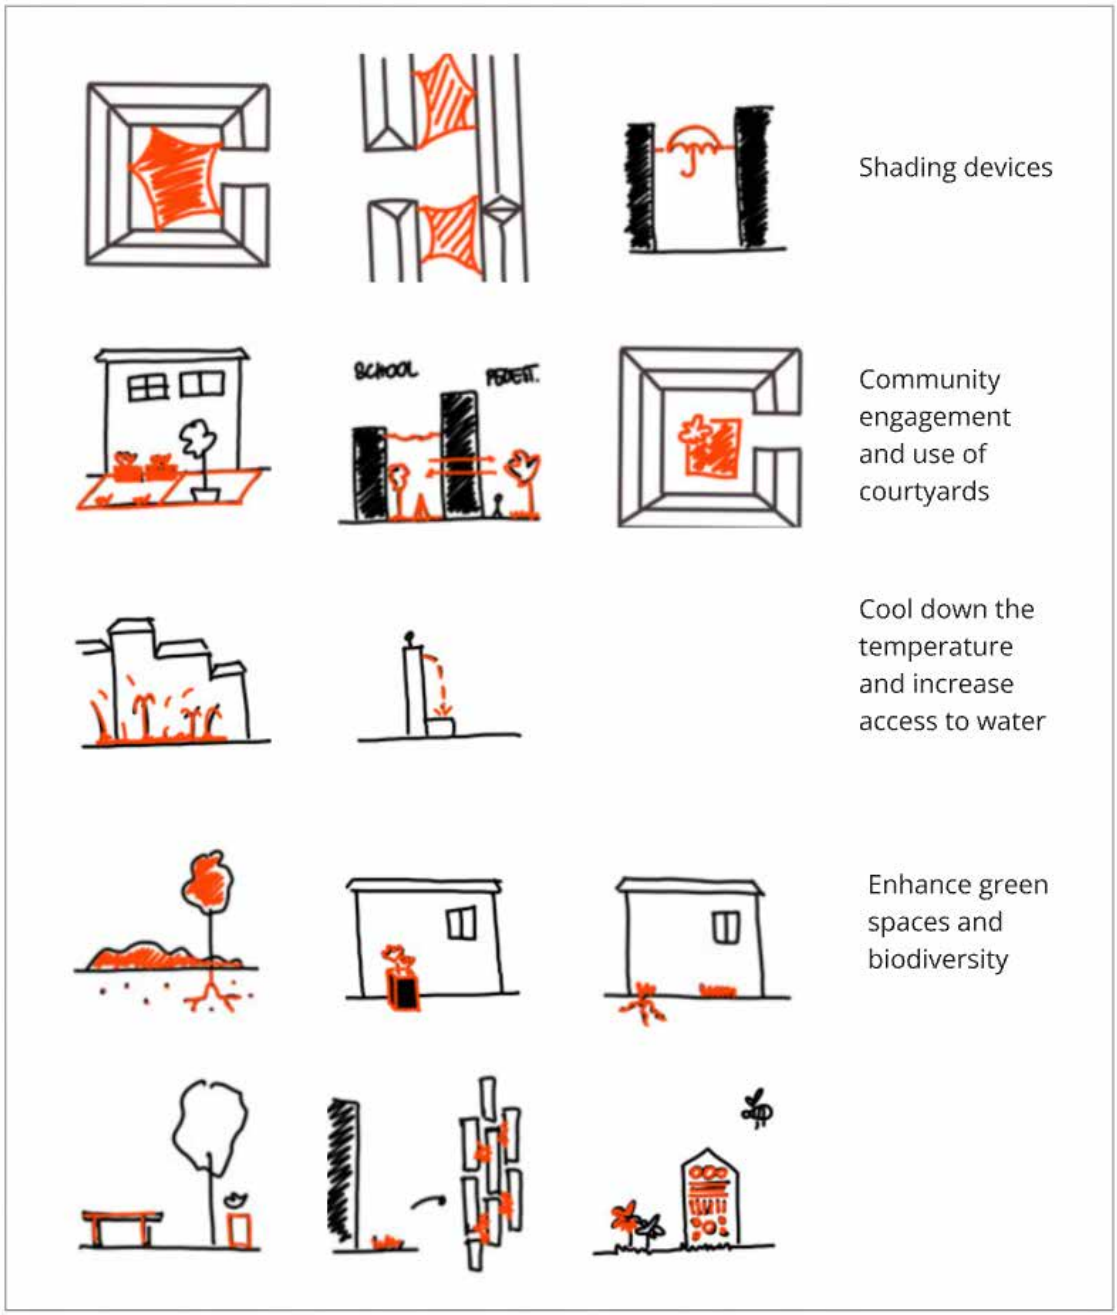

Figure 7. Solutions matrix illustration.

Mapping Actions

All defined solutions were spatially applied to the problem areas identified in the centre of Siena during the analytical phase of this work. The accompanying map (Figure 8) illustrates the locations of all identified hot-spot

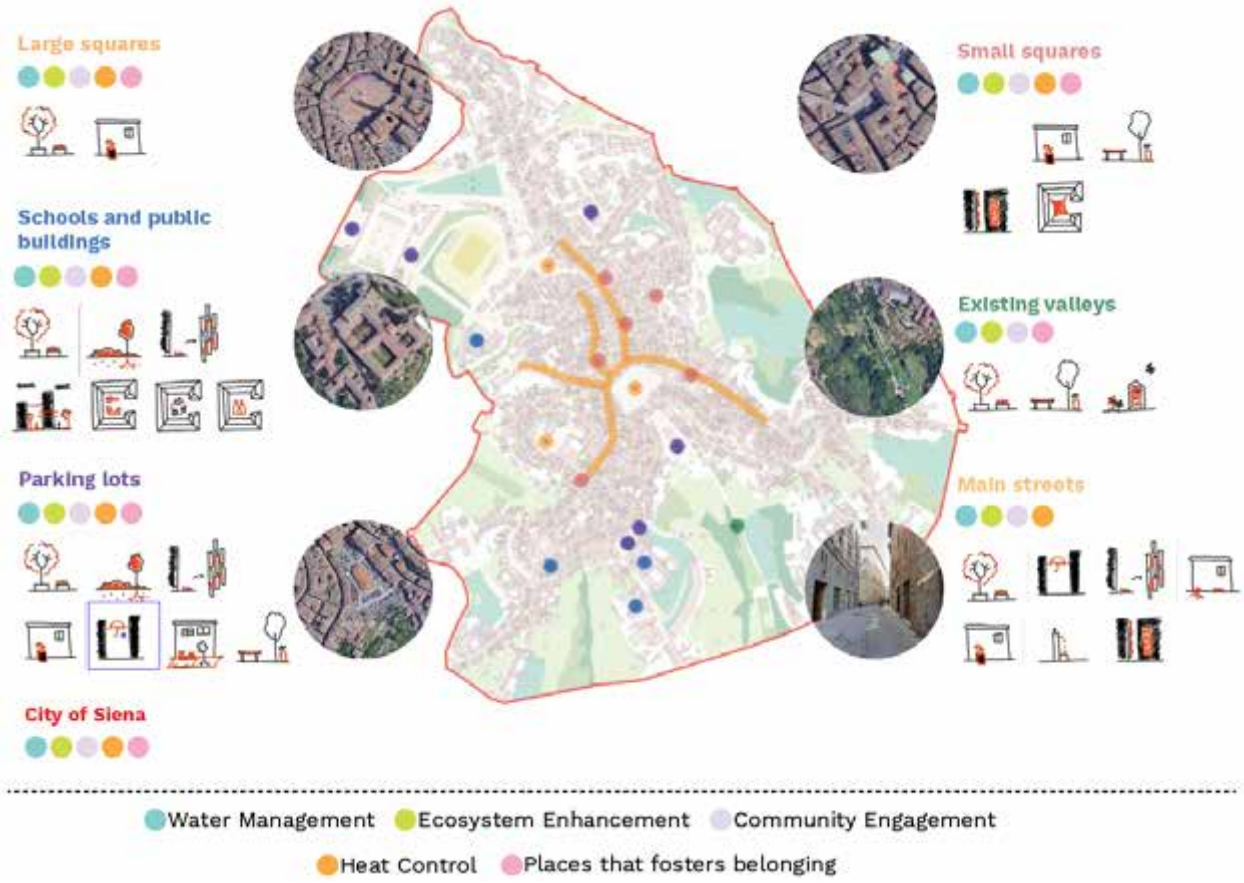

Figure 8. Interventions for climate adaptation map in Siena

Analysis of key urban spaces in Siena reveals specific challenges related to heat absorption, lack of green infrastructure, and limited public amenities. Large squares, while iconic, suffer from excessive heat due to impermeable surfaces and lack of shade, suggesting the need for citizen-involved climate shelters and planted areas to enhance biodiversity and regulate temperature. Schoolyards and public buildings often lack green spaces and could be transformed through soil renaturation, permeable pavements, vegetation, shading structures, and community-managed gardens to improve biodiversity, water retention, and provide accessible, cooled public spaces. Parking lots, prominently located, exhibit low urban quality, contribute to heat effects, and impede water infiltration and social interaction, necessitating similar interventions like soil renaturation, permeable surfaces, planting, and shading, alongside the creation of community gardens and accessible public spaces. Small squares, currently dominated by vehicles and lacking greenery and shade, could be revitalized with planting for biodiversity and heat control, citizen-led climate shelters, shading structures, cooling systems, and accessible, shaded public furniture. Existing valleys, despite their natural presence, lack accessibility and public amenities, indicating a need for pollinator-friendly planting, soil renaturation, enhanced biodiversity, community gardens, and welcoming, shaded public spaces. Main streets, characterized by full artificialization and limited shade and greenery, contribute to the heat island effect, suggesting solutions like increased planting for biodiversity and water retention, permeable pavements, shading structures, expanded green spaces, incorporation of blue elements, use of non-heat-absorbing materials, community gardens, and accessible, cooled public areas, all while maintaining urban mobility. Considering the broader city centre, including incentivizing green development in private courtyards, a combination of these localized solutions can contribute to a more climate-resilient and liveable Siena.

Conclusion

This paper investigated the potential for climate adaptation in Siena, a city distinguished by its exceptionally well-preserved historic fabric and UNESCO World Heritage status, where climate responses must be carefully balanced with cultural conservation. While UNESCO's mandate focuses on protecting cultural heritage, it does not explicitly require member states to address climate change challenges (Nguyen & Baker, 2023). Siena's compact medieval core, characterised by narrow streets, steep topography, and layered historical infrastructures, presents both constraints and unique opportunities for adaptive strategies. Working within the regulatory limits of a UNESCO site complicates asset management for climate adaptation but can also drive innovative, site-specific solutions (Pendlebury et al., 2014).

This project offered an opportunity to critically examine the tension between viewing Siena as a static open-air museum and embracing a dynamic perspective that adapts the city to contemporary and future needs while safeguarding its heritage values. Drawing on a combination of GIS analysis, fieldwork, and international case studies, the study mapped vulnerabilities such as urban heat exposure, limited green infrastructure, and geomorphological challenges within this highly protected environment.

Based on global precedents, four categories of climate adaptation strategies were identified, emphasising how environmental effectiveness can be harmonised with heritage sensitivity. These were translated into locally tailored proposals for Siena, including nature-based interventions embedded within historic street patterns, shaded public microclimates, and the revitalisation of ancient water systems. Consistent with ICOMOS guidance (2019), these site-specific and adaptive solutions respect cultural values while addressing climate risks.

Importantly, the proposed interventions prioritise non-invasive, small-scale actions strategically diffused throughout the city to generate meaningful cumulative impact. This approach aligns with principles of tactical urbanism, favouring reversible and flexible measures that can evolve through stakeholder feedback and municipal collaboration (Lydon & Garcia, 2015). Such flexibility is essential to ensure the long-term relevance and effectiveness of adaptation efforts, while maintaining respect for existing uses and cultural sensitivities.

Although Siena was used as a pilot case to develop this methodology, the framework is intended as a replicable, adaptable toolkit for other historic cities confronting the dual challenges of cultural preservation and climate change. Each application must be carefully contextualised to local histories, urban forms, regulatory frameworks, and cultural landscapes to avoid generic, one-size-fits-all solutions.

This study contributes to the emerging dialogue bridging heritage conservation and climate resilience, offering a place-based planning methodology where formal adaptation frameworks are often lacking. Future research should focus on co-designing interventions with local communities, exploring participatory governance models, and piloting projects to evaluate feasibility, cultural acceptance, and sustainability — ensuring adaptation is both environmentally sound and culturally embedded.

Exploring Low-Carbon Urban Development at the Plot Scale: A Study of Carbon Emission Mechanisms and Empirical Exploration of Micro-Renovation for Emission Reduction

Shumin Wang[1*], Guoao Liu[1], Jianyu Li[1], Xinyu Lin[1*], Mingxing Hu[1]
[1] School of Architecture, Southeast University, Nanjing, China
[*] 230067@seu.edu.cn

Abstract
In response to global climate change, cities - as key spatial carriers of human activity - must refine governance strategies. Focusing on Nanjing's main urban area, this study integrates ODIAC global carbon emission data with multi-source big data and applies Multi-scale Geographically Weighted Regression (MGWR) and Geo-Detector models to analyze drivers of land-use carbon emissions. Results show that functional attributes, spatial forms and carrying capacity characteristics have a spatially heterogeneous impact on carbon emission intensity, with the carrying capacity factors contributing the most and about 60% of the influencing factors having significant synergistic effects. Based on this, a low-carbon planning strategy at the micro-plot level is constructed, and the carbon emission intensity of the plot in Liuhe District is reduced from 6.96 kg/m² to 6.38 kg/m², with an annual carbon emission reduction of 153 tons. This function-form-capacity collaborative control approach effectively reduces urban land-use carbon intensity and supports low-carbon city goals.

Keywords: Urban carbon emissions, Micro-perspective, Multi-scale geographically weighted regression model (MGWR), Geo-Detector, Low-carbon micro - renovation

1.Introduction

As global climate change intensifies, greenhouse gas emissions have become one of the major challenges faced by humanity. Cities, as areas of high population, economic, and social activity concentration, contribute approximately 70% to 80% of global carbon dioxide emissions (Kumar, 2007, Sun et al., 2022, Wang et al., 2023). Therefore, low-carbon urban development has become key to achieving the goals of carbon peak and carbon neutrality. China has proposed the "dual carbon" strategy, aiming to peak carbon emissions by 2030 and achieve carbon neutrality by 2060, which brings unprecedented pressure and opportunities for urban green transformation and planning (Shi, 2022). In this context, a deep scientific understanding of the temporal and spatial distribution characteristics of urban carbon emissions and their driving mechanisms has become the foundation for formulating precise and effective carbon reduction policies and achieving the construction of low-carbon cities.

Urban land, as the basic unit of urban space, aggregates elements such as population, industry, buildings, and transportation, and is the primary source of carbon emissions (Liu et al., 2025). Studies have shown that high-density and functionally mixed urban areas are more conducive to improving energy efficiency and reducing per capita carbon emissions compared to low-density, single-function zones (Zhang et al., 2022). Therefore, accurately grasping the carbon emission patterns at the urban land scale is the foundation for formulating low-carbon urban development strategies. However, most existing carbon emission studies primarily focus on urban or regional scales, using administrative divisions or grid units (Li et al., 2025, Liu and Zhao, 2023, Shen et al., 2023). While such studies can reveal the spatial distribution and evolution of carbon emissions from a macro perspective, their relatively coarse spatial resolution fails to reflect the differences and underlying mechanisms at the micro scale, limiting guidance for low-carbon strategies at specific plots or street block levels.

The research on the factors influencing carbon emissions is diverse. Many scholars start with macro-statistical variables such as population, industry, and energy structure, using tools such as Ordinary Least Squares (OLS), the STIRPAT model (Stochastic Impacts by Regression on Population, Affluence, and Technology) (Shahbaz et al., 2016, Zhou et al., 2015), and machine learning algorithms (Tian et al., 2024a)China (2009-2023 to analyze the driving mechanisms. Meanwhile, some studies have begun to focus on the internal spatial structure of cities, particularly the impact of land use types and spatial form on carbon emissions (Wang et al., 2025, Li et al., 2025). For instance, Wang et al. (2019), using Eindhoven City in the Netherlands as a case study, divided land functions into fourteen categories and analyzed the relationship between different land use types and urban carbon emissions, revealing the differential contribution of various functional land uses to carbon emissions.

However, existing studies mostly emphasize a single dimension or static analysis, lacking a systematic integration of multi-dimensional indicator systems to comprehensively explain the complex mechanisms of urban land carbon emissions.

In order to more comprehensively characterize the influencing factors of urban land carbon emissions, this study divides the attributes of urban land into three main categories: functional attributes, spatial form, and carrying capacity. Functional attributes encompass land use types and their proportions, reflecting the socio-economic functions of the land; spatial form includes physical characteristics such as building form, density, and number of stories, reflecting the organizational structure of urban space; carrying capacity represents the population scale, economic activity intensity, and traffic network density supported by the land, indicating the land's capacity and load level (Zhu et al., 2025, Li et al., 2021). This classification not only aligns with the practical logic of urban planning but also systematically reveals the driving paths of carbon emissions from different perspectives, providing a solid framework for subsequent in-depth analysis based on spatial statistical models.

In recent years, the introduction of spatial statistical tools such as Spatial Lag Model (SLM), Spatial Error Model (SEM), Spatial Durbin Model (SDM), Geographically Weighted Regression (GWR), and GeoDetector has effectively identified the spatial heterogeneity and interaction mechanisms of the factors influencing carbon emissions. For example, Wei et al. (2024) used the Spatial Durbin Model (SDM) to study the driving mechanisms of carbon emissions in China's urban agglomerations. Among them, Multi-scale Geographically Weighted Regression (MGWR) and GeoDetector models have gained increasing attention due to their ability to dynamically capture spatial variations in driving factors and multi-factor interactions (Rong et al., 2022, Zhang et al., 2025). The MGWR model captures the diverse driving mechanisms within regions by allowing variable coefficients to change with spatial location and scale. GeoDetector, on the other hand, identifies key influencing combinations by quantitatively analyzing the explanatory power of factors on spatial distribution and the interactions between factors.

Although existing studies have proposed low-carbon recommendations based on model results (Hurlimann et al., 2021, Woodruff et al., 2022), most lack quantitative evaluations linked to specific plots, making it difficult to verify the actual carbon reduction benefits of planning strategies at the micro spatial scale. Therefore, this study focuses on the micro-plot scale, applying both the MGWR and Geo-Detector models to systematically reveal the influence mechanisms and interactive effects of urban functional attributes, spatial form, and carrying capacity on carbon emissions, exploring their carbon reduction potential in specific plots. By combining empirical cases of micro-updating in typical plots of Nanjing's main urban area, this study quantitatively evaluates the performance of low-carbon planning interventions, filling the research gap on low-carbon micro-update performance evaluation, and providing strong support for the scientific formulation and implementation of precise low-carbon urban planning strategies.

2.Materials and Methods

2.1 **Study Area**

This study focuses on the main urban area of Nanjing as defined in the draft of the city's Land and Spatial Master Plan (2021-2035). The study area is delimited based on natural water systems and major road networks, covering a continuous urban space with a total area of approximately 970 square kilometers (see Figure 1). According to data from the China Carbon Accounting Database (Shan et al., 2017), the annual total carbon dioxide emissions in Nanjing reach 170.39 million tons, ranking second in Jiangsu Province. The choice of the main urban area as the study area encompasses not only the core region of urban development but also typical urban land use structures and carbon emission characteristics, making it both representative and valuable for research.

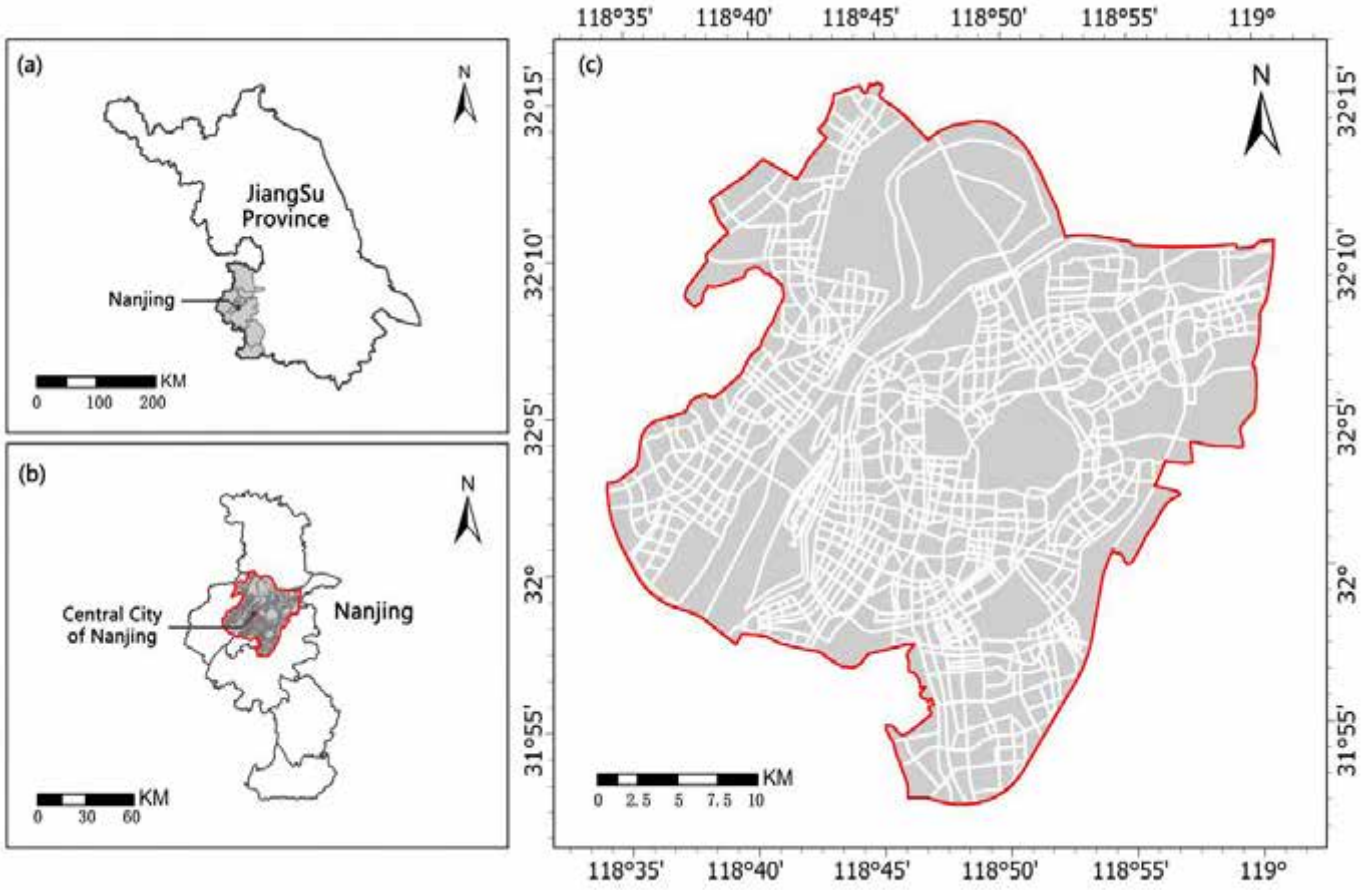

Fig. 1 Study area

2.2 Data Source

The carbon emission data used in this study is sourced from the ODIAC (Open-source Data Inventory for Anthropogenic CO2) global dataset, which is provided by the Center for Global Environmental Research (CGER). This dataset has a 1-kilometer spatial resolution. The data was clipped and regionally aggregated using ArcGIS software to extract the total annual carbon emissions for the main urban area of Nanjing in 2023, which serves as the dependent variable in this study.

The factor indicator system for carbon emissions was constructed with reference to numerous literature reviews and urban planning practices. It systematically integrates the key driving factors of carbon emissions from three dimensions: the functional attributes, spatial form, and carrying capacity of urban land. The functional attributes mainly reflect the nature and proportion of land use; spatial form indicators reflect building characteristics; and carrying capacity reflects the development intensity and spatial carrying capacity of the land. To avoid multicollinearity interference, variance inflation factor (VIF) tests were conducted to rationally eliminate and adjust the preliminary selected indicators, ensuring that the selected indicators have high independence and explanatory power. Ultimately, 14 influencing factors across the three categories were identified (see Table 1), laying a solid foundation for the subsequent model analysis.

Table 1 Indicator System for Influencing Factors and Their Statistical Characteristics

Category	Description	Mean	Standard Deviation	VIF
Functional Attributes	Proportion of commercial/service land	0.162	0.182	3.45
	Proportion of residential land	0.220	0.228	2.98
	Proportion of blue-green space	0.075	0.117	1.12
	Proportion of industrial/logistics land	0.101	0.190	3.87
	Land use mix index	1.218	0.390	4.23
	Land use evenness index	0.708	0.256	3.71
Spatial Form	Average building shape coefficient	0.0155	0.009	2.35
	Average building aspect ratio	2.899	1.237	2.79
	Building density	0.133	0.100	4.15
	Average number of floors	8.598	5.001	3.56
	Floor Area Ratio (FAR)	1.462	1.333	4.87
Carrying Capacity	Population density	97.601	71.651	3.62
	POI Density	557.414	778.443	3.99
	Road network density	0.016	0.009	2.74

2.3 Model Introduction

This study employs two spatial statistical models: Multi-scale Geographically Weighted Regression (MGWR) and Geo-Detector. The aim is to reveal the spatial heterogeneity and multi-factor interaction mechanisms affecting the carbon emission intensity of urban land use.

2.3.1 Multi-scale Geographically Weighted Regression (MGWR)

The MGWR model is an extension of the Geographically Weighted Regression (GWR) model. The difference is that MGWR allows the effect scale of different explanatory variables to vary spatially. By setting a bandwidth parameter for each variable individually, MGWR captures the strength of the effect of each variable on the dependent variable within different spatial ranges. Compared to traditional GWR, which uses a unified bandwidth, MGWR better reflects the diversity of spatial scales of driving factors in complex urban environments, and reveals the differences in the effects of various factors at local and macro scales. This helps identify the carbon reduction potential differences in land use functions, spatial forms, and carrying capacity across regions, improving the model's fitting effect and explanatory power (Laffan and Bickford, 2005).

$$y_i = \beta_0(u_i, v_i) + \sum_{k=1}^{p} \beta_k (bw_k, u_i, v_i) x_{ik} + \varepsilon_i$$

Where y_i represents the carbon emission intensity of the i-th geographic unit, x_{ik} represents the k-th influencing factor for the i-th unit, β_k is the regression coefficient with a location-dependent bandwidth, and ε_i is the error term. MGWR minimizes local weighted squared errors to estimate the spatial heterogeneity coefficients of each variable, achieving precise characterization of the spatial scale of the influence of different factors.

2.3.2 Geo-Detector

Geo-Detector is a factor influence evaluation tool based on spatial statistics, used to measure the degree of consistency between the spatial distributions of explanatory variables and the dependent variable. The core idea is that if an influencing factor shows a high spatial consistency with carbon emission intensity, it has a strong explanatory power for carbon emissions.

Geo-Detector reflects the proportion of variance in the spatial variation of carbon emissions explained by a factor by calculating a statistical value, as defined below:

$$q = 1 - \frac{\sum_{h=1}^{L} N_h \sigma_h^2}{N\sigma^2}$$

Where N is the total sample size, σ^2 is the total variance of carbon emission intensity, N_h and σ_h^2 are the sample size and variance within the h-th subdivision, and L represents the number of subdivisions. The value of q ranges from [0, 1], with a value closer to 1 indicating stronger explanatory power.

Furthermore, Geo-Detector is used for factor interaction analysis. By comparing the combined value of factor interactions with the value of individual factors, it identifies complex interaction patterns such as factor combination enhancement and nonlinear enhancement, revealing the pathways through which multiple factors synergistically affect carbon emissions.

3. Analysis of Spatial Distribution Characteristics and Driving Mechanisms of Carbon Emissions in Nanjing's Main Urban Area

3.1 Spatial Distribution Characteristics of Carbon Emissions

Based on the ODIAC global carbon emission data with a 1-kilometer resolution, combined with the administrative boundaries and land use information of Nanjing's main urban area, this study mapped the spatial distribution of carbon emission intensity in 2023 (see Figure 2). Overall, the carbon emission intensity in Nanjing's main urban area shows significant spatial heterogeneity, with high carbon emission zones concentrated primarily in the urban core and near major transportation hubs.

Specifically, the areas with the highest carbon emission intensity are located to the west of the Xinjiekou commercial district and around Nanjing South Railway Station. These regions have frequent economic activities, high commercial density, and significant population and traffic flow, leading to higher energy consumption and carbon emission levels. High carbon emission units exhibit a clear "core-periphery" gradient structure, with emission intensity gradually decreasing as the distance from the core increases, forming a concentric "layered" distribution pattern. The carbon emissions in the urban periphery, as well as in water bodies and green spaces, are significantly lower. This distribution pattern reflects the dominant role of the urban core as a hub for economic and social activities, contributing substantially to carbon emissions.

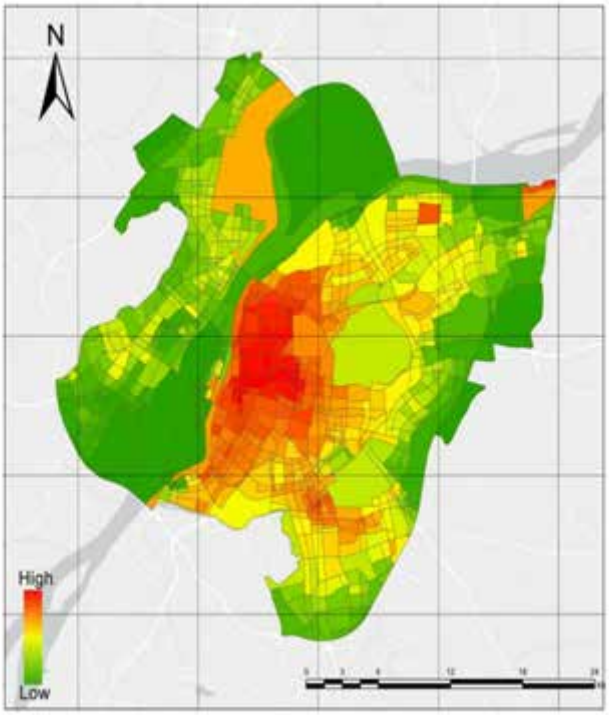

Figure 2 Spatial Distribution Map of Carbon Emission Intensity in 2023

3.2 Driving Mechanism Analysis of Carbon Emissions Based on Multi-scale Geographically Weighted Regression (MGWR)

3.2.1 Performance Comparison

To further analyze the driving mechanisms of carbon emissions in Nanjing's main urban area, this study uses the Multi-scale Geographically Weighted Regression (MGWR) model. Compared to the traditional Geographically Weighted Regression (GWR), the MGWR model is more flexible in capturing spatial heterogeneity and local variations in driving factors by selecting adaptive bandwidths (Omrani et al., 2025). This model can accurately reflect the differences in driving factors across different regions, thereby improving the model's explanatory power and prediction accuracy.

In terms of model performance comparison, we compared the Ordinary Least Squares (OLS), Geographically Weighted Regression (GWR), and Multi-scale Geographically Weighted Regression (MGWR) models. According to the results in Table 2, the MGWR model outperforms both OLS and GWR in all performance metrics. Specifically, the R-squared for MGWR is 0.7386, and the adjusted R-squared (Adj R-squared) is 0.7126, both significantly higher than those of OLS and GWR, indicating stronger fitting capabilities. This suggests that MGWR can better explain the variation in carbon emission intensity. Therefore, MGWR was chosen as the primary model for analyzing the driving mechanisms of carbon emissions in this study.

Table 2 Comparison of Model Fitting Performance

Parameter	Ordinary Least Squares (OLS)	Geographically Weighted Regression (GWR)	Multi-scale Geographically Weighted Regression (MGWR)
R-squared	0.5062	0.6748	0.7386
Adj R-squared	0.4984	0.6028	0.7126
σ^2	0.70862	0.3971	0.2874
AICc	1959.714	1856.1724	1536.6730

3.2.2 MGWR Results Analysis

(1) Functional Attribute Factors

Firstly, the effects of the proportion of commercial and public service land (Figure 3a) and industrial and logistics land (Figure 3d) on carbon emission intensity exhibit significant spatial heterogeneity within the main urban area. The carbon emission intensity of commercial land generally shows a positive correlation, particularly in high-density urban core areas. As the proportion of commercial land increases, the carbon emission intensity also rises (You et al., 2023). Similarly, the effect of industrial and logistics land on carbon emission intensity is positive in most areas, especially in the urban periphery, where the expansion of industrial land tends to bring higher carbon emission levels. However, in certain specific areas of Nanjing, such as the Zhongshan Scenic Area and the southern part of the city, the increase in industrial land did not significantly raise the carbon emission intensity. On the contrary, it exhibited a weak negative correlation.

In contrast, the proportion of residential land (Figure 3b), blue-green space (Figure 3c), land use mix index (Figure 3e), and land use evenness index (Figure 3f) generally show a negative relationship with carbon emission intensity, and their influence mechanisms within the main urban area are consistent, with no significant spatial heterogeneity. Areas with a high proportion of residential land typically have lower carbon emission intensity, which is related to the fact that residential land is primarily used for daily living and has lower energy consumption (Cai et al., 2025), especially when compared to commercial and industrial land. The increase in blue-green space helps enhance the ecological function of the urban environment, thereby reducing carbon emission intensity. Blue-green spaces not only reduce carbon dioxide emissions by increasing carbon sequestration effects but also improve the microclimate and reduce the urban heat island effect, further decreasing energy consumption and carbon emissions. Both the land use mix index and the land use evenness index also show a negative relationship. Previous studies, from the perspective of urban agglomerations, have demonstrated that the rational layout of multifunctional land uses within a plot can effectively reduce carbon emission intensity (Kang et al., 2023). A high land use mix not only helps reduce long-distance travel and traffic congestion but also improves carbon emission outcomes through the introduction of ecological spaces such as parks and green spaces.

(f) Land use evenness index

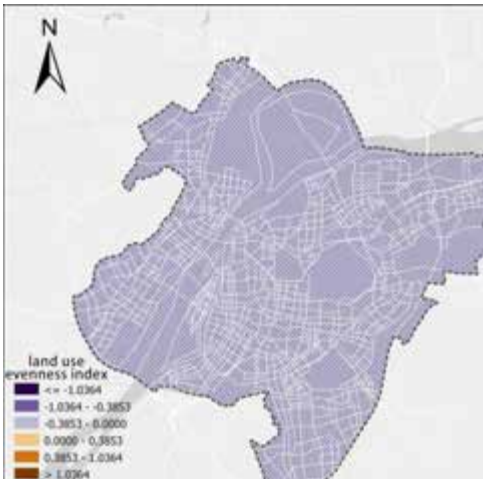

Figure 3 Analysis Results of Functional Attribute Factors

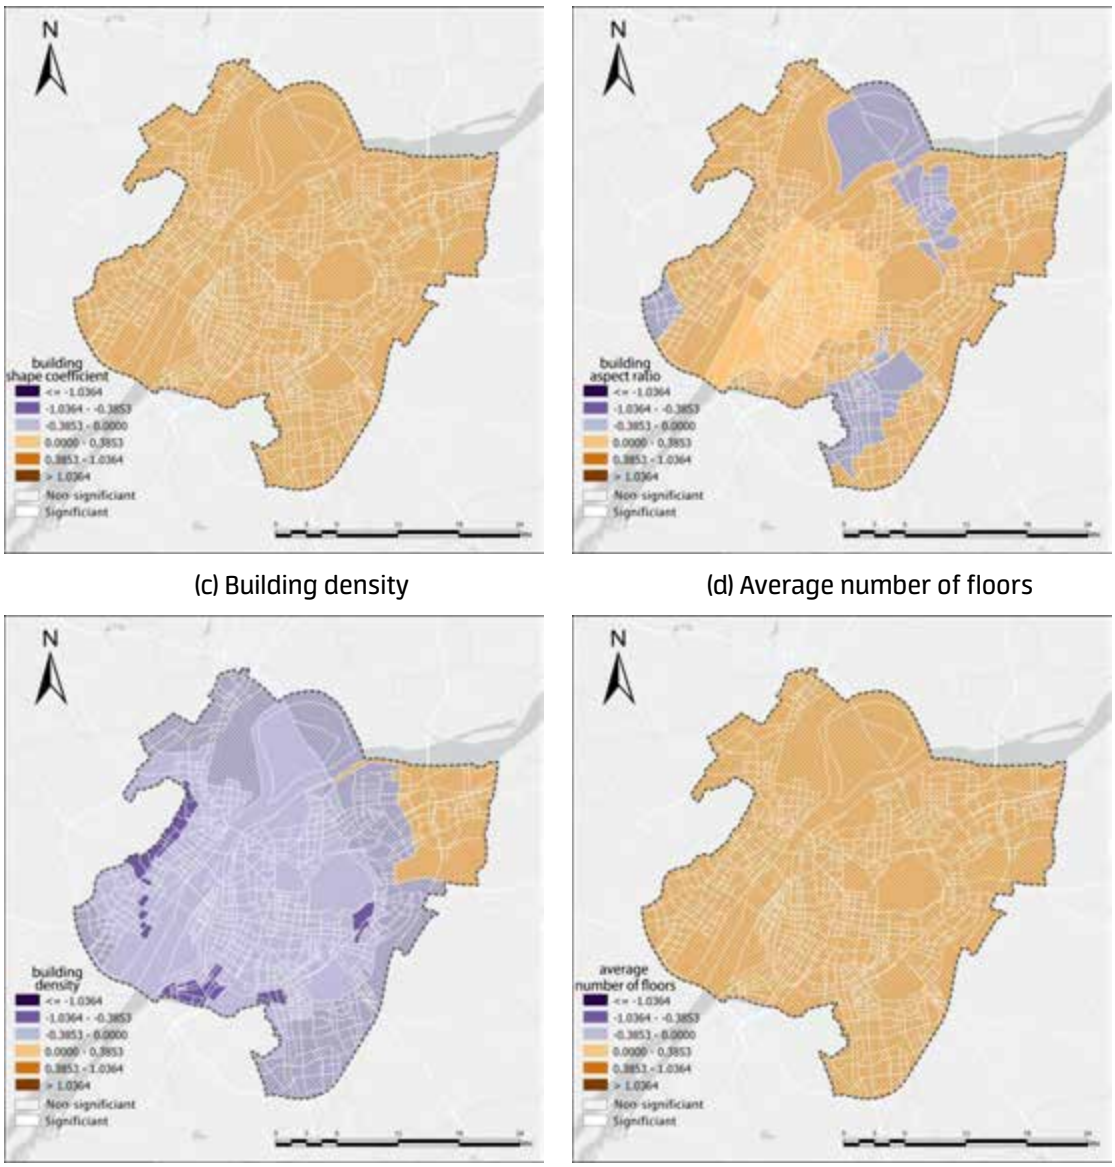
(2) Spatial Form Factor

The average building shape coefficient and average building aspect ratio are important indicators that reflect the extent of building exposure to the external environment. As shown in Figure 4a, the building shape coefficient has a positive global correlation with carbon emission intensity, meaning that as the building shape coefficient increases, the building's contact area with the environment increases, leading to higher energy consumption and, consequently, higher carbon emission intensity. In contrast, the relationship between the building aspect ratio and carbon emission intensity is more complex (Figure 4b). Higher building aspect ratios are generally associated with higher carbon emission intensity, but in areas like Bagua Island, Shuanglong Avenue, Qixia Avenue, and Wuhua Road in Nanjing, a higher building aspect ratio does not significantly increase carbon emission intensity. This may be related to local climatic conditions, building energy efficiency, and the characteristics of the surrounding environment, with microclimate effects potentially having a varying impact on the carbon emission mechanism (Dong et al., 2023).

On the other hand, the relationship between building density and carbon emission intensity shows significant spatial heterogeneity across different regions (Figure 4c). In the Xianlin area of Nanjing, building density is positively correlated with carbon emission intensity, whereas in other areas of the main urban area, building density shows a negative correlation with carbon emission intensity. This suggests that in some areas, a moderate increase in building density helps reduce carbon emission intensity. This is consistent with findings from some urban studies. For example, research in Shanghai has shown that after a certain level of floor area ratio is reached, increasing building density reduces carbon emissions, especially when land use efficiency is improved and urban sprawl is reduced, leading to decreased traffic-related emissions (Tian et al., 2024b, Sun and Song, 2024). Finally, the average number of floors in buildings is positively correlated with carbon emission intensity across all study units in the main urban area (Figure 4d). From a land use perspective, a higher average number of floors per unit area typically indicates a higher concentration of residential and commercial activities, leading to greater carbon emissions per unit area of land.

(a) Average building shape coefficient

(b) Average building aspect ratio



(c) Building density

(d) Average number of floors

Figure 4 Analysis Results of Spatial Form Factors

(3) Carrying Capacity Factors

Figure 5a shows that floor area ratio (FAR) is positively correlated with carbon emission intensity globally, and most regions show high statistical significance. FAR reflects the total building volume per unit land area, meaning that the higher the FAR, the larger the building area, and the higher the energy consumption and carbon emissions. The regression results for population density in Figure 5b show significant spatial heterogeneity. In the central area of the main urban area, population density is positively correlated with carbon emission intensity, indicating that an increase in population density leads to higher energy consumption and carbon emissions. However, in some peripheral areas of the city, population density shows a negative correlation with carbon emission intensity.

Similarly, the relationship between POI density and carbon emission intensity also exhibits spatial differences (Figure 5c). In the city center, POI density is positively correlated with carbon emission intensity, suggesting that more commercial facilities, service locations, and employment opportunities attract large amounts of human and logistical traffic, thus increasing carbon emissions from land use.

However, in some areas to the west of the Yangtze River, POI density shows a negative correlation with carbon emission intensity, indicating that areas with high POI density might promote more green travel and consumption patterns, thus reducing carbon emission intensity.

Finally, Figure 5d shows that road network density is positively correlated with carbon emission intensity across all study units in the main urban area. Although some studies suggest that high road network density helps reduce traffic congestion and encourages green travel at large scales, in the context of urban land use in this study, a dense road network often leads to higher traffic volumes, which in turn increases traffic-related carbon emissions. This indicates that the impact mechanism of road network density is scale-dependent, and different conclusions may be drawn at different scales.

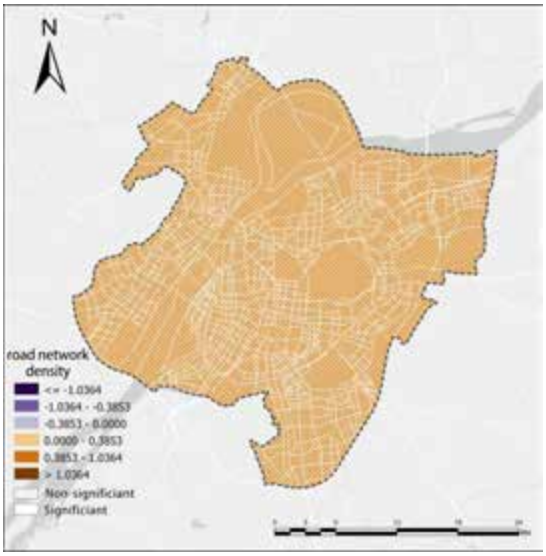

Figure 5 Analysis Results of Carrying Capacity Factors

3.3 Analysis of Factor Interaction Mechanisms Based on Geo-Detector

3.3.1 Analysis of Results from Factor Geo-Detector

This study analyzed the influencing factors of urban land carbon emissions and their explanatory power using Geo-Detector. Geo-Detector provides the explanatory weight (q value) and statistical significance (P value) of each

factor, which are used to assess the contribution of these factors to the spatial distribution of carbon emissions. According to the results (see Table 3), all influencing factors, except for the uniformity index (X6, P value = 0.078), show significant correlations with carbon emission intensity, with P values all less than 0.001. This indicates that most factors can well explain the spatial distribution pattern of carbon emission intensity.

From the q values, it is evident that the carrying capacity factors contribute the most to the spatial variation of carbon emissions. The carrying capacity factors include floor area ratio (FAR), population density, POI density, and road network density. These factors directly reflect the economic, population, traffic, and building load attributes of land units. For example, the q value for population density is 0.407, which means population density can explain 40% of the spatial heterogeneity in carbon emission intensity, making it the most influential factor. The q values for FAR and POI density are 0.340 and 0.343, respectively, indicating that they also play important roles in explaining the spatial distribution of carbon emission intensity. In contrast, the spatial form and functional attribute factors have weaker explanatory power, with generally lower q values.

Table 3: Single-Factor Geo-Detector Analysis Results

Influencing Factor	X1	X2	X3	X4	X5	X6	X7
q value	0.119	0.068	0.084	0.028	0.036	0.009	0.054
P value	0.000	0.000	0.000	0.000	0.000	0.078	0.000
Influencing Factor	**X8**	**X9**	**X10**	**X11**	**X12**	**X13**	**X14**
q value	0.024	0.162	0.113	0.340	0.407	0.343	0.115
P value	0.000	0.000	0.000	0.000	0.000	0.000	0.000

3.3.2 Analysis of Results from Interaction Geo-Detector

Geo-Detector not only analyzes the contribution of individual factors to carbon emission intensity but also explores the interactions between these factors. The interaction Geo-Detector results in Figure 6 show that there are significant interactions between factors, and these interactions generally provide a higher explanatory power for carbon emission intensity than the individual factors alone. In particular, the interaction between population density and POI density has a q value of 0.548, indicating that the combined effect of these two factors can better explain the spatial variation of carbon emission intensity. This result further confirms that population and economic activities are the main sources of carbon emissions in cities, and their interaction amplifies their impact on carbon emissions.

Furthermore, single factors such as the proportion of commercial and public service land, residential land, and industrial and logistics land, when combined with carrying capacity factors (e.g., FAR), show significantly improved explanatory power. For example, the combination of the proportion of commercial and public service land with FAR increases its explanatory power for carbon emissions to 44.87%, while the interaction of industrial and logistics land with FAR explains 36.09% of the carbon emission intensity. These results are much higher than the explanatory power of the factors before the interaction (e.g., the proportion of commercial land at 11.9% and industrial land at 6.84%). This suggests that the influence of functional attribute factors on carbon emissions is not independent but is closely intertwined with factors such as population, economy, and transportation, and thus requires a comprehensive consideration of interactions between these factors.

Overall, among the 91 interaction influence indicators analyzed by the interaction Geo-Detector, 37 show a two-factor enhancement pattern, while the remaining 54 exhibit a non-linear enhancement pattern, accounting for more than 60%. This phenomenon indicates that the spatial distribution of land carbon emission intensity is the result of multiple factors acting together, and the formulation of carbon reduction strategies should consider the combined effects of various factors, rather than the influence of any single factor.

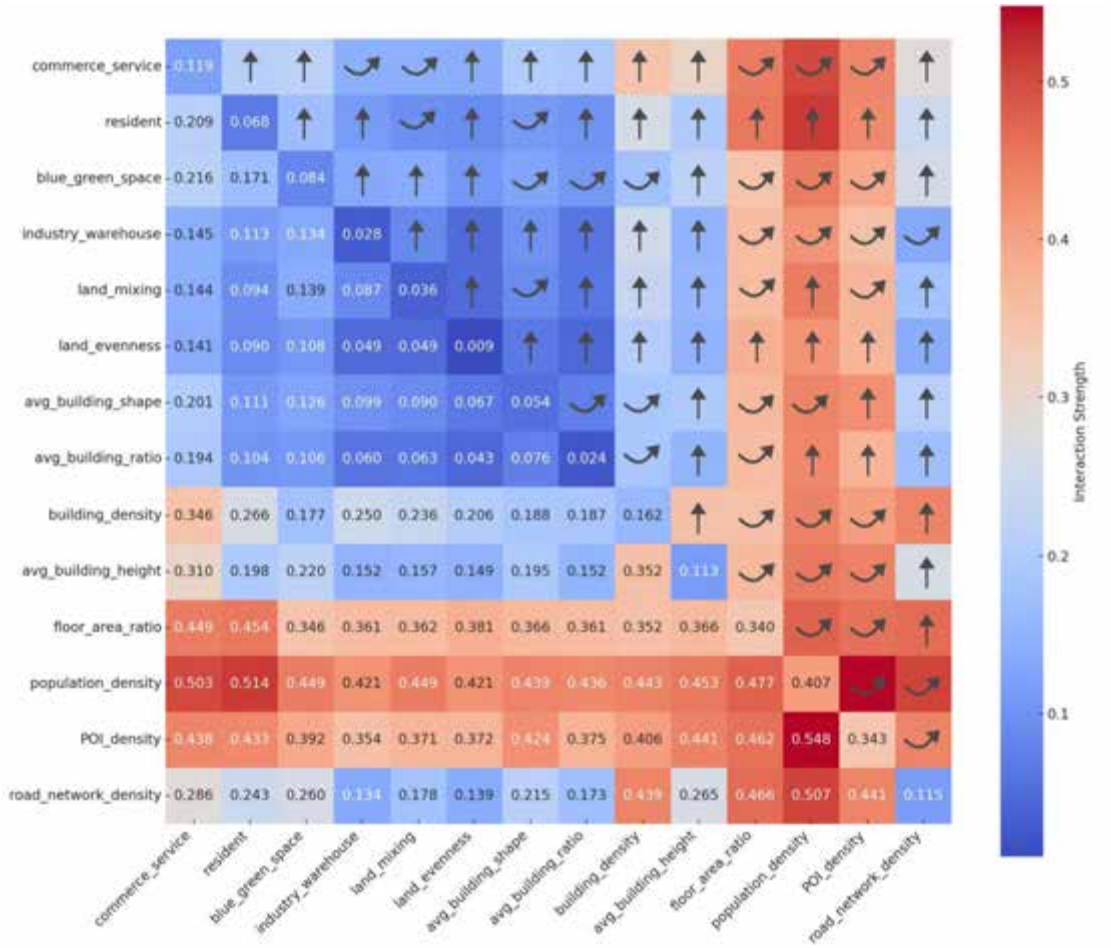

Figure 6 Two-Factor Interaction Strength Detection Results

4. Spatial Micro-Update Scheme Practice under Low-Carbon Guidance

4.1 Site Introduction

The plot selected for the micro-update design in this study is located in the northern part of the study area, within the Liuhe District of Nanjing. The existing buildings on the site are relatively old, with some facades in urgent need of repair. Additionally, there are no sizable green spaces or parks within the site, and public spaces are lacking, indicating a clear demand for urban renewal.

The current situation of the site is illustrated in Figure 7. The land use within the site is primarily residential land , with three commercial areas and some mixed-use commercial and residential land. Except for the high-rise residential area located on the northern side of the site, the remaining residential areas are low-rise (4-6 floors). Additionally, there are sanitation and gas facilities within the site. On the eastern side of the financial and insurance land, there is a section of abandoned railway land, which has lost its practical value. From a land use floor area ratio perspective, except for the high-rise residential area on the northern side (with a floor area ratio of 3.5), the floor area ratio of the remaining land is below 1.6.

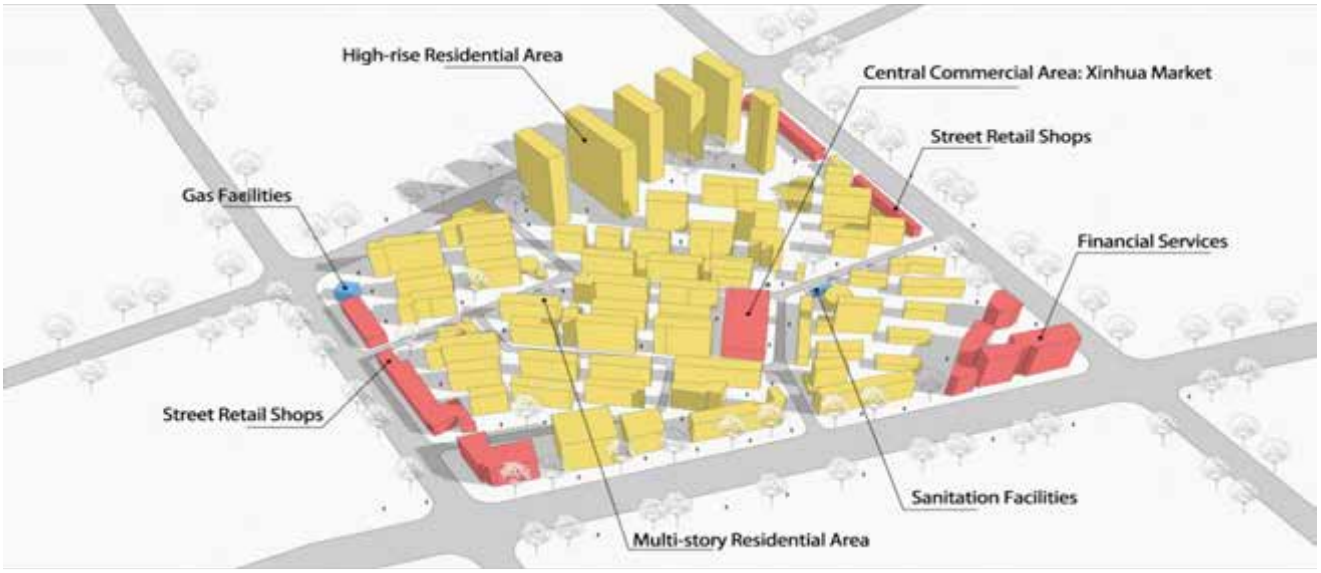

Figure 7 Current Site Situation Diagram

4.2 Micro-Update Scheme

The micro-update scheme proposed in this study focuses on fine-tuning the functional attributes and building forms of urban land plots to achieve a dual enhancement of both low-carbon benefits and environmental quality. Based on the local analysis results of the multi-scale geographically weighted regression model, of the fourteen influencing factors, the proportion of residential land, blue-green space proportion, land use evenness, land use mix, and building density have a negative impact on carbon emission intensity, while the remaining factors show a positive impact. Therefore, the core objective of this scheme is to optimize land use structure and building form, reduce the impact of positive factors, and enhance the negative factors. This will allow for a reduction in carbon emissions and an improvement in environmental quality while maintaining the overall development intensity of the plot.

(1) Fine-Tuning of Land Use Attributes

According to the regression model analysis, carbon emission intensity shows a negative correlation with land use mix, land use evenness, blue-green space proportion, and residential land proportion, and a positive correlation with industrial/logistics land proportion and commercial/public service facilities land proportion. Based on the current situation of the plot and the regression analysis results, the land use attribute adjustments in this scheme mainly include the following aspects:

- Reduce the residential land in the central part of the site from 1.7 hectares to 1.4 hectares. To maintain the land's carrying capacity, the floor area ratio (FAR) of the reduced 1.4-hectare area will be increased from 1.6 to 2.0, ensuring improved land use efficiency.
- Convert the vacated 0.4-hectare residential land into park green space, creating a centralized public space to meet the daily recreational needs of the community (Sun, 2024).
- Transform the abandoned railway land (0.34 hectares) on the eastern side of the site into park green space, constructing a linear park for residents' daily use, providing more green open space.

These fine-tuning measures not only enhance the land use mix and land use evenness but also effectively increase the blue-green space proportion from 0% to 5.05%. While providing public space, these adjustments contribute to a reduction in carbon emission intensity.

(2) Fine-Tuning of Spatial Form

In terms of spatial form adjustments, this scheme maintains the overall spatial structure of the plot while achieving low-carbon effects through localized optimization of building forms. The specific adjustment measures include:

- Break up the long continuous building facades around the site by arranging buildings in a more reasonable layout, thereby reducing the building's aspect ratio and external surface area, which in turn lowers building energy consumption.
- Utilize the existing spatial resources of the site to introduce pocket parks in appropriate locations, providing more green open space for residents.
- Based on the adjusted central park green space and the linear park on the eastern side, design a slow-traffic system running through the site and connect it effectively to the pocket parks, creating a pedestrian-friendly low-carbon commuting environment.
- Implement rooftop greening on some buildings where feasible, increasing green space to further reduce building energy consumption.
- Rebuild buildings that were demolished to make way for park green spaces after adjusting the FAR, to maintain the stability of the total population in the area and avoid socio-economic instability caused by demolition.

These spatial form adjustments make full use of the existing resources within the site, not only optimizing the building layout and improving the quality of public spaces but also creating a suitable walking environment that reduces carbon emissions from transportation. The specific spatial transformation plan is shown in Figure 8.

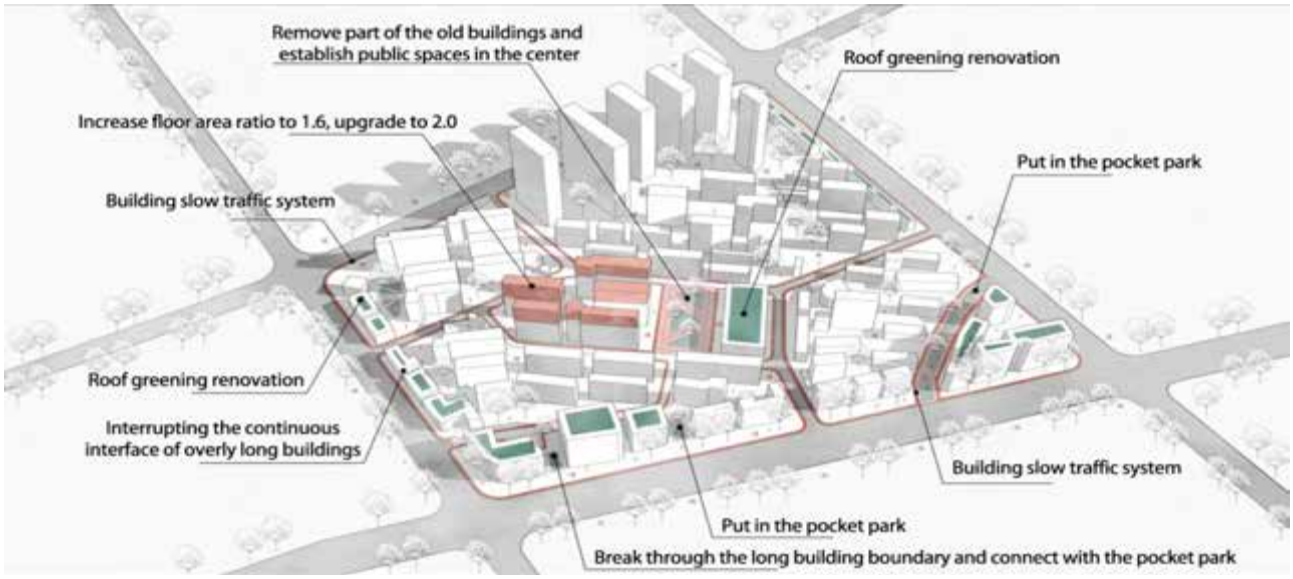

Figure 8 Adjusted Site Situation Diagram

4.3 Low-Carbon Performance Evaluation of the Micro-Update Scheme

The micro-update scheme proposed in this study includes changes in land use type and localized building spatial adjustments, aiming to reduce carbon emissions by optimizing land use and building form. Traditional low-carbon space design studies often focus on qualitative analysis, making it difficult to quantitatively assess the carbon emission performance before and after the design scheme. This study extracts the local regression equations from the multi-scale geographically weighted model for the plot, standardizes the updated influencing factors, and inputs them into the regression model to calculate the carbon emission intensity of the updated plot. This is then compared with the pre-update carbon emission intensity to quantitatively evaluate the low-carbon performance of the micro-update scheme.

According to the comparison results shown in Table 4, the update scheme mainly includes the transformation of residential land into park green space, adjustments in building density, and optimization of floor area ratio (FAR) and land use type. In terms of functional attributes, the proportion of residential land decreased from 70.7% to 68.0%, while the proportion of blue-green space increased from 0% to 5.1%. This change improved the land use mix and evenness, with values rising from 0.801 and 0.499 to 0.947 and 0.590, respectively.

Additionally, the floor area ratio slightly increased from 2.514 to 2.519, but considering the other adjustments, this change contributed little to the reduction in carbon emission intensity.

In terms of spatial form, the building shape coefficient increased from 0.311 to 0.315, indicating a slight increase in the contact area between buildings and the environment, although the change is minimal. The building aspect ratio decreased from 3.624 to 3.207, showing that adjustments to street-facing buildings effectively reduced their external surface area and energy consumption. Building density decreased from 0.233 to 0.221, indicating that appropriately increasing building density in certain areas has a positive effect on controlling carbon emissions.

According to the results from the MGWR regression model, the annual carbon emission intensity of the updated plot is 6.38 kg/m³, which is a reduction of 0.58 kg/m³ (8.38%) compared to the pre-update intensity of 6.96 kg/m³. The total annual carbon emissions for the plot decreased from 1,827.33 tons to 1,674.20 tons, resulting in a reduction of 153 tons of carbon emissions. These results demonstrate that through the optimization of land use attributes and building form in the micro-update scheme, significant carbon emission reduction can be achieved.

Table 4 Comparison of the Micro-Update Scheme Before and After

Variable Type	Variable Name	Effect	Pre-Update	Post-Update	Change
Functional Attributes	Proportion of commercial/ service land	Positive	0.069	0.069	No change
	Proportion of residential land	Negative	0.707	0.680	Decrease
	Proportion of blue-green space	Positive	0.00	0.00	No change
	Proportion of industrial/ logistics land	Negative	0.00	0.051	Increase
	Land use mix index	Negative	0.801	0.947	Increase
	Land use evenness index	Negative	0.499	0.590	Increase
Spatial Form	Average building shape coefficient	Positive	0.311	0.315	Increase
	Average building aspect ratio	Positive	3.624	3.207	Decrease
	Building density	Negative	0.233	0.221	Decrease
	Average number of floors	Positive	10.769	11.361	Increase
Carrying Capacity	Floor area ratio (FAR)	Positive	2.514	2.519	Increase
	Population density	Positive	Assumed unchanged	Assumed unchanged	No change
	POI density	Positive	Assumed unchanged	Assumed unchanged	No change
	Road network density	Positive	0.00	0.016	Increase

5. Discussion and Conclusion

This study thoroughly investigates the spatial distribution characteristics and driving mechanisms of carbon emissions in Nanjing's main urban area. Using multi-scale Geographically Weighted Regression (MGWR) and Geo-Detector models, we analyzed various factors influencing urban land carbon emission intensity and their interactions. The results show that the impacts of functional attributes, spatial form, and carrying capacity on carbon emission intensity exhibit significant spatial heterogeneity. In particular, carrying capacity factors such as population density, floor area ratio (FAR), and POI density contribute the most to carbon emission intensity, with the highest explanatory power.

First, based on the analysis of the three major categories of influencing factors, functional attributes and spatial form factors display significant differentiation. Specifically, different sub-factors do not show uniform characteristics in their mechanisms affecting carbon emission intensity. For instance, factors such as the proportion of commercial and public service land, average number of floors, and FAR have a positive effect on carbon emission intensity in most areas of the main urban region, meaning that an increase in these factors directly leads to a rise in carbon emission intensity. From a low-carbon construction perspective, it is necessary to reasonably limit the upper limits of these factors. On the other hand, factors such as the proportion of residential land, blue-green space, and land use mix generally show a negative effect on carbon emission intensity in most areas, and increasing the proportion of these factors can effectively reduce carbon emission intensity, particularly in urban core areas (Yang, 2023, Sun, 2024).

Furthermore, carrying capacity factors (such as FAR, population density, and POI density) have the highest explanatory power for carbon emission intensity, with the q value for population density being 0.407, indicating the greatest contribution to spatial heterogeneity in carbon emissions. Studies have shown that carrying capacity factors directly reflect the economic, population, traffic, and building load attributes of land units, and are positively correlated with carbon emission intensity (Ming et al., 2024). Based on this, when implementing the micro-update scheme, it is necessary to make targeted adjustments according to the carrying capacity of specific regions.

From the perspective of factor interactions, 60% of the influencing factors show significant synergistic effects, indicating that the spatial distribution of carbon emission intensity in urban land is not determined by a single factor but is the result of multiple interwoven factors. In particular, the interaction between population density and POI density, with a q value of 0.548, shows that their combined effect can better explain the spatial variation of carbon emission intensity. This result further confirms the primary contribution of population and economic activities to carbon emissions (Dong et al., 2023) and suggests that the interaction of these factors amplifies their impact on carbon emissions.

The empirical analysis of the micro-update scheme also validates the above theory. By adjusting land use attributes and optimizing spatial form, the micro-update scheme effectively reduced the carbon emission intensity of the plot. Specifically, through the adjustments in FAR, residential land, and park green space, the carbon emission intensity decreased from 6.96 kg/m^3 to 6.38 kg/m^3, and the total annual carbon emissions decreased by 153 tons, confirming the low-carbon effect of the micro-update strategy in practical application. Additionally, spatial form fine-tuning, such as adjustments in building form and building density, also contributed to reducing carbon emissions, particularly in the adjustments to building aspect ratio and building density, which effectively suppressed carbon emissions.

However, this study also has certain limitations. First, while the MGWR and Geo-Detector models provided a detailed analysis of the influencing factors of carbon emissions, assumptions about the changes in population density and POI density may not fully align with actual conditions. Future research could more precisely simulate the dynamic changes of these factors. Second, although the micro-update scheme has achieved significant reductions in carbon emissions, its comprehensive impact on urban socio-economic benefits, residents' quality of life, and urban sustainability has not been fully explored. Future studies should consider conducting comprehensive evaluations on a broader scale, especially considering the dual context of urban development and residents' needs.

Overall, this study provides a practical basis for low-carbon city construction through the quantitative analysis of the micro-update scheme's low-carbon performance. It demonstrates that optimizing land use attributes, building form, and carrying capacity can effectively reduce carbon emission intensity. The implementation of the micro-update scheme not only improves the environmental quality of the plot but also provides strong support for the realization of low-carbon cities. As low-carbon city construction goals are gradually advanced, the application of the micro-update scheme holds great potential in the renewal of small and medium-sized cities and existing urban blocks. Future work will further explore the comprehensive social, economic, and environmental impacts of the micro-update scheme to ensure the thoroughness and sustainability of low-carbon transformation.

Abstract
Understanding both human and ecological histories in the Anthropocene demands participatory methods that include diverse voices. This research examines community interventions using worldbuilding, which is a systems-thinking approach that imagines alternative realities and challenges existing assumptions through multi-scale analysis using a timeline tool, which is based on Cultural-historical activity theory (CHAT) as an analytical lens to examine chronological triggers in selected case studies.

Through comparative analysis of six case studies (four Belgian, two Turkish), we investigated how participatory design and youth engagement create critical fictions that question current paradigms and explore alternatives for ongoing energy transitions. We examine the role of emotions in transitions, mostly related to energy, and analyze how worldbuilding tools can deepen or change emotional layers related to participatory transition processes. The analysis identifies design strategies where material and embodied elements make speculative practices concrete and generate emotional resonance.

Results demonstrate that worldbuilding serves as an effective participatory methodology for fostering critical dialogue and envisioning just futures rooted in community knowledge while confronting systemic inequalities. The research particularly emphasizes youth agency, often overlooked but vital in shaping these transformative processes.

Keywords: energy transitions; youth; participatory design; worldbuilding; emotions

Introduction: Setting the Context

The Anthropocene shows its presence through "deepening entanglement of human and more-than-human histories," demanding we abandon the comfortable fiction of human separateness. Life reveals itself as fundamentally symbiotic; through symbiogenesis and sympoiesis (Tsing et al. 2017), we discover all organisms "tangled up with each other," bound in "interdependent agential and cognitive systems between humans and non-humans."

In this entangled world, community-based interventions emerge as laboratories of possibility. Through worldbuilding, critical fictions, and speculative design, they make tangible the complex choreographies of more-than-human relationships. These methods enable "worlding", which is a process rooted in "historical materialities of meetings between humans and nonhumans", to create "speculative fabulations" that envision radically different configurations of life.

This work sidesteps the trap of crude anthropomorphism, that peculiar form of human exceptionalism that projects our narratives onto other beings (Chang, 2019). Instead, it cultivates "entirely new modes of attention" attuned to "nonanthropocentric difference" (Haraway, 2016).

Participatory design becomes the vessel for this inquiry, engaging diverse groups, with a specific focus on youth, in reimagining relationships between humans and the more-than-human world. The focus sharpens around critical ecological issues: energy production and consumption, spatial justice, the urgent choreography of ongoing energy transitions.

Critical fictions emerge as potent participatory tools, closely allied with speculative design and design fiction. They harness imaginative thinking to explore potential futures, challenge assumptions, and foster creative problem-solving within energy transitions' complex terrain.

Rather than seeking immediate answers, they use design as a medium for asking deeper questions, creating "what-if scenarios" and "parallel worlds" that probe established values and transcend perceived limitations.

To analyze these interventions, we employ worldbuilding as a theoretical lens, conducting comparative case studies across six community-based interventions in Belgium and Turkey, based on a selection chosen to span grassroots to municipal engagements across different socio-cultural contexts.

A timeline methodology, developed by Devisch (2018) through Cultural-Historical Activity Theory (CHAT) as popularized by Engeström (1987), reconstructs the chronological progression of selected interventions. We map key stages, durations, and critical 'tipping points,' tracing how temporal dynamics shape participants' emotional landscapes and reveal tacit knowledge.

While digital worldbuilding offers powerful lenses for exploring complex systems, our case studies reveal the irreplaceable value of diverse modalities, including non-digital approaches. Analogue, tangible methods prove essential for accessing "knowledge from below," vital for pursuing "radical just futures". It helps in grounding speculative practices in lived realities and ensuring participation beyond digital access or literacy.

Yet something else moves through these participatory spaces; something that resists measurement but shapes everything: the emotional landscapes that emerge when people gather to imagine otherwise. Emotions don't simply accompany worldbuilding; they become its hidden architecture, the invisible scaffolding upon which speculative futures are constructed. A teenager's sudden silence when confronted with climatic disasters, the collective exhale when a group finally names their shared fear, the spark of recognition when someone else's story mirrors your own; these affective moments create the conditions within which new worlds become thinkable.

Our inquiry turns toward these emotional currents, asking how worldbuilding practices don't just engage the mind but activate the full spectrum of human feeling. We begin to notice how certain design strategies trigger emotional responses that either open pathways to collective imagination or close them down, how the materiality creates different affective textures than digital interfaces, and how the temporal rhythms of participatory processes create their own emotional weather systems. The timeline tool becomes not just a method for tracking chronological events, but a way of tracing the emotional geographies that develop as communities move together through speculative territories.

Through this mosaic of worldbuilding lens, temporal analysis, emotional attunement, and diverse engagement modalities, the study seeks novel perspectives on energy systems and spatial justice. It aims toward a framework for co-designing critical fictions in participatory processes with youth: a methodology for imagining otherwise that honors both the rational and the felt dimensions of planetary entanglement.

2. Literature Review

2.1. When Design Becomes Speculation

In the spaces between what is and what could be, speculative design emerges as both methodology and attitude; a way of thinking that refuses the constraints of immediate needs and market demands. These approaches harness imaginative thinking to explore alternative futures, challenge assumptions, and foster creative problem-solving, particularly within energy transitions' intricate choreographies.

Speculative design operates not as pragmatic problem-solving but as a framework for speculating about potential realities, examining broader implications of current trends and proposed solutions (Auger, 2013). It uses design as medium, focusing on concepts and artifacts to ask questions rather than provide immediate answers (Mitrovic et al., 2013). The overlapping territories of Critical Design and Design Fiction share this remove from commercial constraints, employing models, prototypes, and fiction to present alternative products, systems, or worlds (Auger, 2013).

Within this landscape, practitioners distinguish between exploring speculative futures (extrapolations of contemporary systems) and designing alternative presents that reconfigure existing elements, motivations, and structures.

The most poignant speculations stay close to the present, creating "perceptual bridges" between audience's world and fictional concept through the mundane and familiar (Auger, 2013).

Critical fictions weave themselves into this fabric through deliberate creation of "what-if scenarios" and "parallel worlds"; potent instruments for exploring ramifications and challenging established values. These hypothetical situations provoke deeper thinking, encouraging stakeholders to transcend perceived limitations. When someone imagines a "Positive Energy Neighbourhood," they enter a low-stakes, imaginative space where energy transition strategies can unfold their possibilities and reveal their shadows.

2.2. The Architecture of Other Worlds

Worldbuilding emerges as the key mechanism through which speculative design and critical fictions operate; the deliberate construction of fictional settings that embody speculative ideas. From visual arts like murals to digital game art, performance scenography, and participatory design, worldbuilding makes alternative worlds visible and tangible.

This methodology draws from phenomenology's philosophies of experience and pragmatism's emphasis on praxis, informed by cybernetics and imagism. In participatory contexts, it involves collaboratively creating and playing "design language-games" (Ehn, 2017) that bridge different perspectives and practices. Worldbuilding links to creating "alternative nows"; tangible, present-day examples of different realities (Hickey et al., 2012), while challenging purely linear views of time.

The craft of new worlds involves imagining assemblages otherwise, recognizing the world's entangled state where opportunities emerge from exchange rather than imposed expectations (Mitrovic et al., 2021). In gaming contexts, worldbuilding becomes continual cross-disciplinary process involving narrative, gameplay, art, programming, and audio, with intentional gaps inviting audience imagination and co-authoring (Tremblay, 2023). These practices gain deeper resonance when explicitly incorporating systems thinking frameworks (Betley et al., 2021). Worldbuilding "depends on systems thinking" (Bucknell, 2025), offering holistic approaches to understanding "multi-scalar relationships and entanglements" within complex systems. Systems thinking moves beyond discrete parts to examine dynamic interactions, patterns, and underlying causes: particularly through leverage points where interventions prove most effective.

Donella Meadows' work reveals that deeper leverage points at changing system goals or underlying paradigms have far greater potential for lasting change than interventions targeting parameters or buffers (Betley et al., 2021). Critical fictions and worldbuilding function precisely to challenge these deeper points, intervening at the level of mental models—deeply held abstractions, beliefs, and assumptions that drive system function and limit perception of possibility.

The participatory nature of community-based interventions aligns with systems thinking's critical dimension, asking: "Who has power?" "Who is defining the system?" "Whose knowledge counts?" Deep community engagement reveals "subjugated knowledges" and "friction points" symptomatic of deeper systemic barriers (Betley et al., 2021).

The "Emissary" concept (Cheng, 2018) suggests that successful worldbuilding interventions require governance functions to ensure long-term health and growth, reconciling speculation with reality through "Containers", finite projects that act as portals implying further consequences. This function sustains "potential for aliveness" beyond temporary engagement.

2.3. The Emotional Weather of Imagined Futures

Yet something else moves through these speculative territories: the emotional landscapes that emerge when communities gather to imagine otherwise. Beyond cognitive tools for critical thinking, these interventions engage with affect and emotion as "hardwired, shifty and unsteady but palpable" forces more "directly compelling than ideologies" and "fractious, multiplicitous, and unpredictable than symbolic meanings" (Barthes, 1970).

Ordinary affects draw attention to "forces that come into view as habit or shock, resonance or impact" (Stewart, 2007), highlighting "intimate impacts of forces in circulation" and prompting reflection on what one truly cares about (Cheng, 2018). Emotions intertwine with power relations and form social norms (Zembylas et al., 2012); disrupting these norms necessitates changing associated emotions.

Narrative and worldbuilding prove particularly potent here, as story provides "direct route to our emotions" and thus becomes "important to decision-making" (Saltmarche, 2018). Storytelling "creates meaning out of patterns," "coheres communities," and "engenders empathy across difference," making possible feel probable in ways purely rational approaches might not. Emotional events are remembered more clearly, accurately, and for longer periods than neutral events (Tyng et al., 2017), suggesting emotionally resonant narratives significantly enhance impact and retention of envisioned futures.

Critical fictions, by making "alternative possibilities visible or tangible," possess significant potential to cultivate empathy: not only toward other people but crucially toward the more-than-human world implicated in energy transitions. This capacity to foster emotional resonance makes abstract realities more tangible and personally relevant, "expanding our circle of concern" through sympathy and care (Roeser et al., 2016).

The spatial and environmental dimensions of worldbuilding interventions interweave deeply with affect. Emotional space is defined by experiences it affords, aesthetic feelings it inspires, and memories it evokes (Ryan et al., 2016). Even movement through space elicits strong feelings—from "sense of freedom" to "disorientation" of being lost. By designing or reimagining spaces within narrative storyworlds, interventions directly engage participants' emotional responses to environment and potential future states.

The unfolding timeline of participatory processes itself acts as powerful mechanism for revealing and shaping emotional landscapes. As interventions encounter real-world complexities, critical moments or 'tipping points' elicit strong emotional responses offering insights into participants' "underlying concerns, hopes, and anxieties related to energy transitions." These responses reveal tacit knowledge, namely the practical understanding and lived experiences, that might remain hidden in purely hypothetical discussions.

While urgency of climate change and energy transition can generate anxiety, particularly for youth, critical fictions and worldbuilding offer facilitated spaces to explore these feelings within imagined scenarios. Hope, understood as "sense of the possible" that prevents being "overcome by the absoluteness of the present" (Ahmed, 2004), becomes emotional counterpart to fear. Cultivating hope through speculative methods can actively reshape participants' orientation toward future, potentially expanding capacity for action.

2.4. Knowledge from Below

Threading through these practices runs a deeper current: the recognition that effectively navigating energy transitions and pursuing spatial justice requires moving beyond conventional, expert-driven approaches to knowledge production. This involves recognizing "subjugated knowledges" (Halberstam, 2011), forms of knowledge "buried or masked in functional coherences" or "disqualified" as "naïve knowledges, hierarchically inferior knowledges."

Community-based interventions employing speculative design, critical fictions, and worldbuilding offer potent methodologies for accessing, validating, and elevating these subjugated knowledges. Unlike traditional approaches that might "disqualify" non-expert perspectives, creative and narrative-based methods create spaces where lived experiences, local understandings, and non-conventional insights can emerge and integrate into envisioning alternative futures.

This becomes inherently antidisciplinary practice, challenging rigid boundaries and hierarchical structures of established disciplines. Antidisciplinarity resists "mastery" and embraces less conventional ways of knowing, including what might be considered "naïve" or "nonsensical" (Khan, 2021), recognizing these perspectives can offer valuable insights outside dominant frameworks.

The very act of worldbuilding can be seen as "knowledge from below" (Halberstam, 2011), allowing participants to articulate understandings, desires, and concerns through creative expression rather than prescribed technical language. By constructing "microworlds" and speculative scenarios, interventions enable participants to draw on practical knowledge and critique existing systems from lived perspectives. This aligns with "seeing unlike a state" (Halberstam, 2011), contrasting with the state's preference for "legibility," order, and standardization.

Embracing potential "illegibility" and messiness of knowledge derived from diverse community experiences becomes powerful resistance to top-down impositions and source of genuinely innovative solutions. Integrating diverse perspectives: poets collaborating with scientists, bringing together different realms of discourse within "polyvocal" spaces (Wark, 2015); embodies this antidisciplinary spirit, creating conditions where multiple ways of knowing can cross-pollinate and generate new possibilities for collective futures.

3. Methodology: Comparative Case Study through the 'Timeline Tool'

In the tangled web of participatory worldbuilding, emotions don't simply appear. They emerge through a choreography of encounters, materials, and moments that resist easy categorization. To trace these affective currents, we turned to the timeline tool developed by Devisch (2018), itself rooted in the ground of Cultural-Historical Activity Theory (CHAT), as popularized by Engeström (1987). This was an analytical lens that could reveal not just what happened, but how feeling moved through spaces of collective imagination.

The timeline tool becomes more than methodology; it transforms into a practice of archaeological attention, excavating the sedimentary layers of emotional response that accumulate around participatory encounters. Each project timeline unfolds as a sequence of tipping points and triggers, revealing the precise moments when participants' inner landscapes shifted, when new possibilities crystallized, or when resistance hardened into protective withdrawal.

Reconstructing these timelines as sequences of tipping points and triggers provides crucial insights that might otherwise remain buried beneath the surface narratives of project success or failure. We began to notice how certain moments acted as emotional lightning rods, drawing and redirecting the collective energy of worldbuilding processes. The methodology allowed us to pinpoint potential triggers for emotional responses among participants, whose seemingly small gestures or design choices that created ripples across entire groups. These emotional landscapes develop their own topography over the course of interventions, forming peaks of excitement, valleys of frustration, and unexpected clearings where new understanding emerges. By mapping these terrains, we could begin to see patterns in how feelings flow through participatory spaces, how they pool around certain activities, and how they create the affective conditions that either nourish or constrain collective imagination.

Our research questions emerged as interconnected patches in a larger tapestry: What role do emotions play in worldbuilding practices? How does worldbuilding itself become a method for designing with emotions? Our aim crystallized around identifying specific design practices that trigger emotional responses; those moments of methodology that open or close pathways to collective futures.

The analysis unfolded through four interwoven dimensions:

- **Triggers and Emotions**: We traced the delicate choreography between events and feelings, asking what specific moments, materials, or encounters catalyzed emotional responses. Sometimes it was the collages based on historical photo archives during a material speculation exercise; other times, the sudden recognition of one's own story reflected in another participant's vision of the future.

- **Actors and Emotions**: The emotional landscape revealed itself as deeply relational. We mapped not only who experienced emotions, but who triggered them. Youth participants often emerged as unexpected emotional catalysts, their unguarded responses creating permission for adults to access their own vulnerability. Facilitators, too, became emotional actors, their own affective states rippling through group dynamics in ways that shaped entire sessions.

- **Tools and Strategies**: We examined which design strategies generated the most profound emotional resonances. Material practices (e.g. working with found objects) often created embodied pathways to feeling that bypassed rational defenses. Storytelling circles generated different emotional textures than mapping exercises, each tool carrying its own affective potential.

- **Responses and Consequences**: Perhaps most revealing was tracing what emotions triggered in return: moments of breakthrough that led to deeper engagement, or emotional overload that caused participants to withdraw, stand still, or leave entirely. These responses became their own triggers, creating feedback loops that either amplified collective energy or dampened it into protective silence.

From this analysis, we selected design strategies that demonstrated particular potency in generating emotional resonance, illustrating each through the voices of participants themselves. These quotes became more than evidence and became more a series of small windows into the lived experience of worldbuilding, revealing how abstract methodologies translate into the messy reality of collective imagination.

Each selected strategy was chosen not for its representativeness, but for its ability to reveal something unexpected about the relationship between design, emotion, and worldbuilding. In doing so, it hopes that the methodology transcends technique and becomes a practice of collective sensing into possible futures.

4. Comparative Analysis: Worldbuilding and Emotion Across Six Case Studies

What emerges when communities gather to imagine energy otherwise? In the spaces between Brussels' social housing blocks and the broader landscapes of Belgian neighborhoods, between Turkish contexts yet to be fully mapped and European regulatory frameworks, we begin to notice the delicate choreographies through which collective futures take shape. Each intervention carries its own emotional weather, its particular rhythms of hope and frustration, its unique ways of making the impossible suddenly thinkable.

The timeline tool becomes our method of attention: a way of noticing not just what happened, but how feeling moved through these participatory territories. Following Devisch's framework grounded in Cultural-Historical Activity Theory (CHAT) as popularized by Engeström (1987), we reconstruct these interventions as sequences of tipping points and triggers, moments when the emotional landscape shifted, when new possibilities crystallized or dissolved into disappointment.

Six case studies offer themselves as patches in a larger mosaic: four Belgian interventions and two Turkish explorations, each carrying different textures of engagement, different relationships between individual aspiration and collective possibility. Through the analytical lens of triggers and emotions, actors and affects, tools and their consequences, we begin to trace the often-invisible infrastructure of feeling that either nourishes or constrains the emergence of energy alternatives.

Table 1 maps these emotional geographies across selected cases, revealing patterns that resist simple categorization. Notice how *triggers* often emerge not from grand revelations but from quiet realizations, such as the dawning recognition that house-by-house renovation cannot meet climate goals, the slow understanding that traditional energy systems systematically exclude the marginalized. These moments of collective noticing become catalysts for different ways of organizing attention and action.

The *actors* column reveals the complex webs of relationship that either enable or constrain transformation: residents and municipalities, design firms and energy communities, technical experts and neighborhood cooperatives finding themselves in new configurations of possibility. Yet the table also hints at who remains absent, whose voices echo through the margins of these documented interventions.

Tools emerge not as neutral instruments but as specific ways of materializing speculation; from info display panels that make energy visible to workshops that transform everyday objects into vessels for collective dreaming. Each tool carries its own affordances for emotional resonance, its particular capacity to generate either excitement or exclusion.

The *results* column captures something more elusive, in the ways these interventions ripple outward into broader systems of feeling and knowing. Some foster hope and collective agency; others reveal the brutal friction between vision and implementation, generating frustration when co-designed futures encounter regulatory barriers and bureaucratic resistance.

Across these cases, certain patterns begin to emerge from the intersection of worldbuilding and emotion. The most powerful triggers often arise from moments of structural revelation, like when participants suddenly see the systemic nature of problems they had experienced as individual failures. The shift from "how to install solar panels" to questions of "who controls energy, who benefits, and who gets left out" marks a tipping point where technical problems become political possibilities.

The tools that generate the deepest emotional resonance tend to be those that make abstract systems tangible and relational. Display panels don't just show energy data; they create new forms of collective attention. Workshops don't just transfer knowledge; they become spaces where residents can touch and reshape the material conditions of their daily lives.

Yet **Table 1** also reveals the precarious nature of these emotional transformations. The same interventions that foster hope can trigger profound frustration when systemic barriers prevent the implementation of collectively envisioned futures. The gap between participatory imagination and institutional possibility becomes a site of intense affective charge; sometimes generative, sometimes devastating.

As we prepare to expand this analysis across all six cases, including the Turkish contexts that will bring different cultural and institutional textures to our understanding, we begin to notice questions that demand further attention: How do different regulatory environments shape the emotional possibilities of participatory worldbuilding? What happens to collective agency when it encounters the stubborn materialities of existing infrastructure? How do the temporal rhythms of institutional change interact with the more urgent temporalities of climate crisis and community need?

Table 1 becomes not just a record of what happened, but a map of how feeling moves through spaces of collective imagination, or a guide to the emotional infrastructure that either enables or constrains the emergence of energy futures we can believe in.

Table 2 that follows becomes a different kind of listening practice. Where the first focused on external choreographies (triggers and (worldbuilding) tools, actors and outcomes) this one turns inward toward the felt experience of worldbuilding itself. Here we encounter not just what happened, but how it *felt* to happen, how the possibility of energy alternatives registered in bodies and voices, in the spaces between what people said and what they couldn't quite articulate.

Notice how **Potential Emotional Dimensions** invites us to attend to the full spectrum of feeling that participatory futures-making can generate; not just the celebrated emotions of empowerment and collective agency, but also the more difficult textures of overwhelm, confusion, and the grief that comes with recognizing how much needs to change. These dimensions remind us that transformation is never purely celebratory; it carries its own shadows and complications.

The **Emotional Triggers** column returns us to those crucial moments when feelings shifted. But now, through the lens of lived experience rather than analytical observation. Here we might encounter the precise moment when a resident realized their voice actually mattered in technical decisions, or the instant when bureaucratic obstacles transformed collective excitement into bitter disappointment.

Quotes from Interviews become our most direct access to these interior landscapes. The actual words (hesitant, passionate, contradictory) carry affective information. They reveal the ways that transformation sounds when filtered through individual experience yet shaped by collective encounter.

Together, these columns create a more intimate geography of energy transition: one that acknowledges both the political dimensions of systemic change and the deeply personal ways that such change registers in the daily lives of those bold enough to participate in its unfolding. They prepare us to notice not just how worldbuilding happens, but how it feels to build worlds together, and what those feelings might teach us about the conditions that either nourish or constrain the emergence of livable futures.

5. Discussion

Listen closely to the resident from oPEN Lab, speaking about the heat pump that brings migraines alongside promised efficiency: *"It is very annoying when it makes this sound. That is my biggest problem. There is no solution for that."* In these words, we encounter something that technical reports rarely capture—the way transformation sounds in a body, the way progress can become a persistent ache that follows you through your daily routines. This complaint echoes across our comparative landscape, revealing patterns that resist the clean narratives of participatory success. The Architecture Workroom's collaborative visions bump against regulatory barriers; La Pile's energy-sharing dreams encounter the stubborn realities of landlord-tenant relations; the Turkish children's spatial insights confront mega-city pressures that dwarf their small voices. Each case carries its own frequency of friction, its particular rhythm of hope meeting constraint.

Yet notice what else emerges from these same spaces of difficulty. Sofie van Bruystegem's declaration: *"We believe in 'Can do', the joy of trying something"*, which tells that it arrives not despite the frustrations but through them. The Turkish children, despite growing up under the pressure of surrounding mega-projects, develop what Yaşar Adnan Adanalı observes as the perception that is "very clear" and awareness that is "highly developed." The young people at Architecture for All move from timidity to what the Yeşil Gazete (Green Gazette) describes as "a sense of hostility that comes from being the user of that place"; a transformation that sounds less like conventional empowerment and more like the cultivation of productive anger.

The most striking pattern across our cases involves the emergence of what we might call *emotional infrastructures*; the often-invisible networks of feeling that either enable or constrain collective worldbuilding. In La Pile, the monthly newsletters about solar production become more than information transfer; they create new rhythms of collective attention, ways of belonging to energy that had never existed before. The display panel made by residents doesn't just visualize consumption; it materializes a different relationship to power itself.

But these same infrastructures reveal their fragility when they encounter larger systems. The Brussels resident who notes that "the solar panels are from us, but the state uses this energy for itself" identifies a crucial disjuncture—the gap between participatory imagination and institutional capture. The energy belongs to the community in emotional and creative terms, yet remains trapped within regulatory frameworks that extract value elsewhere.

This tension appears differently across contexts. In Genk, the Transisthor mural creates what participants describe as aesthetic appreciation and emotional significance, yet a strategic manager in energy observes that "a lot of people don't know what it is there." The boundary object succeeds at generating conversation among those already engaged while remaining mysteriously invisible to others moving through the same neighborhood. The archive of mining history speaks powerfully to young people who feel connection with the former mining district, yet fails to translate into broader community recognition.

Perhaps the most complex emotional territory involves the relationship between local transformation and systemic change. Across our cases, participants develop profound attachments to small-scale possibilities, where the workshop where Turkish and Syrian children "have taken ownership of this space," the Genk resident who declares gratitude for gaining "a brand new house," the collaborative energy community that enables new forms of collective agency.

Yet these same attachments become sites of particular vulnerability when they encounter the temporal rhythms of institutional change. The Brupower representative's frustration about projects that "stay very local" while lacking pathways to regional scaling captures something essential about the emotional costs of participatory worldbuilding. The very intimacy that makes these interventions meaningful also constrains their capacity to address the systemic dimensions of the problems they engage.

Notice, however, how different cases navigate this choreography of scale differently. The Center for Spatial Justice's documentary approach creates a form of scaling that moves through representation rather than replication, in which the 95cm perspective travels as a method rather than an institution, creating possibilities for recognition across different contexts without requiring identical implementation.

The Architecture Workroom's network approach attempts a different form of scaling; creating connections between local experiments while maintaining their contextual specificity. Yet here too we encounter the emotional friction between vision and implementation, the frustration that emerges when "co-designed visions cannot be practically realised due to external systemic barriers."

The interviews reveal emotional territories that extend far beyond the celebratory narratives often associated with participatory design. DBV Architecten representative's observation about the first test house being "unoccupied and minimally furnished" points toward a crucial gap. Namely, the difference between technical prototypes and the complex realities of inhabited space. When the same techniques encounter "the techniques inside the homes," they generate frustration that might have been avoided through different forms of attention to the social dimensions of technical change.

The Turkish contexts bring additional layers of complexity. The Architecture for All workshops navigate language barriers and cultural differences that create initial timidity, yet this same friction becomes generative when children begin to "become aware of their rights" and develop "information ranging from working conditions to how children feel about working." The emotional trajectory moves through discomfort toward forms of empowerment that couldn't emerge without first encountering difference.

These patterns suggest that the most meaningful transformations often occur not through the smooth implementation of pre-designed interventions, but through the creative navigation of friction itself. The heat pump that causes migraines also provides warmth; the regulatory barriers that constrain energy sharing also reveal the political dimensions of technical choices; the language differences that create initial timidity also enable new forms of cross-cultural solidarity.

One of the most subtle yet significant patterns involves the different temporal rhythms of emotional engagement and institutional change. Participants often develop strong attachments to possibilities within relatively short timeframes; the workshops that generate excitement and creativity, the collaborative design processes that foster hope and collective agency. Yet the implementation of these visions often requires navigating bureaucratic processes that operate on entirely different temporal scales.

This temporal mismatch creates particular emotional challenges. The Architecture Workroom participants who develop integrated neighborhood visions may experience "significant frustration and disillusionment" when external barriers prevent realization. The OPEN Lab residents who expected smooth renovations encountered delays that "brought frustration" and "created mistrust."

Yet some interventions find ways to work creatively with these temporal disjunctures. La Pile's approach of making "structural exclusions visible" rather than offering "scalable technical fixes" creates value that doesn't depend on immediate implementation. The project succeeds by shifting conversations rather than installing technologies, creating emotional and intellectual resources that can persist even when regulatory barriers constrain immediate action.

As we step back from these six patches of engagement, certain meta-patterns begin to emerge about the relationship between emotion and transformation. The most resilient interventions seem to be those that cultivate what we might call livable complexity. These are approaches that can hold both the joy of collective imagination and the frustration of systemic constraint, both the excitement of local possibility and the overwhelm of broader challenges.

This capacity for emotional complexity appears most clearly in cases that avoid simple narratives of either success or failure. La Pile's recognition that "real transition is relational, spatial, and political" creates space for ongoing engagement even when technical solutions remain elusive. The Turkish children's clear perception of

spatial problems becomes valuable regardless of their immediate capacity to reshape urban planning processes. The Architecture Workroom's emphasis on long-term institutionalization points toward approaches that can sustain engagement across the temporal rhythms of both emotional attachment and systemic change. Rather than treating participatory processes as discrete interventions, these approaches create ongoing relationships that can evolve as circumstances shift.

6. Conclusion

What emerges from this comparative analysis is less a set of worldbuilding tools than an ecology of transformation. In other words, a recognition that meaningful change occurs through complex interactions between technical possibilities, social relationships, institutional constraints, and emotional infrastructures. The cases that generate the most sustainable engagement are those that attend carefully to all these dimensions rather than privileging any single aspect.

The emotional geographies revealed through our analysis suggest several crucial insights for future worldbuilding efforts:

- **Friction as Strength**: Rather than obstacles to overcome, the frictions between vision and implementation, between local attachment and systemic change, between different cultural contexts and temporal rhythms, often become the most generative sites for learning and adaptation. The heat pump that causes migraines teaches us something about the social dimensions of technical transition that smooth implementation might never reveal.

- **Infrastructures of Feeling**: The most powerful interventions create what we might call emotional infrastructures. In these ongoing relationships, rhythms of attention and forms of collective meaning-making can persist across changing circumstances. These infrastructures often prove more valuable than specific technical implementations, creating resources for continued engagement even when immediate goals remain unrealized.

- **Scaling Through Empowerment**: Rather than replicating successful interventions, the most effective forms of scaling seem to occur through the circulation of methods, perspectives, and forms of attention that can be adapted to different contexts. The 95cm perspective travels as a way of seeing rather than a specific intervention, creating possibilities for recognition across different urban contexts.

- **Temporal Complexity**: Meaningful transformation requires attending to multiple temporal rhythms simultaneously, where the immediate experience of participation, the medium-term processes of technical implementation, and the longer-term trajectories of systemic change are involved. Interventions that can create value across these different temporal scales prove more resilient than those dependent on immediate technical success.

- **Polyvocal Engagement**: The richest interventions seem to be those that can hold multiple voices and perspectives simultaneously, creating space for both excitement and frustration, both hope and criticism, both local attachment and systemic analysis. This polyvocal capacity enables continued engagement even when participants hold different relationships to the same processes.

Perhaps most significantly, our analysis suggests that the emotional dimensions of participatory worldbuilding are not peripheral to technical and political concerns but constitute the very medium through which transformation becomes possible. The feelings that move through these spaces (i.e., hope and frustration, belonging and exclusion, excitement and overwhelm) don't simply accompany change but actively constitute the conditions under which different futures become thinkable and livable.

As we face the urgent challenges of energy transition and climate change, attending to these emotional geographies becomes not a luxury but a necessity. The futures we need require not just technical innovation and policy change but the cultivation of emotional infrastructures that can sustain engagement with complexity, nurture resilience in the face of setback, and generate the forms of collective imagination necessary for systemic transformation.

The voices captured in our interviews with residents dealing with heat pump noise, with children perceiving spatial injustice, with activists navigating bureaucratic barriers; remind us that transformation is always also a matter of feeling, of the particular ways that change registers in bodies and communities and daily life. Learning

to listen to these voices, to notice the emotional territories they reveal, becomes an essential skill for anyone committed to building worlds we can actually live in.

Figures and Tables:

Table 1: Comparative Analysis of six cases

Case Study	Activity	Trigger	Actors	(Worldbuilding) Tools	Result
Architecture Workroom Brussels (BE)	An initiative designed to accelerate the energy transition at the neighborhood level through collective action and integrated strategies. Recognizing that current renovations are insufficient to meet the ambitious goal of renovating 95,000 homes annually by 2050, the project advocates for a collaborative approach that is more cost-effective and inclusive. Aiming to translate collaboratively developed neighbourhood action plans into tangible interventions and bridge the implementation gap.	-A critical realization emerged that the prevalent house-by-house renovation approach was insufficient to meet the ambitious climate goals. This showed the need for a more collective strategy, a shift towards a neighborhood-wide energy transition model. -The project emphasized the importance of involving a diverse range of stakeholders, while leaving out the focus on isolated experiments. Including local authorities, addressing technical, social, and policy dimensions. -The need for integrated future steps is underlined. The importance of institutionalizing these processes. -Following up after the projects are completed with periodically arranged public programs is a means of building trust with the communities.	Local municipalities, Flemish Region, EU,VITO, KU Leuven, design firms, Residents, neighbourhood groups, cooperatives, 100 Neighbourhoods, Open Workroom network	-Small exhibition. **(Figure 1)** -Public programme, which consist of A series of workshops and debates invited stakeholders to collaborate on integrated neighborhood approaches. -Open workrooms, in which the project opened its doors to support cities, experts, designers, businesses, and policymakers working on strategic transformations, including energy neighborhoods, sponge landscapes, and societal infrastructure. Each track featured a public programme and a small exhibition contributing to a broader transformation.	Shaping systemic change at a local level. Likely fostered hope and a sense of collective agency. Could trigger significant frustration and disillusionment among participants if co-designed visions cannot be practically realised due to external systemic barriers like regulations, bureaucracy, or funding.
La Pile (BE)	Collective envisioning and subsequent implementation of a localised and equitable energy-sharing system within a social housing block (SunSud project). Developing pertinent and equitable solutions through profound community engagement and co-creation.	-Traditional energy systems often exclude marginalized communities, particularly social tenants. This realization prompted a shift towards creating inclusive, community-driven energy solutions. -The establishment of the Pilone energy community marked a milestone. It served as an example of collective energy ownership and management. -The complexities of energy sharing regulations and technical infrastructure highlighted the need for collaborative problem-solving.	City Mine(d), Residents from Brussels' Midi and North neighborhoods, Energie Commune, Pilone Energy Community, Remorque Réno, Technical and Legal Experts	-Residents participated in free workshops focusing on artefacts about energy, design, electronics, and fabrication. -Info display panel to visualize the building's solar energy production and consumption, made by residents. **(Figure 2)** -Monthly newsletters about solar production levels and individual consumption.	SunSud did not offer a scalable technical fix, but rather a provocation: it made the structural exclusions of the energy transition visible. In doing so, it shifted the conversation from "how to install solar panels" to who controls energy, who benefits, and who gets left out. It showed that real transition is relational, spatial, and political.

oPEN Lab (BE)	Renovation of houses into energy-positive buildings in Nieuw Texas. **(Figure 3)** Developing a "technological playground" vision for a neighbourhood. Gathering data on inner climate, energy consumption, and installation performance.The project by DBV Architecten is using prefab timber systems, BIM modeling, **and** Lean planning to test and implement scalable, low-disruption upgrades in a real-world living lab setting.	-Adoption of prefab system (HSB) -Use of BIM modeling -First test house, as it was a prototype, didn't reflect the possible social outcomes. -Residents not foreseeing the end results.	Residents, who experienced disruptions and provided tacit knowledge. Participants in imaginative activities. Architects. Other local NGO members, such as STEBO, WIL, GIGOS, Luca School of Arts	-Co-authored socio-spatial story shaped by logistics, human agency, and infrastructural constraint. -Simulated futures and engineering scripts that anticipate and pre-structure the spatial world. -Worldbuilding in the present tense: rather than modeling utopian futures, the project builds on top of and within the lived complexities of Genk's housing realities. -Incorporating specific activities like the "Wishing Lab" and postcard prompts to encourage imaginative thinking about desired energy futures.	-Established method for minimal disruption renovations Enabled digital prototyping and coordination, however caused delays in process which brought frustration. Exposed real-time technical and social challenges Created mistrust towards WIL and accelerated the feelings of unfairness.
Transisthor (BE)	Artistic and technological creation of speculative narratives about energy futures on a public mural. **(Figure 4)** Collaborative creation of a public mural integrating historical archives and AI-generated future imaginaries.	-Transisthor project uses art printed on solar panels as both an aesthetic and functional medium to engage and activate the community around sustainable energy, with participatory moments serving as natural triggers for awareness and involvement rather than formal trigger tools as used in other evaluation contexts. -Acting as a boundary object, this project triggered conversations around energy in the neighborhood through its tactility.	Specifically targeted youth as key participants. Genk residents. Atelier Zwiep 's youth artists. Soltec (sponsor of solar panels). GIGOS and SAAMO.	-Integrated critical fictions through artistic and technological creation of speculative narratives on a public mural printed on solar panels to show energy transition's urgency. -Pointing out to the neighbourhood's specific energy related history context by looking at mining past and archival photos.	Increased creativity and a sense of shared purpose. engaged participants in imaginative thinking and critical reflection on their relationship with energy. Co-created a dialogue and a tangible piece of critical fiction.
Architecture for All (TR)	Physical prototyping as a form of spatial speculation. Empowering young people to reimagine and physically prototype alternative spatial arrangements. Implementing temporary, low-resource interventions, often with a grassroots and volunteer-based structure. Conducting hands-on workshops.	-Discusses broader architectural concepts and spatial justice, extending beyond energy transition. -Faced direct conflict or resistance in public space and operational vulnerabilities (like burnout or resource scarcity) due to its grassroots/volunteer structure.	NGO: Multeciyim Hemserim (Translation: I am a refugee, my fellow countryman), Yarımburgaz Neighborhood Protection and Solidarity Association, Youth	-Engaged in spatial speculative worldbuilding through empowering young people to reimagine and prototype spatial arrangements. -Employed creative and hands-on methodologies. **(Figure 5)** -Emphasised accessible, analogue, and material approaches (temporary installations).	Encouraged critical engagement with their built environment and the envisioning of possibilities beyond the status quo wihin limited budgets and grassroot movements. Evoked excitement and a sense of accomplishment among young participants. Potential for disillusionment from the limited impact of temporary actions.

Center for Spatial Justice (TR)	Envisioning and working towards "radical just futures" across interconnected issues like environmental justice. The "Mini Citizens of the Mega City" project serves as a tangible speculative prototype. The documentary **(Figure 6)** follows the daily lives of four children from different neighborhoods of Istanbul through the eyes of the children. This approach reveals that cities should be made livable not only for adults but also for children.	-Children are not seen as active citizens in urban life; therefore, children's needs in urban planning -The desire to understand how accessible and livable cities are for children -Conveying the physical obstacles, access problems and spatial injustices in the city -Aiming to raise significant awareness that cities need to be made more inclusive and equitable	Kids. Refugees. Artists and architects, Urban95 initiative.	-Using the documentary as a tool to tell the story of Istanbul through the eyes of three-year-old children. The project aims to make visible the physical obstacles and spatial injustices that children face in the city, with images taken from a height of 95 cm, the height of an average three-year-old child. -The follow-up "#95cm: 3-2-1 Record!" campaign, encouraging individuals to document their own environment from a child's perspective	The documentary "95cm" exposes the inaccessibility of Istanbul from the eye level of a three-year-old child, and strikingly reveals that urban planning is actually made only for the adult, mostly male, body; it turns the understanding that postpones children as 'tomorrow's citizens' into a silent criticism.

Table 2: Comparative Analysis of emotional dimensions

Case Study	Potential Emotional Dimensions	Emotional Triggers	Quotes from Interviews
Architecture Workroom Brussels (BE)	Hope, collective agency, empathy, sense of possibility/determination	Revealing long-term planning schemes in Belgium can lead to distinct emotional trajectories.	Joachim Declerck: "The narratives are a way to reformulate a problem. It's a mix between reality and rhetorics." "We can't reduce the energy transition to a regulation—it's a project to transform society." Hanne Mangelschots: "Local authorities, businesses, and citizens can join forces and create a public-private-civil energy company, as the city of Blankenberge has done, particularly with its Public Social Welfare Centre (CMWOC), in which citizens can acquire shares."
La Pile (BE)	Belonging, solidarity, empowerment, future anxiety, frustration, eco-powerlessness, joy, creativity	Directly confronting energy poverty. Not being able to do long-term plans, thus frustration and anxiety. Advancing social justice through community-driven solutions.	"A core challenge in the Midi and North neighbourhoods is the high percentage of tenants. In "Renover Bruxelles", it has been explicitly identified that the tenant/landlord issue is a major obstacle, where landlords may lack the incentive to renovate unless they can raise the rent, creating fear for tenants." Sofie van Bruystegem "Yeah, so one of the frustrations, for instance, that we sometimes have with CityMined when we do energy sharing on a very local scale, it's that it stays very local and it's hard to find ways to upscale these kind of projects while with an energy cooperative, potentially you could have a structure which is regional and which could share energy on a regional level." Brupower Representative "We believe in 'Can do', the joy of trying something." Sofie van Bruystegem

oPEN Lab (BE)	Frustration, uncertainty, disillusionment, anxiety, overwhelm, gratitude	Overlooked needs or unintended consequences creating mistrust and disagreements, while some residents enjoy it.	"It is very annoying when it(the heat pump) makes this sound. That is my biggest problem. There is no solution for that. I get migraines from it." Resident from oPEN Lab projects "The solar panels are from us, but the state uses this energy for itself. We are not affected by solar energy right now." Resident from oPEN Lab projects "Since the first test house was unoccupied and minimally furnished, it became clear, in the initial stages of the other homes, that the execution of the works was more complex (due to the techniques inside the homes), which caused frustration among the residents." Dbv Architecten Representative "We have gained a brand new house, I don't get it; what else do they(other neighbours) want?" Resident from oPEN Lab projects
Transisthor (BE)	Aesthetic appreciation, Emotional and commemorative significance, Lack of understanding, Positive outlook on making complex concepts accessible	Not seeing long-term implementations of the participatory processes.	"Young people from Winterslag feel a strong connection with the former mining district." Nele Bronckaers "...a lot of people don't know what it is there, because there is no info panel next to this bench... all the people who collaborated on this don't know what it is. Besides on that, even if people were working in the social house, they don't know what it is about." A strategic manager in energy "It allows architecture to be more, while integrating design with energy solutions." A professional from an energy NGO
Architecture for All (TR)	Excitement, creativity, ownership, accomplishment, shared purpose, curiosity	Timidity of language barriers and cultural differences	"The results of the workshop, especially the one with the theme of child labor, were striking; from the beginning to the end of the workshop, a process developed in which children began to become aware of their rights, and information was revealed ranging from working conditions to how children feel about working." Yesil Gazete "Since Turkish and Syrian children have taken ownership of this space, they have made great strides in producing together and adapting to each other's realities, and they are still making progress." Yesil Gazete "The timidity of the early days has now been completely replaced by a sense of hostility that comes from being the user of that place." Yesil Gazete

Center for Spatial Justice (TR)	Contemplation, pressure, Empathy, Trust in youth, empowerment	Some children, particularly those in neighborhoods like Başakşehir, grow up feeling the pressure of surrounding mega-projects, housing projects, and shopping malls. The "Mega Kent" is a complex and multi-layered city, and understanding it requires looking beyond central areas to include peripheral neighborhoods, squatter settlements, and newly built sites. This implies that some areas face greater challenges in terms of urban development.	Yaşar Adnan Adanalı: "Although the children who participated in our study were at most 5 years old, they were able to identify spatial problems better than most adults, and they expressed them in their own unique way." "Children's perception of the environment in which they live is very clear, and their awareness is also highly developed." "In order to make the difficult experiences of children (living in Istanbul) (being a refugee, socio-economic injustice) more visible, we lower the camera to a 95cm perspective and try to look at Istanbul through the eyes of children."

Abstract
This study explores the interrelations among socio-ecological resilience, identity construction, and hydraulic heritage through a case study of the Xiangyang Irrigation System in Huaibei, China. Tracing the system's transformation from a functional irrigation network to a fragmented cultural landscape, the research employs oral history, ethnographic observation, and semi-structured interviews to assess local perceptions. Findings reveal divergent community narratives shaped by varying levels of engagement and benefit. While some residents derive identity from the system's historical and cultural significance, others remain indifferent. The study concludes that hydraulic heritage contributes both to socio-ecological recovery and community identity, positioning it as a vital asset for sustainable regional development.

Keywords: Hydraulic heritage, Socio-ecological resilience, Identity construction, Sustainable development

1 Introduction

At present, the concept of resilience has an increasing impact on the concept of heritage, especially in the discussion of cultural landscapes and social-ecological systems, to explain the adaptive and sufficient capabilities of these complex systems in the face of external disturbances and changes (Rapaport *et al.*, 2018; Mrozek and Mrozek, 2021; Niu *et al.*, 2024)much attention had been given to defining, measuring and enhancing resilience at the community level. In this study we examine if and to what extent does resilience vary among communities of different types. We use type of community as a proxy for social ties in the community, to examine variances in the perceived community resilience. We utilize an innovative measurement of community resilience, Conjoint Community Resilience Assessment Measure (CCRAM. The concept of resilience includes the ability to buffer, adaptability and transformation (Figure 1), emphasising how ecology and society are deeply connected in the built environment (Folke *et al.*, 2002)evidence that has been accumulating in diverse regions all over the world suggests that natural and social systems behave in nonlinear ways, exhibit marked thresholds in their dynamics, and that social-ecological systems act as strongly coupled, complex and evolving integrated systems. This article is a summary of a report prepared on behalf of the Environmental Advisory Council to the Swedish Government, as input to the process of the World Summit on Sustainable Development (WSSD. For heritage landscapes, this concept can reflect the long-term interactive relationship between heritage communities and the surrounding environment temporarily.

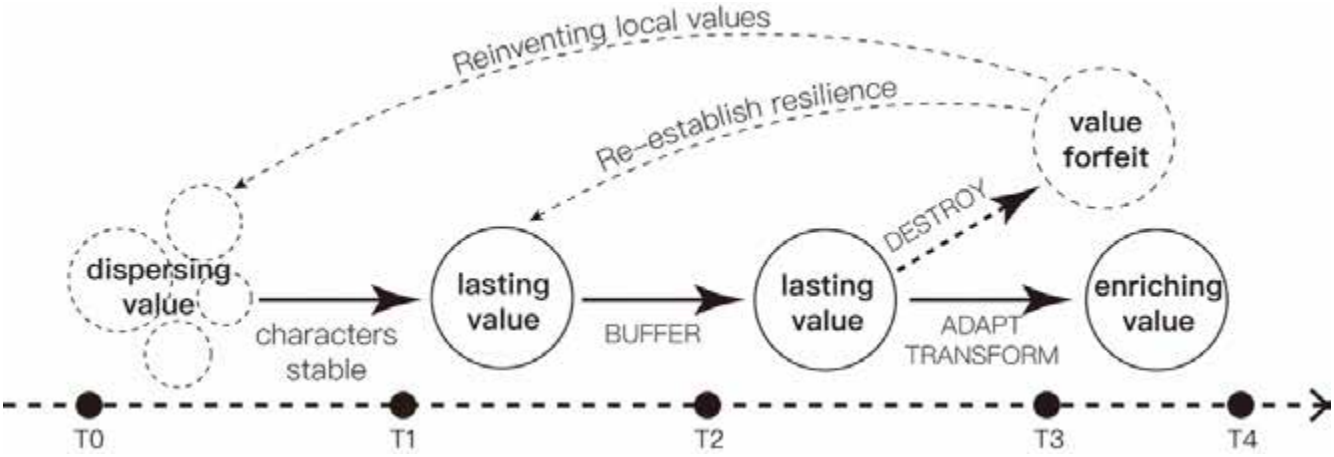

Figure 1 Evolutionary resilience model.

Hydraulic heritage refers to the historical systems designed and built for water management, including aqueducts, irrigation facilities, dams and traditional water use experience (Hermosilla Pla and Mayordomo Maya, 2016). It is a microcosm of the close co-evolution of natural resource management and society. These systems have played an essential role in the fragile environment and ecology, the allocation of water resources, the control of floods, and the improvement of agricultural production levels. Recent studies have found that in addition to the original engineering functions, hydraulic systems are often deeply bound to the cultural structure of the community and shape the community identity and collective memory (Durán-Suárez and Sáez-Pérez, 2019; Wei *et al.*, no date). As can be seen from the inclusion of China's Dujiangyan Irrigation System in the World Heritage List by UNESCO, this type of heritage is not only important as a historical project, but also as a lasting cultural landmark that provides contemporary functions.

This study attempts to answer the role of hydraulic heritage in social ecological resilience by analysing the Xuzhou Xiangyang Irrigation System in the Huaibei region of China. Historically, the Huaibei Plain has been deeply affected by many large-scale hydrological interventions, especially the diversion of the Yellow River into the Huaihe River Basin during the Song Dynasty (1128 AD) (Junya and Wright, 2013). This move was intended to strategically protect the Jiangnan region but caused widespread ecological damage and agricultural degradation in the Huaibei region. Over the next nine centuries, the region's ecological and social resilience was systematically compromised. Villagers struggled with flooding, salinised land, and agricultural stagnation for a long time, earning an unfortunate reputation as "sacrificial locals". In response to Huaibei's complex ecological and social problems, the 30-kilometre Xiangyang irrigation system was built in the context of social mobilisation in the 1970s, covering facilities such as channels, sluices, and pumping stations. It improved agricultural productivity by providing stable fresh water and reducing soil salinisation. In the new century, with the introduction of more advanced regional water resource management technologies, the irrigation function of the Xiangyang system gradually weakened, and the various facility elements lost their spatial associations, but their role in local cultural and historical identity became increasingly evident. The transformation of the meaning of hydraulic heritage highlights the contemporary value of social-ecological resilience.

This study examines the transformation of landscapes, heritage narratives, and social perceptions through a qualitative method, which integrates literature research, semi-structured interviews, participatory observation, and spatial analysis. The purpose is to understand how hydraulic heritage can promote social cohesion, and increase the resilience of eco-social systems while protecting ecological integrity. By understanding how historical infrastructure can adaptively integrate cultural and ecological elements and become a lasting resource for the development of heritage communities, this paper makes theoretical and empirical contributions to the intersection of heritage conservation, resilience theory and sustainable development.

2 Method

2.1 Literature and Archive Review

First, the academic literature and archives on eco-social resilience, cultural landscape, hydraulic heritage and historical hydrology in Huaibei, Jiangsu Province were studied, with a focus on the historical records of "taking the Huai River into the sea" and the subsequent ecological degradation. At the same time, the county annals of the former Tongshan County (now Tongshan District, Xuzhou City), hydrological engineering reports from the 1950s to the 1970s and provincial planning documents were consulted to understand the development timeline of the Xiangyang irrigation system and the positioning of the state-led hydraulic project construction in the Huaibei region under the background of the "Red Flag Aqueduct" spirit. In addition, the relevant international adaptation and resilience theoretical frameworks were sorted out, and combined with UNESCO's papers on cultural landscapes and community identity development to lay the cognitive foundation for this study.

2.2 Semi-structured interviews and participatory observations.

From 2023 to 2024, 21 semi-structured interviews were conducted in Liuquan Town, Xuzhou and neighbouring villages. Interviewees were selected by snowball sampling to ensure that a wide range of ages and social identities were covered, and the diversity of the interviewees' participation in the irrigation system was obtained as much as possible. Interviewees included the following four categories: (1) farmers who participated in the construction and early use; (2) village committee/party and mass workers who participated in village political management and hydraulic heritage maintenance; local cultural researchers and teachers who incorporated the history of the water system into the teaching system; and (3) community residents engaged in related rural

tourism. At the same time, the interviews included open-ended questions on the following topics: (1) personal or collective experience of using the Xiangyang irrigation system; (2) perceived benefits and challenges of the Xiangyang irrigation system in the past and present; (3) emotional and cultural connections to the irrigation system; (4) attitudes towards heritage commercialisation and tourism development; and (5) views on changes in the local ecological environment. All interviews were recorded, transcribed, and coded with knowledge and anonymity.

At the same time, the research team formed an ethnography of the local community by observing the interaction between local residents and the remains of the irrigation system, recording their emotional responses to water-related landmarks, and the stories they told while accompanying observers on walking tours. This record not only took their daily lives related to water as historical objects, but also analysed their current social and spatial structures.

2.3 Landscape Analysis and Spatial Mapping Framework

In order to make the above qualitative data, which are mainly based on oral and observational data, more objective, this study also used GIS tools to conduct a spatial analysis of the local built environment, including: (1) the original layout of the Xiangyang irrigation system based on engineering records and field measurements built in the 1970s; (2) the current local land use patterns and visible remains of hydraulic facilities; (3) recent development activities on related heritage, such as signboards and visiting walkways; (4) satellite images from 1970 to 2024 to record changes in land cover, vegetation and water bodies. This spatial information will be combined with the qualitative content obtained from interviews and observations to track the material state of changes in the irrigation system and explain how specific heritage sites are remembered, used or forgotten. Data analysis will be tested using triangulation methods to understand how hydraulic heritage is interpreted and how it is deconstructed and materially transformed in the context of resilience.

3. Case Study: Xiangyang Irrigation System in Huaibei

3.1 Historical Context: From Floods to Social Marginalisation

The socio-ecological trajectory of Huaibei is highly relevant to one of China's most important water events. During the Northern Song Dynasty, the Yellow River was artificially diverted into the Huai River system. In 1128 AD, under siege by the invading Jurchen army, the Song army broke through the dikes in present-day Kaifeng and released the Yellow River floodwaters southward to form a defensive barrier. Large areas of northern Anhui and Jiangsu provinces were flooded by this river change. However, the long-term ecological and socio-political consequences were much more serious. The wartime strategic shift had a significant impact on the local hydrology. The Yellow River, which previously flowed into the Bohai Sea, then usurped the Huai River channel further south and entered the Huai River basin. This diversion exacerbated local flooding problems due to changes in the river's capacity, leading to chronic waterlogging. At the same time, the large amount of sediment carried by the Yellow River led to local soil salinisation, agricultural abandonment, and large-scale displacement. Historical records show that large tracts of arable land in northern Huaibei became unusable, forming what Qing officials later called "poor mountains and bad waters."

After the 19th century, the Huaibei Plain was widely referred to as "sacrificial locality" (Ma, 2023). This was a marginal territory that was neglected in the allocation of national resources by the entire central government. The fragile ecology brought poverty, food shortages, and social exclusion, and also caused the loss of rural population. Although the Yellow River changed its course again in the 19th century, making the Huaihe River system the main water system in the Huaibei Plain, the ecological resilience was still not ready to be restored, and the salinised plains, broken waterways, and complex social environment still existed. This state also laid the foundation for a series of hydraulic projects in the Huaibei area. Because major infrastructure, including the Xiangyang Aqueduct, is not only an ecological resilience restoration project, but also an initiative to reintegrate this land into social politics.

3.2 Construction of Xiangyang Irrigation System: Engineering Hope and Collective Memory

Despite the long-term instability of the hydrological environment and the marginalisation of geographical conditions, the country launched a nationwide modernisation movement of large-scale hydraulic facilities under the leadership of the Taihang Mountain Red Flag Aqueduct Hydraulic Project in the 1970s (Figure 2).

This type of rural infrastructure project is usually initiated by large-scale mobilisation and has a significant impact on the local agricultural environment.

Figure 2 The fundamental status of the Xiangyang irrigation system.

The Xiangyang system is a set of irrigation hydraulic networks with self-weight water supply and mechanical pump assistance. Its purpose is to introduce fresh water resources from Weishan Lake in the north and newly built small and medium-sized reservoirs to Liuquan Town and surrounding villages to solve the problems of farmland salinisation and poor drainage. According to county-level archives, the system was completed in 1976, with a length of about 33.6 kilometres, including five medium-sized water transfer stations, five large aqueducts, 369 bridges and culverts, five tunnels, and 25 kilometres of high-voltage lines. It is worth noting that this facility was not implemented by a professional engineering corps, but through the labour model dominated by the people's commune, mobilising thousands of villagers and educated youth. Oral histories recorded on the ground testify to the intensity and symbolism of the work. One interviewee, 74-year-old Ms. Zhang, who worked on the project, recalled:

"There were no large machines, and we dug with our hands and shovels. Each household sent a labourer; my husband worked for 38 consecutive days. It was hard to get enough food, but free meals were provided at the construction site, and they said they were "building water (water diversion)" for the village. The work was hard, but we were all proud. The project was our own business."

This participatory practice not only achieved the construction of infrastructure, but also created a sense of "ownership" of public property. Between the 1970s and 1990s, calligraphy and paintings on the facilities, murals in the village, and local songs recorded the entire construction process. Although villagers were not clear about the role of each part of the system, for example, a vital aqueduct was called the "38-hole bridge" by the locals because of the 38 arches that supported the aqueduct. The aqueduct is certainly not a transportation facility, but due to the similarity of the image, the use of "bridge" as an alternative word can better spread the name of the project (Figure 3). The Mao Zedong quotations inscribed on the aqueduct also highlight the complex emotions of the locals, showing the embedding of emotional meaning in the material structure.

Figure 3 "38-hole bridge"

On the other hand, the hydraulic system attains ecological resilience by connecting the originally broken water bodies and providing drainage outlets. This has significantly improved local productivity. The salinity of cultivated land has dropped by more than 30% in five years, and the areas controlled by the Xiangyang Project have gone from being difficult to plant to being able to harvest twice a year. According to villagers, the yield of some lands has doubled compared to before the project was used.

More importantly, the Xiangyang hydraulic system has also reshaped the village settlement model. Due to long-term flooding, the original villages could only be built on high ground. Now the hydraulic system has become an organisational axis, and housing, markets and community centres have been repositioned around these axes. In some villages, bridges and public washing platforms are built near irrigation facilities, which have become their new infrastructure and social space. As a local retired teacher said:

"Hydraulic facilities not only bring fresh water, but also bring intimacy between people. It runs through our lives: irrigating farmland, swimming, washing clothes. It is part of our lives..."

Today, although most of the facilities still retain the integrity of their physical state, they have lost their original irrigation function. Due to the restoration of ecological resilience and new water diversion technology, the Xiangyang system has begun to transform from infrastructure to landscape, and has become an intersection of culture and emotion. It is precisely by capturing this shift that the interpretation becomes a transformation of its function and meaning.

3.3 Decline of Function and Rise of Symbolism

Since the early 2000s, the state of water resources and hydrological conditions in the Huaibei region has changed significantly. With central government investment in large water facilities, the construction of deep well systems, and the expansion of municipal water supply facilities, the region has gradually reduced its reliance on the Xiangyang system. However, unlike most infrastructure that has taken off, the Xiangyang irrigation system has begun a soft evolution, from functional infrastructure to symbolic landscape. This shift was not achieved through formal renaming, but rather through a combination of spatial intervention, community memory, and tourism development. In 2016, Liuquan Town began to promote the "Water Channel Memory Walk", installing interpretive signs along the main waterway, which is about 4.5 kilometres long. These signs include photos of the past, oral texts, and QR codes linking to students' related documentary works. Some local celebrations, such as the Spring Plowing Ceremony and the Mid-Autumn Water Lantern Ceremony, are also held near the key facilities of the waterway to strengthen the symbolic connection.

Many elderly people still describe the water system as a "gift from the past." An 82-year-old villager claimed:

"It may not be carrying water, but it carries our pride. I often go there because it's my old time." The intervention of collective art also adds to this spiritual transformation.

In 2021, a mural project organised by college student village officials (a way for the Chinese government to train grassroots officials) repainted the text on the sluice facilities, emphasising the spiritual role of the great mobilisation project in the 1970s by highlighting some of the political slogans written at the time, which also made these facilities a "red heritage." Although the scale of these practices seems small, they show a spiritual transformation: the old hydraulic infrastructure has become an anchor of rural identity. And this emotion is deeply reflected in the post-agricultural society and semi-urbanised landscape (Figure 4).

Figure 4 Political slogans that have been repaired in the structures

3.4 Landscape transformation: from aqueduct to cultural corridor

In addition to oral accounts and observations, spatial analysis also reveals how the material space of the Xiangyang irrigation system has gradually been integrated into contemporary culture and eco-society. Comparison of satellite images from 1990, 2005, and 2024 shows the following trends:

(1) **Physical form:** Although some river channels have disappeared due to land development, the main water channels remain intact and have become green corridors or channels between fields; the sides of the river channels have also become vegetation buffers, with native vegetation growing on the edge of concrete, becoming an ecological plate for amphibians and butterflies.

(2) **Social form:** In the 13 villages surveyed, administrative buildings, primary schools, public squares and other facilities in five villages have spatial intersections with the remains of the irrigation system;

(3) **Industrial form:** The 2020 tourism plan includes two theme hotels, a hydraulic cultural centre, and a souvenir shop related to hydraulic knowledge. Although the final implementation is different from the plan, it can still capture the symbolic role of the Shuili heritage in the local space.

3.5 The aqueduct as a multi-scalar heritage

The role of the Xiangyang irrigation system in terms of function and meaning can be analysed at different levels: at the micro level (village), it constructs rural neighborhood identity and spatial positioning, such as residents often point to specific landmarks, "the bridge my father built", "above the sluice", "where we played with paper boats", which shows the continued role of heritage as a spatial location marker; at the same time, it is also an aesthetic and social node, promoting the birth of local tourism and public art through narratives of events and memories. At the meso level (township), the hydraulic system has been incorporated into the strategic planning of rural revitalisation. Although it is still lacking in funding, a planning document for 2022 describes it as a heritage system that connects ecological restoration areas, rural cooperatives, and heritage clusters. At the macro level (region), scholars and planners regard this system as a typical example of hydraulic landscape heritage in the Huaibei region.

Thus, the evolution of the meaning of the Xiangyang irrigation system reflects the process of spatial heritage stratification, from functional infrastructure (1970-2000), to post-industrial memory sites (2000-2010), and to polysemic cultural landscapes (2010). This transformation of resilience is reflected not only in the ecology but also in the politics, economy and collective identity of a community. As summarised in an interview with the village party secretary:

"We used to worry about whether there was water in the aqueduct. Now we ask: does it still have meaning? Yes. It flows differently now, but it still connects us."

4. Results

This chapter presents the main empirical findings from the fieldwork. Based on 23 semi-structured interviews and participatory observations, subjects were coded. The analysis revealed that people's perceptions of the transformation of the Xiangyang irrigation system varied across generations, occupations, and geographies, leading to different interpretive patterns.

4.1 Typology of local narratives: four community positions

The subject coding of the semi-structured interviews yielded four different community positions, which we categorise as (1) governors; (2) cultural transmitters; (3) pragmatists; and (4) tool innovators.

(1) Stewards of the aqueduct

This group is mainly composed of older villagers (over 60 years old) .they either directly participated in the construction of the aqueduct or actively used it during its operation. For this group, the irrigation system is not just an infrastructure, but also a moral story of resilience and sacrifice. They see themselves as stewards of the aqueduct's memory. As one 72-year-old woman said:

"This is not just a aqueduct, it is what we built with our youth. If you tear it down, you end our lives."

This group often uses emotional terms, such as calling the irrigation system "our blood vessels," "common works," or "the backbone of the village." They prefer low-tourism, high-ritual space utilisation methods, such as worshiping ancestors by the water.

(2) Cultural disseminators

This group is more composed of middle-aged villagers (40-60 years old), teachers, local cultural researchers, and village cadres. They act as intermediaries between old memories and new interpretations. Many of them did not directly participate in the construction and irrigation work, but grew up listening to the story of the aqueduct. They noticed the material and intangible heritage value of the irrigation system. Local teacher He, 43, said:

"Our students may not know the principles of the irrigation system, but they can understand the meaning behind it. This is the result of the efforts of the Party (CCP) and the collective, and it is also a lesson for us on how to change nature."
This group actively supports heritage education, painting projects, and oral history collections. They are moderately open to tourism development, provided that it conforms to "local values" and "mainstream narratives."

(3) Pragmatists
This group is usually composed of young residents under 35 years old and those who have recently returned to the village. They show ignorance and indifference to the irrigation system and its original function. As a generation living in the context of mechanised agriculture and urban water supply, for them, it lacks direct relevance to daily life. A 27-year-old driver said:

"I cross the bridge (the 38-hole aqueduct) when I deliver to the store, and that's it. It's not part of my life."

It is worth noting that this group is not against heritage, but just thinks it is not a priority in their lives. They focus on reuse projects that can generate short-term benefits, such as whether some facilities can be converted into cafes.

(4) Tool Innovators
This group is small but growing, including local entrepreneurs, tourism planners and youth cooperatives. They see heritage as a tool for economic and social development and propose "adaptive use" of hydraulic facilities. For example, it can be integrated into agricultural tourism experiences, create VR experiences of using hydraulic facilities, or hold seasonal rituals related to them. A 34-year-old B&B owner said;

"If we only view the hydraulic facilities as history, they will disappear sooner or later. But if we view it as a resource, it can play a positive role in the economy, culture and society."

This group tends to prioritise strategic action storytelling and brand creation. Their activities are similar to other heritage-led rural development models in China and are often supported by higher-level governments.

4.2 Intergenerational friction and intra-village dialogue
The positions of these four narrative subjects together reveal a landscape of negotiated governance of heritage rather than shared memory. Multiple interviewees expressed tensions between different generations, especially in the understanding of the symbolic and economic value of the irrigation system. In several villages, intergenerational conflicts arose over the use of heritage for tourism development. In Xixiang Village, the elderly opposed the establishment of a night market near the historic sluice gate, believing that it was "interference with a place of memory." Meanwhile, young entrepreneurs saw it as an opportunity to "revitalise a corner of the village." Similar disagreements occurred in the design of rituals, such as whether the Spring Water Festival should include only traditional rituals or contemporary music performances and webcasts.

To resolve these contested opinions, there were at least four coordination meetings held in different villages. The meetings bring together village elders, youth representatives, local officials, and teachers.

They negotiate the content of facility-related activities and how they should be governed. In Dongma Village, for example, the meeting agreed to limit commercial stalls to one side of the facility, while reserving the other side for ceremonial purposes.

These hybrid governance mechanisms are still being refined, but they represent a grassroots effort to manage in a participatory way. During the interviews, both sides expressed cautious optimism.

"They are listening more now," said one elder. "At least we have a seat at the table."

"It's not about agreement," said a youth representative, "but about recognising what is important to different people.

4.3 Heritage as emotional infrastructure

In addition to its physical infrastructure and cultural brand, the Xiangyang Irrigation System functions as an "emotional infrastructure" that serves as a site for processing individual and collective feelings of loss and belonging. This becomes evident in many of the narratives associated with the aqueduct. For example, five widows whose husbands died during the construction of the aqueduct in the 1970s maintain a memorial corner next to an abandoned hydroelectric station (Figure 5), and every Qingming Festival, they perform rituals such as burning incense and chanting names, and become "aqueduct sisters". A 75-year-old woman, Ms. He, explained: *"When my husband died, I started walking along the aqueduct every morning. It's quiet, but it listens. It remembers."*

Figure 5 Memorial corner by "aqueduct sisters."

Elsewhere, a teenage boy talked about running along the aqueduct when he failed an exam, and an older man described bringing his grandson here to share family stories. In these narratives, heritage is less a structure than a space for reconnection. This emotional significance is not aligned with economic or ecological values, but it is central to the lived relevance of this place. Therefore, when assessing rural heritage frameworks, its role as emotional infrastructure should be included, recognising not only its role but also what it possesses and evokes.

4.4 Spatialized heritage visibility

Using GIS data derived from low-altitude drones and historical satellite maps, we categorise the physical remains of the Xiangyang irrigation system into three levels of visibility.

(1) Structural visibility

Includes intact and readable structures, such as water diversion channels, sluices, or pump houses, which are still clearly identifiable in shape and location. These structures are mainly distributed in Wangma Village and Dongma Village near Weishan Lake. Their integration into the agricultural space has preserved their identity.

(2) Symbolic visibility

This category includes original structures that have been completely or partially demolished, but elements of signs and murals have been retained. For example, the Red Flag Cave in Xipu Village, although the original structure is no longer visible, still retains the Red Flag Cave painting, which tells the story of political propaganda in the 1970s.

(3) Latent or forgotten visibility

In peripheral villages such as Laoquan Village, the material traces of the irrigation system are almost non-existent. Interview results also show the loss of memory. Many young people in the village could not identify the location of previous facilities. However, the landforms and water behaviour still hint at past hydraulic functions. This spatial typology reveals that visibility is not just a peripheral material condition, but also a function of cultural gain and empirical investment.

Villages that are used for investment or receive development plans often maintain material and narrative visibility.

4.5 Functional differentiation between villages
In the 13 villages where field research was conducted, three different development patterns emerged:

(1) Functional heritage villages
In these villages, the remains of the irrigation system still play a certain degree of hydraulic function. In Dongma Village, a water transfer station is used to direct runoff and seasonally irrigate collective vegetable plots, and heritage is embedded in ongoing use (Figure 6).

Figure 6 Desalination plant still in use.

(2) Cultural and tourism villages
Villages such as Wangma Village and Xinjia Village reposition heritage as heritage assets. They install signage, hold annual festivals, and transform abandoned houses into cafes (Figure 7). These villages often receive township-level development funds and appear in development plans.

Figure 7 The house planned to be transformed into a coffee shop.

(3) Marginalised villages
In Xipu Village and Laoquan Village, heritage elements were mostly removed and damaged. These villages often lack official documentation, external investment, or young returnees. Some expressed dissatisfaction in interviews, stating that

"Our facilities are equally historic, but no one promotes us."

This reflects spatial inequalities in heritage valorisation and its connection to economic opportunities.

This phenomenon suggests that the aqueduct heritage is not a unified regional asset, but a diverse landscape, which is shaped by governance priorities, local capacities, and symbolic frameworks.

4.6 Heritage as a governance network
Heritage governance in Liuquan Town operates through a multi-level governance network, including village committees, township agencies, and ad hoc working groups. Spatial analysis of project funding, signage distribution, and festival rituals revealed a striking feature: villages with strong leadership or elite participation were more likely to mobilise external resources. According to interviews and constructed actor networks, Xinjia Village and Dongma Village acted as nodes, coordinating inter-village activities such as storytelling sessions and tour guide training. In contrast, villages with limited connections to the governance network showed a disconnect. A village committee member from Xipu Village said:

"We filled out two applications for heritage funding, but there was no response. Then we heard that other villages already had plaques and visitors."

This suggests that while irrigation systems were once linear structures connecting villages through water flows, they now function as a meaningful governance network that creates spaces for unequal access driven by policy, capital, and culture.

5. Discussion

5.1 Infrastructure Construction of Heritage and Identity

The transformation of Xiangyang Irrigation System shows that infrastructure can be used not only for ecological restoration or economic development, but also as the cornerstone of collective identity. This is consistent with relevant research in the current heritage context. This scholarship believes that heritage is no longer a static, protected monument, but a dynamic process of social production. As shown in the study, hydraulic facilities are not only valued for their functions but also for actively absorbing narratives about production, sacrifice, and life continuation. Through the concept of lieux de mémoire proposed by Nora (1989), hydraulic heritage can be understood as a spatial place for collective memory and value narratives. Abukarki, Uzunahmet and Onur (2023)specifically, Byzantine mosaics in Jordan, where the Byzantine Empire left behind a rich mosaic heritage. Today, these mosaics are replicated in contemporary architectural environments. The purpose of this article is to explore the heritage discourse surrounding Byzantine mosaics in Jordanian contemporary places with a particular focus on the replication and interpretation of the mosaics in contemporary places. To do that, the relationship between the attachments to the Byzantine mosaic places, the community's level of awareness, and the replicated heritage discourse was examined. The research was conducted using several different methods, where structural equation modelling (SEM claimed that when infrastructure is entangled with collective struggles, it becomes a "cultural production tool for self-expression." This study further points out that identity construction is spatially and temporally layered. For young people who have not experienced that history, this series of hydraulic facilities is not a living past, but more like a history that is born with them. Even so, the local look brought by this symbolism also implies the continuity of collective consciousness. Therefore, the term infrastructural identity is particularly appropriate to describe how large-scale technological systems drive the self-perception process of local communities in post-disaster reconstruction. In the case of the Huaibei Plain, this identity is not passively acquired, but actively negotiated through narrative, consciousness, and space and time.

5.2 From functional system to symbolic landscape

The case of the Xiangyang system further illustrates the transformation of infrastructure into landscape, not only in visual and functional terms, but also in ontological terms. The system was originally a modern hydraulic solution to address centuries of ecological fragility. Today, it operates more as a cultural landscape in the sense of UNESCO, a microcosm of human-nature interaction in history. This change is particularly evident in the discussion of the low-visibility typology of the system (Section 4.4) and the village differences (Section 4.5). Where the system's material form is highly visible and memorialised, it is not only a place of memory but also a spatial anchor for development and tourism planning; where it has disappeared, it presents a more fragmented memory with weaker community participation. This also confirms Tilley's (1994) proposition that landscape is not neutral, but is full of meaning, constituted by memory, and organised by politics. The "heritage density" displayed by the spatialisation of the material remains of the aqueduct system reflects the power differences of factors such as funding, social attention, and political discourse. In other words, heritage landscapes are contested even when they are produced.

On the other hand, the transformation from function to symbol does not mean obsolescence. As shown in the case of "Sisters of the Aqueduct" (Section 4.3), the landscape has become a stage for rituals and emotions, and even serves as an ecological facility. This kind of soft resilience allows the space to continue to maintain its social production capacity even if the system loses its original use value.

5.3 The multi-scalar politics of heritage

The recontextualisation of the Xiangyang hydraulic system is far more than the result of a grassroots movement. From the results of Section 4.6, this governance process is multi-party. From the local village committee to the township government, to the county brand planning, each institution has its own understanding of the use of heritage and competing strategies. This reflects memory selection, tourism economy and legitimacy. Ashworth, Ashworth, Graham and Tunbridge (2007) proposed "discordant heritage" and analysed how governance structures mediate or exacerbate conflicts. The emergence of mediation committees (Section 4.2) shows that local actors negotiate and create institutions to ease such disputes. However, from the spatial network analysis, it can be seen that different subjects have obtained disproportionate visibility, resulting in an imbalance in landscape value. This imbalance reflects the differential distribution of symbolic capital proposed by Bourdieu (1986). The visibility of the irrigation system, whether material or immaterial, is a form of capital. Different actors can obtain investment, facilities and status, which shows an asymmetric cultural economic control.

Therefore, post-functional infrastructure can serve as a field for governance experiments. Currently, we see bottom-up heritage planning, cross-village cooperation, and participatory governance, rather than top-down hydraulic projects. All of this has reshaped the imagination and practice of rural governance in China.

5.4 From engineered resilience to evolutionary resilience

The transformation of the Xiangyang irrigation system also demonstrates a paradigm shift in the concept of resilience. It means from engineered resilience that emphasises stability and resilience, to adaptability and identity transformation, to evolutionary resilience. In its original design and construction, the irrigation system embodied engineered resilience, creating a system that conformed to technical rationality to mitigate hydrological dysfunction and agricultural decline. It was linear, technical, and hierarchical, reflecting the modernist desire to control nature (Scott *et al.*, 2020). The results were expressed in terms of food production, water flow, and salinity. However, after the new century, the resilience of the irrigation system has changed. The system now supports community cohesion, educational participation, and tourism innovation. These uses are not residual, but an adaptive reshaping. In essence, it is a transformation of physical infrastructure into cultural and emotional assets. The elements of the irrigation system are reconnected through community values, making it a refunctionalized infrastructure. It is not about water itself, but about what water once meant and what it means again. This also corresponds to Pelling's (2010) resilience framework:

(1)Sustainability: irrigation systems maintain their physical state and core symbols;

(2)Adaptation: irrigation systems take on new uses and meanings;

(3)Transformation: irrigation systems reposition local governance, identity and development goals.

5.5 Emotional resilience

In addition to material and institutional transformations, the emotional role played by the Xiangyang system is arguably the most enduring. Although this is rarely reflected in planning documents, these functions are far-reaching. Emotional resilience refers to the ability of individuals and communities to adapt to social and psychological pressures by rooting themselves in meaningful places. The concept of "ordinary heritage" places everyday attachments on grand narratives. For example, for the aqueduct sisters, heritage is not carefully cultivated, but cultivated through rituals and storytelling. This practice is not commodified and does not require external validation. In this way, they maintain emotional stability in the rapid changes of rural modernisation.

This resilience is particularly important in China's post-rural society. Here, population hollowing out, land consolidation and other issues have caused deep emotional ruptures (Yan, 2010). The persistence and availability of the aqueduct act as a psychogeographical plaster. The results show that heritage management should not only focus on economic and cultural resilience, but also pay attention to the emotional needs of the community. This means that planning needs to support local rituals and uncommodified memory spaces. It also requires managers to realise that heritage management includes not only what is seen and sold, but also what is felt.

5.6 Facility memory and time negotiation

Finally, the transformation of the Xiangyang irrigation system also triggered a re-examination of heritage. The system itself is a product of state intervention in the local area, a machine for dealing with historical scars and political amnesia. The Huaibei Plain has long been considered a "sacrificial area", and its construction allows the region to re-enter the narrative of national development. Then, this facility also realises a bottom-up temporal agency. Narrating the process of recovery in their own way. They reposition loss, remains and the future. For example, villagers compare the state's past neglect with the attention it has received now. Therefore, the Xiangyang system becomes a narrative balance, from forgetting to revival, from hiding to visibility. In this process, it realises what (Tsing, 2015) called "revival in ruins", that is, the ability to construct the future from the destroyed past.

On the other hand, not all participants have the same narrative. As the results show, between the old and the young, between tourism and tradition, between visibility and hiding. These disputes are not the failure of heritage, but the embodiment of vitality. Heritage, like memory, is not fixed, but a negotiated temporality where meanings are layered, modified and activated.

6. Conclusion

This study aims to investigate how post-functional hydraulic heritage can serve as a spatial medium for socio-ecological resilience, identity construction, and place-making. By delving into the history of the historically marginalised Huaibei Plain and the Xuzhou Xiangyang Irrigation System as a hydraulic intervention, this study traces the complex transformation of the irrigation system from an engineering solution to an affective, symbolic, and political infrastructure in the 1970s. Drawing on a qualitative mixed-method approach, we explain how the legacy of the hydraulic system continues to shape the daily experiences, aspirations, and ideals of the local community. The Xiangyang Irrigation System, though almost dry, continues to flow through memory, ritual, imagination, and governance. In this sense, the system is not just a story of hydraulic history, but a living example. How rural landscapes absorb trauma, adapt to change, and find meaning again, not with scars, but through scars.

6.1 Theoretical Contribution

(1) Conceptual expansion. The study of hydraulic heritage as infrastructure extends the concept of facilities beyond the technical aspect. Technical facilities can also be called social-ecological infrastructure, which shapes landscape, culture, and emotions at the same time. As in the case of the Xiangyang system, even though the original hydraulic function has ended, the structure still produces ecological, emotional and institutional meanings. At the same time, this example also establishes two important concepts, namely infrastructure identity and emotional infrastructure. The former refers to how collective identity is engraved on the material of the architectural engineering system, especially under the conditions of common labour and struggle; the latter emphasises the non-economic role of heritage in promoting emotional stability and community cohesion, especially in areas with drastic demographic and cultural changes. These two concepts provide theoretical support for understanding the interaction between heritage memory and place.

(2) Evolutionary resilience of heritage landscapes. Resilience should not only be limited to engineering, but also extend to transformation and reinterpretation. The aqueduct was not only preserved after its elimination, but also became a medium for reconstructing the future of rural areas. This process goes beyond static heritage protection and forms a dynamic negotiation platform.

6.2 Empirical Contributions

(1) Case Extension. This study provides original empirical material for the exploration of post-functional rural infrastructure in China. Through 23 semi-structured interviews, participatory observation and spatial analysis, the study documents how local communities interpret, negotiate and use heritage systems through different methods. These stories highlight the diversity of the social value of heritage.

(2) Method Extension. This study provides a spatial method for evaluating heritage systems. By dividing the system into structural, symbolic and potentially visible components, the uneven typological significance of heritage systems can be understood. This set of methods can be applied to other linear infrastructure heritage.

6.3 Strategic Recommendations

(1) Establishing a post-functional governance framework. Local institutes should identify infrastructure, which is no longer serves its original function, but remains eco-social significance. Governance should include adaptive reuse, participatory place-making, and low-cost interventions.

(2) Putting emotional resilience into rural planning. As ecological resilience has become a requirement in environmental planning, emotional resilience should be admitted in heritage policy. Protect ritual or collective spaces, even if they lack direct economic output.

(3) Promoting multi-scale heritage governance platforms. Mediation conferences mentioned before provide a model for democratic consultation. This heritage should be supported by local governments with funding and training resources, to strengthen grassroots capacity building.

(4) Solving inequalities in heritage visibility. Regional heritage policies should proactively identify marginalised villages and provide targeted support for related initiatives, in order to avoid exacerbating spatial disparities.

6.4 Limitations and Future Directions

(1) Time constraints. This study provides a rapid ethnography of heritage. The meaning and function of the Xiangyang system are constantly evolving, and long-term longitudinal research will help understand how current practices have an impact over time.

(2) Data coverage and sample representativeness. Although 13 villages and 23 interviews were included, the sample cannot guarantee the heterogeneity of Liuquan Town and even the Huaibei Plain. In particular, the views of migrant workers, women under 30 years old, and township-level planners are underrepresented.

(3) Horizontal comparison. Comparison with rural irrigation systems in other contexts can enrich the research depth and test the applicability of my theoretical model in different ecological and cultural regions.

Abstract
This study investigates the spatial relationship between the development scale of High-tech Industrial Development Zones (HTDZs) and regional carbon emissions in China. Using data from 168 national HTDZs, we construct a development index via the entropy method, and employ coupling coordination and multi-scale geographically weighted regression (MGWR) models to assess regional disparities and spatial heterogeneity. Results reveal that while advanced HTDZs achieve higher output with lower emissions, underdeveloped zones face disproportionate carbon burdens due to limited capacity. The findings highlight significant spatial injustice and carbon responsibility shifts. Policy recommendations include region-specific green support systems, emission coordination mechanisms, and enhanced governance. This research provides a scientific basis for promoting low-carbon, equitable, and high-quality development in China's HTDZs.

1 Introduction

Against the backdrop of intensifying global climate change, the notion of a "green transition" has emerged as a central agenda for governments and academic communities worldwide. Addressing global warming and achieving sustainable development are no longer optional choices but have become pressing imperatives for all nations (Liu et al., 2023). In this context, the restructuring and upgrading of economic systems, coupled with effective carbon emission control, have become core tasks for contemporary and future national policymaking and regional governance (Kong et al., 2021). As the world's largest developing country and the top emitter of carbon dioxide, China has put forward the "dual carbon" goals—peaking carbon emissions by 2030 and achieving carbon neutrality by 2060. This ambitious commitment not only reflects China's proactive stance in global climate governance but also imposes new internal demands for realizing high-quality development while significantly reducing greenhouse gas emissions and improving resource efficiency. Guided by these targets, China now finds itself at a critical juncture—pursuing both economic modernization and green transformation in tandem. High-tech Industrial Development Zones (HTDZs), which are specialized economic zones characterized by intensive knowledge capital and open institutional environments, play a pivotal role in this transformation (Wang et al., 2023). Leveraging policy incentives such as tax exemptions and R&D subsidies, HTDZs have become incubators of technological innovation and industrial upgrading. Today, they are strategically embedded in China's national innovation system and hold a prominent position in both the global division of labor and the domestic trajectory of green transition (Hua et al., 2023).

High-tech Industrial Development Zones (HTDZs), which are specialized economic zones characterized by intensive knowledge capital and open institutional environments, play a pivotal role in this transformation (Chen & Liu, 2022). Leveraging policy incentives such as tax exemptions and R&D subsidies, HTDZs have become incubators of technological innovation and industrial upgrading. Today, they are strategically embedded in China's national innovation system and hold a prominent position in both the global division of labor and the domestic trajectory of green transition (Wang & Feng, 2021). With this broader transition underway, the role of HTDZs as the frontier of technological innovation and economic restructuring is undergoing profound change. Since the 1990s, HTDZs in China have expanded rapidly due to policy support, concentrated resource allocation, and capital agglomeration. They have evolved into central nodes in the national innovation network, driving regional economic growth, technological advancement, and structural upgrading (Li et al., 2025). By 2024, China had established 178 national-level HTDZs, widely distributed across eastern, central, and western regions, forming high-tech clusters represented by Zhongguancun in Beijing, Zhangjiang in Shanghai, and the Optics Valley in Wuhan (Yan et al., 2024). However, as HTDZs continue to scale up and their industrial structures grow increasingly complex, their associated carbon emissions have come under closer scrutiny. The rapid expansion of these zones has inevitably brought about rising energy consumption and resource depletion, making them significant contributors to regional carbon emissions. This issue becomes more pronounced in the context of unbalanced regional development and

unequal industrial specialization (Zhong et al., 2024). Significant disparities have emerged across regions in terms of HTDZs' development levels, emission reduction capacities, and green governance models—differences that not only affect the overall effectiveness of carbon mitigation but also raise fundamental concerns of environmental justice.

Existing research on the relationship between HTDZ development and carbon emissions has primarily focused on technological innovation, energy efficiency, or reductions in carbon intensity (Wang et al.; Wang et al., 2022; Li et al., 2025). These studies often presume that HTDZs inherently contribute to low-carbon development. Yet from a broader and long-term perspective, this assumption is contestable. While HTDZs are indeed rooted in high-tech, knowledge-intensive industries that generate green spillover effects, they may also exhibit the classic "three-high" pattern—high input, high energy consumption, and high emissions—during their early development phases (Zhao et al., 2025). This is particularly true for zones located in resource-dependent cities or areas with a narrow industrial base, where the creation of HTDZs may exacerbate rather than alleviate the regional carbon burden. Furthermore, as the model of "enclave economy" and interregional industrial division deepens, some HTDZs have outsourced carbon-intensive and polluting segments of their production chains to smaller cities or rural peripheries, effectively engaging in "carbon leakage." This spatial outsourcing of environmental burden underscores not only the trade-off between economic growth and ecological protection but also deeper concerns about equity in regional development and the fair distribution of environmental responsibilities (Pan et al., 2024). While scholars have examined HTDZs' contributions to green transition—emphasizing innovation-driven growth, resource efficiency, or improvements in green total factor productivity—many studies overlook spatial heterogeneity and environmental equity dimensions (Ouyang et al., 2024; Liu et al., 2025). Despite these insights, few studies have examined the uneven spatial impacts of HTDZ expansion on carbon emissions, particularly within the framework of environmental justice (Kaya, 2021). Existing analyses often rely on administrative comparisons (e.g., across provinces or municipalities) rather than focusing on functional zones like HTDZs. Given the vast disparities in policy support, institutional capacity, and market access among HTDZs across China's regions, the lack of zone-level spatial analysis represents a major research gap (Luo et al., 2024). Moreover, although environmental justice has gained recognition in international climate discourse, its application to China's spatial development policies and HTDZ expansion remains nascent, especially in terms of empirical quantification. These spatial and developmental asymmetries may give rise to several problems: the outsourcing of emission responsibilities, the entrenchment of technological divides, and the externalization of ecological costs—all of which could compromise the overall fairness and effectiveness of China's decarbonization efforts.

In this context, clarifying the relationship between the expansion of HTDZ development scales and regional carbon emissions is both theoretically and practically significant. Theoretically, this paper integrates the perspectives of coupling coordination theory, spatial heterogeneity, and environmental justice. Coupling coordination theory emphasizes the interactive dynamics between development and emissions systems. Spatial heterogeneity theory underscores the non-uniformity of economic, social, and ecological systems across geographic units, challenging the one-size-fits-all policy approach. Environmental justice theory adds a normative dimension—arguing that the burdens and benefits of environmental outcomes must be equitably distributed and that mismatches between responsibility and capacity undermine social cohesion and policy legitimacy.

Guided by these frameworks, this study investigates 168 national-level HTDZs in China. It adopts a multi-method approach combining the entropy method, multi-scale geographically weighted regression (MGWR), and coupling coordination models to analyze the spatial coupling between HTDZ development and carbon emissions. Specifically, the study seeks to answer the following questions: (1) Does the expansion of HTDZs inevitably lead to increased regional carbon emissions? (2) Are there systematic spatial differences in the coupling and coordination between HTDZ development and carbon emissions? (3) Does HTDZ expansion exacerbate regional disparities in carbon responsibility, and does it raise concerns related to environmental justice? (4) How can policy be designed to ensure a synergistic relationship between high-quality development and low-carbon transition?

Compared with existing literature, this paper offers several contributions. First, it shifts the analytical focus from macro-level provinces or cities to HTDZs as functional spatial units, filling a critical research gap. Second, it employs a two-step empirical strategy—first measuring development-emissions coupling using a coordination model, then identifying spatial heterogeneity using MGWR—thus enhancing explanatory power. Third, it extends the debate beyond efficiency to fairness by assessing the spatial inequities in emission burdens and developmental

opportunities. Ultimately, the study aims to inform China's "dual carbon" strategy by offering differentiated policy recommendations for HTDZs, thereby enhancing both the environmental effectiveness and social equity of the green transition.

2. Data and Methods

2.1 Overview of the study area

By 2024, Chinese HTDZs have evolved from "policy lowlands" into "innovation highlands," occupying a pivotal position in global scientific innovation and the international division of labor. As of that year, there were 178 national-level HTDZs across the country, with development scale, industrial configuration, and global influence reaching globally leading standards. The geographic coordinates of these HTDZs were extracted via Baidu Maps based on their official listings. The spatial distribution of HTDZs in China currently follows a distinct "east-strong, west-weak" pattern, with the highest-output zones predominantly located in more economically advanced cities such as Beijing, Shanghai, Guangzhou, and Chengdu. In recent years, several HTDZs have begun to undergo deep transitions toward smart, green development (Figure 1). For example, Beijing's Zhongguancun HTDZ has positioned itself as a national hub for green technology research and demonstration, promoting low-carbon development through breakthroughs in renewable energy, hydrogen power, and energy storage technologies. The Zizhu HTDZ in Shanghai, capitalizing on the ecological resources of Minhang District, is exploring carbon sink trading mechanisms by quantifying the value of ecological products through urban greening and ecological restoration projects to support corporate carbon neutrality. Chengdu HTDZ is currently building a zero-carbon industrial park, equipped with a full life-cycle carbon footprint management platform to monitor and reduce emissions throughout the production chain. Meanwhile, Urumqi HTDZ in Xinjiang is experimenting with carbon emission statistics and monitoring platform to strengthen data governance for regional decarbonization.

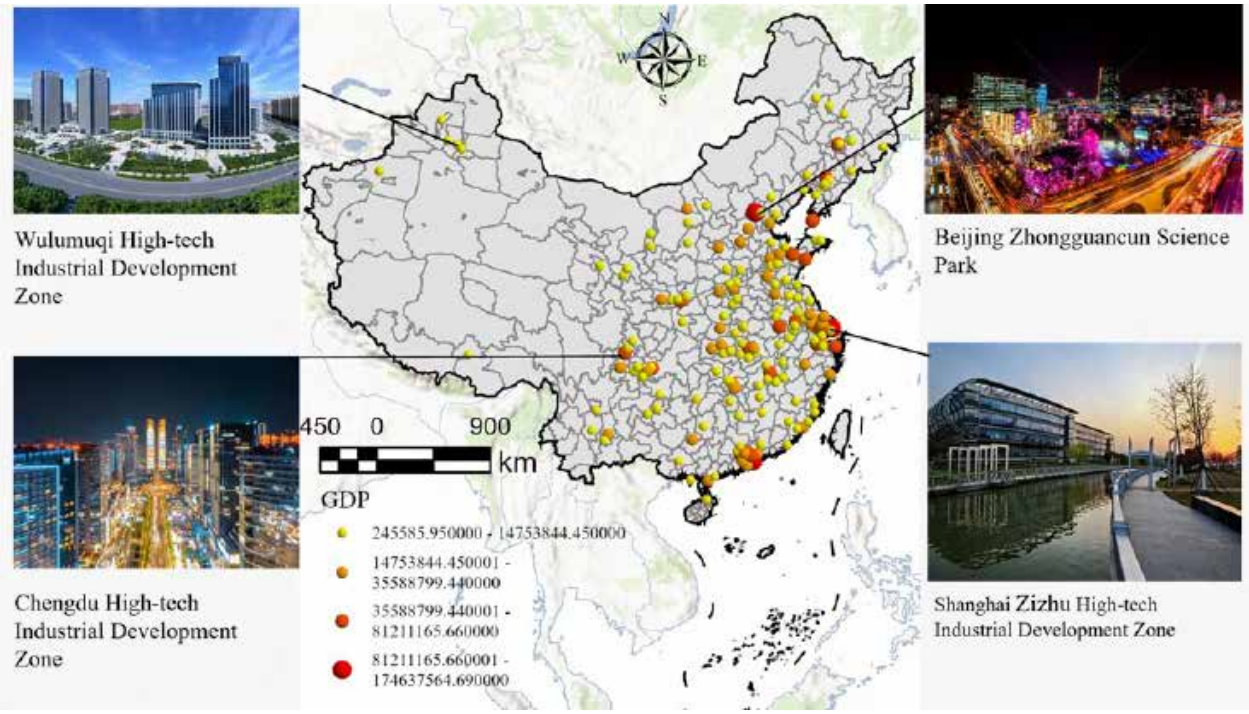

Figure 1 Overview of the study area

2.2 Research Methods

2.2.1 Entropy value method

We used relevant data from the high-tech zone and used the entropy method to calculate the index of investment, gross domestic product (GDP), technical income and export volume, and summarized it into the high-tech zone development scale index. The entropy method has the characteristics of objective weighting, comparability and flexibility. The calculation steps are as follows:

The first step involved standardizing the data by removing the units. The variable y_{ij} represents the data after the dimension was removed.

$$x'_{ij} = \frac{x - x_{min}}{xmin_{max}} \quad (1)$$

$$y_{ij} = \frac{x'_{ij}}{\sum x'_{ij}}, (0 \le y_{ij} \le 1) \quad (2)$$

The second step involved calculating the entropy value (e_j), the differentiation index (g_i), and the weight (w_j) for each indicator.

$$e_j = -k \sum_{y_{ij}} \ln y_{ij} \quad (3)$$

$$k = \frac{1}{\ln m} \quad (4)$$

$$g_j = 1 - e_j \quad (5)$$

$$w_j = \frac{g_j}{\sum g_j} \quad (6)$$

The third step involved calculating the index (c_{ij}) for the j-th indicator of the i-th HTDZ, based on the weights (w_j) of each indicator and the standardized matrix $y=\{y_{ij}\}$.

$$c_{ij} = w_j \times x'_{ij} \quad (7)$$

The fourth step involved summing up the index (c_{ij}) for each indicator to obtain the scale index (c_i) for each HTDZ.

$$c_i = \sum c_{ij} \quad (8)$$

2.2.2 Kernel density

To assess the spatial agglomeration or dispersion of HTDZ development, this study employed kernel density estimation (KDE)—a non-parametric statistical method widely used in ArcGIS to estimate spatial probability distributions. Kernel density values reflect the local intensity of industrial activity and spatial clustering. KDE provides critical insight into spatial hotspots, aiding the identification of dense innovation hubs and peripheral underdeveloped areas.

2.2.3 Coupling Coordination Model

To evaluate the degree of interaction and coordination between HTDZ development and carbon emissions, this study applied a coupling coordination model. Coupling degree is an index that quantifies the interaction intensity between two or more subsystems, indicating whether their evolution is synergistic or antagonistic. However, coupling degree alone may not capture the holistic coordination status due to dynamic inconsistencies among variables across regions. Hence, a comprehensive coupling coordination index was constructed to reflect the balance between economic development and environmental pressure. The formula is as follows:

$$\begin{cases} C = 2\sqrt{H_1 H_2 / (H_1 + H_2)^2} \\ T = xH_1 + yH_2 \\ D = \sqrt{CT} \end{cases} \quad (9)$$

where C is the degree of coupling. H_1H_2 are the normalized values of the selected elements 1 and 2, respectively. D is the coupling coordination degree $D \in$ (0, 1). and the coupling coordination degree is measured in the range of 0 to 1, which is divided into equal intervals at 0.1 intervals. From low to high, they are extremely dysbiscus, severe imbalance, moderate dissonance, mild dissonance, near dissonance, reluctant coordination, primary coordination, intermediate coordination, good coordination and good coordination. T is the harmonic coefficient of elements 1 and 2. x and y represent the weights of elements 1 and 2 respectively.

2.2.4 MGWR

MGWR is a spatial regression model developed on the basis of traditional global regression models (Ordinary Least Squares, OLS) and Geographically Weighted Regression (GWR) (Yin et al., 2024; Zhang et al., 2023). It is designed to explore the geographically varying relationships between dependent/response variables and independent/explanatory variables. The traditional OLS model does not account for potential spatial dependence and spatial heterogeneity among various influencing factors in research, which can lead to biased estimates. To address this spatial non-stationarity, the GWR model is employed. While GWR extends the OLS model by allowing local variations in relationships, it still suffers from a limitation: it uses a single bandwidth value for all variables across different regions, which may oversimplify spatial processes. MGWR improves upon the classical GWR model by incorporating spatially stationary variables, enabling each influencing factor to have its own unique bandwidth value. This enhancement makes the model estimates more accurate and reliable by better capturing the multiscale nature of spatial relationships.

$$y_i = \sum_{k=1}^{m} \alpha_k X_{ik} + \sum_{k=n+1}^{n} \beta_k(\mu_i, v_i) X_{ik} + \varepsilon_i \quad (10)$$

α_k is the global variable regression coefficient. β_k is the local variable regression coefficient. X_{ik} is the kernel density of the kth influencing factor in the i-th selection unit. (μ_i, v_i) is the coordinates of the i-th selection unit. ε_i is the random perturbation term of the i-th selection unit.

2.3 Data source

Development indicators for HTDZs include zone name, construction area, number of employees, enterprise count, GDP, technological revenues, and export volume. Construction area data were extracted from the Torch Statistical Yearbook, while the remaining economic indicators were sourced from the China Statistical Yearbook on Science and Technology. Carbon emissions data were obtained from the Emissions Database for Global Atmospheric Research database (EDGAR), allowing for the integration of environmental metrics into economic analysis (https://edgar.jrc.ec.europa.eu/).

3 Spatial characteristics of the development of HTDZs

3.1 Analysis of spatial heterogeneity in HTDZs

Geographically, the study divides China into seven macro-regions: North China, Central China, East China, South China, Northwest China, Northeast China, and Southwest China. The results reveal significant interregional disparities in the scale indices of HTDZs (Figure 2). Investment and technological scale indices vary substantially across regions, while export indices show relatively smaller disparities. GDP scale indices exhibit relatively uniform distributions across the regions. Geospatial analysis of China's HTDZs reveals persistent regional disparities in developmental patterns. Northern regions, particularly the Beijing-Tianjin-Hebei metropolitan cluster in North China and the Yangtze River Delta in East China, exhibit significantly greater input intensity and technological sophistication, manifested through concentrated capital allocation and dominant R&D expenditure profiles. In contrast, southern regions demonstrate distinctive export superiority, with the Pearl River Delta in South China and urban agglomerations in Central China achieving elevated export volumes attributed to strategic coastal logistics advantages and deep integration within global industrial value chains. Innovation resources display a pronounced north-south bifurcation, characterized by northern HTDZs' command over strategic research infrastructure, while export activities adopt a dual-peak coastal-inland distribution. Coastal zones dominate high-value electronics trade through maritime accessibility, whereas inland clusters specialize in equipment manufacturing, reflecting the spatial articulation of China's dual development strategy that simultaneously cultivates indigenous innovation capacity and promotes export-oriented economic expansion.

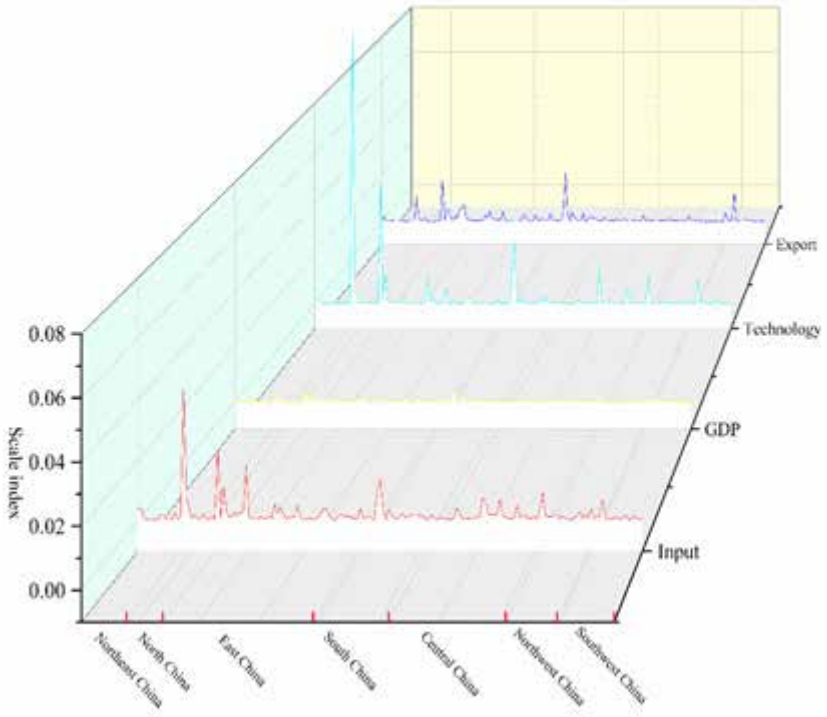

Figure 2 Heterogeneity of HTDZs

3.2 Distribution characteristics of the scale index of HTDZs

Aggregating the standardized indices of investment, technology, GDP, and exports yields a composite development scale index for each HTDZ (Figure 3). Kernel density analysis of these indices shows a "polycentric" spatial structure. Core development clusters are located in Beijing, Shanghai, and Guangzhou, which align closely with the Beijing-Tianjin-Hebei (Jing-Jin-Ji), Yangtze River Delta, and Pearl River Delta city clusters. Secondary peaks appear in Wuhan (Central China), Chengdu (Southwest China), and Xi'an (Northwest China), reflecting the radiating influence of national central cities. In contrast, HTDZs in Northeast China, parts of Northwest China, and much of Southwest China exhibit relatively low development scale values. The limited number of core clusters highlights persistent regional imbalances. While this polycentric configuration strengthens competitiveness in leading regions, it also risks marginalizing peripheral areas into a state of "low-end lock-in," where development stagnates without targeted intervention. Thus, policy mechanisms are urgently needed to enhance interregional factor mobility and collaborative governance.

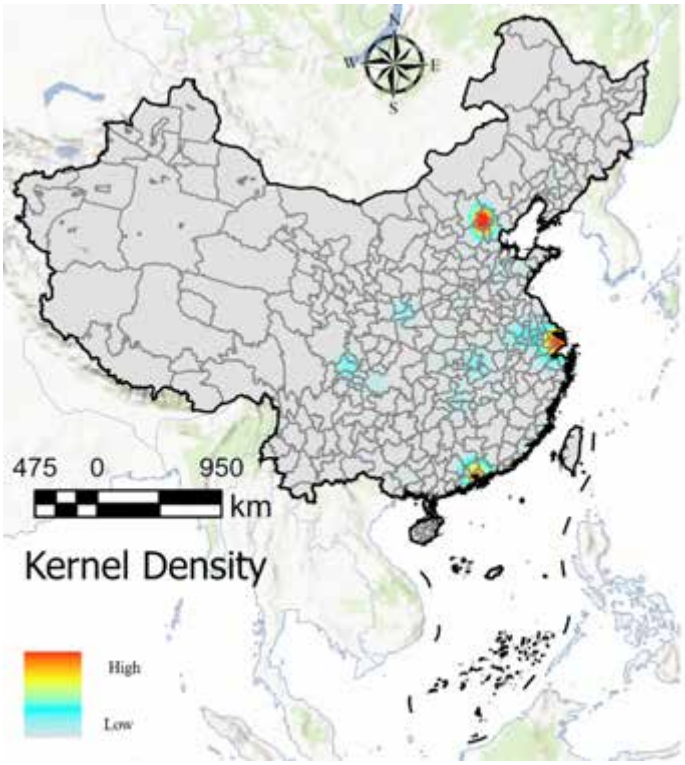

Figure 3 Results of kernel density analysis

4 Analysis of the synergistic nature of HTDZ development and carbon emissions

4.1 Differences between regional HTDZ development and carbon emissions

A significant spatial disparity also emerges in the relationship between economic output and carbon emissions across HTDZs. As shown in Figure 4, HTDZs in East and South China generate higher GDP contributions but maintain comparatively moderate carbon emission intensities, positioning them as low-carbon leaders. In contrast, HTDZs in Northwest and North China yield lower GDP outputs yet face disproportionately high carbon intensities. These findings suggest a spatially unjust distribution of emission burdens—where certain regions enjoy greater economic benefits with lower environmental costs, while others shoulder higher emissions despite lesser development returns. This spatial injustice is exacerbated by several structural mechanisms. First, leading HTDZs in the East often offload carbon-intensive segments—such as metal processing or chemical intermediates—to HTDZs in the Central and Western regions through vertical industrial disintegration. Despite this outsourcing, carbon emissions are still accounted for at the production end, effectively separating environmental responsibility from economic gain. Second, HTDZs in the Central-East region are at the forefront of green R\&D, particularly in hydrogen energy and nuclear fusion, whereas many Western HTDZs still rely on carbon-intensive technologies such as gas-fired boilers. This results in a technology divide and hinders cross-regional transition capabilities.

Third, due to spatial mismatches in policy tools and administrative capacity, HTDZs in core urban regions receive disproportionately higher subsidies for clean energy adoption, further increasing the carbon reduction burden on less-developed HTDZs.

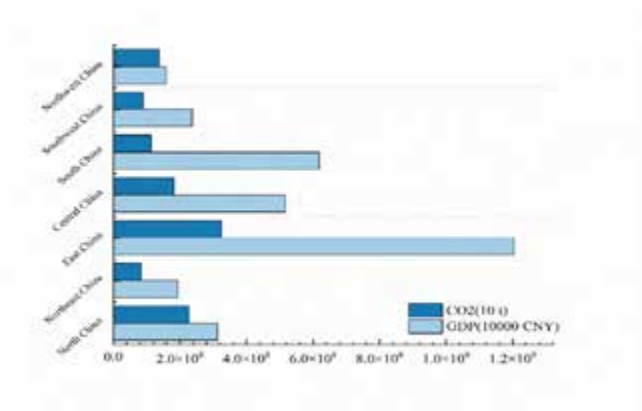

Figure 4 Output value and carbon emission of HTDZs in different regions

4.2 Coupling and coordination analysis of HTDZs and carbon emissions

To enhance the precision of measurement, this study constructed evenly spaced geographic sampling points across the national territory, calculating the micro-regional coupling coordination between HTDZ development and carbon emissions. The results indicate that overall coordination levels remain low nationwide (Figure 5). Nevertheless, relatively better coupling performance is observed in Southeastern China, coastal regions, central urban areas, and selected cities in the Southwest and Northeast. In contrast, most other regions remain in a state of serious imbalance.

These spatial disparities confirm the presence of pronounced environmental justice issues in the coordination between HTDZ development and carbon emissions. Specifically, the division of industrial labor has led to the transfer of high-carbon activities to less-developed regions without commensurate policy compensation or technology support. Meanwhile, institutional and fiscal privileges continue to concentrate in developed HTDZs, thereby deepening the structural disadvantage of others.

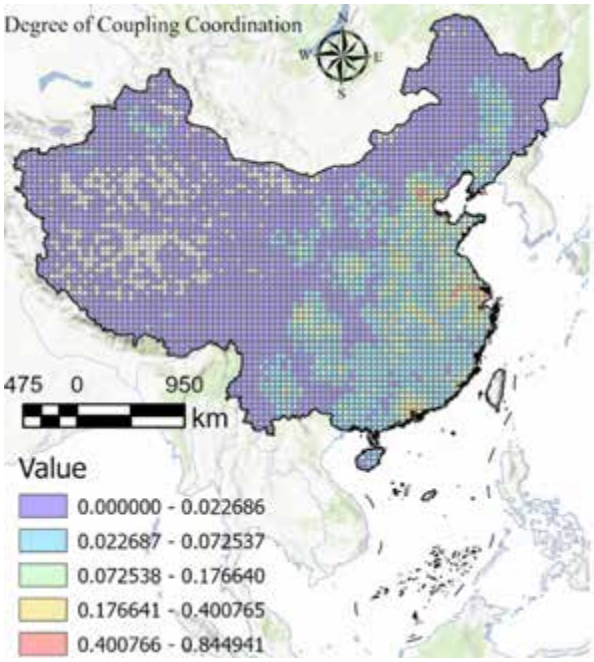

Figure 5 Coupling coordination analysis

4.3 Analysis of the impact of the development of HTDZs on regional carbon emissions

The spatial distribution of HTDZs' influence on regional carbon emissions shows significant spatial differences (Figure 6). The impact is strongest in the central-eastern regions, particularly in the Yangtze River Delta, where HTDZs are large in scale and equipped with advanced low-carbon technologies. Western regions, especially Tibet and Xinjiang, show a weak linkage between HTDZ development and regional emissions, largely due to their reliance on electricity exports and limited local green energy consumption. In these provinces, products such as electrolytic aluminum and polysilicon have high carbon footprints, and despite being powered by renewable energy, the "green electricity is exported, while carbon is retained." In the rest of the country, the influence of HTDZs on regional carbon emissions is statistically insignificant—likely due to the offsetting effect between moderate development scales and incomplete decarbonization measures.

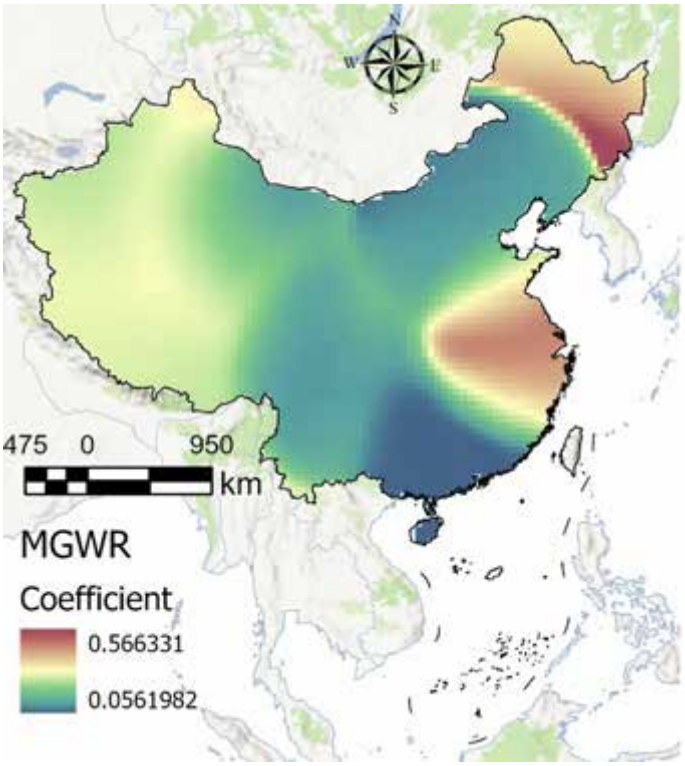

Figure 6 Mgwr model results

5 Conclusions and Recommendations

5.1 Conclusions

This study, guided by the dual perspectives of spatial heterogeneity and environmental justice, systematically investigates the complex relationship between the expansion of high-tech development zones (HTDZs) and regional carbon emissions in China. The main conclusions are as follows:

1. HTDZ development exhibits significant spatial disparities. HTDZs in eastern China—especially those located in major urban clusters such as the Beijing-Tianjin-Hebei region, the Yangtze River Delta, and the Pearl River Delta—are far ahead in terms of investment scale, technological capabilities, and economic output. These areas demonstrate a distinct "polycentric" development pattern. In contrast, HTDZs in central, western, and northeastern China remain at relatively low development levels, highlighting regional imbalances.

2. The relationship between HTDZ development and carbon emissions is spatially heterogeneous. Zones with larger development scales tend to benefit from advanced technologies and managerial efficiencies, resulting in higher resource productivity and lower carbon intensity—exemplifying a "high-output, low-emission" pattern. In contrast, underdeveloped HTDZs often face technological and financial constraints that hinder low-carbon transitions, leading to a "low-output, high-emission" outcome

3. The coupling coordination between development and emissions remains generally weak, though with clear regional variation. Coastal and economically advanced regions exhibit stronger coordination between HTDZ development and carbon emission reduction. However, most central and western HTDZs—particularly those in resource-dependent areas—display low coupling coordination, revealing a mismatch between economic growth and environmental sustainability. This reflects a deeper issue of spatial environmental injustice.

4. Environmental justice concerns are becoming increasingly prominent. Some HTDZs in developed eastern regions transfer carbon-intensive production segments to less-developed central and western zones, resulting in a "carbon responsibility shift." Meanwhile, access to clean energy R\&D and policy resources is highly concentrated in a few core regions. Peripheral zones, with limited capacity for green transition, are left with disproportionate emission burdens, exacerbating regional inequality.

5.2 Recommendations

In response to the pronounced spatial heterogeneity and environmental inequality observed between HTDZ expansion and regional carbon emissions, we propose the following four policy directions to promote greener, more equitable, and more coordinated development.

Develop regionally differentiated support systems for green development. The stark differences in HTDZ development across eastern, central, and western China render uniform policy approaches ineffective. Eastern HTDZs should continue to play a leading role in green innovation and technology diffusion, setting national standards. At the same time, targeted support mechanisms—including fiscal transfers, talent attraction programs, and technical assistance—must be established to assist HTDZs in the central and western regions. For example, a "paired assistance" model could be adopted to facilitate the transfer of green technologies from eastern to western HTDZs, bridging the technological divide and preventing carbon lock-in.

Establish cross-regional carbon emission coordination and burden-sharing mechanisms. To address issues such as carbon leakage and the retention of high emissions in underdeveloped areas, it is essential to develop mechanisms for cross-regional coordination of emission responsibilities. A shift from production-based to consumption-based or life-cycle carbon accounting would allow for more equitable attribution of emissions. Simultaneously, a multi-level carbon compensation system should be introduced—where regions that absorb high-carbon industries receive fiscal incentives and ecological compensation—to foster a synergistic and fair reduction framework.

Enhance the modern governance capacity of HTDZs in green transition. Many HTDZs currently lack robust systems for carbon data collection and green governance. We recommend accelerating the development of integrated platforms for data acquisition, monitoring, and governance to improve the digital management of emissions. A multi-stakeholder governance model—engaging governments, enterprises, research institutions, and the public—should be constructed. Emphasis should be placed on green industry entry thresholds, carbon performance evaluations, and public transparency to ensure effective policy implementation and emission reduction accountability.

Promote the synergy between green finance and technological innovation. Green finance is a critical enabler for HTDZs' transition toward sustainability. Financial instruments such as green credit, green bonds, and carbon markets should be leveraged to incentivize investments in renewable energy, environmental protection, and low-carbon technologies. Moreover, the innovation–application–diffusion chain must be accelerated by establishing green incubators and demonstration projects to facilitate the commercialization of green technologies and enhance the green production capacity of enterprises within HTDZs.

5.3 Limitations and prospects

This study proposed an empirical framework and policy recommendations from the perspective of environmental justice regarding the relationship between the expansion of high-tech zone development scales and regional carbon emissions. However, it still has the following limitations. The MGWR model used in this paper revealed spatial differences in the impact of high-tech zone development on carbon emissions but lacked causal identification methods to uncover the dynamic mechanisms of the influence pathways. Future research could incorporate econometric methods such as regression discontinuity, difference-in-differences, and event studies

to explore the mediating or moderating effects of factors like policy interventions and technological investments in the "development-emissions" relationship. The current environmental justice analysis primarily focuses on spatial comparisons between carbon emissions and development imbalances, lacking further delineation of social group disparities. Subsequent research could integrate micro-level survey data and socioeconomic variables to construct a more comprehensive environmental equity assessment framework, enabling more precise identification of environmental risks faced by disadvantaged regions and populations.

Future studies should focus on a comprehensive analysis framework of "multi-scale, multi-actor, and multi-path," enhancing the integration of data accuracy, mechanism identification, and social equity. This would provide stronger theoretical support and decision-making references for achieving the synergistic goals of regional carbon neutrality and environmental equity.

Abstract
This study aimed to understand whether children living in neighbourhoods with higher particulate matter (PM) concentrations report more air pollution-related issues than children living in neighbourhoods with lower PM concentrations and whether these issues vary across neighbourhoods with different built environment characteristics. Data were drawn from participatory mapping activities with 9–14-year-old children living in eight neighbourhoods of Ankara, Türkiye, objectively analysed urban form characteristics of these neighbourhoods, and $PM_{2.5}$ and PM_{10} measurements in children's places in a heating and non-heating season. Results show that as the built environment characteristics and $PM_{2.5}$ and PM_{10} concentrations of children's neighbourhoods change, the proportions of air pollution-related issues reported by children alter.

Keywords: outdoor air pollution; particulate matter; children's place experiences; neighbourhood; participatory mapping

1. Introduction

Outdoor air pollution is a major threat to global public health, responsible for 4.2 million deaths worldwide in 2019 (World Health Organization, 2021). According to a report published by the World Health Organization (2018), roughly more than 90% of children under the age of 15 years breathe polluted air, affecting their health and well-being negatively. Children are particularly vulnerable due to their higher respiration rates, developing organs and proximity to ground-level pollutants. One major consequence of air pollution is asthma – a chronic inflammatory disease of the airways that usually develops in childhood (Graham, 2004; Hammad and Lambrecht, 2021; Vörös et al., 2019). Some other health impacts of air pollution to children are brain functioning problems (Markevych et al., 2021), issues related to skeletal growth (Sram et al., 2013), increased overweight and obesity (Zhou et al., 2021), increased susceptibility to respiratory infections (Krismanuel et al., 2024), and pneumonia (Nhung et al., 2017).

Additionally, prior research has shown strong associations between air pollution and academic success of children (Miller and Vela, 2013). Even the perception of polluted air may affect children's behaviour and well-being negatively (Chen et al., 2020).

There is a voluminous amount of literature linking built environment to air pollution in children's home and school neighbourhoods (Aydin and Severcan, 2024; Lim et al., 2017; Ortegon-Sanchez et al., 2021; Roche et al., 2024). A closer review of this literature shows that there are two groups of researchers concerned with these relationships. The first group, quantitative researchers, mainly consists of scientists affiliated with the departments of engineering, environmental sciences, and environmental epidemiology (see, e.g., Dadvand et al., 2015; Demirel et al., 2014; Lim et al., 2017; Mohai et al., 2011; Rivas et al., 2014). By objectively measuring outdoor air pollution and built environment, these scholars have largely questioned the physical environmental correlates of outdoor air pollution around children's homes and schools – e.g., living in an urban or rural area, traffic, building density, and neighbourhood greenness. The second group, qualitative researchers, is fewer in number compared to quantitative researchers and is mostly affiliated with the fields of sociology, psychology, and education (see, e.g., Börner et al., 2017; Duran, 2021; Manouchehri and Burns, 2023). The common characteristic of these scholars is that they have directly engaged children in research to understand whether young people perceive the environmental problems in their everyday environments (including air pollution) and the factors that affect children's perceptions. The self-reported data have been presented in qualitative, semi-qualitative or quantitative forms. In general, while these studies are exploratory in nature, their results can inform urban planning and design about how to design neighbourhoods with better air quality. Our review of the literature revealed that there is a lack of interdisciplinary research that bridges these two groups of researchers. Perhaps partly for this reason, we could not find any studies that linked children's negative place experiences regarding air pollution-related issues to the actual outdoor air quality levels of their neighbourhoods with varying built environment characteristics.

Drawing on an interdisciplinary, cross-sectional research project with a novel research design, this study aimed to understand whether children report more negative experiences about outdoor air pollution in school neighbourhoods with higher particulate matter ($PM_{2.5}$ and PM_{10}) concentrations. We also questioned whether these air pollution-related issues are related to the built environment. This study is important because finding a match between high levels of neighbourhood air pollution and a few negative outdoor experiences related to air quality can support the prior claims of qualitative researchers that there is a relationship between built environment, outdoor air pollution and outdoor place experiences of children (Börner et al., 2017). Furthermore, the results presented here may lead future studies to consider the reasons of a possible mismatch between children's negative place experiences related to outdoor air pollution and the actual air quality levels of children's neighbourhoods. They also pave the way for the creation of healthier environments for children.

The remainder of this paper is organised into three main parts. The next section provides a background information about the factors affecting PM concentrations and how these factors may affect children's place experiences. This is followed by the method and results section. The paper concludes with a discussion of the results, implications for urban planning and design, and limitations of the study.

2. Literature review

This section provides a brief summary of the literature relevant to this study.

2.1. *Factors that influence the level of $PM_{2.5}$ and PM_{10} concentrations*

PM (particulate matter), described as the mixture of solid particles and liquid droplets in the air, is one of the most serios air pollution problems in the world (Sun et al., 2014). PM is classified by particle size. Particles with size not exceeding 2.5 μm are known as $PM_{2.5}$ or "fine PM." $PM_{2.5}$ and smaller (ultra-fine particles) are known to be highly dangerous for children's health since they can penetrate deep into their lungs (Pope and Dockery, 2006). PM_{10} refers to particulate matter smaller than 10 μm in diameter.

The sources of PM can be human-made (e.g., transport- or industry-related) or natural (e.g., dust storms, volcanoes). It is commonly accepted that human-made (also called anthropogenic) sources are more important than natural sources in urban areas. Some common sources of $PM_{2.5}$ and PM_{10} in urban areas are related to industrial emissions, domestic heating, vehicle engines, and construction activities. PM_{10} mainly originates from

soil dust resuspension, construction, non-exhaust vehicle emissions and industrial dusts, whereas $PM_{2.5}$ is largely derived from combustion processes (industrial combustion), mining and construction activities, fires or burning of the wood and transformation of gaseous species (Gugamsetty et al., 2012). The main sources of $PM_{2.5}$ and PM_{10} concentrations may vary from one city to another based on their characteristics. For example, Qin et al. (2006) found that in metropolitan New York City, most of the $PM_{2.5}$ concentrations derive from transport (e.g., diesel engines and trucks), whereas another study conducted in an industrialised region of China, Pearl River Delta Economic Zone, showed that the average concentrations of $PM_{2.5}$ in roadside and industrial areas are not significantly different (Wang et al., 2016). Some other studies argued that most of the PM in the atmosphere originates from the construction industry (Cheriyan et al., 2020).

The sources of PM in urban settings are often difficult to detect, posing challenges for urban planners aiming to design neighbourhoods with improved air quality. This difficulty stems partly from the complex nature of PM, which includes both anthropogenic, natural and biological particles such as dust and pollens (Ortega-Rosas et al., 2021). For example, research shows that living close to urban green areas on the one hand and to roads with heavy traffic may increase residents' PM exposure (Capone et al., 2023; McCarty and Kaza, 2015; Vörös et al., 2019). Elevated pollen concentrations may increase PM concentrations. In green open spaces located next to industrial areas, industry-related particles may attach to pollen surfaces, increasing green space users' PM exposure (Ortega-Rosas et al., 2021). However, there is also a great deal of literature showing how green open spaces play a key role in reducing PM concentrations in cities (Han et al., 2020).

Another reason is the complexity of the relationships among the variables. Existing findings regarding the role of built environment in PM concentrations are contradictory, and thus inconclusive. Multiple factors affect an individual's PM exposure: meteorological (e.g., temperature, humidity, wind), physical environmental (e.g., elevation of neighbourhoods, proximity to major roads and industrial facilities, morphology at various scales – like leaf morphology, clustering of the vegetation or land uses) and behavioural (e.g., time of place use, duration of exposure to transport-related pollution) (Adgate et al., 2002; Han et al., 2020; Ning et al., 2018; Qin et al., 2006; Zender-Swiercz et al., 2024). These factors are in relationship with one another, causing an individual's PM exposure to differ from one place or time to another.

Meteorological factors complicate the relationship between built environment and PM concentrations. Higher PM concentrations are linked to higher air temperatures, higher humidity, and lower wind speeds (Jayamurugan et al., 2013). Thus, one can observe different associations between green open spaces (or built-up areas) and PM in different seasons (Sabir et al., 2024). Certainly, the issue that particles can travel long distances with the wind (even from one country to another) makes it challenging for researchers to relate outdoor PM concentrations to a particular built environment variable (like presence of green spaces or traffic). In urban neighbourhoods, temperature and wind speeds can be affected by various built environment features – at meso-scale, e.g., building density, layout of the buildings, and neighbourhood greenness (Bonan, 2008; Spirn, 1987).

Neighbourhoods with higher building density are usually associated with more building surfaces, and thus higher thermal load (Chen et al., 2017). Scholars like Spirn (1987) and Makvandi et al. (2024) discuss how increased building density results in a decrease in air flow at the street level. On the other hand, some scholars linked built environment attributes like building density, street connectivity, land use mix and neighbourhood greenness to greater outdoor physical activity, and thus to lower transport-related PM concentrations (Frank et al., 2006) (for conflicting results, see, e.g., Zlatkovic et al., 2019, who showed that well-connected streets in neighbourhoods is associated with high traffic density, and thus lower air quality).

At the micro-scale, various urban design characteristics may affect PM concentrations. The size of green spaces and layout of planting in these areas (Qiu et al., 2018), and presence of land uses that generate vehicle traffic (e.g., commercial and educational areas, gas stations, bus station, and construction sites) (Razak et al., 2023; Yan et al., 2019; Yang et al., 2017) are some of the factors affecting PM. At certain hours of the day (like school/business opening and closure hours), PM concentrations tend to increase around such land uses (Razak et al., 2023). Increased outdoor $PM_{2.5}$ and PM_{10} concentrations are also associated with proximity to waste dump sites (Chkwu Okeah et al., 2021; Jatau et al., 2024), wood and waste burning activities (Fuller et al., 2014; Mouganie et al., 2023), and outdoor smoking (Acevedo-Bolton et al., 2014).

2.2. *The role of air pollution in children's place experiences: What do we already know?*

Studies show that when children are asked about the problems of their neighbourhoods, they mention a variety of problems related to outdoor air quality: e.g., traffic-related pollution (Börner et al., 2017), industry-related pollution (Börner et al., 2017; Ozbil Torun et al., 2024), smelly trash cans (Loukaitou-Sideris, 2003), smoking (Duran, 2021; Pluhar et al., 2009), places with high pollen concentrations (Pluhar et al., 2009), and problems related to deforestation, urbanisation and replacement of urban green spaces with buildings (Duzenli et al., 2019). Although these problems are known to effect children's place experiences negatively, little is known whether children living in neighbourhoods with higher particulate matter (PM) concentrations report more air pollution-related issues than children living in neighbourhoods with lower PM concentrations, and whether these issues vary across neighbourhoods with different built environment characteristics. This paper aims to fill these gaps in the literature.

3. Method

This study was carried out in the capital of Türkiye, Ankara. Data were drawn from a larger-scale, interdisciplinary research project bringing together urban planners and designers, who were specialised in urban form analysis and children's geographies, environmental engineers specialised in air pollution, and paediatricians specialised in childhood asthma. Our method consisted of eight steps which are explained in the following eight subsections.

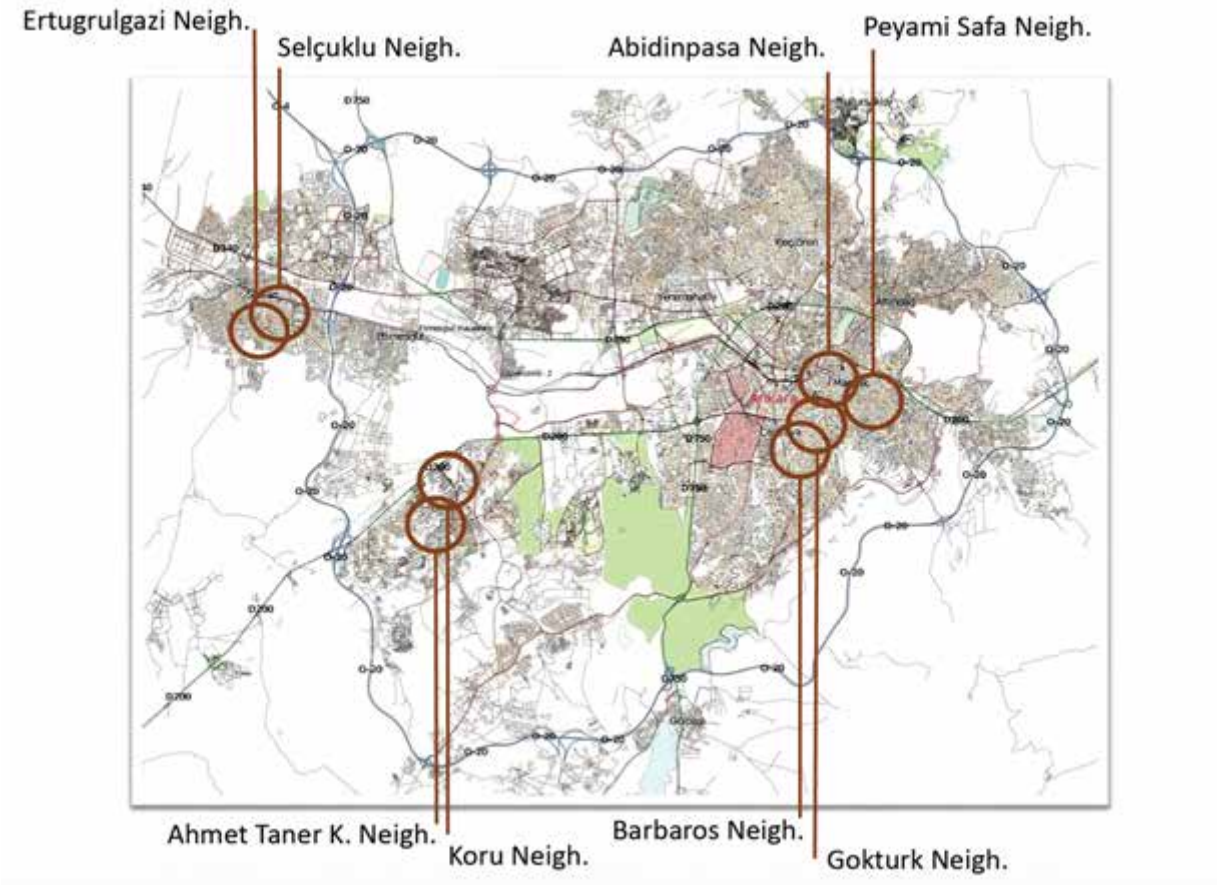

Figure 1. Location of the selected neighbourhoods.

3.1. *Site selection*

This study was conducted in eight neighbourhoods in Ankara: from Cankaya district: Gokturk, Barbaros, Koru and Ahmet Taner Kislali neighbourhoods, from Mamak district: Abidinpasa and Peyami Safa neighbourhoods, and from Sincan district: Selcuklu and Ertugrulgazi neighbourhoods. Figure 1 shows the location of these neighbourhoods in the city. Details of the site selection process can be found in Aydin (2023). All neighbourhoods differed in their built environment characteristics (e.g., proximity to industrial areas, forests, building density, land use mix, street connectivity, neighbourhood greenness, elevation, traffic) (*ibid.*)

3.2. *Investigation of the built environment characteristics of the selected sites*

Built environment characteristics of the selected sites were measured objectively using Geographic Information System (GIS) tools. The process consisted of several steps: (1) obtaining GIS data from the metropolitan municipality, (2) creating 800-meter buffers around all public schools located within the administrative borders of the selected neighbourhoods (these buffer areas represented school neighbourhood areas), (3) field observations to document the most recent land uses, building heights and building typologies in the school neighbourhoods, (4) updating the GIS data set based on the field notes, and (5) GIS-based analysis of built environment attributes of the selected neighbourhoods. Neighbourhood boundaries were defined by joining the boundaries of school neighbourhoods in each administrative area.

For the purpose of this study, we classified the selected neighbourhoods based on their land use mix and neighbourhood greenness. We selected these variables because previous studies have shown their association with PM and they were available in our data set. While our initial aim was to classify neighbourhoods based on some additional built environment variables like building density and proximity to industrial facilities, as we have shown in the following sections of this paper, children rarely mentioned such variables as problems in their neighbourhoods. We could not observe any difference between the average traffic density of the selected school neighbourhoods, which led us not to classify neighbourhoods based on this variable. However, in line with what Frank et al. (2006) suggested, we assumed that compared to children living in neighbourhoods with lower land use mix, children living in neighbourhoods with a higher land use mix would report less vehicle traffic issues.

Table 1. Built environment characteristics of the selected neighbourhoods.

		Neighbourhood greenness
Neighbourhood	Land use mix	
Barbaros	0.69	0.44
Gokturk	0.41	0.54
Koru	0.62	0.66
Ahmet Taner Kislali	0.52	0.68
Abidinpasa	0.50	0.47
Peyami Safa	0.37	0.44
Selcuklu	0.49	0.50
Ertugrulgazi	0.36	0.55

Land use mix, at the building level, was measured by the land use entropy score, indicating the level of land use diversity (Saelens et al., 2003). The index ranges from 0 to 1, where 1 refers to a perfect mix and 0 refers to a perfect homogeneity. Neighbourhood greenness was calculated by dividing the total area of permeable surfaces (softscapes) by the buffer area. Details of the analysis process can be found in the study of Aydin (2023). Table 1 shows the results of these analyses.

3.3. *Participant selection*

Child participants were selected in several stages. First, we selected all the public schools located inside the administrative boundaries of the chosen neighbourhoods. After obtaining the necessary ethical approvals from the university's ethics board and Ministry of Education, we went to the selected schools to distribute the consent forms and explain the study to 9–14-year-old children (third to eighth graders). Sixteen schools were visited for this purpose. All children who wanted to participate in the study and returned the parent-signed consent forms were accepted. This study is based on data drawn from participatory mapping activities with children.

3.4. *Participatory mapping activities with children*

Participatory mapping is a method used for linking children's views of their environments to specific geographical contexts (Ozbil Torun et al., 2024). In our study, we used this data collection technique for various reasons: e.g., to find out the most frequently used places of children so that these places can be used for measuring the outdoor PM concentrations in the further stages of our research, and to document children's negative places experiences. In total, 1687 children participated in participatory mapping activities.

The process started by grouping children into groups of 5-7 in the empty classrooms and conference rooms of the selected schools. Thereafter a trained moderator gave each group of children a 50x70cm poster, which consisted of a high-quality satellite image of the chosen school neighbourhoods and a blank map legend under it. This image showed an area within 800-meter radius of the school. Next, followed by a process where children were shown how to read satellite images, children were asked to pinpoint their homes and the places they frequent and like on the map. Two different procedures were used in this stage: while some participants were asked to explain their responses in detail (e.g., what they do in these places, why they like them) (n=881), others were not asked about such details because of the time restrictions (n=806). Finally, on another blank base map, children (n=1687) were asked to pinpoint the places they see problematic and/or dislike in their school neighbourhoods and discuss the reasons of their responses. Children used unique stickers when documenting their responses and recorded the meaning of each sticker in the legend (Figure 2). The whole process took about 1.5 hours.

Figure 2. Photographs from participatory mapping activities.

3.5. *Data coding and analysis to define children's frequently used places*

We followed a five-step process for the selection of PM measurement sites. First, we digitised 1687 children's positive places in GIS. This process resulted in the coding of 8704 positive places in the selected neighbourhoods. Second, we deleted the overlapping points in ArcGIS to avoid repetition after transferring their content (e.g., how many children mentioned them) into the retained points. This reduced the total number of points into 2355. Third, we investigated the built environment characteristics (e.g., building density, street connectivity, land use mix, neighbourhood greenness, etc.) of the surrounding of these places to select the most spatially unique PM measurements sites in the following stages of the research. Fourth, after normalizing the data, we used a hierarchical cluster analysis to group children's places with similar built environment characteristics. Twenty clusters were produced for each neighbourhood. For clustering, we used Ward's method and squared Euclidian distance. Fifth, we selected the most frequently mentioned place/point from each cluster. Thus, from eight neighbourhoods, 160 points were selected for PM measurements. A range of places were selected such as neighbourhood parks, urban parks, school yards, streets with ground floor retail and home gardens.

3.6. *$PM_{2.5}$ and PM_{10} measurements in children's frequently used places*

$PM_{2.5}$ and PM_{10} measurements were performed in the selected sites twice, one during heating season (March 22 – April 18, 2023, average temperature: 14.8 °C) and another during non-heating season (May 27 – June 15, 2023, average temperature: 20.95 °C). We used two DustTrak aerosol monitors (Model 8530), one for measuring $PM_{2.5}$ and the another for measuring PM_{10} concentrations. In each children's place, we zero calibrated the devices and concurrently carried out the PM measurements for 7 minutes at a height close to children's breathing height (Figure 3). We explained the details of this procedure elsewhere in another paper.

Figure 3. Photographs from $PM_{2.5}$ and PM_{10} measurements.

In our analysis, we considered the data obtained during the last 5 minutes of the PM measurements. Table 2 shows the average $PM_{2.5}$ and PM_{10} concentrations of each neighbourhood in different measurement periods. When presenting the results, the data obtained from Koru and Ahmet Taner Kislali neighbourhoods – two adjacently located neighbourhoods showing similar built environment characteristics – were merged for the reason we explained in next section.

Table 2. Average $PM_{2.5}$ and PM_{10} concentrations (µg/m³) in the selected neighbourhoods.

	Heating season (March-April 2023)		Non-heating season (May-June 2023)	
Neighbourhoods	$PM_{2.5}$	PM_{10}	$PM_{2.5}$	PM_{10}
Barbaros	26.547	24.179	42.421	48.295
Gokturk	20.274	19.158	48.905	58.863
Koru + Ahmer Taner K.	46.979	55.313	17.862	20.800
Abidinpasa	33.126	41.389	33.084	38.516
Peyami Safa	27.274	34.263	36.768	42.789
Selcuklu	48.480	47.130	22.550	25.720
Ertugrulgazi	64.863	72.800	18.032	21.168

Our findings indicate that $PM_{2.5}$ and PM_{10} concentrations diminished in peripheral neighbourhoods of Ankara (Koru, Ahmet Taner Kislali, Selcuklu, and Ertugrulgazi) while escalating in neighbourhoods near the city centre as temperatures rose. In heating season, $PM_{2.5}$ concentrations ranged from 20.27 µg/m³ (in Gokturk) to 64.86 µg/m³ (Ertugrulgazi); PM_{10} concentrations ranged from 19.16 µg/m³ (Gokturk) to 72.80 µg/m³ (Ertugrulgazi). In non-heating season, $PM_{2.5}$ concentrations ranged from 17.86 µg/m³ (Koru and Ahmet Taner Kislali) to 48.90 µg/m³ (Gokturk); PM_{10} concentrations ranged from 20.80 µg/m³ (Koru and Ahmet Taner Kislali) to 58.86 µg/m³ (Gokturk).

3.7. *Analysing children's negative places*

This process consisted of three stages. First, we digitised 1687 children's negative places in GIS, which resulted in the coding of 4171 places in eight neighbourhoods. The distribution of these places across Barbaros, Gokturk, Abidinpasa, Peyami Safa, Koru and Ahmet Taner Kislali, Selcuklu and Ertugrulgazi neighbourhoods were 370, 640, 644, 457, 335, 906 and 819 respectively. In each of these places, children mentioned one problem related to that site (e.g., "*there are gangs here*", "*There is no traffic light in this street junction*", "*there are people burning coal here*", "*there is too much traffic in this street with high vehicle exhaust*"); our GIS data set included these statements. Thereafter we exported this data set to MAXQDA, a content analysis software.

While reviewing children's explanations of their experiences, we categorised these issues based on their themes. To this end, we used a thematic content analysis method to analyse children's statements.

Our findings indicate that six main themes emerged from the data set, one of which pertains to air quality. Out of 4171 issues mentioned by children, 1378 issues were in this category. We revealed 10 sub-categories under the air quality theme. Table 3 presents the distribution of these 1378 issues across these 10 sub-themes and neighbourhoods. Because of the low number of participants in Koru neighbourhood (n=22 children), for the purpose of this study, we merged the data obtained from Koru and Ahmet Taner Kislali neighbourhoods – two adjacently located neighbourhoods showing similar built environment characteristics. This table shows that, in Abidinpasa neighbourhood, 249 children mentioned 179 air quality-related problems in their school neighbourhoods, which corresponds to around 27.8% of all the problems mentioned. Out of 644 mentioned issues in this neighbourhood, 35 (5.4%) were in the category of places with lack of vegetation. Children mentioned various problems related to air quality, including transport- and construction-related air pollution issues, places with smelly trashes and smokers, and places where tree cutting activities take place. These results are in line with most previous research (e.g., Börner et al., 2017; Duran, 2021; Loukaitou-Sideris, 2003; Pluhar et al., 2009). Our results also suggest that neighbourhood characteristics may play a role in the issues mentioned by children. For example, compared to children living far from construction sites, more children mentioned construction related issues in the neighbourhood that gives an edge to construction sites (i.e., Ertugrulgazi).

Table 3. The number and frequency of outdoor air quality-related issues in the selected neighbourhoods.

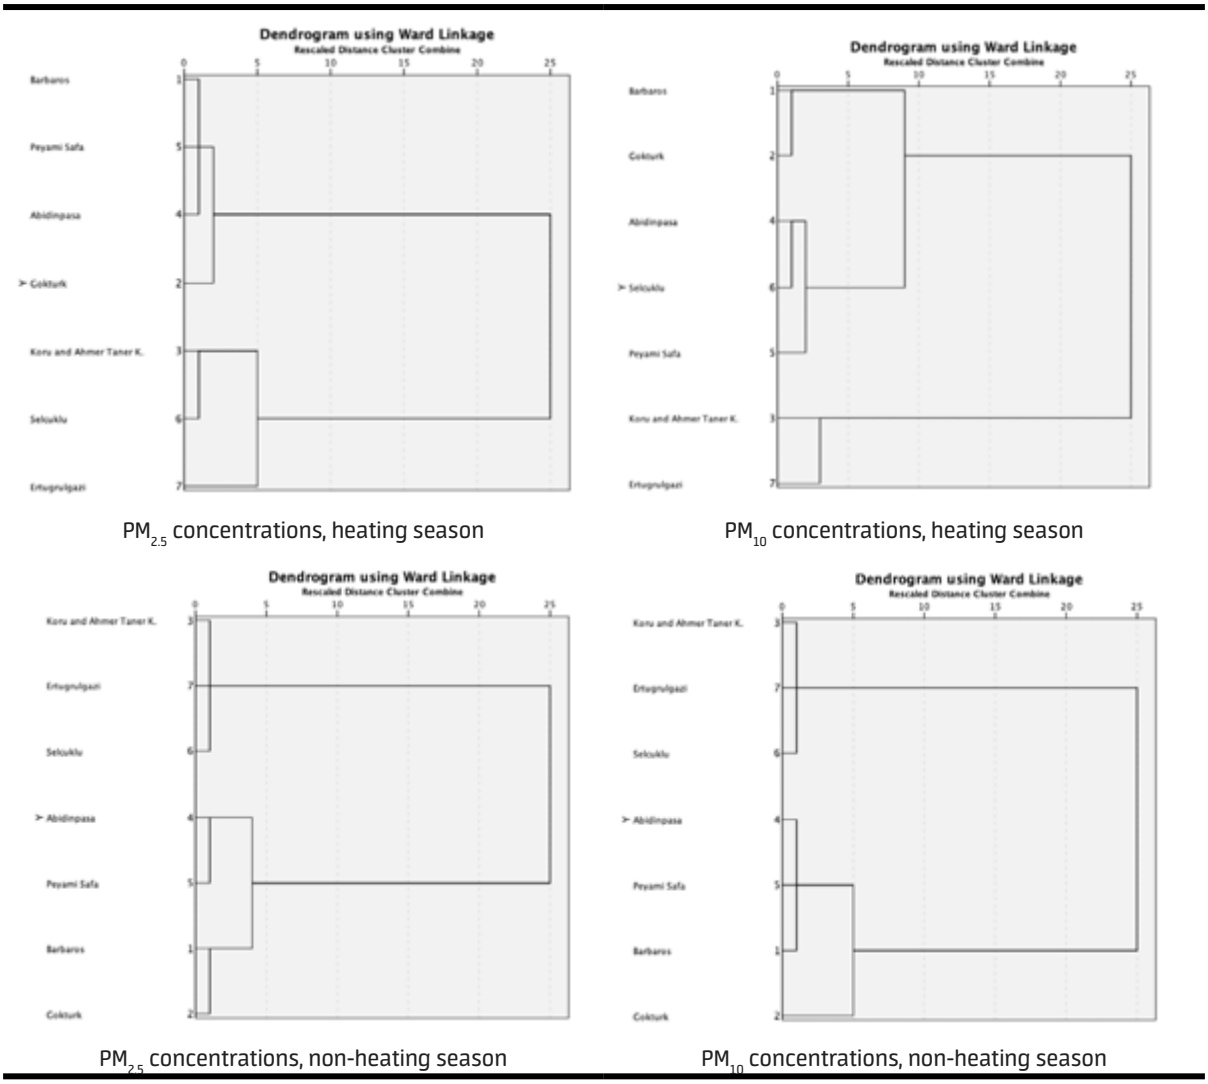
3.8. *Statistical analysis*

To respond the first research question, whether children report more negative experiences about outdoor air pollution in school neighbourhoods with higher particulate matter ($PM_{2.5}$ and PM_{10}) concentrations, we first grouped school neighbourhoods based on their average PM concentrations. Thereafter, we re-categorised the data presented in Table 3 according to our proposed new classification. To achieve the former step, we used a hierarchical cluster analysis based on Ward's method and squared Euclidian distances. As Figure 4 shows, with one exception (i.e., the clustering of the neighbourhoods based on PM_{10} concentrations in heating season), in all cases, the neighbourhoods located in the periphery and inner-city of Ankara were in separate clusters.

To respond the second research question, whether the air pollution-related issues mentioned by children are related to the built environment characteristics of their neighbourhoods, we first grouped school neighbourhoods based on their land use mix and neighbourhood greenness. Next, we re-categorised the data presented in Table 3 according to our proposed new classification. Figure 5 shows how the neighbourhoods in each cluster differed based on their built environment characteristics.

In all analysis, comparisons were made between two groups (e.g., neighbourhoods with lower $PM_{2.5}$ concentrations and higher $PM_{2.5}$ concentrations in heating season). Since the number of children were different in each cluster, we compared the percentage distribution of the air quality-related problems rather than using t-test.



$PM_{2.5}$ concentrations, heating season

PM_{10} concentrations, heating season

$PM_{2.5}$ concentrations, non-heating season

PM_{10} concentrations, non-heating season

4. Results

4.1. *Children's air pollution-related experiences and PM concentrations of their neighbourhoods in different seasons*

In heating season, children living in neighbourhoods with higher $PM_{2.5}$ concentrations did not report more outdoor air pollution-related issues than children living in neighbourhoods with lower $PM_{2.5}$ concentrations (31.4% versus 34.3%), which is an unexpected finding (see Table 4). However, as expected, children living in neighbourhoods with higher PM_{10} concentrations reported more air pollution-related issues than children living in neighbourhoods with lower PM_{10} concentrations (36.8% versus 31.6%). The responses of children in Selcuklu neighbourhood were influential in this outcome as this neighbourhood was in different neighbourhood clusters in heating season. As Table 3 shows, different from the children in other neighbourhoods, more children in Selcuklu reported issues related to high levels of urbanisation. This neighbourhood is also known with its closeness to polluting industrial facilities and construction sites (Aydin, 2023).

Table 4. The number and frequency of outdoor air quality-related issues in neighbourhoods with lower and higher $PM_{2.5}$ and PM_{10} concentrations in heating season

Themes	Neighbourhoods with lower $PM_{2.5}$ concentrations (N=2111 issues) n (%)	Neighbourhoods with higher $PM_{2.5}$ concentrations (N=2060 issues) n (%)	Neighbourhoods with lower PM_{10} concentrations (N=3017) n (%)	Neighbourhoods with higher PM_{10} concentrations (N=1154) n (%)
Places with lack of vegetation	72 (3.4%)	68 (3.3%)	98 (3.2%)	42 (3.6%)
Highly urbanised places	–	7 (0.3%)	7 (0.2%)	–
Places with high traffic volume / the problem of exhaust gas in streets	272 (12.9%)	183 (8.8%)	336 (11.1%)	119 (10.3%)
Places with smelly trashes	230 (10.9%)	277 (13.3%)	323 (10.7%)	184 (15.9%)
Places with smokers	29 (1.4%)	14 (0.7%)	34 (1.1%)	9 (0.8%)
Places where coal burning activities take place	8 (0.4%)	2 (0.1%)	10 (0.3%)	–

Places where people burn fire	14 (0.6%)	12 (0.6%)	24 (0.8%)	2 (0.2%)
Places where tree cutting activities take place	1 (0.04%)	2 (0.1%)	1 (0.03%)	2 (0.2%)
Places where construction/ demolition activities take place	–	14 (0.7%)	2 (0.06%)	12 (1.0%)
Places with poor air quality with unspecified reasons	98 (4.6%)	75 (3.6%)	118 (3.9%)	55 (4.7%)
Total	724 (34.3%)	654 (31.4%)	953 (31.6%)	425 (36.8%)

As expected, in non-heating season, children living in neighbourhoods with higher $PM_{2.5}$ and PM_{10} concentrations reported more outdoor air pollution-related issues than children living in neighbourhoods having lower $PM_{2.5}$ and PM_{10} concentrations (results were the same for $PM_{2.5}$ and PM_{10} based comparisons: 33.3% versus 31.4%) (see Table 5).

Total	654 (31.4%)	724 (34.3%)	654 (31.4%)	724 (34.3%)

4.2. *Children's air pollution-related experiences and the built environment characteristics of their neighbourhoods*

Our results show that compared to children living in neighbourhoods with lower land use mix, more children living in neighbourhoods with higher land use mix reported traffic density and vehicle exhaust-related pollution issues (13.1% versus 8.3%) (see Table 6). Additionally, we observed more smelly trash related issues in neighbourhoods with high land use diversity than to neighbourhoods with less land use diversity (13.9% versus 10.1%).

Compared to children living in greener neighbourhoods (i.e., Koru and Ahmet Taner Kislali) more children living in less green neighbourhoods mentioned a general air quality problem in their neighbourhood environments (4.5% versus 0.6%). However, we found that compared to children living in less green neighbourhoods, more children living in highly green neighbourhoods mentioned places with lack of vegetation.

5. Discussion and conclusion

We found that inner- and outer-city neighbourhoods had significantly different levels of $PM_{2.5}$ and PM_{10} concentrations, which shows the role of built environment in affecting PM concentrations. In a non-heating season, high $PM_{2.5}$ and PM_{10} concentrations in inner-city neighbourhoods can be attributed to factors such as high building density (and thus, increased heat islands) and low green spaces in these areas (Chen et al., 2017; McCarty and Kaza, 2015). Contrarily, low $PM_{2.5}$ and PM_{10} concentrations in peripheral neighbourhoods can be attributed to the presence of greenery and high air circulation (Han et al., 2020). Seasonal variations in PM concentrations in

neighbourhoods can be attributed to many factors, such as reduced industrial activity and domestic heating in summer seasons (Sabir et al., 2024) and neighbourhood location. These factors may explain the seasonal variation in PM concentrations observed in peripheral neighbourhoods adjacent to construction sites and forests (which cool down the air).

Our results support the prior claims of qualitative researchers that there is a relationship between built environment, outdoor air pollution and outdoor place experiences of children. Children reported more negative experiences about outdoor air pollution in school neighbourhoods with higher $PM_{2.5}$ and PM_{10} concentrations in the non-heating season; different and conflicting results are obtained in the heating season for $PM_{2.5}$ and PM_{10} concentrations. This difference in the PM concentrations triggers the following question: Whether children, who participate in participatory mapping activities, are more likely to report issues that are experienced in particular weather conditions? Certainly, one may argue that children are more likely to use outdoor environments in warmer seasons than in a winter season (see Buck et al., 2015). Thus, the results that we presented here for the non-heating season may be more reliable than those presented for the heating season if children's voices are shaped largely by their place experiences. Truly, multiple factors may affect children's perceptions of and ideas about their environments, including shared experiences within the family (Demirkaya et al., 2024). As in all cross-sectional studies, causal inference is limited in our research. Future studies can map children's neighbourhood experiences in different seasons.

In this study, we could not observe any industry-related air pollution issues mentioned by children. Likewise, while the density of the selected neighbourhoods significantly varied from one neighbourhood to another, as Table 3 shows, except for a few children in Selcuklu, none of the children in other neighbourhoods mentioned a problem related to high urbanisation rates. Furthermore, while the neighbourhood greenness values significantly differed across the selected neighbourhoods, lack of vegetation was mostly mentioned as a problem by the children living in the greenest neighbourhoods. One explanation to these findings could be that children's negative place experiences are more likely to be affected by factors that are physically and visually accessible to and that can be easily perceived and grasped by children. For example, in our study, none of the selected neighbourhoods included industrial areas. Another explanation could be that some children might have internalised the problems of their neighbourhoods, leading them to no longer view the drawbacks of their environments, such as the lack of green open spaces in highly dense neighbourhoods, as problems.

We found that compared to children living in neighbourhoods with lower land use mix, more children living in neighbourhoods with higher land use diversity reported traffic density and traffic-related pollution issues. While this result is in line with the findings of Ding and Zhao (2011), who linked places with high land use mix to high traffic density, it is contrary to what Frank et al. (2006) suggested: increasing the land use mix promotes walking behaviour in residents and decreases vehicle traffic. Since this study did not consider traffic density as an explanatory variable and since various contextual factors may affect PM concentrations, future research should investigate the associations between built environment and PM concentrations in the selected neighbourhoods. Future research should also place greater emphasis in conducting longitudinal and control-group studies.

Despite these limitations, the results of this research may provide helpful insights for urban planners to elaborate tailored and context-specific interventions to create healthier environments for children. Since the proportions of air pollution-related issues experienced by children change from one neighbourhood to another depending on their PM and built environment characteristics, our results show the need for targeted interventions and policies to address these issues.

Abstract
This study explores the coordination between capital flows and carbon emissions in China's Yangtze River Delta (YRD) under an environmental justice framework. Using complex network analysis, coordination models, and multiple linear regression, we diagnose spatial disparities in coupling coordination levels across industries. Results reveal low coordination in manufacturing, power, and financial sectors, with most cities exhibiting incoordination, while construction and agriculture show higher synergy. The environmental justice framework highlights regional equity's critical role in aligning economic activities with carbon neutrality goals. Findings emphasize balancing economic growth and environmental sustainability through equitable policies, offering insights for harmonizing industrial decarbonization with development priorities in economically advanced regions.

1. Introduction

During the critical period of global response to climate change, carbon emissions have become a core challenge restricting sustainable development. Meanwhile, capital, as a key element driving economic growth, its cross-regional flow not only reshapes the global economic geography but also profoundly influences the spatial distribution of carbon emissions. The concept of environmental justice emphasizes fairness in the allocation of environmental resources and the assumption of environmental burdens. However, in the process of promoting regional economic development, current capital flows often come with regional imbalances in carbon emissions, and the issue of carbon emission transfer has become increasingly prominent. Core cities with high capital activity transfer carbon emission pressure to peripheral cities through industrial relocation, forming an "agglomeration of capital - diffusion of pollution" environmental injustice trap, which intensifies the contradiction between different regions in terms of environmental rights and development rights. For instance, developed regions transfer energy-intensive industries to less developed regions through capital outflow, which although promotes their own industrial upgrading and low-carbon transformation, imposes more environmental pressure on less developed regions. This phenomenon seriously violates the principle of environmental justice. As the most dynamic growth pole of China's economy, the Yangtze River Delta region achieved a regional GDP of 30,504.5 billion yuan in 2023. All the prefecture-level cities in the Yangtze River Delta have an economic volume of over 100 billion yuan. With less than 4% of the country's land area, it generates nearly a quarter of China's total economic output, and the scale of regional capital flow accounts for a relatively high proportion of the national total. Against this backdrop, in-depth exploration of the coordinated development and coupling mechanism of capital flow and carbon emissions from the perspective of environmental justice not only helps reveal the intrinsic connection between economic development and environmental protection but is also an urgent need for achieving regional fairness and sustainable development. It holds significant theoretical and practical significance for optimizing resource allocation and promoting green and low-carbon transformation.

2. Literature review

Since the emergence of environmental justice theory in the 1980s, it has gradually become a focus of academic attention. Scholars have interpreted environmental justice from various perspectives. Early research mainly focused on the description of environmental inequality phenomena. For instance, an American scholar found through empirical research that minority communities are often more likely to be the sites for hazardous waste treatment facilities, revealing the issue of racial inequality in the distribution of environmental burdens (Bullard R, 2000). With the deepening of research, the connotation of environmental justice has been continuously expanded, covering multiple dimensions such as intra-generational justice, inter-generational justice, and justice among different regions (Schlosberg D, 2007). At the practical level, the environmental justice movement has driven policy changes, and many countries and regions have begun to incorporate the concept of environmental justice into environmental policy-making. However, existing research has relatively insufficient exploration of the manifestation and influence mechanism of environmental justice in economic activities, especially in capital

flows. How to implement the principle of environmental justice in the coordinated development of capital flows and carbon emissions remains to be further studied.

The impact of capital flows on regional economic development has always been an important field of study in economics. Scholars at home and abroad generally believe that capital flows can promote the optimal allocation of capital factors and drive the upgrading of regional industrial structures (Feldstein & Horioka, 1980; Zhang Jun, 2002). Transnational capital flows, through spillover effects of technology and industrial linkage effects, have driven the economic growth of host countries (Pan et al., 2025). Meanwhile, the cross-regional flow of domestic capital is also reshaping the regional economic landscape. For example, the flow of capital from China's eastern regions to the central and western regions has, to a certain extent, promoted the industrialization and urbanization processes in the central and western regions. However, existing research has mostly focused on the quantitative impact of capital flows on economic growth (Zhao & Jiang, 2025), with relatively weak research on the improvement of economic development quality, especially in the aspect of coordinated development with the environment.

There is a considerable amount of research on the relationship between carbon emissions and economic growth. The "Environmental Kuznets Curve" (EKC) theory holds that in the early stage of economic development, carbon emissions will increase with economic growth. When economic development reaches a certain stage, carbon emissions will decrease due to factors such as industrial structure adjustment and technological progress (Grossman & Krueger, 1995). Many scholars have verified and expanded the EKC curve based on data from different countries and regions. Some studies support this theory, while others have found that the relationship between carbon emissions and economic growth varies among different countries and regions (Panayotou, 2003). However, most of these studies have explored the relationship from a macro perspective, with relatively few studies on how capital flows affect the relationship between carbon emissions and economic growth, and a lack of in-depth analysis of the intrinsic mechanism from the perspective of capital flows.

In recent years, the relationship between capital flows and carbon emissions has begun to attract attention. Some studies have pointed out that international capital flows can lead to the "carbon leakage" phenomenon, where developed countries transfer high-carbon emission industries to developing countries through foreign direct investment, thereby reducing their own carbon emissions but increasing the global total (Ahmad & Wyckoff, 2009). At the domestic regional level, the flow of capital from developed regions to less developed regions may also cause similar environmental problems (Niu et al., 2024; Yan et al., 2025; Zhao et al., 2021; Hata et al., 2023). However, existing research mostly focuses on phenomenon description and qualitative analysis, with relatively scarce quantitative research on the coupling and coordination mechanism between capital flows and carbon emissions, especially from the perspective of environmental justice, where the coordinated development path of the two has not been fully explored.

Overall, existing research has achieved certain results in the fields of environmental justice, capital flows, and carbon emissions. However, systematic research on the coordinated development and coupling mechanism of capital flows and carbon emissions from the perspective of environmental justice is still relatively scarce. This study will employ methods such as the capital flow network space model and the coupling coordination degree model to deeply analyze the relationship between capital flow and carbon emissions in different industries within the Yangtze River Delta region, providing theoretical basis and practical guidance for achieving regional environmental justice and sustainable development.

3. Data sources and research methods

3.1. The data sources

The indicators selected for this study include enterprise investment data, carbon emission data, and socio-economic and natural resource statistics in manufacturing, construction, power, transportation, agriculture, and finance. The enterprise investment data for 2022 is sourced from Qixinbao, which covers investment information among enterprises in cities of the Yangtze River Delta region, providing a foundation for constructing the capital flow network. Meanwhile, carbon emission data is obtained from platforms such as the China Greenhouse Gas Working Group to ensure accuracy and authority. Socio-economic and natural resource statistics are all derived from the 2023 Urban Statistical Yearbook.

3.2. Research methodology

3.2.1. Construction of a Spatial Model of Capital Flow Network

The study selected the enterprise investment data from multiple industries in the cities of the Yangtze River Delta region in 2022, including manufacturing, construction, electricity, transportation, agriculture, and finance. The data were cleaned and filtered to remove invalid or abnormal data, ensuring the completeness and accuracy of the data. The cities in the Yangtze River Delta region were regarded as the nodes of the network, and the investment relationships between enterprises were regarded as the edges. Based on the investment flow and investment relationships of enterprises, a capital flow network between cities was constructed. A weighted asymmetric matrix was built based on the investment scale data, and the elements in the matrix represented the investment weight of city i to city j. By calculating the investment flow between each city, the weighted matrix of the capital flow network was obtained, providing basic data for subsequent network analysis.

3.2.2 Network characteristic measurement method

The study selected the degree centrality as the measurement index for the activity level of nodes in the capital flow network. Degree centrality is used to measure the importance of a city in the network, that is, the number and intensity of investment connections between this city and other cities. The calculation formula is the sum of the scale of cross-city outbound investment and inbound investment by enterprises in the city.

$$W = MaxAbs(I_s + I_t) \quad (1)$$

"I_{st}" represents the scale of cross-city outbound investment by enterprises aggregated by city, and "I_{tt}" represents the scale of cross-city inbound investment received by enterprises aggregated by city.

3.2.3. Coupling coordination model

Coupling degree is an important indicator used to measure the degree of interaction between two or more elements in a research system. Due to the significant differences in the selection of indicators, the data is first standardized before calculating using the coupling degree formula.

$$C = 2\sqrt{\frac{U_1 U_2}{(U_1 + U_2)^2}} \quad (2)$$

C represents the coupling degree, U_1 and U_2 are the centrality of the capital flow network and the standardized values of carbon emissions, respectively. In certain circumstances, the coupling degree may not accurately reflect the overall degree and synergy of the two factors. Therefore, a further coupling coordination degree model is employed, and the formula is as follows.

$$D = \sqrt{CT} \quad (3)$$

$$T = \alpha U_1 + \beta U_2 \quad (4)$$

Among them, D represents the coupling coordination degree, where $D \in (0, 1)$; T is the harmonic coefficient of the central degree of the capital flow network and carbon emissions, reflecting the contribution levels of both to the

coupling coordination degree, x and y respectively represent the weights of the central degree of the capital flow network and carbon emissions, with x + y = 1. Their values can be calculated using the entropy weight method. According to the classification standard of coupling coordination degree (Table 1), its coupling coordination degree is divided into ten levels, namely extreme imbalance, severe imbalance, moderate imbalance, mild imbalance, on the verge of imbalance, barely coordinated, primary coordination, moderately excellent coordination, good coordination and excellent coordination.

Table 1 Classification standard of coupling coordination degree

D value interval of coupling coordination degree	Coordination level	Degree of coupling coordination
(0.0~0.1)	1	Extreme imbalance
[0.1~0.2)	2	A serious imbalance between
[0.2~0.3)	3	Moderate disorders
[0.3~0.4)	4	Mild disorder
[0.4~0.5)	5	On the verge of disorder
[0.5~0.6)	6	Barely coordination
[0.6~0.7)	7	Primary coordination
[0.7~0.8)	8	Intermediate coordinate
[0.8~0.9)	9	Good coordination
[0.9~1.0)	10	Great coordination

3.2.4 Multivariate Linear Regression Model

Construct a coupling and coordination mechanism model for urban capital flow and carbon emissions in the Yangtze River Delta region. Analyze it using the multiple linear regression model. The formula is as follows.

$$Y_j = a_1 \ln X_1 + a_2 \ln X_2 + a_3 \ln X_3 + a_4 X_4 + a_5 X_5 + a_6 X_6 + a_7 X_7 + c \quad (5)$$

Y_{ij} represents the coupling coordination degree of capital flow and carbon emission system in industry j of city i. $\ln X_1$, $\ln X_2$, $\ln X_3$, X_4, X_5, X_6 and X_7 are influencing factors, representing GDP, total passenger volume, annual average concentration of fine particulate matter (PM2.5), urbanization rate of permanent residents, total retail sales of consumer goods, local general budgetary revenue, and local general budgetary expenditure. α is the constant term, α_1, α_2, α_3, α_4, α_5, α_6 are the coefficient values of $\ln X_1$, $\ln X_2$, $\ln X_3$, X_4, X_5 and X_6 respectively, and c is the regression constant term.

4. Research on the Regional Characteristics of Capital Flow Linkage Network and Carbon Emissions

4.1 Research on the Multi-industry Capital Flow Linkage Network and Its Structural Characteristics

4.1.1 Research on the Multi-industry Capital Flow Linkage Network in the Yangtze River Delta Region

The capital flow network of manufacturing industry in the Yangtze River Delta presents a "multi-core with multiple sub-centers" structure, with "Shanghai - Suzhou - Hangzhou" as the main core and Yangzhou, Ningbo, Nanjing, Wuxi, and Hefei as the secondary centers. Among them, Shanghai has a relatively strong capital connection with other

regions, while Suzhou and Hangzhou have stronger local connections. Other cities also show a network feature where local connections are greater than external connections. As an international hub, Shanghai has a relatively high proportion of external capital connections and outstanding regional resource allocation capabilities; while Suzhou and Hangzhou have strong local capital connections, reflecting the localization tendency of their industrial clusters, such as Suzhou's electronic information and Hangzhou's digital manufacturing. The local connections of other secondary centers are generally higher than those with other regions, indicating that the manufacturing industry presents a "regional decentralization and concentration" feature. The manufacturing industry network relies on the dual drive of external radiation from core cities and local deepening in secondary nodes, and needs to enhance network collaboration efficiency through cross-city industrial chain division.

The capital network of the construction industry forms a multi-center pattern with five centers in Nanjing, Shanghai, Suzhou, Yancheng, and Hefei. The spatial distribution is more scattered than that of manufacturing. Among them, Suzhou and Nanjing have stronger external connections, and Nanjing and Suzhou undertake the functions of regional infrastructure hubs, mainly connecting cross-provincial projects such as high-speed rail and cross-river passages. While Shanghai, Yancheng, Zhenjiang, and Hefei have stronger local connections, Shanghai and Yancheng are closely related to local urban renewal and coastal development projects. The multi-center pattern of the construction industry is strongly related to the government-led infrastructure investment model, and attention should be paid to the risk of duplication, and a regional major project joint approval mechanism should be established.

The capital network of the power industry presents a "one main with multiple sub-centers" structure, with Ningbo as the strongest local connection and its core position derived from its port location advantage. In 2022, the coal and nuclear power installed capacity in Ningbo accounted for 23% of the total in the Yangtze River Delta. Shanghai has the strongest external connections, mainly transporting electricity to the north of Jiangsu and the Yangtze River Delta. The power network is highly dependent on geographical endowments and needs to strengthen the complementarity between Ningbo and other sub-centers through the construction of special high-voltage transmission channels to avoid the risk of a single energy center.

The capital network of the transportation industry presents a single center in Shanghai and five cities including Suzhou, Hangzhou, Nanjing, Hefei, and Ningbo as sub-centers. Among them, Shanghai has the strongest external connections, mainly undertaking international shipping and transshipment functions in the Yangtze River Delta. Hangzhou has become the only sub-center with balanced local and external capital connections, matching its position as an e-commerce logistics hub. Shanghai's single-pole hub function is temporarily irreplaceable, but it needs to build regional logistics nodes in cities such as Hangzhou and Nanjing to alleviate the pressure of trunk transportation.

The capital flow network of agriculture forms a center structure of Ningbo-Hangzhou-Suzhou, with the intensity of capital connections showing a "core prominent - periphery balanced" feature. Regions with strong connections in Shanghai, Hangzhou, and Hefei all have local connections greater than external connections. It is strongly related to the localized production models such as urban agriculture in Shanghai, tea industry in Hangzhou, and seed industry in Hefei. The agricultural network highly relies on geographical resource endowments and needs to enhance cross-regional capital flow efficiency through technological empowerment , such as research and development in Hefei seed industry - application and transformation in Shanghai.

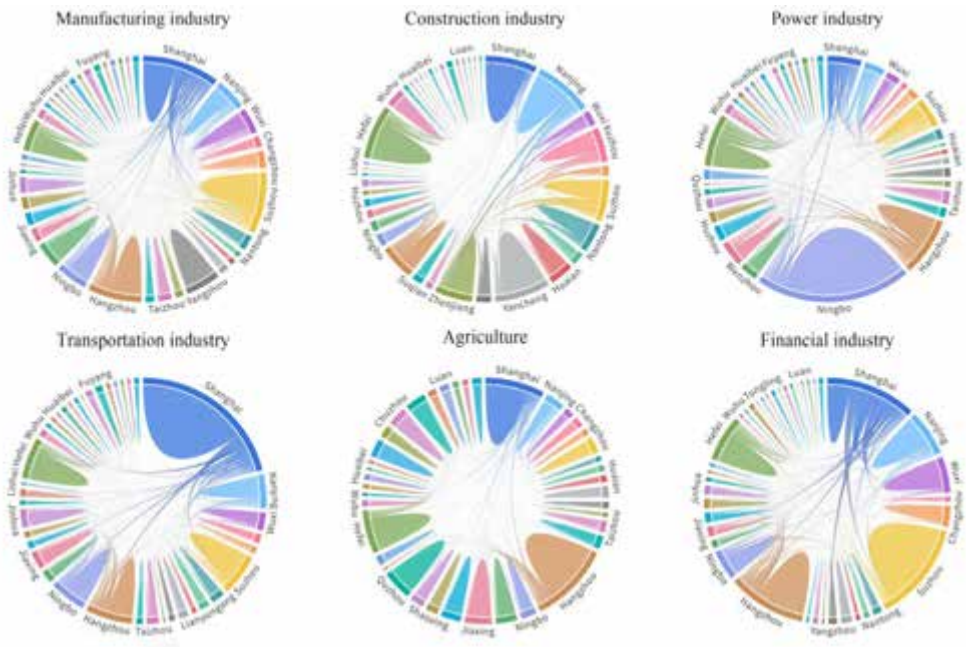

Figure 1 The network connection of capital flow in various industries in the Yangtze River Delta region

4.1.2 Research on the Structural Characteristics of Capital Flow Network in the Yangtze River Delta Region
The centrality of the urban capital flow network in the Yangtze River Delta region was analyzed (Figures 2 and 3). The centralities of cities such as Shanghai, Suzhou, Hangzhou, Hefei, and Nanjing were relatively high. Additionally, the centralities of regions like Ningbo, Zhenjiang, and Yancheng were also high. From the perspective of various industries, compared to other industries, the centralities of manufacturing and construction industries were higher, mainly concentrated in the value ranges of 431-1871 and 274-2352. Among them, the degree values of cities such as Suzhou, Shanghai, and Hangzhou were the highest in the manufacturing industry, while those of cities like Yancheng, Nanjing, and Zhenjiang were the highest in the construction industry. The centrality of the transportation industry was relatively low, mainly concentrated in the value range of 70-235. Shanghai had the highest centrality value. The centrality of the power industry was only concentrated in the value range of 92-270, with Ningbo having the highest centrality, and Hangzhou and Hefei having relatively high centrality. The centrality of agriculture was mainly concentrated in the value range of 92-262, with Hangzhou having the highest centrality, while Shanghai and Hefei had relatively high centrality. The centrality of the financial industry was mainly concentrated in the value range of 81-331, with Hangzhou having the highest centrality, and Suzhou, Shanghai, Nanjing, and Hefei having relatively high centrality as provincial capital cities.

Figure 2 The centrality and cumulative value of capital flow networks in various industries of cities in the Yangtze River Delta region

Figure 3 The distribution of centrality values of capital flow networks in various industries of cities in the Yangtze River Delta region

4.2 Spatial Characteristics Analysis of Carbon Emissions in the Yangtze River Delta Region

The spatial distribution characteristics of carbon emissions in the cities of the Yangtze River Delta region were analyzed (Figures 4 and 5). The total carbon emissions of Suzhou and Xuzhou were the highest. The carbon emissions from manufacturing and the power industry were higher than those from other industries. The carbon emissions from finance and agriculture were relatively lower. From the perspective of the spatial distribution of carbon emissions in each industry, the high-value areas of carbon emissions from manufacturing were mainly concentrated in the "Shanghai-Suzhou-Wuxi-Quanzhou-Nanjing-Ma'anshan-Hefei" urban axis. In addition, the carbon emission values in regions such as Xuzhou, Yancheng, Lianyungang, Hangzhou, Quzhou, Jinhua, etc. were relatively high. The high-value area of carbon emissions from the construction industry was relatively wide, with the highest value area concentrated in Shanghai, while the carbon emission values in cities such as Suzhou, Nantong, Yancheng, Hangzhou, Wenzhou, Ningbo, Xuzhou, Nanjing, Hefei, Fuyang, etc. were relatively high. The high-value area of carbon emissions from the power industry was mainly concentrated in cities such as Suzhou, Zhenjiang, Huainan, etc. The carbon emission values in cities such as Xuzhou, Huaihua, Taizhou, Wuxi, Ningbo, Wenzhou, etc. were relatively high. The high-value area of carbon emissions from agriculture was concentrated in cities such as Yancheng, Xuzhou, Suizhou, Bozhou, and Fuyang, while the highest value area was located in regions such as Lianyungang, Suqian, Huai'an, Chuzhou, Hefei, Suzhou, and Nantong. The high-value area of carbon emissions from the transportation industry was concentrated in Shanghai, with the highest value area located in cities such as Suzhou, Wuxi, Nanjing, Hangzhou, etc. The high-value area of carbon emissions from finance was concentrated in Shanghai and Huainan, while the highest value area was located in cities such as Ma'anshan, Wuhu, Wenzhou, etc.

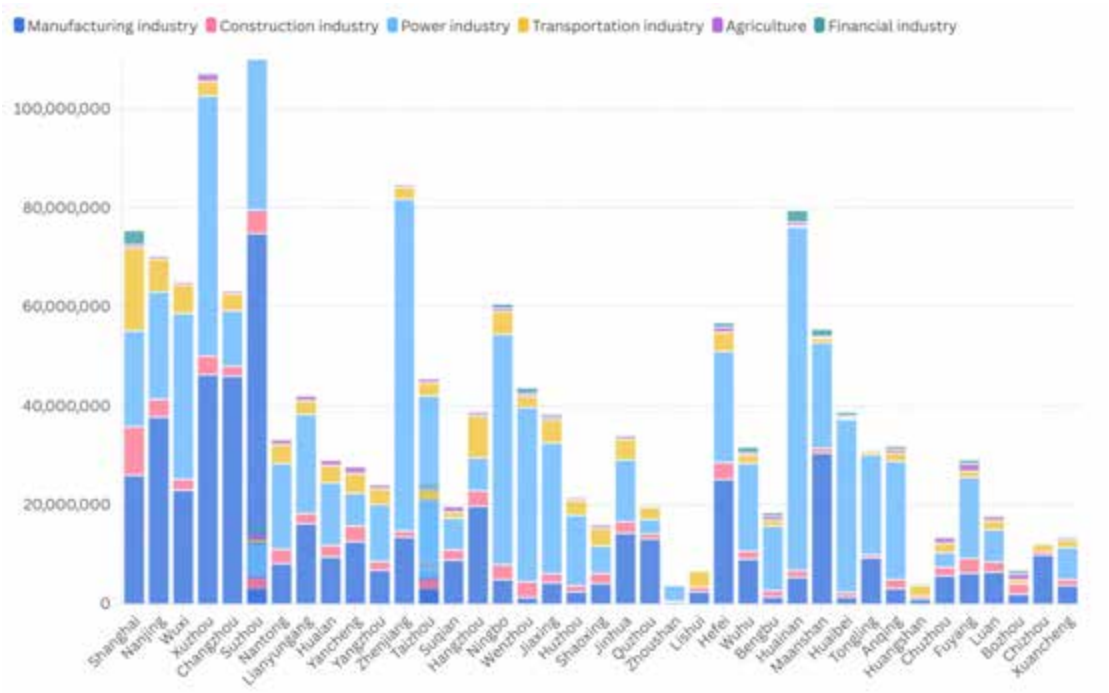

Figure 4 The total carbon emissions of multiple industries in cities in the Yangtze River Delta region

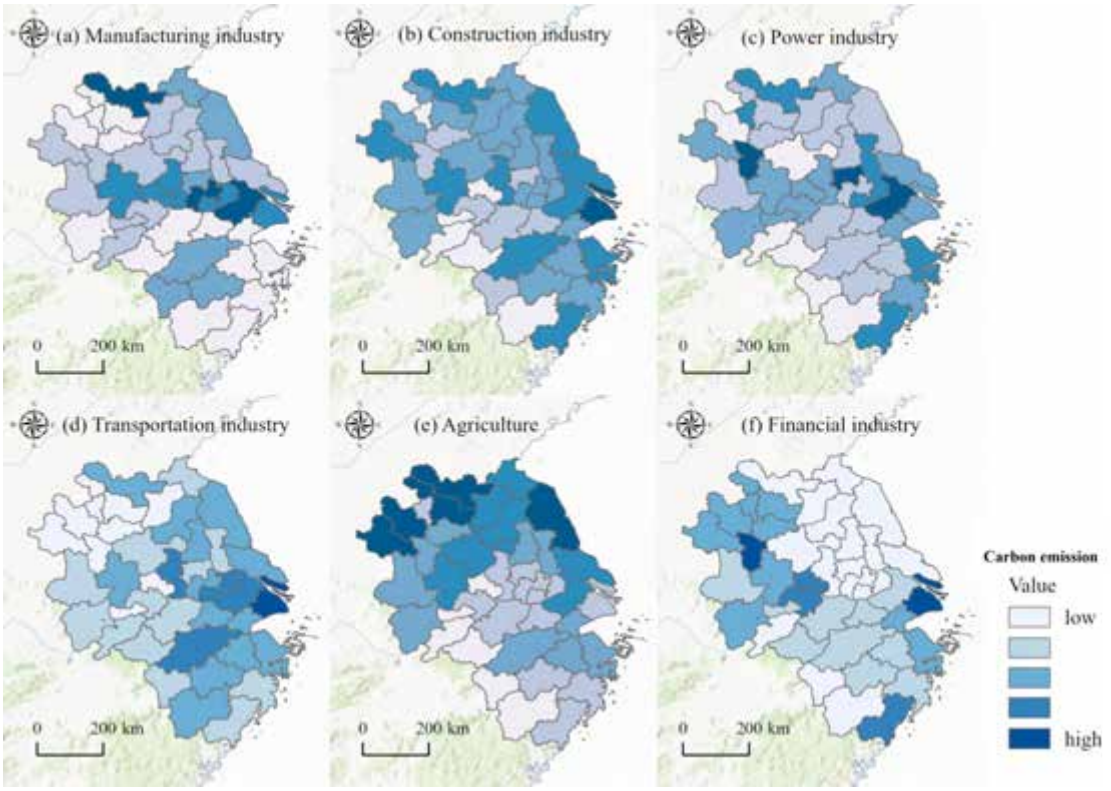

Figure 5 The spatial distribution of carbon emissions in various industries in cities of the Yangtze River Delta region

5. Research on the Coupling and Coordination Mechanism of Capital Flows and Carbon Emission System

5.1 Analysis of the Coupling and Coordination between Capital Flows and Carbon Emissions

Combining the centrality of the capital flow network and the total carbon emissions, an analysis of the current situation of the capital flow and carbon emission system in the cities of the Yangtze River Delta region is conducted (Figure 6). In the manufacturing sector, most cities are in the "low carbon emission - low capital flow" state, while only Suzhou is in the "high carbon emission - high capital flow" state. In addition, Xuzhou and Ma'anshan are in the "high carbon emission - low capital flow" state, while Shanghai and Hangzhou are in the "low carbon emission - high capital flow" state. In the construction industry, all cities are in the "low carbon emission" state, while cities such as Nanjing, Zhenjiang, Yancheng, Shanghai, Hefei, and Suzhou are in the "low carbon emission - high capital flow" state. In the power industry, all cities are in the "low capital flow" state, while cities such as Suzhou, Zhenjiang, and Xuzhou are in the "high carbon emission - low capital flow" state, and Ningbo is relatively balanced. In the transportation industry, most cities are in the "low carbon emission - low capital flow" state, while only Shanghai is in the "low carbon emission - high capital flow" state. In agriculture, all cities are in the "low carbon emission - low capital flow" state. In the financial industry, most cities are in the "low carbon emission - low capital flow" state, while cities such as Hangzhou, Suzhou, and Shanghai are in the "low carbon emission - high capital flow" state.

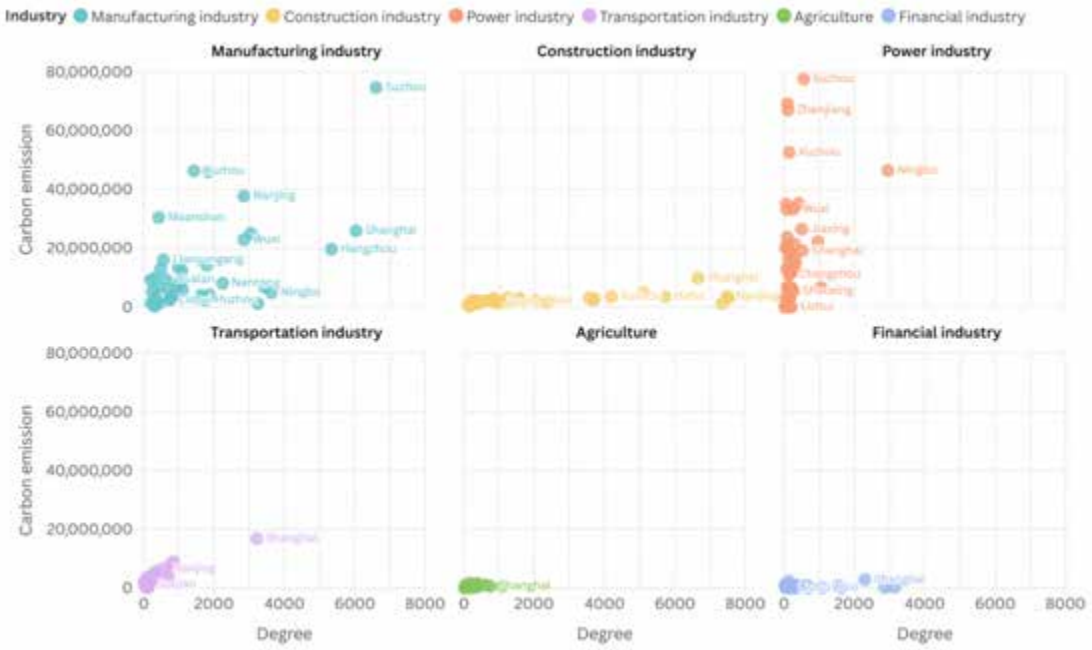

Figure 6 The current situation of multi-industry capital flows and carbon emissions in cities of the Yangtze River Delta region

According to the coupling coordination model, the coupling coordination degree of urban capital flow and carbon emissions in the Yangtze River Delta region in 2022 was calculated (Figure 7). From the perspective of manufacturing, the overall coupling coordination level of cities is relatively low, and most cities are in an uncoordinated state. Only Suzhou is in a high-quality coordination state, Shanghai is in a medium-level coordination state, Changzhou, Nanjing, Hefei, and Hangzhou are in a primary coordination state, Wuxi and Xuzhou are in a barely coordinated state, Tongling and Huaihua are in an extremely imbalanced state. The coupling coordination level of the construction industry is slightly higher than that of manufacturing. Shanghai is in a high-quality coordination state, Suzhou, Yancheng, Nanjing, and Hefei are in a medium-level coordination state, Nantong, Xuzhou, and Hangzhou are in a primary coordination state, Zhenjiang and Huai'an are in a barely coordinated state, and only Tongling is in an extremely imbalanced state. The coupling coordination level of the power industry is relatively low. Only Ningbo is in a good coordination state, Suzhou is in a primary coordination state, Hefei is in a barely coordinated state, and Lishui, Chizhou, and Bozhou are in an extremely imbalanced state. Most cities in the transportation industry belong to uncoordinated areas. Only Shanghai is in a high-quality coordination state, Suzhou is in a primary coordination state, Nanjing and Hangzhou are in a barely coordinated

state, and only Huangshan is in an extremely imbalanced state. The regional coupling coordination level of the financial industry is relatively low. Only Shanghai is in a high-quality coordination state, Hefei is in a primary coordination state, Hangzhou is in a barely coordinated state, and Lishui, Suqian, and Suzhou are in an extremely imbalanced state. The overall coupling coordination level of agriculture is relatively high. Most cities are in a coordinated state. Among them, Hangzhou, Hefei, and Fuyang have the highest coupling coordination levels, and they are in a primary coordination state, while only Tongling and Huaihua are in an extremely imbalanced state.

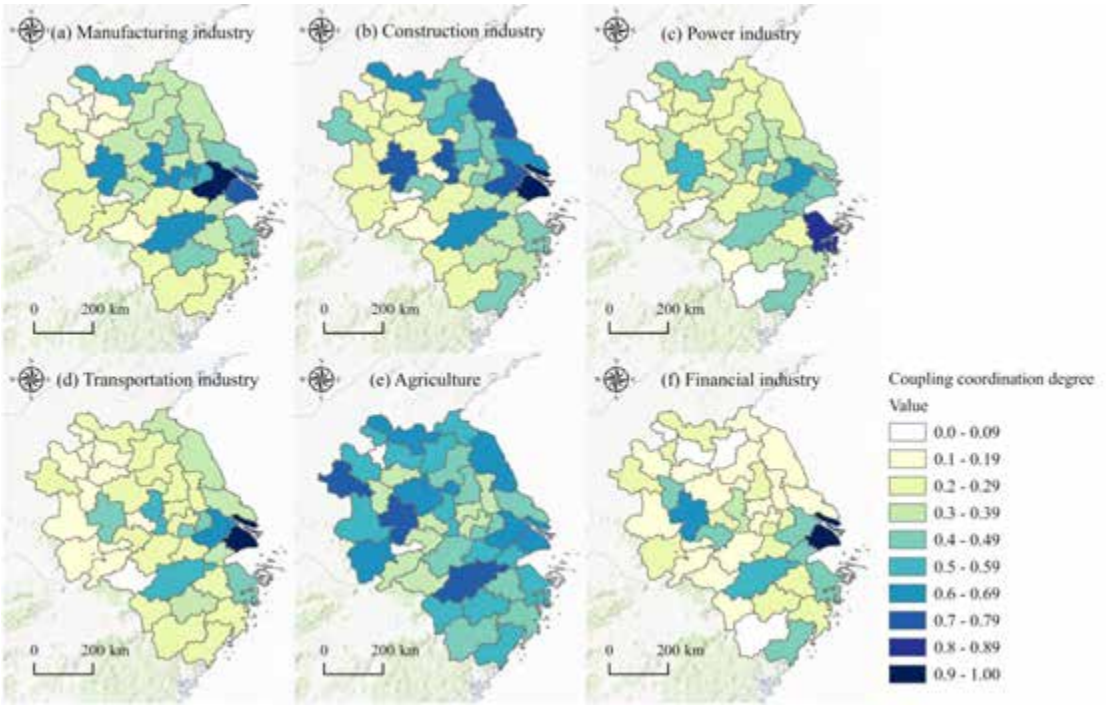

Figure 7 The spatial distribution of the coupling coordination degree between urban capital flows and carbon emissions in the Yangtze River Delta region

5.2 Research on the Coupling Coordination Mechanism of Capital Flow and Carbon Emission System in the Yangtze River Delta Region

Based on multiple perspectives such as social economy, industrial structure, and resource environment, the model was improved through stepwise regression, and the following variables were selected: GDP, urbanization rate of permanent residents, passenger volume, annual average concentration of fine particulate matter (PM2.5), total retail sales of consumer goods, local general budgetary revenue, and local general budgetary expenditure. These indicators were selected as the influencing factors of the coupling and coordination of capital flow and carbon emission system. A multiple linear regression model was used to conduct decomposition analysis of the coupling mechanism for each industry.

From the regression results of the manufacturing industry (Table 2), it can be seen that GDP, local general budgetary revenue and expenditure have a significant impact on the coupling system of manufacturing. Among them, GDP has the greatest impact on the coupling system of manufacturing, and local general budgetary revenue has a relatively significant positive promoting effect on the coupling coordination, while local general budgetary expenditure has an inhibitory effect. For every 1% increase in GDP, the coordination degree of manufacturing increases by 0.114 units, which is lower than that of the construction industry (Table 3), but higher than that of the transportation industry (Table 5), indicating that manufacturing has a moderate dependence on economic scale, but the speed of low-carbon transformation is constrained by the technology lock-in effect, such as the high cost of traditional equipment renewal. The “scissors difference” effect of fiscal revenue lies in that after fiscal revenue increases, it increases subsidies for low-carbon technologies, such as tax incentives for clean production equipment, and due to the preference of fiscal expenditure for infrastructure and projects, it occupies the green investment of manufacturingΔsuch as insufficient funds for the circular transformation of industrial parks. The reverse effect of fiscal revenue and expenditure on coordination degree reflects the target conflict

between local governments in “increasing revenue and reducing expenditure” and “low-carbon investment”. Different from the construction industryΔthe failure of PM2.5 and urbanization lies in that manufacturing may be concentrated in high-pollution industriesΔand there is a “compliance is equivalent to compliance” phenomenon in environmental regulationsΔlacking further emission reduction motivation. The coefficient of urbanization is positive but not significantΔwhich may be due to the fact that urbanization drives manufacturing demand but regional industrial homogeneity weakens the efficiency of the capital flow network. The coupling coordination degree of manufacturing is “bidirectionally pulled” by GDP and fiscal revenue and expenditure and it is necessary to solve the predicament of “relying on high-carbon industries for fiscal revenue increase and suppressing low-carbon investment with fiscal expenditure”. It is recommended to construct a “fiscal-industry” collaborative policy and embed low-carbon transformation into the hard constraints of local fiscal budgets.

Table 2 Regression results of the impact factors in the manufacturing industry

X_6	0.000151	0.000074	2.0500	0.0480	0.000001	0.000301
X_7	-0.000171	0.000053	-3.2300	0.0030	-0.000279	-0.000063
cons	-2.750605	0.579467	-4.7500	0.0000	-3.928223	-1.572987

In the coupled system of the construction industry (Table 3), GDP, annual average concentration of fine particulate matter (PM2.5), and total retail sales of consumer goods play significant roles. Among them, GDP and the annual average concentration of fine particulate matter (PM2.5) have a relatively large positive promoting effect on it, while the relative influence of total retail sales of consumer goods is smaller, but it can also promote the improvement of the coupled system of the construction industry. The construction industry is highly sensitive to the economic cycle, and economic growth directly drives the efficiency of capital flow and the low-carbon transformation. The coordination degree of the construction industry has the highest elasticity with GDP, possibly due to the large proportion of real estate investment in GDP and the linkage of green building policies and economic stimulus plans. The positive effect of PM2.5 may be because of the policy-driven mechanism. Stringent environmental regulations in high-pollution areas promote the low-carbon transformation of the construction industry, such as mandatory use of environmentally friendly building materials. The positive impact of social retail sales of consumer goods may be due to the increase in demand for commercial real estate, which promotes the optimization of the capital flow network. However, the insufficient application of low-carbon technologies leads to limited improvement in coordination degree. Therefore, priority should be given to strengthening the synergy between economic growth and low-carbon buildings, such as including the coordination degree of the construction industry in local GDP assessment and giving priority to supporting green infrastructure projects. Utilize the policy linkage mechanism for PM2.5 governance to implement building carbon quota trading in high-pollution areas. The second is driven by the consumption end. By providing consumption subsidies to guide the demand for low-carbon buildings, such as green housing purchase discounts, the positive effect of social retail sales of consumer goods can be amplified. The coupling coordination degree of the construction industry is highly dependent on economic growth, and environmental regulations (PM2.5) may indirectly promote the low-carbon transformation through the policy-driven mechanism. A “economic-environment-building” tripartite governance system needs to be constructed to strengthen the driving effect of the consumption end on green buildings.

Table 3 Regression results of the impact factors in the construction industry

In the power industry (Table 4), GDP and passenger volume have a significant impact on the coupling system of the power industry. Among them, the impact of GDP is greater and it plays a positive promoting role. However, passenger volume has a marginal significant negative effect on the coupling system of the power industry. For every 1% increase in GDP, the power coordination degree increases by 0.171 units, which is significantly higher than that of agriculture (Table 5) and transportation (Table 4). This indicates that the power system is highly bound to the macroeconomy, and economic growth directly drives power investment and supply-demand matching. As a fundamental energy industry, the coordination degree of the power industry is more sensitive to economic fluctuations. Therefore, it is necessary to be vigilant of the resilience risks of the power system during economic downturns. The potential negative impact of passenger volume may lie in the fact that transportation energy consumption competes for power resources. As passenger volume increases, fuel consumption also increases, indirectly reducing investment in clean power, such as charging piles and rail transit electrification lagging behind. At the same time, there may also be investment competition, where local governments may prioritize transportation infrastructure, weakening the funds for upgrading the power system.

The coupling coordination degree of power is highly dependent on economic growth, but it is necessary to prevent the potential inhibitory effect of the expansion of passenger volume. It is recommended to build a "economic-transportation-power" collaborative policy framework, with a focus on enhancing the initiative of local finance in the power system.

In the transportation industry (Table 5), the GDP, local fiscal general budgetary revenue and expenditure have a significant impact on the coupling system of the transportation sector. The GDP and local fiscal general budgetary revenue have a positive promoting effect, while local fiscal general budgetary expenditure will inhibit the optimization and improvement of the transportation coupling system. The positive effect of local fiscal revenue may be manifested in the enhanced government financial strength, which can support transportation infrastructure, such as high-speed railways and ports, directly improving the system's coordination. The negative effect of local fiscal expenditure may be due to the expansion of expenditure possibly occupying transportation

special funds or reflecting low expenditure efficiency, such as repeated construction and insufficient maintenance. Therefore, considering the priority development of economy and fiscal reform, maintaining GDP growth, and focusing on investing in transportation weak areas, such as rural road networks and multimodal transportation, is necessary. Secondly, optimize the fiscal expenditure structure and establish a transportation special fund to avoid "spreading resources thinly". The coupling coordination degree of transportation is mainly driven positively by economic growth and fiscal capacity, but an unreasonable fiscal expenditure structure will weaken the system's efficiency. It is necessary to promote the coordinated development of "economy - finance - transportation", and focus on optimizing the efficiency of infrastructure investment.

The most significant influencing factors in agriculture are numerous (Table 6). Factors such as GDP, the urbanization rate of permanent residents, local fiscal revenue and expenditure within the general budget, etc., all have a significant impact on the agricultural coupling system. An increase in GDP and local fiscal revenue within the general budget can effectively promote the improvement of the agricultural coupling system, while an increase in the urbanization rate of permanent residents and local fiscal expenditure within the general budget will reduce and inhibit the improvement of the agricultural coupling system. Among them, the impact of GDP is the greatest, reflecting the significant promoting effect of overall economic development on agricultural modernization, such as technological investment and industrial chain integration. The positive effect of local fiscal revenue can be manifested as enhanced local financial strength possibly supporting agricultural subsidies and infrastructure investment. The negative effect of local fiscal expenditure can be reflected as the expansion of expenditure possibly occupying agricultural resources, such as the flow of funds to non-agricultural fields or the reflection of an unreasonable expenditure structure. The urbanization rate of permanent residents has a significant inhibitory effect on the agricultural coupling degree, possibly manifested as labor loss, the transfer of rural population to urban areas leading to a shortage of agricultural labor force, and weakening of production intensification. The reduction of arable land and the expansion of urbanization occupying farmland directly reduce the scale of the agricultural system. Policy bias, with resources favoring urban areas, relatively insufficient agricultural investment, requires through labor substitution technologies and policies for protecting arable land to counteract its negative impact.

The agricultural coupling degree is significantly influenced by economic growth, environmental quality and fiscal policies. Considerable efforts can be made to enhance the efficiency of the agricultural system through "economic-environment-fiscal" collaborative governance. Meanwhile, GDP growth and increase in fiscal revenue remain the key driving forces for improving the efficiency of the agricultural system.

X_7	-0.000208	0.000070	-2.9700	0.0050	-0.000351	-0.000066
cons	-2.190231	0.766556	-2.8600	0.0070	-3.748060	-0.632401

In the financial industry coupling system (Table 7), only the local government's general budgetary revenue within the scope of the general budget has a significant impact on it, but the impact is relatively small. For every 1 unit increase in local government's general budgetary revenue, the financial coupling degree may increase by approximately 0.000157 units. An increase in local government's general budgetary revenue can actively promote the optimization of the financial industry coupling system's fiscal and tax policies or help improve the financial coupling degree. The positive impact of local government revenue may be weaker than that of the manufacturing sector due to the increase in fiscal revenue leading to more investment in green finance, such as establishing green industry funds. However, the effect is much weaker. Therefore, it is necessary to leverage specialized financial policy tools, such as including the carbon intensity of financial institutions in the MPA assessment, directly constraining the carbon-oriented capital flow. It is also recommended that a proportion of the increased local government revenue be invested in a green finance risk compensation fund to amplify the weak positive effect of local government revenue.

The financial industry coupling coordination degree is insensitive to macroeconomic variables. It is necessary to break away from the traditional analytical framework and focus on the optimization of financial policy tools and capital network structure, such as carbon financial product innovation. It is suggested to establish a "fiscal-finance" linkage mechanism, incorporate green finance indicators into local government performance assessment, and prioritize the pilot program of carbon flow accounting in the financial industry.

6. Conclusions and Recommendations

6.1 Conclusions

In terms of regional characteristics, the capital flow networks in multiple industries within the Yangtze River Delta region exhibit differentiated patterns. The manufacturing industry is centered around "Shanghai - Suzhou - Hangzhou", while the construction industry shows a multi-center and dispersed pattern. The power industry, transportation industry, and financial industry have formed network structures of "one main and multiple backups" and "multiple main and multiple backups" respectively, and the agriculture industry has formed a central structure of "combined three cores of Shanghai, Suzhou, and Hangzhou". The analysis of the centrality of

the capital flow network shows that cities such as Shanghai, Suzhou, and Hangzhou occupy important positions in multiple industries, and there are significant differences in the range of centrality values for different industries. In terms of spatial distribution of carbon emissions, the total carbon emissions of Suzhou and Xuzhou are prominent, and the carbon emissions of the manufacturing and power industries are significantly higher than those of other industries. The high-value areas of carbon emissions in each industry show obvious urban clustering characteristics, such as the manufacturing industry being concentrated in the "Shanghai - Suzhou - Wuxi - Changzhou - Nanjing - Ma'anshan - Hefei" axis, while the power industry is concentrated in cities such as Suzhou, Zhenjiang, and Huainan.

At the coupling and coordination mechanism level, the coupling and coordination levels of capital flow and carbon emission systems in various industries within the Yangtze River Delta region vary. The overall coupling and coordination levels of manufacturing, power, and finance are relatively low, with most cities being in an uncoordinated state; the coupling and coordination levels of construction and agriculture are relatively higher. The regression analysis results show that the influencing factors of coupling and coordination degrees among different industries have significant differences. GDP has a significant impact on the coupling and coordination of manufacturing, construction, power, transportation, and agriculture, reflecting the important role of economic growth in the development of various industries; local general budgetary revenue and expenditure show different degrees of promotion or inhibition effects in multiple industries; factors such as environmental regulations (such as fine particulate matter concentration), industrial scale (such as social retail sales of consumer goods), and population urbanization also have an impact on the coupling and coordination of specific industries.

6.2 Recommendations

Strengthen regional collaborative governance, optimize the pattern of capital flow and carbon emissions, break administrative barriers, and establish a collaborative governance mechanism for capital flow and carbon emissions in the Yangtze River Delta region. Based on the status of each city in the capital flow network and its carbon emission characteristics, formulate differentiated development strategies. For example, for cities with high capital flow centrality and large carbon emissions (such as Suzhou), guide them to reduce carbon emission intensity through technological innovation and industrial upgrading; for peripheral cities in capital flow, strengthen infrastructure construction and attract low-carbon industry capital inflow to narrow the environmental and development gap between regions and practice the principle of environmental justice.

Build an industry-specific policy implementation system to promote low-carbon transformation, and implement precise policy intervention based on the coupling coordination influencing factors of different industries. Manufacturing needs to break the deadlock of "relying on high-carbon industries for fiscal revenue growth and suppressing low-carbon investment through expenditures", build a "fiscal-industry" collaborative policy, incorporate the low-carbon transformation goal into the hard constraints of local fiscal budgets, and increase fiscal support for green manufacturing technology research and development; the construction industry should build a "economic-environment-building" tripartite governance system, strengthen the backward pressure mechanism of environmental regulations on low-carbon transformation, and at the same time, through consumption-side policies, enhance the demand for green buildings; the power industry needs to build a "economic-transportation-power" collaborative policy framework, optimize the energy structure, and reduce the potential inhibitory effect of passenger scale expansion on the low-carbon development of the power industry; the transportation industry should promote "economic-fiscal-transportation" coordinated development, optimize the fiscal expenditure structure, and improve the low-carbon efficiency of infrastructure investment; the agricultural sector needs to strengthen "economic-environment-fiscal" collaborative governance, through fiscal subsidies and other policies, encourage the application of low-carbon agricultural technologies; the financial industry should build a "fiscal-financial" linkage mechanism, innovate carbon financial products, incorporate green financial indicators into local fiscal performance evaluations, carry out pilot carbon flow accounting in the financial industry, and leverage finance to support the low-carbon economy.

Improve the supervision and assessment mechanism of environmental justice, establish an environmental justice assessment system covering indicators such as environmental rights distribution and regional development fairness, and regularly assess the coordinated development of capital flow and carbon emissions in the Yangtze River Delta region. Strengthen the supervision of environmental risks during capital flow, prevent developed regions from unjustly transferring environmental burdens to less developed regions through capital transfer.

Encourage public participation in environmental governance, ensure the right to information, participation and supervision of residents in each region in environmental decision-making, and ensure that the principle of environmental justice is effectively implemented in the coordinated development of capital flow and carbon emissions.

Research on the Outdoor Wind Environment of Buildings under the Influence of Hills: The Beigushan Hill in Nanjing

Tian Haoran, Jin Xing, Niu Shengnan, Ma congchao
Affiliation: School of Architecture, Southeast University
Email: tian_haoran@seu.edu.cn

Abstract
In urban planning and architectural design, mountains in complex terrains significantly impact buildings' outdoor wind environments, but research on hill-building interactions remains limited. Taking Beigushan Hill in Nanjing as the research object, this study uses CFD simulation to comprehensively explore the effects of factors like mountain height, building height, and building canyons on outdoor average wind speeds around buildings. It finds that Beigushan's unique terrain forms a high-speed zone on its leeward side, with a hilltop speed-up effect significantly increasing wind speeds around leeward buildings. The interplay of various factors jointly shapes the wind environment. The results provide a scientific basis for architectural design and planning under complex terrain conditions.

Key words: Complex Terrain; Outdoor Wind Environment of Buildings; CFD Simulation

1 Introduction

In the field of urban planning and architectural design, the impact of complex terrains on the outdoor wind environment of buildings is of great significance. Mountains, as common complex terrains, interact with buildings, altering wind direction, wind speed distribution, and pressure changes in the wind field (Alavi et al., 2024; Talwar & Yuan, 2024), and exerting a significant influence on climate-adaptive planning (Guo et al., 2025; Sun et al., 2011), urban thermal-wind environment (Guo et al., 2023; Mei et al., 2025; Sun et al., 2011), natural ventilation of buildings (Lin et al., 2020), pollutant dispersion (Kim et al., 2001), and pedestrian-level wind conditions (Baş et al., 2024; Mittal et al., 2018). Therefore, studying the outdoor wind environment of buildings influenced by mountains can provide a scientific basis for practical engineering optimization and planning decisions.

Complex terrains can modify the dynamic characteristics of atmospheric flow and affect the distribution patterns of wind fields at different spatial resolutions. Taking Nanjing as an example, as shown in Table 1, common terrains include steep terrain, hilly terrain, and low-lying irregular terrain covered by the city (Talwar & Yuan, 2024). Numerous studies have delved into wind field simulations under complex terrain conditions. For instance, literatures (Mei et al., 2025; Kim et al., 2001; Min et al., 2024; Blocken et al., 2015; Conan et al., 2016) have strived to reveal the influencing mechanisms on the wind environment and proposed specific challenges and application directions respectively. Min Zhong and Minghui Lin conducted wind tunnel tests on low-rise buildings in mountainous terrains in coastal areas (Min et al., 2024) and successfully established wind-resistant design criteria for low-rise buildings in mountainous areas; Tanya Talwar and Chao Yuan focused on the natural terrain of high-density residential areas in Singapore and found that the terrain effect is more pronounced under buoyancy-driven conditions (Talwar & Yuan, 2024); Jae-Jin Kim et al. used a two-dimensional numerical model to clearly illustrate the influence laws of hill slopes, building layouts, and their interactions on airflows and pollutant dispersion (Kim et al., 2001).

However, existing research findings are largely confined to aspects such as wind speed profiles, turbulence characteristics, and pressure distributions. Due to the complexity of mountain structures, differences in wind tunnel setups, and the diversity of boundary condition settings, these studies are difficult to compare directly. More crucially, most of the previous research has focused on the impact of relatively high mountains on the wind environment of high-density buildings. There remains a significant research gap regarding the interaction and potential impact between relatively low - lying mountains and buildings, which urgently requires in - depth exploration.

Table 1. Common Terrain Characteristics in Human Settlements (Taking Nanjing as an Example)

Common Terrain Characteristics in Human Settlements	Geographical Concept Definition	Examples in Nanjing
Type I: Steep Terrain	Small mountain ranges generally with an altitude of less than 1000 meters and a relative height of > 200 meters	Such as Zijin Mountain, etc.
Type II: Hilly Terrain	Generally with an altitude of less than 1000 meters and a relative height of < 200 meters	Such as Fangshan Mountain, Mufu Mountain, etc.
Type III: Low - lying Irregular Terrain Covered by the City	Generally with an altitude of less than 100 meters, a relative height of 10 - 60 meters, and a ground slope of 5° - 15°	Such as Qingliang Mountain, Shijingshan Mountain, Beigushan Hill, etc.

This study focuses on the impact of low-lying mountains (hills) within urban building clusters on the average wind speed. Taking Beigushan Hill in Nanjing as an example, it deeply analyzes the influence of factors such as mountain height, building height, and building canyons on the outdoor wind environment of buildings. Section 2 will detail the computational settings and parameters of the numerical simulation; Section 3 will analyze the research results and discuss the role of each influencing factor; Section 4 will summarize the main findings and conclusions.

2. CFD Simulation: Computational Settings and Parameters

2.1 Computational Geometry, Domain, and Grid

The study area is located in Beigushan Hill, a southern branch of the Mufu Mountain range in the north of Nanjing City, Jiangsu Province, China. Its longitude and latitude range from 118° 47' 2.89" to 118° 47' 37.34" E and from 32° 6' 14.42" to 32° 6' 45.83" N, with a total area of 0.351 square kilometers. Nanjing is in the subtropical monsoon climate zone. Meteorological data required for this study, such as air properties, wind direction and speed, temperature, and humidity, are all sourced from the publicly available data of Jiangsu Meteorological Station. In the simulation, the wind direction is set as the dominant summer wind direction in Nanjing - the southeasterly monsoon (θ = 22.5°). The computational geometry of the mountain is constructed based on the digital elevation data with a spatial resolution of 30m provided by ASTER GDEM V3.

In this study, a multi-storey residential building model with a length of 40m × width of 12m × height of 24m was constructed to depict the spatial characteristics of the residential area around the mountain. The longitudinal spacing of all buildings is set at 32m, and the transverse spacing is 40m. This size layout strictly adheres to the requirements of the existing residential design code (Ministry of Housing and Urban-Rural Development of the People's Republic of China, 2018).

Based on this layout, the study further explores the influence of relevant factors such as mountain slope, building height, and building canyons on the wind environment. The specific parameter changes and model settings are detailed in Table 2.

Table 2. Parameter Changes and Model Settings

Parameter Changes	Model Settings
Basic Working Conditions	A1: Building height is 24m, mountain height is H
Changes in Mountain Height (Slope)	B1: Building cluster remains unchanged, mountain height is 0.5H B2: Building cluster remains unchanged, mountain height is 2H
Changes in Building Height	C1: Mountain remains unchanged, building height is 18m C2: Mountain remains unchanged, building height is 30m
Changes in Building Canyons	D1: Building orientation is perpendicular to the incoming wind D2: Building orientation is perpendicular to the incoming wind and arranged staggeredly D3: Based on A1, the building orientation remains unchanged, and the local building canyon morphology on the leeward side of the mountain is changed
Ideal Mountain	E1: Three sinusoidal - shaped mountain peaks, height is H

In the process of constructing the CFD simulation model, the modeling experience of existing CFD studies on complex terrains and urban forms [1, 12, 14-15] was drawn upon. As shown in Figure 1-a, the computational domain and boundary conditions were set following these principles: The inlet boundary and side boundaries were set at a distance of 30H (H is the mountain height) from the building cluster to ensure that the flow is fully developed and the side-boundary effect is eliminated before reaching the reference wind - measuring tower M0. The outlet boundary was set at a distance of 60H from the building cluster to ensure that the flow is fully developed in the wake region. The height of the computational domain is 12H. After calculation, the blockage ratio is in the range of 2.7-2.9, meeting the industry standard requirement of being less than 3%. The computational domain size and the number of meshes were effectively reduced through a working - condition-based modeling strategy. The computational domain was meshed with hexahedral meshes, and local refinement was carried out at the buildings and the mountain. The minimum mesh size is 5m, the maximum size is 50m, and the expansion coefficient of adjacent meshes is controlled at 1.2 (Figure 1-b). For different working - condition settings, the total number of meshes ranges from 1.6 million to 2 million cells, and the average mesh volume quality is greater than 87%.

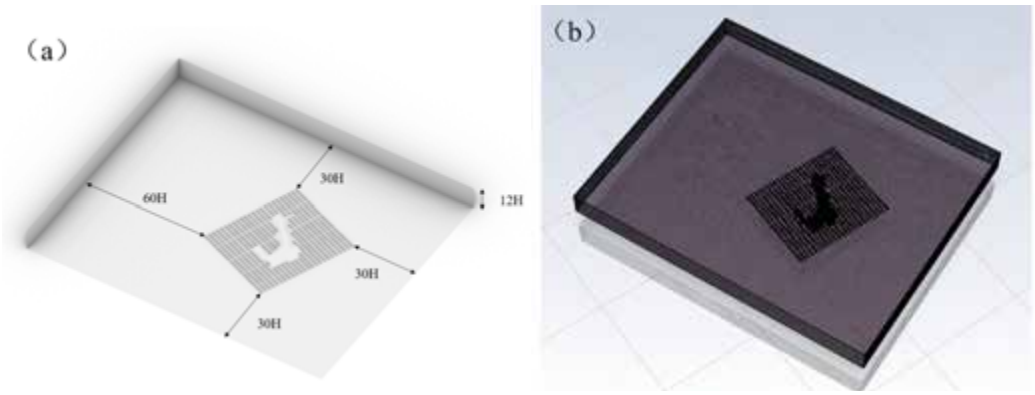

Figure 1. Computational Domain Setup (a) Size of the Computational Domain (b) Meshing and Local Refinement

2.2 Boundary Conditions and Solver Settings

At the inlet of the computational domain, the equations of Richards and Hoxey (1993) were used to impose the inlet profiles of the vertical wind speed profile U, turbulent kinetic energy k, and turbulent dissipation rate ε:

$$U(z) = \frac{U^*}{K} ln\left(\frac{z+z_0}{z_0}\right) \quad (1)$$

$$k(z) = \frac{U^{*2}}{\sqrt{C\mu}} \quad (2)$$

$$\varepsilon(z) = \frac{U^{*3}}{K(z+z_0)} \quad (3)$$

$$U^* = K \frac{U_{ref}}{\left(\frac{H_{ref}+z_0}{z_0}\right)} \quad (4)$$

where *K* is the von Karman constant, typically with a value between 0.40 ± 0.02. In this paper, the value is 0.42; *z* is the height at which the velocity is calculated (m); *Z(0)* is the aerodynamic roughness length (m), which varies depending on the landscape. In this paper, the value is 1 to represent a closed landscape, such as a mature forest, homogeneous city, and village; *Cμ* is the turbulent viscosity constant with a value of 0.09; *U** is the friction velocity, calculated by Equation (4), and the value is 0.49.

Symmetry boundary conditions were imposed on the top and sides of the domain. At the outlet boundary of the domain, a pressure - outlet condition was adopted. For the floor and building surfaces, a no - slip wall boundary condition was used. The commercial CFD code ANSYS/Fluent was used to solve the 3D steady-state Reynolds-Averaged Navier-Stokes (RANS) equations by means of the control volume method. The realizable k-Δmodel was selected to close the equations. For the convective and viscous terms of the governing equations, a second-order discretization scheme was employed. The pressure-velocity coupling adopted the COUPLED algorithm, and standard pressure interpolation was used. The simulation was run continuously until the residuals stabilized and reached a convergent state. Generally, the residual of the continuity equation is equal to or less than 10(-3), and the residuals of the velocity components \(k\) and \(\varepsilon\) are lower than 10(-5).

3. Results and Discussion

3.1 Influence of Beigushan Hill's Terrain on Wind Speed

Beigushan Hill has a unique terrain with four sub-peaks. As shown in Figure 2a, three distinct high-speed bands are generated on its leeward side. From the perspective of aerodynamic principles, due to their special terrain orientation and spatial positions, the northernmost and westernmost peaks have a more significant obstructive and guiding effect on the airflows compared to the two middle peaks, thus resulting in a more prominent acceleration effect on the leeward side. When only the mountain is present, according to the principle of flow around an object in aerodynamics, the mountain forms a shielding effect on the airflows on its leeward side, leading to a decrease in wind speed on the leeward side. However, when a low-height mountain is embedded in the building cluster, the hilltop wind-acceleration effect comes into play (Figure 2b). This effect stems from the fact that when the airflow passes over the hilltop, the streamlines are compressed. According to Bernoulli's principle, the flow velocity increases and the pressure decreases, creating a high-wind-speed zone around the leeward-side buildings in the wake region of the mountain peak. Quantified by data, under the condition of a pure building cluster without a mountain, the overall average wind speed in the study area is 0.552 m/s, which increases to 0.646 m/s when a mountain is present, with an increase of 17.04%.

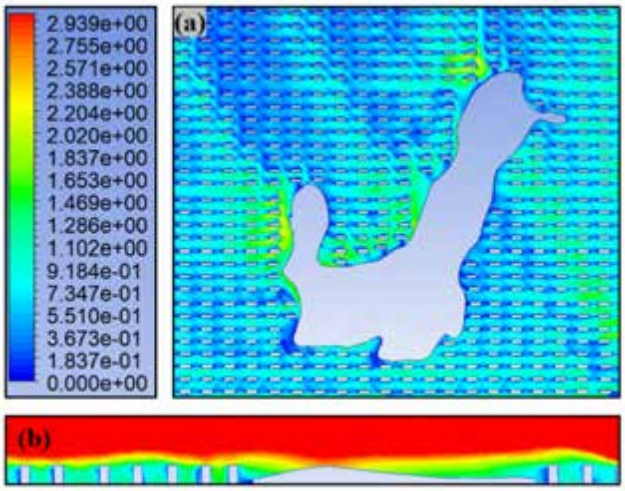

Figure 2. Wind Speed Results (m/s) for Basic Working Condition A1 (a) z=1.5m (b) y-z, x=1340m

For a uniform building array, as shown in Figure 3a, it exhibits a significant wind - blocking effect. The wind speed in the study area decays from 4-4.5 m/s in the free-stream to 0.5-1m/s, which is in line with the expectations of the Urban Canopy Model (UCM). It is worth noting that when the building cluster forms a specific angle with the incoming wind direction, due to the complex flow-around and wake-flow effects among the buildings, a high-wind-speed band will be formed in its wake region. This phenomenon should be avoided as much as possible in future experimental designs to prevent interference with the study of other factors.

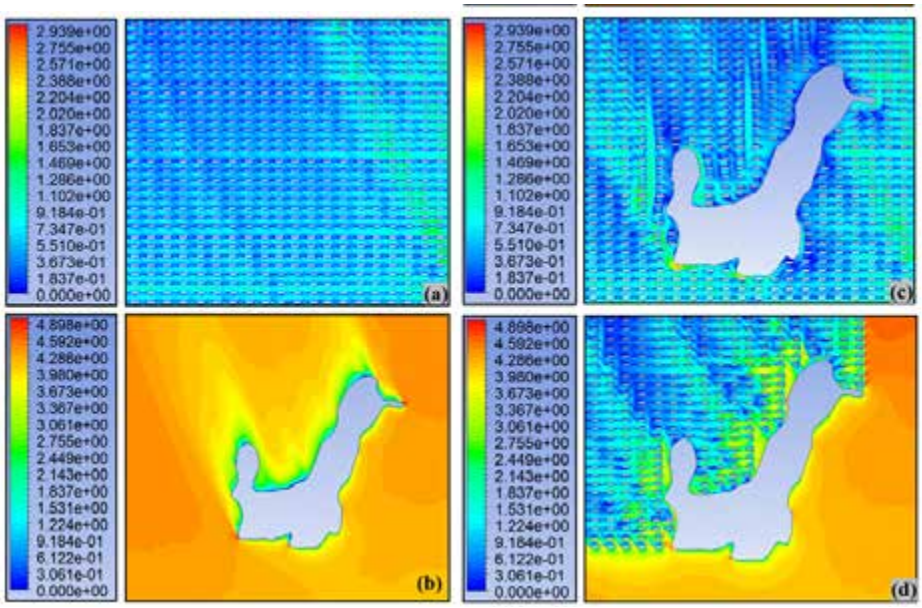

Figure 3. Wind Speed Results (m/s) for Model Validation (a) Wind speed at z=1.5m with only building clusters (no mountain) in the study area (b) Wind speed at z=1.5m with only the mountain (no building clusters) in the study area (c) Wind speed at z=1.5m when the mountain has no slope but a height of H (only mountain shape retained) (d) Wind speed at z=1.5m when buildings on the windward side of the mountain are removed

When only the mountain is present (Figure 3b), it shelters the leeward area. The windward region maintains free-stream wind speeds as it is undisturbed by buildings. On the leeward side, airflow is blocked by the mountain, causing separation and recirculation, reducing the average wind speed from 4-4.5 m/s (upwind) to 1-4 m/s—a 75% decrease from the free stream.

Although a deceleration zone also exists on the mountain's windward side, its size is smaller due to the relatively small windward surface and limited airflow obstruction, with an average wind speed reduction of only 0.5-1 m/s. Meanwhile, local high wind speed points form on both sides of the mountain due to flow-around and acceleration effects.

In scenarios where the mountain interacts with buildings (Figure 3c), corner flow acceleration and airflow separation mechanisms increase local wind speeds on the western side of the mountain. The accelerated airflow experiences a Venturi effect as it passes through mountain-building air ducts. Narrow channels formed by downstream building gaps further concentrate the airflow, creating a sustained high-speed zone.
Simulations with windward-side buildings removed (Figure 3d) still clearly show an acceleration zone on the mountain's leeward side with an unchanged spatial distribution trend. This confirms that the mountain's inherent topographic acceleration effects (e.g., hilltop acceleration, corner flow acceleration) are the primary drivers of the leeward acceleration zone. Without windward buildings to decelerate airflow, wind speeds behind the mountain are higher than in the basic case (A1, Figure 2a). Thus, windward buildings primarily affect local wind speed reduction and have limited impact on the airflow structure of the leeward side, while the leeward high-speed zone is driven mainly by terrain-building coupling effects (e.g., air duct acceleration, separation-reattachment flow).

3.2 Influence of Mountain Height on Hilltop Wind Acceleration Effect

There is a significant positive correlation between the hilltop wind acceleration effect and mountain height (Figure 2a; Figure 4a-b). When the mountain height is 0.5H (Figure 4a), the intensity and continuity of the high wind speed band on the leeward side are weaker compared to Case A1 (Figure 2a) at pedestrian level. This is because lower mountains have limited airflow acceleration capacity and cannot form stable or intense acceleration zones.

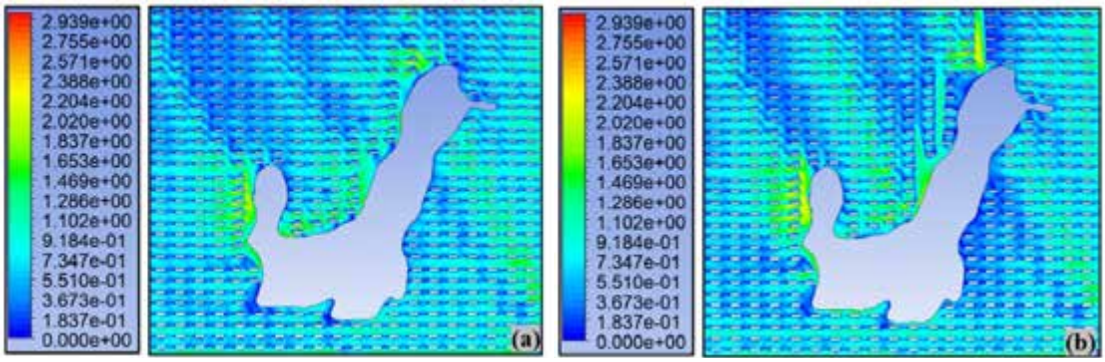

Figure 4. Wind Speed Results (m/s) for Mountains of Different Heights (a) C1 z=1.5m (b) C2 z=1.5m

When the mountain slope in B2 increases to 2H (Figure 4b), the wind speed increase at the hilltop becomes more pronounced, and the spatial continuity and intensity of the high wind speed band on the leeward side are enhanced. In the B1 case, even though the mountain height (18m) is lower than the building height (24m), according to the aerodynamic characteristics of airflow around obstacles of different heights, an acceleration zone on the leeward side of the mountain can still be observed, fully demonstrating that the acceleration effect exists even when the mountain is lower than the buildings.

3.3 Influence of Building Height on Wind Speed Distribution

When studying the influence of building height on wind speed, in C1, the building height is reduced to half of the mountain height (Figure 5a). The distribution trend of the high wind speed band on the leeward side of the mountain is the same as that in the basic working condition A1 (where the building height is 2/3H=24m), and the overall wind speed in the area increases. This is because lower buildings weaken the blocking effect on the airflow, increasing the overall wind speed. In C2, the building height is increased to be close to the mountain height (Figure 5b), and the intensity of the high wind speed band on the leeward side of the mountain increases slightly, but the effect is not significant.

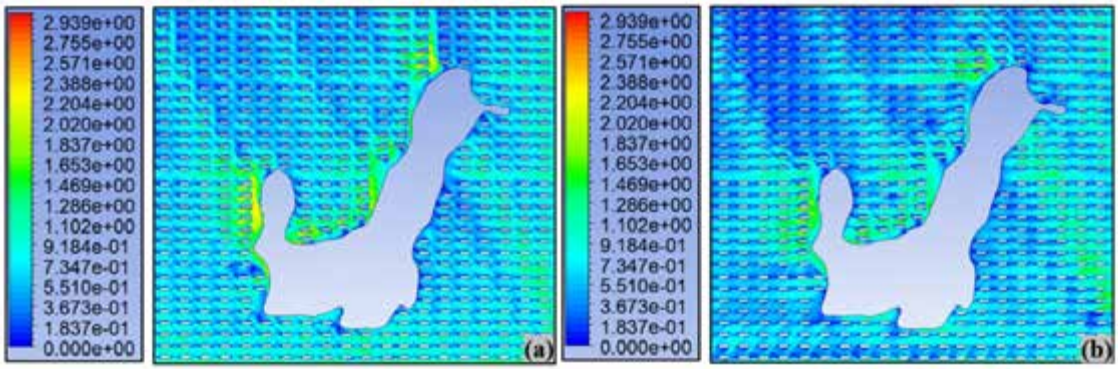

Figure 5. Wind Speed Results (m/s) for Buildings of Different Heights (a) C1, z=1.5m (b) C2, z=1.5m

Meanwhile, due to the enhanced building shielding effect, the overall wind speed in the area decreases, and the area of the calm wind zone increases. In the leeward building canyons, the continuity of the acceleration zone in C2 is significantly enhanced, with accelerated winds flowing westward; in the building canyons of C1, the accelerated winds flow northwestward. This difference may arise from the varying guidance and constraint effects of building canyons on airflow at different building heights.

3.4 Influence of Building Orientation on Wind Speed Distribution

In D1 and D2, the building orientation is changed to be perpendicular to the incoming wind direction. Under D2 conditions, where buildings are arranged in a staggered manner and there is no building canyon acceleration effect on the windward side of the mountain (dominated solely by the hilltop wind acceleration effect), the acceleration zone on the leeward side of the mountain is smaller, with a horizontal extension of approximately 4H (Figure 6b). Figure 6a clearly demonstrates the canyon acceleration effect of buildings: after the incoming wind is accelerated through the windward building canyons of the mountain and then further accelerated by the hilltop, the wind speed in the leeward building canyons reaches 3.5 m/s, significantly extending the length of the acceleration zone to a horizontal range of approximately 14H–26H. In areas without hilltop wind acceleration on both sides of the mountain, where the incoming wind is only accelerated by building canyons, the acceleration effect only persists for a short distance, and wind speeds around buildings farther from the velocity inlet tend to return to lower levels.

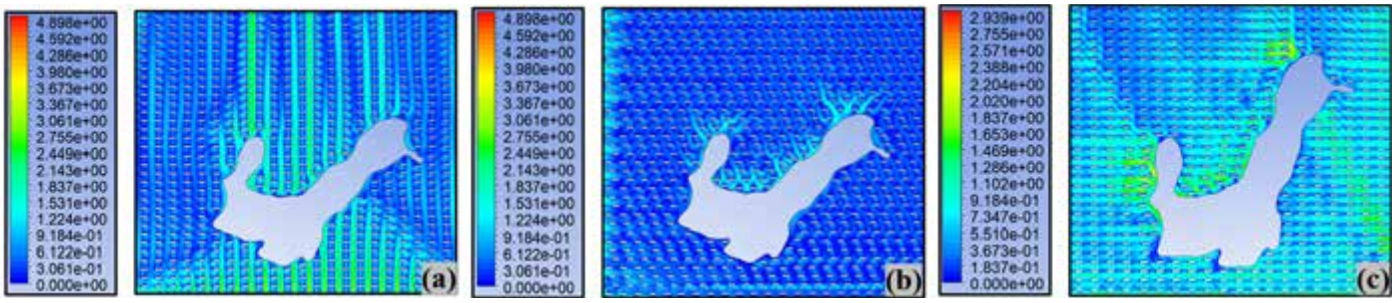

Figure 6. Wind Speed Results (m/s) for Modified Building Canyons (a) D1, z=1.5m (b) D2, z=1.5m (c) D3, z=1.5m

When the mountain and buildings form a continuous air duct, the acceleration zone extends significantly, clearly indicating that the high wind speed band on the leeward side is synergistically enhanced by the hilltop wind acceleration effect and the air duct effect (Figure 6c).

3.5 Comparison of Wind Speed Conditions Between Idealized Mountain and Standard Case

Three distinct high wind speed bands form on the leeward side of the idealized mountain, consistent with the trend observed in the standard case A1 (Figure 7a). Notably, the acceleration zone behind Peak 3 exhibits significantly higher wind speeds than those behind the other two peaks. This is because the incoming wind, pre - accelerated by the upstream buildings, is rapidly accelerated again by the hilltop, resulting in a synergistic effect that greatly enhances the acceleration (Figure 7).

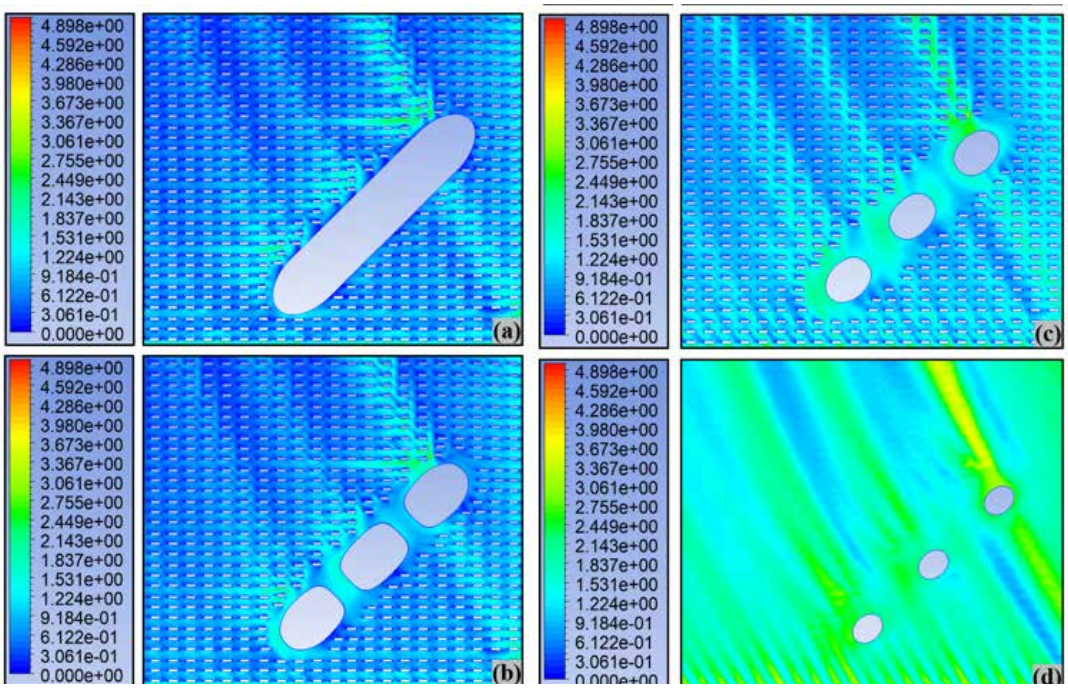

Figure 7. Wind Speed Results (m/s) for the Idealized Mountain (a) z =1.5m (b) z=10m (c) z=20m (d) z=30m

4. Conclusions

This study investigates the impact of low-lying mountains within urban building clusters on the surrounding pedestrian-level wind environment. An improved CFD model was used to simulate the urban wind environment, and the influence of multiple factors on the wind environment was analyzed by setting different working conditions. This paper provides a scientific basis for urban planning and architectural design optimization under complex terrain conditions, and lays a foundation for subsequent in-depth research on wind environments under different climatic conditions, more complex terrains, and multi - factor coupling effects, while offering technical references.

The specific research achievements and findings are as follows:

1. When a low-altitude mountain is embedded within a building cluster, the hilltop wind acceleration effect is significant. Compared with pure building conditions, this effect increases the wind speed around leeward buildings and forms high-wind-speed bands.

2. There is a significant positive correlation between mountain height and the hilltop wind acceleration effect. As the slope increases, the wind speed increase at the hilltop becomes more pronounced, and the spatial continuity and intensity of the high-wind-speed bands on the leeward side are enhanced. However, the acceleration effect still exists even when the mountain is lower than the buildings.

3. Changes in building height affect the high-wind-speed bands on the leeward side of the mountain and the overall wind speed in the area. The guiding and constraining effects of building canyons on airflows differ at different building heights.

4. When the leeward side of the mountain is dominated solely by the hilltop wind acceleration effect, the acceleration zone is small in scope. When the mountain and buildings form a continuous air duct, the acceleration zone extends significantly, indicating that the high-wind-speed bands on the leeward side are synergistically enhanced by the hilltop wind acceleration effect and the air duct effect.

In the field of architectural design and planning, the following series of valuable recommendations can be derived from the above research results, aiming to optimize building layouts and designs, improve wind environment quality, and enhance residential comfort and energy utilization efficiency:

1. Ventilative Building Layout: When planning building clusters, locate buildings with high ventilation requirements (such as hospitals and schools) in the high-wind-speed bands on the leeward side of low-altitude mountains to enhance natural ventilation through the hilltop wind acceleration effect.

2. Layout According to Mountain Height: Mountain architectural design should consider the relationship between mountain height and wind acceleration. The leeward side of high-slope mountains is suitable for installing wind power generation facilities. Meanwhile, building heights should be reasonably arranged to prevent excessive obstruction of airflows.

3. Optimized Building Canyon Design: Determine building heights according to functional and ventilation requirements. For example, in commercial pedestrian streets, adjust heights reasonably to guide airflows through building canyons and create a comfortable breeze environment.

4. Creation of Continuous Air Ducts: When planning large - scale building areas (such as residential communities), rationally design building orientations and layouts to form continuous air ducts between mountains and buildings, thereby promoting air circulation.

Abstract
COP28 emphasised the urgent need to accelerate energy transitions and decarbonisation. Cities, as major centres of energy consumption and carbon emissions, have become critical arenas for implementing these transitions. The EU and IEA have actively promoted Positive Energy Districts, shifting the focus from individual buildings to the district scale to enhance energy efficiency. This study focuses on socio-economic indicators and explores key variables influencing residential electricity consumption (REC). Using Tainan City as a case study, it combines rooftop PV generation potential and REC forecasting to evaluate the electricity self-sufficiency rate of each district. The results indicate that only "total household income" shows a significant positive correlation. Future research could utilise more granular data to improve assessment accuracy and provide evidence-based support for urban energy planning.

Keywords: Positive Energy Districts; PEDs potential; Renewable Energy; Spatial Multi-criteria

1 Introduction

The Intergovernmental Panel on Climate Change (IPCC), in its Sixth Assessment Report (AR6) released in 2023, projected that global temperatures are likely to rise by 1.5°C within the next two decades. This increase is expected to intensify climate-related hazards and may further exacerbate challenges related to energy, water resources, and food security.

In response, the 28th Conference of the Parties (COP28) to the United Nations Framework Convention on Climate Change (UNFCCC) emphasised the need for all countries to enhance their Nationally Determined Contributions (NDCs), improve energy efficiency, and adopt new technologies to advance energy transition and decarbonisation efforts. Over 100 countries have now declared net-zero emissions targets, including Taiwan, which has committed to achieving net-zero emissions by 2050. Taiwan's 2050 Net-Zero Emissions Roadmap outlines four major strategies: energy transition, industrial transformation, lifestyle change, and social transition.

According to the International Energy Agency (IEA), cities account for approximately 75% of global energy consumption and 70% of global greenhouse gas emissions. In this context, **cities—being densely populated areas with high energy consumption and concentrated carbon emissions—have emerged as critical arenas for driving energy transitions and realising net-zero goals.** Consequently, institutions such as the European Union and the IEA have initiated a range of urban-centred energy transition policies and pilot programmes. These efforts have evolved from single-building-scale initiatives, such as near-zero energy buildings (NZEBs), to larger, district-scale approaches exemplified by Positive Energy Districts (PEDs).

The European Union, under the Strategic Energy Technology Plan (SET-Plan), has set a goal of establishing at least "100 PEDs" across Europe by 2025. Simultaneously, IEA Annex 83 has been conducting research into the definitions, implementation methods, tools, and technologies associated with PEDs. Projects such as MAKING-CITY have also provided detailed methodologies and procedures for evaluating PEDs, emphasising that such evaluations must consider not only urban form and energy infrastructure, but also the social structures of the target districts.

Nevertheless, most existing studies on PEDs have focused on location suitability assessments based on comprehensive, objective indicators aimed at aiding policymakers in the strategic deployment of PEDs. While these evaluations help identify areas with higher potential for PED implementation, **the Urban Agenda for the EU underscores the critical role of public participation in energy transitions**.

Given the diverse socio-economic conditions across regions, variations in energy use behaviours and public acceptance (Rolf et al., 2007) may significantly influence the feasibility and effectiveness of PED implementation.

However, current studies seldom address the potential influence of local resident characteristics—such as economic status and demographic composition.

This study proposes the following research objectives:

1. To explore the key factors influencing REC from a "socio-economic perspective", with a particular emphasis on how resident structures affect energy behavior. This aims to address the current research gap in PEDs evaluations, which often overlooks the role of residents.
2. To conduct an empirical study in a selected city in Taiwan, integrating REC forecasting and rooftop PV potential analysis to evaluate the "electricity self-sufficiency rate" of each administrative district. The study further assesses the advantages and challenges of administrative districts as potential PEDs units.

2 Literature Review

2.1 Positive Energy Districts (PEDs)

2.1.1 Definition of PEDs

According to the European Commission, a Positive Energy District is defined as "an energy-efficient district that produces more renewable energy than it consumes, while enhancing regional energy system flexibility through smart management and local storage". Meanwhile, the SET-Plan defines PEDs as "energy-efficient and energy-flexible urban areas or groups of connected buildings which produce net-zero greenhouse gas emissions and actively manage an annual local or regional surplus production of renewable energy." Based on these definitions, **PEDs refer to geographically connected clusters of buildings with internal energy exchanges, aiming to achieve a net-positive energy status through the efficient and flexible use of renewable energy sources.**

The European Energy Research Alliance (EERA) further categorises PEDs into three types based on differences in geographic boundaries and energy balancing approaches: **PED Autonomous**, **PED Dynamic**, and **PED Virtual**. A PED Autonomous has clearly defined geographic boundaries and achieves complete electricity self-sufficiency within the district, allowing energy export but prohibiting external energy input. By contrast, a PED Dynamic allows energy exchange with other PED systems. A PED Virtual enables energy production and storage systems to be located outside the district while still serving energy needs within the area.

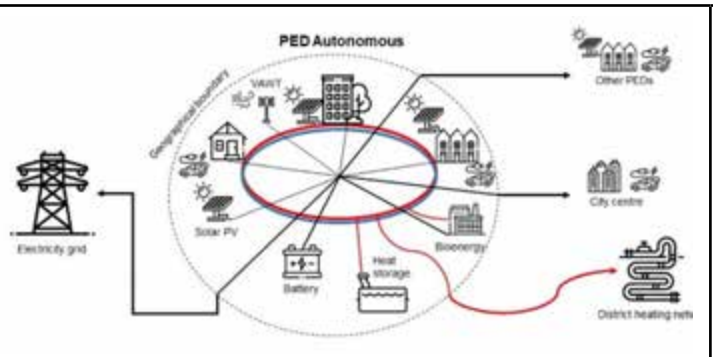

Figure 1. PED autonomous diagram

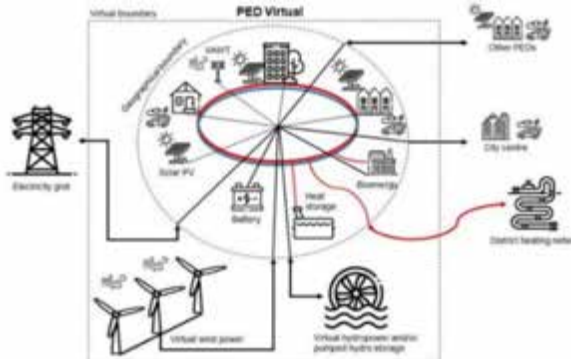

Figure 2. PED virtual diagram

2.1.2 Benefits and Challenges of PEDs

According to the Positive Energy Districts Solution Booklet, compared to achieving zero or positive energy targets at the individual building level, the diverse usage patterns of different building types often make it difficult to reach these goals in isolation, or may lead to energy overproduction and waste. **Therefore, shifting the focus to district- or community-level PEDs allows for more flexible and efficient energy utilisation.**

However, the current definition of PEDs still lacks clarity, particularly concerning "geographic boundaries" (Oscar et al., 2021), which can vary significantly depending on local characteristics. This suggests that a single

PED model may not be applicable across all contexts, and it is essential to consider local conditions during site evaluation. Furthermore, Erkinai et al. (2022) emphasise the importance of accounting for end-users and adopting an area-based policy approach tailored to local conditions, especially regarding fiscal and social dimensions. The study also criticises the idealistic nature of PED Autonomous models, which often overlook urban challenges such as high population density, limited space, and restricted access to renewable energy sources. As a result, the development of "Dynamic and Virtual" PEDs, in conjunction with Virtual Power Plants (VPPs), is regarded as a more viable pathway.

2.1.3 Methods for Evaluating PEDs Locations

Two key uncertainties complicate the definition and planning of PEDs (I. Aparisi-Cerdá et al., 2024). The first is the issue of **geographic boundaries** — the appropriate size and delineation of PEDs may vary depending on city characteristics, which in turn affect the feasibility of renewable energy deployment and local energy consumption. The second is **parameter selection** — identifying suitable PED locations depends on multiple factors across technological, social, economic, and environmental domains, each with a wide array of potential indicators. Therefore, selecting appropriate evaluation indicators is critical in PED planning.

Current methods for identifying promising PED locations often employ Geographic Information System (GIS) overlay analysis (Shnapp et al., 2020; Alpagut et al., 2020). Given the multidimensional nature of these indicators, many studies adopt Multi-Criteria Decision-Making (MCDM) or Multi-Criteria Decision Analysis (MCDA) approaches (Sassenou et al., 2024; I. Aparisi-Cerdá et al., 2024), which combine expert judgement to determine key indicators and their relative weights, followed by quantification and statistical analysis of candidate areas.

2.1.4 Why Taiwan's Urban Context is Suitable for PEDs

Taiwan is heavily reliant on energy imports, and most power plants are located far from the areas where energy is consumed. This spatial separation between energy generation and demand leads to greater transmission losses and, consequently, energy waste. **Given Taiwan's high level of urbanisation and population density, urban areas offer promising opportunities for implementing PEDs that flexibly utilise energy at the district scale.** Additionally, Taiwan faces land scarcity, and the deployment of renewable energy infrastructure often leads to land-use conflicts — particularly with agricultural land — an issue that has drawn strong opposition from environmental groups. Strategically deploying renewable energy in suitable urban areas and managing its distribution efficiently could ease pressure on valuable farmland while helping to safeguard food security.

Among Taiwanese cities, **Tainan stands out for having one of the highest installed capacities of solar photovoltaic systems and considerable solar energy potential.** The local government has taken proactive steps towards urban decarbonisation, including the development of Taiwan's first low-carbon community. However, most solar panels are currently ground-mounted and located in rural areas, far from the urban centres where energy demand is greatest. This spatial mismatch has raised concerns over land use and environmental justice. Consequently, this study selects **Tainan City** as a case area for evaluating potential PED locations. By integrating GIS-based spatial analysis with assessments of renewable energy potential, this research explores the feasibility of implementing PEDs in urban contexts and aims to provide insights for future planning and policymaking in Taiwan.

2.2 Socio-economic Indicators Influencing Residential Electricity Consumption

Residential electricity consumption (REC) is closely linked to household characteristics. Identifying the key factors that significantly influence residential electricity use not only helps to reduce consumption, but can also support forecasting future electricity demand.

Zhifeng et al. (2018) reviewed previous studies on the psychosocial factors influencing residential electricity behaviour. Commonly cited indicators include **household size, presence of children, age of household members, education level, social status, household income, and housing type.** These indicators may have either a positive (i.e. increasing) or negative (i.e. decreasing) effect on electricity use. However, the results vary across regions, indicating that the same indicator may exhibit different effects depending on the local context. This highlights the importance of identifying region-specific influencing factors and exploring the underlying reasons for such variations.

Najeeb et al. (2024) conducted a systematic review of the determinants of REC across South Asia, East Asia, and Southeast Asia, encompassing socio-economic, building-related, locational, and environmental-climatic dimensions. Within the socio-economic domain, several frequently studied indicators were identified. The review found that household income, household expenditure, household size, age of the head of household, and educational attainment of the household head were significantly correlated with electricity consumption. Conversely, indicators such as household size, age of the head, number of children, social class, household occupation, and unit electricity price showed weak or non-significant effects in certain contexts.

In addition, **within the context of the urban energy transition, public perception, acceptance, and willingness to adopt renewable energy are critical social factors. Stakeholders may hold differing attitudes towards renewable energy depending on their roles and interests.** Masoud et al. (2015) found that the acceptance of and willingness to use renewable energy are positively influenced by moral norms, attitudes, and perceived behavioural control (PBC). These factors may be useful in predicting regional willingness to adopt renewable energy technologies.

3 Methodology

3.1 Introduction to the Case Study Area

This empirical case study focuses on the former urban area of Tainan City, encompassing six administrative districts: East District, South District, North District, Annan District, Anping District, and West Central District. The total area of the study region is approximately 176.3 km², with Annan District accounting for the largest share, comprising 60.8% of the total area. As of the end of 2024, the total population of the study area is estimated at around 779,000, with Annan District having the highest population, approximately 203,000. The average population density is around 4,419 people per km².

In terms of building characteristics, the average building age across the area is approximately 33 years. West Central District has the oldest building stock, with an average age of 41 years, while Anping District has the newest, with an average building age of 25 years.

Table 1. List of basic information of the study area

District	Area (km²)	Area proportion	Population	Density (people/km²)	Building average age
East District	13.4	7.6%	181,854	13,556	33
South District	28.0	15.9%	120,151	4,285	36
North District	10.4	5.9%	125,801	12,057	33
Annan District	107.2	60.8%	203,882	1,902	28
Anping District	11.1	6.3%	70,435	6,365	25
West Central District	6.2	3.5%	77,212	12,478	41
Total	176.3	100.0%	779,335	4,419	33

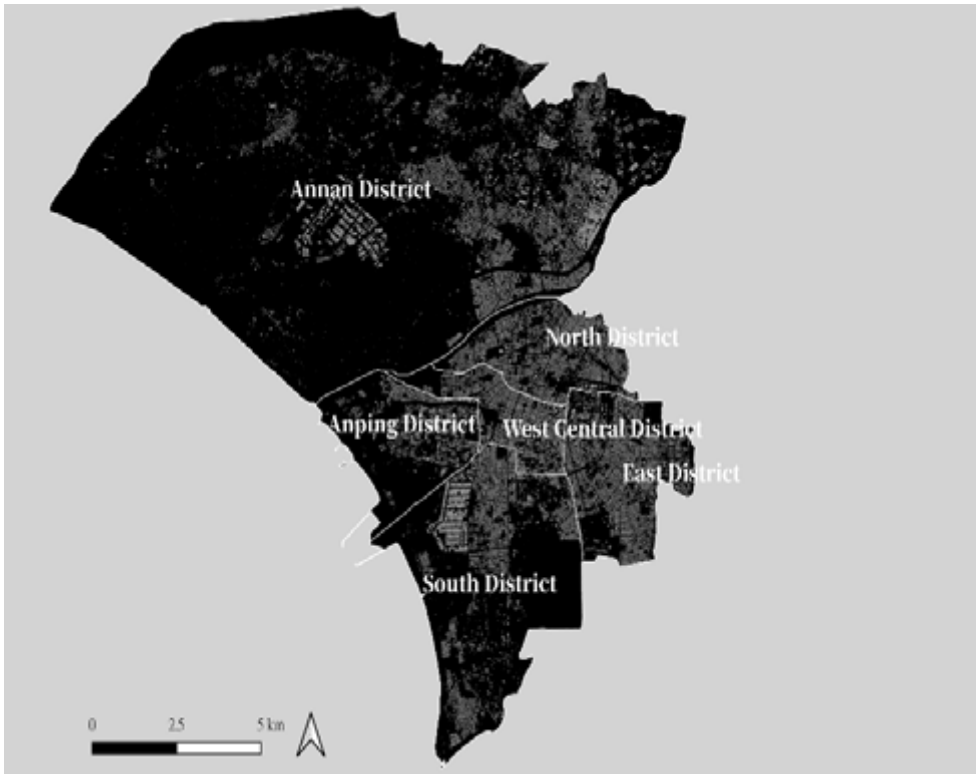

Figure 3. Case Study Area

3.2 Forecasting Trends in REC

Trends in REC are analysed using historical electricity sales data provided by Taiwan Power Company (Taipower). Based on Taipower's statistics, this study calculates annual growth rates from the historical data and applies them to project future electricity demand.

Due to a revision in the statistical reporting format in September 2020, data prior to that date differ substantially in classification and structure, and are therefore excluded from the growth rate calculation. **The study uses the average annual growth rate between 2021 and 2024 for each administrative district to estimate future trends. An exponential growth model is employed to forecast REC from 2025 to 2030.**

3.3 Correlation Analysis Between REC and Socio-economic Indicators

Assuming that Taipower's electricity sales data accurately reflect actual electricity consumption, this study adopts residential electricity sales as the dependent variable to assess the impact of socio-economic indicators on REC. The 2024 residential non-commercial electricity sales figures from Taipower serve as the dependent variable.

Socio-economic indicators are used as independent variables, selected through a review of relevant literature and contextualised for the Taiwanese setting. **Five key dimensions are considered: children, age of household, household size, educational level, and household income.** Each dimension comprises specific evaluation indicators, as illustrated in Figure 5 below.

The most recent data available from official statistical sources are utilised in the analysis. The data are then processed using SPSS statistical software to conduct a **correlation analysis**, examining both the **statistical significance** and the **direction** (positive or negative) of the relationship between each indicator and residential electricity consumption

Table 2. List of socioeconomic indicators in this study

Dimension	Indicators (Year)
Children	• Proportion of population aged 0~15 (2024) • Average number of children per household (aged 0~15 population / number of households) (2024)
Age of household	• Proportion of population aged under 50 (2024) • Proportion of population aged 51~64 (2024) • Proportion of population aged 65 and above (2024)
Household size	• Average number of persons per household (2024)
Education level	• Proportion of permanent residents with higher education (college and above) (2010)
Household income	• Total household income (NTD) (2021)

3.4 Estimation of rooftop PV Generation and Self-Sufficiency Rate

This study utilises government-provided 3D spatial data to estimate the rooftop area of buildings within each administrative district. Based on these estimations, relevant parameters are applied to calculate the potential annual electricity generation from rooftop photovoltaic (PV) systems in each district.

By comparing the estimated rooftop PV generation with REC, the self-sufficiency rate for each district is derived. Furthermore, the study conducts a series of scenario simulations to explore how variations in electricity generation and REC may influence the self-sufficiency rate.

Table 3. Summary of scenario assumptions

Scenario		Electricity generation	REC
Baseline		10% of the rooftop PV area of existing buildings	Actual REC in 2024
Scenario 1 (Pessimistic)	Generation unchanged REC increased	10% of the rooftop PV area of existing buildings	Estimated REC in 2030
Scenario 2	Generation increased REC increased	25% of the rooftop PV area of existing buildings	Estimated REC in 2030
Scenario 3 (Optimistic)	Generation increased REC unchanged	25% of the rooftop PV area of existing buildings	Actual REC in 2024

4 Results

4.1 Forecasting Trends in REC

An analysis of residential electricity sales from 2021 to 2024 across the six districts (Figure 8) reveals that Annan District consistently recorded the highest consumption, followed by East District, with Anping District having the lowest. Regarding growth rates, East and North Districts exhibited negative growth between 2021 and 2023, whereas Annan, Anping, and West Central Districts showed increases. However, all six districts experienced growth between 2023 and 2024.

Based on these trends, the average growth rate over the past three years was calculated for each district (Figure 7). Annan District recorded the highest average growth rate at 2.58%, while East District had the lowest at 0.27%. **These findings indicate that Annan District not only has the highest consumption but also the fastest growth, whereas East District, despite high consumption, shows signs of a declining trend.**
Future REC from 2025 to 2030 is projected using an exponential growth model based on the calculated average growth rates (Figure 9).

Table 4. Average REC growth rate of each district from 2021 to 2024

District	2021-2022	2022-2023	2023-2024	Average
East District	-1.5%	-0.5%	2.85%	**0.27%**
South District	-1.7%	0.3%	2.83%	**0.47%**
North District	-1.3%	-0.5%	2.67%	**0.29%**
Annan District	1.2%	1.7%	4.91%	**2.58%**
Anping District	0.4%	0.3%	4.96%	**1.89%**
West Central District	0.4%	0.1%	2.83%	**1.11%**

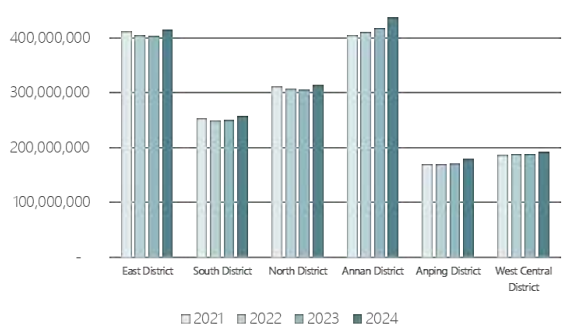

Figure 4. Residential electricity sales from 2021 to 2024

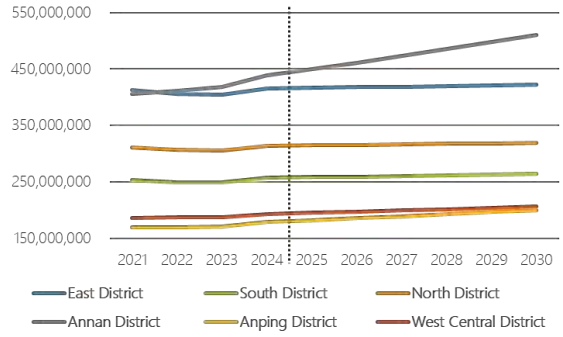

Figure 5. Estimated REC from 2025 to 2030

4.2 Correlation Analysis Between REC and Socio-economic Indicators

Using Pearson's correlation analysis, the relationships between eight indicators across five dimensions and residential electricity consumption were examined. The results show that only the variable *Total Household Income* had a significant positive correlation with REC (Pearson r = 0.814, p = 0.049 < 0.05), consistent with findings from previous literature. All other indicators did not show statistically significant correlations.

Table 5. Pearson correlation results

Dimension	Indicators (Year)	Pearson correlation	Significance (two.sided)
Children	Proportion of population aged 0-15 (2024)	0.214	0.683
	Average number of children per household (aged 0-15 population / number of households) (2024)	0.418	0.410
Age of household	Proportion of population aged under 50 (2024)	0.507	0.305
	Proportion of population aged 51-64 (2024)	-0.520	0.290
	Proportion of population aged 65 and above (2024)	-0.273	0.601
Household size	Average number of persons per household (2024)	0.671	0.145
Education level	Proportion of permanent residents with higher education (college and above) (2010)	-0.046	0.930
Household income	Total household income (NTD) (2021)	0.814	0.049*

* Significance (two.sided) <0.05 was significant

4.3 Estimation of Rooftop PV Generation and Self-Sufficiency Rate Analysis

4.3.1 Estimation of Rooftop PV Generation

The potential rooftop PV generation for each district was estimated by first calculating the available rooftop area using government-provided spatial data, then applying the following formulas:

Estimated Rooftop PV Installation Capacity (kW)= Rooftop area × 0.5 / 10
(0.5: proportion of usable rooftop area; 10 m²/kW: area-to-capacity conversion factor)

Estimated Annual Electricity Generation (kWh)= Installation Capacity (kW) × Average Annual Output per kW
(Average Annual Output = 1,246 kWh/kW)

4.3.2 Electricity Self-Sufficiency Rate Analysis

Three simulation scenarios were conducted to evaluate changes in self-sufficiency rates. In the most optimistic scenario (Scenario 3), Annan District reached a self-sufficiency rate of 40%, while Anping District reached only 17%. **The improvement in self-sufficiency ranged from 26.8% in Annan to 10.9% in Anping, highlighting significant regional disparities in the potential for electricity self-sufficiency.**

Table 6. Electricity Self-sufficiency rate results under different scenarios

District	Area (km²)	Baseline	Scenario 1	Scenario 2	Scenario 3
East District	13.4	**7.82%**	7.69%	19.24%	19.55%
South District	28.0	**12.92%**	12.56%	31.40%	32.30%
North District	10.4	**8.00%**	7.86%	19.66%	20.00%
Annan District	107.2	**16.38%**	14.05%	35.13%	40.94%
Anping District	11.1	**6.81%**	6.09%	15.22%	17.03%
West Central District	6.2	**9.01%**	8.43%	21.07%	22.52%

5 Discussion & Conclusion

This study focuses on two key analyses:
(1) The correlation between REC and socio-economic indicators; and
(2) the assessment of electricity self-sufficiency rates under varying rooftop PV generation and REC scenarios across administrative districts.

The first analysis reveals a generally weak correlation between REC and socio-economic indicators at the administrative district level, except for a significant positive correlation between "total household income" and REC. This suggests that households with higher income levels tend to consume more electricity, likely due to their greater ability to afford electricity costs. Conversely, lower-income groups may exhibit higher sensitivity to electricity pricing, indicating disparities in energy affordability. Furthermore, **the lack of significant associations across most indicators implies that the administrative district scale may be too general to identify the key social-economic factors behind PEDs.** Future research could develop and utilize sub-district level data to improve the accuracy and contextual appropriateness of PEDs.

The second analysis estimates the electricity self-sufficiency rates of each district under different rooftop PV generation and consumption scenarios. The results reveal substantial disparities among districts, likely stemming from differences in historical urban development, and zoning regulations that have led to varied urban forms. Consequently, building types and resident demographics differ significantly across districts. These findings underscore that territorial characteristics play a crucial role in shaping PEDs outcomes, particularly in electricity self-sufficiency. **Moreover, the analysis shows that in urbanized areas of Taiwan, electricity consumption cannot be met solely through rooftop PV generation within administrative boundaries. This highlights the necessity of integrating additional renewable energy sources and electricity-saving measures to achieve positive energy targets.**

In summary, this research uses the administrative district as the unit for evaluating PEDs feasibility, aiming to assess whether such spatial units can serve as the operational basis for implementing PEDs. Aparisi-Cerdá et al. (2024) also suggest that using administrative boundaries is practical due to the availability of statistical data and familiarity among experts, which simplifies the research process. The study further finds that smaller spatial units do not necessarily yield higher self-sufficiency rates. For instance, Annan District—the largest in area among the six studied districts—achieved the highest electricity self-sufficiency rate. However, from an operational standpoint, larger districts may contain more variables, such as higher population diversity and more complex stakeholder dynamics, potentially increasing implementation challenges. Figure 12 summarises the advantages and challenges of using administrative districts as the evaluation unit for PEDs, as well as potential improvements needed to better achieve PED objectives in the future.

Table 7. Summary of Advantages and Challenges of Using Administrative Districts as Statistical Units for PEDs Assessment

Aspect	Advantages	Challenges and Suggestions
Policy Alignment	Using administrative districts for local energy planning enables strong alignment with existing urban planning frameworks. This compatibility facilitates the direct integration of policy objectives and enhances the effectiveness of implementation and oversight.	The delineation of administrative boundaries does not necessarily align with the actual boundaries of energy systems, which may lead to ambiguity in planning, management. Future assessments of PEDs may need to establish formalized, cross-regional energy governance frameworks, including legal agreements and decision-making platforms.
Accessibility of Data	As administrative districts are standard statistical units used by Taiwanese government agencies, data related to them are readily accessible, stable over time, and diverse in scope. This supports systematic analysis of energy demand and socio-economic conditions relevant to PEDs, while also enabling effective policy tracking and impact evaluation.	Due to the differences of administrative districts in terms of size and characteristics, aggregated data at the district level may mask high-potential or high-vulnerability areas, thus reducing the precision of strategic planning. It is therefore essential to develop and utilize sub-district level data—such as neighborhoods, communities, or urban renewal units—to improve the accuracy and contextual appropriateness of PEDs' energy demand and management strategies.
Spatial Scope	Administrative districts typically encompass diverse land-use types such as residential, commercial, and industrial districts, which is beneficial for modelling and implementing PEDs that require energy integration, and distribution across heterogeneous areas. The district-scale spatial boundary also provides the spaces for deploying renewable energy infrastructure, such as solar PV systems, and energy storage.	Large spatial scopes and high land-use diversity make implementing PEDs more difficult due to the variety of energy needs and increased technical challenges. Future efforts should identify sub-areas within administrative districts that demonstrate relative strengths or vulnerabilities and incorporate microgrid development to gradually enhance energy resilience and increase the overall self-sufficiency rate within districts.
Cross-District Coordination and Stakeholder Engagement	Since energy is a transboundary resource, infrastructures such as electricity grids, and thermal networks, often extend beyond administrative boundaries. However, administrative districts possess well-defined local governance structures, allowing them to better coordinate and negotiate in different districts. They can also act as intermediaries for establishing cooperation frameworks with higher levels of government.	When renewable energy infrastructure is across administrative boundaries, challenges often arise related to cost and benefit allocation, and the high coordination costs associated with diverse stakeholders. Future strategies should include the formulation of cooperation agreements, transparent mechanisms for revenue and responsibility sharing, and stakeholder engagement frameworks to reduce resistance and foster PEDs deployment.

6 Limitations and Future Research

Although international definitions of PEDs currently distinguish between three types, there is still no unified standard regarding the appropriate spatial scale or delineation method. Xingxing et al. (2021) reviewed 60 PEDs projects in Europe and found that more than half of them occupy less than 1 km², with only five exceeding 5 km² in size. By contrast, even the smallest administrative district in this case study spans over 6 km²—significantly larger than most European cases. The variation in district size is also reflected in the differences in electricity self-sufficiency, reinforcing the critical role of "urban context" in PEDs planning. This study suggests that although administrative districts provide a practical initial scale for PEDs assessment, further refinement into smaller sub-units may be necessary to improve the precision and contextual relevance of PED strategies.

Finally, future research directions should include more granular consideration of rooftop PV generation potential. This includes data on building age, historical building constraints, structural types, and differences in adoption willingness among residents living in different building forms (Shnapp et al., 2020). On the consumption side, future studies could incorporate projected policy targets, resident behavioral patterns, and socio-economic indicators at the village or neighborhood level to more accurately forecast electricity demand variations across different districts.

Land suitability modelling for Integrated Mangrove Aquaculture to adapt to salinity intrusion using Machine Learning and Deep Learning approaches in southwestern Bangladesh

Shuxian Feng, Tengfei Yu
Affiliation: Shuxian F.
Email: shuxian.feng@mail.polimi.it

Abstract
The Sundarbans mangrove forest, located in southwestern Bangladesh, neighbors numerous vulnerable coastal communities. The mangrove forests play a crucial role in sustaining local livelihood structures and providing key ecosystem services. Climate-induced change risks contributed saline waterlogging, and salinity intrusion in low-lying lands within polders through extreme weather events, such as cyclones, storm surges, as well as coastal flooding inundation. Furthermore, the uncontrolled expansion of brackish shrimp farming has further exacerbated soil and water salinization, posing severe threats to self-sufficient community-based livelihood options.

Nature-based Solutions (NbS) offer essential tools for protecting the Sundarbans mangroves and addressing environmental challenges and livelihood threats faced by surrounding communities, including climate change, ecological degradation, loss of biodiversity, poverty, and food insecurity. The proposed Integrated Mangrove Aquaculture (IMA) practices, aligned with NbS standards and community involvement, are considered as a solution that balances mangrove ecosystem conservation and sustainable community livelihood management. Specifically, IMA provides adaptive responses to soil salinization and saltwater flooding caused by coupled climate risks, both of which increase the vulnerability of local livelihoods, aiming to develop a production model in the local saline environment that is both ecologically and economically beneficial. This study develops a machine learning-enhanced framework to optimize IMA for combating climate-driven salinity intrusion in Bangladesh's coastal communities. We used four machine learning models that integrated 18 biophysical, environmental and socioeconomic variables to assess land suitability for IMA development. Additionally, the data-driven evaluation model provides scientific support for future planning and management, facilitating implementation of IMA in vulnerable communities and ultimately contributing to the Sustainable Development Goals (SDGs).

Keywords: Machine Learning, Deep Learning, Livelihood Vulnerability, Climate Change, Integrated Mangrove Aquaculture (IMA)

1. Introduction

The Sundarbans Impact Zone (SIZ) is a distinctive region defined by its low-lying, deltaic landscape, woven with a complex network of rivers, tidal channels, and estuaries. This terrain, heavily influenced by seasonal monsoon rains and daily tidal fluctuations from the Bay of Bengal, creates a dynamic estuarine environment. Due to its proximity to the Sundarbans mangrove forest—the largest contiguous mangrove forest in the world - and the Bay of Bengal, the SIZ is exceptionally vulnerable to a range of coastal hazards. Storm surges, tropical cyclones, and saltwater intrusion frequently impact the area, posing significant risks to both human communities and ecosystems. However, this diverse ecosystem also presents challenges to human habitation and agricultural activities. The mixture of saline and freshwater conditions makes water management complex, as local communities must adapt to fluctuating water salinity that affects agriculture, aquaculture, and freshwater availability. The intrusion of saltwater during the dry season exacerbates these challenges, limiting crop choices and requiring adaptive agricultural practices to maintain productivity.

The communities living within the SIZ rely heavily on the natural forest resources of the Sundarbans for their livelihoods (Abdullah et al., 2016; Mallick et al., 2021; Mallick et al., 2021), with many engaged in small-scale fishing, honey collection, and subsistence farming. However, economic vulnerability is widespread, exacerbated by frequent natural disasters and limited infrastructure. Poverty rates are high, and many households depend on seasonal and climate-sensitive livelihoods, making them particularly vulnerable to the impacts of climate change. Despite these challenges, local communities have developed traditional knowledge and adaptive practices that allow them to navigate the complex ecological conditions. For example, some farmers have adapted to saline conditions by cultivating salt-tolerant rice varieties or by practicing integrated farming systems that combine aquaculture with salt-resistant crops. Additionally, community-based resource management practices have been established to promote sustainable use of forest resources, such as honey and non-timber products, which provide supplementary income without significantly impacting the ecosystem (Abdullah et al., 2017).

Coastal communities in the south-west zone of Bangladesh have been facing the ongoing and escalating risk of salinity intrusion, which is expected to increase existing livelihood vulnerability. Given the inevitable trend of higher salinity intrusion conditions, the fragility of current polders, and the limitations of traditional approaches in completely eliminating this risk, a strategic shift from "mitigation" to "adaptation" has become imperative. Integrated Mangrove Aquaculture (IMA) offers an innovative and adaptive solution to this pressing challenge by leveraging saline conditions as an opportunity rather than a constraint. A productive and sustainable pattern of shrimp or fish farming that involves strategic planting mangroves inside or alongside the shrimp ponds is referred as IMA. This approach not only boosts agricultural productivity but also contributes to ecosystem restoration by harnessing the ecological services provided by mangroves, such as nutrient cycling, habitat provision, and coastal protection. It relies on natural tidal water exchange for the effective water quality management and the function of mangrove as natural sources of food and nutrients. By utilizing the controlled facilities of daily tidal flows and absorbing abundant mangrove leaf litter in ponds dikes, IMA operates with minimal external inputs, making it a more eco-friendly and cost-effective approach of adaptive production pattern.

The mangrove-based integrated shrimp farming system represents a sustainable aquaculture model for coastal communities that takes into account both economic benefits and ecosystem protection. It can compensate for the mangrove forests degradation often associated with traditional intensive shrimp farming, and contributes to biodiversity protection, coastal community resilience, climate change mitigation, and enhanced food production (Alam et al., 2022).
